Results: 328 Russian SLE patients were enrolled in the study (M/F 30/ 298, mean age 34.4±11.5 years, mean disease duration 106.3±97.9 months; mean SLEDAI 2K 9.6±8.0; mean SDI 0.2±0.6. 34 (10.3%) patients had HADS-depression score of ≥10 and 76 (23.1%) of patients had HADS-anxiety score of ≥10. Patients with depressive score of ≥10 had significantly lower the scales “Planning”, “Emotion health” and “Fatigue” (p<0.0001) of the LupusQoL than those with score <10. Similarly, significant lower “Emotion health” and “Fatigue” (p<0.0001) were noted in those patients with HAD-anxiety score ≥10 compared to those <10 and they also had low score of “Burden to others” unlike those who are not anxious. (Table 1).

Conclusion: Depressive and anxiety symptoms in SLE patients and were associated with significantly poorer HRQoL.

Disclosure of Interests: None declared

DISCUSSION

The PhGA showed stronger and higher correlation with disease activity and low QoL than those with score <10. Similarly, significant lower “Emotion health” and “Fatigue” (p<0.0001) were noted in those patients with HAD-anxiety score ≥10 compared to those <10 and they also had low score of “Burden to others” unlike those who are not anxious. (Table 1).

Conclusion: Depressive and anxiety symptoms in SLE patients and were associated with significantly poorer HRQoL.

AB0569 THE EFFECT OF CUTANEOUS AND MUSCULOSKELETAL SYMPTOMS ON QUALITY OF LIFE IN PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN RENAISSANCE COHORT
Lyubov Vorobyova, Elena Aseeva, Sergey Solovyev. V. A. Nasonova Research Institute of Rheumatology, Intensive care department, Moscow, Russian Federation

Background: Cutaneous and musculoskeletal symptoms is one of the most frequent complaints of patients with systemic lupus erythematosus (SLE) and has been found to occur in up to 70%-95% of patients during the course of the disease. For these reasons, SLE can affect different aspects of the patient’s life, leading to an impairment of HRQOL.

Objectives: The aim of the current study was to assess the effect of cutaneous and musculoskeletal symptoms on HRQol in a cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE).

Methods: Consecutive patients who fulfilled SLICC 2012 criteria for SLE were recruited. Health-related quality of life (HRQol) was assessed by the validated specific questionnaires LupusQol-Russian. Disease activity was evaluated by the SLEDAI-2K, and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI).

Results: 328 Russian SLE patients were enrolled in the study (M/F 30/298, mean age 34.4±11.5 years, mean disease duration 106.3±97.9 months; mean SLEDAI 2K 9.6±8.0; mean SDI 0.2±0.6. Musculoskeletal symptoms were observed in 142 patients, cutaneous and mucosal lesion symptoms -147 patients, respectively. When comparing HRQol in patients with lesions skin and mucosal revealed (Table 1) significant decline HRQol on the scales “Planning” (58.5 ± 28.9), “Intimate Relationships” (65.9 ± 32.1), “Burden to other” (52.9 ± 26) and “Body Image” (57.4 ± 29.1) of the LupusQol questionnaire compared with the patients without skin and mucosal lesions (p<0.002; p<0.001; p<0.03; p<0.0001 respectively).

When evaluating HRQol in patients with SLE and musculoskeletal symptoms were observed in 142 patients, cutaneous and mucosal lesion symptoms (N=186) and without (N=181). The dependence of the indicators of the questionnaire scales LupusQol from musculoskeletal symptoms (Table 2) reduction of almost all scales LupusQol.

Conclusion: Cutaneous and musculoskeletal symptoms on HRQOL.

AB0570 CLINICAL STUDY OF THE DISEASE ACTIVITY AND IMMUNE SCREENING OF PRIMARY SJOGREN’S SYNDROME
Yin Xufang, Zhang Mingxing, Ming Yan, Li Xiaofeng. The Second Hospital of Shanxi Medical University, Taiyuan, China

Objectives: To evaluate the change features of peripheral blood lymphocyte subsets and disease activity in patients with primary Sjogren’s syndrome before and after treatment.

Methods: A total of 30 patients with primary Sjogren’s syndrome in the Department of Rheumatology from the Second Hospital of Shanxi Medical University from January 2016 to December 2018 were enrolled. According to the treatment time of patients, they were divided into baseline group, 0-3 months group, 3-6 months group, and the absolute counts of T, B, NK, Th1, Th2, Th17 and regulatory T cells(Tregs) in peripheral blood of patients before and during the treatment were measured by flow cytometry. The ratio of various cells to Tregs was calculated as well.

The primary Sjogren’s syndrome disease activity was assessed according to the Sjogren’s syndrome disease activity index (ESSDAI) score and compared with 30 healthy people.

Results: The Tregs counts in the disease group were significantly lower than those in the healthy control group (p<0.05), and the ratio of pro-inflammatory lymphocytes to Tregs (Th17/Treg) was higher (p<0.05). Tregs counts in peripheral blood of patients with primary Sjogren’s syndrome has increased significantly after 3-month treatment at the same time, the inflammatory index ESR was significantly lower (p<0.05), the ESSDAI score was significantly lower (p<0.05), and the high remission rate was maintained. However there was no statistically significant increase in Treg cell growth before treatment at 3-6 months and 6-12 months, (p>0.05).

Conclusion: The imbalance between pro-inflammatory lymphocytes and Tregs caused by the significant decrease of Tregs may be the cause of primary Sjogren’s disease activity. We propose to promote the growth of Tregs and maintain the balance between pro-inflammatory lymphocytes and Tregs, which provides a new idea for disease relief of primary Sjogren’s syndrome.
BENEFICIAL EFFECTS OF VACCINATION ON REDUCING RISKS OF INFLUENZA INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Jinquan Yu1, Dan dan Xu2, 1 Distinct HealthCare, Department of Rheumatology, Shenzhen, China; 2 Shenzhen Sixth People’s Hospital (Nanshan Hospital), Nephrology department, Shenzhen, China

Objectives: To investigate the influenza vaccine rate of SLE patients and the reasons for nonadherence to vaccination. To evaluate beneficial effects and safety of influenza vaccination.

Methods: A cross-sectional study was performed among patients with SLE regular follow-up in Distinct HealthCare between June 1 and November 31. Vaccination status and influenza infection condition were surveyed. Demographic information, clinical features and laboratory characters were collected and systemic lupus erythematosus disease activity index (SLE-DAl) was adopted.

Results: 109 SLE patients were recruited, including 42 immunized with trivalent or quadrivalent split virion influenza vaccine and 67 non-vaccinated. There were no significant differences in demographic and clinical characteristics (p>0.05). The influenza vaccination rate was 38.5%. Influenza infection rates in the vaccinated and non-vaccinated were 7.1% (3/42) and 23.9% (16/67), respectively, with a statistic difference (p<0.05). Reasons that non-vaccinated patients reported for nonadherence included refusal by the community health workers due to basic disease of SLE (32.3%), vaccine shortages (27.7%), concerns for potential side effects (23.1%) and insufficient patient education (16.9%). No systemic adverse reactions were observed and no significant increase of disease activity was found in vaccinated patients.

Conclusion: 1. Split virion influenza vaccine is effective in reducing risks of influenza infection in patients with SLE, and also safe.

2. Influenza vaccination is insufficient in SLE patients.

3. Educational intervention of the community health workers and patients is important to increase influenza vaccination rate.

AB0572 INVASIVE MYCOSES IN PATIENTS WITH CONNECTIVE TISSUE DISEASE FROM SOUTHERN CHINA: CLINICAL FEATURES AND ASSOCIATED FACTORS

Dongying Chen1, zhangngy zh angles2. 1 The first affiliated hospital of sun yat-sen university, rheumatology, Guangzhou, China; 2 The first affiliated hospital of sun yat-sen university, rheumatology, Guangzhou, China

Background: Invasive fungal disease (IFD) was well studied in patients with AIDS and organ transplant recipients. A few researches illustrated that patients with connective tissue disease (CTD) were also predisposed to IFD. However, few researches were designed to focus on invasive mycosis (IM) in patients with CTD.

Objectives: To investigate the clinical features and associated factors of IM in patients with CTD from Southern China.

Methods: A retrospective study CTD was performed. Demographic and clinical data were recorded. Associated factors were analyzed by logistic regression analysis.

Results: A total of 32 patients with CTD were included. The incidence of IM was 0.2% in patients with CTD (32/6911) and the highest in patients with ANCA-associated vasculitis (AAV) (7/480, 1.5%). Molds were isolated in 20 sputum specimens (20/29, 69.0%). Aspergillus spp. (81.3%) were the leading strain. Positivity of serum G-test and GM-test was 47.8% (11/23) and 34.6% (9/26), respectively. GM-test was positive in BALF from seven patients. Lung was commonly involved (30/32, 93.8%), Pulmonary nodules (46.7%) and cavitory lesions (36.7%) were common. Ten patients died (31.3%), including three with AAV (42.9%) and seven with SLE (36.8%). Multivariate logistic regression analysis showed that lymphopenia (odds ratio (OR) =3.28, 95% confidential interval (CI) 1.29-8.36, P=0.01) and median-to-high dose of glucocorticoid (GC) (OR=3.40, 95% CI 1.04-11.13, P=0.04) was associated with IM in patients with CTD. Patients with lymphopenia experienced higher risk of co-infection (50.0% vs 0%, P=0.01) and mortality (45.5% vs 0%, P=0.01) compared with patients with normal lymphocyte count.

Conclusion: IM tended to develop in patients with AAV, resulting in high mortality. Sputum culture could be an effective and non-invasive method to diagnose IM. Lymphopenia and median-to-high dose of GC are associated with IM in patients with CTD. Acknowledgment: no

Vascular

AB0573 ASSESSMENT OF PRESENCE, SEVERITY AND RISK FACTORS OF POST-THROMBOTIC SYNDROME IN VASCULAR BEHÇET DISEASE: MUTCENTERED RETROSPECTIVE STUDY

Ayşen Ayşu1,2, Seda Colak2, Ahmet Omma3, Burcu Yağız4, Belkis Nihan Seniz5, Naile Bolca6, Rabia Ergeç7, Haner Direskeneli8, Fatma Albaz-Oner9, 1 University of Manchester, Manchester, United Kingdom; 2 Marmara University School of Medicine, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3 Gülhane Education and Training Hospital, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 4 Ankara Numune Training and Research Hospital, ankara, Turkey; 5 Uludağ University School of Medicine, Internal Medicine, Division of Rheumatology, Bursa, Turkey; 6 Uludağ University School of Medicine, Division of Radiology, Istanbul, Turkey; 7 Marmara University School of Medicine, Division of Radiology, Istanbul, Turkey

Background: DVT (deep venous thrombosis) is the most common form of vascular Behçet Disease (VBD). Post-thrombotic syndrome (PTS) developing after a thrombotic event in lower extremity is the most important complication of DVT and affects negatively patients’ quality of life.

Objectives: We aimed to assess presence, severity and risk factors of PTS and venous disease specific quality of life in VBD

Methods: This study included 96 BD patients (Female/Male:18:78, mean age: 38.8±8.74) with DVT from 3 tertiary Rheumatology centers in Turkey. When vascular involvement developed, mean age was 32.7±8.65 (female: 35.4±10.7; male: 32.09±8; p=0.04) Villalta scale is used to assess PTS and according to scale; PTS is present if score >4 and degree of PTS mild, moderate and severe if score 5-9, 10-14, >14 respectively. The Venous Disability Score(VDS) and the Venous Clinical Severity Score (VCSS) are used to assess the severity of PTS. Patients with trauma, major surgery or recanalization were excluded. PTS rate is 62% (60/96) and VDS score >4 is 47% (45/96).

Disclosure of Interests: None declared.

(VCSST) were used for the assessment of venous disease. Venous disease-specific QoL was measured through Venous Insufficiency Epidemiological and Economic Study Quality of Life/Symptom (VEINES-QoL/Sym) questionnaire. All patients were reanalyzed using color Doppler USG in the Radiology Department by a radiologist. In each patient, a total of 16 superficial and deep veins in both legs were assessed for the presence or absence of obstruction, recanalization, reflux, and collaterals within 1 week following the clinical examination.

Methods: During venous assessment, median disease duration was 9(0-34) years. Eighty(84.2%) patients were under immunosuppressive treatment and 13 of these patients were under anticoagulation treatment in addition to ISs. Duration between first vascular event and venous assessment was 6(1-26) years. PTS was present in 57(61.3%) out of 93 patients and severe PTS was present in 19(19.8%) patients. There was no association between the presence of PTS and sex, disease diagnosis age, and during DVT, presence of relaps. There was no difference among patients with or without PTS according to the anticoagulant usage (p=0.817). Doppler ultrasound examination showed bilateral at 31(31.4%) patients and both upper and lower involvement at 40(41.6%) patients. But, there is no statistically significant difference between the presence of PTS and Doppler findings. In addition to these, there is no statically significant association between PTS and presence of reflux obstruction at any vessel in the affected leg, but there is a correlation between severe PTS and reflux (r=-0.224, p=0.096). VCSS have positive correlation with the presence of reflux (p=0.041, r=0.224). VEINES-QoL/Sym, VCSS and BSAS are significantly worse in patients with PTS (Table 1).

Conclusion: In this study, we found that PTS in lower extremity develops in more than half of the patients with VBD during follow-up, and did not find any predictor factor for development of PTS. About one third of patients with PTS had severe PTS. PTS is an important clinical problem for physicians treating VBD in daily practice. It should be taken into account as much as preventing vascular relapses during follow-up of patients with VBD.

Table 1. Clinical and characteristic features of PTS

### A MONOGENIC DISEASE WITH WIDE RANGE OF SYMPTOMS: DEFICIENCY OF ADENOSINE DEAMINASE 2

**Ezgi Deniz Batu**, Elvin Z. Taskiran, Hatice Asuman Özkara, Süleyman Ünal, Naz Güleray, Abdullah Yildiz, Omer Karadag, Fatma Gürkü, Mualla Çetin, Yelda Bilginer, Hafize Emine Sonmez, Deniz Cagdas Ayyaz, İlhan Tüzün, Seza Özen, Hacettepe University Faculty of Medicine, Division of Rheumatology, Ankara, Turkey; Hacettepe University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey; Department of Medical Biochemistry, Department of Medical Biochemistry, Ankara, Turkey; Hacettepe University Faculty of Medicine, Hacettepe University Center for Fanconi Anemia and Other Inherited Bone Marrow Failure Syndromes, Ankara, Turkey; Hacettepe University Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; Hacettepe University Faculty of Medicine, Department of Immunology, Hacettepe University, Ankara, Turkey

**Background:** Deficiency of adenosine deaminase 2 (DADA2) is an autosomal recessive autoinflammatory disorder caused by ADA2 mutations.

**Objectives:** We aimed to investigate the characteristics of DADA2 patients along with the ADA2 enzyme levels.

**Methods:** 24 DADA2 patients who admitted to the Adult and Pediatric Rheumatology, Pediatric Haematology, and Pediatric Immunology Departments were included. All exons of the ADA2 gene were screened by Sanger sequencing in all DADA2 patients. Serum ADA2 enzyme activity was measured by modified spectrophotometric method.

**Results:** 24 DADA2 patients were included; Group 1, 14 DADA2 patients with polycythemia vera (PV)-like phenotype; Group 2, 9 patients with Diamond-Blackfan anemia (DBA)-like features and one with immune deficiency. 14 PV-like DADA2 patients did not have the typical thrombocytosis seen in classical PV. Inflammatory attacks were evident in only Group 1 patients. Serum ADA2 was low in all DADA2 patients except one who was tested after hematopoietic stem cell transplantation. There was no significant difference in ADA2 levels between PV-like and DBA-like DADA2 patients (Figure 1). ADA2 activities of homozygote family members were about half the level of the control subjects. However, in heterozygote DADA2 patients, serum ADA2 levels were as low as one-third of homozygote DADA2 patients. ADA2 mutations were affecting the dimerization domain in Group 1 patients and in the catalytic domain in Group 2 patients (Table 1).

**Conclusion:** We suggest that enzyme activity of ADA2 should be aimed along with genetic analysis since there are heterozygote patients with absent enzyme activity. Our data confirms a possible genotype-phenotype correlation where dimerization domain mutations are associated with a PAN-like phenotype whereas catalytic domain mutations are associated with hematological manifestations.

**Table 1. Molecular results of ADA2 gene analyses in DADA2 patients (D, dimerization; C, catalytic)**

THE EFFECT OF METABOLIC SYNDROME ON CARDIOVASCULAR DISEASE AND CUMULATIVE ORGAN DAMAGE IN TAKAYASU'S ARTERITIS

Nilüfer Alpay Kaneti1, Sema Kaymaz Tahra, Ayten Yazici1, Ayse Celle3, Mete Karis2, Handan Yarkan-Tuğus, Özay Genç1, Serret Akar6, Fatos Onen5, Kenan Aksu4, Gülden Keser1, Cemal Bes7, Sevil Kamali3, Fatma Albaz-Onen2, Haner Direskeneli3, 1Koc University School of Medicine, Rheumatology, Istanbul, Turkey; 2Narımara University, School of Medicine, Rheumatology, Istanbul, Turkey; 3Kocaeli University School of Medicine, Rheumatology, Kocaeli, Turkey; 4Izmir, Turkey; 5Dokuz Eylül University School of Medicine, Rheumatology, İzmir, Turkey; 6Izmir Katip Celebi University, School of Medicine, Rheumatology, Izmir, Turkey; 7University of Health Sciences, Balıkesir Sadi Konuk Research and Training Hospital, Rheumatology, Istanbul, Turkey; 8Private Office, Istanbul, Turkey

Background: As a result of arterial ischemia, the frequencies of hypertension (HT), ischemic heart disease, congestive heart failure and atherosclerosis have been shown to increase and contribute to mortality in patients with Takayasu's arteritis (TAK). Determining cardiovascular disease (CVD) and associated risk factors in TAK is important for a comprehensive treatment approach and better disease prognosis. Data about the effect of metabolic syndrome (MetS) which is known as a risk factor for CVD on TAK are limited.

Objectives: The aim of this study was to determine the prevalence of MetS in patients with TAK and its effect on CVD and cumulative organ damage.

Methods: A total of 122 TAK patients, followed by Turkish Takayasu Study Group in 7 tertiary Centers and diagnosed according to the 1990 ACR criteria were consecutively assessed for cumulative organ damage (VDI score), history of CVD and MetS as defined by the National Cholesterol Educational Program Adult Treatment Panel III (NCEP ATP III). CVD was defined as coronary artery disease or cerebrovascular event (myocardial infarction or stroke).

Results: Eighty-seven percent of patients were female and the median age was 39 (17-65) years. The frequency of MetS was 14.7% and CVD was 13.1%. The median age, disease duration, smoking prevalence and CVD were found slightly higher in MetS group, without reaching statistical significance. There were no differences in VDI score between the groups (Table 1).

AB0576 SERUM CATHELICIDIN (LL 37) LEVELS IN PATIENTS WITH BEHÇET’S DISEASE AND ITS ASSOCIATION WITH DISEASE ACTIVITY

Melike Zelal Cakir1, Pelin Oktayoglu1, Nuriye Mete2, Mehmet Caglayan1, 1Dicle University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Diyarbakir, Turkey; 2Dicle University Faculty of Medicine, Department of Biochemistry, Diyarbakir, Turkey

Background: Behcet’s disease (BD) is a recurrent multisystem inflammatory disease which is characterized by recurrent episodes of oral aphthous and genital ulcers, ocular inflammation and skin lesions. Anti-microbial peptides (AMPs) such as the cathelicidin (LL-37) and defensins have recently been implicated in the pathogenesis of autoinimmune and autoinflammatory diseases.

Objectives: The aim of this study was to investigate the serum levels of cathelicidin and its potential association with disease activity, and some other laboratory parameters such as erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), white blood cell count (WBC) in patients with BD.

Methods: A total of 45 patients who presented to Dicle University Rheumatology clinics between September 2018 and December 2018 and met the International Study Group Classification Criteria for BD and 37 healthy control subjects who presented to Dicle University Physical Medicine and Rehabilitation clinics for various reasons other than rheumatoid complaints between the same dates were included in this study. Patients’ demographic features, including age and sex, were noted. Duration of disease was also noted, and the disease activity was assessed by means of BD Current Activity Form (BCAF). Laboratory investigations included erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), complete blood count and routine biochemical analyses. Serum levels of cathelicidin (LL 37) were determined by means of human cathelicidin antimicrobial peptide ELISA Kit according to the manufacturer’s protocol.

Results: Serum mean level of cathelicidin (LL 37) in patients with BD was lower than healthy controls but this result was not statistically significant. Cathelicidin levels were not correlated with ESR, CRP, BCAF and WBC (p>0.05).

Conclusion: However serum mean levels of cathelicidin (LL 37) were lower in patients with BD compared to healthy controls, this result was not statistically significant. It may be sourced from our relatively small sample size. To validate cathelicidin (LL 37) value as a prognostic or pathophysiological biomarker, future studies should investigate the levels of cathelicidin LL37 in patients with BD in large cohorts of patients with different levels of disease activity, remission, and relapse.

TOCILIZUMAB IN GIANT CELL ARTERITIS. ROUTE OF ADMINISTRATION: INTRAVENOUS OR SUBCUTANEOUS

Background: Recently, based on the GIACTA trial results, weekly subcutaneous Tocilizumab (TCZ) has been approved for the treatment of Giant Cell Arteritis (GCA). It has showed to be effective and safe.

The aim of this study was to compare the efficacy of TCZ according the route of administration.

Methods: Multicenter study of 134 GCA patients in treatment with TCZ. It was performed a comparative study between 2 groups according the route of administration of TCZ, intravenous (IV) or subcutaneous (SC).

Results: We study 134 patients divided in 2 groups: a) IV TCZ, 104 cases and; b) SC TCZ, 30 cases, with a mean age 73.4±8.2 years vs 71.9±10.6 years, respectively (p=0.501). Disease duration, clinical manifestations and acute phase reactants at TCZ onset were similar in both groups with non-statistical difference. 91.7% patients who received SC TCZ achieved prolonged remission after 12 months of treatment (p<0.043). And the glucocorticoid sparing effect of TCZ was greater in SC groups with non-statistical difference. 91.7% patients who received SC TCZ reached prolonged remission after 12 months of treatment and were able to discontinue prednisone dose after 24 months of follow up. The incidence of adverse events was more frequent in the IV TCZ group, without difference in relation to infections.

Objectives: Our aim was to compare the efficacy of TCZ according the route of administration.

Conclusion: Patients in treatment with SC TCZ, reached prolonged remission after 12 months of treatment and were able to discontinue prednisone dose after 24 months of follow up. The incidence of adverse events was more frequent in the IV TCZ group, without difference in relation to infections.

REFERENCES

Objectives: To describe the characteristics and differences between patients with primary LVV and LVV associated with GCA in a single center.

Methods: Retrospective study of patients with LVV in a University Hospital (January 2013-December 2018). Patients diagnosed with aortitis using an imaging test (PET-CT/angiogram/CT/MRI) were included. GCA was diagnosed by biopsy and/or ultrasound of the temporal artery. The primary LVV was considered by exclusion of inflammatory or infectious causes. Epidemiological, clinical and analytical variables, affected vascular territories and the treatment received in both groups were reviewed.

Frequencies and percentages were used in qualitative variables, mean ±SD in quantitative and for the comparison between groups Chi2 test or Fishers test was used in categorical variables and Student T test or U of Mann-Whitney in quantitative. The statistical analysis was performed with IBM SPSS v.23.

Epidemiological, clinical and analytical variables, affected vascular territories in both groups were reviewed. LVV was considered by exclusion of inflammatory or infectious causes. The final clinical evolution was similar and favorable in both groups. At last visit, after a mean follow-up of 11.94±8.5 months in the primary LVV and 13.44±6mg/week and TCZ (n=2). In LVV associated with GCA, 2 patients were without treatment; CS (n=9), mean dose 4.75±4mg; MTX (n=6), mean dose 3.44±5mg/week and TCZ (n=2). 15 imaging tests were performed 6-10 months after diagnosis. Later, after an average time of 28.7±10.7 months 9 more control PET-CT were requested. TABLE 2.

Conclusion: In this study, younger age at onset and inflammatory low back pain were more frequent in primary LVV with statistical significance. The most affected vascular territory was the thoracic aorta in both groups.

The clinical and analytical evolution was similar in both populations. In the treatment, the only notable thing was the increased use of MTX in the LVV associated with GCA.

68% of the aortitis were diagnosed in the last 3 years due to greater clinical suspicion. PET-CT is a useful tool in the diagnosis of this pathology.

AB0579

COMPARISON OF CLINICAL CHARACTERISTICS OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS BETWEEN RHEUMATOLOGY AND RESPIRATORY MEDICINE: A SINGLE CENTER, RETROSPECTIVE STUDY

Le-Feng Chen, Li Qianhua, Dong-Hui Zheng, Lie Dai, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare but potentially life-threatening systemic necrotizing vasculitis. Multiple organs may be involved and patients initial consulting different departments may have different clinical manifestations.

Objectives: To explore the clinical characteristic of EGPA diagnosed in different departments in our hospital.

Methods: A retrospective study of EGPA patients in Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China.

Results: We included 45 EGPA patients diagnosed between December 2003 and January 2019. There were 29(64.4%) male, with median onset age 46(36~56) years, median time required for diagnosis 24(3~96) months. There were 8(17.8%) patients had history of drug allergy. There were 41(91.1%) patients fulfill the ACR 1990 classification criteria and 40 (88.9%) fulfill the EULAR/ACR 2017 draft classification criteria. Demographic and clinical data of EGPA patients were collected and compared between different departments.

Results: 1) There were 45 EGPA patients diagnosed between December 2003 and January 2019. There were 29(64.4%) male, with median onset age 46(36~56) years, median time required for diagnosis 24(3~96) months. There were 8(17.8%) patients had history of drug allergy. There were 31(68.9%) patients fulfill the ACR 1990 classification criteria or the EULAR/ACR 2017 draft classification criteria. Demographic and clinical data of EGPA patients were collected and compared between different departments.

Results: 2) The main clinical manifestations included asthma-like symptoms (82.2%), limb numbness (37.8%), rash (22.2%), fever (20.0%), gastrointestinal symptom (11.1%) and arthralgias (8.9%). There were 91.1% (41/45) patients had serum eosinophil >10%, 77.8% (35/45) serum eosinophil x10^9/L, 77.5% (34/45) elevated serum IgE, 7.8% (3/44) positive MPO-ANCA or p-ANCA and 18.4% (7/38) positive ANA.

Results: 3) There were 21(46.7%) patients diagnosed at rheumatology, 22(48.9%) at respiratory medicine, 1(2.2%) at dermatology and 1(2.2%) at pediatrics.
Compared with patients diagnosed at respiratory medicine, patients diagnosed at rheumatology had a higher frequency of fever (33.3% vs. 0), rash (33.3% vs. 4.5%), arthralgias (19.0% vs. 0) and limb numbness (57.1% vs. 22.7%), but lower frequency of asthma-like symptoms (66.7% vs. 100%; p<0.05). There were more patients diagnosed at rheumatology received treatment of glucocorticoid (100% vs. 72.7%), immunosuppressive agents (85.7% vs. 4.5%) and intravenous immunoglobulin (28.6% vs. 0) than those diagnosed at respiratory medicine (all p<0.01). Patients diagnosed at rheumatology also received higher initial dose of glucocorticoid than those diagnosed at respiratory medicine [50 (50-100) mg/d vs. 28 (10-40) mg/d of prednisone dosage, P<0.001].

4) Among the 21 patients diagnosed at rheumatology, 14(66.7%) had asthma-like symptoms, who showed significantly longer time required for diagnosis than those without asthma-like symptoms [36(24-120) months vs. 2(2-13) months, P=0.020], but showed no significant difference of onset age between these two groups (P=0.05). 5) The median revisited Five-Factor Score (FFS) was 0(0-1). There were 1(17.6%) patients who had older diagnostic age than those with FFS=0 [65(46-68) years vs. 48(42-53) years, P=0.05], but with no significant difference of onset age or time required for diagnosis. Patients with FFS>1 had higher level of serum IgE [1280(515-4895) IU/mL vs. 241(73-379) IU/mL, P=0.05]; those with FFS<1 had lower mortality rate than those with FFS=0 [65(46-68) years vs. 48(42-53) years, P<0.05].

Conclusion: Clinical manifestations of EGPA were different between rheumatology and respiratory medicine. Rheumatologist may be more aggressive treating EGPA patients with glucocorticoid and immunosuppressive agents than respiratory physician. Multidisciplinary team is needed for the diagnosis and management of EGPA.

AB0581 AN ATYPICAL PRESENTATION OF GIANT CELL ARTERITIS WITH SCALP LUMPS: A CASE REPORT

Ujilalpa Dissanayake, Risiya Hassan. District General Hospital, Kegalle, Sri Lanka

Background: Giant cell arteritis (GCA) also referred as temporal arteritis is a systemic inflammatory vasculitis of unknown etiology which can result in wide range of systemic, neurologic and ophthalmic complications. It predominantly occurs in older people and may be associated with Polymyalgia Rheumatica. It must be treated urgently as it is associated with significant risk of permanent visual loss, stroke, aneurysm and possible death. Diagnosis of GCA can be based on clinical findings such as headache, scalp tenderness, jaw claudication and temporal artery problems, an elevated ESR and biopsy temporal artery showing typical histopathological findings. Diagnosis of GCA may be delayed when presentation is atypical.

Objectives: We report a case of an elderly lady presenting with scalp lump as an unusual presentation of GCA.

Methods: 70 years old lady presented with multiple painful scalp lumps to the surgeon was referred to the Rheumatologist when the excision biopsy of the lump diagnosed the GCA. (Sub cutis medium sized artery with severe arteritis composed with lymphocytes, neutrophils and occasional Eosinophils). On enquiry she revealed a history of generalized malaise and lethargy at the onset of the illness preceded by jaw pain.

On examination she had bilateral hardened thickened palpable non pulsatile temporal arteries. Her scalp was tender with multiple small cystic lumps. Her ESR was highly elevated 141mm/hr. WBC 9.7, Hb 9.5 and PLT 283. Her ANA, liver and renal profiles were normal. Her BL Doppler USS was consistent with BL temporal arteritis.

Results: She was soon started on high dose prednisolone with low dose aspirin which improved her systemic symptoms along with inflammatory markers significantly over a few days. She was referred for eye assessment and the involvement of other systemic large arteries was ruled out.

Conclusion: Most of the cases the diagnosis of GCA is obvious but in patients with uncommon clinical presentation the diagnosis may be difficult. GCA is classified as disease of large vessel vasculitis but typically also involves medium and small arteries. The granulomatous inflammation in the vessel wall leads to obstruction of the lumen and ischemia in the territory distal to it. GCA involves almost all speciality and it is associated with increased mobility and mortality if not diagnosed and treated early. Awareness of rare presentation of GCA avoids unnecessary investigation and delaying the treatment. If there is no rapid improvement of symptoms within few weeks of starting treatment other diagnosis should be considered.
In our cohort there were 2 pts with serious infections: 1 with oropharyngeal and esophageal candidiasis and another with bacteraemia to Pseudomonas aeruginosa. Both pts were under immunosuppressive agents including corticosteroids and rituximab or cyclophosphamide.

Conclusion: Neurologic involvement was part of disease presentation in most pts and the commonest manifestation was mononeuritis multiplex. PDN was prescribed to all pts, in most cases in association with other immunosuppressive drugs. Cyclophosphamide and rituximab (RTX) were used as induction treatment, and mycophenolate mofetil, azathioprine and RTX as maintenance. Intra venous human immunoglobulin was used in pts colonized by multiresistant microorganisms/severe infection with immunosuppression and as a bridging therapy to further immunosuppression. Most pts achieved clinical improvement, documented in electromyography.

AB0582
NEUROLOGIC INVOLVEMENT IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)-ASSOCIATED VASCUITIS – EXPERIENCE FROM A PORTUGUESE CENTER

Ana Catarina Duarte, Sandra Sousa, Ana Cordeiro. Hospital Garcia de Orta, Rheumatology Department, Almada, Portugal

Background: Involvement of peripheral (PNS) and central nervous system (CNS) in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis has been reported in 15-60% and 5-15% of patients (pts), respectively. PNS involvement occurs mainly in eosinophilic granulomatosis with polyangiitis (EGPA) and CNS involvement has been almost exclusively described in granulomatosis with polyangiitis (GPA). Neurologic involvement is associated with a higher morbidity and implies more immunosuppressive treatment in most pts.

Objectives: Evaluate prevalence and clinical features of PNS/CNS involvement in pts with ANCA-vasculitis in a Portuguese center.

Methods: Retrospective analysis of ANCA-vasculitis pts with neurologic involvement followed in our department from January 2016 to December 2018. Data was collected from the Portuguese database REUMA.PT and included demographic data, vasculitis subtype, date of diagnosis, neurologic manifestations and treatment approach.

Results: In total, 11 pts were identified, mostly female (7/11) with mean age of 61±3.3 years (yrs). Five pts had EGPA, 5 GPA and 1 microscopic polyangiitis (MPA). Neurologic involvement was part of disease presentation in 8 pts (5 GPA, 3 EGPA). The other 3 pts had neurologic involvement 7±2.2 yrs after vasculitis diagnosis. At the time of neurologic involvement diagnosis, Birmingham Vasculitis Activity Score was 8±4.3. PNS involvement occurred in 9 pts, all presenting mononeuritis multiplex (MM). From these, 5 had EGPA, 3 GPA and 1 MPA. CNS involvement was reported in 3 pts, 2 with GPA and 1 with EGPA. Pachymeningitis was diagnosed in 1 GPA pt with persistent headache, refractory to analgesics, and thickening and enhancement of the dura mater on postcontrast magnetic resonance imaging. Two pts had cranial mononeuropathy, 1 with EGPA and MM who developed VI palsy 2 yrs after vasculitis diagnosis and 1 pt with GPA and VII palsy at disease presentation who developed XII palsy 8 yrs later. All pts were treated with prednisolone (1mg/kg/day), mostly in combination with other immunosuppressive drugs. The choice of the treatment was based on the age of the pt and other comorbidities. Detailed treatment of these pts and subsequent responses are shown in table 1.

Table 1: Results of pts with neurologic involvement in relation to ANCA-vasculitis

Conclusion: In ANCA-vasculitis pts, neurologic manifestation is common and associated with higher morbidity. Most pts achieved clinical improvement, documented in electromyography. The majority of our referrals to a tertiary care centre had non-specific symptoms, quality of referral and potential for visual loss can lead to over-diagnosis. We have found the majority of our referrals to have been appropriate and complete with 85% meeting ACR criteria for GCA and 92% having up to date inflammatory markers. Despite this, 31% of patients received an alternative diagnosis. Increasing the availability of

AB0583
100 GCA REFERRALS TO A TERTIARY CARE CENTRE: INFLAMMATION, HEADACHES AND CPAP MASKS

Jobie Evans, Natasha Jordan. Cambridge University Hospitals NHS Foundation Trust, Rheumatology, Cambridge, United Kingdom

Background: Giant cell arteritis (GCA) is a large vessel vasculitis typically affecting patients above the age of 50 years. It is the most common cause of vasculitis affecting adults with a UK prevalence of approximately 0.25% of the population above the age of 55 years [1]. Whilst its clinical presentation can often be non-specific, if left undiagnosed it can lead to devastating visual impairment. However, this has to be balanced with the potential for corticosteroid related adverse effects. The threshold for suspected diagnosis and referral to rheumatology centres from the community and acute medical services is therefore low, leading to a relatively high number of referrals with a wide range of clinical features and potential differential diagnoses.

Objectives: To assess the referral characteristics, demographics, management, corticosteroid adverse effects and differential diagnosis of 100 consecutive patients referred with suspected GCA to a tertiary rheumatology centre.

Methods: The notes of 100 consecutive patients referred to the rheumatology department at Addenbrookes hospital between August 2016 and January 2018 with suspected GCA were reviewed. Information on patient demographics, comorbidities, presenting symptoms, availability of up to date inflammatory markers, dates of treatment and clinic review, temporal artery biopsy (TAB) date and result, diagnosis and corticosteroid adverse effects were retrieved.

Results: Seventy three female and twenty seven male patients (average age 72.3 years) were referred within the time period. General practice referred 69% of the cases and common comorbidities included hypertension and type II diabetes. The most common symptoms were headache (97%), scalp tenderness (79%), jaw claudication (35%) and polymyalgia symptoms (34%). Up to date inflammatory markers were available for 91% of referrals and 92% were commenced on corticosteroids before or at the time of referral with an average starting dose of 43.9mg oral prednisolone. A TAB was performed on 85% of patients, with an average time of 9 days between referral and TAB and 40 days between referral and clinic appointment. TAB was positive for GCA in 13/85 patients. Temporal artery ultrasound (TAU) was not available at our centre. The American College of Rheumatology (ACR) classification criteria for GCA were met by 85% of the patients, but only 69% were given a diagnosis of GCA. Other diagnoses included trigeminal neuralgia, temporomandibular dysfunction, toothache and a poorly fitted CPAP mask. Corticosteroid adverse effects were experienced by 45% of patients including weight gain, poorly controlled diabetes, mood and sleep disturbance, and 4% suffered severe complications requiring hospital admission (pneumonia, disseminated nocardia infection and two episodes of upper gastrointestinal bleed).

Conclusion: Suspected GCA is a common referral to rheumatology but the non-specific symptoms, quality of referral and potential for visual loss can lead to over-diagnosis. In our cohort there were 2 pts with serious infections: 1 with oropharyngeal and esophageal candidiasis and another with bacteraemia to Pseudomonas aeruginosa. Both pts were under immunosuppressive agents including corticosteroids and rituximab or cyclophosphamide.
TAU may improve the time to diagnosis and therefore potentially reduce unnecessary exposure to corticosteroids. Our experience highlights the fact that despite a good standard of referral, GCA remains a difficult condition to diagnose and poses an on-going challenge to the rheumatologist.

JOINT PROFILE OF BEHÇET’S DISEASE

Amel Farhat, Khadija Baccouche, Mohamed Amine EL Achech, Nejla El Amri, Hela Zeghidi, Elies Bouajina. Farhat Hached University Hospital, Rheumatology, Sousse, Tunisia

Background: Joint manifestations during Behçet’s disease (BD) are frequent and polymorphic.

Objectives: To analyze these manifestations through 41 cases.

Methods: A retrospective study of 41 patients, collected at the rheumatology department of Farhat Hached University Hospital over a period of 19 years, meeting the criteria of the international study group on BD.

Results: 41 patients with a mean age of 40.21 years (16-66) were collected. The sex ratio=2.41. The articular and mucocutaneous involvement were constant. Also were found ocular manifestations (5cases), neurological (1case), cardiac (1case), gastro-intestinal (1case), venous thrombosis (5 cases), arterial thrombosis (1 case) and an aereumus (2 cases). Joint involvement was revealing in 21 cases (51.2%) occurring during evolution in 20 cases with an average delay of 102 months [6-360]. The most frequent manifestations were arthralgia in 24 cases (58.5%) and arthritis in 17 cases. It was predominantly asymmetric (21 cases), mono articular (13 cases), oligoarticular (16 cases) and polyarticular (12 cases). The knees and ankles were the most affected joints in 32 cases and 25 cases respectively, followed by wrist involvement (12 cases), MCP (5 cases) and elbows and shoulders in 4 cases each. A knee flessum was found in 2 cases. X-rays were mostly normal (35 cases). They showed erosive involvement (1case), joint narrowing (1case), osteonecrosis (2cases) and sacroiliitis (2cases).

Conclusion: Joint manifestations during the BD can be inaugural and take on several clinical aspects. They usually heal without sequelae and do not engage functional prognosis with the exception of rare cases of destructive arthritis.

REJIA-VASCA: JAVERIAN REGISTRY OF PATIENTS WITH POSITIVE ANCA VASCULITIS AT THE UNIVERSITY HOSPITAL SAN IGNACIO 2005–2017

Daniel G. Fernández-Ávila1, Catalina Vilota2, Julián Rondón2, Juan Gutiérrez2. 1Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Bogotá, Colombia; 2Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine, Bogotá, Colombia; 3Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine, Bogotá, Colombia; 4Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine – Rheumatology, Bogotá, Colombia

Background: Vasculitis associated with cytoplasmic antibodies (VAAc) are heterogeneous entities with low prevalence and high morbidity and mortality. These include granulomatosis with polgagglutin (GPA), microscopic polgagglutin (PAM), and eosinophilic granulomatosis with polgagglutin (GEP). European retrospective reviews report an annual incidence of 10-20 cases per million, with peak presentation between 65-74 years, predominantly in males. It has diverse clinical manifestations in multiple systems. In Colombia, there are few clinical records that describe the clinical characteristics of these patients.

Objectives: To describe the clinical characteristics of patients with VAAc in the University Hospital San Ignacio between 2005-2017

Methods: Descriptive cross-sectional study. Patient records were reviewed between January 2005 and December 2017. The records were obtained using search systems in patients who were requested Anti-neutrophil cytoplasmic antibodies - ANCA (Searching software: DISEARCH, LABCORE), obtaining 2072 results. 106 patients met the criteria for classification of the American College of Rheumatology for VAAc.

Results: 106 patients diagnosed with ANCA positive vasculitis. Average age 55 years (± 14.7). 48.4% were women. In-hospital debut in 68.8%. The average number of days of stay was 16.6 days (± 12.22), 56 patients (52.8%) had granulomatosis with polgagglutin (GPA), 45 patients (42.4%) with microscopic polgagglutin (MAP) and 5 patients with eosinophilic granulomatosis with polgagglutin (EGP) (4.8%). 37 patients (35%) presented with alveolar hemorrhage, 22 patients (20.7%) presented renal compromise with rapidly progressive glomerulonephritis. Central nervous system compromise was documented in 25 patients (24%). Regarding the vascular territory, 60 patients (56.6%) received treatment with cyclophosphamide. Plasma exchange therapy was performed in 15 patients (14.1%). 44 patients (41.5%) required renal replacement therapy. The in-hospital mortality of this group of patients was 20.4%, with sepsis being the most frequent cause of death (55%).

Conclusion: In this study, the most frequent positive ANCA vasculitis was granulomatosis with polgagglutin. Multisystemic compromise was present in all groups of patients, the most common being pulmonary and renal, mainly in patients with microscopic polgagglutin, similar to that reported by Solans-Laquè et al in Spain. Within the demographic characteristics, the average age at the time of diagnosis is around 50 years, predominantly in women related to the Mexican study by Hinojosa-Azuala et al. The most frequent cause of in-hospital mortality was sepsis. Clinical information of patients with VAAc is presented in a reference hospital in Colombia. Data are concordant with literature.

AB0586

TAKAYASU ARTERITIS: REVIEW OF DIAGNOSTIC AND CLASSIFICATION CRITERIA IN A 9 CASE SERIES

Andrea García-Guillén, Patricia Moya, Antonio José Barroso-Membrilla, Jaime Félix Díme, José Montiel, José Alberto Hidalgo, Albert Flotats, Alejandro Fernández, Josep Maria Lobet, Berta Magallanes, Ana Láz, Ivan Castells, Hector Corominas, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Takayasu arteritis (TA) is a rare large vessel vasculitis that affects the aorta (Ao) and its main branches. Early diagnosis and the rapid establishment of treatment are key points in the prognosis of the disease. Despite the existence of different classification and diagnostic criteria, early diagnosis of TA continues to be a challenge.

Objectives: 1) To analyze the concordance between the different classification and diagnostic criteria in patients with TA. 2) To describe the demographic, clinical and analytical characteristics of TA.

Methods: Retrospective observational study that included all patients diagnosed with TA according to medical criteria between 1981 and 2018, who were treated at the University Hospital San Ignacio in Madrid.

Results: We included 9 patients (77.8% women) diagnosed with TA. The age at diagnosis was 33 ±16.3 years with a time of evolution of 5.1 ±4.4 years. The other variables are shown in Table 1.

The most frequent vascular territories affected were abdominal Ao (7), descending thoracic Ao (5) and iliac arteries (5). The most common type of arterial lesion was stenosis (8) followed by dilation and aneurysm. 6 patients were treated with corticotherapy as an induction treatment, 5 required chronic immunosuppression and 6 patients required surgery. When reviewing the criteria we observed that all patients met the ACR criteria and 7 patients met the modified criteria by Sharma. However, the agreement with Ishikawa’s diagnostic criteria was poor since 7 patients did not meet them. The different criteria are shown in Table 2.

Conclusion:
- The most frequently affected vascular territory was the abdominal Ao, and the most common type of injury was stenosis.
- The most common clinical presentation was asymmetry of blood pressure between extremities and peripheral pulses, HTA and limb claudication.
- All patients met the ACR 1990 classification criteria and the great majority met the criteria modified by Sharma. The concordance with Ishikawa’s criteria was poor so they should be used cautiously.

AB0588 GASTROINTESTINAL INVOLVEMENT OF BEHCET’S DISEASE IN RUSSIA

Regina Goloeva, Zemfira Alekberova. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Behcet’s disease (BD) is a multisystem vasculitis with unknown etiology and a unique geographical distribution. Intestinal manifestations of BD (IBD) are of particular importance as they are associated with significant morbidity and mortality. Although ileocecal involvement is more commonly described, BD may involve any segment of the intestinal tract as well as the various organs within the gastrointestinal system.

Objectives: To analyze the severity and clinical features IBD in Russia

Methods: The study included 250 patients (male – 177, female – 73) with BD (according to ISGDB 1990 and ICBD criteria 2014). The male-to-female ratio was 2.41; the mean age was 31.5±9.3 yrs, the age of disease onset - 21.81±9.2 yrs, the median of disease duration - 10.25 ±8.32 yrs. All those with gastrointestinal symptoms were subject to a gastroscopy and/or colonoscopy through which Crohn’s disease and ulcerative colitis were excluded by the proteologists.

Results: Patients with gastrointestinal symptoms were 63 of 250 - 25.2% pts, (male – 40, female – 23). Symptoms of IBD include the abdominal pain in 62% pts, distension -55%, diarrhea – 14%, nausea –13%, blood in the bowel movement – 4.7%, the examination revealed: esophageal ulcers (1.6%, four cases), gastric ulcers (3.2%, eight cases), and duodenal ulcers (1.2%, three cases) were found using endoscopy. Also, 6.8% (17 patients) had gastro duodenal ulcers and 14.3% (nine patients) combined gastro intestinal involvement including esophageal and had gastro duodenal ulcers. Colonic ulcers were detected in 9.2% (23 cases) by colonoscopy, two patients had multisegmental diffuse ulceration, three patients had in the sigmoid colon and of everyone else in the ileum. Croftil without ulcers found in 5.6% (14 cases). Two patients had a clinic of appendicitis, the operation found that the appendix is not inflamed. Two patients were 0.8% (were on treatment) urgently operated due to perforation of ulcers of the ileum, the woman held suturing of perforated ulcer, and a man - hemicolectomy. The last patient has a relaparotomy after 1 month and removal of the entire colon.

Conclusion: The IBD in Russia is affected in 1/4 of patients, but heavy refractory forms not often.
ANCA ASSOCIATED VASCULITIS: OUR EXPERIENCE FROM A TERTIARY CARE CENTER OVER 10 YEARS

Anjali Gummadi1, Ankita Singh1, Sandesh Gulania1, Pandara Jan7, Anju Gupta1, Deepthi Suri3, Ankur Jindal1, Biman Saikia1, Armit Rawat1, Surjit Singh2. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatrics, Advanced Pediatric centre, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatrics, Advanced Pediatric centre, Chandigarh, India; 3Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatrics, Advanced Pediatric centre, Chandigarh, India

Background: The anti-neutrophil cytoplasmic antibody (ANCA)- associated vasculitides (AAV) are a group of disorders characterized by necrotizing inflammation of the small to medium vessels in association with autoantibodies. Childhood ANCA vasculitides are rare but can cause organ or even life-threatening systemic vasculitis. Children most frequently present with rapidly evolving, severe disease.

Objectives: To describe the clinical spectrum of ANCA associated vasculitis, the treatment given and follow up.

Methods: A single-centre retrospective analysis of ANCA associated vasculitis over a period of 10 years from 2008 to 2018

Results: Six children (2 boys; 4 girls) were diagnosed to have AAV during this period. Median age at diagnosis was 11.25 years (range 8-18 years). Median delay in diagnosis was 1.5 months (range 1-8 months). Presenting clinical features included lung disease- 4 children; arthritis- 3 (knee, right ankle-left 3rd MCP, left elbow-knee) hemoptysis- 2 children; ear discharge- 1; redness of eye-1; oliguria, gross hematuria-2; anasarca- 2; 2 children had comitant neurological symptoms (left foot drop, quadraparesis with seizures). All children had fever at presentation. Laboratory investigations showed elevated erythrocyte sedimentation rate(ESR) and C-reactive protein(CRP). ANCA testing was positive in 6 children (3 c-ANCA, +PR3, 3 p-ANCA, +MPO). Deranged renal function tests, proteinuria, microscopic hematuria were seen in 4 out of 6 children. Renal biopsy showed pauci immune glomerulonephritis in 4 cases who presented with nephritis. All patients were treated with 5 pulses of intravenous methylprednisolone(30 mg/kg/day) with tapering doses of oral steroids. Intravenous cyclophosphamide pulses was given in 5 children while 1 received additional plasmapheresis (PLEX) 8 cycles. Methylaine therapy included azathioprine (given in 5 children), low-dose prednisolone. Thrombocytopenia was noted in 1 child while on azathioprine; this was subsequently substituted with mycophenolate mofetil. Two children have been lost to follow-up. Median duration of follow-up is 35.5 months (range 8-124 months). All 4 children have attained remission with good compliance and there are no relapses.

Conclusion: Our retrospective analysis indicated that cumulative CR rates and PSL tapering did not significantly differ between low-dose versus high-dose RTX therapy as remission induction therapy in Japanese AAV patients, mostly elderly MPA patients, although there was no significant difference in severe adverse effects such as opportunistic infections between them.

Disclosure of Interests: None declared

Table: Characteristics of children enrolled in study

A SINGLE CENTER RETROSPECTIVE ANALYSIS OF EFFICACY AND SAFETY BETWEEN LOW-DOSE VERSUS HIGH-DOSE RITUXIMAB AS REMISSION INDUCTION THERAPY IN JAPANESE PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Kei Hino1, Manami Hirata, Yuuko Yamamuro, Akiko Ueno, Masahiro Yamamuro, Okayama Saiseikai General Hospital, Center for Rheumatology, Okayama city, Japan

Background: Administration of four once-weekly doses of 375 mg/m2 rituximab (RTX) has been indicated for ANCA-associated vasculitis (AAV) as remission induction therapy. However, randomized controlled trial for Japanese AAV patients has never been conducted, although Japanese AAV patients are characterized by the predominance of elderly patients with microscopic polyangiitis (MPA).

Objectives: To compare the efficacy and safety between low-dose versus high-dose RTX therapy as remission induction therapy in Japanese patients with AAV.

Methods: A single center retrospective analysis of 27 consecutive AAV patients with RTX therapy was performed. Clinical and laboratory variables at diagnosis, rates of complete remission (CR), defined as Birmingham Vasculitis Activity Score (BVAS)=0 and prednisone <7.5 mg/day, adverse effects, and vasculitis relapses following RTX use.

Results: Twenty-five MPA patients and 2 GPA patients (14 males and 13 females) were included in the present study. Twenty-six patients were positive for MPO-ANCA. Their median age was 77 years (range: 40-85 years). Treatments were determined according to the discretion of the attending physician. As remission induction therapy, 18 patients were treated with once or twice (1/2) RTX infusions (375 mg/m2), while 9 patients with 3 or 4 times (3/4) RTX infusions. At 6 months, 55.6% of the 1/2 infusion group (10/18) and 44.4% of the 3/4 infusion group (4/9) reached CR. At 6 months, mean PSL levels were 7.8 mg/day in the 1/2 infusion group and 6.6 mg/day in the 3/4 infusion group. At 18 months, 88.9% of the 1/2 infusion group (16/18) and 77.8% of the 3/4 infusion group (7/9) were survived. 0% of the 1/2 infusion group (0/18) and 33.3% of the 3/4 infusion group (3/9) were relapsed. Severe adverse effects occurred in 38.9% of the 1/2 infusion group (7/18) and in 22.2% of the 3/4 infusion group (2/9).

Conclusion: Our retrospective analysis indicated that cumulative CR rates and PSL tapering did not significantly differ between low-dose versus high-dose RTX therapy as remission induction therapy in Japanese AAV patients, mostly elderly MPA patients, although there was no significant difference in severe adverse effects such as opportunistic infections between them.

POSITIVE PREDICTIVE VALUE OF THE GIANT CELL ARTERITIS REGISTRY IN THE DANISH NATIONAL PATIENT REGISTRY: A VALIDATION STUDY

Peter Hjort1, Philip Therkildsen1, Berit Dalgaard Nielsen1, Ib Hansen1, Annette de Thurah2, Ellen-Margrethe Haug1, 1Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 2Aarhus University Hospital, Aarhus, Denmark

Background: Giant cell arteritis (GCA) is the most frequent systemic vasculitis[1]. The diagnosis is clinical and based on symptoms, histopathology, biochemistry and imaging. In Denmark, diagnostic codes for all in- and outpatient hospital diagnoses are registered in the Danish National Patient Registry (DNPR) [2]. Since GCA can be difficult to diagnose and treatment is initiated on suspicion, we hypothesized that the overall positive predictive value (PPV) of the GCA diagnosis code in the DNPR is low. High data quality is important for future epidemiological research in GCA.

Objectives: To establish PPV of the diagnostic code of GCA in the DNPR. Furthermore, to identify characteristics associated with a high PPV of the diagnostic code.

Methods: 293 patients aged ≥50 years with a first-time register-based GCA diagnosis were included from the DNPR in the period January 2012-January 2018. Patients were sampled based on the ICD-10 codes (M31.5 and M31.6) from two regional hospitals and one university hospital in the Central Region of Denmark. As gold standard we used the medical records (including biochemistry, histopathology and imaging results) and categorized each patient as true GCA or non-GCA. Based on the data from the prescription database, patients were divided into four categories depending on the number of prednisolone prescriptions they received. Two independent investigators (PH and PT) reviewed the medical records. In case of disagreement the final diagnosis was reached by consensus or by expert opinion (ITH). To test how the PPV varied,
Systemic vasculitis involving the breast is a rare clinical condition and may mimic breast cancer or mastitis clinically or radiographically. In this article, we reported a case of polyarteritis nodosa (PAN) with breast involvement and made a summary on the published cases of systemic vasculitis affecting breasts in order to better understand this disorder.

### Methods

We reported a case of PAN affecting breast and conducted a retrospective review of letters reporting patients with the diagnosis of systemic vasculitis involving breasts by using MEDLINE, EMBASE, Web of Science, the Cochrane Library, and Scopus database in any language up to June 1st, 2018.

### Results

A case of a 27-year-old female patient presented with a painful mass of the right breast was diagnosed as PAN by the biopsy. After six months of treatment of full dose prednisone and methotrexate, her condition kept stable and inflammatory markers remained normal. A total of 67 months of treatment of full dose prednisone and methotrexate, her condition kept stable and inflammatory markers remained normal. A total of 67 cases were included, with granulomatosis with polyangiitis (GPA), giant cell arteritis (GCA) and PAN as the main types. The typical manifestation was mass (79.2%, 53/67) in the breast. All the diagnoses were made according to the pathology of the breast biopsy. Glucocorticoid and immunosuppressant were the main therapies. 74.6% (50/67) patients achieved remission during follow-up.

### Conclusion

This is the first study to validate the diagnostic code of GCA in the DNPR. The overall PPV of a first-time diagnosis of GCA in the DNPR is low. The probability of identifying true cases of GCA increases substantially when diagnostic codes are combined with 3 visits and ≥3 prescriptions of prednisolone.

### Disclosure of Interests

A special thanks to Mette Nørgaard for her help.

Disclosure of Interests: None declared

Conclusion: Although pANCA is thought to be associated with ILD or pulmonary fibrosis, we detected equal numbers of c and pANCA in a well-characterised population of ILD patients. Approximately one quarter of patients with p or cANCA had an MDT diagnosis of ANCA-associated vasculitis. The clinical and CT characteristics did not differ between c and pANCA ILD patients. The two-year mortality of patients with ANCA and ILD was significant (22% in cANCA-ILD and 16% in pANCA). In surviving patients, the FVC and DLCO improved over a 24-month period.

THE USEFULNESS OF 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY CT (18F-FDG PET/CT) AS AN IMAGING BIOMARKER IN TAKAYASU ARTERITIS TREATED WITH TOCILIZUMAB

Mikuya Kato1,1, Hanae Okuda2, Tomohiro Kameda1, Taichi Miyagi1, Risa Wakiya1, Shusaku Nakashima1, Hiroshi Shimada1, Mai Mahmoud Fahmy Mansour1, Yuka Yamamoto2, Hiroaki Dubashi1, Kagawa university. Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa, Japan

Background: Disease activity in large vessel vasculitis (LVV) including TAK is traditionally assessed by clinical and serological (ESR, CRP) parameters. Imaging assessment, including FDG-PET, may also be useful to monitor LVV. On the other hand, Tocilizumab (TCZ) treatment showed a favorable trend toward refractory Takayasu arteritis (TAK) (1). Because the TCZ could suppress the CRP or ESR elevation strongly despite the exist of TAK disease activity, clinical and serological (ESR, CRP) parameters could not reflect the disease activity of TAK appropriately.

Objectives: This study objective was to determine the efficacy of 18F-FDG PET/CT on the evaluating the disease activity of TAK treated TCZ compared with clinical and serological parameters.

Methods: Five Patients with TAK were recruited into a prospective, observational cohort. All patients in this study underwent FDG-PET/CT scans at 6 - 12 month intervals before and after TCZ treatment. Serological (ESR, CRP) and clinical assessment were determined at each visit. Disease activity was determined whether scans were active or inactive based on visual inspection of arterial 18F-FDG uptake. To determine the score of arterial FDG uptake assessed qualitatively relative to liver activity in 10 vascular beds with higher scores indicating more vascular inflammation. Additionally, scoring of FDG uptake was conducted to calculate as divided into 4 grade compared with liver activity: 0, no uptake present; I, low-grade uptake (uptake present but lower than liver uptake); II, intermediate-grade uptake (similar to liver uptake); III, high-grade uptake (higher than liver uptake) (2). Clinical and imaging assessments were performed blinded to each other.

Results: All 5 cases (one male and 4 female) were initiated by TCZ treatment. The average age was 42.2±11.6 years old. The disease duration at the administration of TCZ was 176±136 months. The mean dosage of PSL was 6.4±3.72 mg/day. After initiating TCZ treatment, mean CRP values decreased from 1.44±1.80 to 0.032±0.034, and the PSL dose was reduced to 4.00±2.61 mg/day. No serious adverse events were observed. Thorough serum level of inflammatory biomarker such as CRP or ESR had become into normal range in all patients, arterial 18F-FDG uptake also remained in all patients after TCZ treatment. Additionally, clinical manifestations were correlate with site numbers and score of FDG uptake. The change of FDG score could reflect the improvement of clinical manifestation compared with serological biomarkers.

Conclusion: Serological biomarker such as CRP or ESR could not reflect disease activity appropriately in TAK patients treated with TCZ. 18F-FDG PET/CT was more useful for evaluating disease activities in Takayasu arteritis treated with TCZ. Further study might be needed to determine the definition of complete remission in TAK patients treated with TCZ.

**ASSESSMENT OF DAMAGE IN TAKAYASU ARTERITIS PATIENTS WITH VASCULITIS DAMAGE INDEX (VDI) AND TAKAYASU ARTERITIS DAMAGE SCORE (TADS)**

Serra Kaymaz Tahra, Fatma Alibaz-Oner, Haner Direskeneli. Marmara University Faculty of Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** Evaluation of damage in patients with takayasu arteritis is important because of the mortality and morbidity burden caused by the disease. Damage can be associated with treatment or with the disease itself.

**Objectives:** In this study we aimed to evaluate the damage in our Takayasu arteritis patients by using VDI and TADS scores.

**Methods:** Takayasu arteritis patients fulfilling the ACR 1990 criteria and had >3 months follow-up were enrolled in this study. TADS and VDI scores calculated at the end of the follow-up evaluated and compared.

**Results:** 114 patients (F/M: 101/13) were included in the study. The mean age at diagnosis, median symptom duration at baseline visit and mean follow-up duration were 35.3±13.3 years, 12 (0-360) months and 76.9±51.4 months respectively. Mean VDI score was 5.1±2.5 and mean TADS score was 7.9±3.5. At least one disease-related damage item was present in all of the patients for both VDI and TADS meanwhile ≥1 treatment-related damage item was established in 69 (66.1%) patients with VDI and 46 (40.7%) patients with TADS scoring system. Median treatment-related-item number was 1 (0-6) in VDI and 0 (0-3) in TADS. This difference may be due to the lack of disease-related parameters such as diabetes, cataract, osteoporosis, avascular necrosis in TADS. The median number of disease-related items was higher in TADS scoring (4 items vs 8 items). TADS scores include more detailed and higher number of items under vascular intervention and pulse loss categories. Also abrupt and systolic hypertension data is only available in TADS(Table1).

There was no significant difference between patients with relapsing disease and patients with no relapses for both TADS and VDI scores. There was a weak correlation between VDI and cumulative steroid dose ($r=0.19$). No correlation was detected for TADS and cumulative steroid dose. There was a weak correlation between VDI and cumulative steroid dose ($p=0.04$). A positive correlation was observed between the CRP levels before imaging and total m-PETVAS scores ($p=0.01$, $rho=0.52$). In 35/38 imaging assessments the score was >0 and the immunosuppressant agent was changed in 24 (63%) of these patients. Twenty-seven patients received corticosteroids before imaging. No difference in PETVAS scores were present between patients who were taking steroids vs non-steroid use. In 11 patients (29%), PET involvement other than the 9 arterial areas used for assessing the score, were observed. The mean age of this group was higher than the rest of the group (47.2±14.7 vs 35.7±11.2 years).

**Conclusion:** FDG-PET-CT assessment with a modified PETVAS (assessed at one hour) demonstrated higher scores in patients with Takayasu's arteritis.

**CAN A ONE-HOUR QUANTITATIVE ASSESSMENT OF FDG-PET-CT (MODIFIED-PETVAS) BE USEFUL IN TAKAYASU’S ARTERITIS?**

Serra Kaymaz Tahra1, Salih Ozgüven2, Ali Ugur Uenal1, Fatma Alibaz-Oner1, Tunca Oner1, Tanju Yusuf Erdil1, Haner Direskeneli1, Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 1Marmara University Faculty of Medicine, Department of Nuclear Medicine, Istanbul, Turkey

**Background:** FDG-PET-CT is suggested as an imaging method for the assessment of disease activity in Takayasu’s arteritis (TAK). Recently PETVAS, a quantitative score assessed at 2-hours is suggested as an imaging tool for TAK (1). However, most studies with FDG-PET-CT in the literature is performed at one-hour, similar to suggested as the minimum time in recent EULAR recommendations for the use of imaging in large-vessel vasculitis (2).

**Objectives:** In this study, we aimed to evaluate the value of a modified PET Vascular Activity Score (PETVAS) (performed at one-hour) during the initial diagnosis and follow-up of TAK patients.

**Methods:** Patients who are diagnosed with Takayasu’s arteritis and underwent FDG-PET-CT imaging during their follow-up were evaluated in this study retrospectively. FDG-PET-CT imaging was performed at the first hour of FDG uptake. Demographic and clinical characteristics of the patients were recorded from patients’ charts. Physician’s Global Assessment (PGA) was used to determine clinical activity. In the modified PETVAS scoring system, 9 arterial areas (Ascending Aorta, Aortic Arch, Descending Thoracic Aorta, Abdominal Aorta, Right Carotid Artery, Left Carotid Artery, Innominate Artery, Right Subclavian Artery, Left Subclavian Artery) were scored between 0 and 3 according to the PGA uptake (3). The visual analysis using the liver FDG uptake as the reference was also assessed and compared with m-PETVAS score.

**Results:** Thirty-eight imagings of 28 patients (F/M: 22/6, mean age=39.7 ± 14.8 years) were evaluated. Median CRP level was 16.7 (2-126) mg/L. Median m-PETVAS score was 5 (0-27) and m-PETVAS was significantly higher in patients who were accepted as active according to PGA (median PETVAS score 6.0 vs 1.5, $p=0.03$). Similarly, patients who have an active PET assessed with only visual analysis (VA) have higher m-PETVAS scores than patients who were VA inactive (median score 9.0 vs 2.5, $p=0.000$). A positive correlation was observed between the CRP levels before imaging and total m-PETVAS scores ($r=0.01$, $rho=0.52$). In 35/38 imaging assessments the score was >0 and the immunosuppressant agent was changed in 24 (63%) of these patients. Twenty-seven patients received corticosteroids before imaging. No difference in PETVAS scores were present between patients who were taking steroids vs non-steroid use. In 11 patients (29%), PET involvement other than the 9 arterial areas used for assessing the score, were observed. The mean age of this group was higher than the rest of the group (47±14.7 vs 35.7±11.2 years).

**Conclusion:** FDG-PET-CT assessment with a modified PETVAS (assessed at one hour) demonstrated higher scores in patients with Takayasu’s arteritis.
artefactis who were considered clinically active or had increased CRP. However, the scores were lower compared to the original scoring performed at two hours. Therefore, whether one hour investigations have sufficient discriminatory value requires further studies.

AB0598 OSTEOPOROSIS AND RISK OF GIANT CELL ARTERITIS: A COMPARATIVE STUDY

PENDU Claire1, Patrick Tchouante1, Kim Ly2, Jean-François Alexandre3, Natella Aslanbekova5, Khadija Benali5, Solange Gonzalez-Chiappe1, Sarah Lechtman4, Damien Sene4, Cornelia Weyand5, Karim Sacre3, Alfred Mahr1, Sarah Lechtman4, Damien Sene4, Cornelia Weyand5, Karim Sacre6, Alfred Mahr1, 1Saint-Louis University Hospital, PARIS, FRANCE; 2Limoges University Hospital, Limoges, France; 3Bichat University Hospital, PARIS, France; 4Latinoë Alliance University Hospital, PARIS, France; 5Stanford University, PALO ALTO, United States of America

Background: Giant cell arteritis (GCA) and osteoporosis (OP) share many epidemiological features, such as occurrence in people >50 years old and increased incidence in women and northern Europe. Some known risk factors of OP, such as early menopause, nulliparity, low body mass index (BMI) and smoking, have also been linked to increased risk of GCA.

Objectives: We performed this study to investigate a potential link between OP and GCA onset by screening for OP by computed tomography (CT).

Methods: We retrospectively analyzed consecutive patients who underwent temporal artery biopsy (TAB) for suspected GCA in 4 hospitals. Cases and controls were defined by TAB-proven GCA and non-GCA diagnosis, respectively. Selection criteria additionally included 18F-FDG PET/CT at ±30 days (GCA cases) or ±90 days from the date of TAB (non-GCA cases). A radiologist blinded to patients case or control status used thresholds of 110 Hounsfield units (HU) or 135 HU (1). We compared cases and controls for proportion of OP for the entire population and by sex. Statistical analyses involved chi-square and Student t tests for categorical and continuous variables, respectively.

Results: We included 50 cases and 59 controls. The most common diagnoses for controls were neurological involvement (11.3% vs 21.4% p<0.05) resulted more frequent in females versus 0.9% respectively; p<0.01). Erythema nodosum (EN) (59% versus 31% p<0.01) and intestinal ulcerations (GU) and a wide spectrum of skin lesions. Other BS features include ocular inflammation, articular, gastrointestinal, vascular and neurological involvement. Some evidences suggest that in non endemic regions the disease tend to be less severe and women seem to be more commonly affected [1-3].

Conclusion: We included 50 cases and 59 controls. The most common diagnoses for controls were neurological involvement (11.3% vs 21.4% p<0.05) resulted more frequent in females versus 0.9% respectively; p<0.01). Erythema nodosum (EN) (59% versus 31% p<0.01) and intestinal ulcerations (GU) and a wide spectrum of skin lesions. Other BS features include ocular inflammation, articular, gastrointestinal, vascular and neurological involvement. Some evidences suggest that in non endemic regions the disease tend to be less severe and women seem to be more commonly affected [1-3].

AB0599 CLINICAL MANIFESTATIONS OF BEHÇET’S SYNDROME IN A LARGE COHORT OF ITALIAN PATIENTS: FOCUS ON GENDER DIFFERENCES

Pietro Leccese1, Nancy Lascaro1, Maria Carmela Padula1, Teresa Carbone1, Angela Padula1, Salvatore D’angelo2,3, Rheumatology Institute of Lucania (IRel), San Carlo Hospital, Potenza, Italy; 2Basilicata Ricerca Biomedica (BRB) Foundation, Potenza, Italy

Background: Behçet’s syndrome (BS) is a chronic multisystemic inflammatory disorder classified among primary vasculitis. BS clinical hallmarks are mucocutaneous manifestations which include oral aphthosis (OA), genital ulcers (GU) and a wide spectrum of skin lesions. Other BS features include ocular inflammation, articular, gastrointestinal, vascular and neurological involvement. Some evidences suggest that in non endemic regions the disease tend to be less severe and women seem to be more commonly affected [1-3].

Objectives: The aim of this study was to investigate the clinical phenotypes of Italian BS patients with respect to gender and HLA-B51 status.

Methods: We retrospectively evaluated 324 Italian patients (185 males and 139 females), seen consecutively at Rheumatology Institute of Lucania (IRel) from 1st January 2000 to 31st December 2017. Demographics, clinical features during follow-up and HLA status were obtained from a review of medical records. The analysis was limited to patients fulfilling the ISG criteria.

Results: 324 BS patients were identified in our database. 39 (17 males and 22 females) were excluded because did not satisfied ISG criteria and 285 (168 males and 117 females) resulted eligible for the present study. Results are summarized in table 1. We found statistically significant differences in papulopustolar lesions, posterior uveitis and deep venous thrombosis (DVT), which occur more frequently in males compared with females (83.3% versus 46.2%, 37% versus 18.8% and 8.3% versus 0.9% respectively; p<0.01). Erythema nodosum (EN) (59% versus 41.1%, p<0.01), arthralgia (52.1% versus 31.5%, p<0.01) and intestinal involvement (11.3% vs 21.4% p<0.05) resulted more frequent in females compared with males. No differences were found in HLA status (M 67.9% vs F 61.5%).

REFERENCE

Conclusion: In our cohort of Italian BS patients the disease results slightly more prevalent in males. Gender-related differences were observed for posterior uveitis, DVP and papulopustular lesions which are more frequent in males, whereas EN-like lesions, arthralgia and intestinal involvement are more frequently observed in females. These data confirm that BS tend to be less aggressive in Italian female patients. No sex-differences were observed in HLA-B51 status.

Methods: We retrospectively evaluated BD patients according to ICBD (2) and/or ISG (3) criteria who had undergone apremilast therapy (30 mg twice daily) for oral and/or genital ulcers from November 2017 to January 2018 in four different specialized referral Units in Italy (Bari, Firenze, Potenza, Siena). Retrieved data including previous treatments were also collected. Our endpoint was to assess the number of oral and genital ulcers under apremilast treatment. Moreover pain due to ulcers was evaluated with a 100-mm visual-analogue scale (VAS), whereas disease activity was assessed by means of BDCAF score. Paired t-test or Wilcoxon matched-pair signed rank test, if applicable, were used for statistical analysis.

APREMILAST EFFECTIVENESS IN REFRACTORY ORAL AND GENITAL ULCERS OF BEHÇET’S DISEASE: DATA FROM REAL LIFE SETTINGS

Giuseppe Lopalco1, Vincenzo Venerito1, Pietro Leccese2, Giacomo Emmi3, Luca Cantarini4, Nancy Lascaro2, Gerardo Di Scala5, Stefano Gentileschi1, Anna Abbuzzese1, Marco Fornar4, Fabio Cacciapaglia1, Giovanni Lapadula5, Lorenzo Iannone1, University of Bari, Bari, Italy;2Rheumatology Institute of Lucania, Potenza, Italy;3University of Florence, Firenze, Italy;4University of Siena, Siena, Italy

Background: Mucocutaneous lesions represent the earliest and the most frequent manifestations of Behcet’s disease (BD), and may become disabling leading to substantial effect on quality of life. Recently the efficacy of the small molecule inhibitor of phosphodiesterase 4 apremilast in treating oral and genital ulcers has been shown in a phase 2 trial (1), whereas to date no results from real world data are available.

Objectives: The purpose of the present study was to describe our experience with apremilast in treating BD patients with oral and genital ulcers refractory to traditional therapies and previous biologic agents in real life settings

UTILIZATION OF A MULTISPECIALTY TEAM FOR THE DIAGNOSIS OF GIANT CELL ARTERITIS REDUCES PATIENT MORBIDITY

Arash Hassantouffigh, Rachel Lu Do, Joshpaul Dhillon, Christopher Collins, Florina Constantinescu, MedStar Washington Hospital Center, Rheumatology, Washington, United States of America, MedStar Washington Hospital Center, Internal Medicine, Washington, United States of America

Background: Giant Cell Arteritis (GCA) is an autoimmune vasculitis, most commonly seen in older adults with a peak incidence in the seventh decade of life. A diagnosis of GCA is often considered in any patient over the age of 50 years who complains of or is found to have new onset headache, acute visual disturbances, jaw claudication, unexplained fever, or elevated inflammatory markers. Because the manifestations of GCA can vary considerably from patient to patient, often with transient and fluctuating symptoms, an accurate diagnosis can be challenging. Even in the setting of a negative temporal artery biopsy, many patients are treated empirically based on the perceived probability of disease. This approach can lead to significant morbidity from prolonged medication exposure and unnecessary procedures.

Objectives: The aim for this project was to look at the impact of a collaborative effort amongst three specialties, rheumatology neurology and ophthalmology, which composed a consultation based “GCA team”, the goal of which was to improve how GCA is diagnosed and subsequently managed.

Methods: We conducted a retrospective study of all patients suspected to have GCA at our institution over the last 2.5 years that had either been seen by the GCA team or not. The GCA team met either in person or had a conference call to discuss each case and make a joint decision regarding the diagnosis and treatment. Data extracted included patient demographics, symptoms on presentation, labs, biopsy results and cumulative prednisone dose.

Results: A total of 30 patients (19 female, 11 male) were evaluated; 19 were seen by the GCA team and 11 were not. The mean ages of the patients in each group were the similar (GCA Team 70.6 (SD 12.5) vs no GCA Team 70.3 (SD 12.3)). The mean ESR between the two groups was also similar (GCA Team 53.3 (SD 30.2) vs no GCA Team 53.8 (SD 27.2)). The presenting clinical symptoms between the two groups were also comparable: visual complaints (63% vs 73%), headache/jaw claudication (42% vs 45%), and cranial neuropathy (11% vs 9%).

All of the patients not seen by the GCA team underwent bilateral tempo-parietal artery biopsy; however none were positive on histology. Regardless, all were continued on high dose prednisone with a 6 month cumulative mean dose of 5,350mg.

Of the 19 patients seen by the GCA team, 8 were determined to be low probability for GCA and thus were spared temporal artery biopsy. Furthermore, all of the patients were recommended a rapid steroid taper and the cumulative mean dose of prednisone was only 490mg. Over 6 months of follow-up, none of the 8 patients deemed low probability had a subsequent diagnosis of GCA given.

In the 11 high probability GCA patients, 10 underwent temporal artery biopsy (one refused) with 4 biopsies read as positive for GCA. Over 6 months of follow up, none of these patients had flares after they were started on treatment.

Conclusion: While the accuracy of a GCA diagnosis cannot be determined in our cohort of patients not seen by the GCA team, it is likely that evaluation by a multispecialty team would have found several to be low probability for GCA; especially as none of the patients had a positive temporal artery biopsy. We have demonstrated that by adopting a collaborative approach to diagnosing GCA, unnecessary biopsies can be avoided as well as limiting unnecessary prednisone exposure. More prospective data is needed to provide an accurate assessment of this team approach for GCA which can serve as a model for other healthcare facilities.

CLINICAL USEFULNESS OF LUNG ULTRASOUND IN ACTIVE GRANULOMATOSIS WITH POLYANGIITIS WITH LUNG INVOLVEMENT – PRELIMINARY DATA

Anna Masiak, Natalia Buda, Zbigniew Zdrowiecki, Medical University of Gdansk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdansk, Poland

Background: Lung involvement is observed in 43% to 94% of patients with granulomatosis with polyangiitis (GPA) [1]. In about 10% of cases, the lung is the only organ affected and in as many as 30% of patients without clinical symptoms of lower respiratory tract involvement, abnormalities in chest imaging examinations can be found [2]. The efficacy of lung ultrasound (LUS) is very well documented in many pulmonary diseases [3,4]. Single publications indicate its applicability also in diagnostics of complications secondary to systemic connective tissue disease, e.g., lung fibrosis or diffuse alveolar hemorrhage [5,6]. The necessity of repeating chest imaging examinations increases the patient’s exposure to ionizing radiation. Thus, the possibility of limiting such exposure through the application of LUS as the diagnostic modality appears extremely inviting.

Objectives: The aim of this study was to assess lesions detected by ultrasound in patients with active granulomatosis with polyangiitis (GPA) in comparison to abnormalities found by computed tomography (CT).

Methods: We analyzed the clinical and radiological data of 12 patients (5 women/7 men, mean age 47.9 years/range 18-80) with active PR3-ANCA-associated vasculitis with lung involvement (Birmingham Vasculitis Activity Score, BVASv5 mean 5.7/range 1-12). LUS was performed in the sitting and lying positions, using the convex (2.6 MHz) and linear (4-12 MHz) transducers placed to each intercostal space over the chest wall (anterior, lateral and inferior). Chest CT was performed according to a standard protocol with the use of a 64-slice CT scanner made by GE. The images obtained in LUS were compared to changes detected in CT scans. The study protocol was approved by an independent local Bio-ethics Committee (NBKN/474/2018).

Results: In all patients with lungs infiltrations, changes were visible in the LUS, but the visualized infiltrates and caviﬁes include only these lesions that were adjacent to the line of pleura. LUS revealed infiltrates as well as infiltrates with features of disintegration and cavities. Subpleural infiltrates in ultrasound were visualized as hypoechoic round or oval consolidations, without central flow visible in color Doppler (CD) and power Doppler (PD) modes. Caves visualized in LUS were round and anechoic; flow in CD and PD modalities was also absent. In some cases, we observed hypoechoic round or oval infiltrates with features of disintegration, partly ﬁlled in with ﬂuid content (anechoic).

Conclusion: Due to the harmlessness of ultrasonography, LUS can be repeatedly performed. In addition, ultrasound examination can be performed during hospitalization at the patient’s bedside as well as during a visit to the rheumatologist’s ofﬁce.

SCOTLAND’S FIRST FAST TRACK TEMPORAL ARTERY ULTRASOUND REFERRAL PATHWAY FOR SUSPECTED GIANT CELL ARTERITIS

John McLaren, Jane Gibson, Sarah Hallwood. NHS Fife, Fife Rheumatic Diseases Unit, Kirkcaldy, United Kingdom

Background: Giant cell arteritis (GCA) is associated with loss of vision (LOV). Rapid referral for specialist assessment including temporal artery ultrasound (TAU) reduces the risk of LOV and the need for temporal artery biopsy (TAB). Two
Clinical features and treatment in a cohort of patients with Behçet disease in a tertiary hospital of Barcelona

Joan María Mercade Torras, Alfredo Guillén-Del-Castillo, Segundo Bujan Rivas, Jaume Mestre Torres, Roser Solans-Laqué. Barcelona, Spain

Background: Behçet disease (BD) is considered a systemic vasculitis according to the Chapel-Hill classification, which occurs most frequently between latitudes 30 and 45° according to the Chapel-Hill classification, which occurs most frequently in the area of the Old Silk Route. Today, it has the highest prevalence, followed by Japan, in Spain, a prevalence of 7.5 cases per 100000 persons has been estimated. The epidemiological and clinical characteristics of European patients with BD vary with respect to those of the Turkish and Japanese cohorts.

Objectives: Description of clinical features and treatment received in a cohort of patients diagnosed with BD in an Internal Medicine Unit of a tertiary centre from Barcelona.

Methods: Retrospective, observational study. Epidemiological, clinical and laboratory data were obtained from clinical charts. SSPS package was used to perform statistical analysis.

Results: 132 patients (56.6% men) diagnosed over the last 30 years and followed-up until the censoring data were included. 112 (84.8%) were Caucasians, 15 (11.4%) from North America, 4 (3%) Asian and 1 (0.8%) from South America, 2 (1.5%) patients had a family history of BD and 9 patients (6.8%) a family history of other rheumatic diseases. 43.9% (58 patients) were HLA-B51. Oral or genital ulcers were present in 131 (99.2%) patients and skin involvement in 106 (80%) cases. 44.8% had erythema nodosum, 59% had acne-like lesions and 9% had cutaneous vasculitis. Ocular involvement was observed in 69 cases (52.3%); 27 patients unilateral and 8 bilateral anterior uveitis; 14 unilateral and 3 bilateral posterior uveitis; 10 patients unilateral and 14 bilateral panuveitis; 19 unilateral retinal vasculitis and 12 bilateral. Neurological involvement was present in 37 (28%) patients: 10 parenchymal disease and 17 cases non-parenchymal disease (aseptic meningitis or vasculitis); 8 patients benign intracranial hypertension, and 3 had dural sinus thrombosis. Articular involvement was recorded in 79 (59.8%) patients (it was observed 25 monoarthritis, 24 oligoarthritis, 6 poliarthritis and 58 patients had arthropal).

Vascular involvement was present in 43 (32.6%) cases: deep venous thrombosis in 38 patients (11 cases in locations other than the extremities); pulmonary embolism in 7, 21 thrombogenic; and 6 patients aneurysms (only 2 pulmonary arterial aneurysms). Digestive involvement was present in 12 (9.1%) patients, with predominant colon involvement (8 cases).

The most prescribed drugs were corticosteroids (85.6%) and colchicine (77.3%), followed by azathioprine (36.4%) and cyclosporine A (33.3%). Other prescribed drugs were thiadomil (6.1%), chlorambucil (6.9%), methotrexate (4.5%), anti-TNF-alpha therapies (infliximab 6.8% and adalimumab 2.3%), cyclophosphamide (3%), mycophenolate (3.8%), leflunomide (1.5%) and 22% received anticoagulation.

Conclusion: Clinical features of our patients are similar to those of other European cohorts, although a high prevalence of organic involvement (ocular, neurological, vascular and joint) should be highlighted.

AB0605 SERUM NEOPTERIN AND ISCHEMIA MODIFIED ALBUMIN LEVELS ARE ASSOCIATED WITH THE DISEASE ACTIVITY OF ADULT IMMUNOglobulIN A VASCULITIS (HENOC–SCHONLEIN PURPURA)

1. Ahmet Ommra, 2. Seđa Colak, 3. Sevin Can Sandıkçı, 4. Cüdvem Yuce 1Health Sciences University, Ankara Numune Training and Research Hospital, Rheumatology, Ankara, Turkey; 2Health Sciences University, Ankara Numune Training and Research Hospital, Clinical Biochemistry, Ankara, Turkey; 3Hidayet Beyazıt University, Rheumatology, Ankara, Turkey; 4University of Health Sciences, Gülhane School of Medicine, Medical Biochemistry, Ankara, Turkey

Background: Immunoglobulin A vasculitis (IgAV) [formerly called Henoch–Schönlein purpura (HSP)] is an IgA mediated systemic vasculitis which primarily affects skin, gastrointestinal system and small vessels of kidneys. Exact pathogenesis of IgAV remains unknown. A few clinicopathological studies have shown that oxidative stress plays a role in the pathogenesis of vasculitis. Ischemia modified albumin (IMA) and Neopterin increased status of oxidative stress.

Objectives: The aims of the study are to investigate serum neopterin and IMA levels in patients with IgAV and evaluate the association of these markers with disease activity and relapse.

Methods: Thirty-four consecutive adult patients (24 males and 10 females) admitted to the rheumatology clinic of Ankara Numune Training and Research Hospital meeting the IgAV American College of Rheumatology (ACR) criteria were enrolled in this cross-sectional study. Demographic and clinical features of IgAV and control group were recorded into a predefined protocol. Disease activity was categorized as “remission” or “active” according to BVAS, BVAS <1 was accepted “active’’. Serum neopterin levels, hsCRP and IMA were evaluated according to BVAS and compared to healthy control group.

Results: Serum median (IQR) neopterin, IMA levels in patients with IgAV and control group were recorded into a pre-designed group. Disease activity was categorized as “remission” or “active” according to BVAS. BVAS <1 was accepted “active”. Serum neopterin levels, hsCRP and IMA were evaluated according to BVAS and compared to healthy control group.

Conclusion: Oxidative stress is important in HSP pathogenesis. Roles of hsCRP, Neopterin and IMA as potential markers of diagnosis and disease activity seem to be worth studying in the future studies with larger study groups.

AB0606  LONG-TERM BIOLOGICAL TREATMENT IN LARGE VESSELS VASCULITIS: A RETROSPECTIVE SINGLE-CENTER STUDY ON 30 PATIENTS FROM 2011 TO 2018

Francesca Regola1, Giovanni Bosio2, Elisabetta Cerutelli2, Angela Tincani1, Paola Toniati1.1 U.O. Rheumatology and Clinical Immunology, ASST Spedali Civili of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy

Background: Glucocorticoids (GC) are the mainstay in the treatment of large vessels vasculitis (LVV), while conventional immunosuppressants have modest GC-sparing effect. Recent studies show that biological drugs could represent a valid therapeutic option, especially in patients with severe and/or relapsing LVV. Their role in the treatment of LVV is expanding, but only few data are available on their long-term efficacy and safety.

Objectives: Our aim is to describe the 8 years’ experience of a single Italian center in biological treatment of patients with large vessels vasculitis (LVV).

Methods: We collected retrospectively clinical data from 30 patients affected by LVV and treated with biological drugs. Data from 18F-FDG PET and CT or MRI associated with improvement of clinical and inflammatory index (ESR and CRP) were used as criteria of response to treatment.

Results: Between 2011 and 2018 we treated 30 LVV patients (22 women and 8 men) with biological drugs: 10 patients with Takayasu arteritis (TAK), 17 patients with large-vessel giant cell arteritis (LV-GCA) and 3 patients with aortitis. The median age (10th–90th percentile) at the diagnosis was 63 (21-79) years. Biological treatment was started right after the diagnosis in 15 patients, while 15 patients had a long-standing relapsed disease (time between diagnosis and biological therapy 6 (1-43) months).

The mean follow-up time of patients was 26 (4-72) months.

Anti-TNF-α drugs (infliximab, adalimumab, golimumab) were used in 9 patients; while anti-IL6 (tocilizumab) was used in 30 patients. During the follow up, 9 patients (23%) switched to another biological for relapse of the disease or for toxic adverse reactions; in 3 cases multiple switches were made.

Infliximab (IFX) was used in 7 patients for a median period of 12 (3-33) months: 3 patients archived stable remission, 3 had an infusion adverse reaction, 1 had a relapse of the disease after 60 months of therapy. Adalimumab (ADA) was used in 3 patients and then suspended in all of them for relapse of the disease after 3, 12 and 93 months of therapy, respectively. Golimumab was used in 2 patients: one suspended therapy for developing follicular thyroid cancer, one switched to another biological for persistent active disease.

Tocilizumab (TCZ) was used in all 30 patients for a median period of 20 (4-54) months: in 25 cases it was the first line therapy, in the other 5 cases it was used after an anti-TNF-α drug. 25 patients out of 30 (84%) archived stable remission and in 6 of them a dose tapering was possible, with no sign of relapse.

Three patients in TCZ had an adverse reaction; one developed a uveitis and one had a relapse of TAK.

In our last examination 29 out of 30 patients in biological therapy demonstrated long-term efficacy and acceptable safety profile and important steroid sparing effect.

AB0607  SELF-MANAGEMENT BEHAVIOURS IN ANCA-ASSOCIATED VASCULITIS: SECONDARY ANALYSIS OF INTERVIEW DATA

Tim Reynolds1, Emma Dures2, Sue Ashdown3, Peter Cronholm1, Raashid Lupman1, Peter Meherf1, Natalya Mitmar1, Jacqueline Peck3, Joanna Robinson3.1 University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom; 2University of the West of England, Bristol, United Kingdom; 3Patient partner, Oxford, United Kingdom, University of Pennsylvania Perelman School of Medicine, Philadelphia, United States of America; 4University of Oxford, Oxford, United Kingdom; 5University of Pennsylvania, Philadelphia, United States of America, 6Division of Rheumatology, Department of Medicine in Ottawa, Ottawa, Canada

Background: ANCA-associated vasculitis (AAV) is a significant cause of morbidity and mortality. Meeting the challenges of AAV effectively requires patients to engage in self-management, including medical management, role management, and emotional management. Self-management is recognised as a key aspect of chronic disease management and forms an important part of the National Health Service 5-year forward plan and the UK strategy for rare diseases. Nonetheless, there has been limited specific research into the role of self-management in the AAV literature.

Objectives: To explore experiences and views of self-management amongst AAV patients.

Methods: A secondary analysis of all interview transcripts from a previous project exploring health-related quality of life in relation to AAV was performed. Deductive analysis was used to map appropriate areas discussed by patients to the self-management framework proposed by Lorig and Holman. Inductive analysis was used to identify emergent themes that did not fit into this framework.

Results: Interview data were collected from 50 patients with AAV (25 men), from the UK (n=18), USA (n=17) and Canada (n=15). Diagnoses included GPA (n=26), EGPA (n=17) and MPA (n=7). Thirty-four patients were diagnosed within the last 2 years and 16 were diagnosed more than 2 years ago.

From the core tasks proposed in Lorig and Holman’s framework, patients with AAV appear to attribute particular importance to maintaining life roles and to a lesser extent medication management and dealing with the emotions of chronic disease. Core skills necessary to self-manage in AAV include learning to take action as part of self-efficacy, forming productive health-care partnerships, learning about decision making (requiring disease and self-awareness), utilising resources effectively, and problem-solving.

Three themes emerged that were not included in Lorig and Holman’s framework that respondents related to self-management abilities including: 1) support received from family, support groups, and religion; 2) the influence of pre-morbid personality factors; 3) the role patients attributed to developing a foundation of specific AAV knowledge in their subsequent ability to self-manage.

Conclusion: Patients with AAV self-manage in a variety of ways and their needs may change over time. Patients may benefit from support to help manage changing life roles and to deal with the challenges of having a chronic disease. Over time, support may need to shift focus onto core skills including recognising when to take action; forming effective partnerships with healthcare providers, family, and friends; adaptations to day-to-day changes in their condition; utilising resources appropriately; and strategies for problem-solving.

AB0608 TOCILIZUMAB TREATMENT FOR LARGE VESSELS

VASCULITIS: REAL LIFE PRELIMINARY EXPERIENCES

giulia righetti, Vincenzo Venerito, Maria Giannotta, Giuseppe Lopato, Margherita Giannini, Fabio Cacciapaglia, Laura Coladonato, Fiorenzo Iannone, Bart Department of Emergency and Organ Transplantations-Rheumatology Unit, Bari, Italy

Background: IL-6 targeting therapy has been proven to be effective and safe in Giant Cell Arteritis (GCA) as well in Takayasu Arteritis (TA) in RCTs, probably because of the similar pathologic findings and vessel size (Large Vessel Vasculitis, LVV). However, real world data are scarce.

Objectives: The aim of the study was to evaluate the effectiveness of Tocilizumab for LVV in real life settings.

Methods: We retrospectively evaluated, from 2011 to 2017, the outcomes (including glucocorticoid dosage) in patients affected by LVV (according to 1990 ACR classification criteria) who received 8 mg/kg iv Tocilizumab (TCZ) monthly, due to the inadequate response to immunosuppressant. Demographic and clinical characteristics and laboratory findings were collected at baseline and consecutive follow up visits, over 52 weeks. Statistical analysis was performed using the GraphPad Software version 6.5 (San Diego CA USA) using appropriate tests.

Results: We analyzed n.10 patients (6/10 GCA, 4/10 TA) with mean age ($\pm$ SD) 56 $\pm$ 21 years and mean disease duration 41.38 months. Eight out of 10 patients were female. Over the entire observation period, 7/10 also received concomitant methotrexate (mean dose 12.8 $\pm$ 2.7 mg/week) while 2/10 received azathioprine (100 mg/day). Median (IQR) prednisone equivalent dose at baseline was 22.5 (10-25) mg/day. At baseline, median ESR was 49 (31-58) mm/h and median CRP level was 15.4 (1.95-28.53) mg/l. Upon TCZ treatment we observed a good disease control in absence of headache, fever and other LVV clinical signs through 52-week follow up. At 52 weeks, we observed a significant reduction of ESR down to 6.5 (2.75-12.25) mm/h as well as of CRP level, down to 1.5 (0.67-3.47) mg/l (p<0.001). A meaningful steroid sparing effect was also achieved as a significant reduction in prednisone dose down to 5 (1.87-6.25) mg/day (p<0.001). During the 52-week follow up period, 3 patients discontinued TCZ treatment for side effects: 1 for severe neutropenia (at 12 weeks), 1 for avascular areas (at 24 weeks), and 1 for diverticulitis (after 52 weeks).

Conclusion: In our real life experience iv TCZ was effective and safe in LVV treatment, with a good disease control and a significant steroid-sparing effect. Our preliminary findings need to be confirmed in larger cohorts and prolonged follow up.

AB0609 NAIFOLD VIDEO CAPILLAROSCOPY AS A POTENTIAL DIAGNOSTIC TOOL IN SYSTEMIC VASCULITIS

1Doron Rimar*, Francesca Ingegnoli1, Ori Rimar1, Ithak Rosner1, Michael Rosenbaum1, Lisa Kaly1, Nina Boullim1, Abid Awisat1, Gleb Stobiomin2, 1Bari-Zion Medical Center, Rheumatology, Haifa, Israel; 2Istituto Gaetano Pini, Division of Clinical Rheumatology, Milano, Italy

Background: Vasculitides are formally classified by artery size: large, medium or small, yet some overlap is evident as in Takayasu, a large vessel vasculitis manifesting also in retinal arterioles. Nailfold videocapillaroscopy (NVC) enables us to inspect changes in microvasculature. Only several small uncontrolled case series of light capillary microscopy in adult patients with vasculitis were reported in the literature, describing avascular areas and microhemorrhages in granulomatosis with polyangiitis (GPA) patients [1-2] and in [4] Behcet disease, and thin and tortuous capillaries in Takayasu arteritis [5].

Objectives: To characterize nailfold capillary changes by NVC in patients with autoimmune vasculitis compared to healthy controls.

Methods: Consecutive autoimmune vasculitis patients fulfilling the ACR criteria and age and gender matched healthy controls were evaluated by NVC using Optilia Mediscope with a magnification of X200. Patients with peripheral artery disease and ischemic heart disease were excluded. Capillaroscopy images were centrally analyzed. NVC was analyzed, noting: architecture, number of capillaries per field, capillary width, capillary morphology, microhemorrhages, peri-capillary stippling (PCS)- hemosiderin deposits probably representing former capillary leak, slow capillary flow (“rolling” or sludging of red blood cells) and avascularity. Continuous data are presented as the mean $\pm$ SD. Categorical variables are presented as frequencies and percentages. Comparisons of continuous variables were made using 2-tailed t-tests and differences between groups by a 1-Way ANOVA.

Results: Seventeen patients with active vasculitis, 8 patients with vasculitides in remission (11 polyarteritis nodosum, 2 GPA, 3 eosinophilic granulomatosis with polyangiitis, 2 microscopic polyangiitis, 2 Takayasu, 3 IgG4 vasculitis (one with cryoglobulinemia), 1 primary central nervous system vasculitis and 1 lupus vasculitis) were compared to 25 age and sex matched healthy controls. The mean age (59 $\pm$18 vs. 51$\pm$19 vs. 52 $\pm$15), and the percent of females (53%, 50%, 60%), were similar across the groups.

Patients with active vasculitis demonstrated higher rate of “rolling”, 74.1% $\pm$27 vs. 12.5% $\pm$22 vs. 6.5% $\pm$12.7, p<0.001; microhemorrhages or PCS 30.1% $\pm$26.4 vs. 1.5% $\pm$4.5 vs. 1.9% $\pm$1, p<0.05, which reversed correspondently with disease duration <6-4, P=0.05, avascular areas 76% $\pm$19.5 vs. 23.4% $\pm$12.8 vs. 26.5% $\pm$22.5 vs. 6% $\pm$10.5, p<0.01. PCS was observed exclusively in 5 of 17 patients with active vasculitis.

Conclusion: Patients with active vasculitis demonstrate capillary abnormalities, namely: “rolling”, microhemorrhages, avascular areas and neangiogenesis. NVC may be a specific sign of active vasculitis. NVC is an easy, readily available additive tool in the management of vasculitis. Further studies are needed to ascertain the role of NVC in vasculitis.

AB0610 PERSISTENT INFLAMMATION DESPITE TOCILIZUMAB TREATMENT IN 2 PATIENTS WITH LARGE VESSEL VASCULITIS AND AORTIC INVOLVEMENT REQUIREING AORTIC VALVE REPLACEMENT

1Andrea Rubbert-Roth*, 1Thomas Langenegger1, Peter Karl Bode2, Claudia Plofe3, Olaf Chan-Hi Kim1, Johannes von Kempten1, 2Rheumatology Clinic, Kantonsspital St. Gallen, St Gallen, Switzerland, 2Rheumatology Clinic, Kantonsspital Zug, Zug, Switzerland, 3Institute of Pathology and Molecular Pathology, University of Zurich, Zurich, Switzerland, 4Pathology Institute, Triemli Clinic, Zurich, Switzerland, 5Radiology Clinic, Kantonsspital St Gallen, St Gallen, Switzerland, 6Rheumatology Clinic, Kantonsspital St Gallen, St Gallen, Switzerland

Background: Tocilizumab (TCZ) has recently been approved for treatment of giant cell arteritis (GCA). Despite clinical, radiologic and serologic improvement in the majority of patients, it remains unclear whether inflammation of the vascular wall in patients with large vessel vasculitis may persist.

Objectives: To report 2 patients who were treated with TCZ for large vessel vasculitis involving the ascending aorta. The patients underwent aortic valve replacement in both cases and partial replacement of the ascending aortic arch in one case.

Methods: Following therapy with glucocorticosteroids (GC) and TCZ, replacement of the aortic valve and of the partial ascending aorta were performed, followed by a histopathologic examination of the surgical specimen.

Results: We report two female patients, aged 40 and 67 years, both diagnosed with large vessel vasculitis involving the aortic arch. Aortitis of the ascending aorta and significant aortic insufficiency were demonstrated in both patients by PET-CT, MR angiography and transesophageal cardiac ultrasound.

In Pat 1, PET CT and MR angiography revealed vascular inflammation. Intravenous pulse GC was initiated, followed by oral prednisone with stepwise tapering and TCZ iv 8mg/kg/month. Two weeks after the 2nd infusion of TCZ, MR angiography showed significant reduction of gadolinium enhancement in the wall of the ascending aorta and the patient subsequently underwent valve replacement. Pat 2 was diagnosed with vasculitis of the aortic arch by MR angiography. Therapy with oral GC (1mg prednisone/kg) and methotrexate was initiated. After 12 months, the treatment was switched to TCZ 162mg sc once weekly because of inadequate control of disease. The patient was monitored clinically and by PET CT and GCA was considered well controlled over 4 years. Due to continuous enlargement of the ascending aorta resulting in significant aortic insufficiency, the patient underwent replacement of the aortic valve and the ascending aorta.

Both patients showed normalization of CRP and ESR during TCZ treatment.

In summary, despite PET-CT and MR angiography showing reduction in vascular wall inflammation before surgery and CRP and ESR normalized, both patients showed histologically persistent lymphoplasmacellular infiltrates (predominantly CD3+CD4+ T cells in patient 1) and, in addition, giant cells in pat 2.

Conclusion: Despite adequate control of large vessel vasculitis involving the ascending aorta clinically as well as by imaging, the 2 patients reported here had to undergo valve replacement which showed persistent inflammation of the aortic wall despite treatment with TCZ.

AB0611 A NEW SHAPE OF THE TREATMENT OF VASCULITIDES: SINGLE CENTER BIOLOGICAL AGENTS EXPERIENCE

Faith Aboyar, Mehmet Emin Derin, Burak Karakaş, Ali Sabir, Sivas Cumhuriyet University, sivas, Turkey

Background: Vasculitides are a group of inflammatory diseases with different clinical and pathological features of vital importance in various sized and types which may lead to organ failure and inflammation of the vascular wall. The framework for the treatment of vasculitis is similar to that used for many other systemic autoimmune rheumatic disorders, while the specific therapeutic regimen depends upon the nature and severity of the particular disorder (1,2).

Objectives: The aim of this study is to evaluate the efficacy of biological agents in 56 vasculitides patients with resistant/intolerated to cDMARDs.

Methods: Between January 2015 and December 2018, fifty six patients who were diagnosed as vasculitis (Takayasu arteritis-TA, Granulomatosis with polyangiitis(GPA), Giant cell arteritis (GCA) and Behçet Syndrome (BS) at Sivas Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department were included in to the study.

Results: 24 (43%) male and 32 (57%) female were included in the study. The median age of the patients was 56 years (min:19-max: 77) and the median age at diagnosis was 39 years (min 17-max 73). 14 (25%) patients with TA, 22 (39%) patients with GPA, 3 (5%) patients with GCA and 17 (31%) patients with BS included in this study. Tocilizumab treatment was used 6 of 8 patients who were resistant to anti-TNF. In 22 GPA patients with pulmonary and kidney involvement, Rituximab (RTX) treatment was started in 18 patients who were unresponsive to cDMARD and cyclophosphamide therapy. Plasmaexchange were used in 4 (18%) patients with alveolar hemorrhage. Indication of anti-TNF agents in behçet’s syndrome were confirmed 5 cases panuveitis 70%, neuro-behçet 17.5% and vessel involvement 12.5% (Table 1). 1 GPA patient was died and other GPA, TA and BS patients have clinically response. Biological treatment is continued as maintenance therapy.

Conclusion: Biological treatments were used safely and effectively in vasculitis. In particular, RTX treatment is recommended for both induction and maintenance of GPA. Tocilizumab treatment is very effective in TA and GCA. However, large and long-term studies are needed in terms of long-term effects.

AB0612 TEMPORAL ARTERY BIOSPY IN GIAN TCELL ARTERITIS. INTERRELATION OF INFLAMMATORY PATTERNS WITH ANALYTICAL DATA AND CLINICAL MANIFESTATIONS

1Lara Sánchez Bilbao1, Iñigo González-Mazón1, D. Prieto-Peña1, Monica Caldentén-Goercke1, José Luis Martín-Varillas1, Belen Alerza-Mateo1, C. González-Vela2, Miguel A. González-Díaz2, Ricardo Blanco1, 1Rheumatology. Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain; 2Pathology. Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

Background: Giant cell arteritis (GCA) is a systemic vasculitis that affects large and medium vessels, mainly the temporal artery and other arteres of extracranial localization (1).

Objectives: A series of 24 patients with clinical suspicion of GCA proved by a positive temporal artery biopsy (TAB) has been reviewed. Our aim was to assess a) histologic inflammatory patterns in the TAB and b) their possible correlation with analytical and clinical data.

Methods: Prospective study of 24 patients with positive TAB between January of 2016 until January of 2018. Clinical data, included: age, sex, symptoms (cranial, visual or systemic manifestations) and physical examination of the temporal artery. The analytical data registered were: ESR, CRP and haemoglobin. Furthermore, it has been considered if patients were receiving treatment with corticosteroids at the time of the biopsy.

Positive biopsies were classified into four categories: a) inflammation limited exclusively to the small vessels of the adventitia (SVV); b) vasa
vasorum vasculitis (VVV); c) inflammation limited to the adventitia (ILA); and d) transmural inflammation (TMI). The presence of giant cells, thrombosis and distrophic calcification was also noted.

**Results:** We included a total of 24 patients with positive TAB: a) 19 patients (79.16%) presented TMI and b) 5 patients (20.84%) presented ILA. There were no cases with SVV or VVV.

No significant differences at baseline were observed between the 2 groups regarding sex and age, with a mean of 79.6 ± 7.2 years in TMI group and 79.8 ± 7.3 years in ILA group (p = 0.83).

There were no significant differences between the two groups were found in terms of treatment duration prior to BAT and nor in the dose (Prednisone). No significant differences between the two groups with ILA (80%) were receiving treatment with oral glucocorticoid patients in the group with TMI (84.2%) and 4 (of 5) patients in the group and 78.8 ± 7.3 years in ILA group (p = 0.83).

Conclusion: In our sample, we didn’t observe differences between the patterns of inflammation and the analytical and clinical data. It is important to recognise these patterns of inflammation in the TAB to avoid false negatives.

**Disclosure of Interests:** Lara Sánchez Bilbao: None declared, Íñigo González-Mazoín: None declared, D. Prieto-Pería: None declared, Monica Calderón-Goercke: None declared, José Luis Martín-Vallés: None declared, Belén Almenar-Mateo: None declared, C. González-Vela: None declared, Silvia Sartorelli, Corrado Campochiaro, Alessandro Tomelleri, Elena Baldissera, Lorenzo Dagna. IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

**Background:** Takayasu arteritis (TA) is a large-vessel vasculitis usually affecting young women. The age of onset is though variable. Controversial data are reported about differences in disease features according to the age of onset.

**Objectives:** To compare clinical and vascular TA features according to TA age of onset.

**Methods:** We retrospectively evaluated onset demographic and disease features in TA patients followed-up at our Hospital between January 2000 and August 2018. We divided our cohort into 3 groups according to the age of onset: ≤20 (Group 1), 21-40 (Group 2), >40 (Group 3) years.

Diagnostic delay (DD) was defined as the time interval between the first TA symptom and TA diagnosis. Non parametric statistic tests were used.

**Results:** 126 patients (12 male, 114 female) were analyzed. Mean age at onset was 31.46±13.38 years. Group 1 and 3 included 30 (23.81%) patients each, Group 2 66 (52.38%). Mean age at diagnosis was 16.23±13.20 years in Group 1, 29.59±5.80 in Group 2 and 50.87±16 in Group 3. Mean DD was different between the 3 groups: 117.63±79.79 months in Group 1, 56.47±76.98 in Group 2 and 30.68±45.93 in Group 3 (Group 1 vs 2, p=0.021; Group 1 vs 3, p=0.001; Group 2 vs 3, p=0.089). Clinical and laboratory features at TA onset are summarized in Table 1. Among all disease features only arterial hypertension was statistically more prevalent in Group 3 vs Group 1 and 2 (56.67% vs 36.67% and 30.30% respectively, p=0.048). When evaluating vascular involvement, abdominal aorta was more frequently affected in Group 1 (63.33% vs 34.85% and 56.67%, p=0.018) while right iliac and left iliac arteries in Group 3 (40% vs 23.33% and 10.61%, p=0.004; 36.67% vs 23.33% and 12.12%, p=0.024 respectively).

**Abbreviations:** right (R), left (L), common carotid (CC), aorta (ao)
Conclusion: TA patients <20 years might experience a longer DD. Arterial hypertension seems to be a prevalent feature in TA patients >40 years. Vascular involvement seems also be influenced by the age of onset with the abdominal aorta being more frequently affected in younger patients and iliac arteries in older patients.

AB0615 PREVALENCE OF DEPRESSION, ANXIETY, FATIGUE AND SLEEP DISTURBANCES IN PATIENTS OF RA, SLE AND GPA

1SHARMA AMAN, Abhinav Shrivastava1, Sandeep Grover1, Saket Jha1, Gsrsnk Naidu1, Manish Rath1, Sanjay Jain2. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Internal Medicine, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Psychiatry, Chandigarh, India.

Background: The relative frequencies of co-morbidities like depression, anxiety, fatigue and sleep disturbance in RA, SLE and GPA are not fully elucidated.

Objectives: To estimate and correlate the prevalence of depression, anxiety, fatigue and sleep disturbances in patients with RA, SLE and GPA by using time honored scales and PROMIS-HAQ.

Methods: This was a cross sectional study of 183 patients (RA – 57, SLE – 64, GPA – 62). Diagnosis and assessment of depression, anxiety, fatigue was established by patient health questionnaire 9 (PHQ 9). Epworth sleepiness scale (ESS), generalized anxiety disorder assessment scale 7 (GAD 7) and fatigue severity scale (FSS) respectively. PROMIS-HAQ short form 8a was also used to diagnose depression, anxiety, fatigue and its correlation with the above time honored scales was studied.

Results: Mean age of RA, SLE and GPA patients was 45.5 ± 12, 31 ± 9.5 and 42.7 ± 13.5 years respectively. Mean disease duration was 5.7 ± 5.1, 3.3 ± 2.4 and 4.6 ± 4 years in RA, SLE and GPA respectively. Prevalence of depression, anxiety, fatigue, insomnia in RA, SLE and GPA as per standard scales and PROMIS-HAQ is depicted in table 1. The correlation between the standard scales and PROMIS-HAQ for depression [RA (r = .816, p < .001], SLE (r = 0.625, p < 0.001), GPA (r = .772, p < .001)], anxiety [RA (r = .804, P < .001), SLE (r = .799, p<0.001), GPA (0.888, p<0.001)], sleep disturbance [RA (r = .872, p<0.001), SLE (r = .784, p < .001), GPA (r=0.917, p < .001)] and fatigue [RA (r = .815, p < .001), SLE (r = 0.798, p < 0.001), GPA (r=0.805, p <0.001)] was significant.

Table 1. Prevalence of depression, anxiety, fatigue and insomnia by various scales

<table>
<thead>
<tr>

Conclusion: Depression, anxiety, fatigue and sleep disturbance are common in RA, SLE and GPA. PROMIS-HAQ has good correlation with time honored scales for assessment of depression, anxiety, fatigue and sleep disturbance in these disorders.

AB0616 HISPANIC AMERICAN PATIENTS WITH ANCA ASSOCIATED VASCULITIS AND DIFFUSE ALVEOLAR HEMORRHAGE RESPOND COMPARABLY TO INDUCTION TREATMENT

1Simranjit Singh, Francisco Quismorio, Elizabeth Ontis. 1LAC-USC/Keck Medical Center, Rheumatology, Los Angeles, United States of America; 2LAC-USC/Keck Medical Center, Rheumatology, Los Angeles, United States of America.

Background: Hispanic American patients with ANCA-associated vasculitis (AAV) have been reported to have more severe disease and higher

Disclosure of Interests: None declared

damage indices at presentation. One rare but life-threatening complication of AAV is diffuse alveolar hemorrhage (DAH).

**Objectives:** To study the clinical features, course and response to therapy in Hispanic American patients with AAV and DAH seen at a large public teaching hospital that serves medically underserved and low income patients with chronic poor health maintenance.

**Methods:** Among 60 Hispanic American patients with AAV, we retrospectively studied 13 patients with DAH from 2003-2017. Clinical features, laboratory results, diagnostic modalities and treatments given were studied.

**Results:** A total of 13 patients were identified; 6 men and 7 women, mean age of 51±11 years. Anti-PR3 was found in 5 patients, anti-MPO in 8. Nine patients were diagnosed with microscopic polyangiitis and 4 with granulomatous polyangiitis based on ACR criteria or Chapel Hill Consensus Conference definitions. DAH was a presenting manifestation in 12 patients. Gross hemoptysis with hypoxia, drop in hematocrit and chest X-ray infiltrates were seen in all patients diagnosed with DAH. Bronchoscopy with BAL washings confirming diagnosis was done in 10 patients. All patients had multi-organ involvement including nephritis (n=8), peripheral neuropathy (n=1), palpable purpura (n=2), upper respiratory tract involvement (n=4) and eye involvement (n=2). Serum C3 was normal in 12 patients. Renal biopsy in 9 patients showed pauci-immune crescentic glomerulonephritis. Mean BVAS at time of DAH was 21.2±5.1.

All patients underwent induction-remission therapy with pulse methylprednisolone followed by tapering oral prednisone. Induction therapy included IV cyclophosphamide (n=6), rituximab (n=6) and IV cyclophosphamide/rituximab combination therapy (n=1). Nine patients underwent plasma exchange and 5 received IV gamma globulin. Eleven patients required mechanical ventilation; 6 patients needed hemodialysis, 2 temporarily. All 13 patients responded to induction therapy; mean post-induction therapy BVAS was 9.3±3.5. Pulmonary fibrosis after DAH was noted in 2 patients. No early deaths (<6 months) were observed, however 1 patient died within 3 years due to infection. Mean follow-up period was 69±54 months. Maintenance therapy used included prednisone (n=13), mycophenolate mofetil (n=2), azathioprine (n=6) and IV rituximab (n=8). Five patients had clinical relapse, 3 with recurrent DAH. Two patients had minor relapse, defined by their treating physician as requiring increased prednison dose or worsening proteinuria. Mean BVAS at relapse was 15.2±5.5.

**Conclusion:** This first in-depth study of DAH in Hispanic American AAV patients shows that in this socioeconomically disadvantaged patient population, the response to induction therapy is not significantly different from other ethnic groups reported in the literature. DAH remains a severe clinical manifestation of AAV and should be recognized without delay. If treated promptly following EULAR/ERA-EDTA recommendations, good short term response is to be expected.

**AB0617**  
**CUTANEOUS POLYARTERITIS NODOSA TREATMENT: A RETROSPECTIVE CASE SERIES**

*Mohan Stewart,1 Ada Lo2, Kamran Shojainia,1,2*  
1EULAR/ERA-EDTA recommendations, 2University of British Columbia, Internal Medicine, Vancouver, Canada; 3Arthritis Research Canada, Richmond, Canada; 4University of British Columbia, Vancouver, Canada; 5University of British Columbia, Dermatology, Vancouver, Canada; 6University of British Columbia, Pathology, Vancouver, Canada.

**Background:** Cutaneous polyarteritis nodosa (CPAN) is a small-to-medium vessel vasculitis limited to the skin. As it is a rare condition, there is little data available to guide treatment. Previous articles have suggested that colchicine and dapsone be used in mild disease and glucocorticoids in acute flares, with DMRADs such as methotrexate or azathioprine being reserved for moderate to severe disease, or steroid-refractory disease.

**Objectives:** Our objective was to review therapeutic regimens used to treat CPAN and to evaluate patient response.

**Methods:** A retrospective chart review including records from January 2003 to June 2017 was performed to identify patients with both histologic and clinical features of CPAN. We extracted information regarding patient age, clinical presentation, biopsy results, and response to treatment.

**Results:** Thirteen patients were identified who had clinical features of CPAN that were supported by histologic findings on biopsy. The majority of patients were female (92.3%). The average age at diagnosis was 44.9 years and mean duration of follow up was 53 months. All patients had involvement of the lower limbs with the most common cutaneous manifestation being subcutaneous nodules (92.3%), followed by papules (46.2%) and livedo reticularis (30.8%). Eight out of thirteen patients (61.5%) received steroids and three did not experience clinical benefit. Another patient did not respond to prednisone and hydroxychloroquine, but had significant improvement of her symptoms on prednisone and methotrexate. Seven out of nine patients (77.8%) who were treated with methotrexate had a favourable response. Three of those patients responded to methotrexate after failing other therapies such as dapsone, azathioprine, and prednisone.

**Conclusion:** In this case series, we found that most patients had a favorable response to methotrexate and thus the role of methotrexate in treating CPAN merits further investigation. As CPAN often has a chronic relapsing and remitting course, initiating methotrexate at the same time as steroid therapy may lower overall lifetime exposure to steroids.

**A SNAPSHOT OF DISEASE ACTIVITY IN PATIENTS WITH BEHÇET’S SYNDROME: PREDICTIVE FACTORS AND RELATIONSHIP WITH QUALITY OF LIFE**

Rosaria Talarico, Alice Parma, Eralda Zera, Emanuele Calabresi, Chiara Tani, Chiara Baldini, Marta Mosca. Rheumatology Unit, Clinical and Experimental Medicine, Pisa, Italy.

**Background:** Behçet’s Syndrome (BS) is globally characterized by a variable spectrum of disease profile: while prevalent mucocutaneous lesions and arthritis represent the only clinical features in patients with a benign disease subset, there are other patients who develop potentially sight or life-threatening manifestations, due to ocular, neurological or major vascular involvement. Beside the organ involvement, demographic factors could considerably influence the long-term and short-term outcomes of BS.

**Objectives:** The primary aim of the study was to evaluate disease activity in a cohort of BS patients consecutively followed in a BS clinic of a tertiary centre; the secondary aims were to identify potential predictive factors of disease activity and to compare disease activity with quality of life.

**Methods:** One-hundred and thirty patients (71 males and 59 females; mean age 42±8 years, mean disease duration 11±4) with a diagnosis of BS according to the ISG criteria were studied. Disease activity has been evaluated by BDCAF and quality of life by the Short Form (SF) 36. Patients were also categorized in major or minor involvement of BS according or not to the presence of ocular, neurological and vascular involvement in the course of disease. Predictors of long-term outcome were identified by univariate analysis using the log-rank test and by multivariate analysis using Cox proportional hazards regression models.
FAMILY MEMBERS WITH BS MAY NOT CLUSTER IN SIMILAR CLINICAL CHARACTERISTICS

Mulanur Özkorkmaz1,2, Mehmet Engin Tercan, Nasrin Şen, Sibel Yılmaz-Oner, Özcan Keskin1. Karşı Dağlıktar, Kütahya Dumlupınar University, Kütahya, Turkey; 2Kartal Dr. Lutfi Kirdar Training and Research Hospital, Internal Medicine, Istanbul, Turkey; 3Kartal Dr. Lutfi Kirdar Training and Research Hospital, Rheumatology, Istanbul, Turkey

Background: Both genetic and environmental factors may have roles in the pathogenesis of Behcet’s Syndrome (BS). Likewise, occurrence of different clinical cluster of BS may be also influenced by the combination of these two factors. But we do not know the weight of the factors during the emergence of the disease and clinical clusters.

Objectives: We conducted a study for evaluating the frequency of family history for BS in different clinical BS clusters. Furthermore, we assessed the hypothesis that BS patient in the same family generally accumulate in the similar clinical cluster.

Methods: Eighty-five patients and their relatives in our BS cohort were participated to the study. We used International Study Group Criteria for Behcet Disease (ISBD) criteria (1) for classifying our index patients and their first and second degree relatives as BS. We sub-classified BS patient to mucocutaneous, vascular, acne-arthritis-enthesis, eye, neurologic, intestinal and undetermined clusters (2). Firstly, we re-evaluated the family history of our BS patients. Then, the relatives of the patients with already known BS or with having symptoms related with BS were interviewed with phone. All participants have been informed about the study and we have taken consent from them.

Results: Twenty-two (25.9%) of the patients had first or second degree relatives with BS. Furthermore, 27 (31.8%) of our patient were classified to mucocutaneous cluster. In our study, the BS patient with enthesitis-arthritis-acne cluster had highest frequency (44.4%) of family history. However, there was no apparent accumulation of similar findings in index BS cases and their close relatives (Table).

Conclusion: According to result of these studies, there was no finding that supports the hypothesis “BS patients in the same family generally accumulate in the similar clinical cluster”. Still genetic may have major role in the emerging of the BS, such as it is accepted as a member of a group of diseases called MHC-I-opathy (3). However, like most of the diseases, genetic background is not enough for the expression of full-blown disease. Briefly, even in the similar genetic background, multiple and separate hits of environmental or non-genetic factors may take role in the pathogenesis.

REFERENCES
Conclusion: Our data confirm TCZ is highly effective in GCA treatment and has a significant steroid-sparing effect. In our real-life retrospective study, TCZ was also shown to be a safe option in patients with relapsing or refractory GCA.

GENDER DIFFERENCES IN CLINICAL PRESENTATION AND VASCULAR PATTERN IN PATIENTS WITH TAKAYASU ARTERITIS

Alessandro Tomelleri, Corrado Campochiaro, Silvia Sartorelli, Giulio Cavalli, Giacomo De Luca, Elena Baldissera, Lorenzo Dagna. San Raffaele Hospital, Milan, Italy

Background: Takayasu arteritis (TAK) is a chronic large-vessel vasculitis that predominantly affects aorta and its major branches. Although it is more commonly observed in Asian population, it can occur worldwide. TAK affects more frequently women in their second and third decades of life, but occurrence in patients older than 40 years is not rare. Female to male ratio is commonly reported as 9:1.

Objectives: To compare clinical characteristics and pattern of vascular involvement at disease onset according to gender specificity in patients affected by TAK.

Methods: Data from 117 TAK patients (11 male, 106 female) diagnosed according to the ACR criteria from our Centre were retrospectively collected. Differences between men and women with regard to demographic features, diagnostic delay, signs and symptoms attributed to TAK, and arteries involved at diagnosis were compared. Data from 3 published
articles describing sex differences in TAK patients were obtained. A global analysis of these 3 cohorts plus ours (for a total of 578 patients, 108 men and 470 women) was performed. Results: In our TAK cohort, age at disease onset and age at diagnosis were not significantly different between men and women. Diagnostic delay was slightly higher in men. Male patients showed higher involvement of iliac arteries (right, p=0.016; left, p=0.021); female patients suffered more frequently from upper limbs claudication (p=0.026). In the overall analysis, men had higher prevalence of arterial hypertension (p=0.007) and more frequent involvement of abdominal aorta (p=0.026), renal arteries (right, p=0.001; left, p=0.001) and iliac arteries (right, p=0.009; left, p=0.002). Women more frequently exhibited upper limb claudication (p=0.042) and involvement of left subclavian artery (p=0.005), carotid arteries (right, p<0.001; left, p=0.001) and supradiaphragmatic aorta (ascending, p=0.050; arch, p=0.001; descending, p=0.003). Inflammatory markers were more frequently raised in women (p=0.005).

Conclusion: In TAK patients, gender has a strong influence on pattern of vascular involvement and consequently on clinical presentation. Specifically, women have higher involvement of the supradiaphragmatic vessels, whereas in men the abdominal vessels are more frequently affected.

REFERENCES

Figure 1. Vessels affected at disease onset in 578 patients with TAK (108 male, 470 female) from 4 different cohorts, according to gender. Red: higher involvement in women, with statistical significance. Blue: higher involvement in men, with statistical significance. Yellow: no statistically significant difference between women and men.

AB0622 THE EFFICACY OF ADDITIONAL TOCILIZUMAB IN PATIENTS WITH SEVERE POLYMYALGIA RHEUMATICA WHO WERE RESISTANT TO OR INTOLERANT OF CONVENTIONAL THERAPY
Aliko Ueno, Kei Hirose, Manami Hirota, Yuiko Yamamura, Masahiro Yamamura, Okuyama Saiseikai General Hospital, Okayama, Japan

Background: Polymyalgia rheumatica (PMR) is the most common inflammatory disease in the elderly. The 2015 EULAR/ACR recommendations indicate that the management of PMR should be started with glucocorticoids (GCs) and if needed, followed by addition of methotrexate (MTX). The anti-interleukin-6 (IL-6) receptor antibody, tocilizumab (TCZ), has been shown to be effective for PMR.

Objectives: To determine the efficacy and safety of TCZ in patients with refractory PMR who were resistant to or intolerant of GCs plus MTX and characterize the clinical profile of patients who need TCZ.

Methods: Patients were diagnosed with PMR by the 2012 EULAR/ACR provisional classification criteria and treated according to the 2015 ACR/EULAR recommendations for the management of PMR. TCZ was further added to the patients who were GC plus MTX (GC/MTX-resistant or -intolerant). The efficacy of treatment was determined by measuring the disease activity with PMR activity score (PMR-AS). We statistically analyzed the differences in clinical indicators between GC-responders, GC/MTX-responders, and GC/MTX-non-responders who need TCZ therapy.

Results: Ninety-three patients (53 females and 40 males) were the average age of 72.1 ± 9.4 years old, serum CRP 63 ± 42 mg/L, ESR 84 ± 34 mm/hr and blood platelet counts 331 ± 86 ×10^9/L, at the first visit, and had been followed up for 25.4±19.6 months. All of them were treated first with prednisolone (PSL) (15.7± 4.3 mg/day). Relapses occurred in 43 patients (46.2%), at the PSL dose of 6.0 ± 5.6 mg/day, after 8.8 ± 6.7 month-GC treatment. GC was increased in 7 patients, and MTX (8.6 ± 2.9 mg/week) was added in 36 patients. Thirteen patients successfully discontinued GC, while 23 patients (24.7%) were resistant to or intolerant of GC/MTX. Ten of 23 patients agreed with TCZ therapy. Before TCZ addition, they were treated with PSL of 6.0 ± 2.9 mg/day plus MTX of 6.0 ± 3.8 mg/week, and serum CRP 9.7 ± 9 mg/L, blood platelet counts 271 ± 32 ×10^9/L and PMS-AR 15.5 ± 13.5. After 7.3 ± 4.2 month-TCZ treatment, PSL and MTX were reduced to 1.3 ± 1.6 mg/day and 2.2 ± 3.0 mg/week, and CRP, blood platelet counts and PMS-AR decreased to <0.2 mg/L, 191 ± 28 ×10^9/L and 5.7 ± 8.3, respectively. GC could be withdrawn in 7 patients, and 4 patients reached drug-free remission. There were significant differences in blood platelet counts and the initial PSL amount between GC/MTX responders and GC/MTX-resistant patients (p<0.05; Mann-Whitney U test).

Conclusion: TCZ may provide a therapeutic option for patients with refractory PMR who were resistant to or intolerant of GC/MTX. Our retrospective results suggest that patients with severe PMR, who show thrombocytosis and need high dose GC for initial therapy, may be considered for early induction of TCZ.

AB0623 ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS AND RISK OF CEREBROVASCULAR ACCIDENT: A SYSTEMATIC REVIEW AND META-ANALYSIS

1Pairompong Unprasert, 2Kam Wijjanapeecha, 3Wrist Cheungponsiri, 1Faculty of Medicine Siriraj Hospital, Mahidol University, Clinical epidemiology unit, Bangkok, Thailand. 2Mayo Clinic Florida, Jacksonville, United States of America. 3University of Mississippi Medical Center, Jackson, United States of America.

Background: An increased risk of cardiovascular disease, including cerebrovascular accident (CVA), among patients with chronic inflammatory immune-mediated disorders is well-recognized, especially among patients with rheumatoid arthritis and systemic lupus erythematosus [1]. Patients with anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) may
be at an increased risk of CVA as well although the data are still inconclusive as most studies addressing this association were small in size.

**Objectives:** The current systematic review and meta-analysis was conducted with the aims to comprehensively identify all relevant studies and summarize their results together to better characterize the risk of CVA among patients with AAV.

**Methods:** Two investigators independently searched for published studies indexed in MEDLINE and EMBASE database from inception to October 2018 using the search strategy that included the terms for anti-neutrophil cytoplasmic antibody-associated vasculitis and cerebrovascular accident. Eligible studies must be cohort studies (either retrospective or prospective) that compared the risk of incident CVA between patients with AAV and individuals without AAV. They must also report the relative risk or hazard ratio with 95% confidence interval (CI) of this comparison. Point estimates and standard errors from each study were extracted and combined together using the random effect, generic inverse variance technique of DerSimonian and Laird.

**Results:** A total of 5 studies fulfilled the inclusion criteria and were included in this meta-analysis. The risk of incident CVA among patients with AAV was significantly higher than that of individuals without AAV with the pooled risk ratio of 1.49 (95% CI, 1.06–2.01). The statistical heterogeneity was insignificant with an I² of 11%. The forest plot of this meta-analysis is shown as figure 1. The funnel plot of this study was relatively symmetric and did not suggest the presence of publication bias.

**Conclusion:** A significantly increased risk of CVA among patients with AAV was demonstrated by this meta-analysis. Physicians who take care of patients with AAV should be aware of this risk and focus on interventions to modify other conventional risk factors for CVA may be warranted.

**AB0624 SAFETY OF RITUXIMAB BIOSIMILAR FOR THE TREATMENT OF CYTOGLOBULINEMIC VASCULITIS**

Caterina Vaciut1, Marcello Visentin2, Maria Di Cicco2, Francesca Angelotti3, Gianfranco Lajella4, Andrea Manfredi4, Davide Felippini5, Antonio Tavoni5, Milvia Casato5, Laura Castelnovo6, Giuseppe Morl7, Maurizio Pietrogrande8, Gianfranco Lauletta5, Andreina Manfredi1, Davide Filippini3, Antonio Tavoni4, Caterina Vacchi1, Marcella Visentini2, Maria DI Cicco 3, Francesca Angelotti4, san Sebastian, Spain

**Background:** Rituiximab (RTX) represents a treatment in the mixture of cyroglogolinemic vasculitis (MCV). Despite usually well-tolerated, RTX may induce different types of adverse drug reactions, including exacerbation of vasculitis. RTX biosimilars have been recently approved in Europe in the treatment of rheumatoid arthritis, but no data are available about effectiveness and safety of RTX biosimilars in the treatment of MCV.

**Objectives** Aim of the study was to analyse the safety of RTX biosimilar in patients with MCV treated in first-line or after a shift by RTX originator.

**Methods** In a multicenter, prospective, open-label study, we enrolled all MCV patients who treated with RTX originator, either de novo or after a shift by RTX originator. Nineteen consecutive MCV patients (F/M 13/6, mean age 68.3±11.5 months, mean disease duration 94±86 months, 10/19 HCV+ and 6/19 HBV+) were treated with RTX in a six-month period (July-December, 2019). Nine patients were treated with RTX for the first time, while the other 9 patients have already treated with RTX originator and were switched to RTX biosimilar. Twelve patients received a dose of 250 mg/m² of RTX every other week, while 6 were treated with 1 gram of RTX every other week.

**Results** During a month-period after the last infusion, 5 adverse events (AE) were observed, namely 2 vasculitis flares, and 1 urtica, atrial fibrillation occurred during infusion, and 2 episodes of BD were recorded. Three of 5 AE were observed in patients treated with the higher dose of RTX (in particular both cases of vasculitis flare were recorded in patients treated with 1 gram of RTX), while no differences were observed according to the previous treatment with RTX originator (2/9 vs 3/9 AE in patients switch or naïve, respectively).

**Conclusion** Despite the low number of patients, the switch among RTX originator and biosimilar appear to be safe and the number of AE were in line with previous reports about RTX originator. The main limit of this study is the absence of a control group, that doesn’t allow a direct comparison of the safety between RTX originator and biosimilar. Previous reports suggested that higher dosage of RTX are associated to a higher risk of side effects. Also, in our study the occurrence of AE, mainly vasculitis flare, seem to be associated to the dose of RTX, rather than to the switch to biosimilar.

**AB0625 EXPERIENCE IN THE USUAL PRACTICE OF PATIENTS WITH BEHÇET’S DISEASE WHO ARE IN FOLLOW-UP IN THE UVEITIS UNIT OF THE DONOSTIA UNIVERSITY HOSPITAL**

Jesús Alejandro Valero Jaime1, Olga Maiz-Alonso1, Ana Carmen Blanco Esteban1, Andrea De Diego Solás1, University Hospital Donostia, Ophthalmology, San Sebastian, Spain; 4University Hospital Donostia, Ophthalmology, San Sebastian, Spain

**Background:** Behçet’s disease (BD) is an inflammatory, chronic, recurrent, multisystemic process of unknown origin, characterized by the simultaneous or sequential presence of oral aphthae, genital ulcers, uveitis, inflammatory skin lesions, arterial or venous thrombosis, arthritis, inflammatory bowel disease and involvement of the central nervous system (CNS). The highest incidence figures correspond to the countries of the Middle East and the Far East (prevalence <2). The uveitis unit was created in our hospital in 2007, where a rheumatologist and an ophthalmologist jointly visit, so our aim is to report our experience for almost 12 years with this rare disease.

**Objectives:** To describe the demographic, clinical, and analytical characteristics, as well as immunosuppressive and biological treatments used, type of ocular and extra ocular involvement, presence of sequelae, and visual acuity (VA) affection, of the patients that are in follow-up in the uveitis unit of the Donostia University Hospital (DUH).

**Methods:** A retrospective search of all patients with BD and ocular involvement evaluated the uveitis unit since 2007. The computerized medical records were reviewed. The variables collected were: sex, age, immunosuppressive and biological treatments used, and complementary tests. The immunosuppressant’s sought were methotrexate (MTX), azathioprine (AZA), tacrolimus, sulfasalazine (SSZ), cyclosporine (CsA), leflunomide (LEF), cyclophosphamide (GFM), adalimumab (ADA); infliximab (IFX), golimumab (GLM), intravenous immunoglobulins (IVIG). The quantitative variables are shown with the median and interquartile range; the qualitative ones are shown with the absolute value and its percentage.

**Results:** We found 22 patients diagnosed with BD, the average age was 42 years, with a predominance of women (59%). Table 1 shows the clinical characteristics, complementary tests and treatments used in these
INCIDENCE OF SERIOUS INFECTIONS AND PATTERNS OF COTRIMOXAZOLE PROPHYLAXIS IN PATIENTS WITH ANCA-ASSOCIATED VASCUITIDES

2. Department of Nephrology, University of Science and Technology of China, Hefei, China
3. Department of Immunology, Hefei, China
4. Pathology, Hefei, China

Background: Infections are among the most serious complications in patients with ANCA-associated vasculitides (AAV) and contribute significantly in overall mortality.

Objectives: To describe the incidence and risk factors for serious infections, as well as the patterns of cotrimoxazole prophylaxis in AAV patients (GPA and MPA).

Methods: Retrospective, descriptive study of AAV patients followed in a tertiary referral center (Clinical Immunology-Rheumatology Unit and Nephrology department). Patient and disease characteristics treatments and serious infections were recorded.

Results: 54 AAV patients were included (women: 50%, mean age at diagnosis: 59.8 years, mean disease duration: 5.1 years, GPA: 68%, generalized disease: 82%). Most frequent organ involvement was renal (71%), lung (68%), nervous (20%), skin (18%) and mucous membranes/eyes (14%). 21 serious infections were recorded in 16 patients (incidence: 7.2 per 100 patient-years), with respiratory tract infections (43%) and herpes zoster (19%) being the most frequent. Incidence was 6.2 times higher in patients with severe combined lung-kidney involvement and herpes zoster (19%) being the most frequent. Positivity for anti-neutrophil cytoplasmic antibodies (ANCA) and anti-vasculitis-related antibodies (ARA) was significantly associated with the incidence of serious infections. The mean age of 38 cases were 44.1±15.6 years, the mean course was 64.8±90.4 months. Typical clinic manifestations and endoscopic findings existed in 24(63.2%) and 22(57.9%) patients with intestinal Behçet’s disease respectively. The most common (53, 86.8%) symptoms were abdominal pain and diarrhea. The sites of intestinal ulcer were seen more often (22, 57.9%) at the ileum, ileocecal area, on the ileoceleal valve. Most colonoscopic appearance of ulcers were usually well demarcated, oval or round (28, 73.6%). The suggestive histopathological changes were massive neutrophilic infiltration (20, 52.6%), inflammatory granuloma (14, 36.8%) and vasculitis (8, 21%) especially phlebitis.

Conclusion: The diagnosis of intestinal Behcet’s disease depends on the combination of clinic features, endoscopic appearance and histopathological findings. Massive neutrophilic infiltration, inflammatory granuloma and vasculitis point to the possibility of intestinal Behcet’s disease.

CIRCULATING ENDOTHELIAL CELLS MAY BE A MARKER FOR VASCULAR INVOLVEMENT IN BEHÇET DISEASE

Nazife Sule Yasar Bilge1, Eren Gunduz1, Meltem Akay1, Timuçin Kaşgolu1.

1Eskişehir Osmangazi University, Eskişehir, Turkey; 2Koç University, Istanbul, Turkey

Background: Circulating endothelial cells (CEC) are defined in conditions which vascular damage is seen in course of disease such as systemic vasculitis, coronary artery disease and chronic renal failure. CEC is thought to be an indicator of vascular damage (1). Behcet disease (BD) is a systemic vasculitis mostly known with recurrent oral and genital ulceration, uveitis and mucocutaneous lesions. On the other hand vascular involvement such as deep venous thrombosis, cerebral sinus thrombosis and pulmonary artery aneurysm, is an important clinical finding of disease which may cause mortality (2).

Objectives: Our aim in this study was to analyse CEC levels in patients with Behcet disease, to compare them between patients with vascular (Group 1) and mucocutaneous (Group 2) involvement. Also we have compared the results of Behcet patients with patients with thrombosis due to other causes (Group 3) and healthy controls (Group 4). Each group involved 20 participant.

Methods: Blood samples of the patients and healthy controls are drawn into tubes containing ethylene-diamine-tetra-acetic acid (EDTA). A panel of monoclonal antibodies, including anti-CD45 to exclude hematopoietic cells, anti-CD4, -CD34, -CD36, -CD105, -CD106, -CD133, and –CD146 and appropriate analysis gates were used to enumerate resting and activated CECs and circulating and endothelial progenitor cells (CEP).

A hundred microlitre complete blood was added and incubated for 20 minutes at room temperature in the dark. After incubation for 10 minutes with erythrocyte lysing solution at room temperature, centrifugation at 1,800 rpm for 5 minutes was performed. Supernatant was removed and resuspended with PBS and 300,000–400,000 cells were counted with FACSCalibur flow cytometry device.

Results: Mean age, sex distribution and duration of disease were similar in all groups (Table 1).

Conclusion: Increased levels of aCECs may be an indicator of active vascular involvement in BD. But in the current study aCEC levels did not show a difference between groups but none of the patients had active vascular involvement which may cause of this sameness. CEP and resting CEC levels were elevated in both groups of patients with thrombosis. So CEC may be a marker for vascular damage but it is not specific for BD.

Abstract AB0629 Table 2. Comparison of CEC, CEP, aCEC and CECs between groups

AB0630 CLINICAL CHARACTERISTICS ANALYSIS AND LITERATURE REVIEW OF 35 CASES OF PANNICULITIS

Hui Zheng1, Li Rong1, Guozhu Chen1, Liyun Zhang1, Huiqin Hao2. 1Shanshi DaYi Hospital, Rheumatology, Tai Yuan, China; 2Shanshi University of Chinese Medicine, Jin Zhong, China

Background: Panniculitis is a heterogeneous inflammatory disease involving subcutaneous fat. It can be divided into different subtypes according to the clinical characteristics and pathological changes of the disease. Because the cause of panniculitis is unclear, clinical manifestations are diverse, lack of specificity, early diagnosis is difficult, and misdiagnosis and missed diagnosis are prone to occur.

Objectives: To improve the clinical understanding of the disease by retrospective analysis of 35 cases of patients with panniculitis.

Methods: The hospitalized patients with panniculitis were collected from December 2011 to October 2018 in the Shanshi Dayi Hospital Affiliated to Shanshi Medical University. The demographics, clinical manifestations, auxiliary examinations and treatments were analyzed and summarized.

Results: The proportion of males and females in the 55 patients was 1:2.23, with an average of 53.3 years (18-82 years). A total of 52 cases showed a significant statistically different difference between all groups. CEPs, activated CECs (aCEC) and resting CECs (rCEC) were also compared between groups. CEPs were higher in Behcet patients with thrombosis similar to patients with thrombosis due to other causes (p<0.042). Activated CECs levels did not show a difference between groups (p>0.05).

Resting CECs are higher in Groups 1 and 3 than Groups 2 and 4. The detailed analysis of CEC, CEP, activated and resting CECs between groups is listed in Table 2.

Disclosure of Interests: None declared

Results: ILD features on HRCT was found in 11 (11.8%) of 102 patients with MPA. Their median age was 55 [53; 63] years. All of them were ANCA-positive (Table 1). In 5 cases interstitial pneumonia was the first and the sole manifestation that preceded for the occurrence of overt systemic vasculitis. These patients were young for a median of 3 years. The radiologic patterns included non-specific interstitial pneumonia in 5 cases, usual interstitial pneumonia in 3 cases and unclassifiable interstitial pneumonia in 3 cases. The most common clinical manifestations were non-productive cough (82%), progressive dyspnea (82%) and crepitation (27%). The most common extrathoracic manifestations of MPA in patients with ILD were glomerulonephritis with decreased renal function (91%), fever (100%) and arthritis (91%). All patients received induction therapy with glucocorticosteroids combined with cyclophosphamide, rituximab, azathioprine or methotrexate.

AB0632 MAINTENANCE RITUXIMAB IN ANCA ASSOCIATED VASCULITIS – OBSERVATIONAL DATA FROM UNIVERSITY HOSPITAL COVENTRY, UK

1Megan Rutter, Shirish Dubey, Andrew Short. 1University Hospital Coventry and Warwickshire, Department of Rheumatology, Coventry, United Kingdom; 2University Hospital Coventry and Warwickshire, Department of Nephrology, Coventry, United Kingdom

Background: Rituximab is considered an effective 1 maintenance therapy in anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), with reduced relapse rates post induction therapy and comparable adverse event profile to other agents such as Azathioprine 2.

Objectives: To describe the clinical outcomes of all patients receiving maintenance Rituximab for AAV in University Hospital Coventry in UK.

Methods: Records from the Renal and Rheumatology units were used to identify patients receiving maintenance Rituximab. Electronic patient records (EPR) were used to collate laboratory and clinical data.

Conclusion: ILD is a rare manifestation of MPA, which can precede systemic manifestations. ANCA-associated vasculitis should be included in the spectrum of differential diagnosis in patients with ILD.

AB0631 INTERSTITIAL LUNG DISEASE – A RARE MANIFESTATION OF MICROSCOPIC POLYANGIITIS

Ekaterina Vinogradova 1,2, Nikolai Bulanov 2, Elena Shchegoleva 3, Larisa Akulina 1, 2, Anastasia Zykova, Pavel Novkov 2, Sergey Moiseen 2, 3, Lomonosov Moscow State University, Moscow, Russian Federation, 2Sechenov University, Moscow, Russian Federation

Background: Interstitial lung diseases (ILD) are a group of diffuse inflammatory and/or fibrotic lung disorders with similar clinical, radiologic and histopathologic features. The coexistence of ILD and ANCA-associated vasculitis has been reported in case reports and small case series.

Objectives: The aim of this study was to assess the prevalence, clinical and radiological characteristics of ILD in MPA patients admitted to the Rheumatology Department of our hospital.

Methods: This retrospective single center cohort study included 102 patients diagnosed with MPA according to CHCC 2012 and EMA algorithm. We assessed Birmingham Vasculitis Activity Score (BVAS) at disease onset and VDI (Vasculitis Damage Index) at the end of the follow up in each patient. ANCA type and titer were assessed by enzyme-linked immunosorbent assay (ELISA). The results of repeated high resolution computed tomography (HRCT) of the chest were analyzed and interstitial changes (focal ground-glass opacity, reticular pattern, honeycombing, traction bronchiectasis) were classified in four patterns: non-specific interstitial pneumonia (NSIP), typical interstitial pneumonia, possible interstitial pneumonia, and “inconsistent” usual interstitial pneumonia (UIP).

Results: ILD features on HRCT was found in 11 (11.8%) of 102 patients with MPA. Their median age was 55 [53; 63] years. All of them were ANCA-positive (Table 1). In 5 cases interstitial pneumonia was the first and the sole manifestation that preceded for the occurrence of overt systemic vasculitis. These patients were young for a median of 3 years. The radiologic patterns included non-specific interstitial pneumonia in 5 cases, usual interstitial pneumonia in 3 cases and unclassifiable interstitial pneumonia in 3 cases. The most common clinical manifestations were non-productive cough (82%), progressive dyspnea (82%) and crepitation (27%). The most common extrathoracic manifestations of MPA in patients with ILD were glomerulonephritis with decreased renal function (91%), fever (100%) and arthritis (91%). All patients received induction therapy with glucocorticosteroids combined with cyclophosphamide, rituximab, azathioprine or methotrexate.

AB0632 MAINTENANCE RITUXIMAB IN ANCA ASSOCIATED VASCULITIS – OBSERVATIONAL DATA FROM UNIVERSITY HOSPITAL COVENTRY, UK

1Megan Rutter, Shirish Dubey, Andrew Short. 1University Hospital Coventry and Warwickshire, Department of Rheumatology, Coventry, United Kingdom; 2University Hospital Coventry and Warwickshire, Department of Nephrology, Coventry, United Kingdom

Background: Rituximab is considered an effective 1 maintenance therapy in anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), with reduced relapse rates post induction therapy and comparable adverse event profile to other agents such as Azathioprine 2.

Objectives: To describe the clinical outcomes of all patients receiving maintenance Rituximab for AAV in University Hospital Coventry in UK.

Methods: Records from the Renal and Rheumatology units were used to identify patients receiving maintenance Rituximab. Electronic patient records (EPR) were used to collate laboratory and clinical data.

Conclusion: ILD is a rare manifestation of MPA, which can precede systemic manifestations. ANCA-associated vasculitis should be included in the spectrum of differential diagnosis in patients with ILD.

Disclosure of Interests: None declared
Results: We identified 38 patients, with the diagnosis of AAV made 11 months to 19 years previously. 16 (42%) had been diagnosed within the last five years. Age range was 19-87 years old with roughly half (21; 54%) being male. Maintenance Rituximab was started between January 2010 and September 2018. Most patients received a fixed 6 monthly pro- tocol. Seven patients (18%) died within the observation period. More details in table 1 below.

† Renal transplant patient ] In 2/3 (67%) patients associated with poor compliance/missed doses Y In patients who completed 2 years maintenance Rituximab

Conclusion: The effectiveness of Rituximab as a maintenance therapy in AAV is borne out by this real world data, with 31/38 patients demonstrating full clinical response. Longer term treatment and low grade disease continue to be issues as evidence for optimal management strategies is lacking. Infections, including severe infections necessitating admission, were common. PR3 positive patients are over-represented, in keeping with the known higher rate of relapse.

AB0632B TB OR NOT TB, THAT IS THE VASCULITIC QUESTION

Salma Khalid, Sarah Bartram. Salisbury District Hospital, Salisbury, United Kingdom

Background: It is important to remember that there are many disorders that can mimic the clinical, radiographic and histological features of vasculitis. Tuberculosis (TB) is often referred to as the great imitator and therefore, needs to be considered early in the differential diagnosis of vasculitis.

Objectives: To emphasize the importance of being aware of noninflammatory mimics of vasculitis to be able to avoid unnecessary and potentially harmful immunosuppression.

Methods: We report a challenging case of a patient presenting with an inflammatory subglottic lesion.

Results: A 67-year-old lady initially presented to otolaryngology (ENT) with hoarseness and and restriction of breathing. Nasendoscopy revealed a subglottic lesion with oedema and inflammation. Biopsy showed florid necrotising granulomatous inflammation. Upon questioning, patient revealed a history of epistaxis and nasal crusting requiring regular nasal douching. She also reported lack of energy, loss of appetite, but denied any rash, weight loss or night sweats. She suffered with a severely dry mouth that was causing difficulty swallowing. She also complained of an occasional cough with small amount of phlegm which she attribute to the smoking. She had also noted to have deranged liver function test around this time. Gastroenterology advised that there was no clear cause for the transaminitis and an autoimmune screen was requested. Given the chest findings on CT, a sputum sample was sent for microscopy and culture. The patient had been started on dexametha-sone on admission by ENT and reported substantial improvement in the hoarseness of voice and shortness of breath. ANCA then came back negative, as did the connective tissue screen. While the rheumatology team was considering how to further manage the possible vasculitis, the spu tum smear came back positive for acid fast bacilli and the diagnosis was clinched: our patient was suffering with the extremely rare laryngeal tuberculosis, along with pulmonary TB. She was started on anti-tuberculosis medication that have been introduced incrementally given the deranged liver function tests. The patient was doing well on her most recent follow up in the respiratory department.

Conclusion: Greater awareness of vasculitis mimics like TB and a high index of suspicion are needed when assessing a patient presenting with the protean manifestations of suspected vasculitis. It is therefore prudent to include TB in the differentials, whenever consider vasculitis.

Scleroderma, myositis and related syndromes

Fecal Calprotectin in Patients with Systemic Sclerosis

Objective: to examine fecal calprotectin as a simple method to diagnose GI disorders and disease activity in SSc.

Methods: Totally 46 patients with SSc were invited by telephone, who have been referred to sayyad shirazi Hospital and the rheumatologists offices in Gorgan and their information has been registered there. Seven patients did not enter our study because of having items in exclusion criteria like Diabetes, a history of GI operation and having other connective tissue diseases at the same time.

Results: Nineteen patients with SSc were newly visited. Male to female ratio was 1:2.67 and the age range was 19-75 years and the median of age which was 42, was divided in to two groups: young (intestinal disorders) was done. The patients in our study according to the definition in 2015 ESC/ERS guideline. The NVC (Medcap®3.0, DS MEDICA) was used to detect microvascular change and average capillary density and the number of capillaries/view were calculated. Also, existence of giant capillaries, hemorrhage and patterns of capillary changes were also documented. Transthoracic ultrasound cardiology (UCCI) was performed using IE33 with 5MHz sector probe SS-1 (Philips). Exercise loading was done with an ergometer (Lode), Ejection fraction (EF), velocity of tricuspid regurgitation jet (TR jet), tricuspid annular plane systolic excursion (TAPSE) were examined in a supine position. Tricuspid regurgitation pressure gradient (TRPG) was calculated using velocity of TR jet based on Bernoulli principle. Exercise loading was started at 25 Watt, and then increased 25 Watt every 3 minutes and TRPG at maximum exercise was also calculated. Parameters of NVC were compared with those of UCCI. Patients with 'pre-clinical' PAH were defined as patients 1) asymptomatic, 2) who did not meet the definition of PH by right heart catheterization (RHC), 3) whose probability of PH is lower than PH that is 'lower than PH that is not immediately' by UCCI, 4) who did not see any UCCI signs for PH based on the guideline and 5) who did not have severe interstitial lung disease, especially% FVC< 70% and/or area of ILD based on CT scan was <20% of the entire lung field.

Results: Nineteen patients with SSc were newly visited. Male to female ratio was 1:2.67, mean age 63 ± 13 years, and mean disease duration was 138 ± 109 months. Ratio of limited skin type was 79%. 37% were with ILD and 11% were with PAH confirmed by RHC. There is no correlation between TRPG at rest and the density of capillaries. However, there is a significant, negative correlation between TRPG at exercise and the capillary density. Parameters of NVC were compared with those of UCCI. Patients with 'pre-clinical' PAH were defined as patients 1) asymptomatic, 2) who did not meet the definition of PH by right heart catheterization (RHC), 3) whose probability of PH is lower than PH that is not immediately' by UCCI, 4) who did not see any UCCI signs for PH based on the guideline and 5) who did not have severe interstitial lung disease, especially% FVC< 70% and/or area of ILD based on CT scan was <20% of the entire lung field.

Ratio of limited skin type was 79%. 37% were with ILD and 11% were with PAH confirmed by RHC. There is no correlation between TRPG at rest and the density of capillaries. However, there is a significant, negative correlation between TRPG at exercise and the capillary density. Parameters of NVC were compared with those of UCCI. Patients with 'pre-clinical' PAH were defined as patients 1) asymptomatic, 2) who did not meet the definition of PH by right heart catheterization (RHC), 3) whose probability of PH is lower than PH that is not immediately' by UCCI, 4) who did not see any UCCI signs for PH based on the guideline and 5) who did not have severe interstitial lung disease, especially% FVC< 70% and/or area of ILD based on CT scan was <20% of the entire lung field.

Results: Nineteen patients with SSc were newly visited. Male to female ratio was 1:2.67, mean age 63 ± 13 years, and mean disease duration was 138 ± 109 months. Ratio of limited skin type was 79%. 37% were with ILD and 11% were with PAH confirmed by RHC. There is no correlation between TRPG at rest and the density of capillaries. However, there is a significant, negative correlation between TRPG at exercise and the capillary density. Parameters of NVC were compared with those of UCCI. Patients with 'pre-clinical' PAH were defined as patients 1) asymptomatic, 2) who did not meet the definition of PH by right heart catheterization (RHC), 3) whose probability of PH is lower than PH that is not immediately' by UCCI, 4) who did not see any UCCI signs for PH based on the guideline and 5) who did not have severe interstitial lung disease, especially% FVC< 70% and/or area of ILD based on CT scan was <20% of the entire lung field.
Conclusion: Our study suggests that the finding of NVC, especially the extent of capillary loss, is correlated with disease process of PAH, even subclinically, and may predict the progression to PAH in SSC. Since NVC is non-invasive, NVC can detect earlier PAH candidates and contribute to the improvement of prognosis.

AB0635 POTENTIAL BIOMARKERS OF SKIN CHANGES IN SYSTEMIC SCLEROSIS
Radim Bečvář, Hana Stórkánová, Barbora Šumová, Maja Šprítová, Sabina Orska, Ladislav Senott, Michal Tomčík, Institute of Rheumatology, Praha, Czech Republic

Background: Skin fibrosis is a hallmark of systemic sclerosis (SSc). There are no widely accepted biomarkers of skin involvement in this condition. Several serum or plasma markers have been studied in patients with SSc - monocyte chemotactic protein-1 (MCP-1), chemokine (C-X-C motif) ligand 2 (CXCL2), interleukin-13 (IL-13), and some more recognized such as - platelet derived growth factor (PDGF), transforming growth factor-beta 1 (TGF-beta 1), epidermal growth factor (EGF) and basic fibroblast growth factor (bFGF).

Objectives: The aim of this study was to assess several circulating biomarkers which may be relevant to the fibrosing process and further to correlate the obtained data with clinical indicators specific for SSc skin involvement.

Methods: 59 SSc patients (M/F 9:50; mean age 52.1 years, mean disease duration 6.7 years, 36 patients with limited cutaneous SSc and 23 with diffuse cutaneous SSc. As a control group 36 healthy individuals matched to sex and age were examined. Serum concentrations of bFGF, granulocyte-colony stimulating factor (G-CSF), granulocyte-macrophage colony stimulating factor (GM-CSF), MCP-1, PDGF, IL-8 and 13 were analysed using commercial multiplex kit. The following clinical examinations were performed: modified Rodnan skin score (mRSS), Hand Mobility in Scleroderma Test (assessing hand function) (HAMS), Cochin Hand Function Scale (hand function) (CHFS), Delta Finger-to-Palm Distance (extension-flexion) (dFTP), Inter-lip Distance (inter-lip), Inter-incisor Distance (inter-incisor), and Mouth Handicap in Systemic Sclerosis Scale (mouth opening) (MHISS). For statistical evaluation Spearman’s correlation coefficient was used.

Results: When compared with healthy controls serum concentrations of bFGF (p<0.001), G-CSF (p<0.0001), GM-CSF (p<0.0001), MCP-1 (p<0.0001) IL-8 (p<0.0001), and IL-13 (p<0.0001) were significantly elevated in SSc cohort. PDGF levels were increased in SSc patients with only a lower significance (p<0.01). bFGF, G-CSF, MCP-1 and IL-8 levels correlated significantly (p<0.05) with mRSS and HAMS. GM-CSF levels correlated with mRSS and HAMS and there was only a trend for negative correlation with inter-incisor. The was no correlation of IL-13 and PDGF levels with the evaluated clinical data.

Conclusion: Our results have shown that G-CSF, GM-CSF and IL-8 play a substantial role in SSc fibrosing process. Potential biomarkers as bFGF, G-CSF, MCP-1 and IL-8 correlated with a few clinical indices of SSc skin involvement.

AB0636 INFLUENCE OF CARDIOVASCULAR RISK FACTORS ON NAILFOLD VIDEOCAPILLAROSCOPY IN THE STUDY OF CONNECTIVE TISSUE DISEASES
Diego Benavent, Laura Nuño, Gemma Bonilla, Diana Peiteado, Chamarada Plasencia, Victoria Navarro-Compañ, Irene Monjo, Alejandro Villalva, Sara García-Carazo, Carolina Tomero, Patricia Bogas, Elisa Fernández, Miguel Berrad, Ana Castilla, Pilar Aguado, María-Eugenia Miranda-Canas, Eugenio de Miguel, Alejandro Balsa. Hospital Universitario La Paz, Madrid, Spain

Background: Nailfold videocapillaroscopy is a non-invasive technique used to assess Raynaud syndrome. It is mainly used for the early diagnosis of connective tissue disorders (CTD) such as systemic sclerosis. There is some evidence that capillaroscopy findings may be altered by microcirculatory abnormalities in patients with cardiovascular risk factors (CVRF).

Objectives: To analyze the influence of cardiovascular risk factors on nailfold capillaroscopy in patients with Raynaud or suspect of CTD.

Methods: An observational and descriptive study of consecutive patients that underwent a videocapillaroscopy examination for the study of Raynaud syndrome was conducted. A “capscope” model videocapillaroscope from Ophtha was used, with a fixed magnification of 200x. Examination was made on 8 hand fingers, with 2 images per finger. The patients had to be at least 30 minutes in a fixed warm temperature room and without smoking 1 hour before the performance of the test. The following capillaroscopic parameters were considered: nailfold morphology, capillary loop enlargements, megacapillaries, microhaemorrhages, avascular areas and signs of neoangiogenesis. Demographic information (including age, gender and previous diagnosis) and cardiovascular risk factors (including arterial hypertension (HT), diabetes mellitus (DM), dyslipidemia (DL) and smoking habit) were collected. The influence of cardiovascular risk factors on nailfold capillaroscopy was analyzed, using univariate and multivariate logistic regression models, adjusted for possible confounders.

Results: Out of the 136 included patients, 91% were women. Mean age was 54.6 ± 18.7 years. Raynaud syndrome was reported in 83% patients, with a mean duration of 6.1 ± 5.7 years and 12% of the patients had a previous diagnosis of CTD, including systemic lupus erythematosus (5%), systemic sclerosis (4%), undifferentiated connective tissue disorder (2%) and mixed connective tissue disease (1%). Regarding CVRF, HT was observed in 25%, DM in 7%, DL in 23% and past or current smoking habit in 32%. Capillaroscopic findings were: loop enlargements (81%), megacapillaries (30%), microhaemorrhages (46%), signs of neoangiogenesis (71%) and avascular areas (20%). Regarding the capillaroscopic pattern, 46% presented a normal or non-specific pattern; 31% a microangiopathy pattern and 23% a scleroderma pattern (of which 58% had an early or active scleroderma pattern and 42% a late scleroderma pattern). A new diagnosis of CTD was made in 24 patients (18% of the cohort). In the group of patients without CTD, HT was associated with microhaemorrhages (p = 0.02) and avascular...
areas (p = 0.007), and there was a tendency to association between smoking habit and megacapillaries (p = 0.08). After adjusting for confounding factors for this group, an association between CTD and microhaemorrhages (OR = 1.9; p = 0.01) and avascular areas (OR = 2.12; p = 0.007) was found. The multivariate study showed no relationship between CVRF and capillaroscopy patterns.

**Conclusion:** In our cohort we found an increased frequency of microhaemorrhages and avascular areas in the nailfold capillaroscopy in patients with arterial hypertension. The presence of cardiovascular risk factors could have an influence on the microvascular ulcer and therefore on the findings of the capillaroscopy. More studies are required to better assess these findings.

**Conclusion:** This analysis is showing that patients fulfilling VEDOSS criteria include a subgroup of patients with very mild, long-standing disease. This observation has major impact on the management of VEDOSS patients, as this subgroup requires different follow up and treatment strategies compared to VEDOSS patients with early, progressive disease.

AB0638

ABSENCE OF LUNG INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS WITH SILICONE IMPLANTS

V. Braun-Moscovici1, M. Braun2, D. Markovits1, A. Babir-Gurman1, 1Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, B. Shiner Rheumatology Institute, Haifa, Israel; 2Belinson Hospital, Sackler School of Medicine, Tel Aviv University, Liver Institute, Petach Tikva, Israel.

Background: Although many cases have been reported for the last 3 decades, the correlation between silicone breast implants (SBI) and systemic sclerosis (SSc) is yet unclear.

Objectives: To assess the prevalence of breast implants in a well-characterized SSc cohort followed at a dedicated tertiary center and to define characteristics that might differ between SSc patients with implants and those without.

Methods: A prospectively maintained database was interrogated regarding the prevalence of breast implants and the disease characteristics. Female patients aged 20 to 55y (215 patients) followed at our center between 2003-2018 were included. SBI cases were identified and their characteristics tabulated. Each SBI patient was matched with 2 controls matched for age, disease duration and type of disease. We used descriptive statistics, multivariate comparisons and multivariate analysis for correlations.

Results: 11 pts with SBI were found, 6 with diffuse (median age 37.5, range 32-55, median disease duration 3.5 y, range 1.5-8y, median mRSS 13.5, range 8-26) and 5 with limited SSc (median age 38, range 33-45, median disease duration 8y, range 3-32y, mRSS 2, range 2-5). The prevalence of SBI in the 20 to 55 y cohort is 5%, similar to the estimated prevalence in the general population. All had their implants instilled before the diagnosis of SSc (median 10y, range 4-13y). Four pts were first diagnosed with SSc within a year from diagnosis of silicon leakage. RNA polymerase 3 was positive in 3 patients, ScCtO in 3 others, antinuclear antibodies in 1 patient and 4 others were positive only for antinuclear antibody. There were no differences in the prevalence of digital ulcers, gastrointestinal involvement, skin score or the serologic profiles between the two groups. However, none of the SBI pts developed interstitial lung involvement, compared to 72% of the matched diffuse patients (p=0.001). None of the SBI pts developed interstitial lung involvement, compared to 72% of the matched diffuse patients (p=0.001).

Conclusions: The rapid referral to a specialized centre for SSc and a tailored therapeutic approach, should always be considered in SSC patients with implants.

PREDICTION OF MAJOR VASCULAR COMPLICATIONS IN SYSTEMIC SCLEROSIS (SSC)

Cosimo Bruni1, Edoardo Rosato2, Vanessa Maestripleni1, Antonietta Gigante2, Giulia Tesei1, Marco Chiostri1, Gemma Lepri1, Silvia Bellando Randone1, Serena Guiducci1, Sergio Castellani1, Maria Bodi1, Marco Matucci-Cerinic1.

1Careggi University Hospital, Firenze, Italy

Background: in SSc, Digital ulcers (DU), scleroderma renal crisis (SRC) and pulmonary arterial hypertension (PAH) are major vascular complications (MVCs). Among the variables used to follow-up SSc patients, nailfold videocapillaroscopy pattern (NVCp), estimated pulmonary systolic arterial pressure (sPAP), diffusion capacity of carbon dioxide (DLCO) and renal resistive index (RRI) on renal vascular Doppler ultrasound have previously shown to be predictive for MVCs development. Moreover, circulating endothelin-1 (ET1) levels have been associated with MVCs.

Objectives: to identify clinical, instrumental and laboratory predictors of MVCs development in SSc.

Methods: SSc patients fulfilling the 2013 ACR/EULAR criteria were enrolled from two SSc-care units. Data regarding clinical manifestations, instrumental and laboratory evaluation for renal, cardiac and cardiovascular involvement were collected. ET1 serum levels were measured with an ELISA kit.

Results: 380 patients [aged 57 (46-68) years, 12% males] were enrolled in the study, with 42.4% prevalence of MVCs at baseline. Previously known associations were significantly confirmed between presence of MVCs and AGE, dsSSc, RRI on renal vascular Doppler ultrasound, presence of telangectasias on nailfold capillaroscopy and presence of digital ulcers.

Conclusions: The data show that the most stringent factors predicting MVCs are sPAP and joint involvement in MVCs complicated and naive patients, respectively. These 2 items, together with mRSS and telangiectasias, should always be considered in SSC long-term follow-up to shape up a tailored therapeutic approach.

AB0640

SURVIVAL AND MORTALITY PREDICTORS IN SYSTEMIC SCLEROSIS: RESULTS FROM A MONOCENTRIC ITALIAN COHORT

Fabio Cacciapaglia1, Marco Forzano2, Fabio Montilli3, Livio Urso3, Sergio Colella2, Laura Lauridano1, Maria Grazia Areti1, Emanuela Praino1, Giuseppe Lopalco1, Florenzo Iannone1, Polichino di Bari, Rheumatology Unit, Department of Emergency and Organ Transplantations, Bari, Italy

Background: Systemic sclerosis (SSc) is a connective tissue disease with a poor prognosis and disease-related pulmonary fibrosis, pulmonary arterial hypertension (PAH) and cardiac involvement accounted for most deaths (1). However, a decrease in mortality is seen in the last decades thanks to the opportunity of new screening and therapeutic strategies (2).

Objectives: to estimate the global survival and any predictor of mortality in a monocentric cohort of SSc patients with a 10-years follow-up.

Methods: We performed a retrospective analysis examining the medical records of our longitudinal SSc cohort with a median (IQR) follow-up of 56 (25-82.5) months in our Scleroderma Unit since January 2009. All clinical, laboratory and instrumental findings have been recorded and analyzed using Chi-squared tests, Kaplan-Meier curves, log-rank tests, and Cox proportional hazards modeling.

Results: We collected data from 347 SSc patients (female n. 319 (91.9%); mean (SD) age at diagnosis 50.6 (15.9) years, median (IQR) disease duration 8.75 (4.1-14.9) years; diffuse cutaneous involvement (dsSSc) n=176 (48.4% patients) fulfilling the 1980 ARA and/or 2013 ACR/EULAR classification criteria. All patients were positive for ANA, while anti-Tipo-1 were found in 145 (41.8%), CENP-B in 139 (40.1%) patients. Fifteen (4.3%) patients were positive to other autoantibodies (Anti-RNA polymerase III, anti-Pm/Scl) while anti-ENA were negative or unknown for 48 (13.8%) SSc patients. Intestinal lung disease (ILD) was present in 53 (45.5%), pulmonary arterial hypertension, diagnosed by right heart catheterism, (Group 1 PAH) was found in 17 (4.9%), and 22/347 (6.3%) patients presented pulmonary hypertension combined with ILD (Group 3 PH-ILD). The overall survival rates were 89.1% and 87.3% at 5 and 10 years, respectively. As reported in Figure 1, the 5-years global survival was significantly impaired by the presence of PAH or PH-ILD, while isolated ILD did not impact the survival. The univariate and multivariate analysis showed that dsSSc, higher age at diagnosis, delayed referral to our Scleroderma Unit, body mass index and absence of heart (H) or lung (L) involvement (No H/L) were independent predictors of 5-years mortality (Table I). While gender, disease duration, specific autoantibodies, basal Rodnan skin score, smoking, renal or gastrointestinal comorbidities, NYHA functional class, steroid or immune-suppressive treatments did not reach the statistical significance.

Conclusion: Our study demonstrated a global 10-years survival rate over 85%, and the presence of PH without or with ILD represents the main negative predictor. The rapid referral to a specialized centre for SSc and early treatment with effective agents for PH could further improve prognosis.

VITAMIN D SERUM LEVELS AND THE RISK OF DIGITAL ULCERS IN SYSTEMIC SCLEROSIS: A LONGITUDINAL STUDY

Cristian Cairini, Eugenia Bertoldo, Alice Pozza, Paola Caramaschi, Giovanni Orsoni, Davide Gatti, Maurizio Rossini, Ombretta Viapiana. Rheumatology Unit, University of Verona, Verona, Italy

**Background:** Vitamin D is known to influence the immune system in many different diseases although longitudinal studies on systemic sclerosis (SSc) are still missing.

**Objectives:** This study wants to investigate if variations in vitamin D serum levels (25OHD) over time affect digital ulcers (DUs) in SSc.

**Methods:** This is a retrospective study on 65 patients. Data on disease characteristics and 25OHD were collected in 2011 and 2016.

**Results:** The mean age of our cohort was 58 (12) years with a mean disease duration of 9.5 (5.3) years. Most of our patients had a limited subset (69.2%). At baseline 50.8% and 41.5% after 5 years had 25OHD <30 ng/mL. Supplemented patients (6750 IU/week) at baseline were 39 (60.2%) and 45 (69.2%) at the end of follow-up. Nevertheless, 31 (47.7%) had a decrease of 25OHD in 5 years. In univariate analysis, patients with incident digital ulcers (DU) had a decrease in 25OHD as compared to patients with no incident DU (-17.4 (37.0) vs. 13.0 (89.5), p=0.018). No differences in 25OHD variations were found for other disease characteristics. In multivariate analysis correcting for previous DU and mRSS at baseline, patients with a decrease in 25OHD had an increased risk of developing DU (OR [95% CI]: 16.6 [1.7 to 164.5], p=0.017).

**Conclusion:** In this study we have shown that a decrease in 25OHD increases the risk of developing DUs and that vitamin D supplementation with the doses currently recommended may be insufficient in SSc. Further studies in wider cohorts are needed to confirm these results and to evaluate the effectiveness of a more aggressive or different vitamin D supplementation.

**Disclosure of Interests:** Cristian Cairini: None declared, Eugenia Bertoldo: None declared, Alice Pozza: None declared, Paola Caramaschi: None declared, Giovani Orsoni: Speakers bureau: F Iannone has received consultancy declared, Maria Grazia Anelli: None declared, Emanuela Praino: None declared, Sergio Colella: None declared, Laura Coladonato: None declared, Fabio Cacciapaglia: None declared, Marco Forzieri: None declared, Marco Fusco: None declared, Maria Aparicio-Espinar: None declared, Lourdes Mateo: None declared, Anne Riveros: None declared, Laia Gilfe: None declared, María Sapuésa-Gomez: None declared, Águeda Prieto-Español: None declared, Anisa Nack: None declared, Anahy Brandy-García: None declared, María Teresa Balsemarsho: None declared, Eva Martínez-Cáceres: None declared, Ana Luisa Oliva: None declared, Bibiana Quirau: None declared, Susana Hidalgo: None declared, 1Hospital Universitari Germans Trias i Pujol, Rheumatology, Badalona, Spain; 2Hospital Universitari Germans Trias i Pujol, Immunology, Badalona, Spain; 3Hospital Universitari Germans Trias i Pujol, Dermatology, Badalona, Spain.

**Background:** Myositis specific antibodies have gained special importance in last years. Its knowledge has allowed stratifying patients in different clinical phenotypes, predicting with greater accuracy prognosis and establishing a clinical attitude to follow. SAE1/2 antibody (anti-small ubiquitin-like modifier activating enzyme) was first described in 2007 in patients with amyopathic dermatomyositis with cutaneous and digestive involvement. Its prevalence ranges from 8% in European cohorts to 3% in Asians.

**Objectives:** Describing myositis specific antibodies (MSA) in a cohort of inflammatory myopathies. To characterize the clinical phenotype of SAE1/2 antibody in our cohort and to compare it with the rest of MSA.

**Methods:** Patients diagnosed of dermatomyositis in a tertiary hospital from 1978-2018, according to the criteria of Bohan and Peter (1975) and according to Dalakas classification criteria (2015). Clinical and analytical data, including the immunological profile were collected, as well as the treatments received and the evolution of the disease.

**Results:** Out of 46, 41 dermatomyositis had positive antinuclear antibodies (ANA). 55% percent had ANA titles >/=1/640, being the fine speckled pattern the most frequent (43%) followed by coarse speckled and homogeneous (13.6% each). 72% had MSA, the most frequent being anti-Jo1 (27.3%) followed by MDA5 (18.2%) and SAE1/2 (15%). Up to 40% had two or more antibodies, being the association with antibodies Ro52 and Ro60, the most frequent. 5 patients presented positivity against SAE antibody. In comparison to the rest of MSA, 80% presented with cutaneous debut (p = 0.00), being the most frequent manifestations heliotrope erythema (p = 0.00), Gottron papules (p = 0.10) and skin rash (p = 0.00). 60% had pathological capillaroscopy compared to 15% (p = 0.00). Muscular balance was preserved in 60% of patients. Sixty percent had dysphagia vs 9% (p = 0.00). Two of them had lung involvement (alveolar hemorrhage and rapidly progressive pneumonitis). In comparison with SAE negative group, patients presented more pulmonary hypertension (44.5 vs 34 mmHg), without reaching significant differences. No significant differences were found between muscle enzyme levels’ neither acute phase reactants.

As complications, one patient presented a myocarditis with quickly rapidly progressive pneumonitis that required high doses of corticotherapy and another one alveolar hemorrhage, which was treated the same way. All patients required corticotherapy at doses of mg/kg, requiring two of them to be treated with DMARDs (methotrexate and dolquine) and one of them with immunoglobulins due to cutaneous involvement. Mortality rate was 40% due to rapidly progressive lung affection and cardiopulmonary arrest.

**Conclusion:** Higher prevalence of SAE1/2 antibody in our cohort may be explained due to the use of amplified myositis antibodies kit that specifically includes this antibody. These patients typically present with cutaneous involvement and dysphagia but also lung affection as a complication. Studies with larger samples should be performed in order to know the prognosis of this antibody specificity.

**Disclosure of Interests:** None declared

AB0643 CLINICAL AND ANALYTICAL DESCRIPTION OF A DERMATOMYOSITIS SERIES OF PATIENTS

Jordi Carrims-Fábregas1, Clara Esteve-Cols2, Ivette Casasfont-Sole1, Lourdes Mateo1, Laija Gilfe1, Anne Riveros1, Maria Aparicio-Espin1, Aninka Nach1, Metanía Martínez-Morillo1, Clara Sangüesa-Gómez1, Anahy Brandy-García1, Águeda Prior-Español1, Mónica Munera-Campos1, Eva Martínez-Cáceres1, Isabel Bielsa-Manzo2, Josep Roca3, Alejandro Olive1, Quiñant-Sánchez Bibiana1, Susana Holgado1,2.

1Hospital Universitari Germans Trias i Pujol, Rheumatology, Badalona, Spain; 2Hospital Universitari Germans Trias i Pujol, Immunology, Badalona, Spain; 3Hospital Universitari Germans Trias i Pujol, Dermatology, Badalona, Spain; 4Hospital Universitari Germans Trias i Pujol, Epidemiology, Badalona, Spain

Background: Dermatomyositis (DM) is an idiopathic inflammatory myopathy. The recent years has increased its knowledge thanks to best characterization of myositis-specific antibodies that correlate with different clinical phenotypes.with different clinical phenotypes.

Objectives: To describe the clinical and analytical features of a series of dermatomyositis: clinical debut, clinical manifestations as well as the treatments received and the evolution of the disease.

Methods: Patients diagnosed of dermatomyositis in a tertiary hospital between the years 1978-2018 according to the criteria of Bohan and Peter (1975) and according to Dalakas classification criteria (2015). Clinical, analytical and immunological profile data were collected, as well as treatments received and the evolution of the disease.

Results: A total of 59 inflammatory myopathies diagnosed between the years 1985 and 2018 were included. 46 were dermatomyositis (78%), 9 polymyositis (15%) and 4 necrotizing myositis (7%). 69% were women and 22% were smokers. Clinical debut at 54 ± 17 years. The initial manifestation was pulmonary in 26.7% followed by cutaneous manifestations (24.4%) and the muscular (22.2%), while a 17.8% started skin and muscular manifestations at the same time. 45.5% behaved like a myopathic DM while a 26% as amyopathic DM and antisynthetase syndrome respectively. 38% presented interstitial involvement being the most common non-specific interstitial pneumonitis (76%) followed by usual interstitial pneumonitis (17%). In these patients, DLCO was decreased (mean of 58.9% and 13.2) as well as the FVC (average of 58%, 2.5L). 73.3% presented cutaneous involvement being the most common manifestations the Gottron papules (37.8%) and the heliotrope rash (35.6%), and up to 27% had cuticular affection. 64% had muscle involvement, affecting proximal and symmetrical. Neck flexors were affected in a 38% of patients while 20% had dysphagia. Only 3 patients presented dysphonia (7%) and 2 myocarditis.

Analytical data

Muscular enzymes
- CK: 821 ± 1260U/mL
- LDH: 425 ± 300U/L
- Aldolase: 11.5 ± 11U/L
- Acute phase reagents
- ESR: 30 ± 23 mm
- RCP: 13 mg/l ± 25
- Myositis specific antibodies
- AntiJo1: 27%
- MDA5: 16%
- SAE1/2: 15%

Conclusion: 80% received corticotherapy at a dose of mg/kg/day and 20% required high doses of metiprednisolone due to muscular involvement or pulmonary, 18% immunoglobulins and 17% cyclophosphamide. As maintenance 80% received disease modifying anti-rheumatic drug in addition to corticosteroid therapy in descending doses (azathioprine 22%, doxilune 15%, tacrolimus 13.3%, rituximab 11%) due to muscle (29.9%), cutaneous (24.4%) and pulmonary involvement (22.2%). As complications, 2 cases of the syndrome were registered hemophagocytic virtually all patients they presented pulmonary hypertension (mean 34 ± 12 mmHg). 5 patients (11.1%) were diagnosed with neoplasia, two of them after the diagnosis of DM. The mortality was 24%. 3 patients died due to a rapidly progressive pneumonitis, another 2 due to alveolar hemorrhage and three of them due to complication of the neoplasic disease.

Dermatomyositis occurs in a variable way, with predominance of pulmonary, skin and muscle manifestations. They require corticotherapy and immunosuppressive treatment for maintenance, even so, mortality is high.

Disclosure of Interests: None declared

AB0644 RESULTS OF A TRAINING COURSE FOR CALCULATION OF THE MODIFIED RODNAN SKIN SCORE IN SCLERODERMA

1Gencay Can; Aydan Köken Avşar1, Sinem Burcu Kocaer, Gökçe Kenar1, Dilek Somaz1, Hanadi Yarkan-Tuğsa1, Duygu Temiz Karadag1, 2Neslihan Göğeç2, Servet Yolba1, Hakan Babaoglu1, Alper Yıldırım1, Mügebe Ener Yayıla3, İlyas Ercan Okatan1, Alper San1, Didem Arslan Tuğ1, Fatos Ören1, Süleyman Serdar Koca1, Ali Akdoğan1, Merih Birtik1, 3Dokuz Eylül University Faculty of Medicine, Rheumatology, Izmir, Turkey; 4Martin Devlet Hastanesi, Rheumatology, Martin, Turkey; 5Izmir Katip Çelebi University, Rheumatology, Izmir, Turkey; 6Ağrı Devlet Hastanesi, Rheumatology, Ağrı, Turkey; 7Çanakkale Devlet Hastanesi, Rheumatology, Çanakkale, Turkey; 8Çukurova University, Rheumatology, Adana, Turkey; 9İzmir University, Rheumatology, Izmir, Turkey; 10Gazi University, Rheumatology, Ankara, Turkey; 11Çukurova Universitesi, Rheumatology, Adana, Turkey; 12Fatih University, Rheumatology, Elazığ, Turkey

Background: Scleroderma is a connective tissue disease that is characterized by fibrosis of the skin. The modified Rodnan Skin Score (mRSS) is a measure generally used to assess the skin thickness in patients with scleroderma.Data on the effectiveness of the mRSS training courses differ in the literature.

Objectives: The objective of our study was to evaluate the effectiveness of the mRSS training course in rheumatology fellows in the rheumatology departments.

Methods: The study included 6 fellows from the departments of rheumatology. Participants were given a 1-hour-long theoretical training, including dermal involvement, and mRSS assessment by 3 rheumatology experts experienced in scleroderma, which was followed by an applied training on 4 patients for one-hour. Participants scored two patients before and after training on a form, which included 17 domains with a total score range between ‘0’ and ‘5’. Then using the SPSS15 software program, inter-rater reliability was assessed with intraclass correlation (ICC) analysis for both pre- and post-training mRSS. Fleiss’ kappa was used to measure the degree of agreement according to 12 Rodnan score areas before and after the training.

Results: The ICC value for pre-training and post-training total Rodnan scores was 0.867 (95% CI 0.625-1.00, P=0.05), and 0.905(95% CI 0.045-1.00, P<0.02), respectively. Individual analysis of score areas showed that after the training there was an increase in degree of agreement in some of these areas, while there was no difference in one area, and it decreased in others (Table 1).

Table 1. The ICC value and percentage of agreement of the modified Rodnan skin score in scleroderma

Conclusion: Several studies have demonstrated the applicability, reliability, and validity of mRSS, a measure of dermal involvement, and that evaluation of the score requires experience, and an applied learning process. In the literature, the inter-rater ICC values during previous training courses are reported to range between 0.378 and 0.921(1). These studies show differences in terms of the number and experience of participants,
Cannabidiol in the treatment of pain related to systemic sclerosis skin ulcers: Our experience

Objectives: Evaluate our experience to define the efficacy of cannabidiol (CBD), one of the constituents of Cannabis sativa, in the treatment of skin ulcers (SU) in patients with systemic sclerosis (SSc).

Methods: Twenty-five SSc patients (F/M 22/3, mean age 52.3 ± 12.9 years) were consecutively included. In all patients the disease was complicated by longstanding, painful SU resistant to opioids. Pain was classified as severe, according to WHO guidelines, in all subjects. The local treatment with CBD was applied daily for the treatment of SU-related pain. We performed both an evaluation by the patients and a local evaluation by the medical staff at the end of treatment.

Results: The local treatment with CBD produced a significant reduction of symptoms daily: self-evaluation of pain at the same time in the evening, oral (five drops bid) as local treatment (two drops in the site of SU) for the treatment of SU-related pain. We performed both an evaluation by the patients and a local evaluation by the medical staff at the end of treatment.

Conclusion: Our study suggests that the use of CBD as a local therapy is effective and safe in maintaining analgesia in patients with SSc, not only would it be essential for an adequate healing of a local wound.
AB0647 ASSOCIATION OF VASCULAR BIOMARKERS WITH SYSTEMIC SCLEROSIS CLINICAL FEATURES AND NAILFOLD VIDEOCAPILLAROSCOPY ALTERATIONS: CROSS SECTIONAL STUDY

1Jelena Celic*, Aleksandra Antovic2, Quan Tang3, Maja Zlatanovic1, Slavica Pavlov-Doljovic1, Ivica Jeremic1, Aleksandra Kadic2, Karin Gunnarsson3, Aninka Nordin4, Jelena Vojnovic5, Mirjana Sekil Bukilica5, Nemanja Damjanov1.

1University of Belgrade, School of Medicine, Institute of Rheumatology, Belgrade, Serbia; 2Karolinska Institute, Department of medicine, Rheumatology Unit, Stockholm, Sweden; 3University of Nis, Faculty of Medicine, Nis, Serbia

Background: The most reliable markers reflecting endothelial activation and injury in Systemic sclerosis (SSc), are intercellular adhesion molecule (ICAM1), vascular cell adhesion molecule (VCAM1), E selectin (Es) and P selectin (Ps) (1).

Objectives: To assess concentrations of these vascular biomarkers in SSc patients (pts) in comparison to healthy controls (HC) and in relation to disease manifestations.

Methods: Patients who fulfilled the 2013 ACR/EULAR SSc classification criteria and have never been treated with endothelin receptor antagonist, phosphodiestrase inhibitor 5 or prostanoids were eligible. Exclusion criteria were overlap syndromes, other autoimmune and cardiovascular diseases, diabetes mellitus, thrombosis, pregnancy, active infection or neoplastic diseases. Our study included 53 SSc pts [34 limited (lcSSc) and 19 diffuse cutaneous SSc (dcSSc)] and 31 age- sex matched HC. Serum concentration of ICAM1, VCAM1, Es and Ps were measured using a commercial ELISA kit (Quantikine; R&D Systems), expressed as ng/mL. Clinical evaluation of patients was obtained, including nailfold videocapillaroscopy (NVC). Disease activity was assessed by the revised EUSTAR activity index. Statistical analysis was done in R. Student’s test or ANOVA, otherwise Mann-Whitney U or Kruskal-Wallis tests were used. Pearson’s or Spearman’s correlation were done depends on nature of data. ICAM1 cut off value was assessed with ROC analysis. Association were performed with uni- variate logistic regression for NVC alterations and multivariate for Anti-TopoI/Scl70 antibodies (aTSA).

Results: Concentration of all markers were elevated in SSc pts compared to HC (ICAM1 p<0.001, VCAM1 p<0.001, Es p<0.05, Ps p<0.05). Different disease subsets exhibited higher values of ICAM1 and VCAM1 respect to HC (ICAM1 p<0.05, VCAM1 p<0.001). Concentration of ICAM1 was higher in dcSSc compared to lcSSc (p<0.05). ICAM1 level were independently associated with positive aTSA (OR 1.2, 95% CI 1.02 –1.35, p<0.001), with distinguishing cut off value of 34.94 (Sn 0.90%, Sp 0.60%, AUC 0.85). ICAM 1 was positively correlated with the erythrocyte sedimentation rate (r 0.3, p<0.05) especially within disease duration > 3 years group (r 0.4, p<0.05). Higher levels of ICAM1 was found in diffus e disease and injury of Systemic sclerosis (SSc).

Conclusions: ICAM-1 could be used as a novel inflammatory marker. Recently studies are ongoing for objective easy markers (1).

AB0648 CORRELATIONS BETWEEN NEUTROPHIL/LYMPHOCYTE RATIO AND CLINICAL CHARACTERISTICS OF PATIENTS WITH SYSTEMIC SCLEROSIS

1CUOMO Giovanna1, Francesco Masini2, Kloidian Gjeloshi2, Francesco Guarino2, Fiammetta Danzo2, Luigi Elio Adinolfi2, Ciro Romano2, 1University of Campania Luigi Vanvitelli, Medicina di precisione, Caserta, Italy; 2University of Campania Luigi Vanvitelli, Department of Medical and Surgical Sciences, Caserta, Italy

Background: The ratio of neutrophils to lymphocytes (NLR) is considered as an additional marker of dSSc. Elevation of ICAM1 and Ps concentration in active group, but without significant differences (p>0.05). T

Methods: Our study is based on a retrospective analysis. We collected in a data base clinic and epidemiological characteristic of SSc patients. Fifty-two patients (46 female; 10 subset diffuse) with SSc were enrolled consecutively for analyse the correlations. We considered the correlation with NHL and skin core, ulcers, pitting scars, gastro-intestinal events, fibrosis on HTGR, respiratory parameters (FVC, DLCO), PAPs, diastolic abnormalities, capillaroscopy alterations and activity index (2). Student’s t-test was used for comparison averages, correlation among variables were assessed by Spearman’s correlation testing.

Results: Sociodemographic and clinical characteristic were reported in table 1. The correlation analysis statistically significant is summarized in table 2: NLR vs skin score, DLCO, PAPs, and activity index. The correlation analysis between NLR and presence of ulcers and pitting scars was considered not quite significant. There were no correlations between other parameters and NLR.

Conclusion: NLR values correlated negatively with DLCO value, and positively with PAP value, skin score and activity index NLR level may serve as inflammatory marker in patients with SSc.

AB0649  
B CELL DEPLETION THERAPY IN VERY EARLY SYSTEMIC SCLEROSIS. A POTENTIAL WINDOW OF OPPORTUNITY?

Dimitrios Dagoumis1, Pantelis Kranitis2, Ioannis Antonopoulos3, Konstantinos Melisaropoulos1, Stamatis-Nick Liossis1, 1Patras University Hospital, University of Patras Medical School, Rheumatology, Patras, Greece; 2Patras University Hospital, Radiology, Patras, Greece; 3Patras University Hospital, Rheumatology, Patras, Greece

Background: Our group, among others, has shown that B cell depletion therapy may improve skin thickening and interstitial lung disease (ILD) related to systemic sclerosis (SSc). All studies assessing the clinical efficacy of B cell depletion therapy in SSc have recruited patients with established disease fulfilling the old classification criteria. In our previous studies we have found that patients with shorter disease duration had a better clinical response to RTX.

Objectives: It is unknown whether treatment in very early SSc can affect long term outcomes. We aimed at assessing the effect of rituximab (RTX) in patients with very early SSc.

Methods: We report 2 cases where RTX was administered within 24 months from the appearance of Raynaud’s.

Results: A 56 year-year-old female with an 18-month history of Raynaud’s developed interstitial lung disease (ILD) with extensive ground glass lesions, a normal FVC (82%) but decreased DLCO (44%). A diagnosis of SSc was made based on the presence of positive anti-centromere antibodies, puffy fingers, telangiectasies, ILD and Raynaud’s. Six months following RTX treatment, her PFT’s had increased (FVC 94% and DLCO 55%) and chest HRCT showed an obvious improvement. One year later the patient no longer reported dyspnea. She remained on RTX for 5 years with no respiratory symptoms, stable PFTs and no evidence of disease progression. The second case is a 27-year old female with a 1-year history of Raynaud’s, puffy fingers, positive anti-Scl70 and capillaroscopy. Within a few months her skin thickened rapidly reaching an MRSS of 12 and developed tendon friction rubs. Six months following RTX treatment skin thickening had almost resolved; she only had mild sclerodactyly. Tendon friction rubs disappeared. The patient received 8 consecutive RTX courses throughout a period of 4 years. During this period the patient remained in a steady clinical condition with no signs of disease progression.

Conclusion: It is generally accepted that autoimmunity/immune dysregulation and vasculopathy are the primary events in SSc that eventually trigger the fibrotic process. Based on this pathogenetic model, one can hypothesize that a therapeutic intervention early in the disease course, prior to the appearance of fibrotic manifestations could potentially prevent permanent organ damage. Our data suggest that there may be a window of opportunity in SSc. This is why we propose that large scale, controlled studies assessing the efficacy of RTX (or other immune based therapies such as mycophenolate) in patients with very early disease are highly needed.

AB0650  
PERSPECTIVES AND UNMET NEEDS OF PATIENTS WITH POOR PROGNOSIS SYSTEMIC SCLEROSIS ON AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION CARE: A QUALITATIVE STUDY

1Carolijn de Bresser, Julia Spierings, Femke van Rijn-Brouwer; 2Anne Peters, Madelon Vonk; 3Alexandre Voskuyl; 4Jeska de Vries-Bouwstra; 5Marijke Kars; 6Jacob M. van Laar; 7University Medical Centre Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands; 8University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology and Department of Nephrology and Hypertension, Utrecht, Netherlands; 9Leiden University Medical Center (LUMC), Department of Medical Decision Making, Leiden, Netherlands; 10Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands; 11Amsterdam UMC, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; 12Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands; 13Julius Center for Health Sciences and Primary Care, Department of Medical Humanities, Utrecht, Netherlands

Background: Autologous hematopoietic stem cell transplantation (HSCT) can induce long-term remission in patients with diffuse cutaneous systemic sclerosis (dcSSc). Nevertheless, it is an intensive treatment with risk of treatment related mortality and associated adverse events requiring long-term hospital admission. Little is known about the psychosocial impact of HSCT on patients with dcSSc. Additionally, post-discharge care is currently not standardized.

Objectives: To gain more insight in the experiences of patients during and after HSCT and to identify unmet needs in current care.

Methods: Semi-structured interviews were conducted with dcSSc patients that underwent HSCT in four academic hospitals in the Netherlands. Interviews were transcribed verbatim and analyzed with NVivo12.

Results: Eight patients were interviewed (5 males and 3 females, mean age 48 years (SD 10), mean disease duration 4.6 years (SD 1.9), mean time since HSCT 3.2 years (SD 2.4). At inclusion mean SDAQ was 1.3 (SD 1.1) and mean ESSO-SLE 0.86 (SD 0.21). While patients were satisfied with the frequent, low-threshold contacts with physicians and nurses, the decision-making process followed by HSCT and recovery was mentally taxing. Although patient education was experienced as extensive pre-treatment, participants reported they only felt the real impact of it during therapy. Patients felt anxious throughout the hospital stay and they could not recall most events from that period. Feelings of losing control over health and over time were frequently described. Support of family and friends was important during treatment. Apart from the practical aid, they provided emotional support, helping to cope with emotions and to find purpose. Furthermore, a specialized nurse involved in psychosocial support and care management was highly valued. Still, participants felt lonely and misunderstood due to invisible disabilities, such as fatigue and pain. Six months after HSCT, patients experienced less stress. It was often hindered. There were unmet needs. Patients preferred to be better informed about what to expect after admission. Structured and written instructions should include themes such as self-management, practical tips and prognosis of recovery. Participants would advise peers to keep a diary and even take photos during HSCT and hospital stay, in order to help recollect and assimilate past events. Peer-support was recommended by most patients.

Conclusion: HSCT had a large impact, both physical and emotional. We identified unmet needs regarding patient education on rehabilitation and psychosocial support in the period following HSCT.

AB0651  
THE INFLUENCE OF RITUXIMAB THERAPY ON THE DYNAMICS OF THE BASIC PARAMETERS AND ACTIVITY OF SYSTEMIC SCLEROSIS

Oksana Desinova, Maysya Starovoytova, Lida P. Ananyeva, Ludmila Garzanova, Olga Koneva, Olga Ovsyannikova, V.A.Nasonova Institute of Rheumatology, Moscow, Russian Federation

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by skin and multi-organ involvement induced by overproduction of autoantibodies by B cells.

Objectives: To assess the influence of Rituximab (RTX) therapy on the dynamics of the basic parameters and activity of SSc during long-term follow-up.

Methods: There were 90 SSc patients (pts) in the prospective study. 75% were women; 57% pts had diffuse SSC. SSc was confirmed ACR/ EULAR criteria. The average duration of the disease was 5.8 years and of the study was 27 months. For the purpose of the analysis, a group of pts was selected that had no less than two evaluation points from 12 to 42 months and had received 2.9±1.1 g RTX in average during follow-up period. The examination included both routine clinical laboratory parameters and special research. We evaluated the modified Rodnan skin score (mRSS), forced vital capacity (FVC), diffusing capacity of carbon monoxide (DLCO), the Valentini Disease Activity index, estimated glomerular filtration rate (eGFR) before and after completed RTX. All pts included in the study received treatment with vascular, anti-inflammatory and/or immunosuppressive medicines. The average dose of prednisolone was 11.8±4.4 mg/day.

Results: In general, more than 90% pts demonstrated different kinds of improvements. A reliable improvement was documented based on a number of indicators, which reflect typical features of the disease. Thus, skin induration was reduced (skin score decreased), lung functional capacity
increased (increase of FVC of more than 5%). The skin score was reliably decreased from 11.2±9.3 to 6.2 ±4.9 (p<0.0001), FVC was increased from 76.9±19.9 to 84.7±20.9% (p<0.0001), also the increase of DLCO from 46.3±18.3 to 47.8±16.9% from the proper amount was detected. The Valentini Disease Activity index reliably reduced from 2.9±1.7 to 1.38±1.2 points (p<0.0001). Under the RTX therapy, the decrease of glucocorticoids dose was insignificant, but statistically reliable. Thus, prednisolone dose reduction from 11.8±4.4 to 9.2±2.2 mg/day was achieved. Clinically significant but reliable decline of eGFR from 100.2±23 to 94.6 ±2 ml/min/1.73m² was detected.

Conclusion: Thus, RTX has a positive influence on the basic parameters of SSc, mainly on skin damage and lung functionality, reduces the general disease activity. The influence of the RTX on kidney function requires further long-term study.

Disclosure of Interests: None declared

OCTC INTERVAL PROLONGATION IN A SCANDINAVIAN COHORT OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES AND SYSTEMIC SCLEROSIS: CORRELATIONS WITH CLINICAL VARIABLES

Sine Søndergaard Korpholm1, Maryam Dastmalchi2, John Borde Knudsen2, Axel Cosmus Diederichsen3, Ingrid E. Lundberg3, Daniel C. Andersson4, Nanna Witting5, Søren Jacobsen2, Tina Fris6, Markus E. Krogager1, Louise Pyndt Diederichsen1, Odense University Hospital, Department of Rheumatology, Odense, Denmark; Karolinska University Hospital, Department of Medicine, Rheumatology Unit, Stockholm, Sweden; Odense University Hospital, Department of Cardiology, Odense, Denmark; Karolinska Institutet, Department of Medicine, Rheumatology Unit, Stockholm, Sweden; Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden; Rigshospitalet, Department of Physiology and Pharmacology, Copenhagen, Denmark; Rigshospitalet, Copenhagen University Hospital, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; Statens Serum Institut, Department of Autoimmunology and Biomarkers, Copenhagen, Denmark

Background: Idiopathic inflammatory myopathies (IM) are rare devastating diseases characterized by progressive muscle weakness and muscle fatigue. IM frequently affects other organs pointing to IM as a systemic inflammatory disease. Cardiac involvement is associated with poor prognosis. The symptoms are often subclinical and therefore overlooked. QTc prolongation has been detected in patients with systemic sclerosis (SSc). Autoantibodies are important diagnostic tools to confirm IM and are present in approx. 60% of IM patients. Autoantibodies are increasingly being recognized as markers for specific organ involvement. A biomarker for cardiac involvement has yet to be elucidated.

Objectives: The aim is to generate new knowledge about cardiac involvement in IM detected by electrocardiography (ECG) and to evaluate possible associations between autoantibodies and cardiac involvement detected on ECG in a cohort of IM patients compared with ECG changes in a cohort of SSc patients.

Methods: In a Scandinavian cohort, 263 IM patients (130 polymyositis patients, 77 dermatomyositis patients, and 56 inclusion body myositis patients) and 102 SSc patients were investigated by ECG and basic cardiovascular and disease specific assessments according to international guidelines. IM patients were tested for myositis specific autoantibodies (MSAs); anti-Jo-1, anti-PL-7, anti-PL-12, anti-Cy, anti-JE, anti-ARF, anti-Mi-2, anti-MAA, anti-TIF1γ, anti-NXP2, anti-SAE1, anti-HMGCR) and myositis associated autoantibodies (MAAs); anti-PM/Scl70, anti-PM/Scl, anti-Ro/52, anti-Ku, anti-CNA1).

Results: Twenty two IM patients (8.49%) had abnormal QRS duration versus one SSc patient (1.06%) (p = 0.012). SSc patients had significantly longer QTc duration than IM patients (QTc = 432.7 ms ± 22.2 and 426.4 ms ± 23.6, respectively) (p = 0.03).

Multivariate regression analysis revealed that increased C-reactive protein (CRP) (p = 0.008), gender (p = 0.002), and hypertension (p = 0.007) were associated with QTc duration in IM patients. Likewise, pulmonary arterial hypertension was associated with QTc duration (p = 0.001) in SSc patients.

In analysis of pooled data for IM patients and SSc patients, factors associated with QTc duration were increased CRP (p = 0.005), gender (p = 0.001), and hypertension (p = 0.01).

Conclusion: Both IM patients and SSc patients had ECG changes though no particular pattern was shown. The findings support our hypothesis on cardiac involvement in IM patients. No significant association was found between presence of either myositis specific or myositis associated autoantibodies and ECG changes. This could be due to the relatively low number of each autoantibody. There is a need to conduct larger prospective studies to identify a possible autoantibody for cardiac involvement in IM.

Disclosure of Interests: The authors would like to thank all participating patients and the study personnel at the including centres.

AB0653 SERUM CARDIAC BIOMARKERS BUT NOT SUBCLINICAL CARDIOVASCULAR MAGNETIC RESONANCE ABNORMALITIES ASSOCIATE WITH SYSTEMIC SCLEROSIS ASSOCIATE WITH THE DEVELOPMENT OF CARDIOVASCULAR EVENTS

1Raluca-Bianca Dumitru, Lesley Anne Bissell1, Bana Erhayem2, Graham Fentz2, Ananthi Kidamb1, Peter Swedo3, Helina Donica2, Agata Buslja3, John Biglands4, John Greenwood2, Francesco Del Gallo4, Sven Plein1, Maya Buch1, 1Leeds Institute of Rheumatology and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; 3Department of Biochemical Diagnostics, Lubeck, Poland; 4National Institute for Health Research, Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Primary cardiac disease in systemic sclerosis (SSc-PCD) is associated with a poor prognosis when clinically evident. Subclinical SSc-PCD is described in up to 2/3 of SSc patients when sensitive methods are employed. The prognostic implication of these findings is not clear.

Objectives: To describe the prevalence of cardiovascular magnetic resonance (CMR) abnormalities, their association with clinical phenotype and cardiac biomarkers, and whether cardiac biomarkers and CMR predict the development of cardiovascular (CV) events.

Methods: Patients fulfilling the ACR/EULAR criteria for SSc, with no CV disease (CVD), diabetes and no more than 1 CV risk factor had 3Tesla CMR, including late gadolinium enhancement (LGE), myocardial perfusion, T1 mapping for T1 native and extracellular volume (ECV) quantification, and cardiac biomarkers measured. CV events were defined as episode of myocardial, heart failure, rhythm disturbances and/or echocardiography. Subclinical abnormalities including systolic dysfunction, diastolic dysfunction > grade 1 or regional wall motion abnormalities. 47 healthy volunteers (HV) with comparable age and gender served as controls.

Results: 83 SSc patients were recruited, median (IQR) age of 54 (49, 54), 84% females and 33% dcSSc, 40% had ILD, 24% a history of digital ulceration (HuDU) and 29% were on Ciclosporin. CMR showed higher ECV% and T1 native, markers of diffuse fibrosis in SSc compared to HV [mean (SD) 30 (4) vs 25 (3), p<0.000; 1241 (76) vs 1206 (55), p=0.003]. Lower myocardial perfusion reserve reserve (MPR) was also noted in SSc patients [mean (SD) 2.0 (8) vs 3 (1), p<0.000]. None of the HV had LGE-fibrosis, whilst 16 (20%) of the patients had a non-ischemic LGE pattern. Left ventricular (LV) volume and function were similar between HV and SSc patients. Presence of LGE associated with hsTnI and lower forced vital capacity (rho=0.283, p<0.032; rho=0.217, p=0.5). Multivariate analysis revealed an association of T1 native with mRSS and CRP (B=0.5, p=0.02; B=0.218, p=0.049), ECV% associated with NTproBNP and HuDU (B=0.305, B=0.310, p<0.005). 73/83 had >1 year available clinical and echocardiography follow up data with a mean (SD) duration of 24 (20) months. 12/73 had a CV event judged to be SSc-PCD. LV mass associated with CV events(p=0.043) (Table 1), whilst univariate regression analysis showed that both hsTnI (OR=1.014, p=0.014) and NTproBNP (OR=1.005, p=0.026) but none of the CMR variables associated with the development of CV events.

Conclusion: Asymptomatic SSc patients with no overt CVD demonstrate both focal and diffuse fibrosis, which are associated with cardiac biomarkers and markers of SSc disease activity. Whilst hsTnI and NTproBNP associated with the development of CV events, none of the measures of fibrosis did although a higher LV mass was noted in this.
NAILFOLD MICROVASCULAR CHANGES IN MIXED SCLERONET®: A PATIENT-CENTERED

The capillaroscopic scores of enlarged capillaries, giant capillaries, microhemorrhages were found significantly higher in SSc versus MCTD patients.

Results:

Statistical analysis was performed by non-parametric tests.

NVC parameters were compared at T0 with 10 random SSc patients involved in the first NVC analysis (T0), and during a three-year follow-up. Furthermore, 10 lipofillings for DUs non-responsive to pharmacological therapy were carried out.

Conclusion:

In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microvascular damage does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients.

AB0655 SCLERONET®: A PATIENT-CENTERED MULTIDISCIPLINARY APPROACH TO SYSTEMIC СLEROISIS
Ibària Galetti, Lauretta Bonini. GILS – Gruppo Italiano Lotta alla Sclerodermia, Milan, Italy

Background: Systemic Sclerosis (SSc) is a rare connective tissue disease which may affect almost the whole body.1 Because of its clinical complexity and heterogeneity, a multidisciplinary approach is helpful to patients.

Objectives: The project aims at providing evidence that a multidisciplinary approach allows to early detect and rightly treat diseases linked to SSc determining an improvement of the Quality of Life (QoL) for patients.

Methods: GILS, the Italian SSc Patient Organisation, selected 4 expert centers in Milan (where over one thousand patients are treated), among those able to diagnose and cure SSc in its different and difficult aspects.

Results: The monthly meeting is held with patient representatives (PRs). No private data are discussed. Hospitals General and Sanitary Managers must give a positive evaluation every year in order to continue ScleroNet® project.

Evaluation: The project needs to keep ScleroNet® patient-centered and to focus the attention on the QoL, whose improvement has been described by patients but not yet supported for all interventions by questionnaires.

Common inclusion and exclusion criteria have been established. Cardiologists performed 110 assessments through EKG, echocardiography and cardiopulmonary exercise testing. These tests gave the following diagnosis: 16 non-ischemic cardiomyopathy (after BNP and troponin dosage as well as cardiac MRI) got an immunosuppressive therapy; 22 PAHs; 34 diastolic functions; 23 respiratory disease. The rest did not receive a specific diagnosis but still in follow up. 70 perioral lipofillings have been carried out: body weight rose by 2 to 3 kg after 4 months in patients with low BMI thanks to a greater mouth opening. Moreover, a better elasticity of the perioral area led to better 70 perioral lipofillings have been carried out: body weight rose by 2 to 3 kg after 4 months in patients with low BMI thanks to a greater mouth opening. AB0654 NAILFOLD MICROVASCULAR CHANGES IN MIXED CONNECTIVE TISSUE DISEASE: DIFFERENCES WITH SYSTEMIC SCLEROSIS
Alberto Sulli1,2, Giorgia Ferrari1, Carmen Pizzorni1, Sabrina Paolino1, 2, Vanessa Smith4, Elisa Alessandri1, Massimo Patanè1, Maurizio Cutolo1.
1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; 3Department of Internal Medicine, Ghent University, Ghent, Belgium; 4Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium

Background: Detailed nailfold capillary abnormalities have not been described in mixed connective tissue disease (MCTD) as well as their changes over time, unlike systemic sclerosis (SSc) which microvascular damage has been classified and validated by nailfold videocapillaroscopy (NVC) in specific and progressive scleroderma patterns ("Early", "Active", "Late") (1-5).

Objectives: Aim of this study was to retrospectively compare detailed MCTD nailfold capillary abnormalities with those of SSc patients at first visit, and to monitor MCTD capillary changes over time.

Methods: Ten patients (mean disease duration 6.4±2.4 years, mean age 50±19 years,) affected by MCTD (Kasukawa’s criteria) were enrolled. Patients with either anti-extractable nuclear antigen positivity different from U1RNP or anti-dsDNA antibodies were excluded. Main capillary parameters (scores of enlarged capillaries, giant capillaries, microhemorrhages, capillary ramifications, as well as absolute number of normal and total capillaries per linear millimeter) were assessed in MCTD patients at their first NVC analysis (T0), and during a three-year follow-up. Furthermore, NVC parameters were compared at T0 with 10 random SSc patients matched for disease duration (6.4±1.4 years) and age (51±17 years). Statistical analysis was performed by non-parametric tests.

Results: The capillaroscopic scores of enlarged capillaries, giant capillaries and microhemorrhages were found significantly higher in SSc versus MCTD patients at T0 (2.0±0.5 vs 1.9±0.6 p=0.04, 1.6±0.7 vs 0.7±0.5 p=0.02, 1.25±0.7 vs 0.7±0.7 p=0.05, respectively). Moreover, the absolute number of both total capillaries and normal capillaries were found significantly lower in SSc versus MCTD patients (5.8±1.9 vs 7.6±1.8 p=0.04 and 0.45±1.0 vs 3.0±3.2 p=0.009). On the contrary, no statistically significant difference was observed at T0 for the other capillary parameters (including capillary ramifications) between the two groups of patients.

With the limit of a different pharmacological background among patients, no statistically significant variation of the scores, as well as of the absolute value of the above reported capillary parameters was observed during the 3 years of follow-up in MCTD patients. No statistically significant correlation was observed between capillary parameters and MCTD clinical aspects (Raynaud phenomenon, dysphagia, dyspnoea, scleredactyly, sicca syndrome, telangiectasias and arthalgia) at first visit and during follow-up.

Conclusion: In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microvascular damage does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients.

Abstract AB0655 Table 1. NVC measures in SSc patients with CV events versus SSc patients with no CV events at first NVC analysis (T0) and during a three-year follow-up. In SSc patients, no statistically significant variation of the scores, as well as of the absolute value of the above reported capillary parameters was observed during the 3 years of follow-up in MCTD patients. No statistically significant correlation was observed between capillary parameters and MCTD clinical aspects (Raynaud phenomenon, dysphagia, dyspnoea, scleredactyly, sicca syndrome, telangiectasias and arthalgia) at first visit and during follow-up.

Conclusion: In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microvascular damage does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients.
delimited area, according to their specific problems. ScleroNet® seems to enable the experts to networking specifically on SSc, giving the opportunity of sharing their knowledge. Without ScleroNet® the timing of treatment and/or diagnosis would have been delayed. Nevertheless, due to the fact that it is a work-in-progress and some experts have been enrolled in a second stage, data are available only for some interventions. The use of validated questionnaires and indicators are necessary to measure and prove the value of ScleroNet®.

AB0566 ANTISYNTHETASE SYNDROME: CLINICAL VALUE OF SOLOMON’S AND CONNORS’ DIAGNOSIS CRITERIA

1María Gréco*, María Jesús García de Yébenes2, Inmaculada Alarcón1, Anaíry Brandy-García1,4, Ilígo Rúa-Figueroa1, Estebali Loza2, Teresa Oton2, Juan Carlos Quevedo-Abeledo1, Carlos Rodriguez-Llorente1, Loreto Carmona1,2.
1Hospital Universitario Gran Canaria Dr. Negrín., Las Palmas, Spain; 2Instituto de Salud Musculoesquelética, Madrid, Spain; 3Hospital Universitario Germans Trias i Pujol, Barcelona, Spain; 4Hospital Universitario Central de Asturias, Oviedo, Spain

Background: Two antisynthetase syndrome (ASSD) diagnosis criteria sets have been proposed; both consider mandatory the presence of anti-aminoacyl transfer RNA synthetase (ARS) autoantibodies. Solomon’s criteria consider major clinical criteria (intestential lung disease (ILD) and fulfillment of Bohan and Peter criteria for DM/PM) and minor criterions (arthritis, Raynaud’s phenomenon (RP) and mechanic’s hands (MH)) (1). In contrast, Connors criteria evaluate the presence of at least one of the prior mentioned clinical features except myositis, and includes the presence of fever without other cause (2).

Objectives: 1) To evaluate the performance of Solomon’s and Connors’ criteria in patients with clinical suspicion of ASSD or myositis and positive ARS. 2) To describe their clinical characteristics.

Methods: We performed an observational retrospective study in two centers. All patients with clinical suspicion of ASSD or myositis, and positive ARS in the myositis immunoblot (Euroimmun assay) were included.

Results: We analyzed 37 patients; 70.3% woman, with a mean age at the moment of the ARS detection of 51.4 (SD±14.0) years, median time from the first symptom to the ARS detection of 4.0 (SD±5.8) years, and time of evolution of 7.69 (SD±6.51) years. The frequency of ARS was: anti-Jo1 (n=17), anti-PL12 (n=8), anti-PL7 (n=4), anti-EJ (n=4), and anti-OJ (n=4).

ARS diagnosis fulfillment and clinical manifestations:
1) Patients that met Solomon and Connors’ criteria (n=17, 45.9%):

- At disease onset: ILD (n=6, 35.9%), muscle weakness (MW) (n=5, 29.4%), and arthritis (n=4, 23.5%).
- During disease development: ILD (n=14, 82.3%); arthritis (n=13, 76.5%); MW (n=10, 58.8%); mechanic hands (n=10, 58.8%); Raynaud phenomenon (n=6, 47.0%); and fever (n=3, 17.5%).

2) Patients that only met Connors’ criteria (n=17, 45.9%):

- At disease onset: ILD (n=5, 29.4%), MW (n=3, 17.6%), or arthritis (n=5, 29.4%).
- During disease development: Arthritis (n=8, 47.0%); ILD (n=6, 35.3%); MW (n=6, 35.3%); Raynaud phenomenon (n=6, 35.3%); fever (n=5, 29.4%); and mechanic hands (n=1, 5.9%).

Relative risk (RR) of the different clinical manifestation for Solomon’s criteria fulfillment:
- MH RR=2.98 (95%CI 1.5-5.6; P=0.002), ILD RR=9.2 (95%CI 1.1-9.2; P=0.013); other manifestations does not presented significant RR.

Conclusion: More than three quarter of all patients presented as first clinical manifestation one of those included in the ASSD classic triad (ILD, MW and arthritis). These manifestations showed increasing rates during the disease development, being more frequent in patients that met Solomon’s criteria than in those who only met Connors’ criteria; more than twice as high in for ILD, and almost twice for MW and arthritis. This suggests that patients who met Solomon’s criteria, at disease onset presented incomplete clinical forms, and their clinical progression favored the criteria fulfillment. On the other hand, we cannot predict if the patients that only met Connors’ criteria are going to fulfill Solomon’s criteria; nevertheless, our results suggests it.

To conclude, our results suggest that: 1) Connors criteria might be considered for screening of ASSD; 2) Solomon’s criteria can be considered as the first gold standard for the ASSD diagnosis; 3) the presence of mechanic hands or ILD indicates a high probability of Solomon’s criteria fulfillment in patients with positive ARS.

AB0657 ANTISYNTHETASE SYNDROME: NON-ANTISYNTHETASE ANTIBODIES, CLINICAL MANIFESTATIONS AND OVERLAPS

1María Gréco*, María Jesús García de Yébenes2, Inmaculada Alarcón1, Anaíry Brandy-García1,4, Ilígo Rúa-Figueroa1, Estebali Loza2, Teresa Oton2, R. López-Sánchez1, Laura Cerecero3, Loreto Carmona1,2.
1Hospital Universitario Gran Canaria Dr. Negrín., Las Palmas, Spain; 2Hospital Universitat Germans Trias i Pujol, Barcelona, Spain; 4Hospital Universitario Central de Asturias, Oviedo, Spain

Background: The antisynthetase syndromes (ASSD) are characterized by the presence of anti-aminoacyl transfer RNA synthetase (ARS) autoantibodies and other features including myositis, arthralgias, interstitial lung disease (ILD), Raynaud’s phenomenon (RP), mechanic hands (MH), and fever. Two ASSD diagnosis criteria have been developed; those proposed by Connors, and the stricter criteria proposed by Solomon (1, 2). Additionally, other symptoms of connective tissue diseases (CTD) can be present.

Objectives: To describe a series of patients with positive ARS and analyze: 1) the associated non-ARS antibodies, 2) the clinical manifestations that are not included in the different ASSD diagnosis criteria; and 3) the initial diagnosis attributed by the Rheumatologist in the clinical records.

Methods: We performed an observational retrospective study in two hospitals. All patients with clinical suspicion of ASSD or myopathy and positive ARS in the myositis immunoblot (Euroimmun assay) were included.

Results: We analyzed 37 patients; 70.3% woman, with a mean age at the moment of the first symptom of 50.5 (SD±14.0) years, and 51.4 (SD±14.0) years at the moment of the ARS detection. The frequency of ARS was: anti-Jo1 (n=17), anti-PL12 (n=8), anti-PL7 (n=4), anti-EJ (n=4), and anti-OJ (n=4).

Associated non-ARS antibodies: anti-Ro52 (n=17, 46.7%); anti-PM/Scl75 (n=6, 16.2%); anti-PM/Scl100 (n=5, 13.5%); anticientromere (n=3, 8.1%); rheumatoid factor (n=2, 5.4%); anti-CCP (n=2, 5.4%); and anti-DNAd (n=2, 5.4%). Other antibodies detected only once: Anti-SRP, U1RNP, LAC, anti-M2, Anti-cardiolipin, anti-DNA.

- Most frequent clinical manifestations not included in the ASSD diagnosis criteria: Raynaud’s (n=10, 27%); dermamyositis rash (n=9, 24.3%); and SICCA symptoms (n=7, 18.9%).

- First diagnosis attributed by the clinicians in the medical records: ASSD (n=19, 51.35%), dermatomyositis/polyarthritis (DM/PM) (n=13, 35.1%), overlap syndrome (n=3, 8.1%), systemic lupus erythematosus (SLE) (n=3, 8.1%), primary Sjögren’s syndrome (SS) (n=2, 5.4%); rheumatoid arthritis (RA) (n=2, 5.4%); undifferentiated CTD (UCTD) (n=2, 5.4%); and Systemic Sclerosis (SSc) (n=1, 2.7%).

Overlaps included 2 DM/PM-Ssc and 1 DM/PM-SSc, and both UCTD was described with Ssc pattern. Thus, of the 18 cases not diagnosed as ASSD, 6 (33.3%) presented DM/PM diagnosis pattern and 6 (33.3%) Ssc pattern.
**Role of Nailfold Capillaroscopy in Cardiopulmonary Exercise Test (CPET) is a widely used examination to predict the progression of chronic obstructive pulmonary disease or post-transplant lung function, and it has also been examined in the context of respiratory tract involvement and pulmonary hypertension in systemic sclerosis (SSc).**

**Objectives:** As CPET provides a general overview of the aerobic metabolism, influence by pulmonary, cardiac and vascular function, the purpose of this investigation was to assess if development of poor overall disease outcome could be predicted by CPET.

**Methods:** Twenty-nine SSc patients (M/F=5/24; DSSc/LcSSc=16/13) were investigated repeatedly with CPET and followed for a mean of 3.7 (range 1-7) years. The clinical features of the patients were the following: alveolitis (n=15), pulmonary fibrosis (n=16), digital ulcers (n=13), 5 of them required bosentan therapy, macroangiopathy (n=8), GERD (n=26), Barrett metaplasia (n=19), gastrointestinal angioathy (n=5), motility disorder (n=10), pulmonary artery hypertension (Ppulm>40mmHg) or the decrease of carbon-monoxide diffusion capacity (DLCO) >2% /year, or increase in pulmonary artery pressure (ΔPpulm) >3mmHg/hour. Parallel with the CPET, conventional disease activity check-ups have been performed too (echocardiography, chest CT, resting lung function tests, clinical examinations). The correlations between the CPET measurements and conventional findings and the predictive value of CPET parameters at the first visit to the future developments of the composite end-point have been examined.

**Results:** Various CPET results (anaerobic threshold, AT, work rate, WfR, desaturation) have significantly correlated with worsening DLCO (p<0.05; Pearson's correlation). The changes of AT during follow-up and desaturation are predictive to the appearance of the end point designed to comprise multiple features of the disease. This makes CPET a promising non-invasive examination method to estimate the progression of disease in patients suffering from systemic sclerosis.

AB0660 SEXUAL HEALTH IMPAIRMENT IN WOMEN WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Background: Idiopathic inflammatory myopathies (IIM) are a group of disorders characterized by skeletal muscle inflammation that can cause functional impairment including sexual dysfunction.

Objectives: To assess sexual function, pelvic floor function and sexual quality of life of women with IIM compared to age-/sex-matched healthy controls (HC). To subanalyze sexual function in sexually active individuals.

Methods: In total 27 women with IIM [mean age: 54.2, disease duration: 7.3 years, dermatomyositis (DM, 10)/polymyositis (PM, 13)/necrotizing myopathy (MNMA, 3)/inclusion body myositis (IBM, 1)], who fulfilled the Bohan/Peter 1975 criteria for DM/PM, and 27 healthy women (mean age: 54.2) aged 18-83 were included. 11 women with IIM and 11 HC were sexually active. All patients completed the following questionnaires: Sexual Activity Profile; HAQ: Health Assessment Questionnaire; LD: lactate dehydrogenase. Abbreviations: FIS: Fatigue Impact Scale; BDI-II: Beck Depression Inventory II; PISQ-12: Pelvic Floor Distress Inventory Questionnaire, SA: sexually active; ns: not significant.

Results: Compared to HC, patients with IIM had significantly higher prevalence and greater severity of sexual impairment (FSFI, BISF-W), dysfunction of pelvic floor (PISQ-12), and worse sexual quality of life (SQoL-F) (table 1). There were no significant differences in sexual function between PM and DM. Even sexually active IIM patients reported significantly greater sexual health impairment compared to sexually active HC. Sexual health impairment in IIM was associated with laboratory markers of disease activity, health status, physical activity, fatigue and depression (table 2).

Worse scores in IIM were associated with disease activity/health status, physical activity, fatigue and depression. Acknowledgement: Supported by AZV-16-33574A, MCHCR 023728.

AB0661 ASSOCIATION OF ANTI-MDA-5 AUTOANTIBODY WITH AUTOIMMUNE ASSOCIATED HEMOPHAGOCYTIC SYNDROME IN DERMATOMYOSITIS

Background: Autoimmune associated hemophagocytic syndrome (AAHS) is a rare complication in dermatomyositis (DM). We previously demonstrated by multivariate analysis that one of factors associated with mortality in AAHS is DM (OR 5.57 [95% CI 1.08–28.65], P 0.05) among connective tissue diseases (1). Objectives: To find out underlying immunological characteristics, we examined the DM patients with AAHS.

Methods: We examined 31 new onset patients with idiopathic inflammatory myopathies (IIM) including clinically amyopathic dermatomyositis (CADM) admitted to our hospital between January 2009 and December 2018. Three patients had been diagnosed as AAHS proven by bone marrow aspiration. We examined these patient clinical and laboratory characteristics.

Results: Two patients were diagnosed as DM and one was CADM. We found that these 3 patients were associated with interstitial pneumonia. Laboratory tests of all 3 patients showed hyperferritinemia and high titer of anti-MDA5 antibody. All patients were diagnosed as AAHS by bone marrow aspiration smear. Two of them died on the 12th and on the 75th hospital day, respectively, in spite of intensive therapies.

The utility of nailfold capillaroscopy (NFC) has largely been evaluated in patients with Raynaud’s Phenomenon (RP). However, in equatorial countries, RP occurs in only 79% (1) and 84% (2) of patients in Singapore and Malaysia respectively. In the early stages of Systemic Sclerosis (SSc), patients may develop autoantibodies or puffy fingers before the onset of RP (3).

Objectives: There is no data on the utility of NFC in patients with non-RP features suggestive of the scleroderma-spectrum of diseases (SSc, mixed connective tissue disease, dermatomyositis). We aim to compare the utility of NFC for the early diagnosis of the SSc-spectrum of diseases in patients who present with and without RP.

Methods: Patients referred to our institution for NFC evaluation from March 2010 – March 2017 were recruited. Patients with confirmed diagnosis of a connective tissue disease were excluded. Eligible patients were divided into 4 groups: (I) RP with or without positive ANA; (II) Undifferentiated non-RP features to suggest SSc-spectrum diseases and negative ANA; (III) Undifferentiated non-RP features to suggest SSc-spectrum diseases and positive ANA ≥1400 and (IV) Positive SSc-associated autoantibodies without features to suggest SSc-spectrum diseases. Images were analysed at 200x magnification using a software analysis program. Patients were noted to have normal, aspecific or SSc pattern on NFC, defined by the presence of ≥1 giant capillary, avascular areas or ≥2 dilated capillaries with areas of hemorrhage.

Results: 133 patients were recruited (mean age 55 years, 87% female; 76% Chinese, 7% Malay, 10% Indian, 7% other ethnicity). ANA was positive in 74 (82.2%) patients (n=25 anti-centromere, n=3 anti-Scl70). Taking into consideration NFC patterns, the clinical outcomes were normal in 32 patients (35.6%), connective tissue disease (CTD) suspected in 33 patients (36.7%), and definite CTD in 25 patients (27.6%). Diagnostic yield for SSc-spectrum of diseases was highest in Groups I and III (Table 1).

Conclusion: In patients without RP, NFC was most useful to confirm a diagnosis in those with undifferentiated features to suggest SSc-spectrum of diseases and positive ANA.

Figure 1. Change in FVC of 59 patients of SSc with ILD after 5 years of follow up.

Figure 2. Change in FVC of 46 patients of SSc with ILD taking MMF after 5 years of follow up.

Conclusion: This prospective study was carried out with aim to determine progression of ILD in patients with systemic sclerosis with ILD over period of 5 years. In our study, there was no statistically significant change of FVC over period of time. Worsening of lung function with deterioration in FVC >10% was seen in only 13 patients (22%) (P<0.01). Our findings are similar to study done by Le Gouellec et al in which 75 patients with scleroderma and ILD were followed over period of 72 months of which 26% patients showed significant worsening of FVC (>10%)1. In our study there statistically significant decline in DLCO and increase in PAH over period of 5 years (p<0.001). In study carried out by Le Gouellec et al studying Scleroderma/ILD, there was significant decline in DLCO over period of 72 months of follow up1. In study done by Stephanie C. Mathai et al, there was progressive increase in PAH when patients with scleroderma and ILD with PAH were followed up for period of 4 years2...

AB0067  SPECIFICITY OF ANTI-TRNA SYNTHETASE AUTOANTIBODIES CORRELATED WITH CLINICAL COURSE AND PROGNOSIS OF MYOSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Yasushi Kondo, Yoko Nakagome, Kazuki Hirano, Yasushi Koyama, Shos Sasaki, Katsuyoshi Kuniyabashi, Yuto Iizumi, Chiho Yamada, Shrir Salo, Tokai University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Isehara-shi, Japan

Background: Interstitial lung disease (ILD) is associated with mortality among patients with idiopathic inflammatory myopathy (IIM). Anti-aminoacyl-RNA synthetase (anti-ARS) autoantibodies have been identified highly specific for IIM and coincidence of ILD. It has been identified that non-Jo1 positive anti-ARS patients may have decreased survival rate. However, differences of characteristics and prognosis in myositis-associated ILD with an individual anti-ARS autoantibody have not been clarified.

Objectives: To compare the characteristics and cumulative survival of myositis-associated ILD with different positivity of anti-ARS antibodies.

Methods: We investigated retrospectively all consecutive patients with myositis-associated ILD evaluated from 1999-2017. All autoantibodies were screened by using RNP and protein immunoprecipitation assays. Demographic data, laboratory findings and chest computed tomography (CT) images were obtained.

Results: Among 105 patients with myositis-associated ILD, enrolled, 47 had anti-Jo1 antibody and 58 had non-Jo1 antibody, anti-ARS (n=20), anti-PL12 (n=12), anti-PL7 (n=11), anti-KS (n=8) and anti Cu (n=7). The diagnosis at first visit were polymyositis (PM; n=28), dermatomyositis (DM; n=42), clinically amyopathic dermatomyositis (CADM; n=3) and antisynthetase syndrome (ASS; n=31). Most common causes of death in this study were exacerbation of ILD (n=10, 71.4%). Anti-Jo1 positive patients had better ILD prognosis than non-Jo1 patients (log rank test, p = 0.03). The prevalence of rapidly progressive ILD (RP-ILD) and upper lung field lesions in CT scans were significantly higher in anti-ARS positive patients (p=0.02 and p=0.05, respectively). Although the prognosis of ILD was not significantly different among 6 anti-ARS antibodies, anti-ARS positive patients had poor ILD prognosis than anti-Jo1 patients with the 5-year unadjusted cumulative survival was 73% and 95%, respectively.

Conclusion: Our data confirm the characteristics and outcomes of myositis-associated ILD are distinct by anti-ARS antibodies and highlighted that anti-ARS antibody positivity associated with relatively poor prognosis and RP-ILD.

AB0068  ASSOCIATION OF ANTI-RNA POLYMERASE III ANTIBODY AND BREAST IMPLANTS RUPTURE IN ITALIAN PATIENTS WITH SYSTEMIC SCLEROSIS

1Marla Grazia Lazzaroni1, Cristian Caimmi2, Eugenia Bertoldo3, Franco Franceschini4, Angela Tincani5, Paolo Airò1.
1ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy; 2University of Brescia, Molecular and Translational Medicine Department, Brescia, Italy; 3Azienda Ospedaliero Universitaria Integrata, Rheumatology Unit, Verona, Italy

Background: Several epidemiological studies have investigated the link between silicone breast implants (SBI) and Systemic Sclerosis (SSc). Although discordant data were reported, a recent analysis of SBI followed by United States Food and Drug Administration post approval studies, including nearly 100,000 individuals, described an association of SBI with a higher rate of SSc (Standardized incidence ratio 7.00), compared with normative data. The analysis of clinical associations in patients with SSc is complicated by the heterogeneity of the disease, both on immunological and clinical terms. Interestingly, a specific association of anti-RNA polymerase III antibody (anti-RNAP3) and SBI in Japanese patients with SSc was described in a single-center cohort. Moreover, an association of anti-RNAP3 with breast cancer, particularly when synchronous with SSc onset, was also demonstrated.

Objectives: To evaluate the association of SBI with SSc in Italian patients classified according to their SSc-related autoantibodies.

Methods: 562 consecutive women with SSc, classified according the 2013 ACR/EULAR criteria, were evaluated for the presence of SSc-specific autoantibodies (anti-topoisomerase-I (anti-Topo-I), anticentromere (ACA), and anti-RNAP3) in two Italian University centres. For each patient, history of breast cancer and SBI were recorded.

Results: Anti-RNAP3 antibodies were found in 4.6%, anti-Topo-I in 22.2% and ACA in 57.3% of total SSc women (Table 1). Comparing anti-RNAP3 vs anti-RNAP3 patients, a significantly higher frequency of breast cancer (15.3% vs 4.1%; p=0.026), SBI (11.5% vs 1.1%; p=0.006) and SBI rupture (11.5% vs 0.2%; p=0.0003) was found. Notably a higher rate of SBI rupture without breast cancer in anti-RNAP3 vs anti-RNAP3 was also noted (2/22 (9.1%) vs 0/514 (0%); p=0.0016).

Conclusion: In this large Italian cohort, a higher prevalence of SBI and SBI rupture in anti-RNAP3 compared to anti-RNAP3 SSc patients was confirmed, regardless of the history of breast cancer. This preliminary observation should be confirmed in multicentre cohorts, particularly regarding the connection between SSc and SBI rupture.

AB0069  THE EFFECTS OF BOSENTAN FOR TREATMENT OF DIGITAL ULCER IN KOREAN PATIENTS WITH SYSTEMIC SCLEROSIS: PROSPECTIVE, MULTICENTER, OPEN-LABEL TRIAL

1Young Ann Lee, Hyun-Sook Kim, Bo Young Kim, Yun Sung Kim, Sung Jae Choi, Jung Ran Che, 1The Soonchunhyang University Seoul Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Gangneung Asan Hospital, Internal Medicine, Gangneung, Korea, Rep. of (South Korea); 3Chosun University Hospital, Internal Medicine, Gwangju, Korea, Rep. of (South Korea); 4Korea University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); 5Pohang St. Mary's Hospital, Internal Medicine, Pohang, Korea, Rep. of (South Korea)

Background: Bosentan is an orally administered dual endothelin-1 (ET-1) receptor antagonist approved in the EU for reducing the number of new digital ulcers in patients with systemic sclerosis (SSc) and ongoing digital ulcer (DU). Oral bosentan therapy was beneficial and generally well tolerated in patients with DU associated with SSc. A total of 3 RCTs were identified. The first two were high quality (RAPIDS-1 and RAPIDS-2) with 122 and 188 patients and treatment durations of 16 and 24 weeks, respectively. Both studies showed that, compared with placebo, bosentan significantly reduced the number of new ulcers; however, it did not have an effect on the healing of preexisting ulcers and pain.

Objectives: This study evaluated the efficacy and safety of bosentan in DU secondary to SSc in Korean patients.

Methods: From December 2013 to December 2017, a prospective, multicenter, open-label trial was performed to investigate the complete healing of DU and tolerability of bosentan in Korean patients with SSc. The SSc
patients were included as having active DU or pulmonary arterial hypertension who had active DU in the last 3 months. A DU was defined as an area with visually discernable depth and a loss of continuity of epithelial coverage, which could be denuded or covered by a scab or necrotic tissue. If the area was denuded, the ulcer was designated active. If denudation could not be judged because of the presence of overlying scab or necrotic tissue, ulcers presenting with features, including underlying pain, based on investigator clinical judgment to be consistent with loss of epithelialization, epidermis, or dermis, and requiring treatment, were designated as active. The effectiveness and tolerability of bosentan was monitored within 24 weeks of study treatment, while healing of DU, largest diameter and the new incidence were also assessed up to week 24.

Results: The primary objective of this study was to assess the efficacy of bosentan in reducing DU including the complete healing rate. Secondary endpoints included development of new DU, assessment of discontinuation, measures of nailfold capillaroscopic (NFC) change. Thirty-five SSc patients were enrolled and seventeen patients were included in the NFC analysis. Mean age was 50.5 year-old, 85.7% was woman, 68.6% of DU in Korean patients with SSc. However, the size of the remaining cases was slightly increased from 4.1 to 5.2 mm, with no statistical significance. There was no statistically significant difference in the semi-quantitative changes of NFC before and after bosentan treatment.

Conclusion: Administration of bosentan over 24 weeks was statistically associated with complete healing and significant reduction in net number of DU in Korean patients with SSc. These angiodysplasias can affect the intestine occasionally as well as the stomach.

Disclosure of Interests: None declared.

a commercial technique of IB to detect TIF1γ (Euroimmun), however, commercial kits sometimes elaborate antigens without using whole protein structure. To date, there are no studies that study the agreement between the commercial kit and homemades IB.

### Objectives:

- To compare the commercial IB results of Anti-TIF1γ with homemade IB.

### METHODS:

Observational retrospective study that included adult patients with some determination of Anti-TIF1γ antibodies since 2014 in two tertiary level university hospitals. We collected demographical and clinical data of all patients. Taking into account their diagnoses we grouped them into: Cancer Associated Myositis (CAM), DM without cancer, Systemic Autoimmune Diseases (SAD) non-DM and other diagnoses. Subsequently, the clinical agreement with the IB results of Anti-TIF1γ performed by commercial (cIB) and homemade (hIB) technique were analyzed. A p value < 0.05 was considered statistically significant.

### RESULTS:

- Of all DM (CAM and DM without cancer), 12 were positive for both techniques, 5 presented discordant results (4 hIB positive with negative cIB and 1 cIB positive with negative hIB). 15 DM were negative for the two techniques, of which 8/15 had other antibodies associated with Autoimmune Myopathy (3 NXP-2, 1 MIZ, 1 MDAS, 1 SAE, 1 Jo1 and 1 Ro52).
- When we analyzed patients with CAM with both techniques, 10/13 presented positive hIB vs 8/13 cIB positive. DM without cancer, 6/19 had positive hIB vs 5/19 cIB positive. The specificity and specificity of each test was evaluated in CAM and DM without cancer, being 61.5% and 73.7% respectively for cIB (p = 0.071), compared to 76.9% and 68.4% for hIB (p = 0.029).
- In non-DM SAD group, 1 patient had positive determination for both techniques, 3 had positive cIB with negative hIB, and 3 cIB negative with positive hIB. We also found other antibodies in 6/7 patients with non-DM SAD. The 9 patients with other diagnoses were: 1 positive for both techniques and 8 positive for cIB and negative for hIB.

### CONCLUSIONS:

HOMEMADE IB with 155 kDa recombinant protein was superior to cIB to detect TIF1γ in our serie of patients with CAM. This could have clinical implications in screening and early detection of neo-plasia that affect false negative by cIB.

A positive cIB in patients not suspected as a SAD were negative for hIB in the major part of cases. It would be recommended to check the commercial IB using homogeneous homemades IB, due to its known clinical-therapeutic implications.

**AB0672 RENAL INVOLVEMENT IN PATIENTS WITH DERMATOMYOSITIS AND POLYMYOSITIS**

Simeon Monov1, Daniela Monov2, Rossika Shumaliyeva3, Elena Miloshova4.

1Medical University – Sofia, Department of Rheumatology, Sofia, Bulgaria;
2Medical Institute, Medical University – Sofia, Department of Internal Diseases, Sofia, Bulgaria.

### Background:

Dermatomyositis (DM) and polymyositis (PM) are characterized by moderate to severe muscle weakness and inflammatory lesions in the muscle. They lead to frequent, and, in some cases, life-threatening extramuscular (lung, cardiac, neurologic, kidney) complications.

### Objectives:

The aim of this study was to determine the incidence, the severity, the course and outcome of renal diseases in patients with DM or PM.

### Methods:

We identified 84 patients (68 female, 16 male) with the diagnosis of DM and 23 (14 female, 9 male) with PM. Diagnosis of DM and PM was based on the ENMC classification. The mean follow-up was 5.6 ± 3.8 years. Evaluation of extramural involvement was mainly performed in the presence of suggestive clinical signs. Autoantibodies were detected by ELISA. Acute kidney injury (AKI) was defined as an acute doubling of serum creatinine level. Chronic kidney disease (CKD) was defined if an estimated glomerular filtration rate (eGFR) <60 ml/min on at least 2 measurements 3 months apart.

### Results:

Of the 107 patients, 26 were found to have suffered varying degree of renal involvement. All the 26 patients (22 patients with DM and 4 with PM) had varying degree of proteinuria and haematuria. Renal involvement consisted of AKI in 4 patients and CKD in 18 patients.

### Conclusions:

The study confirms that renal involvement in DM and PM is common and should be considered in the differential diagnosis of adult myositis. Early diagnosis and initiation of effective treatment may prevent serious complications such as renal failure. The study also suggests that renal involvement may contribute to increased morbidity in these patients and should be considered at the initial diagnosis.
patients (6.3%) presented with only positive anti-centromere. CP was nor-
mal in 191 patients, while in 45 patients scleroderma pattern was
observed and in 19 patients nonspecific pattern suggestive of SAD was
seen. Capillaroscopic findings: in each of the 23 patients diagnosed with
SSc, 21 patients had scleroderma pattern. Of the 6 patients with SLE
CP was normal in 4 patients, while one patient had abundant tortu-
sity. Likewise, the 6 patients with Sjögren’s syndrome, only one patient had
a nonspecific pattern suggestive of SAD. Of the 7 patients with MCTD,
four had nonspecific CP, two had a scleroderma pattern and one had tortu-
sous pattern. The 2 patients with overlap (myopathy-scleroderma and
Lupus-scleroderma) both had a pathological CP with scleroderma pattern.

Conclusion: Our study demonstrates that the evidence of scleroderma
pattern is very specific of SSc. However, in certain diseases such as
MCTD, overlap syndromes and inflammatory myopathies, we can also
see this pattern. In other SAD, CP is usually normal or may show some
nonspecific changes.

AB0674 RETROSPECTIVE STUDY OF A COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS IN A TERTIARY CARE HOSPITAL

David Moyano Bueno1, Luis Gómez-Lechón2, Olga Martínez González2, Ana Isabel Tumón2, Carlos A. Montilla Morales2, Cristina Hidalgo2
1Complejo Asistencial Universitario de Salamanca, Dermatology, Salamanca, Spain; 2Complejo Asistencial Universitario de Salamanca, Rheumatology, Salamanca, Spain

Background: Systemic sclerosis (SS) is an autoimmune disease of unknown etiology, characterized by the presence of fibrosis and vasculopathy
in skin and multiple internal organs such as the lungs, the kidneys and the digestive tract. The course of the disease is unpredictable and could remain relatively stable or have a rapid evolution. Multiple studies have been carried out to determine the clinical characteristics and sur-
vival prognosis on SS patients.

Objectives: To analyze the demographic characteristics, clinical features, treatment and prognosis in a SS disease cohort.

Methods: We performed an observational and retrospective study of
patients with SS. The patients had been attended by the Rheumatology
department of a tertiary care hospital. We collected demographic, clinical
and analytical variables, as well as treatment and prognosis. We classi-
fied the disease employing the LeRoy and Medsger, VEDOSS criteria
and 2013 ACR/EULAR criteria.

Results: Of our 43 patients, 36 (83.7%) were female and only 7 (16.3%) were male. The average age was 60.4 years (SD 15.6), the average age at diagnosis was 53.3 years (SD 17.6) and the mean time of evolu-
tion of the disease was 7.9 years (SD 6.3). Of all the patients, 3
patients (6.9%) died, the mean age at death being 53.6 years (SD 23.7) and the mean time from diagnosis to death of 19 years (SD 10.1). The most frequently occurring presentation was limited SS (with 18 patients
(41.9%), followed by preescleroderma with 14 patients (32.6%), diffuse
SS with 6 patients (14%) and escleroderma sine escleroderma with 2
patients (4.7%). Three patients (7%) were labeled with MCTD. SS was
associated with other autoimmune diseases in 20% of patients. Five
(11.6%) patients developed neoplasms throughout the course of the study. The rest of the clinical characteristics are listed in Table 1 and 2, as well as the strength of association of these with the type of SS, cal-
culated using chi square and Fischer test.

Conclusion: Worthy of noting in our cohort is the absence of sclero-
derma in more than 40% of our patients, probably because the new cri-
teria have allowed us to diagnose the disease at an earlier stage and also due to the scarce frequency of puffy fingers with respect to other larger series. Digestive involvement was the most frequent visceral mani-
festation, followed by pulmonary manifestations, specifically interstitial lung disease (ILD). Despite the small sample size, lung disease was signifi-
cantly associated with the two forms of systemic sclerosis, but not with
the antibody pattern. Both the ILD and the pulmonary arterial hyperten-
sion (PAH) were more frequent in patients with SSc. Mortality in all
cases was due to interstitial lung involvement. As is frequently described, SS is associated with other systemic autoimmune diseases, constituting
an overlap syndrome.

BODY COMPOSITION IN MYOSITIS PATIENTS AND THE ASSOCIATION WITH DISEASE SPECIFIC FEATURES, PHYSICAL ACTIVITY AND PLASMA LEVELS OF INFLAMMATORY CYTOKINES

1,2Sabina Oreska⁎, Maja Špritovič⁎, Petr Česák⁎, Ondrej Marecek⁎, Hana Storkánová⁎, Hana Smurová, Barbora Helmanková⁎, Kateřina Kubinová⁎, Martin Klein⁎, Lucia Vernerova⁎, Olga Růžičková⁎, Karel Pavelka⁎, Ladislav Šenolt⁎, Heman Mann⁎, Jiří Vencovsky⁎, Michael Tomčík⁎, 1,2Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic; 2Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic

Background: Skeletal muscle, pulmonary, and articular involvement in idiopathic inflammatory myopathies (IIM) limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition.

Objectives: To assess body composition and physical activity of IIM patients and healthy controls (HC) and the association with selected inflammatory cytokines in IIM.

Methods: 54 patients with IIM (45 females; mean age 57.7; disease duration 5.8 years; PM (22)/DM (25)/IMNM (7)) and 54 age-sex-matched HC (45 females; mean age 57.7) without rheumatic/tumor diseases were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. We assessed body composition (densitometry: IDXNAR; bioelectrical impedance: BIA2000-M), physical activity (Human Activity Profile, HAP questionnaire), disease activity (MITAX and MYOACT activity score), muscle involvement (manual muscle test, MMT-8 and functional index, F2I) and plasma levels of 27 cytokines (commercial multiplex ELISA kit, Bio-Rad Laboratories). Data are presented as mean±SD.

Results: Compared to HC, patients with IIM had a trend towards significantly increased body fat’s (BF%) as assessed by IDXNAR (39.9±7.1 vs. 42.4±7.1 %, p=0.077), but significantly decreased lean body mass (LBM) as assessed both by IDXNAR (45.6±8.1 vs. 40.6±7.2 kg, p=0.001) and BIA (52.6±8.8 vs. 49.7±9.0 kg, p=0.003), and increased extracellular mass body cell mass (ECM/BCM) ratio (1.06±0.15 vs. 1.44±0.42, p<0.001), reflecting deteriorated nutritional status and worse muscle predispositions for physical activity. Compared to HC, IIM patients had significantly lower bone mineral density (BMID: 1.2±0.1 vs. 1.1±0.1 g/cm², p=0.001), Disease activity duration negatively correlated with BMD (r=-0.392, p=0.004) and LBM-BIA (r=-0.272, p=0.047). Disease activity assessed by both MITAX and MYOACT positively correlated with LBM-BIA (MITAX: r=0.296, p=0.031; MYOACT: r=0.335, p=0.013) and LBM-DEXA (MITAX: r=0.341, p=0.012; MYOACT: r=0.368, p=0.007), similarly as with basal metabolic rate (BMR; MITAX: r=0.336, p=0.014; MYOACT: r=0.351, p=0.010), and fat free mass (FFM; MITAX: r=0.338, p=0.014; MYOACT: r=0.356, p=0.009). CRP was positively associated with BF% assessed both by DEXA (r=0.276, p=0.035) and BIA (r=0.306, p=0.025). Higher BF%-DEXA was associated with worse physical endurance (F2I: r=-0.311, p=0.026) and worse ability to perform physical activity (HAP: r=0.292, p=0.032), MMT-8 score negatively correlated with ECM/BCM ratio (r=-0.385, p=0.006). Plasma levels of IL-10a positively correlated with body mass index (BMI, r=0.359, p=0.009), BF% (r=0.363, p=0.009), and visceral fat (VF, r=0.409, p=0.003). Plasma levels of MCP-1 positively correlated with ECM/BCM ratio (r=0.387, p=0.005). Increased plasma levels of IL-10 were associated with decreased LBM (r=-0.473, p=0.014).

Conclusion: Compared to healthy age-sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease activity and duration, inflammatory status, skeletal muscle involvement, and physical activity. Plasma levels of several inflammatory cytokines were associated with alterations of body composition in IIM patients and highlight the potential role of inflammatory status on impaired body composition during the course of IIM.

TREATMENT OF IDIOPATHIC INFLAMMATORY MYOPATHIES – A SINGLE CENTRE EXPERIENCE

1Jaka Ostrowska⁎, Ziga Rotas1, Matija Tomši2⁎, Aljoša Hocevar1,2, 1University Medical Center, Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 2University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: There is no consensus or recommendations for the treatment of idiopathic inflammatory myopathies (IIM).

Objectives: We explored how we treated incident IIM patients in our secondary/tertiary rheumatology centre.

Methods: We retrospectively included all biopsied and physically active patients with IIM diagnosed between January 2010 and June 2018, who were followed at least 6 months. The remission inducing treatment and the treatment at the last follow-up were recorded.

Results: During the 102-month period we identified 102 IIM cases (71.6% female, median (IQR) age 62.7 (52.2–72.1) years): 27.5% dermatomyositis, 22.5% anti-synthetase syndrome, 14.7% myositis in an overlap syndrome, 13.7% immune mediated necrotizing myopathy, 11.5% polymyositis, 6.3% cancer associated myositis, 2.9% inclusion body myositis (IBM), 1% unspecified myositis. 94 (92.2%) patients received glucocorticoids (GC), 18/94 (17.6%) as monotherapy. The remaining 81 (79.4%) were treated with additional immunomodulatory agents (Table 1), most commonly methotrexate. In addition to therapy presented in Table 1, 13 (12.7%) also received human immunoglobulins (IVIG), one (1%) received plasma exchange therapy.

Conclusion: The 8 (7.8%) cases who were not treated with GC received methotrexate, rituximab, and 4 no additional treatment (1 paraneoplastic polymyositis received chemotherapy, 2 IBM, 1 mild polymyositis in elderly, multimorbid patient).

In the first 6 months following diagnosis, 11 patients died (3 due to infection, 2 as a consequence of IIM, 1 due to haemorrhagic shock, 5 of unknown causes), and were lost to follow-up. The remaining 86 patients were followed for a median (IQR) 37.7 (20.2–62.6) months. At last follow-up 49 (57%) patients were still receiving GC, 8 (9.3%) in monotherapy. 9 (10.5%) cases were off GC and other maintenance treatment. Maintenance treatment at last follow-up is presented in Table 2. Treatment was changed in 13 (15.1%) patients (due to progression of pulmonary involvement in 3, active myositis in 4, pulmonary involvement progression and active myositis in 1 and due to intolerance to medication in 6 cases). In addition to therapy presented in Table 2, 2 (2.3%) patients received IVIG (1 concurrently with rituximab and myophenolic acid due to recalcitrant anti-synthetase syndrome and 1 due to IBM complicated with dysphagia).

Voulgaris, 9Dimitris Daoussis, 10Konstantinos Thomas, 11Georgios Georgioupolous, 12Georgios Voufectakis, 13Dimitris Vassilopoulos, 14Petros Stilkacias, 15Joint Rheumatology Program, National and Kapodistrian University of Athens Medical School, Athens, Greece, 16University of Ioannina, Medical School, Ioannina, Greece, 17University of Patras, Medical School, Patra, Greece, 18Aristotle University of Thessaloniki, Medical School, Thessaloniki, Greece, 19University of Thessaly, Medical School, Larissa, Greece, 20University of Crete, Medical School, Crete, Greece

**Background:** The pathophysiology of Systemic Sclerosis (SSc) encompasses autoimmunity, microvascular damage and fibrosis of the skin and internal organs. Accordingly, the two mainstays of treatment comprise antiproliferative and vasoactive regimens. So far there are limited data regarding the actual use of these agents in daily clinical practice.

**Objectives:** To describe current treatment modalities based on standard practice decisions according to published recommendations and/or guidelines for SSc, as well as to determine to which extent different disease modifying agents, namely antiproliferative and vasoactive drugs, are administered to these patients.

**Methods:** Consecutive patients from 7 academic rheumatology departments across Greece who fulfilled the 1980 American College of Rheumatology criteria for classification of SSc and were examined between January 2016 and December 2018 at least once, were included in the study. Patients’ medical records were analyzed and antiproliferative and vasoactive agents administered anytime during the disease course were recorded.

**Results:** A total of 457 patients (87% women, 51 diffuse SSc, 62% with pulmonary fibrosis, 55% with digital ulcers, mean ± SD age at diagnosis 49 ± 13.1 years, disease duration 10.4 ± 8 years) were studied. Methotrexate was the most frequent antiproliferative agent ever administered (53% of patients, 55% of them with diffuse SSc) followed by cyclophosphamide (26%, 78% of them diffuse), mycophenolate (11%, 63% of them diffuse), azathioprine (10%, 64% of them diffuse), rituximab (8%, 84% of them diffuse) and tocilizumab (3%, 68% of them diffuse). Among antiproliferative agents, endothelin receptor antagonists (ERA) were most frequently ever administered in 39% of patients (64% with diffuse SSc) followed by loprost in 7% (55% diffuse) and 5 phosphodiesterase (PDE) inhibitors in 5.5% of patients (62% diffuse). Among vasoactive agents used, the greatest retention rate at last follow-up visit since initiation had ERA (82%) and PDE inhibitors (86%). Of note, 20% of SSc patients (90% women, 70% limited SSc, age at diagnosis 50 ± 13.2 years, disease duration 8.4 ± 6.4 years) had never been treated with either antiproliferative or vasoactive agents, whereas 41% had ever received only antiproliferative and 8% only vasoactive therapy. Moreover, 1/5 of patients with pulmonary fibrosis had never received antiproliferative treatment, whereas 1/3 of patients with digital ulcers had never received vasoactive drugs (Table).

**Conclusion:** About 20% of contemporary SSc patients, including patients with pulmonary fibrosis and digital ulcers, have never received antiproliferative or vasoactive therapy, possibly reflecting the spectrum of benign disease and/or a subgroup of under-treated patients.

AB0679  **SKIN ULCERS IN SYSTEMIC SCLEROSIS: 10 YEARS’ FOLLOW-UP OF 211 PATIENTS FROM A MONOCENTRIC COHORT IN THE NORTH EAST OF ITALY**

Pamela Polli, Elisabetta Zanatta, Mara Felicetti, Maria Favaro, Mariagrazia Lorenzin, Roberta Ramonda, Franco Cozzi, Andrea Doria, Rheumatology Unit, Department of Medicine DIMED, University of Padova, Padova, Italy

**Background:** Microvascular involvement plays a pivotal role in the pathogenesis of systemic sclerosis (SSc). Among vasculopathic manifestations, skin ulcers (SU) stand out for their high prevalence.

**Objectives:** The aim of this study was to evaluate the prevalence and the subtype of SU, the association with clinical phenotype and pharmacological approach in the cohort of sclerodema patients attending our tertiary referral centre.

**Methods:** We retrospectively evaluated clinical records of patients affected with SSc according to ACR/EULAR 2013 criteria, attending the Rheumatology Unit of Padova University. Patients with SSc sine scleroderma, overlap syndrome and with a follow-up lower than 24 months were excluded. We evaluated the epidemiological and clinico-serological data, including autoantibody pattern, laboratory data (such as haemoglobin, ESR, CRP), organ involvement and pharmaceutical treatments. Prevalence of SU, type of occurrence (isolated, recurrent and persistent episodes) and site (digital and localized at the lower limbs, between knuckles and ankle/feet) were recorded. Statistical analysis was performed by SPSS v. 24.

**Results:** 211 patients were included in the study: 187 female and 24 male, aged 60.8 ±12.4 years, 147 (70%) with limited cutaneous and 64 (30%) with diffuse form. During the follow-up period of 120 months (50-216), 105 (50%) patients experienced at least one episode of SU: 74 experienced digital ulcers, 11 presented only SU at lower limbs and 20 both kinds of ulcers. Demographic, laboratory and clinical features of our cohort are shown in Table 1. At the multivariate analysis, diffuse cutaneous form, younger age at diagnosis, telangietasias and joint involvement were independently associated to SU. Among 105 patients who experienced at least one episode of SU, 69 (66%) had recurrent/ persistent ulcers. The latter group needed a combination of drugs, including: calcium-channel blockers (90%), low-dose aspirin (75%), protonadoids (85%) and/or endothelin receptor antagonists (58%); 27% requested opioids for analgesia. Concerning SU at lower limbs, 19/31 patients (61%) had macrovascular involvement and 14/31 (45%) persistent ulcers; 6/31 (19%) underwent autologous skin grafting.

**Conclusion:** In our cohort SU occur more frequently in SSc diffuse cutaneous form and are associated with visceral and articular involvement.
Digital ulcers tend to recur during the disease course requiring several drugs, while SU at lower limbs tend to be more persistent.

AB0680 NAIFOLD VIDEOCAPILLAROSCOPY PATTERN CORRELATES WITH ORGAN INVOLVEMENT AND DISEASE OUTCOME IN SYSTEMIC SCLEROSIS: A SINGLE-CENTER OBSERVATIONAL STUDY

REPA ARGYRO, George Bertisias, Nikolaos Koukas, Nestor Avgoustidis, Maria Terizaki, Paraskevi Kyfonidou, Prodromos Sidiropoplos. University Hospital of Heraklion. Department of Rheumatology, Clinical Immunology and Allergy, Heraklion, Greece

Background: Systemic sclerosis (SSc) is characterized by systemic autoimmunity, vasculopathy and fibrosis. Naifold Videocapillaroscopy (NVC) is a safe method to detect and to analyze morphological microvascular abnormalities in SSc patients. There is circumstantial evidence to suggest an association between NVC abnormalities and disease severity, particularly vascular manifestations. 1

Objectives: To evaluate the association of NVC patterns with demographic, clinical, laboratory features and disease progression in the SSc cohort of University Hospital of Heraklion.

Methods: Retrospective study (2011-2018) of SSc patients who underwent NVC at single center. NVC findings were classified into three distinct patterns namely early, active and late according to Cutolo et al. 2 NVC patterns were correlated with the clinical characteristics of the patients. We also correlated baseline NVC patterns with the progression of the disease at 3 years.

Results: 62 patients [88.6% women, mean age of diagnosis 49.6 years, range 18-82] were included. Compared to early/active pattern, patients with late pattern were more likely to have diffuse SSc (dSSc) (p=0.006), Interstitial Lung Disease (ILD) (80.0% vs 38.1% p=0.002) and esophageal involvement (80.0% vs 47.6% p=0.003). There was a trend for increased frequency of Pulmonary Arterial Hypertension (PAH), digital ulcers (DU) and calcinosis in patients with late pattern (p=0.079, p=1.103 and p=0.079 respectively). Patients with active NVC pattern were more likely to have arthritis (early/active/late: 36.4%/75.9%/55.0%, p=0.054). A total 42 patients had NVC data at the time of SSc diagnosis. At 3 years there were no significant differences regarding disease progression, although patients with late NVC pattern had more hospitalizations due to infections (33.3% vs 9.1%, p=0.191), higher death rate (16.7% vs. 8.3%, p=0.543), need to use cyclophosphamide (33.3% vs 17.4%, p=0.391) and/or bosentan (40.0% vs 22.7%, p=0.426).

Conclusion: In this single-center SSc cohort, NVC pattern was found to correlate with organ involvement especially ILD, esophageal involvement and dSSc. Serious infections and treatment intensification were also more frequent among patients with late NVC pattern. NVC may be a useful prognostic marker for SSc patients.

AB0681 SCLERODERMIC HAND: SUBCLINICAL JOINT INVOLVEMENT?

Laura Belloli, Cinzia Casu, Mariaeva Romano, Elisa Verdutci, Maria Di Cicco, Emanuela Schito, Valeria Campanella, Michel Chevallard, Marina Muscarà, Davide Antonio Filippini, Oscar Massimiliano Epis. Grande Ospedale Metropolitano Niguarda, Milan, Italy

Background: Systemic sclerosis (SSc) is a chronic autoimmune connective tissue disorder of not fully understood aetiology characterized by vascular and fibrotic abnormalities in the skin and internal organs. Musculoskeletal involvement, mainly affecting hands and feet, is frequent in SSc and represents a major cause of disability. Ultrasonography is a non-invasive, cost-effective imaging modality which is able to detect the presence of joint involvement in SSc.

Methods: 61 consecutive patients (60 women) were enrolled. Each patient has completed a dichotomous survey to evaluate the presence of joint symptoms (presence of pain, swelling, morning stiffness in the last 3 months). Subsequently a rheumatologist - blinded to clinical data and survey results - performed the ultrasound examination of hands and wrists to evaluate the presence of effusion, synovial hypertrophy, power-Doppler signal, erosions and tenosynovitis defined according to the OMERACT definitions. The ultrasound examination was performed using the Esaote MyLab70 with a multifrequency linear probe (6-18 MHz).

Results: Of the 61 patients analyzed, 29 showned joint involvement on the ultrasound examination (47.5%), in particular, 37.93% had tendon involvement and 72.41% joint involvement (Table 1). 31 patients did not report joint symptoms (50.82%) but 13 (41.93%) still had ultrasound alterations (Table 2).

Table 1. Musculoskeletal involvement in SSc

| Joint effusion | 14/29 (48.28%) |
| Synovial hypertrophy | 18/29 (62.07%) |
| Erosions | 2/29 (0.69%) |
| Tenosynovitis | 11/29 (37.93%) |
| Power-Doppler signal | 9/29 (31.03%) |

Table 2. Musculoskeletal involvement in asymptomatic patients

| Joint effusion | 3/13 (23.08%) |
| Synovial hypertrophy | 8/13 (61.54%) |
| Erosions | 0/13 (0%) |
| Tenosynovitis | 5/13 (38.46%) |
| Power-Doppler signal | 3/13 (23.08%) |

Conclusion: Musculoskeletal involvement is frequent in SSc and can be asymptomatic in more than 20% of patients. The ultrasound examination can make it possible to detect articular and periarticular involvement at an early stage of the disease before the onset of disability.

CIRCULATING FIBROCYTES IN LIMITED CUTANEOUS SYSTEMIC SCLEROSIS PATIENTS: CORRELATION WITH DERMAL THICKNESS

Barbara Ruaçu, Stefano Soldano,1,2 Vanessa Smith,1 Sabrina Paolino1, Carmen Pizzoni2, Paola Contini3, Paola Montagna1, Samuele Tardito1, Maurizio Cutolo4, Research Laboratory and Academic Division of Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; 3Department of Internal Medicine, Ghent University, Ghent, Belgium; 4Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Italy; 5Division of Clinical Immunology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy

Background: Systemic sclerosis (SSc) is characterized by early skin impairment (1,2) and the modified Rodnan skin score (mRSS) is the validated method to assess the severity of this impairment. Whilst skin high frequency ultrasound (US) is a relatively new technique to measure dermal thickness (DT) (2-4).

Recent findings have reported the important contribution circulating fibrocytes make in the early stage of dermal repair and fibrosis. Indeed, as fibrocytes may be an important source of activated fibroblasts/myofibroblasts, it is reasonable to presume that they could be responsible for the increase in these cells observed in the tissue of SSc patients (5-7).

Objectives: The aim of this study was to identify any correlation between the modified Rodnan skin score (mRSS) and dermal thickness (DT) measured by skin high frequency ultrasound (US) and the percentage of circulating fibrocytes in patients with limited cutaneous systemic sclerosis (lcSSc).

Methods: After obtaining approval and written informed consent and the Ethics Committee approval 8 lcSSc patients (7 females, 1 male) and 5 (4 females, 1 male) age-matched healthy volunteers (CNT) were enrolled. The lcSSc patients fulfilled the 2013 ACR/EULAR criteria for SSc (8). DT was evaluated by both mRSS and US (18 and 22 MHz probes), in all SSc patients and CNT, in the standard 17 skin areas evaluated by mRSS. The percentage of circulating fibrocytes was obtained by isolating them from the peripheral blood mononuclear cells (PBMCs) in all lcSSc patients and CNTs. Non-parametric tests were used for the statistical analysis.

Results: The percentage of circulating fibrocytes was positively correlated with DT-US, evaluated by the 22 MHz and the 18 MHz probes (p=0.04 and p=0.03, respectively) and mRSS (p=0.04) in lcSSc patients. Conversely, there was no correlation between these parameters in the CNT group (p=0.05).

Conclusion: The study demonstrates a significant relationship between DT, evaluated by both mRSS and US and the percentage of circulating fibrocytes in lcSSc patients. This observation may well support the hypothesis that circulating fibrocytes make a crucial contribution to skin fibrosis progression.

ROLE OF ELASTIN AND ELASTASE ANTIBODIES IN DEVELOPMENT OF PNEUMOSCLEROSIS IN PATIENTS WITH SYSTEMIC SCLERODERMA

Background: Disturbed elastin metabolism, emerging pathological soluble isoforms followed by triggering of autoimmunity show that the biopolymer under study is associated with the pathogenesis of polyorganic lesions in systemic sclerosis. Elastin catabolism is promoted by elastase, an enzyme with a broad-range substrate specificity. It is the balance of a dynamic elastin–elastase system that determines physiological functioning of organs and tissues containing elastic fibres: the skin, ligaments, lungs, and vascular walls. Antibodies to elastin and elastase are unique predictors of development of pulmonary conditions in systemic scleroderma, which is now considered to be one of risk factors for pulmonary lesion.

Objectives: Developing highly sensitive markers of pulmonary remodeling at early stages of systemic scleroderma with participation of humoral immunity to the elastin–elastase system in the development of pulmonary lesion in systemic scleroderma requires further detailed study.

Methods: Patients for the study were selected from the department of rheumatology at the Emergency Care Municipal Hospital 25 in the city of Volgograd. The main group incorporated 42 persons with the diagnosis of systemic scleroderma verified by ACR/EULAR diagnostic criteria of 2013, without any exclusion criteria. There were 11 men and 31 women aged 23-70 among the systemic scleroderma patients. The mean age of patients was 44±15.4. The control group incorporated 30 healthy donors at the Volgograd Regional Blood Transfusion Station. Antibodies to elastin and elastase were determined in the blood serum by indirect enzyme immunoassay utilizing insoluble forms with enhanced antigen content according to the original technique by Connors et al (1990).

Results: Compared with the control group, patients with systemic scleroderma showed a considerably higher rate of antibodies to elastase (52%) and elastin (38%). The upper normal level of antibodies to elastin was in the range of 0.131 absorbance units, of antibodies to elastase – 0.131 absorbance units. The mean value of elastin antibodies in the blood of systemic scleroderma patients was 0.125 ± 0.068 absorbance units. The value of elastase antibodies was 0.143 ± 0.071 absorbance units. The elevated level of elastin and elastase antibodies in the patients was associated with pulmonary lesion (basal pulmonary fibrosis – 20 (47.6%), pulmonary hypertension – 11 (26.2%), and adhesive pleurisy – 7 (16.7%). In one half of cases the pulmonary lesion was asymptomatic, diagnosed by accessory investigations like X-ray of chest organs, respiratory function study, EchoCG which were administered to assess the extent of abdominal organ inflammation and in differential diagnosis with cardiac insufficiency. The level of elastin antibodies in systemic scleroderma patients with pulmonary lesion was 0.149 ± 0.074 absorbance units, and of elastase antibodies – 0.146 ± 0.043 absorbance units, which was considerably higher than mean values in the control group.

Conclusion: By determining antibodies to elastin and elastase by the proposed technique of enzyme immunoassay at early stages of systemic scleroderma one can predict lesions of pulmonary parenchyma presenting with various clinical signs, and exacerbation of fibrosis processes.

DO WE DIAGNOSE ALL THE ANTISYNTHETASE SYNDROME?

Meribel Salés Lizarraburu, Sonia Minguez, Saul Malo Gelman, Roser Tureu, Mercè López de Recalde, Basilio Rodríguez, Jaume Trápè, Damíà Perich, Anna Muñoz, Sandra Ros, Oscar Bernadich, Josep González.

1Althaia Xanxa Asistencial Universitaria de Manresa, Rheumatology, Manresa, Spain; 2Althaia Xanxa Asistencial Universitat de Manresa, Clinical Laboratory, Manresa, Spain; 3Althaia Xanxa Asistencial Universitaria de Manresa, Pneumology, Manresa, Spain; 4Althaia Xanxa Asistencial Universitaria de Manresa, Internal Medicine, Manresa, Spain

Background: Antisynthetase syndrome (AS) is an autoimmune disease characterized by the presence of antimyosin/IRNA-synthetase antibodies (anti-ARS) and clinical manifestations that may include interstitial lung disease (ILD), myositis, non erosive arthritis, Raynaud’s phenomenon (RP), fever and mechanic’s hands. Until the Connors diagnostic criteria appeared in 2010, these patients with anti-ARS antibody were classified as a mixed connective tissue disease (MCTD), myositis, or as a separate scleroderma like condition and not associated with a specific syndrome.

Objectives: To identify patients with anti-ARS antibodies from our hospital since June 2015, when the immunity laboratory was inaugurated, and to verify if they fulfilled the AS criteria.

Methods: Retrospective observational study carried out in a regional hospital in Barcelona with a reference population of 260,000 inhabitants. All patients with any anti-ARS antibody (Jo1, PL7, PL12, EJ) positive were selected, determined by the Dot Blot Polymiositis/Scleroderma IgG D-Teck. We applied Connors diagnostic criteria and collected demographic, clinical and instrumental data, and types of antibodies.

Results: We identified 18 patients with anti-ARS antibody, 9 anti-Jo1 (53%), 4 anti-PL7, 3 anti PL12 and 1 anti-EJ. Of these, 13 had values of Jo1 > 1/80, 3 values of 1/80 and 1 negative. Other antibodies identified were anti-Ro52 in 4, anti-DNA in 4 and anti-Scl70 in 1. All patients except one met AS criteria. None of anti-DNA positive subjects met criteria for erythematous systemic lupus or systemic sclerosis. The majority

1802

AB0868
were women (88%) with a mean age at diagnosis of 62 years (27-83 years), 16 Caucasians and 1 Asian. The clinical manifestations reported were: 5 myositis (29%), 11 ILD (6 BOOP and 5 NSIP) (65%), 6 arthritis (2 polyarthritis, 2 oligoarthritis, 1 palindromic, 1 shoulder girdle syndrome) (35%), 3 Raynaud’s phenomenon (17.5%), 2 mechanic’s hands (11%) and 6 fever (35%). Only one patient had the classic triad (myositis, arthritis, ILD, Jo1), 2 had myositis with ILD (Jo1), 1 myositis with arthritis (PL12), 1 ILD with arthritis (PL7), 7 ILD (Jo1, PL7, PL12), 3 arthritis (Jo1), 1 RP (Jo1) and 1 fever (Ej). Ten had a nailfold capillaroscopy performed, 7 of them had any alteration: 1 active systemic sclerosis pattern and 6 nonspecific (6 ramified capillaries and 3 microhemorrhages).

Conclusion: Our immunologically defined cohort has fewer clinical manifestations than described in clinically defined cohorts (AENAS group and EuroMysitis). Only 20% of patients had myositis and 70% had a single non-mysitis clinical manifestation associated with anti-ARS antibody.

Actually, it involved de-novo diagnosis of AS in half of them.

In patients with suspected AS with low or negative ANA, antibody blot determination is definitive.

Nailfold capillaroscopy in undefined cases is a fundamental tool for diagnosing AS.

EFFECTIVENESS OF SPECIALIZED AND INTENSIVE ADL TRAINING IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES – PRELIMINARY RESULTS OF A ONE-YEAR CONTROLLED STUDY

Maja Špitrová1, Sabina Oreska2, Hana Štorkánová2, Barbora Heřmanková1, Petr Česká1, Adéla Rathoušská1, Kateřina Kubinová1, Martin Kleiri1,2, Lucia Vernerová1, Olga Růžičková2, Helmut Mann3, Karel Pavelka2, Ladislav Senčíl2, Jiří Vencovsky2, Maja Špitrová1, Sabina Oreska2, Hana Štorkánová2, Barbora Heřmanková1, Petr Česká1, Adéla Rathoušská1, Kateřina Kubinová1, Martin Kleiri1,2, Lucia Vernerová1, Olga Růžičková2, Helmut Mann3, Karel Pavelka2, Ladislav Senčíl2, Jiří Vencovsky2.

Background: Idiopathic inflammatory myopathies are characterized by muscle weakness, caused by inflammation and immune changes in the affected muscles, which lead to a limitation in the execution of day-to-day activities (ADL). The aim of our study was to investigate the impact of specialized and intensive ADL training on muscle strength and endurance, depression and QoL of IIM patients.

Methods: Patients were assessed by a physician and a physiotherapist blinded to intervention at months 0, 3, 6, and 12. Patients also filled out patient reported outcomes questionnaires and provided blood for routine laboratory analysis and bio-banking. Data analysis was performed between groups and within the group.

Results: Compared to the observed statistically significant deterioration in the CG over the intervention period, we found a statistically significant improvement in the IG in objectively assessed strength and endurance of muscles as well as in subjectively assessed functional abilities and depression (Table). During the follow-up period, there was a significant deterioration or stagnation of the achieved positive results in the IG. Nevertheless, improved functional ability during the intervention period persisted in the IG in the follow-up period as well. Only numerical improvements in the IG during the intervention compared to the numerical deterioration in CG, that did not reach statistical significance, were observed in some subjectively assessed domains of QoL (SF-36) and fatigue (FIS – in physical dimension).

EVALUATION OF CARDIOVASCULAR DETERMINANTS OF DISEASE OUTCOME IN SYSTEMIC SCLEROSIS

Mariann Kalázi1, Renáta Laczik2, Pál Soltész2, Katalin Hodosi1, Szilvia Szamosi1, Zoltán Szekearczy1, Gabriella Szűcs1, 1University of Debrecen, Faculty of Medicine, Department of Rheumatology, Debrecen, Hungary; University of Debrecen, Faculty of Medicine, Department of Angiology, Debrecen, Hungary.

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease characterized by microvascular abnormalities. Cardiopulmonary and vascular manifestations in SSc are the most important survival factors in the disease.

Methods: We enrolled 312 consecutive patients (286 females and 24/8% males, mean age 62.3 years, average disease duration 108 months) referred at our department from 2000 to 2018, with a diagnosis of SSc confirmed according to the 2013 ACR/EULAR criteria (3). All patients underwent clinical, instrumental and laboratory evaluation. In 93 patients, negative for anti-topoisomerase I antibodies (aSc70) and anti-centromere antibodies (ACA), the presence of aRNAP3 antibodies was evaluated by an ELISA method (QUANTA LiteTM RNA Pol III).

Results: we found a limited form of disease in 229 patients (73.4%) and a diffuse form in 83 (26.6%). Eighty eight (28.2%) patients were positive for aSc70, 112 (35.9%) for ACA and 17 (5.4%) for aRNAP3. In the whole group, 44 (14%) patients had a positive familiar history for neoplasms while 105 (33.6%) had a history of neoplasms and/or precancerous conditions. Among these 105 cases, 44 (41.9%) were malignant, 50 (47.6%) benign and 11 (10.5%) had precancerous conditions. The most frequent neoplasms were breast carcinomas (14 cases/14.9%), thyroid (7 cases/7.4%), lung and kidney (3 cases/3.1%), melanomas (5 cases/5.3%). The most frequent precancerous condition was Barrett’s esophagus (7 cases/63.3%). Regarding the antibody profile, 5 (4.8%) patients were positive for anti-RNAP3 and only 2 (1.9%) of these patients presented a malignant neoplasm, breast cancer in both cases. In 30 cases (28.6%) these neoplastic/precancerous conditions had arisen in the close period (±36 months) at the SSc diagnosis and only 3 of them were anti-RNAP3 positive. Among the evaluated risk factors, only familiarity was significantly associated with the development of neoplasia (p = 0.003), confirmed at the multivariate analysis (OR 2.9, IC95% [1.5-5.7], p=0.002).

Conclusion: Our study evaluated not only malignant neoplasms, but also benign neoplasms and precancerous conditions and identified familiarity as the only significant risk factor. In our cohort we did not find any relationship between the presence of anti-RNAP3 antibodies and the development of neoplasms, not even stratifying for the type of neoplasm.

Objective: Correlations between different cardiovascular parameters (ejection fraction (EF), diastolic dysfunction, wall motion disturbance, estimated systolic pulmonary arterial pressure (sPAP), flow-mediated vasodilatation, arterial stiffness parameters (augmentation index - Aix, pulse wave velocity - PWV) and diastolic fraction and death were measured.

Methods: Thirty-six SSc patients were involved who underwent detailed arterial stiffness and vasodilatation examinations in 2007. In our work a 10-year period was analysed till 2017 following the progression of organ manifestations and survival.

Results: During the 10-year follow-up, 13 of the 36 patients died. The average survival time was 26.59 (22.36-37.64) years. Significant correlation was found between the initial Aix and PWV with cardiac wall motion disturbance (p = 0.018 and p = 0.016), Aix with restrictive ventilation dysfunction (p = 0.029) and PWV with obstructive ventilation dysfunction (p = 0.015). During the 10-year period, the occurrence of diastolic dysfunction was significantly increased (p = 0.0016), the incidence of arrhythmia did not change significantly. A significant risk factor for survival has been the decrease in EF (p = 0.011), where 1% reduction in EF was associated with 1.9% increase in mortality and 1 mmHg increase in sPAP involved 13% increase in mortality.

Conclusion: Based on our findings vascular stiffness parameters can be good predictors not only of the survival but also of the pulmonary complications with restrictive ventilation disturbances also in SSc.

Disclosure of Interests: Mariann Kalázi: None declared, Renáta Laczik: None declared, Pál Soltész: None declared, Katalin Hodosi: None declared, Szilvia Szamosi: Speakers bureau: Roche, Zoltán Szekearczy Grant/research support from: Pfizer, UCB, Consultant for: Pfizer, Abbvie, Roche, Sanofi, Lilly, Novartis, Speakers bureau: Pfizer, Abbvie, Roche, Sanofi, Lilly, Novartis, Gabriella Szűcs Speakers bureau: Actelion, Roche, Sager DOI: 10.1136/annrheumdis-2019-eular.2454
progression and skin involvement, we started MP with prednisone (mean dose 8mg, a day), observing no significant changes after treating for 8 months on skin or lung disease, only improving the hands edema.

Case 8: woman diagnosed at 47 years old with diffuse SSC, having telangiectases, sclerodactyly, positive ATA and NSIP. At 100 months from diagnosis, after 6 cyclophosphamide cycles followed by azathioprine (both ineffective) due to lung function (FVC 76%, FEV 83%, DCO 26%) and skin (mRSS 30) worsening, MP and prednisone (mean dose 15mg, a day) were started. Currently, we are still waiting to assess clinical response.

Conclusion: Despite it is not included in EULAR current recommendations for SSC complications, our patients have remarkably improved with MP, especially skin involvement, with a good safety profile. These data reaffirm those obtained in previous studies and encourages us to continue considering its use.

AB0692 ASSESSING RECOVERY TIME AFTER COLD CHALLENGE AND THUMB INVOLVEMENT CAN HELP RULE OUT SYSTEMIC SCLEROSIS IN PATIENTS PRESENTING WITH RAYNAUD'S PHENOMENON

1Anniek van Roon1, Arie Van Roon1, Alja J. Steen2, Hendrika Bootsm2, Andries Smit1, Douwe J. Mulder1, 1University of Groningen, University Medical Center Groningen, Internal Medicine, division Vascular Medicine, Groningen, Netherlands; 2University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands.

Background: Distinguishing primary Raynaud's phenomenon (PRP) from Raynaud's phenomenon secondary to systemic sclerosis (SSc) is crucial in the early detection of SSc. Recently we reported that patients with more severe vasculopathy suffer from a prolonged ischemia time during Raynaud's attack. [1] Additionally, it appears that the thumb is more frequently involved in SSc, where it seems to be spared in PRP. [2] These two characteristics are easily recognized by patients and physicians, and can help rising awareness for SSc.

Objectives: The aim was to study if the recovery of a Raynaud's attack and involvement of the thumb are differentiators for SSc in patients with Raynaud's phenomenon (RP).

Methods: A stepwise cooling and recovery procedure was performed, provoking an RP attack, in patients with PRP and SSc. One hand was submerged up till the radiocarpal joint in water. The water temperature was lowered in steps of 3 degrees Celsius every four minutes, from 33 until at least 9 degrees Celsius. Afterwards ten minutes of recovery in room air of 23 degrees Celsius was observed. During the procedure perfusion of the fingertips was assessed by photo-electric plethysmography.

Results: In total 18 patients with SSc and 88 patients with PRP underwent the procedure. Seventeen (94%) SSc patients had no restoration of perfusion after ten minutes in one or more fingers, compared to 28 (41%) PRP patients (figure 1), with a negative predictive value of 98%. During cooling, 17 (94%) SSc patients developed abnormal perfusion in the thumb compared to 48 (71%) PRP patients (p=0.036), with a negative predictive value of 95%. There was no difference in involvement of the other fingers during cooling (all p>0.05). Positive predictive values were low.

Conclusion: In patients with RP, when there is restoration of perfusion in all fingers after ten minutes or when the thumb is spared, the presence of an underlying SSc is very unlikely. Although this objective measurement needs to be verified with patient's reports, these results suggest that these simple signs can help physicians to assess if the patient needs to be referred for additional tests.

AB0691 INCREASED CARDIOVASCULAR RISK IN MIXED CONNECTIVE TISSUE DISEASE: EVALUATION OF MACROVASCULAR INVOLVEMENT AND ITS PREDICTORS BY AORTIC PULSE WAVE VELOCITY

Konstantinos Triantafyllias1, Michele De Blasi1, Freya Lütgendorf1, Lorenzo Cavagna1, Marco Stortz2, Julia Weinmann-Merke1, Stavros Konstantinides2, Peter Galle3, Andreas Schwarting2. 1ACURA Rheumatology Center, Bad Kreuznach, Germany; 2University and IRCCS Policlinico S. Matteo Foundation, Rheumatology, Pavia, Italy; 3Internal Medicine I, Division of Rheumatology and Clinical Immunology, University Medical Center of the Johannes Gutenberg University Mainz, Germany, Mainz, Germany; 4Center for Thrombosis and Hemostasis, University Medical Center of the Johannes Gutenberg University Mainz, Germany, Mainz, Germany; 5Internal Medicine I, Division of Gastroenterology; University Medical Center of the Johannes Gutenberg University Mainz, Germany, Mainz, Germany.

Background: Macrovascular involvement and cardiovascular (CV) risk have not been sufficiently studied in patients with mixed connective tissue disease (MCTD). In particular, the gold standard assessment method of aortic stiffness carotid-femoral pulse wave velocity (cfPWV) (1) has never been evaluated in patients with this disease.

Objectives: Aims of the present study were to examine cfPWV in MCTD and to evaluate its associations with MCTD associated parameters and traditional CV risk factors.

Methods: cfPWV measurements were performed in 43 MCTD patients and 107 healthy controls. The difference between cfPWV in the two groups was statistically examined and subsequently controlled for the effect of possible confounding factors. Association of cfPWV with MCTD associated organ involvement, routine laboratory parameters and immunoserological markers was also evaluated. Finally, relationship of cfPWV with medications and traditional CV risk factor was examined.

Results: Adjusted statistical analyses for confounding factors showed significantly higher cfPWV values in MCTD patients in comparison to controls (p<0.001). cfPWV correlated in both the patients and the control group significantly with age (r=0.67, p<0.001 and rho=0.69, p<0.001 respectively), diastolic arterial pressure (p=0.024 and p=0.032 respectively) and mean arterial pressure (r=0.44, p=0.004 and rho=0.49, p=0.001 respectively). Moreover, cfPWV correlated in the control group with systolic arterial pressure (p=0.001) (Fig. 1). Higher cfPWV values could be documented in the subset of MCTD patients without lung involvement (p=0.049).

Conclusion: To our knowledge, this is the first study to show that patients with MCTD have significantly higher aortic stiffness and thus CV risk in comparison to controls. Except the disease itself, age and blood pressure were the main predictors of cfPWV.

Abstract AB0692 Figure 1. Percentage of patients with and without restoration of perfusion in all fingers during 10 minutes of recovery, measured in one hand by photoplethysmography.

AB0693 DUROMETRY: HARD FACTS IN SYSTEMIC SCLEROSIS – A SYSTEMATIC LITERATURE REVIEW

1,2 Amber Vanhaecke, 3 Maurizio Cutolo, 2 Sven Verschueren, 2 Sabrina Paolino, 2 Carmen Pizzorni, 1,2 Vanessa Smith. 1 Ghent University, Department of Internal Medicine, Ghent, Belgium; 2 Ghent University Hospital, Department of Rheumatology, Ghent, Belgium; 3IRCCS San Martino Polyclinic Hospital, University Of Genoa, Research Laboratory And Academic Division Of Clinical Rheumatology, Department Of Internal Medicine, Genoa, Italy; 4VIB Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium

Background: Fibrosis represents one of the main characteristics of systemic sclerosis (SSc), with skin and internal organ involvement being its main clinical expressions. The modified Rodnan Skin Score (mRSS), using clinical palpation to estimate skin thickness, is considered the current ‘gold standard’ to measure skin involvement in a semi-quantitative way. The mRSS has been judged as fully valid through the Outcome Measures in Rheumatology Clinical Trials (OMERACT) Filter, however a high risk of observer bias exists. Therefore, a new challenge for the SSc community is to define a reliable tool, able to more precisely investigate skin involvement in SSc patients, which would be of great value in clinical trials. Durometry, able to objectively investigate skin hardness, might address this need. Objectives: To appreciate the validation status of durometry in SSc patients, guided by a systematic literature review. Methods: Relevant full-text articles using durometry in SSc patients were identified through a systematic literature search in PubMed, EMBASE and Web of Science, according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Besides this systematic search, an additional hand search was performed through reference list screening. All retrieved records were screened by two raters based on title, abstract and full-text level to finally include manuscripts eligible for quality appraisal and data extraction. The finally included manuscripts were analysed according to the OMERACT Filter 2.0. Results: The systematic search yielded 94 records, of which 50 were unique. Seven records were retained for full-text review and analysis, comprising one randomised clinical trial (RCT). The pillar feasibility was well documented in 3 studies [1-3]. Of note, the credibility (i.e. having face validity) of durometry was considered to be valid, as was stated by Kissin et al. [1]. Concerning the pillar truth: content validity was confirmed as durometry correlated well with histological findings (i.e. myofibroblast score and hyalinized collagen, r=0.69 and 0.78 respectively) [4], construct validity was confirmed as a moderate to high significant correlation with the total mRSS was documented in 5 studies (correlation coefficients ranging 0.59-0.81) [1, 3-6]. Concerning the pillar discrimination, the sensitivity to change in the context of one RCT was confirmed [2], inter-rater reliability was confirmed as intraclass correlation coefficients (ICC) ranged from 0.61-0.91 in 2 studies, of which one RCT [1, 3], intra-rater reliability has not been confirmed as this was shown as only investigated in a cohort 5 SSc patients (ICC 0.86-0.94) and thus solid evidence was lacking [1]. The sensitivity to change in situations of change (i.e. change over time, discrimination between SSc patients or between SSc patients and controls) was not confirmed, since solid evidence was lacking in literature.

Conclusion: Current systematically identified evidence suggests partial validation of durometry in SSc patients according to the OMERACT Filter 2.0. Further dedicated studies are needed to completely validate this tool in SSc, more specifically concerning the pillar ‘discrimination’.

Disclosure of Interests: None declared

Methods: Relevant full-text articles using durometry in SSc patients were identified through a systematic literature search in 3 electronic databases and a hand search of reference lists, according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. All retrieved articles were screened on title, abstract and full-text level. Additionally, a pilot study was conducted in a cohort of non-selected consecutive SSc patients to assess the intra-rater reliability of durometry, by having an anchor rater performing 3 cycles of durometry measurements at 17 skin sites approximating those of the mRSS. Reliability was described by calculating the intraclass correlation coefficient (ICC).

Results: A total of 94 records were identified through the systematic search of which a total of 40 unique titles were screened. After a thorough screening of all titles and abstracts, 7 manuscripts were eligible for full-text review. Finally, of these, only 2 manuscripts fulfilled the predetermined inclusion criteria to be included, as they documented the reliability of durometry as an outcome. Hence, both manuscripts were included in the final analysis for quality appraisal and data extraction. Regarding intra-rater reliability, Kissin et al. reported ICC values ranging from 0.86-0.94 in a small cohort study including 5 diffuse SSc patients (DcSSc) [1]. Regarding inter-rater reliability, ICC values ranged from 0.82–0.96 according to a multicentre randomised clinical trial (n=43 DcSSc) by Merkel et al., and 0.61-0.85 according to Kissin et al. [1,2]. Finally, only 5 fulfilled the predetermined eligibility criteria to be included for quality appraisal and data extraction.

Subsequently to this systematic review, an additional pilot study investigating the intra-rater reliability was performed. Seventy-four SSc patients (61 women; 13 LSSc, 53 LoSSc and 8 DcSSc) underwent durometry assessment in this pilot study. The ICC values for intra-rater reliability ranged between 0.93-0.99.

Conclusion: The systematic literature review revealed that reliability, in particular intra-rater reliability, of durometry in SSc is nearly unexplored territory. The findings of our very pilot study, demonstrating as first an excellent intra-rater reliability of durometry measurements in a large unselected cohort of SSc patients, could confirm the explorative findings previously reported in a small cohort study. Hence, our results stepped forward to the need for intra-rater validation of durometry.
DETECTION OF COEXISTING MYOSITIS-SPECIFIC AUTOANTIBODIES WITH LINE AND DOT IMMUNOASSAYS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

1,2 Jean-Baptiste Vulteke*, Xavier Bossuyt2,4, Kristl G. Claeyss5,6, Doreen Dillaerts, Nele Vanhorebeek1, Koen Poensen1,8, Jan Lenaerts1, Rene Westhovens1,7, Philip Van Damme7,8,10, Daniel Blockmans11, Petra De Haes11, Ellen De Langhe1,2.

Background: Myositis-specific autoantibodies (MSAs) can be identified in up to 60% of patients with idiopathic inflammatory myopathies (IIM) (1). Based on previous immunoprecipitation studies, MSAs are considered to be mutually exclusive (1), but detection of coexisting MSAs with line or dot immunoassays (LIA/DIA) has not been described (2-3).

Objectives: To determine the prevalence of detection of coexisting MSAs with different LIA/DIAs in patients with IIM, assess the concordance between different assays and describe the clinical phenotype of patients with coexisting MSAs.

Methods: Cross-sectional assessment of prevalence of coexisting MSAs as detected by two LIAs (Euroline Autoimmune Inflammatory Myopathies, Euroimmun, Lübeek, Germany) and ImmunoStrip Myositis Advanced LIA, Trinity Biotech, Buffalo, USA) and one DIA (12 IgG Dot, Alphadia, Mons, Belgium), concordance between these assays and clinical phenotype of patients with coexisting MSAs in a single-center cohort of patients with a diagnosis of one of the subtypes of IIM as diagnosed by the treating physician.

Results: Nineteen of 145 patients (12%) had coexisting MSAs on at least one assay; 5 on the DIA (3.5%) and 5 (3.5%) and 11 (7.6%) on the LIA. Of the 12 IgG Dots, 8 were concordant between LIAs/DIAs; of the 5 (3.5%) and 11 (7.6%) on the LIA. The three combinations of these patients were anti-Jo-1 and anti-NXP-2, anti-Jo-1 and anti-TIF1-gamma, and anti-SAE and anti-NXP2 autoantibodies. The first two patients had an antisynthetase syndrome and the last patient an overlap myositis phenotype. Among the 20 patients with coexisting MSAs, 5 had an antisynthetase syndrome, 2 had an Sjögren syndrome, 4 had scleroderma and 1 had an overlap myositis syndrome. The remaining 11 patients were divided into 3 groups: 6 with one MSA, 4 with 2 MSAs, and 1 with 3 MSAs. The concordance between LIAs/DIAs of patients with coexisting MSAs was low to moderate.

Conclusion: Detection of coexisting MSAs with LIA or DIA occurs in a minority of patients with IIM with varying prevalence between assays from different manufacturers. The combination of more than 1 MSA is not concordant between LIAs/DIAs in the vast majority of patients, suggesting that in most patients detection of coexisting MSAs with LIAs/DIAs reflects a problem of specificity of the assays for the involved autoantibodies.

LOW DOSE CYCLOPHOSPHAMIDE AND PIRFENIDONE MIGHT WORK IN SYNERGY TO RELIEVE INTERSTITIAL LUNG DISEASE WITH CONNECTIVE TISSUE DISEASE: A PRELIMINARY OBSERVATIONAL STUDY

Qingran Yan, Lichong Shen, Xiaoxiang Chen. Renji Hospital, Shanghai; Shaoting University School of Meicine, Department of Rheumatology, Shanghai, China

Background: There are anti-inflammation and anti-fibrosis agents available for connective tissue disease associated interstitial lung disease (CTD-ILD). A clinical study has been initiated to assess the combination of two CTD-ILD agents together, but whether they can spare dose for each other is unknown.

Objectives: This preliminary study is aimed to observe outcomes of CTD-ILD patients receiving cyclophosphamide plus pirfenidone as a rescue therapy, with each agent at about one third of routine dosage.

Methods: We enrolled CTD-ILD patients who did not improve their symptoms (dyspnea or cough) after at least one-month steroids treatment (prednisone: 1mg/kg daily). Patients who had adjusted immunosuppressive agents other than steroids or had received anti-fibrotic medications within three months before enrollment were ruled out. We switched the treatment into pulse cyclophosphamide (0.4g/m2 monthly) combined with pirfenidone (300mg twice per day). Besides, we reduced the steroids to prednisone 0.5mg/kg daily and then tapered routinely. All the patients were followed up for 12 months.

Results: We enrolled seven patients, of whom two had anti-synthetase syndrome, two had Sjögren syndrome, two had scleroderma and one had mixed connective tissue disease. The media DLCO was 51% of prediction (range 47.7% to 63%) and media FVC was 72.3% of prediction (range 39% to 81%). The media 6MWD was 275m (range202 to 324m). At the end of 12-month follow-up, all the patients regained functional independence with a median 52.7% increase of 6-minute walk distance (range34.4% - 86.3%). Pulmonary function tests showed improved forced vital capacity (median improvement 13.4%, range 0-35.0%) and DLCO (median improvement 6.3%, range 1.7%-16%). The HRCT score had a median decrease of 20.1% (range 11.7% to 29.6%). For quality of life assessment, the SGRQ total score had a median improvement of 53.3% (range 19.5% to 61.7%). Of note, no adverse events were observed during the 12-month follow-up.

Conclusion: Our study provided preliminary but promising clinical evidence for a new strategy in treating CTD-ILD, that cyclophosphamide and pirfenidone might work in synergy and spare dose for each other. A well-designed controlled study is needed to further establish its safety and efficacy.

VALIDATION OF 2017 CLASSIFICATION CRITERIA FOR ADULT AND JUVENILE IDIOPATHIC INFAMMATORY MYOPATHIES PROPOSED BY EULAR/ACR IN CHINESE PATIENTS

Xiuhui Zhang, Xinlei Yang, Lanlan Ji, Zhiqli Zhang. Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China

Background: Idiopathic inflammatory myopathies (IIMs) are heterogeneous diseases characterized by muscle weakness and muscle inflammation. Although the Bohan and Peter criteria proposed in 1975 are most widely used[2], there are some limitations. Firstly, they did not clearly specify how to exclude other forms of myopathy disease. Secondly, each criterion is not well defined either. EULAR and ACR jointly proposed the classification criteria for adult and juvenile IIMs and their major subgroups in 2017. The data-driven criteria exhibited high sensitivity and specificity. But most of the patients (62.6%) in the data were Caucasians, the performance of the criteria in Asian patients is unknown, which was one of the important limitations[3].

Objectives: To evaluate the ability of 2017 EULAR/ACR Classification Criteria for Adult and Juvenile Idiopathic Inflammatory Myopathies (IIM) to
classify IIM in comparison with 1975 Bohan and Peter criteria in Chinese patients.

Methods: Two hundred and twenty-one in-patients with suspected IIM (including 40 children) were retrospectively included in this study. The performance of 2017 EULAR/ACR criteria was evaluated by sensitivity, specificity, positive predictive value, negative predictive value and classification rate, in comparison to the 1975 criteria, with clinical diagnosis as the gold standard.

Results: The sensitivity, specificity, positive predictive value, negative predictive value of the 2017 EULAR/ACR criteria in IIM classification were 92.7%, 80.0%, 90.1% and 90.4%, respectively, in contrast to the 1975 Bohan and Peter criteria of 84.0%, 52.2%, 61.8%, and 77.9% (Fig 1). The classification rate of 2017 criteria was also much better than that of 1975 criteria (90.2% vs. 67.4%). The performance of the new criteria in general, as well as the new criteria with muscle biopsy was better. Most IIM patients were correctly further subclassified by the classification tree. The positive rate of myogenic lesion in electromyography (EMG), muscular inflammatory edema in magnetic resonance Imaging (MRI) and specific antibodies of myositis were significantly higher in IIM group than those in control group (p<0.001, all).

Conclusion: The 2017 EULAR/ACR criteria exhibited high sensitivity, specificity, classification rate in the Chinese IIM patients, which was superior to the 1975 criteria. The new criteria showed potentials as clinical classification criteria in the future.

Figure 1. Performance of 2017 EULAR/ACR criteria and 1975 Bohan and Peter criteria.

CARDIOVASCULAR RISK FACTORS ARE HIGHER IN MALNOURISHED PATIENTS WITH SYSTEMIC SCLEROSIS

Anna Wojtczak1, Marcin Zietkiewicz2, Zbigniew Zdrojewski3, Sylwia Mańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland

1Medical University of Gdańsk, Department of Clinical Nutrition, Gdańsk, Poland

Background: Cardiovascular disease (CVD) is a well known complication in rheumatoid arthritis and systemic lupus erythematosus. Atherosclerosis (ATS) and its impact on CVD in patients with systemic sclerosis (SSc) still remains unclear. Most of studies are suggesting higher frequency of CVD in SSc in comparison to healthy controls. CVD is a leading cause of death in most developed countries, whereas in SSc population it ranges from 20 to 30%. The etiology of ATS in SSc is unknown. Traditional risk factors, endothelial dysfunction and inflammation can contribute to ATS in SSc population. However, there is lack of data about the impact of the nutritional status on CVD factors in SSc patients.

Objectives: The aim of the study was to determine CVD factors among SSc patients depending on the nutritional status.

Methods: In 55 patients with SSc (72.7% well-nourished, 18.1% malnourished, 9.1% pre-cachexia) and 49 healthy controls we measured markers of endothelial dysfunction (asymmetric dimethylarginine - ADMA), inflammation (C-reactive protein - CRP, high sensitivity C-reactive protein - hs-CRP, interleukin 6 - IL-6) and dyslipoproteinemia (oxidized low-density lipoprotein - ox-LDL, high-density lipoprotein- HDL, low-density lipoprotein – LDL and total cholesterol). Nutritional status was determined with subjective global assessment (SGA), body mass index (BMI), bioelectrical impedance analysis (BIA) and anthropometric measurements.

Results: Well-nourished SSc patients had significantly higher level of IL-6 (6.4±10.1 vs. 2.8±3.6 pg/ml; p=0.002) and lower HDL cholesterol (49.9 ±11.6 vs. 57±13.6 mg/dl; p=0.011) in comparison to healthy control. In malnourished SSc patients there was higher concentration of ADMA (1.68 ±0.53 vs. 1.24±0.34 µmol/l; p=0.003), CRP (18±28.6 vs. 2.4±2.5 mg/l; p=0.04), IL-6 (21.6±34.9 vs. 2.8±3.6 pg/ml; p=0.004) and lower HDL cholesterol (42.5±18.3 vs. 57±13.6 mg/dl; p=0.01) in comparison to healthy control. Pre-cachexia SSc group had significantly lower total cholesterol (166.8±28.5 vs. 219.3±40.9 mg/dl; p=0.008) and LDL cholesterol (96.8±21.6 vs. 139.8±31.6 mg/dl; p=0.007). There were no differences in concentration of oxLDL and hsCRP in those groups.

Conclusion: Nutritional status may play role in risk of CVD in SSc patients. Although its contribution to morbidity and mortality rates in CVD in SSc is yet to be established.

**Background:** Certolizumab pegol (CZP) is an Fc-free, PEGylated anti-TNF with an established efficacy and safety profile in axial spondyloarthritids (axSpA) in clinical trial settings.1

**Objectives:** To report CZP effectiveness and safety in patients (pts) with axSpA, including ankylosing spondylitis (AS), radiographic axSpA and non-radiographic (nr) axSpA subpopulations, in routine clinical practice in Europe.

**Methods:** CIMAX (NCT02354105) was a non-interventional multicentre prospective cohort study observing CZP treatment response and safety over 12 months in a real-world clinical cohort of axSpA pts newly prescribed CZP. The primary outcome was change from baseline (CFB) in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) to Week (Wk) 52 in pts with available data, with additional outcomes pertaining to effectiveness and safety. Outcomes were evaluated for AS and nr-axSpA subpopulations (diagnosed according to local practice). Pts who received ≥1 dose CZP were followed up for adverse events (AEs) (Safety Set [SS]); those with baseline and ≥1 post-baseline BASDAI assessment were included in the effectiveness analyses (Full Analysis Set [FAS]). Outcomes are reported using observed case data with no imputation.

**Results:** 682 axSpA pts were enrolled from 101 European sites, of whom 490 (71.8%) completed the study. Of those enrolled, 672 formed the SS (AS: 469; nr-axSpA: 201) and 564 the FAS (AS: 384; nr-axSpA: 179); 2 (SS)/1(FAS) pts with unconfirmed AS/nr-axSpA were included in the overall axSpA population. 27.5% (185/672) AS axSpA pts had previous anti-TNF exposure (AS: 31.1% [146/469]; nr-axSpA: 18.4% [37/201]). BASDAI data were available for 77.8% (439/564) pts at Wk52. In pts with available data, all clinical outcomes were improved at Wk52 in both subpopulations (Table). At baseline, the mean BASDAI was 6.1. At Wk52, the mean BASDAI CFB in pts with available data (n=439) was −2.9 (AS: −2.9 [n=301]; nr-axSpA: −2.8 [n=137]). For pts with and without prior anti-TNF exposure, BASDAI at baseline was 6.1 in both groups (n=165 vs n=299, respectively), and at Wk52, the mean BASDAI CFB was −2.6 (n=127) vs −3.0 (n=312) (AS: −2.7 vs −3.0; nr-axSpA: −2.2 vs −3.0). In the SS, 37.9% (255/672) pts experienced AEs; 20.7% (139/672) experienced drug-related AEs and 6.3% (42/672) serious AEs (1.8% [12/672] reported serious infections); these data were comparable between AS and nr-axSpA (Table).

**Conclusion:** This is the first multicentre European study to evaluate CZP effectiveness and safety in both axSpA subpopulations in routine practice. Improvements were observed in all signs and symptoms in pts who remained on treatment to Wk52; >70% of those enrolled completed the study. No new safety signals were identified following application of CZP to real-world rheumatological practice.

**AB0699** EFFECT OF SWITCHING BETWEEN TUMOR NECROSIS FACTOR INHIBITOR IN SPONDYLOARTHRITIS

*Hedia ben abiti*, Sonia Rekik, Soumany Boussaid, Samia Jammali, Hela Sahli, Elhem Cheour, Mohamed Elleuch.

**Background:** The introduction of new drugs, in particular tumour necrosis factor inhibitor (TNFi) has revolutionized the treatment of spondyloarthritids (SpA). Meanwhile, about 30% of patients do not reach sustained, long-term efficacy with the first-line TNFi. To date, there is no recommendations available for the treatment of SpA patients after first TNFi failure.

**Objectives:** In this study we assessed the effectiveness of a second and third biotherapy in patients with SpA with an inadequate response to previous TNFi and to analyze the survival of the second biotherapy.

**Methods:** This study included patients with SpA who had had at least two biotherapies. Treatment response was noted at 3 months. At 6 months, we assessed the maintaining of effectiveness in SpA. We studied the elements of a good response to the second biotherapy.

**Results:** Our population of study included 30 SpA. During the second treatment, response rate was achieved by 80% after 3 months. No difference was noted between first and second TNFi among switchers. 86, 7 maintained response at twelve months. For axial forms, decrease in BASDAI was significant at 3 months. For peripheral forms, an improvement of the swollen and tender joint counts was observed and was significant at 3 months. Four patients have received a third TNFi. Response rate was achieved by all of them after 3 months. All of them maintained response at 6 months. The elements of a good response founded were: the early age of the SpA starting (<30 y.o), the high value of initial CRP, the use of ESSG criteria, the SpA type, the extra articular signs, the first biotherapy and the response at 3 months to it, the drugs taken when second biotherapy were initiated a low initial EVA and BASFI.

**Conclusion:** These real-life data show that, after discontinuation of a first TNFi, switching to a second biotherapy in SpA is related to significantly improving of clinical effectiveness compared to a first TNFi.

GOLIMUMAB PERSISTENCE IN BIOLOGIC NAÏVE AND NON-NAÏVE PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS OF THE GO-PRACTICE STUDY

Philippe Bertin, Philippe Goupille, Florence Tubach, Jean Quanich, Eric Lespessailles, Najat Gouyette, Naoual Harid, Jean-Marie Fayette, Bruno Fautrel, René-Marc Filpo, University Hospital of Limoges, Limoges, France; University Hospital of Tours, TOURS, France; Pitié Salpêtrière University Hospital, PARIS, France; Private practice Toulouse, TOULON, France; Hospital of Orléans, Orléans, France; MST France, Courbevoie, France; Clinsearch, Malakoff, France; University hospital of Lille, LILLE, France

Background: Golimumab (GLM) was the latest anti-TNFα therapy to be indicated in the treatment of chronic inflammatory rheumatic diseases. The pivotal GO-AFTER study [1] and the ongoing observational GO-BEYOND study investigate GLM efficacy in rheumatoid arthritis (RA) patients who previously received biologics. However, clinical studies of GLM in axial spondyloarthritis (AS) are lacking. Using data from the GO-PRACTICE study, we examined GLM persistence in patients with AS.

Objectives: Primary objective was to estimate GLM persistence at 2 years from initial prescription, as a first line of treatment (in biologic naïve patients:BN) and as a second or further line of treatment (in biologic pre-treated patients:BP). Persistence was estimated with the Kaplan-Meier method. Secondary outcomes included assessing disease activity (ASDAS) evolution and patient-reported evaluations of disease activity (BASDAI), pain (VAS), functional ability (HAQ) and quality of life (EQ-5D and SF-12).

Methods: Observational, prospective, multicenter French study, that recruited adult patients with RA, psoriatic arthritis or AS, who were newly prescribed GLM. Patients were followed-up over 2 years; data were collected at baseline (BL), 1 year and 2 years. This abstract presents results from the AS cohort of GO-PRACTICE.

Results: 478 patients with AS (constituting 63% of the total cohort) from 134 sites were included from January 2015 to March 2016. Mean age was 43 years, 55% were female, 61% were BN (n=291) and 39% (n=187) were BP. Mean duration of AS was 5.5 and 10.7 years in BN and BP patients, respectively (P<.001). At BL most were prescribed 50 mg GLM monthly (97%). Co-treatments were disease-modifying anti-rheumatic drugs (34%), corticosteroids (17%) and NSAIDs/analogesics (80%). GLM persistence over 2 years was significantly higher in BN than BP patients (59.2% vs 45.1%, P<0.01). For those still on GLM at 2 years, disease activity (Table1) and patient assessments showed significant improvements for both, BN and BP patients, with improvements being greater in BN patients. GLM was well tolerated in AS patients (n=478), with 46 (9.6%) discontinuing due to intolerance. Among BN patients, 18 (6.2%) discontinued GLM due to primary treatment failure, compared to 28 BP patients (15%). GLM was re-prescribed for 21% of the 241 patients persisting on GLM at 2 years. Post-hoc multivariate analysis showed that being female was a risk factor for GLM discontinuation in AS patients (HR1.9, IC95% 1.4-2.6).

Table 1. Disease activity at BL and 2 years for BN and BP patients with AS persisting on GLM

*P is from a 2-factor repeated-measures model testing the significance of the effect of prior biologic treatment on score evolution, adjusted to time

Conclusion: GLM is associated with clinical improvements and good persistence in AS patients, especially those who are biologic naïve.

AB0702 TREATMENT EFFECT OF TUMOR NECROSIS FACTOR A INHIBITORS ON MAGNETIC RESONANCE IMAGING PROGRESSION IN PATIENTS WITH SPONDYLOARTHRITIS: A META-ANALYSIS

Yupeng Huang, Yuehong Chen, Tao Liu, Sang Lin, Geng Yin, Qibing Xie. West China Hospital, Sichuan University, Chengdu, China

Background: Treatment effect of tumor necrosis factor α inhibitors (TNFi) in patients with spondyloarthritis (SpA) had been proved by plenty of studies that could remarkably decrease symptoms, signs, and laboratory inflammatory markers. Simultaneously, the treatment effect of TNFi on delaying radiographic progression in SpA was often reported, including magnetic resonance imaging (MRI) which has a high sensitivity on detecting the earliest inflammation.

Objectives: The aim of this meta-analysis was to summarize the treatment effect of TNFi on MRI progression reflected by SPARC score in SpA patients.

Methods: Comprehensive search was conducted in the electronic databases of OVID Medline, OVID EMbase and Cochrane library on Nov.27, 2018. All randomized controlled trials (RCTs) focused on MRI progression and disease activity in SpA patients treated with TNFi were included. Primary outcome was the Spondyloarthritis Research Consortium Canada (SPARC) MRI scoring system, accompanied with or without other outcomes, including Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis disease activity index (BASDAI), Bath Ankylosing Spondylitis functional index (BASFI), C-reactive protein (CRP). Data were pooled by mean differences (MD) with 95% confidence interval (CI) and publication bias was assessed by funnel plot. Sensitivity analysis was performed to test the result robustness.

Results: Totally 10 RCTs enrolled 1006 patients with high methodology were included. Compared with control group, TNFi significantly improved SPARC score at sacroiliac joint (SIJ) (MD=-2.64, 95% CI 2.43-3.25), SPARCC score of spine (MD=1.87, 95% CI 1.27-2.46), ASDAS (MD=-0.96, 95% CI 0.71-1.20), BASDAI (MD=-1.15, 95% CI 0.51-1.78), BASFI (MD=-0.95, 95% CI 0.51-1.40), and CRP (MD=-4.64, 95% CI 1.06-8.23) in double-blind phase. Subgroup analyses by disease subgroup and individual TNFi showed treatment effect of TNFi on delaying MRI progression was not affected by disease subgroup and individual TNFi. Sensitivity analysis showed the treatment effects of TNFi versus placebo were consistent with TNFi versus controls, suggesting the results of the study were robust. The funnel plot of SPARC score at SIJ based on TNFi versus control in double-blind phase was asymmetric, suggesting there might have potential publication bias.

Conclusion: TNFi are effective to treat SpA patients and delay MRI progression which are assessed by SPARC score and treatment effect is consistent among disease subgroups and individual TNFi.

AQUILA STUDY IN GERMANY – REAL WORLD ADHERENCE AND PERSISTENCE OF SECUKINUMAB TREATMENT IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS PATIENTS – AN INTERIM ANALYSIS

Ula Kiltz1,2, Janat Peterli3, Veronika Winkelmann4, Hans-Peter Tony5, on behalf of the AQUILA Study Group. Rheumatodentrum Rhein, Herne, and Ruhr University, Bochum, Germany. Novartis Pharma GmbH. Clinical Research, Immunology, Rheumatology and Dermatology, Nürnberg, Germany; Medizinische Klinik II, Universitätshospital, Rheumatologynam, Würzburg, Germany

Background: Secukinumab (SEC) has been shown to be an effective treatment for patients (pts) with ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in several phase III studies. Clinical studies reduce confounding factors, but do not guarantee the same results in real world where treating physicians deal with comorbidities, adherence and persistence challenges. Especially medication adherence has a direct impact on health outcomes. However, there is limited information on the adherence and persistence of SEC in routine care.

Objectives: The aim of this interim analysis is to report baseline (BL) characteristics and to assess adherence rate as well as treatment persistence of SEC in AS and PsA pts under real world conditions.

Methods: AQUILA is an ongoing, non-interventional study enrolling 2000 AS or PsA pts under real world conditions. The study is ongoing. All pts were treated with SEC. At treatment start with SEC, pts presented with a number of extra-articular manifestations/comorbidities: plaque psoriasis 11.6% (n=36) in AS and 66.3% (n=425) in PsA, uveitis 6.4% (n=20) in AS and 1.7% (n=11) in PsA, depression 15.4% (n=48) in AS and 15.4% (n=99) in PsA, coronary heart disease 3.5% (n=11) in AS and 7.5% (n=51) in PsA, stroke 0.6% (n=2) in AS and 1.9% (n=12) in PsA, and heart insufficiency 1.6% (n=5) in AS and 3.0% (n=19) in PsA. Adherence rates for SEC [95% CI] at week 52 were 64.5% [58.3,70.5] and 56.0% [51.5, 60.4] for AS and PsA, respectively.

Results: This interim analysis describes 952 pts (AS n=311, PsA n=641) who were included at BL. In total, 51.4% (n=489) of the pts were female and 48.6% (n=463) male, mean age was 50.8 years and 67.8% (n=645) were pretreated with Bx. At treatment start with SEC, pts presented with a number of extra-articular manifestations/comorbidities: plaque psoriasis 11.6% (n=36) in AS and 66.3% (n=425) in PsA, uveitis 6.4% (n=20) in AS and 1.7% (n=11) in PsA, depression 15.4% (n=48) in AS and 15.4% (n=99) in PsA, coronary heart disease 3.5% (n=11) in AS and 7.5% (n=51) in PsA, stroke 0.6% (n=2) in AS and 1.9% (n=12) in PsA, and heart insufficiency 1.6% (n=5) in AS and 3.0% (n=19) in PsA. Adherence rates for SEC [95% CI] at week 52 were 64.5% [58.3,70.5] and 56.0% [51.5, 60.4] for AS and PsA, respectively.
Methods: An independent market analytics firm administered a survey with US rheumatologists (n=104) on the treatment landscape for AS and nr-axSpA. To qualify, rheumatologists had to spend the majority of their professional time in clinical practice, manage a minimum of 50 AS or nr-axSpA patients, and have been in practice between 2 and 35 years. Respondents answered questions pertaining to their practice, the demographics of their AS/nr-axSpA patients, their treatment approaches for each type, as well as attitudinal statements. The survey was administered online in February 2018 and respondents were compensated for their participation. A similar study was also conducted in 2017 allowing for year over year comparison. The data were collected and analyzed in SPSS.

Results: Three-quarters of rheumatologists reported they treated their AS and nr-axSpA patients in a similar manner, though there was a higher use of NSAIDs and local steroids in non-radiographic disease, and more biologic/JAK in AS. More established TNF inhibitors such as adalimumab, etanercept, and infliximab dominated biologics/small molecule preference, collectively accounting for approximately three-quarters of all biologic treatment in AS or nr-axSpA patients, use of biologics increased from 2017. Projected off-label use of tofacitinib in the following three months is also expected to increase.

Conclusion: Rheumatologists are less likely to use biologics/small molecules for nr-axSpA, but when they do, use of brands is similar to those used in AS. While TNF inhibitors continue to account for the majority of biologic/small molecule prescriptions for these conditions, rheumatologists project increased use of agents with alternative mechanisms of action in the future.

Disclosure of Interests: None declared

DIFFERENCES IN RHEUMATOLOGISTS’ TREATMENT PREFERENCES FOR ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLARTHRITIS

PhD position: Lynn Price. Sphera Global Insights, Exton, United States of America

Background: The lack of a formal indication for Non-Radiographic Axial Spondylarthritis (nr-axSpA) has meant that many US rheumatologists fundamentally treat it as an early manifestation of Ankylosing Spondylitis (AS) and seldom differentiate their treatment approach when using biologics/small molecules.

Objectives: This study sought to gain a better understanding of the number of AS and nr-axSpA patients rheumatologists manage, recent changes made in treatment, and how AS and nr-axSpA patients are differentiated beyond radiographic evidence. The study also evaluated the differences in use of biologics/small molecules for the treatment of AS and nr-axSpA and rheumatologist projected changes in the management of these two conditions.

AB0707

LTBI SCREENING IN SPONDYLOARTHRITIS PATIENTS PRIOR TO ANTI-TNF TREATMENT AND FOLLOW-UP IN AN ENDEMIC AREA

Andrea Shimabuco, Ana Medeiros, Renata Miossi, Karina Bonfiglioli, Julio Maiores, Celio Gonçalves, Percival D. Sampaio-Barros, Claudia Goldenstein-Schainberg, Fernando Souza, Leandro Prado, Michelle Lopes, Eloisa Bonfa, Célia Sand. Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Rheumatology Division, Sao Paulo, Brazil

Background: Screening for latent tuberculosis infection (LTBI) remains a concern in endemic regions for anti-TNF eligible patients and recent researches have shown peculiarities between the inflammatory arthropathies such as different groups of spondyloarthritides (SpA).

Objectives: To evaluate the long-term efficacy of LTBI screening and treatment in patients with Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA) receiving TNF blockers in a single center.

Methods: A total of 218 SpA patients (135 AS and 83 APS) were screened for LTBI before receiving anti-TNF (infliximab, adalimumab, etanercept, certolizumab pegol, and golimumab) treatment using the tuberculin skin test (TST), chest X-ray (CXR) and history of previous exposure to tuberculosis (TB). Patients were regularly followed every 2-3 months and asked about infectious symptoms or new exposure. TST was not repeated regularly. LTBI patients were treated with isoniazid (300 mg/day) for 6 months, according local guidelines.

Results: One hundred and eight patients (49.5%) were treated with a single anti-TNF agent and the total duration of biological treatment was approximately six years (5.9 ± 4.0). INF and ADA were most often used among the 422 treatment cycles analyzed, representing 45% and 30% respectively. LTBI screening was positive in 82 patients (38%): 69 (84%) were TST-positive, 23 (28%) had a history of TB exposure and 5 (6%) had abnormal CXR. As isolated variables TST positivity and previous exposure accounted for 58(71%) and 11 (13%) LTBI diagnosis. There were some distinct patterns between APS and AS patients screening: despite APS patients had more cases of previous TB than AS patients (6% vs 0.7%, P= 0.03), they had a lower frequency of LTBI (30% vs 42%, P = 0.04). Among LTBI patients, TST positivity was lower in SpA than AS patients (64% vs 93%, P = 0.002), even with more previous exposure (52% vs 18%, P = 0.02) and in patients with peripheral arthritis (27% vs 42%, P = 0.03). During follow-up, 11 patients developed active TB: 5 under ADA, 5 under INF and 1 under ETA treatment. Five cases (45%) were extrapulmonary: 3 pleural, 1 peritoneal and 1 spondylocostitis. Four (36%) cases occurred in patients with a positive LTBI screening and 7 in patients without LTBI. There was no difference in drug survival.
according to type or class of anti-TNF, disease subgroups, duration or use of synthetic drugs and prednisone. Four (36.3%) cases occurred in the first year, median 5.3 (1.2-8.8) months after initiating anti-TNF exposure, 2 of them (50%) in patients with positive LTBI. Seven cases were probably due to re-exposure since occurred later, median 21.9 (14.2-42.8) months (5 in patients with negative LTBI screening). Six patients (54.5%) re-initiated treatment with ETA. Only the patient who developed pulmonary TB under ETA had a second TB infection after 18 months of therapy.

Conclusion: Despite the adequate screening and treatment of LTBI according to local guidelines, TB still occurs in spondyloarthritics patients under anti-TNF therapy, even in the first year of treatment. These data point to LTBI screening/treatment failure, maybe due to anergy, mainly in PsA patients, with peripheral disease, low adherence or re-exposition in an endemic environment. The high frequency of extrapulmonary disease is also a diagnostic challenge.

Background: Immunogenicity of anti TNF monoclonal antibodies leads to poor or secondary loss of response. Methotrexate reduces anti-drug antibodies (ADA) to adalimumab at week 26 in spondyloarthritics (SpA).1

Objectives: Herein we sought to examine adalimumab long term persistence in ADA positive versus ADA negative SpA patients.

Methods: The CoMARIS study (Combination of Methotrexate and Adalimumab to Reduce Immunization in patients with axial SpA) is a 26-week prospective, randomised, open-labelled, multicentre study in which patients received adalimumab 40 mg subcutaneously (s.c.) every other week either in combination with MTX 10 mg s.c. for 26 weeks or without MTX. In a post hoc analysis, we reviewed the charts of patients to assess adalimumab persistence. A Cox model analysis was performed to test the following covariates: MTX combination or not, sex, presence of ADA at week 26.

Results: Data from 104 patients (54 without MTX and 50 with MTX) were reviewed, and time of adalimumab discontinuation was collected. The median time of follow-up was 210.57 weeks. ADA positivity at week 26 was the only covariate associated with adalimumab persistence. The median retention rate of adalimumab in ADA positive patients was 56.9 weeks, as compared with 98.6 weeks in those without ADA (log rank: p=0.015). In the Cox model analysis, the presence of ADA at week 26 increased the risk of adalimumab discontinuation by 1.78 [IC 95%=1.11-2.85], p=0.016.

Conclusion: Immunogenicity is a key factor that contributes to adalimumab discontinuation in SpA. MTX at initiation may therefore be consid ered in combination in SpA patients.

Background: Dysbiosis can be found in inflammatory joint diseases and induces alterations of the protective function of the intestinal barrier (1). Yet, intestinal inflammation exists in ankylosing spondylitis, which is as much severe as the disease is active (2). Benefits of diets and their influence on the microbiota diversity and inflammation deserve to be studied in spondyloarthritides.

Objectives: The aim of the study was to investigate the nutritional profile in active spondyloarthritides.

Methods: An observational prospective monocentric study based in a french rheumatology department based in Limoges was conducted between February and July 2018, demographic and disease data were collected, in addition to the treatments and the food frequency questionnaire. Voluntary patients over 18 years of age with spondyloarthritis defined by ASAS classification were included. Patients with a diagnosis of inflammatory bowel disease or a bariatric surgery history were excluded of the study. The primary outcome was the correlation between omega-3, vitamin C, refined sugars, fibers and ultra-processed food intakes and the disease activity assessed by ASDAS CRP and BASDAI scores.

Results: Among 140 patients included, there was no statistically significant difference in omega-3, vitamin C, refined sugars, fibers or ultra-processed food intakes between patients with active spondyloarthritis (BASDAI ≥ 4 or ASDAS CRP ≥ 1.3) and patients with inactive disease. The quality of life score and fatigue score were more important in the active and very active disease forms, likewise for the digestive symptoms but there was no link founded in the different nutrients intakes, neither with the associated treatment.

Conclusion: Although our study did not find any nutritional profile in active spondyloarthritides, there was an alteration of quality of life and more digestive symptoms in the active group. Future researches are however required to explore the impact of dietary intakes on the disease activity of spondyloarthritides.

**RETNAL AND CHOROIDAL VASCULAR STRUCTURES ARE AFFECTED IN AXIAL SPONDYLOARTHRITIS: AN OPTICAL COHERENCE TOMOGRAPHY STUDY**

Berktay Akmaz1, Fahrettin Akay2, Dilek Salmaz1, Oray Gerekz3, Gokhan Kabaday1, Idil Kurut1, Servet Akar1, Izmir Katip Celebi University, Faculty of Medicine, Ophthalmology, Izmir, Turkey, Izmir Katip Celebi University, Faculty of Medicine, Rheumatology, Izmir, Turkey

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. Ocular inflammation is one of the most common extra-articular manifestations of axSpA, mainly form of acute anterior uveitis (AAU). However posterior segment of the eye was rarely evaluated. The inaccessibility of posterior structures like choroid and retina to direct examination led clinicians to use non-invasive imaging techniques. Optical coherence tomography (OCT) is an imaging technology
**Objectives:** To examine the role of musculoskeletal ultrasound (US) and magnetic resonance imaging (MRI) in assessing femoral cartilage thicknesses in patients with AS and healthy controls, and to study the correlation between femoral cartilage thicknesses measurements and disease parameters.

**Methods:** Twenty five patients with AS (17 males and 8 females), and twenty five age, sex and BMI matched healthy individuals were included. For all patients assessment of disease activity, spinal mobility, functional limitation and radiological changes were done. Thickness of the femoral articular cartilage was measured by MRI using 1.5 Tesla MR machines.

**Results:** AS patients had thinner femoral cartilage thickness than the healthy controls at all MRI measurement sites, with statistically significant differences at medial femoral condyle and intercondylar area in both right and left knees (p<0.05). According to MRI examination, AS patients had statistically significant (p<0.05) thinner cartilage thickness at all subdural visions of femoral and tibial condyles than the healthy controls. Femoral cartilage thickness measurements either assessed by US or MRI was negatively correlated with age, age at onset of the disease, and measures of disease activity and radiological changes. Positive correlation between ultrasonographic total femoral cartilage thickness and MRI total femoral cartilage thickness was found (r=0.49, p<0.02).

**Conclusions:** Patients with ankylosing spondylitis seem to have thinner femoral cartilage thickness than healthy controls. Correlations of knee cartilage thickness (assessed by US and MRI) with demographic data and disease parameters reflect useful value of US and MRI in determining early cartilage loss in AS patients.

**BALANCE AND FALLS IN AXIAL SPONDYLOARTHRITIS: A CROSS SECTIONAL STUDY**

Kenlyn Brenda Mewes, Betania Longo, Ana Paula Beckhauser de Campos, Juliana Simioni, Thelma Laroca Skare. Hospital Universitário Evangélico Mackenzie, Department of Rheumatology, Curitiba, Brazil

**Background:** Spondyloarthritis (SpA) patients may suffer of balance loss predisposing them to falls.

**Objectives:** To study balance impairment and falls in SpA patients and its association with clinical and epidemiological variables, disease activity, functional and metrology indexes.

**Methods:** Cross sectional study of 55 SpA patients with axial disease. Clinical and epidemiological were collected from the charts. Balance was assessed by Berg Balance Scale(BBS). The following instruments were applied: ASDAS (Ankylosing Spondylitis Disease Activity Score)-ESR, ASDAS-CRP, BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), BASFI (Bath Ankylosing Spondylitis Functional Index), BASMI (Bath Ankylosing Spondylitis Metrlogy Index) and ASQoL (Ankylosing spondylitis quality of life questionnaire). The number of falls in the last year was collected.

**Results:** In this sample, 30.9% had high risk of falls by the BBS and 25.4% recalled having at least one fall in the last years. The BBS values were lower in those with white ethnic backgroundp<0.01), and smokers(p=0.03) and with HLA-B27(p=0.03) and correlated inversely with BASDAI(p<0.08), ASDAS-ESR(p<0.32) and ASDAS-CRP(ho=0.33), BASFI(ho=0.71.p<0.0001), BASMI(ho=0.80; p<0.0001), ASQoL(ho=0.57; p<0.001) and age(ho=0.50.p<0.001). Multivariated analysis showed that BASFI and BASMI were independently associated with BBS(p=0.02 and
0.001 respectively). Patients with falls had lower BBS (p=0.03) and loss of balance correlated with impairment of the quality of life (rho=0.56; p=0.001).

Conclusion: Balance is impaired in 1/3 of SpA patients and the BBS is associated mainly with functional and metrology indexes, showing that patients with severe cumulative damage are more affected.

### AB0716 ESTABLISHMENT OF BASDAI CUT-OFFS FOR THE DISEASE ACTIVITY STATES BASED ON ASDAS CUT-OFFS IN TAIWANESE ANKYLOSING SPONDYLITIS PATIENTS

1. Hein-Hua Chen1, Ting-I Pan2, Yi-Ming Chen1, Yi-Hsing Chen1, Wen-Nan Huang1, Tsu-Yi Hsieh1, Kuo-Lung Lai1, Wei-Ting Hung1, Yin-Yi Chou1, Chih-Wei Tseng1, Yi-Da Wu1, Chia-Wei Hsieh1, Cheng-Tsai Lin1, Taichung Veterans General Hospital; Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 2. Tunghai University, Department of Industrial Engineering and Enterprise Information, Taichung, Taiwan, Republic of China

Background: The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) has been widely utilized to evaluate disease activity in patients with ankylosing spondylitis (AS). However, the cut-off of BASDAI used to indicate high disease activity (i.e., >4) was determined arbitrarily and was suggested as a criterion to initiate biological therapy for AS patients. The Ankylosing Spondylitis Disease Activity Score (ASDAS) has been developed as a new composite index to assess AS disease activity. The cut-off values for disease activity states have been defined and validated for ASDAS-CII was selected as a criterion of starting biological therapy. However, the BASDAI cut-off values corresponding to the ASDAS cut-off values for disease activity states were unknown.

Objectives: The purpose of this study was to estimate the corresponding BASDAI and ASDAS cut-off in a Taiwanese AS cohort.

Methods: Since November 2016, we assessed the Ankylosing Spondylitis Disease Activity Score (ASDAS) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) regularly and recorded demographic and disease activity, comorbidity, family history, medication use for AS patients in Taichung Veterans General hospital (TCVGH) using an electronic patient reported data system linked to an electronic medical record system. We identified 489 AS patients with complete baseline demographic and assessment data from the TCVGH electronic data system during 2016/11-2018/10. We used receiver operating characteristic (ROC) curves with Youden’s J statistic to determine the cut-off values of BASDAI that correspond to ASDAS disease activity cut-offs (i.e., 1.3, 2.1 and 3.5).

Results: We included a total of 489 AS patients [114 (23.3%) females, mean age 44.1 years (S.D. 13.9), mean symptom duration 18.0 years (S. D. 11.9), 152 (31.1%) current biologic users]. Mean BASDAI, ASDAS-ESR and ASDAS-CRP scores were 2.1 (S.D. 1.3), 1.6 (S.D. 0.8) and 1.5 (S.D. 0.9) respectively. Mean levels of CRP and ESR were 0.6 mg/dl and 12.2 (S.D. 14.0) mm/hr respectively. Based on ASDAS-CRP, the numbers (%) of AS patients with inactive disease (<1.3), low disease activity (1.3-2.1), high disease activity (2.1-3.5) and very high disease activity (>3.5) were 210 (42.9), 171 (35.0), 88 (18.0) and 20 (4.1) respectively. Based on ASDAS-ESR, the numbers (%) of AS patients with low disease activity, high disease activity and very high disease activity were 202 (41.3), 174 (35.6), 96 (19.6) and 17 (3.5)

Disclosure of Interests: None declared

respectively. The best trade-off BASDAI values corresponding to ASDAS-CRP 1.3, 2.1 and 3.5 were 2.1, 2.6 and 2.8, respectively.

Conclusion: The estimated optimal BASDAI value that corresponds to the recommended ASDAS cut-off ≥2.1 for biological therapy initiation was lower than the recommended BASDAI cut-off of ≥4 in this Taiwanese AS cohort.

AB0717 RELIABILITY OF SACROILIAC JOINT RADIOGRAPHS IN THE EARLY SPONDYLOARTHRITIS ESPERANZA COHORT

Carolina Tornero1, Claudia Urrego-Laurín2, Maria Luz García-Vivar3, Cristina Fernández-Carbajal1, Chia-Wei Hsieh4, Ching-Tsai Lin5, Hsin-Hua Chen6, Nan Huang7, Jose Francisco Garcia Llorente8, Eugenio de Miguel9. Disclosure of Interests: Carolina Tornero: None declared, Claudia Urrego-Laurín: None declared, Maria Luz García-Vivar: None declared, Cristina Fernández-Carbajal: None declared, Chia-Wei Hsieh: None declared, Ching-Tsai Lin: None declared, Hsin-Hua Chen: None declared, Nan Huang: None declared, Jose Francisco Garcia Llorente: None declared, Eugenio de Miguel: None declared.

Background: X-Ray sacroilis is the cornerstone in the diagnosis of the ankylosing spondylitis (AS). It is clear that the presence of sacroilis is a specific lesion in long standing AS, but little evidence exists on the reliability of this image technique in early axial spondyloarthritis (axSpA), which associates with reduced structural damage. This is relevant because some rheumatologists and pharmacological authorities feel more confident with the diagnosis of AS rather than with non radiographic axial spondyloarthritis (nr-axSpA) forms. On the other hand, according to various research studies, clinicians are subject to potential bias when interpreting radiographs, influenced by their pretest clinical judgment.

Objectives: The main objective of this study is to determine the reliability of X-Ray sacroilis in the early diagnosis of axSpA.

Methods: This study included 290 radiographs of the SI joints from patients of the Esperanza early spondyloarthritis cohort. Nine readers, blinded for the diagnosis, participated in the reliability exercise, all of them experienced rheumatologists and members of the Spanish spondyloarthritis working group (GRESSER). Patients with axSpA were classified as having AS if the radiographic criteria of the modified NY criteria (presence of radiographic changes in the SIJ of at least grade II bilaterally or at least grade III unilaterally) were fulfilled. The gold standard was the categorical opinion of at least five of the expert readers. For the statistical analysis, the Chi-square and Kappa tests were performed.

Results: The table shows mean kappa values and the agreement reached by each reader. The mean kappa achieved was fair (0.375, range 0.146 - 0.652) and the mean agreement was 73.7% (range: 58.7% - 90%). When the categorical opinion of X-Ray sacroilis of at least 5 readers as gold standard was applied, 61 patients were classified as AS and 229, as nr-axSpA. Nevertheless, this scenario varied from 31 to 138 among the readers when the x-ray evaluation was performed by only one reader.

Conclusion: Reliability of X-Ray SIJ in an early SpA cohort was weak among nine experimented readers and the diagnosis of AS was subject to a high variability. At least in doubtful cases, a central evaluation performed by highly qualified readers is advisable.

AB0718 IDENTIFYING AXIAL SPONDYLOARTHRITIS IN THE UNITED STATES: A POSSIBLE ROLE FOR CHIROPRACTORS

1Aluf Deodhar, 2Shreevesh Bhalerao, 3Oregon Health and Science University, Portland, United States of America; 4Equilibrium, Portland, United States of America.

Background: Approximately 19% of the general population in the United States has chronic back pain (CBP), with 5%-6% of these cases classified as inflammatory back pain (IBP).1 According to the US National Health and Nutritional Examination Survey, ~15% of patients with IBP have axial spondyloarthritis (axSpA),2 which can cause irreversible structural damage in the spine, loss of function, and a decreased quality of life. The diagnosis of axSpA is commonly missed, as patients seek care for back pain (BP) from a variety of non-rheumatology providers, including chiropractors.2 Overall, nearly 50% of patients seek chiropractic care for BP.3 However, not much is known about the prevalence of different types of BP (acute, chronic, IBP, and BP due to axSpA) in patients seeking chiropractic care in the United States.

Objectives: To investigate the types of providers sought by patients with BP and the prevalence of acute BP, CBP, IBP, and axSpA in patients with BP seeking chiropractic care in the United States. A secondary objective was to investigate how frequently chiropractors refer patients with BP to a rheumatologist.

Methods: PubMed literature searches were performed for all English language articles published through December 2017 to determine which providers are sought by patients with BP as well as the percentage of patients with BP being referred to a rheumatologist following chiropractic consultation. Search terms included “chiropractic,” “chiropractor,” “axial spondyloarthritis,” “ankylosing spondylitis,” “inflammatory back pain,” “chronic back pain,” “acute back pain,” “low back pain,” “sacroiliac joint,” “sacroiliac pain,” “back pain epidemiology,” “rheumatologist,” and “rheumatology.” The full text of relevant articles was evaluated for specific data and BP statistics in this care setting.
Results: Only 7 articles that described the types of providers sought by patients with BP were identified (Table 1). Among patients with BP, 7%-45% sought chiropractic care; 26%-70% sought care from general practitioners, and 3%-37% sought care from rheumatologists. Patients who sought chiropractic care were mainly white, female, aged < 65 years old, and of higher socioeconomic and education status. Patients with CBP seeking rheumatologic care had a mean duration of CBP of 14-28 years and were mostly women (56%; age range, 41-50 years); of these, 1% were referred to a rheumatologist by chiropractors for symptoms suggestive of SpA. Data regarding the prevalence of different types of BP (e.g., acute, CBP, IBP) in US chiropractic practices were not available. No articles describing axSpA in patients in chiropractic care were identified.

Discussion:

Chiropractors, as primary spine care providers in the United States, are playing an increasingly larger role in the diagnosis and treatment of BP, with 7%-45% of patients with BP seeking chiropractic care. However, there are conflicting data on the types of BP treated by chiropractors in the United States. Nonetheless, since approximately 15% of patients with IBP have axSpA, it is very likely that many patients seeking care from chiropractors in the United States have undiagnosed axSpA. Untreated axSpA could have a significant impact on the general health and quality of life of patients; therefore early diagnosis and treatment is crucial.[1]

Disclosure of Interests: Atul Deodhar Grant/research support from: Abbvie, AstraZeneca, Biogen, BMS, Celgene, Gilead, Galapagos, Genentech, GSK, Janssen, Merck, Novartis, Pfizer, UCB. UCB has informed our prospective cross-sectional single-centre observational study, due to start in February 2019. We will assess the sensitivity and specificity of MRE as a screening tool for axSpA in a cohort of 600 CD patients, two with increasing age and only one with IBD location.

AB0720 IMPACT OF SPONDYLOARTHRITIS ON THE MALE SEXUAL FUNCTION: LIMITING FACTORS

1Alia Faza1, Leila Rouach1, Mourad Dali Khereddine2, Saoussen Miladi1, Kmar Denuiniche1, Leila Souabni1, Selma Chekk1, Selma Kassab, Kauthwer Ben Abdelghani1, Nouira Yassine2, Ahmed Laatar1, 1Inngol slim hospital, 2Rheumatology, tunis, Tunisia

Background: The impact of Spondyloarthrits (SpA) on patients’ sexual life and erectile function has been gathering the attention of the scientific community over the last decade. Several factors may condition sexual function for SpA patients: microangiopathy, pain, decreased range of motion, joint swelling and extraarticular features such as fatigue.

Objectives: To assess the erectile function and the sexual desire in a cohort of male patients with SpA and to identify the factors related to the disease limiting the sexual life.

Methods: This is a cross sectional study including sexually active male patients with SpA (ASAS criteria). A questionnaire was performed, consisting in two parts. One part filled by a rheumatologist with data of the disease (demographics, the presence of a coxitis, disease activity (BASDAI and ASDAS), function index (BASFI) and current treatment). The other part consisted in a questionnaire filled by an urologist, with data on pain during intercourse, the international index of erectile function (IEEF5), intensity and frequency of sexual desire and disease impact on private life. For statistical analysis, we used Khi2-test for qualitative variables and Student-test for quantitative variables. A p value ≤0.05 was considered significant.

Results: We included 37 male patients with SpA, 18.9% had psoriatic arthritis, 51.4% had ankylosing spondylitis and 29.7% had inflammatory bowel disease spondyloarthrits. The mean age was 42.5 ± 1.8 years. Sixty two percent of patients were married. Mean disease duration was 11.4 ± 7.1 years. The mean disease activity and functional scores were as follow: BASDAI=2.57 ± 1.96, ASDAS CRP=2.38 ± 1.09, BASFI=2.59 ± 2.54)

For the treatment side: 40.5% were on NSAIDS, 70.3% on csDMARDs and 56.8% of patients were on biotherapy (33.3% on Adalimumab, 52.4% on infliximab and 14.3% on Etanercept). The mean visual analog pain scale during intercourse was 2.97 ± 1.89 and the erectile function was deteriorated in 80.6% of patients.

Conclusion: Our results suggest the impact of SpA on patients’ sexual function. Pain during intercourse and the limitation of the sexual desire were the most limiting factors of the sexual function.

AB0721 EPIDEMIOLOGICAL, CLINICAL AND PROGRESSION FACTORS OF SPONDYLOARTHITIS IN A TERTIARY CARE HOSPITAL 1Ismael González Fernández, Carlota Iñiguez, Aníta Crespo Golmar, Ximena Elizabeth larco Rojas, Carolina Alvarez Castro, Clara Moriano, Alejandra López Robles, Manuel Martín, Elvira Diez Alvarez, María Eva Vallejo Pascual, Trinidad Pérez Snowdon1, 1University Health Care Complex of Leon, 2Rheumatology, Leon, Spain, 3University of Leon, Faculty Economics and Business Sciences, Leon, Spain

Background: Spondyloarthitis (SpA) is a heterogeneous group of diseases that predominantly affect the axial skeleton, with a debut generally before 45 years. Among the factors favoring radiological progression1 are among others, high levels of CRP, tobacco consumption and diagnostic delay.

Objectives: To describe clinical-epidemiological characteristics and analyze possible factors of radiological progression (based on the development of syndesmophytes) in patients with a diagnosis of SpA in our hospital.

Methods: Retrospective, descriptive observational study of patients diagnosed with SpA (New York, ASAS and AMOR criteria) in the University Health Care Complex of León for 45 years (1973-2018).

Results: A total of 218 patients were collected, 59.6% were men and 40.4% were women with an average age of onset of symptoms of 30.56 ± 12.06 years and a diagnosis of 35.59 ± 12.26 (diagnostic delay defined by a median of 2 years before the great dispersion of data). 81.2% have HLA-B27 positive. 64.2% come predominantly León capital, also highlighting other areas such as La Bañeza (9.6%) and Astorga (6.4%). 13.8% are ex-smokers, 18.8% are active smokers and 67.4% are non-smokers. 68.3% made their debut with inflammatory low back pain.

67% developed some anterior uveitis throughout its evolution. 72.9% have axial involvement and 27.1% joint axial and peripheral involvement. 89.9% met criteria New York (NY), 8.3% criteria ASAS and 1.8% criteria AMOR for the diagnosis of SpA. 17.4% developed syndesmophytes. The activity of the disease was assessed by BASDAI and PCR (taking the reference point of our laboratory, 5 mg/l as the cut-off point) at the time of diagnosis and in the last control performed, showing that 87.6% presented a BASDAI ≥ 4 at the time of diagnosis while in the last revision 84.9% has BASDAI ≥ 4; the elevated levels of CRP appeared in 54.45%, normalizing in 73.9% in the last control. We observed that the age of diagnosis <45 years (p 0.000289) in our sample is related to less progression due to the probable early initiation of biological treatment (18.2% in <45 years, 11% in ≥ 45 years); while both elevated CRP at diagnosis (p 0.003) and exposure to tobacco (p 0.036) present a higher rate of syndesmophytes due to a probable higher inflammatory activity. For other variables (Sex, HLA-B27, BASDAI, diagnostic delay, presence of uveitis and NSAIDs), we did not obtain a statistically significant relationship.

Conclusion: - Most part of patients with SpA are young men, with HLA-B27 positive and axial involvement with debut as inflammatory back pain that meet NY criteria.
- High levels of CRP at diagnosis (p 0.003) and tobacco consumption (p 0.036) have been associated, in our sample, with greater radiological progression while the age of diagnosis <45 years is related to lower progression (p 0.000289) may be due to the early introduction of biological treatment (18.2% in <45 years, 11% in ≥ 45 years).

AB0722 DOES THE ULTRASOUND OF SACRIOILIAC JOINTS CONTRIBUTE TO THE DIAGNOSIS OF SPONDYLOARTHRITIS?

Dorra Ben Nessim, 1Wida Harmik, 1Kassem Maatallah, 1Hend Riahi, Haranne Ferjani, 1Dhaa Kaffel, Med Montazer Khiri, 1Kassab Institute, Rheumatology, Manouba, Tunisia, 2Kassab Institute, Radiology, Manouba, Tunisia

Background: Although pelvic radiography is a robust imaging modality to detect sacroiliitis, radiographic changes require at least 5 years to develop after symptom onset, hence the increasing interest in new imaging tools in the field of spondyloarthritis (SpA). Whereas the diagnostic utility of magnetic resonance imaging (MRI) and computed tomography (CT) of sacroiliac joints (SJI) has been extensively studied in many cohorts, the contribution of SJI ultrasound (US) in the diagnosis of SpA has been little-studied.

Objectives: The objective of this study is to assess the performance of SJI US for detecting sacroiliitis and to determine its sensitivity and specificity in patients with SpA.

Methods: Consecutive patients, aged 16 years and over, consulting for symptoms suggestive of SpA (inflammatory back pain, enthesitis or dactylitis...) from February 2014 to February 2017 were enrolled in this cohort. Eligible patients underwent physical examinations, laboratory tests, SJI US, CT and/or MRIs, following a standardized protocol. Patients with a conventional radiography showing a confirmed sacroiliitis (grade 3 or 4) were not included. The US was considered positive when showing a unilateral or bilateral vascularization (Doppler signals). Then, resistive index (RI) was measured. After analyzing clinical and radiological data and HLA typing, two experienced rheumatologists, blinded to US results, proposed the classification of the patients into 2 groups: confirmed SpA or no SpA. Their final diagnosis was considered the gold standard in interpreting the results of US examination.

Results: Forty-five patients, 10 men and 35 women, with an average age of 39 years were included. The mean duration of symptoms was 75 months (6 years). A family history of SpA was noted in 2.22% of
pneumonia. A personal history of Reiter’s syndrome was noted in 2.22% of patients and of uveitis in 6.66%. Morning stiffness was noted in 60% (n=27) of patients. Good response to nonsteroidal anti-inflammatory drugs (NSAIDs) and to physical activity were respectively reported by 42.22% (n=19) and 57.8% (n=26) of patients. Twenty-seven per cent of the patients were HLA-B27+. Fifty-one per cent of the studied patients fulfilled the ASAS criteria for axial SpA and 46.7% fulfilled the AMR criteria. After a follow-up between 2 and 3 years, the diagnosis of SpA was confirmed by the referring rheumatologists in 31 (68.9%) patients and excluded in 14 (31.1%) patients. Among the 31 patients with confirmed SpA, 61.3% (n=19) had a positive US (with a mean RI estimated at 0.75) and 38.7% (n=12) had a normal US. Among the 14 patients in whom SpA was excluded, 50% (n=7) had a positive US (with a mean RI estimated at 0.71) and 50% had a normal US. Sensitivity and specificity of US examination were estimated at 61.3% and 50%. Positive and negative likelihood ratio were estimated at 73% and 36.8%. Association between US findings and rheumatologists’ diagnosis of SpA was not statistically significant (p=0.47).

Conclusion: US contribution in the diagnostic of SpA has been little-studied. In our study, although US of SJ did not lack specificity, it has a satisfactory sensitivity and positive likelihood ratio. In fact, this tool is more valuable by its positivity which indicates a high probability of spondylitis. However, further investigation is needed in order to assess its performance for ascertaining spondylitis.

Background: Articular manifestations may differ in ulcerative colitis (UC) and Crohn’s disease (CD). Genetic and non-genetic factors like sex, smoking, and presence of HLA-B27 were previously shown to modify the expression of articular and other extraintestinal manifestations of IBD.

Objectives: The aim of this study is to document disease features and factors affecting the expression of articular manifestations in Turkish patients with IBD-related (enteropathic) arthritis under treatment with disease modifying antirheumatic drugs (DMARDs).

Methods: Data regarding enteropathic arthritis (EA) were collected from the TREASURE database, a nation-wide multicenter observational registry of inflammatory arthritis patients.

Results: Among 4066 patients with seronegative spondyloarthropathies (SpA), 156 (3.8%) had EA, not reflecting a true prevalence due to selection bias. Demographic and clinical features according to IBD groups were summarized in Table 1. Rates of prevalence of sacroiliitis were similar between patients with UC and CD (39.9% and 60.1%, p=0.086 respectively). Rates of HLA-B27 positivity were 31.6% and 7.1% in patients with and without radiographic sacroiliitis, respectively (p<0.01). Enthesitis, dactylitis, psoriasis, family history for SpA, ESR, CRP, BASDAI and ASDAS levels had similar distributions in patients with and without radiographic sacroiliitis. Rates of “never-smoked” (26.5% vs 64.7%) and “current smoking” (32.4% vs 17.6%) significantly differed in patients with and without sacroiliitis (overall p=0.012).

Conclusion: Our data confirm an association between smoking status and disease manifestations, particularly radiographic sacroiliitis.

Disclosure of Interests

may not be assumed to be factors of AS worsening.

alteration of prescriptions compared with CS. Taken together, pregnancy and VD significantly between vaginal delivery (VD) and CS (OR 0.72, 95% CI 0.45–1.14).

Conclusion

Among 6,821 female patients with AS, 996 patients in the delivery group

Background

Ankylosing spondylitis (AS) affects the sacroiliac joints and commonly occurs in those at the reproductive age. Women with AS have a higher rate of cesarean section (CS) compared with healthy controls.

Objectives

This study determined the effect of pregnancy and delivery methods on AS worsening by analyzing prescription pattern.

Methods

Based on the Korean Health Insurance Review and Assessment Service claims database, subjects comprised female patients aged 20–49 years with an AS. Alteration of prescriptions was defined by changing the at two time periods of 1–2 years pre-delivery and 1-year post-delivery. We compared alteration of prescriptions between AS patients with delivery and 1:1 matched AS patients without delivery. In addition, among AS patients with delivery, alteration of prescriptions according to delivery method was evaluated.

Results

Among 6,821 female patients with AS, 996 patients in the delivery group were younger, had a higher proportion of non-drug use, and had lower rates of comorbidity than the no delivery group. The alteration of prescriptions did not differ between the AS with delivery and the AS without delivery groups (OR 0.76, 95% CI 0.56–1.05). Furthermore, the overall alteration of prescriptions did not differ significantly between vaginal delivery (VD) and CS (OR 0.72, 95% CI 0.45–1.14).

Conclusion

The rate of alteration of prescriptions was comparable between the AS patients with and without delivery. There was no association between VD and alteration of prescriptions compared with CS. Taken together, pregnancy and VD may not be assumed to be factors of AS worsening.

ASSOCIATION BETWEEN RADIOGRAPHIC PROGRESSION AND CARDIOVASCULAR RISK IN SPONDYLOARTHRITIS: DATA FROM COSPARR REGISTRY

Ladehesa Pineda Lourdes1, Gómez García Ignacio2, María del Carmen Castro Villegas2, Pedro Seguí Azpilicueta3, María del Carmen Abalos-Aguilera3, Bautista Aguilar Laura4, Inmaculada Concepción Aranda-Valera5, Rocío Segura5, Rafaela Ortega Castro6, Clemencia López-Medina7, Puche Larrubia María Ángeles8, Alejandra Escudero Contreras9, Judit Lopez-Pedrezas10, Font Ugalde Pilar11, Garrido Castro Juan Luis12, Alejandro Escudero Contreras9, Pedro Seguí Azpilicueta: None declared, María del Carmen Abalos-Aguilera: None declared, Bautista Aguilar Laura: None declared, Inmaculada Concepción Aranda-Valera: None declared, Rocío Segura: None declared, Rafaela Ortega Castro: None declared, Clemencia López-Medina: None declared, Pérez Sánchez Laura: None declared, Puche Larrubia María Ángeles: None declared, Charly López-Pedrezas: None declared, Font Ugalde Pilar: None declared, Garrido Castro Juan Luis: None declared, Alejandro Escudero Contreras: None declared, Eduardo Collantes Estevez: None declared, Jiménez Gómez Yolanda: None declared

Conclusion: Presence of atherosclerosis is associated with age, disease duration and radiographic damage in SpA. Age and structural damage especially in the cervical spine predicted a greater CV risk. Thus, it is important to identify these patients in order to maintain tight control and avoid development of CV disease.

WHAT IS THE IMPACT OF MRI ON THE PERFORMANCE OF THE ASAS CLASSIFICATION CRITERIA IN PATIENTS PRESENTING WITH UNDIAGNOSED BACK PAIN?

1Walter P. Maksymowych1, Raj Carmora2, James Yeung3, Jon Chan3, Liam Martin1, Sibel Aydin1, Dianne Mosher1, Ariel Masetto1, Stephanie Keeling1, Olga Zouinil2, Sherry Rohkar2, Joel Paschke1, Amanda Carapellucci2, Robert G. Lambert1, 1University of Alberta, Edmonton, Canada; 2CaRE Arthritis, Edmonton, Canada; 3McMaster University, Hamilton, Canada; 4James Yeung Rheumatology, Vancouver, Canada; 5Arts Health Center, Vancouver, Canada; 6University of Calgary, Calgary, Canada; 7University of Ottawa, Ottawa, Canada; 8University of Sherbrooke, Sherbrooke, Canada; 9Lawson Health Research Institute, London, Canada

Background

Several cohorts have reported the performance of the ASAS classification criteria in settings where clinical, radiographic, and MRI features have been simultaneously incorporated into the diagnostic evaluation in arriving at a gold standard for the testing of the criteria. MRI improves diagnostic precision but access is limited and it is therefore still important to understand how the criteria perform in a setting where diagnostic evaluation can be conducted sequentially before and after MRI assessment. We hypothesized that the ASAS criteria would demonstrate enhanced specificity when MRI is available due to enhanced diagnostic precision.
MAGNETIC RESONANCE IMAGING IN SYMPTOMATIC AXIAL SPONDYLOARTHRITIS

All patients

(-10 to +10 scale)

Subset of patients with MRI

(-10 to +10 scale)

axSpA and <-4 confidence >7 for diagnosis of axSpA

We aimed to test the impact of adding MRI to the diagnostic evaluation on the performance of the classification criteria in unselected patients referred with undiagnosed back pain who have presented with acute anterior uveitis (AAU), psoriasis, or colitis to their respective specialists.

Methods: Consecutive patients ≥45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA, and MRI evaluation is ordered per rheumatologist decision. The rheumatologist determines the presence or absence of axial SpA and the degree of confidence in the diagnosis (-10 (definitely not SpA) to +10 (definite SpA)) at 3 consecutive stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. We calculated the sensitivity and specificity of the ASAS criteria and the component imaging and clinical arms using the stage 2 and 3 diagnostic assessments by the local rheumatologist as gold standard.

Results: A total of 246 patients were recruited, 47.6% being diagnosed with axSpA (61.5% male, age 33.7 years, symptom duration 7.6 years, B27 positive 52.1%), after final diagnostic evaluation. Sensitivity/specificity of the ASAS criteria, imaging arm, clinical arm after stage 2 diagnostic evaluation for the entire cohort were 67.4/85.7%, 39.7/95.2%, 48.9/87.6%, respectively (Table). For the subset of 146 patients who had MRI and had diagnostic evaluation at both stage 2 (pre-MRI) and stage 3 (post-MRI), sensitivity of the criteria was greater but specificity was lower when tested against the stage 3 diagnosis. This was particularly apparent in the clinical arm.

Conclusion: The ASAS criteria were less specific when MRI assessment was added to the process of diagnostic evaluation, which could reflect rheumatologist over-interpretation of both clinical and radiographic findings in this population with higher pre-test probability of axSpA.

AB0727 MAGNETIC RESONANCE IMAGING IN SYMPTOMATIC BACK PAIN IN INFLAMMATORY BOWEL DISEASE: STRUCTURAL LESIONS AND HLA-B27 IMPROVE THE DIAGNOSTIC ACCURACY IN AXIAL SPONDYLOARTHRITIS

1Xavier Michelen-Vega1, 2Leticia Garcia-Montoya1, 2Gabriele De Marco1, 2Dennis Magonagne1, 2John Hamlin3, 2Christian Sellinger1, 2Helena Marzo-Ortega1, 2NIHR Leeds Biomedical Research Centre, LHT and LIARM, University of Leeds, Leeds, United Kingdom; 2Belfagio University Hospital (IDIBELL), Barcelona, Spain; 3Department of Gastroenterology, LHT, Leeds, United Kingdom

Background: Inflammatory bowel disease (IBD) related arthropathy may manifest as peripheral arthritis, dactylitis or enthesitis as well as inflammatory back pain (IBP) due to sacroiliac joint (SIJ) and/or spinal inflammation. HLA-B27 correlates with the presence of MRI determined SIJ bone marrow oedema (BMO) in axial spondyloarthritis (axSpA) and axial psoriatic arthritis (PsA) patients. The prevalence of HLA-B27 positivity is low in IBD and patients may already be on therapy that potentially modifies MRI spinal lesions at the time of imaging.

Objectives: To evaluate the utility of MRI to aid the diagnosis of axSpA in IBD patients with IBP and to explore the relationship of MRI abnormalities with HLA-B27 status.

Methods: Cross-sectional, retrospective audit of consecutive MRI scans of the SIJ and spine performed (2008-2018) in a large teaching hospital. All scans were requested in IBD patients presenting with IBP and clinical suspicion of axSpA. Demographic and clinical data were retrieved from the medical notes. Decision from the clinician whether the patient had axSpA related to the IBD was also recorded. MRI scans were scored by 2 readers using the semiquantitative Leeds Scoring System (BMO grade from 0 to 3). An overall score for inflammatory (sum of SIJ and Spine BMO scores) and structural lesions (sum of lesions per quadrant) was calculated.

Results: MRI scans from 119 IBD (Crohn’s n=82, ulcerative colitis n=31, and undifferentiated IBD n=6) patients were available for analysis. 63.9% were female, mean age 38.7 years at time of MRI with mean age of IBP onset 36.3 years. The majority (n=65/83, 78.3%) were HLA-B27 negative (missing data n=36). Thirty subjects were receiving biologic therapy for IBD. A summary of MRI findings (SIJ and spine) is shown on Table 1.

PREVALENCE AND SEVERITY OF CLINICAL AND IMAGING AXIAL Spondyloarthritides IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Tadashi Okano, Kentaro Inui, Koji Mandai, Yutaro Yamada, Yuko Sugioka, Osaka City University Graduate School of Medicine, Osaka, Japan

Background: Some patients with inflammatory bowel disease (IBD), such as ulcerative colitis (UC) and Crohn’s disease (CD), develop spondyloarthritis (SpA). Inflammatory back pain (IBP) is one of the most important signs of axial SpA. However, changes in conventional radiography take a long time to appear as typical changes, such as erosion, sclerosis, or ankylosis. Magnetic resonance imaging (MRI) is useful for assessing axial involvement. High-quality imaging modalities can detect the inflammatory condition in the joints and enthesis more sensitively than clinical assessment or conventional radiography.

Objectives: This study aimed to examine the clinical and imaging prevalence or severity of axial SpA in patients with IBD.

Methods: A total of 56 patients, including 39 with UC (19 males, 20 females) and 17 with CD (10 males, 7 females) were included. The Assessment of SpondyloArthritis International Society (ASAS) Expert Criteria were used to assess IBP. The criteria were fulfilled if at least four of the following questions were answered by “yes”: (1) did your back pain start when you were aged 40 or younger?; (2) did your back pain develop gradually?; (3) does your back pain improve with exercise?; (4) do you find that there is no improvement in your back pain when you rest?; and (5) do you suffer from back pain at night, which improves upon getting up? Image evaluation was performed blindly by two readers. Conventional radiography was evaluated by the modified Stoke AS Spine Score (mSASSS) in the spine and the Grade of modified New York criteria (mNY) in the sacroiliac joints. In MRI, spinal and sacroiliac joints were evaluated by the Spondylo-arthritis Research Consortium of Canada (SPARCc) score.

Results: Among the 56 patients with IBD, 21 had IBP by clinical examination and 11 had pain in the sacroiliac joints. In conventional radiography, the average mSASSS score was 8.9 in patients with IBP and 6.5 in patients without IBP (p = 0.257). Eleven patients had bilateral Grade 2 or unilateral Grade 3 of the mNY, and three (27.3%) of these patients had sacroiliac pain and eight (17.8%) did not have sacroiliac pain (p = 0.477). In spine MRI, nine (42.9%) patients with IBP and nine (25.7%) IBP patients without IBP had an SPARC score of > 2 (p = 0.184). In sacroiliac MRI, one (9.1%) patient with sacroiliac pain and 12 (26.7%) patients without sacroiliac pain had an SPARC score of > 2 (p = 0.216).

Conclusion: Even without clinical symptoms of SpA, significant inflammatory findings are detected by MRI. Imaging might be important, regardless of the presence or absence of clinical symptoms, in patients with IBD.

AB0729 ASSESSING THE DIFFERENCES IN TIMES TO GENERAL PRACTITIONER PRESENTATION AND DIAGNOSIS, AND OUTCOMES FOR AXIAL SpondyloArthritis PATIENTS IN DIFFERENT ETHNIC GROUPS

Ammanda Owusu-Agyei, Ayna Verdiyeva, Marian Chan. Luton and Dunstable University Hospital, Luton, United Kingdom

Background: Axial spondyloarthritis (axSpA) is a condition characterised by inflammatory back pain +/- extra-articular manifestations. There is a known delay to diagnosis1. Management includes phototherapy, non-steroidal anti-inflammatory drugs (NSAIDs) and biologic agents2. The Luton & Dunstable University Hospital, UK Rheumatology department looks after an ethnically diverse population of patients with the condition.

Objectives: The objectives of this study were to compare time from symptom onset to General Practitioner (GP) presentation, time from symptom onset to diagnosis, and response to treatment between different ethnic groups.

Methods: 124 patients with an axSpA diagnosis, according to the Assessment of SpondyloArthritis international Society (ASAS) criteria were used to analyse data. Results: The mean age was 44 years. 64 (64%) patients were male and 36 (36%) were female. 48 (48%) and 27 (27%) patients were HLA-B27 positive and negative respectively. HLA-B27 status was not available for 25 (25%) patients. Ethnicity breakdown showed 58 White British patients; 12 Pakistani; 7 White Other; 6 Bangladeshi; 5 White Irish; 5 Asian; 4 Indian and 3 Black Caribbean. There were 70 Caucasian (White British, etc...
Irish or Other) and 30 non-Caucasian patients. 49 patients (36 Caucasian and 13 non-Caucasian) had confirmed radiographic axial SpA. 17 patients (10 Caucasian and 7 non-Caucasian) had confirmed non-radiographic axial SpA.

For those presenting within 1 year of symptom onset, BASDAI data were available for 5 out of 7 Caucasian and 2 out of 5 non-Caucasian patients. The mean BASDAI decrease was 5.65 in non-Caucasian patients compared to 1.62 in Caucasian patients. For those presenting after 1 year of symptom onset, BASDAI data were available for 15 out of 26 Caucasian and 10 out of 19 non-Caucasian patients. Mean BASDAI decrease was 2.26 in non-Caucasian and 1.93 in Caucasian patients.

BASDAI data were available for 43 out of 70 Caucasian patients and 18 out of 30 non-Caucasian patients, regardless of time of presentation. The mean decrease in first measured BASDAI was smaller in Caucasian patients compared to non-Caucasian patients (Mean BASDAI decrease: 2.49 compared to 2.66).

Conclusion: There is a shorter mean time of symptom onset to GP presentation and diagnosis in non-Caucasian patients compared to Caucasians. There is a higher response to treatment in patients who present within one year of symptom onset. This may support the hypothesis that early diagnosis leads to better outcomes.

AB0730 RECLASSIFICATION INTO VERY HIGH CARDIOVASCULAR RISK AFTER CAROTID ULTRASOUND IN PATIENTS WITH AXIAL SPONDOLOARTHRITIS

Juan Carlos Quevedo-Abelado1, Javier Rueda-Goto2, Fernanda Genre3, Alfonso Corrales1, Vanessa Hernández-Hernández2, Esmeralda Delgado-Frias4, Sonia Peña Montelongo5, Carlos Rodríguez-Lozano1, Miguel A. González-Gay4, Iván Ferraz-Amaro6, Hospital Universitario de Gran Canaria Dr. Negrín, Division of Rheumatology, Las Palmas de GC, Spain; 2Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, IDIVAL, Santander, Spain; 3Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, IDIVAL, Division of Rheumatology, Santander, Spain; 4Hospital Universitario de Canarias, Division of Rheumatology, Tenerife, Spain

Background: Axial spondyloarthritis (a-SpA) are associated with an increase in cardiovascular (CV) morbidity and mortality. Subclinical atherosclerosis, in the form of carotid plaques, is more frequent in this patients than in healthy controls. How the presence of carotid plaque affects the reclassification of CV risk in a-SpA has not been studied before. Besides, it is not known if this reclassification can be explained by characteristics related to the disease.

Objectives: To analyze whether the reclassification of CV risk after performing carotid ultrasound is more frequent in this patients compared to controls and whether this reclassification can be explained by characteristics related to the disease such as activity, functional damage or morphology scores.

Methods: Study of 343 a-SpA patients according to ASAS criteria and 177 controls with no previous history of CV events, diabetes or chronic kidney disease. The clinical characteristics and risk profile were analyzed in patients and controls by SCORE. The presence of plaques and intima-media thickness (cIMT) was determined by carotid ultrasound. The differences in the presence of reclassification between patients and controls and the factors associated with this in patients with a-SpA, were analyzed by multivariate regression analysis.

Results: Patients with a-SpA compared to controls disclosed a higher presence of hypertension (p<0.000), dyslipidemia (p<0.000) and smoking (p<0.000). Consequently, patients also showed a significantly higher SCORE than controls (0.6 IQR [0.1-2.0] vs. 0.1 [0.0-0.4], p=0.000). The presence of carotid plaque (36% vs. 25%, p=0.010) and cIMT (0.641 ± 0.121 vs. 0.602 ± 0.115 mm, p=0.001) were higher in patients compared to controls. Moreover, the possibility of being reclassified into very high-risk category after ultrasound was superior in patients (34% vs 25%, p=0.037). The possibility of being reclassified was associated, both in patients and controls, with an older age, male sex, abdominal circumference, hypertension and dyslipidemia. Contrary, body mass index and...
The association between periodontal disease and rheumatoid arthritis is well-recognized [1]. Porphyromonas gingivalis is probably the link between the two conditions. On the other hand, the data on the

After 2 y FUP, pts with AS still prevailed among men (table 2). TSS increased in both groups: in female pts from 3 [2; 4] to 4 [3; 6] (p<0.05), in male pts from 4 [4; 6] to 5 [5; 6] (p<0.05). But, however, in female pts TSS remained less than in male pts over 2 y FUP (table 2). CRP level still was higher in male pts (p<0.05). Progression from non-radiographic axSpA to AS between male and female pts didn’t differ - 5 (15.5%) vs 6 (17.2%), p>0.05 respectively, after 2 y FUP. In both groups rate of SI radiographic progression after 2 y decreased (p<0.05) and did not differ between them.

</tbody>
</table>

Conclusion: 1. Rate of SI radiographic progression in male and female pts with axSpA in the first 2 y from the onset of disease is higher than in further. 2. Rate of SI radiographic progression between male and female pts with axSpA is not differ. 3. Male pts with AS more than female pts in CORSAR cohort. It can be explained that male pts had higher CRP level than female pts.

**AB0731**

**RATE OF SACROILIITIS RADIOGRAPHIC PROGRESSION IN MALE AND FEMALE PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS**

Daria Rumiantceva, Tatiana Dubinina, Anastasiya Demina, Shandor Erdes. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** According recent studies radiographic progression (mSASSS) of male patients (pts) with ankylosing spondylitis (AS) higher than in female pts [1, 2].

**Objectives:** To compare radiographic progression of early axial spondyloarthrits (axSpA) in male and female pts over 2 years (y) of follow-up (FUP).

**Methods:** the research included 68 pts with early axSpA (ASAS criteria, 2009) from Moscow CORSAR cohort with disease duration <5 and age onset <45 years. The mSASSS index is not suitable for assessing radiographic progression at an early stage of axSpA, because at that stage of the disease, the cervical and lumbar spine have practically no damage. Sacroiliac joints (SIJ) radiographs and CRP performed at baseline and after 2 y of FUP. Radiographic SIJ stages scored according to the modified New York criteria grading system. To assess the progression in SIJ, total stage of sacroiliitis (TSS) calculated, by determining sum score stages of sacroiliitis (SI) in the left and right SIJ (from 0 to 8 points).

The following formula used to calculate the rate of SI radiographic progression:

\[
\text{Rate of SI radiographic progression} = \frac{TSS^2 - TSS^3}{\text{FUP}}\times12
\]

\*TSS - initial total score stages of SI, TSS - FUP total score stages of SI.

Pt's mean age was 28.5 (5.8) y, average disease duration - 24.1 (15.4) mo, 63 (92.6%) pts were HLA-B27 positive.

**Results:** Initially, among men there were more pts with AS than among women and they had a higher TSS and higher CRP level (table 1). Rate of SI radiographic progression in male and female pts with axSpA at baseline did not differ.
association between periodontal disease and ankylosing spondylitis are still relatively limited.

**Objectives:** The current systematic review and meta-analysis was conducted with the aims to identify all published studies that investigated the risk of ankylosing spondylitis among patients with periodontal disease versus individuals without periodontal disease and summarize their results together to better characterize this relationship.

**Methods:** Two investigators independently searched for published studies indexed in MEDLINE and EMBASE database from inception to October 2018 using the search strategy that included the terms for periodontal disease and ankylosing spondylitis. The inclusion criteria are as follows: (1) Case-control or cohort studies that compared the risk of ankylosing spondylitis between patients with periodontal disease versus individuals without periodontal disease (2) Individuals without periodontal disease were used as comparators in cohort studies while individuals without ankylosing spondylitis were used as controls in case-control studies and (3) Effect estimates and 95% confidence intervals (CI) of the association of interest were reported. Point estimates and standard errors from each study were extracted and combined together using the random effect, generic inverse variance technique of DerSimonian and Laird.

**Results:** Of 554 retrieved articles, a total of 7 case-control studies with 41,575 participants met the eligibility criteria and were included into the meta-analysis. The risk of ankylosing spondylitis among patients with periodontal disease was significantly higher than individuals without periodontal disease with the pooled odds ratio of 2.16 (95% CI, 1.48–3.16). The statistical heterogeneity was low with an I² of 45%. The forest plot of this meta-analysis is shown as Abstract AB0732 figure 1. Funnel plot was created for evaluation of publication bias. The plot was relatively symmetric which did not suggest the presence of publication bias in favor of studies with positive results.

**Conclusion:** A significantly increased risk of ankylosing spondylitis among patients with periodontal disease was demonstrated in this study. This observation may provide more understanding of the pathogenesis of this chronic inflammatory arthritis.

**AB0733 AN EYE FOR THE HEART: ARE RETINAL VASCULAR PARAMETERS ASSOCIATED WITH CARDIOVASCULAR DISEASE IN ANKYLOSING SPONDYLITIS?**

1Giannes van Bentem1, Milad Baniaamam2, Buki Kinaci3, Aled van de Kreeke4, Merve Kocyigit1, Erik Serné4, Michael Nurmohamed1,2, Frank Verbraak3, Irene van de Horst-Bruinsma1.

**1Amsterdam Rheumatology and Immunology Center, location Amsterdam University Medical Center, VUMc, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology Center, location Reade, Amsterdam, Netherlands; 3Amsterdam University Medical Center, location VUMc, Ophthalmology, Amsterdam, Netherlands; 4Amsterdam University Medical Center, location VUMc, Internal medicine, Amsterdam, Netherlands**

**Background:** Chronic systemic inflammatory in patients with ankylosing spondylitis (AS) contributes to the development of cardiovascular disease (CVD). Microvascular changes are thought to precede clinically overt CVD and its early recognition could improve timely treatment. The microvascular function of the retina and fingertips are easily accessible for non-invasive visualization. Furthermore, previous studies have shown an association between CVD and respectively retinal morphology and digital microvascular function (fingertips), in patients without rheumatic diseases. The retinal and digital vasculature could provide an unique opportunity to recognize early signs of CVD in AS patients.

**Objectives:** To investigate whether retinal vascular parameters and digital microvascular function in AS patients are associated with the 10 year CVD risk.

**Methods:** Cross-sectional study in AS patients (diagnosis according to modified New York criteria) between 50-75 years without a history of diabetes mellitus or cerebrovascular disease. Consecutive patients were recruited consecutively from the Rheumatology outpatient clinic of the Amsterdam UMC, location VUMc and Reade. Patient characteristics, CVD (risk factors), disease duration/activity (ASDAS), C-reactive protein and lipid profile were assessed. The digital microvascular function (the reactive hyperemia index, RHI) was tested through endo Peripheral Arterial Tone measurement at the finger tips (EndoPAT). Retinal vascular parameters were assessed through fundus photography, and identified with Singapore I Vessel Assessment (SIVA) software: central retinal artery and vein equivalent (CRAE, CRVE), arteriovenous ratio (AVR), curvature tortuosity arterioles and venules (cTOArTa, cTOArTv), fraxial dimension of arteries and venules (FiDia, FiDIV). SIVA parameters were reported as continuious values. The Framingham risk score (FRS) was calculated and classified based on the 10 years CVD risk (low risk <10%, intermediate risk 10–20%, high risk >20%). Linear regression analyses were used to determine the association between the FRS categories and retinal parameters or digital microvascular function (RHI), correcting for age and disease duration.

**Results:** Fifty-three AS patients were included (age 60±6 years, 55% female, 74% HLA-B27 positive, disease duration 35 years ±13, ASDAS 2.3±1.0). Fifty-five% was currently treated with NSAIDs and 47% with a TNF inhibitor. Based on the FRS, 36% had a high risk of CVD in the next 10 years, 42% an intermediate and 12% a low risk. In multivariable analyses, patients with an intermediate and high risk of CVD (FRS) had a significantly lower diameter of the central retinal artery (CRAE; p<0.01 for both risk groups) and arteriovenous ratio (AVR; only for high risk; p=0.03) as compared with patients with a low risk. There was no association between the RHI and the cardiovascualr risk.

**Conclusion:** This study suggests an association between the 10 years CVD risk and the morphology of the retinal arterial vessels in older AS patients (>50 years). This is in accordance with some other studies reporting on atherosclerosis in the general population. No association was found between CVD risk and microvascular function in the fingertips. In conclusion, the measurement of retinal vascular parameters might be a new technique to detect early stages of atherosclerosis in AS.

**AB0734 CHANGES IN HEIGHT AND BODY MASS INDEX OVER TIME IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS, TREATED WITH TUMOR NECROSIS FACTOR-α INHIBITORS**

1Elizaveta Vasilenko1, Olga Nikolaeva1, Anna Dadalova1, Ekaterina Gaydikova2, V Macurov1, Innia Gaydikova1, 1North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, St. Petersburg, Russian Federation; 2TITMO University, St. Petersburg, Russian Federation

**Background:** Monitoring of height and body mass index (BMI) is an important for patients with axial spondyloarthritis (axSpA). Reduction of height not only reflects spine remodeling, but affects various indexes, such as BMI (fig.1). However, BMI calculations assume that the adult patient’s height is a constant. Therefore these calculations may be inaccurate in patients whose height is susceptible to decrease.
Objectives: To evaluate changes in height and BMI over time in patients with axSpA, treated with tumor necrosis factor-α inhibitors (TNF-α-i).

Methods: The study included 51 patients with axSpA (ASAS criteria 2009). All the patients were treated with TNF-α-i for one and 4 years. The patient's height and weight measured before the treatment. Only patients with stable weight (variability ± 2.0 kg from baseline) were included in the study.

Results: Mean age of axSpA patients at baseline was 40.22±13.51, 34 (74.5%) were male, disease duration 12.77±6.82, duration of TNF-α inhibitors treatment 5.64±2.21 years, all the patients had inactive disease. In 19 patients with axSpA diagnostic delay was 8 years. Patients' height varied between 1.55–1.92 m (average height 1.73±0.07 m), Male's mean height was 1.78±0.05 m, women's – 1.63±0.05 m. Height decrease over time in patients with AxSpA was 3.74±1.83 cm (from 1.0 to 15.0 cm). Maximal decrease in height was shown in patients with 10 years after the first symptoms emerged. Mean weight in patients who had height loss was 79.75±12.7 kg. Among patients who had decrease of height and stable body mass the difference between BMI at subsequent measurement and the time of treatment initiation (ΔBMI) was 1.15 kg/m²; BMI at baseline – 26.25±3.34 kg/m², over time of observation BMI – 27.39±3.38 kg/m².

Conclusion: Height loss in axSpA is significant even in patients with inactive disease. Height loss affects BMI calculation that could lead to overestimation of cardiovascular risk, obesity and could change all of the BMI-dependent areas. Correction of BMI calculation for the patients with unstable height and stable body mass is needed.

AB0734C REMISSION IN AXIAL SPONDYLOARTHRITIS: A DELPHI-METHOD QUESTIONNAIRE AMONG EXPERTS TO EVALUATE THE AVAILABLE ASSESSMENT TOOLS TO MEASURE DISEASE ACTIVITY AND TO DEVELOP A CONSENSUS DEFINITION OF REMISSION

Background: Several definitions of remission in axial spondyloarthritis (axSpA) have been proposed based on the available disease activity assessment tools, but to date we lack a universally accepted definition of remission for the development of clinical trials or routine clinical practice.

Objectives: To explore the degree of agreement that exists among the experts managing patients with axSpA regarding the assessment tools available to evaluate disease activity in these patients and to develop a consensus definition of clinical remission in axSpA.

Methods: As a consensus method, we followed the modified Delphi methodology. A scientific committee developed 80 statements that were submitted in 2 rounds (in September and October 2018, respectively) to a panel of 152 rheumatologists from 27 countries.

Conclusion: Bony bridge in LV is not only more developed and correlated with ankylosis in FJ, but also more correlated with limitation of anterior lumbar flexion than that in AV. We suggest bony changes of LV should be also included in radiographic score system for more sensitive detection of radiographic progression in AS.

Disclosure of Interests: None declared

Results: Agreement was reached for 56 of the 80 proposed items (70%). The panelists concluded that although a definition of remission in axSpA is not currently available, there is consensus that it is possible to achieve remission in this disorder. There was agreement that the definition of remission in axSpA should include: pain, fatigue, functional impairment, mobility, extra-articular manifestations, peripheral involvement, joint inflammation, disease activity, laboratory tests, quality of life, need for treatment, progression of the disease, and both physician and patient global assessments. It is recommended that a therapeutic goal when starting treatment in patients with axSpA, the ideal objective being remission, but low disease activity (LDA) may also be acceptable as an alternative objective, being ASDAS the preferred tool to assess disease activity with cut-off values of < 1.3 for remission and ≤ 1.3 to < 2.1 for LDA. A proposal for clinical remission was reached for the first time at the meeting and is based on the ASDAS cut-off value associated to the absence of extra-articular (psoriasis, uveitis, inflammatory bowel disease) and peripheral (arthritis, enthesitis, dactylitis) activity, as well as the absence of inflammation assessed by the normalization of CRP levels and absence of radiographic progression.

Conclusion: This work offers consensus recommendations and a proposal of clinical remission that may be useful in the management of patients with axSpA.

Psoriatic arthritis

Ab0735 SAFETY AND EFFECTIVENESS OF USTEKINUMAB IN PSORIATIC ARTHRITIS. A MULTICENTRIC STUDY

Method: Retrospective and multicentric study. Epidemiological and clinical data were collected through the electronic medical record of all patients with PsA who started UST due to rheumatological indication in 14 hospitals of Catalonia and the Balearic Islands (Spain).

Results: 152 patients were included, 116 (76.3%) with 45mg and 36 (23.8%) with 90mg. 55.9% were women, mean age 54.79 (12.5) years and mean disease duration 209 months. 132 patients (87%) had oligo (30.3%) or polyarticular involvement (56.6%). 26.8% had enthesitis and 36.2% dactylitis. 48.0% had erosions, 35.4% had previous surgery, and 39 of them (38.8%) had received 2 or more. 54.6% of the patients were taking DMARDs and 39.5% glucocorticoids. The baseline DAS 28 was 3.97 (1.45), C reactive protein (CRP) was 2 mg/dl (2), SJC was 4.0 (5.4), and PASI was 6.5 (8.4). There were no significant differences in clinical and epidemiological data between patients at 45 or 90 mg except in obese patients (58.4% in 90mg vs 40% in 45mg, p < 0.038). Overall, there was a significant decrease in DAS28, SJC, TJC and PASI in the first month of treatment, with more pronounced improvement in skin (PASI and BSA) than in joints outcomes, where the curves reached a plateau at 6 months. There were no significant differences between joint and/or skin outcomes between 45 and 90 mg doses.

Conclusion: This analysis demonstrates that UST, administered to PsA patients in a routine clinical care setting, is safe and effective in improving skin and joint outcomes. 61.2% of the patients continued with the treatment after an average of 19m of follow-up. Joint and skin outcomes reached significant differences from the first month. The efficacy seems faster in those patients with fewer lines of previous biological therapies. One third of the patients interrupted the therapy due to joint inefficacy.

Ab0736 GENDER INFLUENCE ON TREATMENT EFFECTIVENESS IN PSORIATIC ARTHRITIS

Diego Benavides Chamarro Plasencia, Victoria Navarro-Compañ, Alejandro Villalba, Diana Peiteado, Gemma Bonilla, Elisa Fernández, Alejandro Balsa. Hospital La Paz, Rheumatology, Madrid, Spain

Background: Gender has been lately suggested as influential in the response to treatment with biological drugs in spondyloarthritis, such as psoriatic arthritis (PsA). However, data about the association between gender and treatment response in axial PsA (axPsA) or peripheral PsA (pPsA) are scarce.

Objectives: To analyze the association between gender and treatment response to biological therapy in patients with axPsA and pPsA.

Methods: An observational cohort study was conducted, prospectively collecting data from 108 patients treated with biological therapeutics (01/2014 and 7/11-2017) from 2002-2018. Patients were divided into two groups according to their clinical predominant manifestation: axPsA or pPsA. Disease activity indexes (ASDAS and BASDAI for axPsA and DAPSA and DAS28 for pPsA) were collected before starting drug and 6 months later (baseline and 6m visit, respectively). Low disease activity (LDA) was defined as ASDAS <2.1 or BASDAI <4 (axPsA) or 50% in DAPSA (DAPSA50) or DAS28 > 12. First, the frequency of male- and female-patients achieving LDA and clinical improvement at 6m were compared using Fisher test, separately for axPsA and pPsA. Second, the association between gender and each of the clinical indexes was analyzed using logistic regression models adjusted for confounders (age, disease duration, previous biologics, smoking habit, body mass index (BMI), baseline DMARDs and baseline disease activity (ASDAS or BASDAI for axPsA or DAPSA or DAS28 for pPsA).

Results: Out of 108 included patients, 55 (51%) had predominant axPsA and 54 (49%) pPsA. In the group of axPsA, 35 (64%) were males, 33 (60%) were non-smokers, 33 (60%) had a BMI ≥ 25, with mean (SD) baseline disease activity of ASDAS: 3.3 (1.0) and BASDAI: 5.4 (2.0). Frequency of patients achieving clinical response was higher in males than females (LDA: 74% vs 37%; p=0.02, respectively) (Table 1). After adjusting for confounders, male gender was significantly associated with higher probability of achieving LDA (ASDAS OR=4.4; p=0.03 and BASDAI OR=6.0; p=0.01), and improvement (dASDAS: OR=4.8; p=0.04 and DAPSA50: OR=5.19; p=0.03). In the group of pPsA, 20 (37%) were
ACHIEVEMENT OF RAPID3 NEAR REMISSION OR LOW DISEASE SEVERITY IS ASSOCIATED WITH RESIDUAL LEVELS OF ARTICULAR AND EXTRA-ARTICULAR MANIFESTATIONS OF ACTIVE PSORIATIC ARTHRITIS IN SUBJECTS TREATED WITH APREMILAST

1Martin Bergman, M Elaine Husni1, Yusuf Yazici2, Laura C. Coates4, Sven Richter5, Michele Brunori5, Lichen Teng5, Arthur Kavanaugh6.

Background: The Routine Assessment of Patient Index Data 3 (RAPID3) is an outcome measure of disease activity widely used in the USA as part of routine care and is derived from patient self-reported measures. Health Assessment Questionnaire-Disability Index (HAQ-DI) or multidimensional HAQ [MDHAQ], Pain visual analog scale [VAS] and Patient’s Assessment of Disease Activity [PtGA] VAS. However, the lack of more objective, traditional physician assessments, such as joint counts, may lead to residual active disease that will be missed.

Objectives: To examine trajectories for improvement in RAPID3 score over time and PsA manifestations not measured specifically by RAPID3 in subjects achieving RAPID3 near remission (REM) or low disease severity by Week 52.

Methods: Pooled analyses of the phase III PALACE 1, 2 and 3 studies were performed for subjects assigned to receive APR 30 mg twice daily (BID) at baseline (BL). Subjects with available scores on RAPID3 components (PtGA, VAS and HAQ-DI) at baseline (BL) and Week 52 (near REM: <3; low: >3 to ≤6; moderate: >6 to ≤12; and high: >12 to 30). Mean RAPID3 scores were assessed from BL through Week 52. Other measures of PsA disease activity were reported longitudinally by RAPID3 category at Week 52.

Results: The analysis included 376 APR subjects, with 42 with near REM and 42 with low severity at Week 52. Overall, mean RAPID3 trajectories improved overtime with greater mean improvements observed for those achieving RAPID3 near REM and low disease severity by Week 52. At a mean level, subjects in moderate RAPID3 at baseline were associated with achievement of RAPID3 near REM or low disease severity by Week 52 with APR (Figure). Many subjects who achieved RAPID3 near REM or low disease severity at Week 52 showed improvements in articular and extra-articular disease activity, although not all manifestations were controlled at Week 52 (Table); mean TJC was higher than expected in subjects achieving RAPID3 targets at Week 52 and there was no association between low mean RAPID3 and mean Psoriasis Area and Severity Index (PASI) scores.

Conclusion: At a mean level, subjects in moderate RAPID3 at baseline were associated with achievement of RAPID3 near REM or low disease severity with APR by Week 52. Achievement of RAPID3 targets was associated with improvement, but not necessarily control, of all articular and extra-articular manifestations. Complementing the RAPID3 measure with joint and skin assessments may help to evaluate achievement of treatment goals in clinical practice.
DUAL NEUTRALISATION OF INTERLEUKIN (IL)-17A AND IL-17F WITH BIMEKIZUMAB IN MODERATE-TO-SEVERE PLAQUE PSORIASIS: 60-WEEK RESULTS FROM A RANDOMISED, DOUBLE-BLINDDED, PHASE 2B EXTENSION STUDY

1Andrew Blauvelt*, Kim A. Papp2, Joseph F. Merola3, Alice B. Gottlieb4, Tatiana Korotaeva1. 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Clinical Hospital of the KKVD MH KK, Krasnodar, Russian Federation; 3Central State Medical Academy, Moscow, Russian Federation; 4Icahn School of Medicine at Mount Sinai, Department of Dermatology, New York, United States of America; 5UCB Biosciences Inc., Raleigh, United States of America; UCB Pharma, Brussels, Belgium; Dermatology Centre, Salford Royal Hospital, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background: Psoriasis is a chronic, systemic, immune-mediated inflammatory disease associated with prominent skin manifestations. One in four patients with psoriasis also has psoriatic arthritis1. In skin disease preceding joint manifestations in most patients2. Interleukin (IL)-17F shares structural homology and pro-inflammatory function with IL-17A. Preclinical and early clinical data support dual neutralisation of IL-17F, together with IL-17A, as a novel targeting approach for the treatment of immune-mediated inflammatory diseases. Bimekizumab, a monoclonal antibody that potently and selectively neutralises both IL-17A and IL-17F, is in development for the treatment of psoriasis, psoriatic arthropathy and ankylosing spondylitis3,4,5. In the 12-week BE ABLE 1 study (NCT02905006), bimekizumab provided rapid and substantial clinical improvements in patients with moderate-to-severe plaque psoriasis, with a safety profile consistent with previous bimekizumab studies.

Objectives: The objectives of this Phase 2b extension study (BE ABLE 2; NCT03010527) were to assess the long-term safety and efficacy of bimekizumab every four weeks for an additional 48 weeks (60 weeks' total exposure).

Methods: BE ABLE 1 responders (≥90% reduction in Psoriasis Area Severity Index (PASI90) at Week 12) receiving placebo or bimekizumab 64mg, 160mg, 160mg (320mg loading dose [LD]) remained on the same dose; non-responders (≤PASI90 at Week 12) were re-assigned from placebo/bimekizumab 64mg to 160mg or from 160mg/160mg (LD) to 320mg. Patients previously receiving bimekizumab 320mg/480mg received 320mg. The primary variable was the exposure-adjusted incidence rate (EAIR) of treatment-emergent adverse events (TEAEs); efficacy assessments were secondary.

Results: 217 patients were enrolled. Across all doses, BE ABLE 1 responders generally maintained complete or almost complete skin clearance for up to an additional 48 weeks: PASI90: 80–100%, non-responders imputation (93–100%, observed); PASI100: 70–83% (80–96%); Investigator Global Assessment: 78–100% (98–100%). PASI100 was achieved by 33–76% (40–82%) of non-responders (Week 48). EAIR of TEAEs was 206.1/100 patient-years (n=184/217 [85%]). EAIR of serious TEAEs was 6.2/100 patient-years (n=15/217 [7%]); no serious TEAE was reported by ≥1 patient. The most frequent TEAEs were oral candidiasis and nasopharyngitis. No cases of suicidal ideation/behaviour, major adverse cardiac events, or inflammatory bowel disease were reported. No new safety findings were observed.

Conclusion: Nearly all BE ABLE 1 responders completing 60 weeks of bimekizumab treatment maintained complete or almost complete skin clearance, with a safety profile consistent with previous studies.

AB0738

THE PREVALENCE OF PSYCHOLOGICAL DISORDERS IN PATIENTS WITH SEVERE PSORIASIS WITHOUT PSORIATIC ARTHRITIS IN CLINICAL PRACTICE: DATA FROM A SINGLE DERMATOLOGICAL SETTING

1Marka Chumakutova, 2Alkes Khotko, 2Larisa Kruglova, 3Svetlana Gliukhova. 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Clinical Hospital of the KKVD MH KK, Krasnodar, Russian Federation; 3Central State Medical Academy, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) and Psoriasis (PsO) are associated with different psychological disorders. Depression is a risk factor for development of PsA among PsO patients (pts). Diagnosis of PsA in dermatological practice is still problematic. The prevalence of psychological disorders in patients with severe PsO without PsA is limited in the Russian Federation.

Objectives: To study the prevalence of anxiety, depression and fatigue in pts with severe PsO without PsA in a single dermatological setting.

Methods: 99 unselected pts (male-23/female-76) with severe plaque PsO, mean age 45.82±14.04 years, BSA 56.35±9.11%, PASI 22.50 ± 5.13 were included. PsO was diagnosed by the CASPAR criteria. Anxiety, depression and fatigue were identified by the Hospital Anxiety Scale (HADS-A), HADS-Depression (HADS-D) and Functional Assessment of Chronic Illness Therapy (FACIT) (points) accordingly. The HADS-A/HADS-D was defined as normal - 0-7; presence of disorders - 8-10; psychiatric morbidity >11 points, accordance FACIT 43.6±9.4 matched with healthy control. The lower the level of FACIT corresponded to higher fatigue. The number of pts with FACIT>30 were calculated. All pts were treated with different synthetic DMARDs, mostly Methotrexate (subcutaneous 15-20 mg every week), biological DMARDs according local therapy according

\[ \text{DO} \text{I}: 10.1136/annrheumdis-2019-eular.1860 \]

\[ \text{DO} \text{I}: 10.1136/annrheumdis-2019-eular.4166 \]
to the national guidelines. Mm%, chï2, i-test were performed. All p<0.05 were considered to indicate statistical significance.

**Results:** 20 out of 99 pts (20.2%) had PsA. In all group mean HADS-D/ HADS-A/FACIT were 2.59±3.88/4.61±5.54/4.47±5.61 accordingly. In PsO pts with or without PsA presence of disorders/psychiatric morbidity by HADS-D/A/FACIT were seen totally in 20 out of 79 pts (25.3%)/in 2 out of 20 pts (10%) accordingly (chï2, p=0.24). No significant difference were found between groups. In PsO pts without/with PsA presence of disorders/psychiatric morbidity by HADS-D were seen totally in 20 out of 79 pts (25.3%)/in 2 out of 20 pts (10%) accordingly (chï2, p=0.025). In PsO pts without/with PsA presence of disorders/psychiatric morbidity by HADS-D/A/FACIT were seen in 2 out of 79 pts (2.53%)/in 2 out of 20 pts (10%). No significant difference were found between groups (chï2, p=0.17).

**Conclusion:** In our real dermatological clinical practice cohort of pts with severe PsO subclinical and clinical anxiety and depression were detected in about 30% of cases. This fact should be taken into account for the early detection of pts at risk for developing PsA.

**AB0740 USE OF SECUKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS: IMPACTS OF COMBINATION WITH METHOTREXATE**

'Denis Choquette', Louis Bessette, Loïc Choquette Sauvageau, Isabelle Ferdinand, Paul Harouei, Frédéric Massicotte, Jean-Pierre Pelletier, Jean-Pierre Raynauld, Marie-Anaïs Rémillard, Diane Sauvageau, Édith Villeneuve, Louis Coupal. *Institut de Recherche en Rhumatologie de Montréal (IRRM)*, Rhumatologie, Montréal, Canada; **Centre de l’Ostéoporose et de Rhumatologie de Québec** (CORQ), Rhumatologie, Québec, Canada

**Background:** Secukinumab (SECU) is a human IgG1 monoclonal antibody that binds to the protein interleukin-17A approved for the treatment of psoriasis, ankylosing spondylitis, and psoriatic arthritis (PsA). Recent presentations data suggest that combination with methotrexate (MTX) in patients with PsA may not be as necessary as in rheumatoid arthritis as it improves neither efficacy nor sustainability (1,2,3,4).

**Objectives:** This analysis describes the use of SECU with or without MTX.

**Methods:** The data of patients with psoriatic arthritis seen since January 1. 2016 at the Institute de Recherche en Rhumatologie de Montréal (IRRM) and the Centre de l’Ostéoporose et de Rhumatologie de Québec (CORQ) were extracted from the Rhumadatab® clinical database and registry on January 7, 2019. Selected patients initiated SECU either without (MTX-) or with MTX (MTX+). The collected data include baseline characteristics (socio-demographic variables, concomitant and past medication, comorbidities and the Charlson comorbidity index (CCI)), variables measured over time (laboratory test results, patient and physician-reported outcomes, and disease activity measures such as minimal disease activity (MDA), CDAI and DAS28(4-ESR) and persistence data (treatment duration, reason for cessation). The groups were compared to identify potential confounder, and persistence data were analyzed using Kaplan-Meier and proportional hazard methods.

**Results:** A total of 96 patients were prescribed SECU since January 1, 2015. Of those, 49% (n=47) treated with MTX. No significant differences in baseline (at treatment initiation) were observed between the MTX+ and MTX- groups. Average age at treatment initiation was 52.4 (standard deviation=11.3) and 53.7 (13.4) in the MTX+ and MTX- groups respectively. Women represent 45% and 55% of these groups, and the average body mass index was 29.9 (6.2) and 28.1 (6.0) kg/m². Patient global, pain and fatigue assessments, made on a visual analogue scale ranging from 1 to 10, were 4.9 (2.6), 5.3 (2.9) and 4.3 (2.9) in the MTX+ group and 6.3 (2.2), 6.9 (2.1) and 6.5 (2.9) in the MTX- group. Among the 38 (40%) patients ceasing therapy, the principal reason for cessation was “inefficacy” (MTX+: 15/17 (88%) vs MTX-: 15/21 (71%)). Patients remaining on treatment at last follow-up had an average treatment duration of 1.7 (0.8) and 1.5 (0.7) years. The improvement in CDAI, HAQ and the percentage of patients reaching MDA are similar for both groups. No difference in retention was observed between the MTX+ and MTX- groups (log-rank p=0.4867). These results remain unchanged when we adjust for age at treatment initiation, gender, disease duration, and comorbidities (Charfon comorbidity index).

**Conclusion:** Combining MTX to SECU does not improve its sustainability over time. Efficacy was also the same for both cohorts.

**AB0741 ACHIEVEMENT OF CDAPS A LOW DISEASE ACTIVITY OR REMISSION IS ASSOCIATED WITH CONTROL OF ARTICULAR AND EXTRA-ARTICULAR MANIFESTATIONS OF ACTIVE PSORIATIC ARTHRITIS IN SUBJECTS TREATED WITH APRAMILIST**

‘Lauren C. Cotiles’, Philip J. Mease, Frank Behrens, Ana-Maria Oteiza, Alexis Ongé, Michele Brunori, Lichen Teng, Benoît Guerette, Josef S. Smolen. *Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*; **Swedish Medical Center and University of Washington School of Medicine, Seattle, United States of America**; **Division of Rheumatology, Goethe University and Fraunhofer Institute IME-TMP, Frankfurt, Germany**; **Johns Hopkins Arthritis Center and Johns Hopkins University School of Medicine, Baltimore, United States of America**; **Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States of America**; **Celgene Corporation, Summit, United States of America**; **Medical University of Vienna, Vienna, Austria

**Background:** Therapeutic targets for psoriatic arthritis (PsA) include the achievement of remission (REM) or low disease activity (LDA), measured by the Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA [0-154]), a composite of swollen and tender joints counts (SJC and TJC), Patient’s Assessment of Pain (PAP) and Patient’s Global Assessment of Disease Activity (PGA).

**Objectives:** We examined the trajectories for improvement in cDAPSA, its core components and PsA domains in subjects achieving REM or LDA, patients not meeting cDAPSA among subjects achieving CDAPS A REM or LDA by Week 52.

**Methods:** Pooled analyses of the phase III PALACE 1, 2 and 3 studies were performed for subjects assigned to receive apremilast (APR) 30 mg twice daily at baseline (BL). Subjects with cDAPSA components available at baseline (BL), measured on a 7-point scale ranging from 0 to 6 (0=inactive to 6=very active) were included and grouped according to the cDAPSA categories reached at Week 52 (REM: ≤4; LDA: >4 to ≤13; moderate disease activity: >13 to ≤27; high disease activity: >27). We then traced their mean cDAPSA trajectory from BL to Week 52.

**Results:** No differences in core PsA domains, speakers reported longitudinally by cDAPSA category reached at Week 52.
Results: A total of 375 APR subjects were included in the analyses. Achievement of REM or LDA by Week 52 was associated with lower mean cDAPSA at BL, and these subjects had continuous improvements in disease activity from BL to Week 52 (Figure). Among subjects who achieved REM/LDA by Week 52, more were classified as having LDA (mean cDAPSA: 8.5) or moderate disease activity (mean cDAPSA: 16.6), respectively, at Week 16. Furthermore, subjects who achieved REM or LDA by Week 52 showed early improvement, with no/mild articular and extra-articular disease activity by Week 52 with APR (Table).

Conclusion: In the subgroup of subjects who achieved cDAPSA REM or LDA, early improvement was seen in disease activity by Week 16 and sustained to Week 52 with continued treatment. Subjects achieving cDAPSA REM or LDA exhibited no or mild disease activity in enthesitis, dactylitis, function and skin psoriasis by Week 52.

AB0742 ACHIEVEMENT OF PASDAS LOW DISEASE ACTIVITY AND VERY LOW DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH CERTOLIZUMAB PEGOL OVER 4 YEARS AND THE OVERLAP WITH DAPSA AND MDA DISEASE ACTIVITY TARGETS

1Laura C. Coates, Joseph F. Merola, Oliver FitzGerald, Arthur Kavanaugh, Alice B. Gottlieb, William Tillett, Lars Bauer, Bengt Hoepken, Tommi Nummela, Philip J. Mease, Philip Hellkell, Désirée van der Heijde,11 NuFField Orthopaedic Centre, Oxford, United Kingdom; 2Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States of America; 3St Vincent’s University Hospital and Conway Institute for Molecular Research, University College Dublin, Dublin, Ireland; 4Division of Rheumatology Allergy and Immunology, UC San Diego School of Medicine, La Jolla, CA, United States of America; 5Department of Dermatology, ICAhn School of Medicine at Mt Sinai, New York, NY, United States of America; 6Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; 7UCB Pharma, Monheim, Germany; 8Swedish Medical Center and University of Washington, Seattle, WA, United States of America; 9Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 10Leiden University Medical Centre, Leiden, Netherlands

Background: Psoriatic Arthritis Disease Activity Score (PASDAS),1 Disease Activity Index for Psoriatic Arthritis (DAPSA),2 and the minimal disease activity (MDA) criteria3 are instruments recommended for evaluating disease activity (DA) in psoriatic arthritis (PsA). RAPID-PsA demonstrated the sustained efficacy of certolizumab pegol (CZP) across the spectrum of PSA symptoms.4 A substantial proportion of patients (pts) completing 4 years’ treatment achieved DA targets; >75% reached DAPSA low DA (LDA) or remission (REM), and almost 60% had MDA (>57 MDA criteria), half of whom also achieved very low DA (VLDA) (77 MDA criteria).5

Objectives: To report the proportion of pts who achieved PASDAS VLDA and LDA over 216 weeks (wks) CZP treatment, and the overlap in pts achieving PASDAS, DAPSA and MDA.

Methods: RAPID-PsA (NCT01087788) was double-blind and placebo-controlled to Wk24, dose-blind to Wk48, and open-label (OL) to Wk216.6 Outcomes reported for pts randomised to CZP at Wk0 (200 mg every 2 wks or 400 mg every 4 wks, following a 400 mg loading dose at Wk0/1). DAPSA change from baseline (CFB); pts achieving PASDAS LDA (>1.9–3.2), PASDAS VLDA (≤1.9), DAPSA LDA (>4–<14), DAPSA REM (<4), MDA and VLDA to Wk216; and the overlap in pts achieving PASDAS VLDA, DAPSA REM, and VLDA, at Wk216. Data are summarized for observed cases per visit. Pts withdrawing between scheduled visits had their final assessment values assigned to the next scheduled visit timepoint.

Results: Of 409 pts randomised, 273 received CZP from Wk0, of whom 248 (60.8%) completed Wk24 and 163 (67.0%) completed Wk216. The mean (SD) baseline PASDAS was 6.0 (1.6): in the high DA range, CFB at Wk216 was −3.4 (1.5). Of pts completing Wk216, 66.3% (118/178) were in PASDAS LDA or VLDA (PASDAS VLDA: 36.5% [N=65]) less than the proportion reaching DAPSA LDA or REM (70.2%), but more than those achieving MDA or VLDA (57.8%) (Figure A).

At Wk216, of pts achieving PASDAS VLDA, a large proportion (71% [46/65]) had VLDA based on MDA criteria (Figure B1) and most (94% [61/65]) achieved DAPSA REM (Figure B2). Almost all pts achieving VLDA (96.1% [50/52]) were also in DAPSA REM (Figure B3). After 4 years’ CZP treatment, 25.8% (46/187) pts achieved the PASDAS VLDA, DAPSA REM and VLDA.
Conclusion: A substantial proportion of pts completing 4 years’ CZP treatment achieved PASDAS LDA or VLA, and the vast majority who achieved PASDAS VLA at Wk216 also reached DAPSA REM and/or VLDA. 1 in 4 pts achieved the most stringent DA target with all 3 instruments.

REAL-WORLD EFFECTIVENESS AND SAFETY OF APREMILAST IN BELGIAN PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSIS FROM THE MULTICENTRE, PROSPECTIVE, NON-INTERVENTIONAL APOLO STUDY

Kurt de Vlam1, Adrien Nzeusseu2, Marie-Joëlle Kaiser2, Johan Vanhoof2, Philip Remans3, Mariëtte Van den Berghe4, Silviana Di Romano5, Filip van den Bosch6, Sofie Leroux7, Virginie Vanhoof8, Rik Lories9,1,1. Skeletal Biology and Engineering Research Center, University Hospital Leuven, Leuven, Belgium; 2University Hospitals Saint-Luc, Brussels, Belgium; 3Department of Rheumatology, CHU Sart Tilman Liege, Belgium; 4Department of Rheumatology, ReumaClinic Genk, Genk, Belgium; 5Department of Rheumatology, ASZ Aalst, Aalst, Belgium; 6Department of Rheumatology, University Hospital Saint-Pierre, Brussels, Belgium; 7Department of Rheumatology, Ghent University Hospital, Gent, Belgium; 8Celgene BeLux, Braine-l’Alleud, Belgium

Background: Real-world evidence on effectiveness and safety data for patients (pts) with psoriatic arthritis (PsA) in the Belgium clinical practice setting is lacking.

Objectives: To assess the effectiveness and safety of apremilast (APR) in pts with active PsA from routine clinical practice in Belgium.

Methods: In this multicenter prospective, non-interventional study (APOLO), the PsA Response Criteria (PsARC) response 6 months after APR initiation was the primary endpoint. PsARC response was defined as improvement in ≥2 and no worsening of any of the following 4 measures: tender joint count (TJC; 0–66), swollen joint count (SJC; 0–66), Physician’s Global Assessment of Disease Activity (PGA) and Patient’s Global Assessment of Disease Activity (PiGADA). Other endpoints included PsAID12, HAQ-DI; Physician’s and Patient’s Numerical Rating Scale (NRS) assessing disease activity for the most affected joint, psoriasis-affected body area surface (BSA), enthesis, dactylitis, pain and pruritus. The current analysis is based on observed data.

Results: The first 55 of a planned 150 Belgian pts receiving APR for up to 6 months were evaluated. Mean age was 52.5 yrs, mean BMI was 27.1 kg/m2 and 47.3% were female. Mean durations of psoriasis and PsA were 15.8 yrs and 8.1 yrs, respectively; <80% of pts were biologic-naive. At baseline (BL), mean (SD) SJC was 8.0 (5.4), mean (SD) TJC was 12.7 (9.5) and mean (SD) body surface affected was 12.3% (20.8%); 31.0% of pts had dactylitis and 47.8% had enthesis. In total, 35 pts (63.6%) continued APR treatment for 6 months; 20 (36.4%) had discontinued APR (insufficient effectiveness: 21.8%; adverse events: 10.9%, intolerence: 3.6%). After 6 months of APR initiation, 69.6% of pts had a PsARC response. Mean changes from BL in SJC were –4.4 (Month 3) and –5.7 (Month 6), with improvements in SJC (defined as ≥30% decrease per PsARC) observed in most pts (Month 3: 78.3%; Month 6: 83.3%). Comparable results were seen for TJC: Mean changes from BL were –7.2 (Month 3) and –6.7 (Month 6), with improvements observed in most pts (Month 3: 78.3%; Month 6: 80%). Decreases in PGA score of ≥1 from BL were observed in most pts at Months 3 (73.7%) and 6 (66.7%). Mean (SD) Physician’s NRS scores decreased from 5.6 (2.6) to 2.5 (2.0) at Month 6. Among pts with enthesitis at BL who had data available at Month 6, 54.5% achieved a score of 0. Among pts with dactylitis at BL who had data available at Month 6, 27.1% (20.8%) at BL to 7.5% (14.7%) at Month 6. An improvement of ≥20% in HAQ-DI at Month 6 was achieved by 73.1% of pts. Improvement were also seen in PGA score, overall pain and pruritus. No new safety and tolerability concerns from known overall safety profile of APR. No new safety and tolerability concerns from known overall safety profile of APR.

Conclusion: Results from this real-world PsA study confirmed an improvement in disease activity with APR in both physician-assessed and pt-reported outcomes for most pts. Overall, improvements were observed after 3 months of APR treatment and were maintained up to the 6-month observation period. Safety and tolerability were similar to the known profile of APR.

AB0744

EFFICACY OF IXEKIZUMAB IN ACTIVE PSORIATIC ARTHRITIS (PSA) PATIENTS WITH AXIAL PAIN STARTING BEFORE AGE 45: A SUBGROUP ANALYSIS OF SPIRIT-P1 AND SPIRIT-P2 PHASE 3 CLINICAL TRIALS

1Atul Deodhar*, Alexis Ogdie2, Talia Muram3, David Sandoval2, Vladimir Genewu3, Peter Nash1, 1Oregon Health and Science University, Portland, United States of America; 2University of Pennsylvania, Philadelphia, United States of America; 3University of Birmingham, Birmingham, United Kingdom

Background: The efficacy and safety of ixekizumab (IXE), an IL-17A antagonist, was investigated in patients with active psoriatic arthritis (PsA) in the SPIRIT-P1 and SPIRIT-P2 clinical trials.

Objectives: To investigate the efficacy of ixekizumab on axial pain, fatigue, stiffness, and physical function in a subset of patients with PsA self-reporting axial pain starting before the age of 45 years at baseline.

Methods: Patients with PsA in the intent-to-treat populations of SPIRIT-P1 (Biologic-naïve; NCT01695239) and SPIRIT-P2 (Inadequate responders or intolerant to 1 or 2 TNF inhibitors; NCT02349295) with baseline patient-reported axial pain (≥4 Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) question 2), high-sensitivity C-reactive protein (hsCRP) >5 mg/L, and <45 years old were included in this post-hoc integrated analysis.

Results: Axial pain and stiffness significantly improved at Weeks 16 and 24 in patients with PsA treated with IXEQ4W or IXEQ2W versus PBO (p<0.05; Table 1). Fatigue significantly improved at Week 16 in patients treated with IXEQ4W or IXEQ2W versus PBO and at Week 24 with IXEQ2W versus PBO (p<0.05). Total BASDAI scores significantly improved at Weeks 16 and 24 in patients treated with IXEQ4W or IXEQ2W versus PBO (p<0.01). Physical function significantly improved at Weeks 16 and 24 in patients treated with IXEQ4W or IXEQ2W versus PBO when assessed by HAQ-DI or SF-36 PCS (p<0.05).

Conclusion: Ixekizumab treatment yielded significantly higher improvements than placebo in axial pain, fatigue, stiffness, and physical function at Weeks 16 and 24 in the integrated PsA subpopulation self-reporting axial pain at baseline. These analyses were limited by a lack of baseline axial imaging.

AB0746 WORKING STATUS AND FACTORS ASSOCIATED WITH WORK PRODUCTIVITY AMONG PEOPLE WITH PSORIATIC ARTHRITIS

Düdem Erimen, Halise Hanbe Gezer, Svetap Acer Kasman, Mehmet Tuncay Duruöz, Marmara University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Rheumatology Division, İstanbul, Turkey

Background: Work disability is an important functional outcome measure in psoriatic arthritis (PsA) and includes unemployment and loss of work productivity. 

Objectives: The aim of this study is to investigate the working status and the factors associated with work productivity in patients with PsA.

Methods: Patients with PsA according to Classification Criteria for Psoriatic Arthritis (CASPAR) were included in the study consecutively, without sample selection. Data about age, sex, disease duration (month) were noted. Disease activity was assessed with DAPSA (Disease Activity in Psoriatic Arthritis) and BASDAI (Bath Ankylosing Spondylitis Disease Activity Index). The Health Assessment Questionnaire (HAQ) was used to evaluate physical disability. The Psoriatic Arthritis Quality of Life (PsAQoL) scale was used to assess the quality of life. Fatigue and stiffness were assessed on the Visual Analogue Scale (VAS). Anxiety and depression were evaluated with HAD (Hospital Anxiety and Depression) scale.

Assessing work disability, we asked some questions to the patients including employment status, and early retirement, changing or reducing work due to PsA. We used WPAI: PsA (Work Productivity and Activity Impairment Questionnaire) to evaluate the impact of PsA on work productivity. WPAI: PSA consists of six questions: the percentage of absenteeism (work time missed due to PsA), the percentage of presenteeism (reduced productivity at work due to PsA), an overall work impairment (combines absenteeism and presenteeism) and percentage of impairment in daily activities.

The association between WPAI: PsA scores and HAQ, PsAQoL, HAD, fatigue and stiffness was determined by Spearman's correlation coefficient. The Mann Whitney-U test was used to compare the means of groups.

Results: The mean age of 60 patients (38 female, 22 male) with PsA was 48.13 (SD: 11.53) years. The median (min-max) duration of disease was 36 (3-384) months. 63.33% of the patients were not working and 57.89% of these patients were housewives, and 23.68% were retired. 11.66% of the patients with PsA were unemployed. There were no patients who were retired early due to the disease. Percentage of the stopping work, changing work or reducing working hours due to PsA was 3.3%, 6.7% and 10%, respectively.

There was no significant difference between the working and not-working groups of patients according to the disease duration, DAPSA, BASDAI and HAQ scores (p>0.05).

Conclusion: Work disability is an important functional outcome measure in psoriatic arthritis (PsA) and includes unemployment and loss of work productivity.

Disclosure of Interests: None declared.

AB0747 RESPONSE TO SECUKINUMAB AMONG NAIVE AND BIOLOGICALLY EXPERIENCED PATIENTS WITH PSORIATIC ARTHRITIS

Sheila Faruq, Ann O. Riordan, Muhammad Haroon, Fahd Adeeb. University Hospital Kerry, rheumatology, Tralee, Ireland

Background: Secukinumab is a recombinant human monoclonal immunoglobulin IgG antibody that selectively targets IL-17A and blocks its interaction with the IL-17 receptor. Inhibition of the downstream effects of this proinflammatory cytokine thereby interferes with key psoriasis disease pathways while promoting normalization of immune function and skin histology.

Objectives: The aim of the study was two-fold; firstly, to compare the response to Secukinumab in psoriatic arthritis (PsA) patients who were biologically-naive and experienced, and secondly to compare the response between smokers and non-smokers.

Methods: In collaboration with the National Psoriatic Arthritis Registry of Ireland, patients who were diagnosed and treated as PsA at University Hospital Kerry between March 2017 and October 2018 were included in this population-based cohort study. Patients demographic, clinical characteristics, treatment strategies (including response rates and adverse effects) were captured at baseline and at follow-up outpatient visits.

Results: A total of 96 patients were identified and included in the study (mean age of 56.6 years; male to female ratio of 1:1.49 males, 47 females). Of these patients, 15 received Secukinumab (7 biologically-naive patients, 8 patients with previous treatment failure to anti-TNF agents (3 patients received one anti-TNF, 5 received two different anti-TNFs). In the biologically-naive group, 5 patients (71%) had complete response to Secukinumab, one patient (14.3%) had complete improvement of joint symptoms but remained fatigued (high BRAFT score) while 1 patient (14.3%) had no improvement. At 7 of these patients were exposed to cigarette smoking (6 current smokers, one ex-smoker). In patients who previously failed anti-TNF, five (62.5%) remained symptomatic (tender & swollen joints, PROMs and BRAFT score remained high) despite treatment with Secukinumab. Only three patients (37.5%) responded well to treatment. Two of the eight patients never smoked (both did not respond to Secukinumab) while the other 6 patients (3 responded, 3 had no response) were ex-smokers.

Conclusion: In our study, Secukinumab demonstrated better response to the biologically-naive PsA patients, while smoking did not increase the risk of disease activity among PsA patients receiving Secukinumab.

Disclosure of Interests: None declared

AB0748 EVOLUTION ON HEALTH-RELATED QUALITY OF LIFE IN PSORIATIC ARTHRITIS PATIENTS

1Dailler Freites Nuñez, Leticia León, Judit Font, Alfredo Madrid García, Zulema Rosales, Lydia Abasolo,2 Benjamin Fernandez, Luis Rodríguez Rodriguez,1,2 Hospital Clínico San Carlos, Rheumatology, Madrid, Spain,1 Instituto de Investigación Sanitaria San Carlos, Rheumatology, Madrid, Spain

Background: Psoriatic arthritis (PsA) is a chronic, progressive and inflammatory arthritis. It is considered a multifaceted disease, with a high impact on patient’s psychological and physical well-being, with patients reporting lower health-related quality of life (HRQoL). Data of burden of disease is substantial and even though there are some studies that identify risk factors with longstanding PsA, there exists a need for properly designed studies to learn more about the evolution of HRQoL throughout the follow-up in this condition.

Objectives: To analyze the evolution on HRQoL in patients with PsA and to evaluate factors that may influence this evolution.

Methods: Retrospective longitudinal observational study including incident patients diagnosed with PsA from 2007 to 2016, and followed-up until loss of follow-up or December 2017; with at least two registered visits; having received any iCD9/CD10 diagnosis code of PsA; and with symptoms onset after 16 years of age. Patients were collected from the rheumatology outpatient clinic of a tertiary hospital (Hospital Clínico San Carlos, Madrid, Spain). Clinical information was collected from a departmental electronic health record, including demographic, clinical, comorbidities, treatment, and HRQoL related variables (measured with the Rosser
Results: We included 187 patients, with a median follow-up of 3.6 years (interquartile range: 0.8 to 6.3). 48% were women, with a median age at the onset of symptoms and diagnosis of 45 and 49 years, respectively. 86% of patients had a personal history of Psoriasis. Regarding clinical manifestations during the follow-up, 83%, 30%, 26%, and 22% of the patients presented with peripheral arthritis, inflammatory low back pain, enthesitis and dactylitis, respectively. In addition, they received treatment with nonsteroidal antiinflammatory medications (NSAIDs), oral glucocorticoids and disease-modifying antirheumatic drugs (DMARDs) 71%, 52% and 82%, respectively. 20% received biological agents. The Rosser median value at the first visit was 0.986, with an slight increase after the first 2 years and a decline after 5 years of follow-up (Figure 1). With respect to the variables independently associated with HRQoL during follow-up, the history of osteoporotic fractures (p = 8.1x10-18) and chronic obstructive pulmonary disease (p = 5.0x10-8) were associated with a poorer quality of life. Conversely, treatment with methotrexate during the evolution of patients with PsA was shown to be effective and safe in PsA patient after a year of treatment in clinical practice regardless patient's gender.

Conclusion: We have identified different factors associated with HRQoL during the evolution of patients with PsA. We observed that the presence of certain comorbidities were independently associated with a worse HRQoL. In addition, regarding different treatments, the use of methotrexate and bone-forming agents were independently associated with a better HRQoL.

Disclosure of Interests: None declared

Background: The latest data show that axial involvement in psoriatic arthritis (PsA) patients (pts) is associated with significantly worse disease status and widespread impairment of patient-reported outcomes (PRO’s) (1). Objectives: To analyze clinical characteristics and PRO’s in PsA pts with and without radiographic sacroiliac joints (rSI) in the Russian Psoriatic Arthritis Registry (RU-PsART). Methods: 385 pts (MF=172/213) with PsA according to CASPAR criteria were included in the RU-PsART. Data was collected from 25 rheumatology clinics from various regions of the Russian Federation. Median age 45 (Min 20-Max 80) years, disease duration 3.4 yrs (4 months-32 yrs). Pts underwent standard clinical examination of PsA activity. All pts were studied for patient global disease activity (PGA) and patients’ pain measured by Visual Analogue Scale (VAS), and Health Assessment Questionnaire (HAQ). Physician’s global assessment of disease activity (PGA) was measured by VAS. The examination included X-ray of sacroiliac joints (pelvic radiographs). rSI was defined as bilateral grade ≥2 or unilateral grade ≥3. Pts were split into two groups (gr): those with rSI (rSI(+)) and those without rSI (rSI(-)). Medians and quartiles [Me (Q25; Q75)], Min; Max), U-test and ORs with 95% CI were performed. All CI >1, p <0.05 were considered to indicate statistical significance. Results: gr. rSI(+) included 214 (55.6%) cases (M/F 172/42), gr. rSI(-) included 171 (44.4%) cases (MF=66/105). Median age in gr. rSI(+) was 45 [Min 20-Max 80] yrs, in gr. rSI(-) it was 46 [Min 21-Max 82] yrs. Significant differences were revealed between gr. rSI(+) and gr. rSI(-). In Leeds Enthesitis Index (LEI): in gr. rSI(+) LEI was 0 [0-2], in gr. rSI(-) it was 0 [0-1] (p<0.002). In frequency of dactylitis: in gr. rSI(+) 71 pts had dactylitis, 143 did not have; in gr. rSI(-) 32 pts had dactylitis, 139 did not have. OR 2.2 [1.3-3.5]. In PGA: in gr. rSI(+) it was 56.5 [42.3-70.0], in gr. rSI(-) it was 50.0 [30.0-60.0] (p = 0.00). In patients’ pain: in gr. rSI(+) it was 50.0 [40.0-70.0], in gr. rSI(-) it was 50.0 [20.5-58.8] (p=0.000). In PG: in gr. rSI(+) it was 54.0 [40.0-69.5], in gr. rSI(-) it was 40.0 [25.5-50.0] (p=0.000). In HAQ scores: in gr. rSI(+) it was 1.0 [0.6-1.5], in gr. rSI(-) it was 0 [0-2.2] (p<0.002). Conclusion: Axial involvement is identified in more than half (55.6%) of the PsA pts. The presence of axial involvement in PsA pts is associated with significantly worse disease status as measured by frequency of enthesitis and dactylitis, worse PRO’s and with the reduction of patient’s functional capacity. Consequently, the diagnostics of axial involvement is critical in clinical practice.

1EuroSpA Research Collaboration, On behalf of the DANBIO (Denmark), ARTIS (Sweden), SCCM (Switzerland), NOR-DMARD (Norway), ATTRA (Czech Republic), Teuma.pt (Portugal), BIOSADASER (Spain), ROB-FIN (Finland), biorx.si (Slovenia), ICEBIO (Iceland), TURKBIO (Turkey), RRBR (Czech Republic), Reuma.pt (Portugal), BIOBADASER (Spain), ROB-FIN ARTIS (Sweden), SCQM (Switzerland), NOR-DMARD (Norway), ATTRA (Czech Republic), Teuma.pt (Portugal).

Objectives: To investigate Tumour Necrosis Factor Inhibitor (TNFi) retention rates at 12 months (primary objective), 6 and 24 months, and remission rates at the same time-points in biologic-naïve patients with PsA from the EuroSpA Collaboration.

Methods: Prospectively collected data on PsA patients from 12 European registries were uploaded through the secure Virtual Private Network pipelines to the EuroSpA server, and pooled. Baseline characteristics were investigated with non-parametric descriptive statistics. TNFi retention rates (Kaplan-Meier statistics), and 28-joint Disease Activity Score (DAS28) and C21 DAPSA28 were calculated, including LUNDEX adjustment. For patients initiating 1st TNFi after January 1st 2009, the following sub-cohorts were also studied: patients known to be fulfilling ClASsification for Psoriatic Arthritis (CASPAR) criteria and patients with one or more swollen joints (swollen joint count (SJC)>1) at baseline.

Results: Overall, 14,261 patients with PsA initiated a 1st TNFi. Baseline characteristics of the pooled population are shown in the Table. The median 12-month retention rate (95%CI) was 77% (76-78%), ranging from 68-90% across registries (Figure). Overall, DAS28/DAPSA28 remission rates at 6 months were 56%/27% (LUNDEX-adjusted: 45%/22%). In patients initiating a 1st TNFi after 2009 with registered fulfillment of CASPAR criteria (n=1,980) or registered ≥1 swollen joint at baseline (n=5,803), the retention rates and remission rates were similar to those found overall (Table).

Conclusion: Approximately half of >14,000 patients with PsA who initiated 1st TNFi treatment in routine care were in DAS28-remission after 6 months, and three out of four were still on the drug after 1 year.

AB0753 COMPARING COMPOSITE MEASURES OF DISEASE ACTIVITY IN PSORIATIC ARTHRITIS: RESULTS FROM A RANDOMIZED PHASE 2 TRIAL WITH GUSELKUMAB

1Philip Hellwell, 2Atul Deodhar, 3Alice B. Gottlieb, 4Wolf-Henning Boehncke, 5Xie L. Xu, 6Stephen Xu, 7Yuhua Wang, 8Elizabeth C. Hsia, 9Dafna D. Gladman, 10Christopher T. Ritchlin, 11University of Leeds, Leeds, United Kingdom; 12Oregon Health and Science Univ, Portland, United States of America; 13Icahn School of Med at Mount Sinai, New York, United States of America; 14Geneva University Hospitals and Dept of Pathology and Immunod, Geneva, Switzerland; 15Janssen Research and Development, LLC, Spring House, United States of America; 16Univ of Pennsylvania, Phila, United States of America; 17University of Toronto, Krembil Research Institute, Toronto, Canada; 18University of Rochester Medical Center, Rochester, United States of America

Background: Psoriatic Arthritis Disease Activity Score (PsAS), GRAppa Composite score (GRACE) Index, modified Composite Psoriatic Disease Activity Score (mCPDAI), and Disease Activity Index for Psoriatic Arthritis (DAPSA) are composite indices recently developed to assess disease activity in psoriatic arthritis (PsA). A Gusekumab (GUS) is a monoclonal antibody targeting interleukin-23 that has demonstrated efficacy in a phase 2 PsA trial.3

Objectives: To compare the effect of GUS on disease activity in psoriatic arthritis (PsA) as measured by these composite indices.

Methods: In this Phase-2 trial, patients with active PsA (≥3 tender, ≥3 swollen joints, C-reactive protein ≥3 mg/L, ≥3% body surface area) were randomized 2:1 to subcutaneous GUS 100mg (n=100) or placebo (PBO, n=49) at Wk0, Wk4, and every 8 wks through Wk44. At Wk16, patients with ≤5% improvement in swollen plus tender joints could early-escape treatment. PASDAS and GRACE indices were more sensitive than mCPDAI and DAPSA in detecting changes upon treatment and distinguishing guselkumab treatment effects relative to placebo. Residual disease activities among guselkumab-treated patients who achieved low disease activity at Week24 based on each PsA composite index are summarized in the Table.

Conclusion: Regardless of the PsA-specific composite index employed, GUS significantly improved disease activity and achieved clinically meaningful therapeutic targets such as low/minimal disease activity or remission. PASDAS and GRACE indices were more sensitive than mCPDAI and DAPSA in detecting changes in disease activity by guselkumab treatment.

AB0754 CLINICALLY MEANINGFUL IMPROVEMENT IN SKIN AND NAIL PSORIASIS IN BIO-NATIVE ACTIVIE PSORIATIC ARTHRITIS PATIENTS TREATED WITH INTRAVENOUS GOLUMUB: RESULTS THROUGH WEEK 52 FROM A PHASE-3 STUDY

1M Elaine Husni, 2Philip J. Mease, 3Soumya D. Chakravarty, 4Sheily Kafka, 5Diane D. Harrison, 6Dennis Parenti, 7Lilianne Kim, 8Kim Hung Lo, 9Elizabeth C. Hsia, 10Arthur Kavanaugh, 11Cleveland Clinic, Cleveland, United States of America; 12Swedish Med Center and U of Wash School of Med, Seattle, United States of America; 13Janssen Scientific Affairs, LLC, Horsham, United States of America; 14Drexel University College of Med, Philadelphia, United States of America; 15Janssen Research and Development, LLC, Spring House, United States of America; 16Univ of Penn Medical Center, Phila, United States of America; 17Univ of CA San Diego, San Diego, United States of America

Background: GO-VIBRANT is a Phase 3 trial of intravenous (IV) golumub (GLM) in adult patients (pts) with active psoriatic arthritis (PsA), Clinically meaningful improvements in skin and nail psoriasis (PsO) and in Dermatology Life Quality Index (DLQI) that were significantly greater than placebo (PBO) at weeks (wks) 14 & 24 were previously reported.1

Objectives: To evaluate improvement in skin and nail PsO and DLQI with IV GLM through wk52.

Methods: Adult bio-native PsA pts with active disease (≥3 swollen & tender joints, CRP ≥0.6mg/dL, active plaque psoriasis or documented history), despite treatment w/csDMARDs &/or NSAIDs, were randomized to IV GLM 2mg/kg at wks 0/4 & every 8 wks thereafter or PBO at wks 0/0/4/12/20 with crossover to GLM at wk24. Pts with ≥3% body surface area (BSA) and Severity Index (PSAI, 0-72) of 75/50/100% improvement scale,
modified Nail Psoriasis Severity Index (mNAPSI, 0-130) in pts with mNAPSI >0 at BL, and DLQI (0-30) scale.

Results: 394 pts (PBO:n=198; GLM:n=196) had >33% BSA psoriasis at BL; 76.5% had mNAPSI>0 at BL(mean 18.6). Pts on IV GLM achieved a greater PASI 75 response rate (RR) vs PBO at wk24 (64.8% vs 13.1%, p<0.001). At wk52, PASI 75 RR was maintained in pts who continued IV GLM treatment and increased numerically in those who crossed-over from PBO to IV GLM at wk24 (71.9% and 60.6%, respectively). At wk24, pts on IV GLM achieved significantly greater PASI 90/100 RR vs PBO (8.1% vs 0.001). At wk52, both BL MTX, PASI 90/100 responses were maintained in those who continued on IV GLM and increased numerically in PBO to IV GLM pts (Table). The mean decrease (improvement) from BL in the mNAPSI score was also greater with IV GLM vs PBO at wk24, overall and in groups ≥BL MTX. At wk52, mNAPSI RR was maintained with continual IV GLM and increased numerically in PBO to IV GLM pts (Table). At wk24, the mean decrease (improvement) from BL in DLQI was greater with IV GLM vs PBO (−8.1 vs −1.9, p<0.001). At wk52, mean DLQI improvement was maintained in pts continually on IV GLM and increased numerically in PBO to IV GLM pts (−7.8 vs −5.8). Similar patterns were seen in subgroups ≥BL MTX. In pts with DLQI improvement >1 at baseline, rate of simultaneous achievement of both PASI 50 response & improvement in DLQI was greater at wk24 with IV GLM (59.2%) vs PBO (8.1%, p<0.001). At wk52, both were achieved by 56.6% on IV GLM vs 41.4% of PBO to IV GLM pts. Similar patterns were seen for simultaneous achievement of both improvement in DLIQI ≥5 APASI 75/90/100 at wk 24 and 52.

Conclusion: Clinically meaningful improvements in skin and nail psoriasis and psoriasis quality of life after IV GLM treatment of PsA pts were maintained from 24 to 52 weeks of treatment.

AB0755 REGIONAL AND TEMPORAL VARIATION IN THE BASELINE PROFILE OF PSORIATIC ARTHRITIS PATIENTS INITIATING ADALIMUMAB FOLLOWING FAILURE OF NON-BIOLOGIC TREATMENT IN CANADIAN ROUTINE CARE

1 Majed Khraishi, Louis Bessette, Samuel Silverberg, Boulos Harouei, Andrew Chow, Yatish Sethy, Valencia P. Remple. 1 Memorial University of Newfoundland, St-John’s, Canada, 2 Université Laval, Faculty of Medicine, Quebec City, Canada, 3 Etobicoke General Hospital, Toronto, Canada, 4 Centre hospitalier de l’Université de Montréal, Montreal, Canada, 5 University of Toronto, Faculty of Medicine, Toronto, Canada, 6 Grey Bruce Health Services, Owen Sound, Canada.

Background: Treatment selection in routine clinical care is driven by treatment guidelines, physician judgment, patient preferences, and regional reimbursement policies, which may vary over time and among geographic regions.

Objectives: The objective of this analysis is to investigate the regional and temporal variability of the profile of anti-TNF naïve psoriatic arthritis (PsA) patients at initiation of adalimumab (ADA) treatment following failure of initial non-biologic treatment.

Methods: COMPLETE-Psa is an ongoing Canadian observational study of anti-TNF naïve adults with active PsA who require change in their current treatment as per the judgement of their treating physician. Patients are followed for up to 2 years. Regional variation was assessed for the following regions: British Columbia/Manitoba (BC/MB), Newfoundland/Nova Scotia (NL/NS), Ontario (ON), and Quebec (QC). Temporal variation was assessed for the following periods: 2012-2014 and 2015-2017. Multivariate linear regression was used to evaluate the independent impact of region and time period on disease activity (DAS28) and patient functional health.

Results: A total of 278 patients were included, of whom 68 (24.5%) were from BC/MB, 25 (9%) from NL/NS, 104 (37.4%) from ON, and 81 (29.1%) from QC. One hundred fifty-three patients (55%) were enrolled in 2012-2014 and 125 (45%) in 2015-2017. Use of univariate analysis, significant regional variation at ADA initiation was observed for the following disease parameters: BSA<3% (from 42.3% in ON to 76% in NL/NS, p=0.003), morning stiffness (from 60.9 min in QC to 119.7 in BC/MB, p=0.049), WLO productivity loss score (from 8.4% in BC/MB to 12.9% in NL/NS, p=0.028), and DLQI (from 3.5 in NL/NS to 7.9 in ON, p=0.007); and for the initiation of ADA monotherapy vs. ADA combination therapy (range from 9.9% in QC to 27.9% in ON; p=0.022). No differences were observed in demographics (other than race: Caucasian range from 85% to 100%; NL/NS vs BC/MB, 90.0% vs 85.0%, p=0.070), TJC (9.5 vs. 8.1; p=0.074), and DAPSA (30.8 vs. 27.8; p=0.083) at ADA initiation was observed for the most recent time period. Using multivariable analysis to adjust for age, gender, BSA levels, and corticosteroid use, there was no regional or temporal variation in DAS28 and HAQ.

Conclusion: The results of this analysis demonstrate that there is significant regional and temporal variation in the profile of PsA patients initiated on ADA treatment in Canadian routine care. The impact of this profile variation on treatment outcomes requires further investigation.

AB0756 COMPARATIVE CHANGE IN QUALITY OF LIFE MEASURES IN PRECLINICAL AND ESTABLISHED PSORIATIC ARTHRITIS PATIENTS UNDER SECUKINUMAB TREATMENT. DATA DERIVED FROM THE PROSPECTIVE OPEN LABEL PSARTROS STUDY

Eleni Kampylafka1, Matthias Engbrecht2, Koray Tascilar2, Veronika Lerchen2, Christina Linz3, Arnd Kleyer4, David Simon5, Jürgen Rech2, Georg Schett2, Axel Hueber2,6. 1Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 2Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 3Sozialstiftung Bamberg, Bamberg, Germany

Background: Psoriasis (PsO) and psoriatic arthritis (PsA) differentially impact patients’ quality of life (QoL) due to pain, mental changes in the context of chronic inflammation and impaired physical function. Effective anti-inflammatory therapy has shown to be effective to improve QoL in PsO and PsA patients. However, the impact of anti-inflammatory therapy on QoL may be different in the earliest stages of PsA as compared to established disease.

Objectives: To perform a detailed comparative investigation of the effect of interleukin (IL)-17 inhibition with 300 mg secukinumab (SEC) on QoL in patients with very early PsA/pre-PsA and established PsA.

Methods: Patients from the IVEPsA study (1) on very early PsA/pre-PsA (N=20) and the PSARTROS (2) study on established PsA (N=20) were longitudinally assessed for SF-36, DLQI, PsAID and HAQ-DI at baseline and after 4, 12 and 24 weeks. All patients received SEC treatment: 19/20 pre-PsA patients and 17/20 established PsA patients completed the study. Changes from baseline values were evaluated using linear mixed effects models adjusted for baseline values of each scale, gender, age and disease duration, and plotted as model coefficients and respective 95% confidence intervals that represent adjusted mean absolute improvement from baseline. Scale signs were inverted as necessary to ease interpretability.

Results: Significant and rapid improvements were observed in both pre-PsA and established PsA treated with SEC with regard to pain (SF-36 bodily pain, BP), general health perception (GH), dermatology quality of life index (DLQI) and PsA impact of disease (PsAID), as well as in the SF-36 component scores (mental component score of SF-36, MCS and physical component score of SF-36, PCS). Physical function-oriented instruments like SF-36 physical functioning (PF), role limitation due to bodily pain, BP), general health perception (GH), dermatology quality of life index (DLQI) and PsA impact of disease (PsAID), as well as in the SF-36 component scores (mental component score of SF-36, MCS and physical component score of SF-36, PCS). Physical function-oriented instruments like SF-36 physical functioning (PF), role limitation due to

Conclusion: Pain, mental health, general health perception and impact of disease rapidly improve in both very early PsA/pre-PsA and established PsA patients treated with SEC. These data support the concept that very early treatment of PsA leads to significant improvement in QoL with the additional benefit of prevention of bone damage as previously shown (1, 2).

AB0757 ANALYSIS OF THE PROGNOSTIC VALUE OF THE 12-ITEM PSORIATIC ARTHRITIS IMPACT OF DISEASE (PSAID-12) QUESTIONNAIRE FOR EVALUATION OF PSORIATIC ARTHRITIS ACTIVITY (PSA) BY DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA) IN ROUTINE CARE: DATA OF THE RUSSIAN PSORIATIC ARTHRITIS REGISTRY (RU-PSART)

1Anastasia Koltakova1, Elena Loganova1, Elena Gubara2, Yuila Korsakova2, Tatiana Korosteva1, Maria Sedunova1, Igor Pristsavskiy2, Irina Umnova1, Irina Bordareva3, Snezana Kudishina3, Evgeny Nasonov3. 1Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2St. Petersburg Clinical Rheumatology Hospital No.14, St. Petersburg, Russian Federation; 3Omsk Regional Hospital, Omsk, Russian Federation; 4Kemerovo Regional Hospital, Kemerovo, Russian Federation; 5Vladivostok Clinical Hospital No.2, Vladivostok, Russian Federation

Background: The PsAID-12 is an instrument for assessment the impact of PsA on patients’ lives by examine both physical and psychological components of health. DAPSA is a valid and discriminative tool for evaluation of the PsA activity. There is limited data about the PsAID-12 correlations with PsA activity by DAPSA in clinical care [1]. The Russian Psoriatic Arthritis Registry (RU-PSART) collected data from 25 rheumatology clinics in the Russian Federation regions.

Objectives: To investigate the predictive value of the PsAID-12 for evaluation of PsA activity by DAPSA in real-world settings.

Methods: 138 (male/female–79/59) patients (pts), median age 40 (Min/Max-23-71), with PsA, according to CASPAR criteria, were included in

REFERENCES

ACKNOWLEDGEMENTS: This study was supported by an unrestricted grant from Novartis.
the RU-PsART after signing consent participation forms. Every 6 months (259 visits total) all pts underwent evaluation of PsA activity: The Tender Joint count (TJC68), Swollen Joint Count (SJC66), Leeds Enthesitis Index (LEI), physician’s global disease activity (PhGA) VAS, CRP (mg/l), ESR (mm/h), by PROs - patient pain global assessment VAS, PsA activity state by DAPSA. All pts were divided into 2 groups based on disease activity state by DAPSA: the first one with results ≤14 that interpreted as Remission and Low Disease Activity (REM and LDA) and second one with results >14 that interpreted as Moderate and High Disease Activity (MoDA and HDA). Pearson correlation coefficient and ROC-curve analysis were performed. All p<0.05 were considered to indicate statistical significance.

Results: The Significant positive correlations between the PsAID-12 and all parameters of PsA activity, PROs were found (table 1). The high prognostic value of the PsAID-12 for PsA activity by DAPSA showed by ROC-curve analysis (AUC=0.89, CI 95% (0.85-0.93)). The threshold for MoDA and HDA (DAPSA >14) by PsAID was 1.

Conclusion: The PsAID-12 has a significant prognostic value for PsA activity by DAPSA. The questionnaire doesn’t include any physician’s or laboratory’s data, so it could be useful as a simple instrument for pts’ self-control and prognosis disease activity in daily clinical practice.

AB0758 PERSISTENCE AND DRUG SURVIVAL RATES OF THE FIRST-LINE BIOLOGICAL (B) DMARDS IN PATIENTS (PTS) WITH PSORIATIC ARTHRITIS (PSA) FROM THE RUSSIAN PSORIATIC ARTHRITIS REGISTRY (RU-PsART)

Irina Kropotkina1, Elena Loginova1, Anastasia Koltakova1, Elena Gubar1, Yulia Korsakova1, Maria Sedunova1, Igor Pristavsky2, Irina Umnova2, Irina Bondareva2, Srezana Kudishina2, Evgeny Nasonov2, 1Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg, Russian Federation; 3Omsk Regional Hospital, Omsk, Russian Federation; 4Kemerovo Regional Hospital, Kemerovo, Russian Federation; 5Vladivostok Clinical Hospital No.2, Vladivostok, Russian Federation

Background: Persistence with bDMARDs has only been studied recently in the last few years. But this information is very relevant for choice of bDMARDs treatment in real-life practice. RU-PsART collected data from 25 rheumatology clinics in the Russian Federation.

Objectives: to investigate drug survival and persistence rates, reasons for discontinuation of first-line bDMARDs in PsA pts in clinical practice.

Methods: 170 (MF=87/83) PsA pts according to CASPAR criteria, median (Me) age 43 (Mn 19 – Max 74) years (yrs.) who were treated with first-line bDMARDs were included in the present analysis. All information concerning the data for starting/withdrawing bDMARDs and reasons for discontinuation were taken at the time of being included to the RU-PsART registry. Pts took the following bDMARDs: Adalimumab (ADA) (57pts), Infliximab (INF) (40pts), Ustekinumab (UST) (96pts), Etanercept (ETN) (23pts), Golimumab (GOL) (14pts). Drug survival rate was evaluated with Kaplan-Meier cumulative analysis, Me [Min-Max]%.

Results: 71 out of 170 pts (41.8%) were treated with mono-bDMARDs and 99 out of 170 pts (58.2%) were treated with a combination with different sDMARDs. Among them ADA/INF/UST/ETN/GOL were used in combination with MTX in 66.7%/72.5%/33.3%/65.2%/35.7% of pts accordingly. During long-term observations GOL had better persistence among ITNF agents. UST has shown significantly higher cumulative survival and persistence rates compared to ADA (p<0.05, Log Rank tests). No significant differences were found between UST and other ITNF biologics (Fig.1).

Conclusion: In our real practice PsA pts cohort bDMARDs with different mechanisms of action were well tolerated and effective. During long-term observational periods UST has shown better cumulative survival rates compared to ADA.

Disclosure of Interests: Tatiana Kropotkina Speakers bureau: Novartis, Celgene Corporation, AbbVie Inc, Biocad, Janssen, Pfizer, UCB, Lilly, Elena Loginova Speakers bureau: Novartis, Celgene Corporation, Biocad, Janssen, AbbVie Inc, Anastasia Koltakova: None declared, ELENA GUBAR: None declared, Yulia Korsakova Speakers bureau: Celgene Corporation, Janssen, Maria Sedunova: None declared, Igor Pristavsky: None declared, Irina Umnova: None declared, Irina Bondareva: None declared, Srezana Kudishina: None declared, Evgeny Nasonov Speakers bureau: Pfizer, Inc., MSD, Novartis, AbbVie Inc., Celgene Corporation, Biocad, Janssen, UCB, Inc.

Background: Patients with psoriatic arthritis (PsA) have an increased cardiovascular (CV) risk. We should have strategies for primary cardiovascular prevention in PsA. But there is no evidence of CV risk management and arterial stiffness about biologics in patients with PsA.

Objectives: To examine the effect of biologics plus conventional synthetic (cs) DMARDs on arterial stiffness in cs DMARDs resistant PsA patients in a cohort study design.

Methods: 38 PsA patients with moderate to severe active disease despite cs DMARDs treatment (disease activity score: DAPSA ≥10 score=14) were received Biologics plus cs DMARDs. All patients have no previous history of CV. Arterial stiffness was assessed with cardio-ankle vascular index (CAVI, modified pulse wave velocity (PWV)) and augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) at baseline and 24 weeks of follow-up. Clinical data were collected at regular visits.

Results: 35 PsA patients (18 patients adalimumab, 13 patients infliximab, and 4 patients ustekinumab, respectively) completed this study. Treatment with biologics (10.8 ± 1.86 and 9.46: 1.14%; p = 0.006), attenuated the CAVI significantly from baseline to 24 weeks follow up. Treatment with biologics (36.4 ± 3.8%, p = 0.008) and the AIx@75 significantly from baseline to 24 weeks follow up. DAPSA score improved significantly from baseline to 24 weeks (17.45±5.3, 5.44±3.43; p=0.01). There are no significant differences among biologics about CAVI and Aix@75. Surprisingly, biologics improves arterial stiffness independently of its effects on disease activity, since even in high disease activity (4 cases; DAPSA score>28) is halted.

Conclusion: These findings suggest that combination therapy, biologics with cs DMARDs not only reduced PsA disease activity but also limited vascular damage in patients with cs DMARDs resistant active PsA.

SECUKINUMAB FOR THE TREATMENT OF PSORIATIC ARTHRITIS IN REAL LIFE: AN ITALIAN EXPERIENCE

1Elena Fracassi, Maurizio Rossi1, Mauro Cattaneo1, Antonio Carletto1. Rheumatology Unit, University of Verona, Verona, Italy; 2Rheumatology Unit, A.O.U. Policlinico Vittorio Emanuele, Catania, Italy; 3Rheumatology Unit Department of Medicine, University of Padova, Padova, Italy; 4Rheumatology Unit, ASL Taranto, Taranto, Italy; 5Rheumatology Unit, ASL BT Andria – DSS4 Barletta, Italy, Barletta-Andria-Trani, Italy; 6Rheumatology Unit, Department of Clinical Medicine and Surgery, University Federico II, Napoli, Italy

Background: Secukinumab is a novel treatment for psoriatic arthritis (PsA) but data from real life are still missing.

Objectives: The aim of this study is to evaluate a wide cohort of PsA patients on secukinumab followed in 7 Italian rheumatologic centers.

Methods: Two-hundred and seventy-nine patients affected by PsA and on secukinumab were enrolled. Data on disease characteristics, previous and ongoing treatments, comorbidities and duration of follow-up were collected. In particular DAPSA and ASDAS were used to assess articular and axial disease activity.

Results: Mean age of our cohort was 53±11 years and BMI 26.4±5.1 kg/m² with 67% of patients being female (63.8%). Mean disease duration was 9.7±7.5 years and mean follow-up was 10.9±6.8 years. For 100 patients (35.8%) secukinumab was their first line biologic treatment and 41 patients (31.7%) received it as a downward trend for M12 (15). During the PsA evolution, in addition to arthritis, patients also presented enthesitis (60.9%), nail involvement (39%) and dactylitis (31.7%).

Conclusion: This is one of the first real life studies on secukinumab and shows a very good efficacy and safety of this treatment in PsA patients, also for the articular manifestations, as shown by a significant decrease of DAPSA over a 12-months follow up.

Méndez, Méndez, Spain

Background: Tofacitinib (TOFA) is the first inhibitor of JAK kinases with approval for the treatment of psoriatic arthritis (PsA) in Europe (July 2018)1. TOFA has shown efficacy in refractory patients to anti-TNF. Objectives: A) to assess efficacy and safety of TOFA in the first cases in Spain in clinical practice. B) to compare the profile of clinical practice patients with clinical trial.

Methods: Study of 41 patients of clinical practice with PsA treated with TOFA in Spain. The diagnosis of PsA was made using CASPAR criteria. Patients who received at least one dose of TOFA were included. Results are expressed as percentage, mean±SD or median [IQR].

Results: 41 patients (23/18±), mean age of 50±10.7 years (table 1). Pattern joint involvement was as follows: peripheral (n=25), axial (1) and mixed (15). During the PsA evolution, in addition to arthritis, patients also presented enthesitis (60.9%), nail involvement (39%) and dactylitis (31.7%).

Disclosure of Interests: Federica Martinis: None declared, Cristian Caimmi: None declared, Rosario Foli: None declared, Elisa Visalli: None declared, Giorgio Amato: None declared, Roberta Ramonda: None declared, Augusto Ortolan: None declared, Mariagrazia Lorenzin: None declared, Angelo Semeraro: None declared, Leonardo Santo: None declared, Emanuela Praino: None declared, Maria Sole Chimenti: None declared, Niccolò Segaud: None declared, Raffaele Scarpaghi: None declared, Francesco Caso: None declared, Luisa Costa: None declared, Elena Fracassi Speakers bureau: Novartis, Maurizio Rossini: None declared, Antonio Carletto Speakers bureau: Roche, Novartis, MSD, Abbvie, Bristol-Myers Squibb, UCB, René-Marc Filpo Consultant for: Honoraria from Novartis as steering committee of this survey.

Background: In the placebo (PBO)-controlled Phase III ASTRAEA study (ClinicalTrials.gov, NCT01860798) in psoriatic arthritis (PsA), abatacept (ABA) 125 mg SC weekly significantly increased the ACR20 response rate at Week 24 versus PBO (39.4% vs 22.3%, respectively; p<0.001; primary endpoint).1 Numerical benefits in physical function, enthesitis and dactylitis and a modest impact on psoriasis lesions were also seen at Week 24. Efficacy was maintained or improved up to Week 52.2

Objectives: To assess ABA safety up to 2 years in patients (pts) enrolled in ASTRAEA.

Methods: Pts with active PsA were randomised 1:1 to ABA or PBO for 24 weeks followed by 28 weeks’ open-label (OL) ABA (total time on study: 52 weeks); pts without ≥25% improvement in joint counts at Week 16 (early escape) were switched to OL ABA (total time on study: 44 weeks).1 Pts could subsequently receive OL ABA in a 52-week long-term extension (LTE; Year 2) for the collection of safety data. The proportions of pts in the cumulative ABA population (all pts who received ≥1 dose of ABA at any time in the study) with AEs (all AEs, serious AEs [SAEs], deaths, AEs leading to discontinuation), laboratory marked abnormalities and anti-ABA antibodies over the cumulative ABA period (date of first treatment dose to end of LTE) were recorded in 1-year and 6-month intervals.

Disclosure of Interests: José Luis Martín-Varillas: None declared, Eva Galindez: None declared, Esteban Rubio Romero: None declared, AgustíSELLAS-FERNÁNDEZ: None declared, Roberto Daniel Gonzalez Benitez: None declared, Beatriz Joven-Ibáñez Speakers bureau: Celgene, Novartis, MSD, Pfizer, AbbVie, and Janssen, José Campos Esteban: None declared, Olga Maiz: None declared, Raul Veroz Gonzalez: None declared, Alfonso Corrales: None declared, Natalia Palmou-Fontana: None declared, Belén Aleniza-Mateo: None declared, J. Loricerα: None declared, Miguel A González-Gay Grant/research support from: Prof. MA González-Gay received grants/research supports from AbbVie, MSD, Jansen and Roche, Speakers bureau: Consultation fees/participation in company sponsored speaker’s bureau from Pfizer, Lilly, Sobi, Celgene, Novartis, Roche and Sanofi, Ricardo Blanco Grant/research support from: AbbVie, MSD, and Roche, Consultant for: Abbvie, Pfizer, Roche, Bristol-Myers, Janssen, Speakers bureau: Abbvie, Pfizer, Roche, Bristol-Myers, Janssen

Results: Overall, 398 pts were included in the analysis of the cumulative ABA period (213 received ABA from study Day 1; 185 completed initial randomisation to PBO and received ABA thereafter). Of these, 322 pts entered the LTE (initial randomisation: ABA, n=162; PBO, n=160) and continued to receive OL ABA beyond the 28-week OL period. Of 162 and 160 pts initially randomised to ABA and PBO, respectively, 19 (11.7%) and 21 (13.1%) pts discontinued ABA in the LTE. Median (range) number of ABA injections in the cumulative ABA period to end of LTE was 80 (1–130). Safety during the cumulative ABA period over 2 years is shown (Table 1); 6-month interval safety data will be available at time of presentation. In the LTE, there were 3 SAEs of infection (osteomylellitis, intervertebral discsitis and cellulitis) and 3 pts discontinued due to infection (hepatitis A, Epstein-Barr virus, intervertebral discitis). No malignancies or deaths were reported, and no autoimmune events were reported as serious or led to ABA discontinuation during the LTE. AEs, SAEs and AEs of special interest occurred with a similar frequency regardless of concomitant MTX use or prior TNFi inhibitor (TNFi) use. The proportion of pts with anti-ABA antibodies during the cumulative ABA period was higher during the post-treatment period (>22 days after last dose; 37.1% [91/245]) than in the on-treatment period (first treatment dose date to ≤21 days after last dose; 7.1% [28/392]). No apparent relationship between anti-ABA antibodies and efficacy in the on-treatment period or AEs suggestive of systemic immune reactions was seen.

Conclusion: Abatacept was well tolerated up to 2 years with no new safety signals during the LTE in this Phase III study in PsA. There was no impact of concomitant MTX use or prior TNFi exposure on the safety profile of abatacept. The occurrence of anti-abatacept antibodies had no impact on abatacept efficacy or safety.

AB0765 THE IMPACT OF PSORIASIS SEVERITY ON OUTCOMES AMONG PSORIATIC ARTHRITIS PATIENTS RECEIVING ADALUMABUM

Lara Mendez1, Isabel Madroñal García1, Esteban Rubio-Romero1, Lourdes Rodriguez-Freidel1, Clara Aguilera Cost1, María Dolores Arola Durán1, Marina Gomez-Vázquez1, hospital universitario virgen del rocio, rheumatology, seville, Spain; 1HOSPITAL UNIVERSITARIO VIRGEN DEL ROCIO, dermatology, seville, Spain

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease mediated by the immune system, which affects the musculoskeletal system and the skin. It is a disease with increased expression of TNF-alpha and IL23/IL17 cytokines, which are therapeutic targets whose neutralization has a great impact on the control of the disease.

Ixekizumab is a monoclonal antibody inhibitor of IL-17 indicated for the treatment of moderate-severe psoriasis and PsA. Ixekizumab is administered subcutaneously every 4 weeks, and according to the latest studies, it is a well-tolerated drug and an effective treatment option with significant improvement in the quality of life of patients with cutaneous psoriasis and PsA.

Objectives: Describe the clinical characteristics, tolerance, safety and survival of a cohort of patients diagnosed with psoriasis or PsA, who have started treatment with Ixekizumab.

Methods: An observational, cross-sectional and retrospective study was conducted on a cohort of 29 patients who started treatment with Ixekizumab in our hospital in the last year (2018). The data were obtained through the review of patients’ medical records and through telephone contact to carry out quality of life questionnaires (DLQI).

Results: Twenty-nine patients were included, of which 22 were males (79.5%). The mean age of the patients was 47 years. Of the cases included, 22 of the patients presented cutaneous Psoriasis (75.8%), 6 of the patients with PsA (20.7%) and 1 patient presented dermatomyositis antIMDA 5 (3.5%). Of the 29 patients included, 24 (82.2%) did not present adverse effects. Of the 5 patients who presented adverse effects, in 100% of the cases they were mild. All patients had received prior therapy with disease modifying drugs (DMARDs), and 31% were naive to biological therapy. A total of 4 patients required concomitant therapy with corticosteroid treatment, 3 of them with PAs and 1 with dermatomyositis anti MDA 5. The average of the DLQI of the patients analyzed was 4 and an average PASI of 1 after the start of the treatment, obtaining an Overall improvement of the skin.

A statistically significant Pearson correlation of 0.895 was found between DLQI and PASI (dependent variable), with a strong degree of association. In which patients with a lower score in the DLQI had a lower PASI.

Regarding the pain produced by the autoinjection, measured to the EVA scale, it was 2 (mild pain), and none would abandon the treatment for this reason. Of all the patients, 9.1% abandoned the treatment due to inefficacy.

Conclusion: The treatment with Ixekizumab presents some promising results in the treatment of cutaneous psoriasis and PsA. Treatment with Ixekizumab presents a significant improvement in the quality of life of patients.

Ixekizumab is a well-tolerated drug with good efficacy in the short-term. It has also been shown to be a safe drug among the patients included in the study.

However, long-term studies with a larger number of patients are required to evaluate the efficacy and safety of Ixekizumab.

Disclosure of Interests: None declared

Methods: Pts with baseline PASI and BSA available from ADEPT, a phase 3, randomized, double-blind, PBO-controlled trial of ADA 40 mg every other week, were included in this post hoc analysis. Pts were sub-grouped based on baseline PASO severity (severe PsO: PASI >12 OR BSA ≥10%; mild-to-moderate PsO: PASI <12 AND BSA <10%), relative to overall study population. Clinical outcomes at wk 24 were assessed by attainment of minimal disease activity (MDA), remission and low disease activity (LDA) by disease activity index for psoriatic arthritis (DAPSA), and PASI50/75/90; function and structural progression were assessed by the % of pts experiencing HAQ-DI normal values (0.25) and improvement from baseline ≥0.22 (MCID), and the % of pts having change from baseline in mTSS ≥0.5 in the modified total Sharp score (mTSS) respectively. A logistic model with treatment group baseline PASI/BSA and PASI/BSA by treatment interaction was fit for each outcome variable. P-values for interaction term and baseline BSA/PASI were calculated. Non-responder imputation was used for missing clinical and functional endpoints. 25th percentiles were imputed for missing radiographic data. Treatment-emergent adverse events (TEAEs) were monitored throughout.

Results: Of the 163 pts enrolled in the study with baseline PASI and BSA, only 23% (n=37; ADA: 17; PBO: 20) were classified as having severe PsO and had similar characteristics to those with mild-to-moderate PsO, except for numerically higher physician’s global assessment, dactylitis, and enthesis scores. Following 24 wks of treatment, 41% of ADA-treated pts achieved MDA and 45% achieved DAPSA LDA or better, a finding consistent irrespective of baseline PsO severity (Table). 72% of ADA-treated pts with baseline PsO did not exhibit any structural progression by mTSS (≥0) through 24 wks as compared to 55% receiving PBO. Logistic regression analyses confirmed limited role that PsO severity played across examined outcomes. DAPSA remission was more likely at wk 24 among pts with higher baseline PASI scores, and this effect was less apparent with ADA treatment. TEAEs appeared comparable between ADA and PBO groups; fewer infectious AEs occurred in the ADA severe PsO group treated with the lower dose of ADA. 25OHD deficiency was more likely among ADA pts at wk 24 versus PBO treated pts.

Conclusion: Prevalence of severe PsO in this population of PsA pts was consistent with previous observations. Treatment with ADA was associated with better PsA outcomes compared to PBO irrespective of the degree of PsO severity at baseline.

Disclosure of Interests: Joseph F. Merola Consultant for: Biogen IDEC; Abbvie, Amgen, Eli Lilly and Company, Novartis, Pfizer, Janssen, UCBB. Samumed, Celgene, Sanofi Regeneron, Merck, and GSK, Laura C Coates Consultant from: Abbvie, Celgene, Lilly, Novartis and Pfizer. We did not observe any significant correlation between the 25OHD values and the activity parameters of the PsA. However, we observed lower levels of 25OHD in obese patients. At 3 years, the BMD remained stable in the majority of patients (68.1%) receiving antiresorptive treatment, and it worsened in 2 patients despite treatment with bisphosphonates. We registered new fractures in 7 patients (4 VF, 1 femur fracture and two patients had more than one fracture). New fractures were not correlated with age, 25OHD deficiency or previous osteoporotic treatment. We observed greater progression of BMD in patients exposed to tobacco.

Conclusion: More than half of patients with PsA have a low BMD (53.8%) and 33.3% deficient levels of 25OHD. Our study confirms results found in general population: classic risk factors, such as smoking, are related to BMD progression. It is important to evaluate BMD in these patients and intervene early.

MULTI-SYMPHOM IMPACT ON THE EQ-SD INDEX IN BIO-NATIVE ACTIVE PSORIATIC ARTHRITIS PATIENTS: AN ANALYSIS THROUGH WEEK 24 OF THE GO-VIBRANT STUDY

Alexis Ogdie*, Li Nan2, Steve Peterson2, Chetan Karyekar2, Souryna D. Chakravarty2,3, Shelly Kafka4, Jessica A. Walsh5,6,7,8.
1Penneman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States of America; 2Janssen Global Services, LLC, Horsham, PA, United States of America; 3Janssen Scientific Affairs, LLC; Horsham, PA, United States of America; 4Drexel University College of Medicine, Philadelphia, PA, United States of America; 5University of Utah, Salt Lake City, UT, United States of America

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesis and skin and nail psoriasis. The impact of skin and joint components of the disease on patient health-related quality of life has been described in...
previous research (1,2) but the impact of other major clinical manifestations has not been similarly characterized.

Objectives: To quantify the impact of the major clinical manifestations of PsA on patient reported health related quality of life, as estimated by disease state preference (utility) derived from the EQ-5D index in a randomized clinical trial.

Methods: This analysis used data from a multicenter, randomized, double-blind, placebo-controlled trial of intravenous (IV) Golimumab in biologic naïve patients with active psoriatic arthritis (GO-VIBRANT study). Patient baseline characteristics of the GO-VIBRANT study population have been previously described (3). Core outcome measures recommended by OMERACT (Outcome Measures in Rheumatology Clinical Trials) and guideline on utility mapping by ISPOR (International Society for Pharmacoeconomics and Outcomes Research) were used to guide initial attribute selection. Utility was derived from patient responses to the EQ-5D index, which assesses mobility, self-care, usual activities, pain/discomfort, and anxiety/depression, and was completed at weeks 0, 8, 14, and 24 in the trial (placebo-controlled period). EQ-5D index is used as a measure of overall health and is an outcome commonly used in health economic analyses. Multivariate analysis was performed using a Mixed-Effect Repeated Measures model based on observed data until week 24 in pooled patient population.

Results: Based on univariate analyses and evaluation of collinearity between variables, the following attributes were included in the multivariate models: age, gender, region, PsA disease duration, PASI score, enthesis, dactylitis, tender joint count (TJC), swollen joint count (SJC), C-reactive protein (CRP mg/L) and Health Assessment Questionnaire-Disability Index (HAQ-DI). In the final model, PASI score (β=0.00126, p=0.0006), enthesis (β=0.01237, p=0.03), TJC (β=0.00112, p<0.0001), CRP (β=0.0007, p<0.0001) and HAQ-DI (β=-0.1664, p<0.0001) were all statistically significantly associated with the EQ-5D index. A sensitivity analysis among a subgroup of patients who had spondylitis with peripheral joint arthritis as their primary arthritic presentation of PsA showed that spinal pain (β=-0.0101, p<0.0001), as measured by question #2 of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), was also statistically significantly associated with the EQ-5D index in the multivariate model.

Conclusion: Multiple PsA clinical manifestations including psoriasis, enthesitis, TJC, spinal pain, CRP, and physical function were statistically significantly associated with utility among PsA patients as derived from the EQ-5D index. These findings indicate that consideration of multiple clinical manifestations of PsA is warranted when evaluating the impact of PsA on patients.

REFERENCES

Conclusion: In pts with active PsA, faster, clinically meaningful pain improvements were reported in pts receiving tofacitinib 5 mg BID vs pts receiving PBO who switched to tofacitinib 5 mg BID at Month 3. After switch from PBO to active treatment, pain improvement was observed in line with pts receiving active treatment from Day 0. To achieve pain improvement at greater thresholds, longer duration of active treatment was required.

AB0769 PATIENT IDENTIFIED TREATMENT GOALS IN PSORIATIC ARTHRITIS: DECREASING PAIN AND INCREASING ACTIVITY LEVEL ARE HIGH PRIORITIES

Alexis Ogdie, M Elaine Huynh, Kathleen Bush, Christina Burgess, Saumya Reddy, Jose Scher, Jessica A. Walsh. 1 University of Pennsylvania, Philadelphia, PA, United States of America; 2 Cleveland Clinic, Cleveland, OH, United States of America; 3 New York University, New York, NY, United States of America; 4 University of Utah, Salt Lake City, United States of America

Background: Treatment goals for physicians are primarily focused on improving musculoskeletal and cutaneous signs and symptoms of psoriatic disease. Studies have reported that perceptions of psoriatic arthritis (PsA) disease control are often divergent between patients and physicians. Moreover, specific patient goals are uncommonly discussed or elicited in routine clinical practice.

Objectives: To examine patient reported treatment goals through direct questioning on what they most want to improve about their disease and how an effective treatment would improve their lives.

Methods: Patients in the Psoriatic Arthritis Research Consortium (PARC) completed standardized assessments between 2017-2018. PARC is a longitudinal observational cohort study conducted at four institutions in the United States: University of Pennsylvania, Cleveland Clinic, New York University, and University of Utah that includes a range of patient and physician disease measures. Answers to two open-ended questions (questions included on figures) were qualitatively categorized into response categories and descriptively reported in this cross-sectional study. While patients were encouraged to provide the one best answer, many listed multiple themes. We also examined differences in responses by gender, self-identified race (Caucasian vs non-Caucasian), and whether a change in disease modifying anti-rheumatic drug was recommended (yes/no) on the date the questionnaire was completed.

Results: Among 82 patients with PsA enrolled, mean age was 48.3 (SD 13.2), 38 (46%) were female, and 57 (70%) of patients were changing therapy. The mean swollen (0-66) and tender (0-68) joint counts were 4.3 (SD 6.0) and 8.5 (12.2) respectively, mean psoriasis body surface area was 3.2% (SD 10.0), and mean physician and patient global assessments were 4.6 (SD 2.0) and 4.7 (2.6) respectively. Patient answers to the two questions are shown in the figures. Decreasing pain was the most commonly cited goal for improvement (56%) with skin improvement the second most commonly reported goal for improvement (12%). Goals for successful therapy were more diverse. Decreasing pain was most common (18%) but general improvement in life (18%), the ability to be more active (15%), participate in recreational activities (9%), function at work (11%) and exercise (5%) were common responses. There were no significant differences in responses according to race or age groups. There was no significant difference in responses according to gender or therapy change. However, all patients reporting fatigue or enjoyment as important outcomes for improvement were women.

Conclusion: In order to inform goals of care for patients with PsA, both physician and patient treatment goals should be defined to achieve optimal treatment success. In this study, while the majority of patients reported pain and activity as the most important outcomes for improvement, patient goals were heterogeneous. This underscores the importance of eliciting patient treatment goals on a regular basis to best individualize management in PsA.

SYMPTOMS AND IMPACTS IN PSORIATIC ARTHRITIS: FINDINGS FROM QUALITATIVE PATIENT INTERVIEWS

1Alexis Ogdie*, Kaleb Michaud2,3, Evo Alemao4, Miroslawa Nowak4, Rachel Bruce5, Kendra DeBusk6, Sarah Cantor7, Carlijn Hintzen8, Philip J. Mease9,10.
1University of Pennsylvania, Philadelphia, United States of America; 2FORWARD, The National Databank for Rheumatic Diseases, Wichita, United States of America; 3University of Nebraska Medical Center, Omaha, United States of America; 4Bristol-Myers Squibb, Princeton, United States of America; 5IQVIA, New York, United States of America; 6IQVIA, Amsterdam, Netherlands; 7Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, United States of America

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease resulting in significant symptom burden.1 Over time and without adequate treatment, PsA can lead to disability and reduced patient quality of life.2 Fatigue is among the most common symptoms,3 but is complex and difficult to measure. The most burdensome symptoms that impact PsA patients need to be better understood in order to select patient reported outcomes (PRO) instruments and items to measure fatigue.

Objectives: 1) Identify the signs and symptoms of PsA experienced by patients, with a focus on fatigue, and how the disease and its treatment(s) impact patients’ lives. 2) Assess the content validity of select PRO instruments and items to measure fatigue.

Methods: Qualitative interviews were conducted among patients with PsA recruited through the FORWARD database. The most frequently experienced symptoms and impacts of PsA and the degree to which they disturbed patients’ lives were tabulated. Disturbance was evaluated on a scale from 0 (not at all) to 10 (greatly disturbs). Patients reporting fatigue were probed to describe the experience in their own words, and descriptors were recorded. Interviews were conducted and assessed on a rolling basis and recruitment continued until concept saturation was achieved.

Results: Nineteen PsA patients were interviewed for this study. A core set of PsA symptoms were identified by nearly all patients and with moderate to high average disturbance ratings (Figure 1): joint pain, skin symptoms, stiffness, swollen/inflamed joints, and fatigue. The most salient impacts (Figure 2) were sleep disturbance, physical disability, effects on daily activities, and feelings of frustration. Most common descriptors of fatigue included “fatigue,” “tiredness,” “lack of energy,” “mental fatigue,” and “exhaustion.”

Conclusion: Salient symptoms were consistent with those previously reported, along with a broader range of symptoms and impacts, which included fatigue. In addition to physical disability, others such as sleep disturbance, frustration, and effect of daily activities were common high impact themes that emerged.

IMPROVEMENT IN MORNING STIFFNESS IN SUBJECTS WITH PSORIATIC ARTHRITIS IS ASSOCIATED WITH IMPROVEMENTS IN PAIN, PHYSICAL FUNCTION AND PATIENT GLOBAL RESPONSE TO TREATMENT

1Ana-Maria Odbra1, Jessica A. Walsh2, Peter Nash3, Lichem Teng4, Benedicte Guerre5, Rieke Alten6, Johns Hopkins Arthritis Center and Johns Hopkins University School of Medicine, Baltimore, United States of America; 2University of Utah School of Medicine, Department of Internal Medicine, Division of Rheumatology, Salt Lake City, United States of America; 3University of Queensland, Brisbane, Australia; 4Celgene Corporation, Summit, United States of America; 5Schloßpark-Klinik University of Medicine, Berlin, Germany

Background: Stiffness is an important component of inflammatory arthritis and plays a role in psoriatic arthritis (PsA) flare. Patients with inflammatory arthritis report difficulty with activities, “slowing down” due to stiffness and reduced quality of life. Stiffness is hard to quantify because it cannot be measured directly.

Objectives: We examined morning stiffness in PsA patients treated with apremilast (APR) for 16 weeks in the ACTIVE study and explored the relationship between improvements in morning stiffness and pain, physical function and Patient’s Global Assessment of Disease Activity (PiGAs).

Methods: Subjects who met CASPARD criteria for PsA, were biologic-naive and had prior exposure to ≤1 conventional disease-modifying anti-rheumatic drug (DMARD) were randomized (1:1) to APR 30 mg twice daily or placebo (PBO) for 24 weeks. Subjects initially randomized to PBO were re-randomized to APR or PBO at week 12. The PiGAs for patients’ quality of life (QoL) was measured using a 0–100 scale with lower scores indicating better quality of life. Clinical data were collected at baseline and every 2 weeks.

Results: Nineteen PsA patients were interviewed for this study. A core set of PsA symptoms were identified by nearly all patients and with moderate to high average disturbance ratings (Figure 1): joint pain, skin symptoms, stiffness, swollen/inflamed joints, and fatigue. The most salient impacts (Figure 2) were sleep disturbance, physical disability, effects on daily activities, and feelings of frustration. Most common descriptors of fatigue included “fatigue,” “tiredness,” “lack of energy,” “mental fatigue,” and “exhaustion.”

Conclusion: Salient symptoms were consistent with those previously reported, along with a broader range of symptoms and impacts, which included fatigue. In addition to physical disability, others such as sleep disturbance, frustration, and effect of daily activities were common high impact themes that emerged.

Disclosure of Interests: Alexis Ogdie Grant/research support from: (To my university) Novartis, Pfizer, Grant/research support from: Novartis, Pfizer, Grant/research support from: Novartis, Pfizer, Consultant for: AbbVie, Bristol-Myers Squibb, Celgene, Corrona, Eli Lilly and Company, Novartis, Pfizer, and Takeda, Consultant for: AbbVie, Amgen, Bristol-Myers Squibb, Celgene, Corrona, Eli Lilly, Novartis, Pfizer Inc, Takeda, Consultant for: AbbVie, Amgen, BMS, Celgene, Corrona, Lilly, Novartis, Pfizer, Takeda, Consultant for: AbbVie, Amgen, BMS, Celgene, Corrona, Lilly, Novartis, Pfizer, Takeda, Kaleb Michaud Grant/research support from: Pfizer (within past 2 years), Evo Alemao Shareholder of: Bristol-Myers Squibb, Employee of: Bristol-Myers Squibb, Miroslawa Nowak Shareholder of: Bristol-Myers Squibb, Employee of: Bristol-Myers Squibb, Michael E. Husni Grant/research support from: Janssen, Kathleen Bush: None declared, Christina Burgess: None declared, Soumya Reddy Consultant for: Amgen, UCB, Novartis, Pfizer, Abbvie, Joe Scher Grant/research support from: Pfizer, Novartis, Consultant for: Janssen, UCB, Novartis, Amgen, Jessica A. Walsh Grant/research support from: AbbVie, Pfizer, Consultant for: AbbVie, Celgene, Lilly, Novartis DOI: 10.1136/annrheumdis-2019-eular.4349
were switched to APR at Week 16 (early escape) or Week 24. Duration of morning stiffness and severity, assessed by subjects’ reported categories of stiffness (none, mild, moderate, moderately severe, severe), was reported. In the post hoc analysis, changes in morning stiffness severity and effect on pain, physical function and PIGA from baseline to Week 16 were compared between treatment arms. An analysis of covariance model adjusting the baseline value was used in the analysis, where missing values were imputed using the last-observation-carried-forward approach.

**Results:** A total of 219 subjects were randomized (APR: n=110; PBO: n=109), and 192 remained in the study through Week 16. APR and PBO groups were balanced with respect to baseline tender joint count (mean [SD]: 17 [13] vs. 18 [14]), swollen joint count (mean [SD]: 9 [5] vs. 10 [6]) and severity of morning stiffness (moderate to very severe: 87% vs. 80%), as well as previous use of DMARD (67% vs. 72%), baseline use of non-steroidal anti-inflammatory drug (69% vs. 68%) and oral corticosteroid use (12% vs. 13%). Mean [SD] duration of morning stiffness at baseline was shorter with APR vs. PBO (48 [49] vs. 72 [127] minutes). Baseline PIGA (mean [SD]: 5.9 [2.1] vs. 6.1 [2.0]).

**Patient’s Pain Numeric Rating Scale (NRS; mean [SD]: 6.1 [1.9] vs. 5.8 [2.2]).** Health Assessment Questionnaire-Disability Index (HAQ-DI; mean [SD]: 1.3 [0.6] vs. 1.2 [0.6]). Short-Form Health Survey version 2 (SF-36v2) Physical Component Summary (mean [SD]: 32.4 [9.2] vs. 33.9 [8.3]), SF-36v2 Physical Functioning subscale (mean [SD]: 33.2 [11.2] vs. 34.2 [10.1]) and SF-36v2 Bodily Pain domain (mean [SD]: 35.4 [7.6] vs. 37.4 [7.8]) scores were similar in the APR and PBO groups, respectively.

As early as Week 2, a significantly greater proportion of APR vs. PBO subjects experienced morning stiffness severity improvements (≥1 category improvement) (43% vs. 21%; P=0.007). Significant improvements in morning stiffness severity were sustained through Week 16 in APR vs. PBO subjects (46% vs. 26%; P=0.0015). Subjects with improvements in morning stiffness severity in the APR and PBO groups showed consistent improvements in pain, physical function and PIGA at Week 16 (Table). In patients with unchanged stiffness severity, greater improvements were observed across outcome measures in the APR vs. PBO group, although the change from baseline was less than the improved stiffness group. Worsened morning stiffness was associated with lack of improvement in other patient-reported outcome measures.

**Conclusion:** Physical-naive PsA subjects treated with APR for 16 weeks, improvement in morning stiffness severity was evident as early as Week 2 and associated with improvements in pain, physical function and PIGA response.

**Disclosure of Interests:** Ana-Maria Orbai*.

**Efficacy of Gusekumab in Psoriasis Patients with Self-Reported Psoriatic Arthritis with Involvement of the Scalp, Nails, Hands, and Feet: A Pooled Analysis from 2 Pivotal Phase 3 Psoriasis Studies**

Joseph F. Merola1, Soumya G. Chakravarty2,3, Yin You1, Shelly Kafka2, Chetan Karyekar4,5, Ana-Maria Orbai*. 1Brigham and Women’s Hospital and Harvard Medical School, Boston, United States of America; 2Janssen Scientific Affairs, LLC, Horsham, United States of America; 3Drexel Univ College of Med, Philadelphia, United States of America; 4Janssen Research and Development, LLC, Horsham, United States of America; 5Johns Hopkins U School of Medicine, Baltimore, United States of America

**Background:** VOYAGE 1 & 2 were the pivotal Phase 3 GUS trials for plaque psoriasis (PsO).1,2

**Objectives:** Here we compare efficacy of GUS vs PBO & vs adalimumab (ADA) on PsO involving scalp, nail & palmoplantar (palmoplantar pustular PsO excluded per protocol) in a a subgroup of pts with self-reported psoriatic arthritis (PsA), given the association between these distinct PsO phenotypes & PsA.

**Methods:** VOYAGE 1 (n=837) & VOYAGE 2 (n=992) enrolled adult pts who had plaque PsO for ≥6 months, an Investigator Global Assessment (IGA) score ≥3, PASI score ≥12, ≥10% BSA involvement at baseline (BL), & were candidates for phototherapy or systemic treatment for PsO. Pts were randomized to GUS, PBO or ADA at BL, &/or crossover to GUS at wk48. This post-hoc analysis used observed pooled efficacy data for scalp-specific Investigator Global Assessment (ss-IGA), Physician’s Global Assessment (PGA) of Hands &/or Feet (hf-PGA), Fingernail PGA (f-PGA), & Nail Psoriasis Area & Severity Index (NAPSI) in subset of pts self-reporting PsA.

**Results:** In VOYAGE 1 & 2 combined, 335 (18.3%) PsO pts self-reported PsA (PBO 76, GUS 153, ADA 106). Baseline demographics were generally comparable across all 3 treatment groups, with history of methotrexate use: PBO 64.5%, GUS 70.6%, ADA 61.3%. A significantly greater proportion of GUS-treated pts achieved a ss-IGA score of 0/1 (absent/very mild) at wk16 vs PBO, & at wk24 vs ADA (Figure A). Significantly higher proportions of GUS-treated pts achieved a hf-PGA score of 0/1 (clear/almost clear) vs PBO at wk16 with numerically greater differences at wk24 vs ADA (Figure B). At wk16, proportions of pts achieving a f-PGA score of 0/1 (clear/minimal) were 47.6% for GUS vs 17.0% for PBO (p=0.001). The proportions of pts achieving an I- PGA score of 0/1 for GUS vs ADA were comparable at wk16 (47.6% vs 46.4%) & wk24 (67.0% vs 60.9%), but were higher for GUS by wk48 (82.5% vs 57.5%, Table). Mean (SD) improvement from BL in NAPSI score was significantly higher for GUS vs PBO & ADA at wk16 (47.6% vs 46.4%) & wk24 (67.0% vs 60.9%), but were higher for GUS by wk48 (82.5% vs 57.5%, Table). In VOYAGE 1 & 2 combined, 335 (18.3%) PsO pts self-reported PsA showed clinically meaningful improvements vs ADA in ss-IGA & hf-PGA scores at wks16 & 24. Although improvements in 1- PGA & NAPSI were similar in pts treated with GUS vs ADA at earlier timepoints, numerically greater differences were observed with GUS by wk48, likely requiring the additional duration to discriminate between treatments in this slow-growing cutaneous appendage.

AB0774 PSORIATIC ARTHRITIS IMPACT OF DISEASE QUESTIONNAIRE SCORES ARE CORRELATED WITH DISEASE ACTIVITY, AS MEASURED BY CDAPSA, IN PATIENTS WITH PSORIATIC ARTHRITIS

Disclosure of Interests: Ana-Maria Orbai; Klaus Krueger; Frank Behrens; Uta Kitzb; Benoît Guerette; Lillian Mellars; Michele Brunori; Jurgen Wollenhaupt; Johns Hopkins Arthritis Center and Johns Hopkins University School of Medicine, Baltimore, United States of America; Rheumatologische Praxis Munchen, Munchen, Germany; Division of Rheumatology, Goethe University and Fraunhofer IME-TMP, Frankfurt, Germany; Rheumazentrum Ruhrgebiet, Heine and Ruhr-University of Bochum, Bochum, Germany; Celgene Corporation, Summit, United States of America; Schlin Klinik Hamburg Elbek, Klinik für Rheumatologie, Hamburg, Germany.

Background: LAPIS-PsA is an ongoing, national, 52-week, multicenter, prospective, non-interventional study assessing long-term treatment with apremilast (APR) in adult patients with active psoriatic arthritis (PsA) in routine clinical practice in Germany.

Objectives: The current interim analysis assesses the clinical effectiveness of APR, as measured with the Clinical Disease Activity Index for PsA (cDAPSA) and its core components, as well as PsA health-related quality of life (HRQoL), measured with the 9-domain PsA Impact of Disease Questionnaire (PsAID9). In addition, correlations between cDAPSA and PsAID9 were assessed.

Methods: The interim analysis included data obtained at baseline (BL), Visit 1 (V1; 1 month), Visit 2 (V2; 3 months) and Visit 3 (V3; 7 months); all available data for patients treated with APR 30 mg twice daily were included in the analysis. A subgroup analysis was performed among patients categorized by cDAPSA disease activity scores at BL. Clinical characteristics and disease assessments at BL and V1-V3 were compared. Mean PsAID9 scores and proportions of patients meeting the PsAID Patient-Acceptable Symptom State (PASS), defined as a PsAID9 score of 4, were assessed by cDAPSA category at BL. Analyses are based on data as observed at each visit. Pearson's correlations were calculated between cDAPSA and PsAID9 at BL, V1, V2 and V3.

Results: A total of 394 patients were included in the analysis population (mean age: 55.1 years; female: 55.1%; previous biologic use: 25.4%). At BL, patients had a mean PsAID9 score of 5.3 and a mean cDAPSA score of 26.6. Continuous improvements in swollen/tender joint counts and patient-reported pain and disease activity were observed with continued APR treatment (Table). Patients reported incrementally reduced mean cDAPSA scores and consistent improvements in PsAID9 scores from BL to V3. Patients with low disease activity (cDAPSA <13 to ≤27) at BL had a mean (SD) PsAID9 score of 3.4 (1.7) with 71.1% in PsAID9 PASS (Figure). Those with moderate (cDAPSA >13 to ≤27) and high (cDAPSA >27) disease activity had mean (SD) PsAID9 scores of 5.3 (1.9) and 6.1 (1.8), with 26.6% and 11% showing PsAID9 PASS, respectively. At follow-up visits, greater proportions of patients achieving cDAPSA low disease activity or remission also achieved PsAID PASS (Figure). Significant moderate to high correlations were observed between cDAPSA and PsAID9 at BL (Pearson's coefficient r=0.43), V1 (r=0.51; P=0.0001), V2 (r=0.64; P=0.0001) and V3 (r=0.64; P=0.0001).

Conclusion: Results from this observational PsA study of APR demonstrate a significant correlation between disease activity, as assessed by cDAPSA, and PsA-specific life impact/HRQoL, as measured by PsAID9. More patients met the PsAID PASS cutoff while achieving remission or lower disease activity, and improvements in PsA disease activity are associated with the PsAID PASS from a life impact perspective.

AB0774 PREDICTORS OF SWITCHING IN A RETROSPECTIVE ITALIAN COHORT OF PSORIATIC ARTHRITIS PATIENTS RECEIVING BIOTECHNOLOGICAL DRUGS FOR AT LEAST 3 YEARS

Disclosure of Interests: Augusta Ortolan; Pamela Polito, Federico Benetti, Mara Falcetti, Mariagrazia Lorenzini, Roberta Ramonda. Rheumatology Unit, Department of Medicine DIMED, University of Padova, Padova, Italy.

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory disease typically treated, in its moderate-severe form, with biologic disease-modifying antirheumatic drugs (bDMARDs). However, refractory patients are not infrequent, and they are commonly managed by switching from one bDMARD to another. Since the chance of observing a good clinical response decreases according to line of treatment, it would be important

Conclusion: Our aim was to compare characteristics of patients who could maintain the same bDMARD over time (non-switchers) with those of refractory patients in whom bDMARD switch was necessary (switchers), and to evaluate predictors of switching.

Methods: PaA patients attending the Rheumatology Unit of University of Padova, classified according to CASPAR criteria and starting a first line bDMARD, were enrolled in the present retrospective study. We only included patients who maintained a bDMARD regimen (with or without switching) for at least 3 years, to ensure more complete follow-up data. Demographic data, comorbidities, clinimetric and anthropometric indexes, collected at baseline and once a year for every follow-up year and registered in the patient’s records, were used. Disease activity was evaluated through Disease Activity in Psoriatic Arthritis (DAPSA), Leeds Enthesitis Index (LEI), Psoriasis Area and Severity Index (PASI). An overall Body Mass Index (BMI) category, summarizing data from the whole follow-up, was assigned to each patient, according to the BMI category which occurred more frequently in the patient’s record. Then the variable was treated as categorical grouping underweight and normal-weight patients (base category), overweight and class I obesity (2‘ category), and class II and III obesity (3‘ category). Baseline characteristics for switchers and non-switchers were compared through chi-square or Fisher exact test, for categorical variable and t-test or Mann-Whitney test, for continuous variable, as appropriate. Logistic regression analysis was conducted to assess predictors of therapeutic switch. All variables associated to the outcome with a p<0.2 at univariate analysis were included in the initial multivariable model. Backward selection was applied to select the most significant predictors.

Results: One-hundred-eighty-nine PaA patients were enrolled with a mean follow-up time of 7.0±3.5 years. Their characteristics at the beginning of bDMARDs therapy are outlined in Table 1. Among the patients, 51 became switchers and 138 remained non-switchers. Their baseline features did not differ significantly, with the only exception of LEI, higher in switchers (0.5 ± 0.2 vs 0.2 ± 0.6, p=0.05). When predictors of switch were evaluated, the independent variables positively associated to the outcome at univariate analysis with p<0.2 were: male sex (OR 1.57; 95% CI 1.09, 2.26), obesity together with respect to normal-weight patients (OR 2.18) were able to independently predict the odds of switching.

Conclusion: Obesity and entheseal involvement, as expressed by LEI, seem to be the most useful predictor in order to identify patients who are more likely to switch, in line with data from literature that highlight a lower response of bDMARDs in obese patients.

1] Ustekinumab in psoriatic arthritis: need for studies from real-world evidence.

Disclosure of Interests: None declared

Conclusion: The duration of psoriasis was 14.8 ± 12.8 years, and 6.3 ± 6.5 years for the arthritic. 34.5% were oligoarticular forms, 13.8% polyarticular forms, and the remaining 51.7% were mixed forms. The distal interphalangeal joints synovitis was present in 38% of the patients and dactylitis in 24%. 17 patients were naïve to biologic drugs (29.3%), UST was second line in 25.9%, third in 32.8%, fourth in 10.3% and fifth in 1.7% of patients. Half of the patients were treated with MFX. In the baseline situation, 9.4% had low activity, 75% had moderate activity, and 15.6% had high activity by DAPSA index. At the end of the analysis, 12.5% were in remission, 59.4% in low activity, and 28.1% in moderate activity, according to the DAPSA index. There were no patients in high activity. That is, 72% were in DAPSA remission/low activity. The average reduction of DAPSA was 9.53 ± 5.52 (McNemar’s p <0.0005). The only factor associated with remission/low DAPSA activity was baseline DAPSA, OR 1.51 (1.02-2.22), p = 0.044. In 6 patients, the drug was discontinued (4 due to lack of efficacy and 2 due to poor tolerance or adverse effects).

Disclosure of Interests: None declared

To compare rates of myocardial infarction (MI), stroke and revascularization by treatment type in patients with PsA.

Methods: We conducted a population-based cohort study of treated PsA patients in the MarketScan database in 2014-2016. The cohort entry was the date of the first prescription for a study drug (apremilast only or in combination with ≥1 other study drugs, anti-TNF-α biologics only, other...
biologics and DMARDs (OBDDs) only, corticosteroids only, OBDDs + corticosteroids and anti-TNF-α biologics with OBDDs and/or corticosteroids) after March 21, 2014, the date on which apremilast was approved. Patients were followed from cohort entry through censor date, defined as the first of the following: index date (date patient became a case), end of record or end of study period (December 31, 2016). MI and stroke cases required 1 inpatient diagnosis plus 2 additional diagnoses on separate days; revascularization required a procedure code for revascularization without MI or stroke, all >7 days after cohort entry. A patient was considered currently exposed from the prescription date through the prescription duration + 30 days. We calculated incidence rates (IRs) and 95% confidence intervals (CIs) for each outcome per 100 patient-years among the entire population and in the subgroup of patients with no history of serious cardiovascular disease (CVD).

**Results:** The study population included 51,971 patients (median age: 52 years, 52% female, 4.0% serious CVD history). IRs were low for all outcomes, and differences between treatments did not reach statistical significance (95% CIs for IRs were overlapping). Among the 187 MI cases, IRs (95% CIs) as follows: for apremilast only, 0.10 (0.01, 0.35); anti-TNF-α biologics only, 0.13 (0.09, 0.19); anti-TNF-α biologics with OBDDs and/or corticosteroids, 0.31 (0.22, 0.43); OBDDs only, 0.32 (0.23, 0.44); corticosteroids only, 0.44 (0.27, 0.68); OBDDs + corticosteroids, 0.45 (0.24, 0.76); and apremilast in combination, 0.49 (0.20, 1.02). Among the 79 stroke cases, IRs (95% CIs) were as follows: for corticosteroids only, 0.08 (0.02, 0.22); anti-TNF-α biologics only, 0.09 (0.06, 0.13); for OBDDs only, 0.10 (0.05, 0.17); anti-TNF-α biologics with OBDDs and/or corticosteroids, 0.12 (0.06, 0.20); apremilast only, 0.15 (0.03, 0.43), or in combination, 0.14 (0.02, 0.51); and OBDDs + corticosteroids, 0.21 (0.08, 0.45). Among the 292 revascularization cases, IRs (95% CIs) as follows: for apremilast only, 0.25 (0.08, 0.57), anti-TNF-α biologics only, 0.36 (0.29, 0.44); anti-TNF-α biologics with OBDDs and/or corticosteroids, 0.37 (0.27, 0.50); OBDDs + corticosteroids, 0.38 (0.19, 0.68); apremilast in combination, 0.42 (0.15, 0.92); OBDDs only, 0.48 (0.36, 0.61); and corticosteroids only, 0.49 (0.31, 0.73). Among patients with no serious CVD history, IRs were generally lower but results were not materially different from the main analyses.

**Conclusion:** Rates of MI, stroke and revascularization were low for treated PsA patients and were similar across treatments.

**IMPACT OF DISEASE IN A SPANISH POPULATION WITH PSORIATIC ARTHRITIS**

Rubén Queiró Silva1, Juan D. Cañete2, Susana Gómez3, Ana Cabest3, 1Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain; 2Hospital Clínic, Rheumatology, Barcelona, Spain; 3Pfizer Medical Dpt., Madrid, Spain

**Background:** Patients with psoriatic arthritis (PsA) experience significant disability and reduced quality of life, resulting from the emotional distress and functional impairment associated with psoriatic skin lesions, as well as joint disease. Patient reported outcomes are important to evaluate healthcare interventions and to reflect the impact of PsA on patients’ lives.

**Objectives:** The aims of the present study were to describe disease characteristics of PsA patients with an acceptable symptoms state (PsAID score<4) as well as to analyze predictive factors for PsAID<4.

**Methods:** Post-hoc analysis of data from a cross-sectional observational, multicenter study, aimed at evaluating the prevalence of MDA in a Spanish population with PsA, to describe their characteristics and to evaluate the association between MDA and the impact of the disease as assessed by the PsAID questionnaire. The original study included 227 adult patients of both genders diagnosed with PsA according to CAPSAR criteria with at least one year of disease evolution and on treatment with biological and/or conventional synthetic disease modifying anti-rheumatic drugs (cDMARD). The PsAID questionnaire reflects the effect of PsA from the patient’s perspective. It is composed of 12 physical and psychological domains. PsAID score < 4 identified patient-acceptable symptoms state.

**Results:** 122 patients with a PsAID score < 4 were included. Demographic and clinical characteristics of the study population are shown in Table 1. Overall, 53/102 (52.0%) and 83/122 (68.0%) patients presented articular or skin remission, respectively. 76/122 (62.3%) of patients were in MDA state; the majority presented a low disability state according to HAQ (85.2%). A moderate relationship between HAQ<0.5 and PsAID<4 (k=0.532) and between MDA and PsAID<4 (k=0.3594) were observed. Multivariable logistic regression analysis showed that patients with distal interphalangeal joint (DIP) involvement (odds ratio [OR] [95%CI]), 0.402 [0.203-0.799]; p=0.009), family history of PsA (OR: 0.252 [0.089-0.716]; p=0.010) and

**PSA PATIENTS REACHING MINIMAL DISEASE ACTIVITY5/7 IMPROVE IN ALL FIELDS OF PSAID**

Jose Pinto-Tasende1, Clara Ventín1, Maria Caiero1, Alvaro Seijas2, Rodrigo Aguirre2, Maria Teresa Silva1, Francisco Blanco1. Hospital Universitario A Coruña, Rheumatology, A Coruña, Spain

**Background:** Patients with psoriatic arthritis (PsA) show impact on physical and psychological aspect of the disease and it can be measured with the PsA Impact of Disease (PsAID) questionnaire. Impact of disease should improve if patient reach a minimal disease activity (MDA).

**Objectives:** To assess the association between MDA and PsAID questionnaire in patients with PsA from daily clinical practice.

**Methods:** A cross-sectional study was carried out in consecutive patients who fulfilled CASPAR criteria and who were treated according to routine treatment. Patients in MDA state were 36 (50%) and median of total score of PsAID was 4.70 (0.85-9.40). All fields of PsAID improved if they reached MDA 5/7 (p<0.01). MDA 5/7 was also related to age, duration of the disease, CRP and DAPSA (see table).

**Conclusion:** Fifty percent of PsA patients achieve MDA in daily clinical practice. MDA patients had a significantly lower impact of the disease according to PsAID.

MDA: Minimal disease activity; SD: Standard deviation; BMI: Body mass index. CRP: C-Reactive Protein; HBP: High blood pressure; DIP: Distal interphalangeal joint disease. DM: Diabetes mellitus; PASI: Psoriasis Area and Severity Index; HAQ: Health Assessment Questionnaire; PsAID: Psoriatic Arthritis Impact of Disease. CI: confidence intervals

Conclusion: There are discrepancies between the treatment goals (MDA) and the impact of disease as assessed by PsAID. Clinical characteristics such as DIP involvement, inflammatory load (PCR) and genetic factors (familial history) seem to be associated with a lower probability of being in an acceptable symptoms state in PsA patients.

Methods: A cross-sectional study was conducted with 136 consecutive patients with PsA (CASPAR criteria). Sociodemographic and anthropometric data, CVRF, disease activity according to DAPSA categories, HAQ, MDA, and CVR measured by SCORE chart, was collected. An Mt>800 μm and/or the presence of carotid plaque (Mannheim consensus), defined a high CVR by ultrasound. We analyzed the concordance (kappa) between the MDA response and the low activity and remission categories according to the DAPSA. Clinical variables of PsA associated with a high CVR were evaluated by multivariate analyses.

Results: Intima-media thickness values correlated well with CVR categories according to SCORE (p < 0.0001). 40% of patients included in the low and moderate risk categories according to the SCORE risk chart were reclassified as high CVR after the ultrasound examination.

In the multivariate analysis, some characteristics of the disease were independently associated with a high CVR.

This reveals that patients with enthesitis and/or structural damage are those who tend to have a high CVR. When comparing DAPSA and MDA criteria, we found a moderate correlation between the MDA response and the DAPSA low activity (κ = 0.52, p < 0.0001) and between MDA and DAPSA remission (κ = 0.47, p < 0.0001).

Background: Psoriatic arthritis (PsA) patients usually have a high prevalence of cardiovascular risk factors (CVRF) and cardiovascular events, which makes the routine estimation of cardiovascular risk (CVR) highly advisable. Currently, this risk is estimated through classic risk scores (SCORE, Framingham), however, the values of these scores may underestimate the real CVR of these patients.

Methods: We aimed to analyze whether carotid ultrasound is a useful tool for estimating CVR in patients with PsA, and if it is capable of correcting the estimated risk using classical tables. We also analyzed the usefulness of the MDA criteria and the DAPSA categories for clinical decision making in real practice.

Disclosures of Interests: None declared DOI: 10.1136/annrheumdis-2019-eular.4794

The high CVR in our population is related not only to classical CVRF, but also to the inflammatory load (enthesitis) and structural damage (erosions) of PsA. DAPSA is an appropriate instrument for clinical decision making in routine practice because it correlates reasonably well with stringent therapeutic goals such as MDA.

criteria were subsequently sub-classified using the Moll and Wright classification criteria based on the manifestations of PsA at their index outpatient visit. This subtype was then compared to their Moll and Wright subtype at the last outpatient visit prior to January 3, 2019. While it was possible for patients to display more than one subtype simultaneously, the classification made at baseline and at latest visit reflected the predominant Moll and Wright subtype of the patient, in the opinion of the expert treating rheumatologist.

Results: 76 patients were identified as meeting entry criteria, with none being in remission at the index visit. Mean age of patients at the latest visit was 60.2 ± 12.6 years, and 47.4% were male. Median time between the index visit and latest visit was 7 years (IQR: 5 to 8 years). 42.1% of patients had the same Moll and Wright subtype at both visits. Table 1 presents the distribution of Moll and Wright subtypes at index visit and latest visit. Table 2 reports the changes, or lack thereof, in subtype between visits. 22/76 patients (28.9%) were in remission at the latest visit. Of the patients in remission, 12 (54.5%) were being treated with a biologic, DMARD, and/or steroid.

Conclusion: In this retrospective analysis there was a persistence of Moll and Wright subtype in 42.1% of psoriatic arthritis patients over the median time of 7 years. Whether patients who maintain Moll and Wright subypes respond differently to targeted therapy for PsA should be evaluated in prospective trials.

ASSOCIATION OF MICA POLYMORPHISM AND SERUM LEVELS WITH PREDISPOSITION TO PSORIATIC ARTHRITIS

| Renata Sokolik, Marta Dratwa, Joanna Wielnińska, Milena Iwaszkówna, Monika Chaszczewska-Markowska, Piotr Wiland, Katarzyna Bogunia-Kubiś |
| Wrocław Medical University, Department of Rheumatology and Internal Medicine, Wrocław, Poland; Polish Academy of Sciences, Laboratory of Clinical Immunogenetics and Pharmacogenetics, Hereditary Institute of Immunology and Experimental Therapy, Wrocław, Poland |

Background: Psoriatic arthritis (PsA) is a multifactorial chronic inflammatory disease manifested by joint inflammation and cutaneous psoriasis. The precise etiology of PsA remains unknown, however both genetic and environmental factors contribute to development of this immune-mediated disease.

**Objectives:** This present study aimed to assess whether polymorphism within gene coding for major histocompatibility complex (MHC) class I chain-related A (MICA) proteins could be a prognostic factor of PsA.

**Methods:** For this purpose 77 PsA patients and 234 controls were enrolled to the study on MICA polymorphic variants. Genotyping for MICA alleles was performed using a LightSNiP assay. In addition the MICA serum levels were studied in 66 patients and 99 controls employing Luminex assay.

**Results:** Interestingly, MICA polymorphism was found to affect the susceptibility to PsA. The presence of the A (Val) variant was found to increase the risk of PsA (OR = 1.932, p = 0.022).

**Conclusion:** These results imply that MICA polymorphism may constitute a risk factor of PsA and be associated with MICA serum levels in PsA patients. Supported by the National Science Centre (Poland) grant 2016/21/B/NZS/01901.

SECUKINUMAB PROVIDES IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS, REGARDLESS OF THE TIME SINCE DIAGNOSIS: POOLED RESULTS FROM THE SECUKINUMAB PHASE 3 TRIAL PROGRAM

| Vibeke Strand, Oliver Fitzgerald, Laura C. Coates, Jessica A. Walsh, Juan D. Carbonell, Peter Nash, Eric Davenport, Luminia Pricop, Gregory Hustache, Isabelle Gilleoteau, Aurore Yocolly, Matthias Augustin, Stanford University, Palo Alto, United States of America; University College Dublin, Dublin, Ireland; University of Oxford, Oxford, United Kingdom; University of Utah School of Medicine, Salt Lake City, United States of America; Hospital Clinic and IDIBAPS, Barcelona, Spain; University of Queensland, Brisbane, Australia; RTI Health Solutions, Research Triangle Park, United States of America; Novartis Pharmaceuticals Corporation, East Hanover, United States of America; Novartis Pharma AG, Basel, Switzerland; Novartis Global Service Center, Dublin, Ireland; University Medical Center Hamburg-Eppendorf, Hamburg, Germany |

Background: Psoriatic arthritis (PsA) can have a profound impact on health-related quality of life (HRQoL). Secukinumab (SEC), a fully-human IL-17A inhibitor, has been shown to improve symptoms and HRQoL in patients (pts) with PsA.

**Objectives:** To evaluate the impact of SEC on HRQoL, assessed using the Short Form-36 Health Survey (SF-36), in pts with PsA stratified by time since first diagnosis (<2 yrs or ≥2 yrs).

**Methods:** Pts were randomized to either subcutaneous placebo (PBO) or SEC 150 mg (FUTURE 2, 3, 4, 5), 150 mg no load (NL; FUTURE 4, 5). Pts were randomized to either subcutaneous placebo (PBO) or SEC 150 mg (FUTURE 2, 3, 4, 5), 150 mg no load (NL; FUTURE 4, 5). Doses were administered at baseline (BL) and Wks 1–4, followed by every 4 wks (or every 4 wks from BL to Wk 16; observed data are presented at Wk 52. The proportion of pts reporting improvements ≥ minimum clinically important differences (MCID) in SF-36 physical (PCS respondents), mental component summary (MCS respondents), and individual SF-36 domains was also assessed. Non-responder imputation was employed for missing values in responder analyses. Fisher’s exact test was used to compare the proportion of responders.

Disclosure of Interests: None declared
Results: A total of 2049 pts were included: 681, 461, 572, and 335 in the PBO, SEC 300 mg, 150 mg, and 150 mg NL groups, respectively. Of these, 34%, 30%, 32%, and 33% were classified as <2 yrs since PsA diagnosis (overall: 32%). Mean times since diagnosis were 0.8 yrs across treatment groups in the <2 yrs subgroup, and 8.6-10.1 yrs in the ≥2 yrs subgroup. The least squares mean (LSM) changes from BL to Wk 16 in PCS and MCS were significantly improved with all doses of SEC vs PBO in both <2 yrs (PCS: BPO = 0.8 vs 6.5 [p<0.0001]; 4.8 [p<0.001], 3.8 [p<0.01], 2.8 [p<0.01], 3.8 [p<0.001]) for the 300 mg, 150 mg, and 150 mg NL groups, respectively: MCS: BPO = 1.3 vs 4.0 [p<0.01]; 4.4 [p<0.01], 3.8 [p<0.05]) and ≥2 yrs since diagnosis (PCS: BPO = 1.9 vs 6.9 [p<0.0001], 5.3 [p<0.0001], 5.5 [p<0.0001]; MCS: BPO = 0.9 vs 3.6 [p<0.01], 2.8 [p<0.01], 3.0 [p<0.01]) groups. Improvements in individual SF-36 domains were reported with SEC vs PBO in the overall population and both subgroups (Figure). At Wk 16, the proportion of PCS responders was significantly higher with SEC vs PBO, in both <2 yrs (PBO: 38.5% vs 300 mg: 69.1%. [p<0.0001]; 150 mg: 59.5% [p<0.01]; 150 mg NL: 53.6% [p<0.05]) and ≥2 yrs (PBO: 43.8%; 300 mg: 64.6%; [p<0.001]; 150 mg: 59.4% [p<0.01]; 150 mg NL: 65.8% [p<0.0001]) in those <2 yrs vs ≥2 yrs from diagnosis. Improvements in PCS, MCS, individual domains, and MCID responses with SEC were sustained to Wk 52.

Conclusion: SEC offered significant, clinically meaningful and sustained improvements in HRQoL (SF-36) in pts with PsA, regardless of time since diagnosis.

Merola, Diamant Thaci, Nicola Booth, Steve Lobosco, Gary Milligan, Matthew Huffman, Julie Brit, Walther Krueger, Elizabeth Houldsworth,*University of Bath, Bath, Somerset, United Kingdom; 2Harvard Medical School, Boston, United States of America; 3Comprehensive Center for Inflammation Medicine, Ratzeburger Allee, Germany; 4Adelphi Real World, Macclesfield, United Kingdom; 5Eli Lilly and Company, Indianapolis, United States of America, 6Hippokrates Universitaires de Geneve, Geneva, Switzerland

Background: PsA is a chronic inflammatory arthritis with heterogeneous clinical manifestations. Disease burden and quality of life (QoL) is affected by both joint and skin aspects of the disease (1,2). Given variability among patients of the extent and severity of joint and skin symptoms, the relative impact of each aspect on overall burden to the patient has not been well quantified.

Objectives: Describe the relative impact of joint and skin symptoms in PsA in a real-world population through an assessment of patient perception of symptom importance, QoL, and work productivity.

Methods: Cross-sectional survey of rheumatologists and dermatologists and their PsA patients in Australia, Canada, France, Germany, Italy, Japan, Spain, UK, and US. Physicians provided data on patient Body Surface Area (BSA) psoriasis coverage at the time of survey. Patient self-reported data included perceptions of symptom importance, EQ-SD, Psoriatic Arthritis Impact of Disease (PsAID12), and Work Productivity and Activity Impairment (WPAI: SHP) Index. Patients were compared according to BSA (BSA=0 vs. BSA>0), using parametric and non-parametric tests as appropriate.

Results: Data were collected for 3200 patients with PsA by 454 rheumatologists and 238 dermatologists. 556 patient self-completed questionnaires were also collected. Mean age was 49 years. 46% female, 69% had a BSA >0. Patients with BSA>0 had mean tender joint count (TJC) of 5.2 and mean swollen joint count (SJC) of 4.8. Patients with BSA=0 had mean TJC and SJC of 2.0 and 1.5, respectively. Across all patients, when asked to prioritize the burden of symptoms, 62% of patients prioritized joints and 38% prioritized skin. In patients with BSA>0, 35% still prioritized skin as most important, 41% indicated they experienced anxiety/depression as a result of their PsA, with 62% indicating both joint and skin symptoms were the cause (28% joint alone, 9% skin alone).

Patients with BSA >0 reported significantly worse QoL and work productivity and activity impairment than BSA=0 (EQSD index 0.79 vs. 0.85, p<0.0001; EQSD VAS 71.98 vs. 77.68, p<0.0001; PsAID 2.91 vs. 1.66, p<0.0001; WPAI overall 25.61 vs. 16.32, p<0.0001).

Conclusion: The majority of PsA patients prioritize joint symptoms over skin. Patients with any joint/skin involvement likely have worse quality of life than in the general population (3). PsA patients report that both joints and skin have an impact on their QoL and work productivity with significantly greater impact in those who have skin involvement. Treatment goals focusing on both components of PsA would optimize patient outcomes.

Subclinical myocardial involvement in psoriatic arthritis patients

Background: Psoriatic arthritis (PsA) is a systemic inflammatory disease affecting 15-30% of patients with psoriasis. Patients with PsA present a higher risk of left ventricular systolic dysfunction compared to controls. GLS measured by speckle tracking was lower in PsA patients (mean =-19.79, s.d. = 1.65) than controls (mean =-21.24, s.d. = 1.61). Regression analysis showed statistically significantly lower GLS scores with increasing CRP and ESR. Baseline median (IQR) of CRP was 7.4 (5.6-13.4) in PsA and 2.2 (1-2.8) in controls. Baseline median (IQR) of ESR was 29 (2-42) in PsA and 15 (12-19) in controls. There were no differences in other variables studied.

Methods: Sixty patients (29 males) and 34 healthy controls (18 males) participated in the study. The patients’ mean age was 50.7 years (s.d. = 17.42). They were subjected to 2D transthoracic echocardiography, tissue Doppler imaging, and speckle tracking echocardiography, in order to evaluate left ventricular systolic function with conventional indices such as ejection fraction (EF), and with novel indices such as global longitudinal strain (GLS). Diastolic dysfunction was also assessed in both groups. Blood tests including CRP and ESR were conducted. Disease duration and severity scores, PASI and DAS 28, were also recorded. The statistical analysis was conducted with SPSS v23.0.

Results: Linear regression analysis showed statistically significantly impaired left ventricular systolic function (p<0.001), as assessed with global longitudinal strain (GLS), in PsA patients (mean =-19.79, s.d. = 1.65) compared to the controls (mean =-21.24, s.d. = 1.61). The results were adjusted for age and gender. Ejection fraction, on the contrary, did not show any statistically significant difference between the two groups (p=0.535). Left ventricular diastolic function did not present significant differences between the two groups. GLS showed no association with disease duration, severity scores or the blood tests.

Conclusion: PsA patients present a higher risk of left ventricular systolic dysfunction compared to controls. GLS measured by speckle tracking echocardiography is a useful tool in revealing this subclinical myocardial impairment.

Drug survival of secukinumab for psoriatic arthritis in a real-world setting

Background: Secukinumab is a newly introduced biologic therapy against IL-17 which has been approved for Psoriatic Arthritis and has showed efficacy in clinical trials, but real world data is still lacking.

Objectives: This study aims to analyze secukinumab drug survival for psoriatic arthritis in a real world environment.

Methods: Multicentric observational, longitudinal retrospective study conducted at 4 tertiary hospitals in Madrid region. Patients with clinical diagnosis of psoriatic arthritis which had received at least one dose of secukinumab between January 2016 and October 2018 were included. With follow up period till December 31, 2018. Medical records were reviewed to collect data about psoriatic arthritis involvement, comorbidities, previous DMARD and biDMARD therapies and its reasons for discontinuation, duration of secukinumab therapy, reasons for discontinuing secukinumab therapy and adverse events. Statistical analysis was performed including bivariate analysis (considering withdrawal of drug during study period or not) and survival analysis with Kaplan-Meier and Cox regression.

Results: 177 patients that initiated secukinumab therapy in the recruitment period were included. 123 patients were on 150 mg dose and 54 on 300 mg dose. Average follow up period was 13 months (SD 8.28; range 1-34) In the bivariate analysis, a higher proportion of biologic-naïve patients was found among the group without secukinumab withdrawal during the study (40% vs 23%, p 0.07). No other differences were observed between both groups regarding demographic characteristics nor comorbidities (tobacco exposure, hypertension, diabetes mellitus, dyslipidemia, ischaemic heart disease or malignancy). Median survival time for secukinumab in the Kaplan-Meier analysis was 21.2 months (IC 95%; 14.3 - 22.2), with an average of 19.9 months. One event was censored due to lost to follow-up. Secukinumab treatment was withdrawn in 79 patients (44.6%). Reasons for discontinuation were lack of effectiveness (37%), either primary (40 patients) or secondary (26 patients), adverse events (9 patients, 0.5%), elective surgery in one patient and latex allergy in other. The only variable associated to higher drug survival in Cox regression analysis was biologic-naïve status. No differences in drug survival were found in all other variables studied (gender, age, secukinumab dosage, illness duration, clinical features, tobacco exposure and rest of comorbidities).

Conclusion: As secukinumab was marketed in 2016, real-world setting studies lack long term data. This mean follow up period in our study was 13 months. Most of withdrawals were to lack of effectiveness. Median survival was 21.2 months, significantly higher in biologic-naïve patients. No other differences were found in all other variables studied. Probably real-world data differ from those of clinical trials.

High treatment satisfaction of therapy with ustekinumab in patients with active psoriatic arthritis due to early and long-term treatment response and high tolerability – results of the non-interventional study sustain

Disclosure of Interests: None declared

Background: SUSTAIN is a prospective, multi-center non-interventional study in Germany. 

Objectives: The objectives are to observe long term efficacy and safety, quality of life and further patient reported outcomes in patients with active psoriatic arthritis (PsA) under treatment with ustekinumab in routine clinical care.

Methods: In this study nearly 400 patients were planned to be included at 75 centers for 160 weeks with documentation at intervals at week 0 and 4 and then every 12 weeks. The treatment with ustekinumab is according to the label. Besides demographic data, the following data will be documented: Number of swollen and tendon joints, tender entheses, amount of skin psoriasis (BSA and PASI), patient reported outcome concerning disease activity of PsA and pain, Health Assessment Questionnaire (HAQ), quality of life (SF-12), sleep quality (VAS), satisfaction with therapy of patient and physician, safety (adverse events/serious adverse events), pharmacoeconomic aspects, number of patients with “Minimal Disease Activity” (MDA), number of patients with MDA at week 28 and 52. For the present interim analysis baseline data of 336 patients and results of the documented visits up to week 112 were analyzed.

Results: For the present analysis 336 patients (57% women) at 75 centers were observed. The number of documented patients was 310 at week 4, 318 at week 16, 278 at week 28, 160 at week 76 and 108 at week 112. At time of inclusion into the study, patients had arthritis at small (73.2%) and/or large (52.4%) joints, spinal involvement (17%) and enthesitis (13%). For 30.1% of patients, the medical history revealed structural bone damage and 2.1% had uveitis present at time of inclusion. Mean age was 54 years (22-85), mean BMI 30 kg/m² (19-52). The mean ustekinumab dose was 0.7 mg/kg body weight (0.2-1.3). 54.5% of the patients had as prior medication at least one TNF inhibitor and 44% used MTX as concomitant medication.

The data extension of the present interim analysis demonstrated relevant improvements with high treatment satisfaction and good safety and tolerability after 4 weeks and up to 112 weeks. The data show the maintenance of these treatment results up to week 112, i.e. reduction in the number of tender joints from a mean of 10.0 (CI 95% 8.6/11.3) at baseline to 1.8 (1.1/2.5) at week 112. The number of swollen joints improved from 4.1 (3.4/4.9) at baseline to 0.7 (0.3/1.0) at week 112. In the same period, skin symptoms (PASI) declined from 8.4 to 1.0 and pain assessment (VAS) declined from 56.0 to 34.3. Of the 96 patients who completed the week 112, 30.2% reached MDA at week 28 and 29.2% reached MDA at week 52.

Efficacy of the therapy with ustekinumab was assessed as “very good” or “good” by 91.1% of the treating physicians and by 89.9% of the patients at week 112. Until data cut off point (45 months after study start), 105 SAEs have been documented, of which only 14 were related to ustekinumab as assessed by physician of treatment center. 3.9% of patients discontinued treatment with ustekinumab (N=121), mainly due to an adverse event. Safety of therapy with ustekinumab was assessed as “very good” or “good” by 100% of the treating physicians and by 100% of the patients at week 112.

Conclusion: The present interim analysis of the prospective non-interventional study SUSTAIN confirmed relevant improvements with high treatment satisfaction and good safety in patients with active psoriatic arthritis treated with ustekinumab after 4 weeks and demonstrated that these effects were maintained at least up to 112 weeks in routine care.

Disclosure of Interests: Joerg Wendler Consultant for: Roche Pharma AG, AbbVie, Jannissen Cilag, Novartis, Speakers bureau: Roche Pharma AG, AbbVie, Jannissen Cilag, Novartis, Peter Wagener: None declared, Frank Hamann: None declared, Nils Damann: None declared, Evgenia Movshovich: None declared, Frank Behrens (G ThrA) research support from: AbbVie, Pfizer, Roche, Chugai, Prophylaxis, Bioline, Novartis, Consultant for: AbbVie, Pfizer, Roche, Chugai, UCB, Bristol-Myers Squibb, Celgene, MSD, Novartis, Biotest, Janssen, Genzyme, Eli Lilly, Speakers bureau: Ad board: AbbVie, Pfizer, Roche, Chugai, UCB, Bristol-Myers Squibb, Celgene, Novartis, Biotest, Janssen, Genzyme, Eli Lilly. DOI: 10.1136/annrheumdis-2019-eular.4655
Results: The study included 5062 PsA patients. Data showed an increase in use of bDMARDs in recent years (Fig 1). The trend in increasing use of bDMARDs was not affected by age, sex, and ethnicity. Elaercept was the most commonly used bDMARD (10.1%) over time, whereas, methotrexate was the most commonly used cDMARD (25.9%). A decrease in use of infliximab was noted along with the introduction of adimumab, golimumab and ustekinumab. Notably, a decrease in the utilization of cDMARDs, but not corticosteroid use, was seen with the advent of bDMARDs (Fig 2). However, this decrease in cDMARD use was not observed in patients treated with infliximab [Correlation Coefficient 2.69% (-47.5%, 51.6%), P=0.921]. Conclusion: More PsA patients are using bDMARDs in recent years in lieu of cDMARDS. This change in PsA management highlights a need for further research on the relative safety, efficacy, and cost of biologic agents to better guide evidence-based treatment decisions.

AB0788 LUPUS CO-MORBIDITY IN PATIENTS WITH PSORIATIC ARTHRITIS: A POPULATION-BASED CASE-CONTROLLED STUDY

Danielle Korkus1, Tal Gazitt2, Ilan Feldhaimer2, Idit Lavii4, Amir Haddad2, Erez Ba’at3, Sari Greenberg-Dotan2, Amnon Cohen1,3,7, Devy Zisman2, The Ruth and Bruce Rappaport Faculty of Medicine Technion, Haifa, Israel, 3Carmel Medical Center, Rheumatology Unit, Haifa, Israel, 4Central Headquarters, Clalit Health Services, Chief Physician’s Office, Tel Aviv, Israel, 5Carmel Medical Center, Department of Community Medicine and Epidemiology, Haifa, Israel, 6Faculty of Health Sciences, Ben-Gurion University of the Negev, Sha’al Research Center for Family Medicine and Primary Care, Beer-Sheva, Israel

Background: Patients with psoriasis and psoriatic arthritis (PsA) can develop a variety of comorbidities including metabolic syndrome, diabetes, hypertension, cardiovascular diseases and depression. Comorbidities, in turn, may influence the therapeutic regimen and affect treatment results. Previous studies show a high incidence of coexistence of psoriasis and systemic lupus erythematosus (SLE). Unlike psoriasis, the coexistence of PsA and SLE has been reported only in case reports. The purpose of this study was to assess agreement by experts on recommended disease activity assessment in PsA patients and to develop a consensus definition of clinical remission.

Methods: The study, which was conducted from 2002-2017, is a retrospective study on a PsA cohort consisting of 4,836 PsA patients matched for age and sex with 24,180 randomly selected control patients. Data on this cohort was derived from the database of more than 4.3 million people enrolled in the largest health care provider in Israel, Clalit Health Services. The database was used to extract demographic data, such as age, sex, ethnicity and socioeconomic status; clinical and laboratory manifestations of SLE; medication dispensation and SLE-inducing medications. T-test was used to compare continuous variables and a Chi-square test was used for categorical variables. All tests were 2-sided; p values of <0.05 were considered statistically significant.

Results: The PsA study group consisted of 4,836 subjects, at a median age of 56±15, 2603 (53.8%) of whom were females. The control group consisted of 24,180 subjects matched for age and sex. 18 patients (0.37%) in the PsA study group, and 39 patients (0.16%) in the control group where diagnosed with SLE (p=0.002). SLE patients without co-existing PsA had higher anti-double stranded DNA (anti-dsDNA) positivity (92.3% vs 66.7%, p=0.022) and positive anti-cardiolipin (ACL) antibodies (46.2% vs 16.7%, p=0.041). No other significant differences were observed between the two groups in terms of clinical and laboratory manifestations of SLE. PsA patients with concomitant SLE compared to PsA patients without SLE were more often female (100% vs 53.7%, p<0.0001), had more osteoporosis (38.9% vs 12.8%, p=0.005) and were more likely to be treated with beta blockers (27.8% vs 9.8% p=0.027). Usage of medications with known potential to induce SLE prior to diagnosis of SLE was higher in the study group of PsA patients (11 out of 18 patients) than in the control group, but there was no difference in SLE manifestations between these two groups. Cutaneous manifestations associated with later onset of SLE included proton pump inhibitors (PPI) [0.27% in the PsA cohort vs 0.1% in the control group (p=0.004)], beta blockers [0.33% vs 0.16% (p=0.011)], angiotensin converting enzyme inhibitors, and angiotensin II receptor blockers [ACE-I] (0.35% vs 0.03%, p=0.001), thiazide diuretics [0.35% vs 0.1% (p=0.001)], anti-tumor necrosis factor (anti-TNF) agents [0.4% vs 0.2% (p=0.002)]. Conclusion: A 2.3 fold increase in the prevalence of SLE in PsA patients than in the control group was found in our study population. There were no significant differences in the clinical and laboratory manifestations of SLE between these two groups. The positive correlates between SLE and PsA may point to common underlying pathogenetic pathways and may affect treatment choices and medication development. More research is needed for a better understanding of this diseases association.

AB0788B RECOMMENDATIONS FOR DISEASE ACTIVITY ASSESSMENT AND DEFINITION OF CLINICAL REMISSION IN PSORIATIC ARTHRITIS: A DELPHI-BASED EXPERT CONSENSUS

Raquel Almodovar1, Juan D. Cañete2, Eugenio de Miguel2, Jose Antonio Pinto Tasende1, Rubén Guerón Silva1, 1University Hospital Fundación Alcorcón, Madrid, Spain, 2Hospital Clínico e IDIBAPS, Barcelona, Barcelona, Spain, 3University Hospital La Paz, Madrid, Madrid, Spain, 4Complexo Hospitalario Universitario de A Coruña, A Coruña, Spain, 5Central University Hospital of Asturias, Asturias, Spain

Background: Patients with psoriatic arthritis (PsA) have heterogeneous clinical presentations, with diverse articular and dermatological features and varied disease courses and outcomes, so the assessment of disease activity implies important difficulties. Although the goal of treatment of PsA is to achieve remission, there is no a universally accepted definition. Objectives: The purpose of this study was to assess agreement by experts on recommended disease activity assessment in PsA patients and to develop a consensus definition of clinical remission. Methods: A modified Delphi approach was used as a consensus method. A scientific committee of experts provided 86 statements that were submitted in 2 rounds to a panel of 130 Spanish experts in PsA (in September and October 2018, respectively), addressing issues regarding the current assessment of remission, variables that should be included in the assessment of PsA patients and the definition of remission, and the use of disease activity scores. Results: The expert panel reached agreement for 53 proposed statements (81.6%). There was consensus that the definition of remission in PsA should include: the absence of signs and symptoms, physical well-being, absence of impact of the disease, the absence of inflammation and progression in imaging tests (radiography and magnetic resonance) and the absence of inflammation measured by biomarkers (ESR, CRP). It is recommended to use some index designed specifically for the assessment of disease activity and the variables that should include the minimal assessment of PsA patients are: painful/swollen joints, enthesitis, dactylitis, axial involvement, skin and nail involvement, physical function, quality of life, structural damage assessed by imaging techniques, CRP, both patient and physician global assessment, both patient and physician skin assessment and extra-articular manifestations. The use of a treat-to-target (T2T) strategy should be considered in PsA patients, especially in those with...
PSORIATIC ARTHRITIS IN PATIENTS DIAGNOSED WITH PSORIASIS: ASSISTING DERMATOLOGY CONSULTATION IN A COHORT OF THE DOMINICAN REPUBLIC

Artely Altagracia Tapia Bézé, Franchesca Alziveiro Polanco, Esthela Loyola de López, Carmen Tineo, Glenny Paulino, Catherine Rodríguez, Idelfi Sánchez, Hospital José María Cabral y Bézé, Santiago De Los Caballeros, Dominican Republic

Background: Psoriatic arthritis (PsA) is a disease of an inflammatory, heterogeneous nature that involves skin, nails, peripheral and axial joints, as well as the entheses. Due to its systemic involvement, it makes diagnosis and therapy a challenge in clinical practice. (1) It has been estimated that around 6% to 41% of patients with Psoriasis (PsO) will develop PsA, finding an accumulated incidence of 1.7% at 5 years of diagnosis of PsA, 3.1% at 10 years and 5.1% at 20 years. (2) In the Dominican Republic we do not have studies that characterize this pathology, so it would be interesting to be able to specify the clinical course, as well as the risk factors and associated prognoses for the development of this entity.

Objectives: To determine the factors associated with psoriatic arthritis in patients diagnosed with psoriasis attending the Dermatology service. Methods: A multicenter, descriptive study of primary and secondary source data collection was conducted at the Psoriasis clinic of the Regional University Hospital José María Cabral and Bézé, Cibao Regional Dermatological Institute and the Foundation to support patients with psoriasis and psoriatic arthritis (FUNAPAPSO), in the period of August-December 2018, the universe consisted of 304 patients, 103 patients met inclusion criteria. After signing informed consent, a form was completed that included general, clinical, serological and image data. Analysis of the variables was performed and Chi 2 was used, considering statistical significance p < 0.05.

Results: Of a total of 103 patients with psoriasis, the mean age was 40 ± 13 years, 63.1% male, 36.9% female. The prevalence of psoriatic arthritis by CASPAR criteria was 36.89%. The presentation of arthritis was asymmetric oligoarthritis in 56.52%, symmetric polyarthritis 21.74% and distal interphalangeal arthritis 13.04%. Radiographic findings were present in 7.7% (p = 0.00) of patients with PsA. The forms of presentation of PsO that were most associated with arthritis were plaques 48.57% (p = 0.00) and drop 12.5% (p = 0.01). The quality of life was average in patients with PsA and a proposal for definition of clinical remission was made that may be useful in the management of PsA patients.

Conclusion: Based on the available evidence and expert consensus, recommendations have been made for disease activity assessment in PsA and a proposal for definition of clinical remission was made that may be useful in the management of PsA patients.

AB0789 AN EHEALTH TOOL TO PREPARE A FIRST ORTHOPAEDIC CONSULTATIONS: A USE AND USABILITY STUDY

1Ariek Claassen*, 2Thea Vliet Vlieland2, 3Vincent Jjf Busch3, 4Henk J. Schers4, Frank van den Hoogen1,5, Cornelia van den Ende1,5, 6Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands; 7Leiden University Medical Center (LUMC), Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; 8Sint Maartenskliniek, Department of Orthopaedic Surgery, Nijmegen, Netherlands; 9Radboud University Medical Center, Department of Primary and Community Care, Nijmegen, Netherlands; 10Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands

Background: The use of eHealth technology to prepare first orthopaedic consultations for patients with hip or knee osteoarthritis seems promising. Exploration of data on use and usability of an educational eHealth tool can reveal potential modifications that may increase engagement and effectiveness.

Objectives: 1) to identify use and usability of a standalone educational eHealth tool for patients with suspected hip or knee osteoarthritis (OA), 2) to explore if recorded questions in the eHealth tool were in line with an existing widely used question prompt list, and 3) to investigate if user characteristics are related to use and usability.

Methods: We used data of 144 patients who used the educational eHealth tool to prepare an upcoming first orthopaedic consultation. We defined ‘users’ and ‘non-users’ based on opening the tool at least once or not. ‘Users’ were specified as ‘active’ and ‘passive’. Recorded questions in preparation for the upcoming consultation were categorized into 3 themes: ‘What are my options?’, ‘What are the possible benefits and harms of those options?’, and ‘How likely are each of the benefits and harms to happen to me?’, or in a ‘remaining’ category. Usability was measured using the System Usability Scale (SUS, 0-100). We collected data on demographic and clinical characteristics, knowledge on OA and internet and smartphone usage in daily life. Characteristics associated with ‘users’ and ‘non-users’ were analysed using multivariable logistic regression analysis.

Results: A total of 116 (81%) participants used the educational eHealth tool, of whom 87 (75%) were ‘active users’. Out of 3 components (Information, My consultation and Medication), Medication was least used (34%). Based on the recorded questions of users a fourth predefined question could be proposed, i.e. “What is my situation at this moment?”. Mean (SD) SUS score was 64.8 (16.0). No difference was found in SUS scores between superficial and active users (mean difference (95% CI): 0.04 (-1.69, 1.77)). Participants with higher baseline knowledge on OA (OR (95% CI): 1.2 (1.0, 1.4)), who used the internet less frequent in daily life (OR (95% CI): 0.6 (0.5, 0.9)) were more likely to use the educational eHealth tool. We found no differences in demographic and clinical characteristics between superficial and active users.

Conclusion: Based on the results of this study it can be concluded that the use of an educational eHealth tool to prepare a first orthopaedic consultation in patients with hip and knee OA is feasible. Results provide points for improvements to the content of the tool to improve usability. No clear practical implications were found in this study to support implementation of the educational eHealth tool in specific subgroups.

EVALUATING THE EFFECTIVENESS OF INTRA-ARTICULAR KNEE INJECTION USING ALLOGENIC PLATELET DERIVED LYOPHILIZED GROWTH FACTORS IN EGYPTIAN PATIENTS WITH SYMPTOMATIC PRIMARY KNEE OSTEOARTHRITIS

1Rasmia Elphohay,2 Amany Diab1, Hala Elgndy1, Hossam Fahmy2, Kamel Gado1
1Kasr Alainy School of Medicine, Cairo University, Egypt; 2Internal Medicine, Cairo, Egypt

Background: Using intra-articular injections of autologous platelet-rich plasma (PRP) has shown promising results in treatment of knee osteoarthritis (KOA). Its regenerative properties depends on the amount of growth factors (GF) released after platelets activation. Using large-volume of blood for obtaining allogenic PRP can provide higher concentrations of platelet and GF. However once prepared, PRP is stable for only 8-hours. Freeze drying (lyophilization) can be used to stabilize the biological materials for prolonged storage without causing their damage [1].

Methods: 30 patients with symptomatic primary KOA, diagnosed according to revised criteria of the ACR (2), were enrolled. Local ethical approval was obtained. All patients had given a written informed consent. The study group was equally randomized into intervention and control groups. Both was subjected to baseline functional assessment using WOMAC score; evaluating pain, stiffness, and physical function (3), and ultrasonography (US) assessment of knee effusion. The patients in control group were kept on their medications without intervention. The intervention group was received two doses of L-GF; at baseline and after 2-months. L-GF was prepared from platelets derived from individual whole blood donations. Each unit of platelets was tested in and found to be non-reactive for HBsAg, HIV I & II antibodies, HCV antibodies and antibodies to Treponema Paldum, by licensed assay methods. Seronegative plasma were further examined by Nuclear Acid Testing. Further viral inactivation by UV-radiation and Riboflavin by the Mirasol system was done. The platelets in the buffy coat layer were activated using CaCl2 to release their GF. Excess water, cellular elements and fibrinogen were removed and the remaining GF were “ultraconcentrated.” Lyophilization of the obtained GF was then processed. The L-GF was supplied as powder in tightly sealed container and was stored at 2° to 8° C. Prior to use, reconstitution of the product was done using 1-ml saline and 1-ml lignocaine then the mixture was kept at ambient temperature for 5-min. to ensure complete protein re-hydration. After 6-months the WOMAC score and knee US were repeated for all participants. Then percent of improvement of WOMAC and US detected effusion were calculated for all patients.

Results: The patients in the intervention group was significantly older (56 ±9 years) and had higher BMI (38±5.3 kg/m²) in comparison to control (44±11 years, 33±5.6 kg/m²). Both groups showed statistically insignificant difference regarding the baseline total WOMAC score and radiographic assessment. Post injection pain was reported by all patients in intervention group, it lasted only for 2.4±0.83 hours and was graded as mild. The mean of total WOMAC score and its 3-components in addition to knee effusion were decreased significantly in the intervention group after 2 months and 6 months of follow-up (figuer-A). After 6-months, the intervention group showed statistically significant percentage of improvement regarding WOMAC scores and effusion in comparison to the control (figuer-B).

Conclusion: Allogenic L-GF was well tolerated and showed encouraging results in patients with symptomatic KOA, regarding improvement of pain, stiffness and function in addition to decreasing knee effusion.

ONE VERSUS TWO INJECTIONS OF INTRA-ARTICULAR HIGHLY CROSS-LINKED HYALURONAN YEARLY IN PATIENTS WITH KNEE OSTEOARTHRITIS: INSIGHTS FROM ROUTINE CLINICAL PRACTICE

Tsvetoslav Georgiev, Rumen Stoilov, University Hospital “St. Ivan Rilski” – Sofia, Clinic of Rheumatology, Sofia, Bulgaria

Background: Hyaluronic acid (HA) is a natural polysaccharide, which is an important structural component of synovial-fluid and cartilage. There are different injectable forms of HA used for clinical application. Highly cross-linked/high-molecular-weight hyaluronans (HMWHA) provide additional stability and improve functionality [1], resulting in longer bioavailability in the knee joint and promoting viscoeluduction [2]. A direct comparison between the two most common injection protocols of HMWHA in our routine practice is of great practical interest, since viscosupplementation is among the most commonly used treatment modalities for patients with knee osteoarthrits (KOA) in Bulgaria [3].

Objectives: Our aim was to compare the clinical effectiveness of two different regimens for injecting intra-articular HMWHA in KOA patients under ‘real-world’ conditions in routine clinical practice.

Methods: This prospective, open-label, observational study included 50 patients with KOA who were followed for a period of 1 year. They were divided into two therapeutic arms according to their preselected treatment regimen: patients injected once with HMWHA (n = 25; group 1) at baseline and patients injected twice 6 months apart with HMWHA (n = 25; group 2). A 100-mm visual analogue scale (VAS) for pain, disease-specific (Western Ontario & McMaster Universities Osteoarthritis Index [WOMAC]) and generic (health assessment questionaire – disability index [HAQ-DI]) questionnaires were used to evaluate patients at baseline, three months, six months, and one year later. Standardized radiographs were obtained at baseline and after one year. The response to the treatment was determined using the OMERACT-OARSI set of responder criteria [4].

Results: A single injection of HMWHA resulted in a statistically significant improvement in pain even at 12 months (ΔVAS = 10.12 ± 14.5 mm, p < 0.05), although the effect progressively decreased after the third month when ΔVAS was 18 ± 14.31 mm, p < 0.05 (Figure 1). If the two regimens of HA injections were directly compared, the mean difference of pain improvement for the year of follow-up was about 9 mm in favor of group 2, but this result was not “statistically” significant (10.12 vs 19.16 mm, p > 0.05). Physical function was statistically improved in both

PATIENTS WITH KNEE OSTEOARTHRITIS: INSIGHTS FROM ROUTINE CLINICAL PRACTICE

Tsvetoslav Georgiev, Rumen Stoilov, University Hospital “St. Ivan Rilski” – Sofia, Clinic of Rheumatology, Sofia, Bulgaria

Background: Hyaluronic acid (HA) is a natural polysaccharide, which is an important structural component of synovial-fluid and cartilage. There are different injectable forms of HA used for clinical application. Highly cross-linked/high-molecular-weight hyaluronans (HMWHA) provide additional stability and improve functionality [1], resulting in longer bioavailability in the knee joint and promoting viscoeluduction [2]. A direct comparison between the two most common injection protocols of HMWHA in our routine practice is of great practical interest, since viscosupplementation is among the most commonly used treatment modalities for patients with knee osteoarthrits (KOA) in Bulgaria [3].

Objectives: Our aim was to compare the clinical effectiveness of two different regimens for injecting intra-articular HMWHA in KOA patients under ‘real-world’ conditions in routine clinical practice.

Methods: This prospective, open-label, observational study included 50 patients with KOA who were followed for a period of 1 year. They were divided into two therapeutic arms according to their preselected treatment regimen: patients injected once with HMWHA (n = 25; group 1) at baseline and patients injected twice 6 months apart with HMWHA (n = 25; group 2). A 100-mm visual analogue scale (VAS) for pain, disease-specific (Western Ontario & McMaster Universities Osteoarthritis Index [WOMAC]) and generic (health assessment questionaire – disability index [HAQ-DI]) questionnaires were used to evaluate patients at baseline, three months, six months, and one year later. Standardized radiographs were obtained at baseline and after one year. The response to the treatment was determined using the OMERACT-OARSI set of responder criteria [4].

Results: A single injection of HMWHA resulted in a statistically significant improvement in pain even at 12 months (ΔVAS = 10.12 ± 14.5 mm, p < 0.05), although the effect progressively decreased after the third month when ΔVAS was 18 ± 14.31 mm, p < 0.05 (Figure 1). If the two regimens of HA injections were directly compared, the mean difference of pain improvement for the year of follow-up was about 9 mm in favor of group 2, but this result was not “statistically” significant (10.12 vs 19.16 mm, p > 0.05). Physical function was statistically improved in both
groups (p < 0.05) without any statistically significant difference. Respondents in the first group in the end of the year were 40% (10/25) and 60% (15/25) in group 1 and group 2, respectively (p > 0.05). In the end of the follow-up period HAQ-DI did only statistically improve among patients in group 2.

Fig.1. Mean change in 100-mm VAS values for pain over time in both groups

Conclusion: If maximal symptomatic relief is our primary goal, it would be logical to choose a two-injection regimen. However, if we take into account the financial aspect, we may be satisfied with a single injection of highly cross-linked HA over a year.

AB0792 CURCUMIN IN OSTEOARTHRITIS TREATMENT: THE PRESENT STATE OF EVIDENCE

1Maria Goular1, Daniela Parta2, Luis Cunha3, Stevin Zung3, 1Ache Laboratories, Medical, São Paulo, Brazil; 2Ache Laboratories, São Paulo, Brazil; 3Ache Laboratories, medical, São Paulo, Brazil

Background: Osteoarthritis (OA) is a degenerative disease of the joint occurring in elderly population. According to World Health Organization, its worldwide prevalence ranges from 11.8% to 12.7%. Since it is known that OA has an inflammatory cause, with IL-1 being the key cytokine, that OA has an inflammatory cause, with IL-1 being the key cytokine, that IL-1 and TNF-a being the key cytokines that drive the production of inflammatory mediators and matrix-degrading enzymes, the compounds with anti-inflammatory properties are targeted as therapeutic options for osteoarthritis treatment. Curcumin is a plant-derived compound extracted from the rhizomes of turmeric (Curcuma longa). It has been demonstrated as an effective anti-inflammatory and antioxidative agent. In vitro studies have shown that curcumin can block the activation of NF-kB system in the chondrocytes. Therefore, it prevents the apoptosis of chondrocytes, suppress the release of proteoglycans and metalloproteinases and expression of cyclooxygenase, prostaglandin E-2, and inflammatory cytokines in chondrocytes. Besides its influence on inflammatory markers, clinical trials also demonstrated curcumin’s effects in pain and function in patients with osteoarthritis.

Objectives: The purpose of this paper is to critically review evidences regarding the role of curcumin in osteoarthritis treatment.

Methods: PubMed/MEDLINE, Lilacs, and SCIELO databases were searched using the terms “curcumin” AND “osteoarthritis” without imposing time limitations. The search was limited to humans and to the English and Portuguese languages. Studies that met the following inclusion criteria were included in the review: 1) clinical trials that evaluated the effects of curcumin on osteoarthritis. The selection phase involved a review of abstracts and an examination of the full text based on the eligibility criteria and the last search was conducted on January 2019.

Results: Overall, 9 clinical trials involving a total of 797 patients met the inclusion criteria. The studies have a degree of heterogeneity concerning the dosage, treatment duration, objectives and endpoints, but the main objectives were to evaluate the efficacy and safety of curcumin in osteoarthritis treatment. All studies have shown a beneficial effect of curcumin supplementation in the treatment of osteoarthritis, mainly in reduction of pain, stiffness, improvement of physical function, decrease the use of NSAIDs and other painkillers. Results also showed a decrease on inflammatory markers.

Conclusion: The studies demonstrated that curcumin is clinically effective as a long term adjuvant treatment of osteoarthritis further to an excellent tolerability. However, large and well-designed randomized controlled trials are warranted to confirm the use of curcumin in osteoarthritis treatment.

AB0793 LONG-TERM USE OF AMTOLMETIN GUACIL IN PATIENTS WITH OSTEOARTHRITIS, RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

Andrey Karatseev, Evgeny Nasonov. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Long-term use of nonsteroidal anti-inflammatory drugs (NSAIDs) is used to control of chronic pain in osteoarthritis (OA), rheumatoid arthritis (RA) and to prevent the progression of ankylosing spondylitis (AS). Amtolmetin guacil (AMG), which has a low risk of gastrointestinal complications, may have advantages for long-term use.

Objectives: To evaluate the effect and safety of long-term use of AMG. Methods: AMG 600-1800 mg/day was prescribed to 442 patients with OA (60.6 ± 10.2 years, women 88.7%), 126 with RA (55.0 ± 14.0 years, women 84.2%) and 73 with the AS (47.0 ± 12.0 years, women 30.0%). The primary end point was the dynamics of pain on a numerical rating scale (NRS), additional for OA - WOMAC pain and HAQ, for RA - DAS28-CRP, for AS - BASDAI, BASFI and ASDAS-CRP. The result of treatment was evaluated on 3 consecutive visits after 3 months (9 months of treatment).

Results: After 9 months 65.2% of OA patients, 75.3% of RA patients, and 82.2% of AS patients continued to take AMG. In end of study, the median of pain decreased with OA from 5.6 [4.1-6.9] to 3.4 [1.7-5.1], with RA from 5.8 [4.0-7.5] to 3.4 [2.0-4.8], with AS from 5.8 [4.2-7.5] to 3.1 [1.5-5.0] NRS (p <0.001). In OA WOMAC pain decreased from 127 [24-159] to 13.7 [14-40], p <0.001, HAQ from 0.54 ± 0.44 to 0.34 ± 0.26, p <0.001. With RA, the average value of DAS28 decreased from 4.81 ± 1.18 to 4.30 ± 1.24, p <0.05. In AS, the median BASDAI index decreased from 4.5 [1.0-8.0] to 3.0 [0.0-8.0], p <0.001. The number of AS patients with high activity on the ASDAS-CRP index (> 3.5) decreased from 76.9% to 25.8%, p <0.001. The BASFI index has not changed. 77.9% of patients with OA, 77.0% of patients with RA, and 74.5% of patients with AS were satisfied with the results of AMG treatment.
AMG tolerability was good. 15-25% patients had mild dyspepsia. Discontinuation of therapy due to side effects was only in 6 patients (0.9%). The development or worsening of arterial hypertension, as well as other cardiovascular complications, was not observed.

Conclusion: AMG is an effective, well-tolerated NSAIAD, which is appropriate for long-term treatment of OA, RA and AS.

AB0794 PATIENTS GENOTYPE AND OA TREATMENT EFFICACY

Ludmila Smolina1, 1Ludmyla Khimion2, Olexandr Burianov2, Natalia Kicha1, Tetiana Syluk1, Taras Omenchko2, Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine, 2Bogomolets National Medical University, Kyiv, Ukraine

Background: It is known that some genes (FDPS, LCT, VDR) which determine the calcium, vitamin D and lactate metabolism may have impact on osteoarthritis (OA) development and course, and thus, has a possible influence on OA treatment efficacy.

Objectives: To determine the influence of genetic factors (genotyping of FDPS, LCT, VDR) on the efficacy of standard and modified treatment (with use of the platelet autologous plasma (PAP) in the early stages of knee OA.

Methods: WOMAC index and the frequency of genotype variants for the FDPS, LCT, and VDR genes were studied in 96 patients (57 women, 38 men, 41.7 ± 1.2 years old) with primary knee OA (X-ray stage I-II). All patients had OA exacerbation with no clinical evidence of synovitis. Enrolled patients were divided into 2 groups: the first group consisted of 49 patients (27 women, 22 men, mean age 41.7 ± 1.2 years) who agreed to receive standard OA treatment (NSAIAD, exercises, orthopedic devises – as needed) and 3 intra-articular PAP injections (2 courses in 12 month, plasma volume 12-15ml/course, total platelet count per injection 1260,24 ± 22,1x10 9). The second group - 47 patients with OA who received standard treatment. Both groups were comparable by age, gender, body mass index and initial WOMAC. Genetic parameters and its influence on OA course and treatment efficacy was analyzed during 12 months.

Results: The earliest age (37.2 ± 2.01 years) of clinical manifestation of knee OA was connected to homozygous genotype variants: LCT (relative risk 6.3:1), FDPS (relative risk 6.5:1) and VDR (relative risk 6.8:1). The earliest age (37.2 ± 2.01 years) of clinical manifestation of knee OA was connected to homozygous genotype variants: LCT (relative risk 6.3:1), FDPS (relative risk 6.5:1) and VDR (relative risk 6.8:1). The earliest age (37.2 ± 2.01 years) of clinical manifestation of knee OA was connected to homozygous genotype variants: LCT (relative risk 6.3:1), FDPS (relative risk 6.5:1) and VDR (relative risk 6.8:1). The earliest age (37.2 ± 2.01 years) of clinical manifestation of knee OA was connected to homozygous genotype variants: LCT (relative risk 6.3:1), FDPS (relative risk 6.5:1) and VDR (relative risk 6.8:1). The earliest age (37.2 ± 2.01 years) of clinical manifestation of knee OA was connected to homozygous genotype variants: LCT (relative risk 6.3:1), FDPS (relative risk 6.5:1) and VDR (relative risk 6.8:1).

Conclusion: age of knee OA clinical manifestation and the treatment efficacy was analyzed during 12 months.

Disclosure of Interests: None declared

AB0795 IMPACT OF PRIMARY HAND OSTEOARTHRITIS ON MICROSTRUCTURE AND BIOMECHANICS IN FINGER JOINTS

David Simon1, Koray Tasciar1, Sarah Unbehend2, Sara Bayat3, Timo Meinderink3, Andreas Berlin1, 1, 2Jürgen Rech1, Axel Hueber1, 1, 2, Arnd Kleyer3. 1Friedrich-Alexander University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany, 1Universitätsklinikum Würzburg, Würzburg, Germany, 2Institute of Forensic Medicine, Aarhus University, Aarhus, Denmark, 1Aalborg University Hospital, Orthopaedic Surgery Research Unit, Aalborg, Denmark, 3Skeleborg Regional Hospital, Department of Clinical Medicine, Silkeborg, Denmark

Background: Despite distinct aetiologies of joint diseases, the osteoarthritic end-stage of primary osteoarthritis and rheumatoid arthritis are described using similar radiological features. However, primary and secondary osteoarthritis may be different at the bone-cartilage unit depending on the pathogenesis.

Objectives: The main purpose was to investigate the histological differences in the bone-cartilage unit of the hip joint in patients with primary osteoarthritis and patients with secondary osteoarthritis due to rheumatoid arthritis.

Methods: Femoral heads were obtained during arthroplasty from 12 patients with primary osteoarthritis and six patients with secondary osteoarthritis due to rheumatoid arthritis.

Results: Twelve femoral heads from healthy age- and sex-matched subjects were obtained post-mortem. Femoral heads were investigated, using stereological methods to provide unbiased quantitative data. The femoral head, articular cartilage, calcified cartilage, subchondral bone, and osteophytes were measured.
Conclusion: Patients with secondary osteoarthritis due to rheumatoid arthritis had thinner articular cartilage and calcified cartilage but were otherwise not significantly different from patients with primary osteoarthritis. Thus, the inflammatory joint in rheumatoid arthritis was associated with a more pronounced loss of cartilage than the degenerative joint disease in primary osteoarthritis. The thicker calcified cartilage in primary osteoarthritis has been attributed to endochondral ossification; this does not seem to be the case in rheumatoid arthritis.

AB0797 GRANULYSIN MEDIATED CYTOTOXICITY AND ITS SERUM CONCENTRATION IN PATIENTS WITH KNEE OSTEOARTHRITIS

1-2Gordana Laskarin1, Tatjana Kehler1, Viktor Persic1, 5, Merica Aralica2, Bozena Curko-Cofek3, Marija Rogoznica1, Ivan Rosovic3, Tamara Kauzlarc-Zivkovic4, Sandra Rusac-Kukic5, Daniel Rukavina1, 5, 6

1Faculty of Medicine, Department of Physiology and Immunology, Rijeka, Croatia, 2Specialized Hospital “ThalassoTherapia-Opatija”, Department of Rheumatology, Opatija, Croatia, 3Faculty of Health Studies, Departments of Medicine, Department of Medical Rehabilitation, Rijeka, Croatia, 4Specialized Hospital “ThalassoTherapia-Opatija”, Opatija, Croatia, 5Faculty of Health Studies, Rijeka, Croatia, 6Faculty of Medicine, Department of Physiotherapy and Immunology, Rijeka, Croatia, 7Specialized Hospital “ThalassoTherapia-Opatija”, Department of Rheumatology, Opatija, Croatia, 8University of Rijeka, Department of Biotechnology, Dept. Biomedical Sciences in Rijeka, Rijeka, Croatia

Background: In OA joint, synovial membrane contain immunocompetent cells (1-4), which produce predominantly pro-inflammatory cytokines (2,5), justifying the name “osteoarthritis” and directing the development of disease towards mild systemic inflammatory condition (6). Granulysin (GNLY) is mediator of cellular immunity expressed in T and NK cells in 15 KDa precursor and 9 KDa cytoplasmic form (2). It is regulated by interleukin 15. We investigated GNLY expression in peripheral blood lymphocytes and GNLY mediated apoptosis in vitro, serum concentration of IL-15 and the correlation of GNLY expression with intensity of the pain in the knee of OA patients and with 6-minute walk distance.

Objectives: Women with knee OA (20), and healthy control (17) were medically examined, and their blood samples tested. All of them signed informed consent before medical sampling of peripheral blood (PB).

Methods: Visual analogue scale (VAS) of pain and results of 6-minute walk test were noticed in all participants. Peripheral blood mononuclear cells were isolated by gradient density centrifugation and intracellular GNLY labeling in CD3-CD56-NK cells, CD3+CD56- T cells and CD3 +CD56- NK cells was performed and analyzed by flow cytometry. NK cells' apoptotic activity against NK sensitive K-562 cells was measured in 18-hour PKH-26 (red) cytotoxicity assay with evaluation of propidium iodide-annexin V+ target cells by flow cytometry. In some samples anti-GNLY and/or anti-perforin antibodies were added. IL-15 concentration was measured by ELISA. Nonparametric Kruskal-Wallis and Mann-Whitney U-test, as well as Spearman correlation test were used for statistical evaluation.

Results: In lymphocytes of OA patients GNLY expression and NK cell-mediated apoptosis of K-562 cells did not differ significantly from the healthy control. In OA patients only, RC8 antibody against cytosolic GNLY molecule significantly decreased apoptosis of K-562 cells. RF10 anti-15 kDa GNLY did not show such effect. Anti-perforin antibody completely abolished apoptosis in both groups tested and the effects of additionally added RC8 or RF10 anti-GNLY antibodies were not observed. Serum IL-15 concentration in healthy controls and OA patients was low and did not show statistically significant difference. GNLY expression in lymphocytes, and particularly in NK subset, positively correlated with VAS of pain and 6-minutes walking distance.

Conclusion: In OA patients, GNLY mediated apoptosis is involved in apoptosis of NK sensitive K-562 cells in vitro and might be involved in the killing of damaged joint cells in vivo after direct contact.

Background: The literature suggests that women with knee osteoarthritis (OA) perceive greater disability and a lower functional level before total
ART- QUALIVIE: ASSESSMENT OF THE QUALITY OF Disclosure of Interests: DOI: 10.1136/annrheumdis-2019-eular.4120 Patrice Vincent4, Hakima Miotti5, Isabelle Bardoulat5, Cathy Maillard5. men seemed to perceive less symptoms and restrictions in daily activities Conclusion: Preoperatively, men reported a longer duration of symptoms was longer in men than women: <1 year: 11.3% versus 9.6%, 1-5 years: 38.8% versus 49.7%, 5-10 years: 18.3% versus 20.0% and > 10 years: 31.5% versus 20.7%. Finally, women had significantly higher expectations of postoperative outcomes of TKA between men and women regarding the duration of symptoms and preoperative expectations were examined by the means of the Chi-Square test and independent t-test and difference with the 95% Confidence Interval (CI) respectively. Results: A total of 1543 patients, 556 men (mean age 71 (SD 8), 32.3% paid employment) and 987 women (mean age 71 (SD 9), 20.3% paid employment) were included. Women had more pain preoperatively than men, 5.3 (SD 3) versus 4.3 (SD 3) at rest and 7.1 (SD 2) versus 6.2 (SD 9) during activity, respectively. Furthermore, on each KOOS subscale compared to women, the duration of symptoms was longer in men than women: <1 year: 11.3% versus 9.6%, 1-5 years: 38.8% versus 49.7%, 5-10 years: 18.3% versus 20.0% and > 10 years: 31.5% versus 20.7%. Finally, women had significantly higher expectations of postoperative TKA outcomes than men, 67.4 (SD 19) and 70.2 (SD 19), respectively (Mean Difference: 2.79, 95% CI 0.84-4.75). Conclusion: Preoperatively, men reported a longer duration of symptoms and had lower expectations of TKA outcomes than women. However, men seemed to perceive less symptoms and restrictions in daily activities despite a longer duration of symptoms.

AB0799 ART- QUALIVIE: ASSESSMENT OF THE QUALITY OF LIFE OF PATIENTS WITH KNEE OSTEOARTHRITIS SIX MONTHS AFTER TREATMENT WITH THREE INTRA-ARTICULAR INJECTIONS OF ARTHRUM H 2% 1Mika Maravic1; Christian Pascaretti2, Paolo Insalaco2, Antoine Lesort3, Patrice Vincent1, Hakima Miotti4, Isabelle Bardoulat5, Cathy Maillad5. LCA pharmaceuticals (France) – LCA pharmaceuticals (France) – LCA Pharmaceutical, Chartres, France – LCA Pharmaceutical, Chartres, France.

Background: Knee osteoarthritis (KOAG) is a chronic condition affecting mainly the elderly and considered as the leading cause of disability after cardiovascular disease. KOA is characterized by functional discomfort and deformities, leading to a deterioration in the quality of life (QoL) of patients.

Objectives: The main objective was to demonstrate that 3 intra-articular injections of ARTHRUM H 2% improves the physical QoL of patients over a 6-month period. Methods: A French observational, prospective, multi-centre study was conducted between 2012/2017 in 30 French centres in patients over 40 suffering from knee pain. WOMAC scores were collected at baseline and at 2, 6 and 12 months. The primary endpoint was the change in WOMAC scores from baseline to 180 days (paired Student t-tests). Logistic regression analyses were used to identify the main drivers of significant increase of physical summary score, adjusted for sociodemographic and health covariates. Results: Of the 134 patients treated with ARTHRUM H 2% included in the study, 115 were evaluable for the primary outcome (non-expansible data for 19 patients). The baseline characteristics of the analysable population were as follows: mean age of 66.4 years (±10.7); majority female (66.4%); mean BMI of 28.7 (±5.3) kg/m² (43.3% overweight and 35.1% obese); KL grade KOA grade I: 13.6%, II 40.2%, III 46.2%, localization: uni-compartimental 53.0% (78.6% medial, 15.7% lateral, 5.7% patellofemoral), bi-compartimental 40.2% and tri-compartimental 6.8%. Regarding management history, respectively 6.7% and 44.8% of patients had previously received physical therapy or rehabilitation, and visco-supplementation (2.2 treatments on average). Comorbidities observed in 73.9% of patients were metabolic-related in 54.5%, cardiovascular-related in 46.3%, gastrointestinal-related in 20.9%, and neuropsychiatric-related in 8%. A clinically and statistically significant improvement in the QoL of patients was observed with an increase from 40.0 at baseline to 44.8 at 6 months (p<0.001). A significant improvement was achieved during the 3 months following visco-supplementation (D0: 40.0 vs. D90: 44.8) and maintained from three to 6 months from baseline (D90: 44.8 vs. D180: 44.9).

The factors significantly associated with an improvement in QoL were: grade III KOA (OR=5.254, p=0.032), grade II KOA (OR=3.507, p=0.100), and a single history of osteoarthritis (OR=2.936, p=0.044).

Conclusion: ART-QUALIVIE is a French study providing real-world data on the evolution of QoL of visco-supplemented KOAG patients. It has demonstrated the positive impact of ARTHRUM H 2% on the QoL of patients over the 3 months following injections maintained until 6 months after treatment.

Objectives: Different biomarkers were selected to be measured in APPROACH patient samples for prospective predictive and prognostic analyses. Here we describe the biological rational, reference ranges and technical performance of the selected biomarker.

Methods: The APPROACH cohort includes 300 OA patients recruited based on the APPROACH enrichment model (www.approach.eu), in the period from 2017 and 2019. Serum and urine will be collected at baseline, 6, 12 and 24 months, as well as pain, radiographic and MRI assessments.

Results: Eighteen exploratory and technically validated biomarkers reflecting joint tissue (i.e. cartilage, bone, synovium) turnover were chosen based on following characteristics; i) has shown association with OA pathogenesis (published data such as OA1); ii) has shown diagnostic or prognostic potential 2; iii) GLP or GMP certified assay production with acceptable technical performance (e.g. precision and linearity data, table); iv) readily availability of the kits from consortium partner or from third party vendor. The markers will be tested asking following research questions: Can the markers alone or in combination subgroup patients into different phenotypes which display different progression rates, or with different pain and radiographic profiles. Also, we will test whether a change in markers are correlated with change in the clinical assessments scores. Results from these analyses may provide insight to the potential usage of the biomarkers in drug development.

Conclusion: The APPROACH consortium is the first European study that attempts to establish robust technical performance criteria and reference intervals for osteoarthritis-related soluble biomarkers in an effort to develop biomarker panels that can identify patients with different OA phenotypes.

RELIABILITY OF A NOVEL ULTRASONOGRAPHIC SCALE FOR ACTIVITY OF KNEE OSTEOARTHRITIS

Mohammed A. Mortada, Ghada Dawa, Armany Ebaid, Lobna Kolb, Youmna A. Amer. Faculty of Medicine, Zagazig University, Rheumatology and Rehabilitation, Zagazig, Egypt

Background: Knee osteoarthritis

Objectives: To assess the reliability of a novel ultrasonographic scale of activity in knee osteoarthritis (OA)

Methods: A cross-sectional observational study included 110 patients with knee pain who fulfilled the American College of Rheumatology (ACR) criteria for knee osteoarthritis (OA). All patients were subjected to clinical assessment WOMAC scale (Western Ontario and McMaster Universities Index of Osteoarthritis and global visual analog scale) and functional assessment using health assessment questionnaire (HAQ). Ultrasonographic assessment of activity was done By 3 rheumatologists with different levels of experience in musculoskeletal Ultrasonography (1-12 years). Ultrasonographic assessments were done according to (MOAKA scale) that was proposed by the first author (table 1).

Results: There were high kappa values both in intraobserver and interobserver evaluation of activity of knee OA using the proposed (MOAKA) ultrasonographic scale (0.85 and 0.75 respectively). There were positive correlations between MOAKA score and all WOMAC subscales (pain, stiffness and function) \( r=0.4, P=0.02, r=0.35, P=0.001 \) and \( r=0.4, P=0.01 \) respectively. Also there were a strong positive correlation between MOAKA score and both (VAS and HAQ) \( r=0.86, P=0.001 \) and \( r=0.71, P=0.001 \).

Conclusion: US can reliably detect the activity of Knee OA. Good agreement was found between the proposed US grading scale and WOMAC & HAQ scores. MOAKA US scale is simple and reliable.

CYTOKINE PROFILE IN SYNOVIAL FLUID FROM PATIENTS WITH OSTEOARTHRITIS WITH OR WITHOUT CALCIUM CRYSTALS

Francesca Oliviero, Paola Gallozi, Marta Favero, Davide Tietto, Mariagrazia Lorenzin, Augusta Ortolan, Leonardo Punzì, Anna Scanu, Roberta Ramonda

University of Padova, Department of Medicine, Padova, Italy, Centro for Gout and Metabolic Bone and Joint Diseases, Rheumatology, SS Giovanni and Paolo, Venezia, Italy

Background: The most important pathogenetic calcium crystals that can be found in synovial fluid (SF) are calcium pyrophosphate (CPP) and basic calcium phosphate (BCP) crystals. We and others have demonstrated that a good portion of patients with osteoarthritis (OA) have these types of crystals in their SF and that they are associated with a higher inflammatory state independently from the disease severity.

Objectives: The aim of this study was to investigate the levels of IL-1b, IL-8, IL-6, IL-10, CCL2 and OSM in the SF of patients affected with OA considering the presence of CPP crystals and the positivity to the alizarin red test (a non-specific test for BCP crystals). A sub-analysis has been conducted subdividing patients according to their Kellgren-Lawrence (K-L) radiographic score.

Methods: Synovial fluid was collected from 69 OA consecutive patients diagnosed according to the EULAR criteria. Forty patients were negative to (CPP-) and 29 positive to (CPP+) CPP crystals. A standard analysis was performed for each sample including, white blood cell (WBC) count, differential cell count, crystal search under polarized light microscopy and alizarin red test. The cytokines were measured after appropriate dilutions by ELISA (Thermofisher) and expressed as pg/mL. The Mann-Whitney test was used to investigate differences between the groups of patients positive and negative to CPP; the Spearman rank test was used for correlations, while the Kruskal-Wallis to compare the groups according to the K-L score.

Results: With respect to the group of CPP-, the group of CPP+ patients had higher levels of WBC count (251.7±199.3 vs 176.3±161.8 cells/mm³; p=0.004), PMN% (5±4±1:54; p=0.0001), IL-1b (8.9±2.6±29 vs 4.6±12.2; p=0.0001) and IL-8 (53.7±45.83 vs 26.2±35.94; p=0.0003). No differences were instead observed for the other cytokines considered. We did not find any differences subdividing patients according to the SF positivity to the alizarin red staining. Some correlations were observed in the whole group of patients between IL-1 and IL-8 (p=0.004), IL-1 and PMN (p=0.0006), IL-8 and WBC (p=0.001), IL-8 and PMN (p=0.0001), IL-10 and IL-8 (p=0.04), IL-10 and WBC (p=0.014), CCL2 and IL-8 (0.006). Although no differences have been found analysing the variables in the groups subdivided by the K-L scores, all the cytokines showed higher levels in patients with a K-L score equal to 2.

Conclusion: Although associated with higher inflammatory SF indices and IL-1 and IL-8 levels, calcium crystals still play an undefined role in OA. More studies are warranted to evaluate if patients with calcium crystals in their SF might need a more specific treatment.

SYNOVIAL INTERLEUKIN-4 LEVELS ARE ASSOCIATED TO RADIOGRAPHIC SEVERITY OF KNEE OSTEOARTHRITIS. A CROSS-SECTIONAL STUDY

Silvia Garcia-Cirera, Joan Calvet, ORELLANA CRISTOBAL, Noemi Navarro, Maria Garcia Manrique de Lara, Jordi Gratacos-Masmith, Hospital Universitari Parc Taulí Sabadell, Rheumatology, Sabadell, Spain

Background: Radiographic severity is used in routine clinical practice to evaluate knee osteoarthritis (KOA) structural damage. There are no conclusive studies on the associations between synovial inflammatory markers and the different features of radiographic damage in KOA.
OBJECTIVES: To evaluate the association between inflammatory markers in synovial fluid with the different features of radiographic severity in patients with OA.

METHODS: Cross-sectional study of 114 female patients aged 50-85 with symptomatic primary KOA with significant joint effusion (>4 mm at midline patellar line) confirmed by ultrasound. The following information was collected: age, KOA symptoms duration, body mass index; plain standing knee Rx in semi-flexion were evaluated for radiographic severity by modified OARSI atlas evaluating separately osteophytes (OPH) and joint space narrowing (JSN). The OPH score was obtained searching for marginal osteophytes in both medial and external femoral condyles and tibial plateau, scoring 0 to 3 in each quadrant, for a total score ranging from 0-12. Due to the high number of different scores obtained, and sometimes with a low number of patients, we grouped osteophytes scores 1-2 as mild, 3-6 as moderate, and seven or more as severe osteophyte count. JSN was scored in both medial and lateral knee compartments, grading the joint space 0 to 3 in each one, for a total score ranging from 0 to 6. A JSN score of 0 was considered as normal, 1-2 as moderate and 3 or more as high JSN severity. Five inflammatory markers: TNF alpha, high sensitivity C-reactive protein (hsCRP), interleukin 6 (IL-6), interleukin 8 (IL-8) and calprotectin were measured by ELISA following manufacturer recommendations for synovial fluid dilutions. A comparison between medians of the three groups was carried out and a multivariate analysis controlled by age, symptom duration, BMI and all five inflammatory markers were performed.

RESULTS: A significant association for symptom duration and synovial IL8 was observed for osteophytes (p=0.0001 and p<0.05, respectively), which remained after adjustment (p=0.002 and p=0.037, respectively). Regarding symptom duration, the differences were related to high severity osteophyte index, compared to moderate or low stages (p=0.0005 and p=0.002, respectively), while for IL-8 the differences were associated to a low OPH severity index compared with a moderate osteophyte score (p=0.011), with IL-8 levels approximately 33% less than the moderate OPH score (p=0.011).

For JSN, in the adjusted analysis, patients with a high JSN score had synovial IL-8 levels of 40% more than those with JSN 0 (p=0.035), while no differences were found between the moderate JSN score and the other two degrees. Regarding hsCRP, 30% higher levels were found in patients with a JSN moderate degree compared with JSN 0 (p=0.035), while no significant differences were observed between severe and the other two degrees.

CONCLUSION: Interleukin-8 IL 8 was the inflammatory marker associated to radiographic severity as evaluated by osteophyte count and joint space narrowing score on plain radiography in patients with knee osteoarthritis. The study included 6448 patients with knee OA (mean age 57.8 years). The primary outcome was pain reduction ≥30 mm VAS. All patients received oral avocado/soybean unsaponifiables (ASU) 300 mg/day within 3 months and ketoprofen isoyne salt (KLS) 320 mg/day within 2 weeks at the beginning of the study. A 100 mm visual analog scale (VAS) was used to assess pain intensity. The result of treatment was evaluated on a scale of 0-5 points, where 0 – no effect, 5 - excellent effect. The criteria for a “good response” to therapy were: pain reduction ≥50% and treatment result ≥ 4 points. The value of the studied factors was determined using odds ratio; 95% confidence interval (OR; 95% CI).

RESULTS: After 3 months of therapy the pain level decreased from 63.7 ± 12.0 mm to 14.2 ± 11.7 mm. A good response to treatment was noted in 87.4% of patients. Sex, body mass index ≥ 30 kg/m², type 2 diabetes, poor effect of NSAIDs and SYSADOAs in history did not affect the clinically important improvement (MCII), from baseline to 6-month follow-up (range 3-9 months), as >3.8, <3.8, or within 3.8 units. Statistical significance was studied with one-way analysis of variance (ANOVA) and chi-square.

RESULTS: Among 173 OA patients, 22 (13%) were improved, 95 (55%) unchanged, and 56 (32%) worsened 6 months later. The 3 groups did not differ significantly in age, gender, ethnicity, educational level or BMI (Table). Patients who improved compared to those who were unchanged or worsened had significantly lower baseline RAPID3, pain and patient global VAS, and morning stiffness. The patients who improved also had lower, but not statistically significant, physical function score and fatigue VAS. No differences were seen among the 3 groups in numbers of symptoms or self-report painful joint counts (Table).

**Abstract AB0805 WHAT FACTORS AFFECT THE RESULT OF LONG-TERM ANALGESIC THERAPY FOR OSTEOARTHRITIS? DATA FROM A MULTICENTER OPEN STUDY OF ORAL AVOCADO/SOYBEAN UNSAPONFABLES EFFECTIVENESS**

Flena Popghzega, Andrey Karateev, Alexander Lia, Vera Amirdzhanova, Ekaterna Filatova, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Symptomatic slow-acting drugs for OA (SYSADOAs) and oral nonsteroidal anti-inflammatory drugs (NSAIDs) play a central role in the pharmacological management of osteoarthritis (OA). Factors affecting the effectiveness of OA therapy should be taken into account.

**Objectives:** To identify factors affecting the effectiveness of long-term analgesic therapy in patients with OA.

**Methods:** The study included 6448 patients with knee OA (mean age 57.8 ± 10.2 years, 70.9% women), with pain level ≤40 mm VAS. All patients received oral avocado/soybean unsaponifiables (ASU) 300 mg/day within 3 months and ketoprofen isoyne salt (KLS) 320 mg/day within 2 weeks at the beginning of the study. A 100 mm visual analog scale (VAS) was used to assess pain intensity. The result of treatment was evaluated on a scale of 0-5 points, where 0 – no effect, 5 - excellent effect. The criteria for a “good response” to therapy were: pain reduction ≥50% and treatment result ≥ 4 points. The value of the studied factors was determined using odds ratio; 95% confidence interval (OR; 95% CI).

**Results:** After 3 months of therapy the pain level decreased from 63.7 ± 12.0 mm to 14.2 ± 11.7 mm. A good response to treatment was noted in 87.4% of patients. Sex, body mass index ≥ 30 kg/m², type 2 diabetes, poor effect of NSAIDs and SYSADOAs in history did not affect the clinically important improvement (MCII), from baseline to 6-month follow-up (range 3-9 months), as >3.8, <3.8, or within 3.8 units. Statistical significance was studied with one-way analysis of variance (ANOVA) and chi-square.
result. The effectiveness of treatment was less in patients >65 years (OR 0.418; 95% CI 0.342-0.509, p<0.001), OA stage ≥ 2 by Kelgren-Lawrence (OR 0.556; 95% CI 0.298-0.738, p<0.001), with rest pain (OR 0.690; 95% CI 0.596 - 0.800, p<0.001), synovitis (OR 0.780; 95% CI 0.673-0.900, p=0.001), and sensory symptoms such as burning, pain cold, electric shocks (OR 0.530; 95% CI 0.458-0.613, p<0.001).

Conclusion: the ASU and KLS combination allows to achieve successful pain control in OA. A number of factors: age >65 years, OA stage ≥2 by Kelgren-Lawrence, rest pain, synovitis, and sensory symptoms are associated with the worst result of treatment.

AB0806 EFFICACY MANAGEMENT AND ADHERENCE EVALUATION OF DICLOFENAC IN THE TREATMENT OF KNEE OSTEOARTHRITIS PAIN

Qiu Yudian, Jianhao Lin, Hu Li, Yunfei Hou. Inst. of Arthritis, Peking Univ. People's Hosp., Beijing, China

Background: The incidence of knee osteoarthritis is increasing day by day. The accompanying pain has seriously affected people's quality of life. No relevant researches have studied the relationship between pain relief and adherence after taking NSAIDS in outpatients.

Objectives: To investigate the effect of diclofenac on pain control of knee osteoarthritis and the relationship between pain relief and medicine adherence. To evaluate the pain relief rate of patients with different initial pain.

Methods: 120 patients with knee osteoarthritis were recruited from the outpatient department of osteoarthritis, Peking University People's Hospital. The population was randomly divided into the experimental and control group. The baseline and follow-up contents were interviews including socio-demographic factors, evaluation of knee pain, WOMAC and MMAS-8 questionnaire. The experimental group was given regular follow-up and medication advice, while the control group was only given observational records at the middle and late stages. SPSS25.0 nonparametric T test and one way ANOVA were used to evaluate the efficacy of diclofenac in relieving knee osteoarthritis pain and the relationship between pain relief and adherence.

Results: A total of 120 patients with knee osteoarthritis at baseline were randomly enrolled and 108 patients were followed up. 55 patients in the experimental group and 53 patients in the control group (1) The 2-week adherence of test group/control group was 86.38%/84.78%(P=0.01), the 6-week adherence of test group/control group was 75.24%/35.22%(P<0.01). The 2-week and 6-week adherence of test group and control group were significantly different (P<0.015 and P<0.01). (2) The pain relief rate at 2 and 6 weeks in the experimental group was 67.56% and 69.41%, respectively, the pain relief rate was significantly higher than baseline (P<0.01), but there was no significant difference between the two groups (P=0.739). The pain relief rates at 2 and 6 weeks in the control group were 45.61% and 29.03% and was significantly higher than baseline (P<0.01), there was a significant difference between the two groups (P<0.01). In the evaluation of 2 and 6 weeks, the pain relief rates in the experimental group were significantly different from those in the control group (P<0.01). (3) The initial pain scores of different degrees did not affect the adherence and pain relief rates in the experimental group. In the control group, the 2-week adherence of severe pain patients was higher than that of mild and moderate pain patients (P<0.01), but the 6-week follow-up adherence shows no significant difference in patients with different degrees of initial pain (P=0.073), the 6-week adherence of patients with moderate/severe pain (38.07%42.6%) was significantly different from the 2-week adherence (68.34%/84.77%)(P=0.01),the 6-week pain relief rate (18.46%/29.72%) in patients with mild/moderate pain was lower than the 2-week pain relief rate (48.72%/47.44%) (P=0.052/P<0.01). (4) The patients with better adherence have the higher pain relief rate (P < 0.01).

Conclusion: For patients suffering from knee osteoarthritis pain, diclofenac 150 mg/day for 6-week is recommended. Regular follow-up can improve adherence significantly, increased adherence can improve the pain relief rate significantly, the pain relief rate may not be related to the patient's initial pain score. It is suggested that clinical workers should supervise the medication of patients with knee osteoarthritis and make regularly follow up.

AB0807 FOLLOW-UP OF PATIENTS WITH HIP OSTEOARTHRITIS WHO RECEIVED VISCOSUPPLEMENTATION: HOW NEW TECHNOLOGIES CAN HELP

Mariaeva Romano, Laura Belloli, Elisal Verduci, Cinzia Casu, Valeria Campanella, Marina Muscarà, Davide Antonio Filippini, Emanuela Schito, Maria Di Cicco, Oscar Massimilliano Epis, Samsung Electronics Italia: M.Cammarlatt, G.Locatelli MDApp srl, Y.Carrillo, A.Colombini, Grande Ospedale Metropolitano Niguarda, Reumatologa, Milano, Italy

Background: Digital health innovations have opened up several opportunities to help patients with rheumatologic conditions and their treating clinicians in improving routine healthcare.

Objectives: To evaluate the applicability of a wearable smartwatch for monitoring patients with hip osteoarthritis who received viscosupplementation. Samsung Electronics Italia and MDApp srl supported the present study.

Methods: Consecutive patients with hip osteoarthritis who received viscosupplementation with hyaluronic acid between November 2017 and May 2018 were enrolled in this observational study. All patients gave their informed consent. A Samsung Gear smartwatch was given to each patient and was worn during the day for measuring daily steps, walking distance, and mean velocity. Patients were asked to wear the smartwatch starting from one week before infiltration (T0), until two weeks before (T1). Patients were assessed with Lequesne index and WOMAC score at T0 and T1.

Results: Overall, 24 patients (7 male and 17 female, mean age 44 years-old) were enrolled. Of these, 70% has worn the smartwatch for most of the time (range 90-100%). An improvement of velocity (45%), an increase of daily steps (29%), and walking distance (25%) were seen. Similarly, Lequesne index and WOMAC score were consistent with subjective improvement. Most of the patients (95%) declared to be satisfied with this digital health study.

Conclusion: Samsung smartwatches proved to be an effective tool for tracking and recording medical parameters linked with perceived general health. Health technologies are more than an accessories and could be useful in chronic musculo-skeletal diseases because they allow to ease remote diagnosis and to monitor patients' symptoms and clinical response. Telemedicine could fill the gap between patients and healthcare, with a reproducible and objective tool, enhancing patients' engagement with the treatment plan. The high patients' satisfaction further support the use of digital health technology.

COMBINATION OF ORAL PARACETAMOL AND TOPICAL NSAIDS FOR OSTEOARTHRITIS PAIN: A SYSTEMATIC SCOPING REVIEW OF THE LITERATURE

John Bell1, Vidhu Sethi2, Kamran Siddiqui3, Philip G. Conaghan1, 1Graduate School of Health, University of Technology Sydney, Sydney, Australia; 2GlaxoSmithKline Consumer Healthcare, Singapore; 3Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: Topical NSAIDs and paracetamol (APAP) are frequently used for osteoarthritis (OA) pain.1,2 In real-world settings, combination treatment is common,3,4 with more than one-quarter of patients using topical NSAIDs with oral non-opioid analgesics such as APAP.2

Objectives: We conducted a systematic scoping review to: understand current recommendations on concomitant use of topical NSAIDs and APAP for OA pain; evaluate the extent of supporting evidence for this practice; and identify literature gaps.

Methods: We searched PubMed and the Cochrane Library for clinical studies (database inception to January 2019) of topical NSAIDs in OA in which APAP was given concomitantly, either regularly (combination treatment) or as needed (rescue treatment). Grey literature searches were conducted to identify clinical practice guidelines for management of OA from leading organizations.

Results: After removing duplicates, the literature searches returned 375 articles, of which 66 were clinical studies of topical NSAIDs in OA and were reviewed further. Of these, we identified 1 randomized controlled trial (RCT) evaluating efficacy and safety of combination treatment with APAP and a topical NSAID, in which 43 patients with knee OA currently treated with APAP were randomly assigned to double-blind treatment with ketoprofen plaster or placebo for 4 weeks.5 Results showed that the combination of APAP-topical ketoprofen was statistically significantly more effective in pain reduction (P=0.03) and physician’s global assessments (P=0.01) compared with APAP/placebo. Of the remaining 65 topical NSAID studies, another 37 (57%) allowed rescue treatment with APAP during the treatment period (including 34 RCTs; 1 open-label extension of 2 RCTs; 1 patient preference study; and 1 single-arm open clinical trial). Because none of these studies randomly assigned patients to the combination, it was not possible to evaluate efficacy or safety of the combination based on these data. Review of OA guidelines identified 3 major organizations—EULAR, NICE, and ESCCEO—that recommend or allow concomitant use of topical NSAIDs and APAP for specific joint pain.

Conclusion: In clinical practice, drug combinations are frequently used to manage OA pain, and some OA treatment guidelines allow the use of topical NSAIDs concomitantly with APAP. Very limited supporting data are available, with only a single small RCT demonstrating the efficacy and safety of the combination. However, it may be inferred from the fact that more than half of the topical NSAID studies identified allowed APAP rescue therapy that this combination is generally perceived to be efficacious and well tolerated. Additional, larger RCTs are needed to confirm the benefit of this commonly used analgesic combination in managing OA pain.

A STUDY TO COMPARE ARTICULAR CARTILAGE VOLUME IN HEALTHY AND OSTEOARTHRITIC KNEE AND ITS CORRELATION WITH CLINICO–RADIOLOGICAL SEVERITY

Sudeep Sri Divastava, Rajeswar Nath Sri Divastava, Amar Chandra Sharma, King George’s Medical University, Orthopaedic Surgery, Lucknow, India

Background: Knee Osteoarthritis (KOA) is a persistent debilitating disease characterized by loss of articular cartilage. Known to be a disease of elderly, it may not be necessarily so, as the loss in articular cartilage volume (ACV) begins early but detected very late on X-rays and by that time no therapy works and joint replacement is the only answer.

Objectives: To determine the role of ACV in early diagnosis of KOA, which may not only monitor disease progression from a very early stage, it may also open a gateway to slow down or stop the structural changes involved in KOA.

Methods: 60 Cases and equal number of age, sex matched controls were recruited. Each subject had MRI of the knee to monitor ACV and to determine ACV at the knee. ACV was measured manually by means of image processing on an independent workstation using semi-automated machine GE Signa. VAS for knee pain and WOMAC for pain, stiffness and disability were recorded for clinical severity and X-rays for radiological severity by KL grading.

Results: With age, a statistically significant inverse correlation of ACV was found in both healthy and osteoarthritic knees. Height, weight and BMI were independent of ACV in healthy knee. In KOA, a significant positive correlation of ACV was observed with height, a significant inverse correlation with WOMAC scores and significant difference with sub-scales of WOMAC index (pain, stiffness and physical function). The statistical difference in ACV between the two categories of WOMAC scores (<32 and >32) was significant.

Conclusion: This study concluded that ACV is significantly lower in osteoarthritic knee as compared to healthy adult knee. This study also found that KOA in females occurs at an early age and progresses slowly whereas in males occurs late and progresses rapidly. ACV may become one of the most promising tools for early diagnosis of KOA and in monitoring disease progression.

INTRA-ARTICULAR CNTX-4975 FOR PAINFUL KNEE OSTEOARTHRITIS: ASSESSMENT OF COOLING METHODS FOR REDUCING PROCEDURAL PAIN

Randall Stevens1, Kimberly Guedes1, Nilam Misty1, Duncan Lascelles1, David Ball2, 1Centrexion Therapeutics Corp, Boston, United States of America; 2IMAC Clinical Research, Manchester, United Kingdom

Background: CNTX-4975 is a long-acting, trans-capacitance injection in phase 3 trials for treatment of moderate to severe pain associated with knee osteoarthritis (OA). Intra-articular (IA) CNTX-4975 injection produces short-lived procedural pain that can be ameliorated with joint cooling. A prior analysis (Cohort 2) demonstrated that a circumferential circulating ice water wrap (CCIWW) more effectively lowered IA knee temperature and reduced procedural pain than an ice pack on top of the knee (3.4 vs 7.3, respectively, on a numeric pain rating scale [NPRS] 10 minutes post-CNTX-4975).

Objectives: Subjects were enrolled in 2 separate cohorts (C3/C4) to: compare effects of 2 circumferential cooling methods on IA and skin knee temperature and procedural pain (C3); and assess procedural pain with an abbreviated cooling schedule and with vs without post-CNTX-4975 cooling (C4).

Methods: Eligible subjects were adults aged 45–75 yrs with >3 months of bilateral moderate to severe OA knee pain. All subjects received each
cooling device on opposite knees; IA CNTX-4975 injections and other procedures on the left and right knees were separated by 7 (±2) days. See Figure for study design. IA and skin temperatures were recorded throughout the procedures. Subjects rated procedural pain at prespecified times using NPRS (0=no pain; 10=worst possible pain).

Results: Five subjects enrolled in and completed each cohort (mean age, yrs: C3, 57.6; C4, 59.6; each 80% male). In C3, mean IA temperatures decreased with both methods; mean temperatures at baseline and 105 minutes were 33.7°C and 26.7°C for ice-gel pack cooling and 32.4°C and 28.2°C for CCIWW. Skin temperature reductions between cohorts were similar; mean temperatures were 28.8°C and 14.3°C (ice-gel pack) and 28.7°C and 15.2°C (CCIWW). Mean IA temperatures in C4 at baseline and 55 minutes (15 minutes post-CNTX-4975 and/or end of last cooling period [CCIWW only]) were 33.6°C and 28.7°C; mean temperatures were 28.8°C and 26.7°C for ice-gel pack and 27.8°C and 18.8°C for CCIWW. Pain levels before CNTX-4975 were low. Procedural pain were 28.5°cooling and 32.1°cooling period [CCIWW only]) were 33.6°line and 55 minutes (15 minutes post-CNTX-4975 and/or end of last practice.

The ice-gel pack and CCIWW effectively reduced IA knee pain was not increased in the absence of post-injection cooling in C4. More effectively by CCIWW in C3 and ice-gel pack in C4. Procedural pain was reduced more effectively by CCIWW in C3 and ice-gel pack in C4. Shorter cooling time and low pain levels observed with IA CNTX-4975 and ice-gel pack cooling in C4 suggest that this strategy may be feasible in clinical practice.

Conclusion: These results suggest that intra-articular injections of hyaluronic acid plus chondroitin sulfate in patients with knee OA are efficient and safe. A single injection of the drug resulted in statistically significant reduction of pain and stiffness, reduction in NSAIDs intake, as well as improvement in patients’ quality of life and function.

PAIN CATASTROPHIZING SCORE AND GAIT, TOGETHER WITH WOMAC, ARE ALTERED IN KNEE OSTEOARTHRITIC PATIENTS UNDERGOING ARTHROPLASTY SURGERY, COMPARED WITH PATIENTS FOLLOWING CONSERVATIVE TREATMENT. PRELIMINARY RESULTS FROM HOLOA PROJECT

Laura Tío1, Francisco Castro1,2, Simone Tassani3, Santos Martínez1,4, Raul Torres1,4, Raquel Arredondo1, Miguel Ángel González-Ballester3,5, Joan Carles Monllau1,4, Jérôme Noailly3, Jordi Monfort1,2.

1IMIM, Barcelona, Spain; 2Hospital del Mar, Rheumatology service, Barcelona, Spain; 3Pompeu Fabra University, BCN MedTech, DTIC, Barcelona, Spain; 4Hospital del Mar, Orthopedic Surgery and Traumatology service, Barcelona, Spain; 5ICREA, Barcelona, Spain

Background: Osteoarthritis (OA) is a pathology that includes several disorders that produce the same symptomatology: pain, functional impotence and inflammation. It lacks therapies that act over the physiopathology of the disease, rather than over the symptoms [1]. Patients’ phenotyping is essential to describe the disorders underlying the OA symptoms, and would allow applying treatments to the altered conditions, in a personalized medicine approach.

Objectives: The HOLOA project aims to design a multivariate model that allows classifying knee OA patients according their characteristics in 3 areas: pain, clinical/morphological characteristics and articular defects. The present work is a preliminary study with the aim to describe the clinical and gait dynamics differences between OA patients classified by treatment: conservative (CNS) vs arthroplasty surgery (ART).

Methods: Prospective study of OA patients graded 2-3 in KL scale and classified by treatment. Both groups are paired by genre, age, and BMI. The studied variables are: WOMAC index (Pain (Wp), Stiffness (Wst) and Function (Wf), Hospital Anxiety and Depression Scale (HADS), London Chest Activity of Daily Living scale, Modified Baecke Physical Activity Questionnaire, Pain Catastrophizing Score (PCS), pain threshold (according to the extended peripatelar map of Arent-Nielsen) pain sensitization at the tibia anterior surface, pain temporal summation (these 3 parameters are measured with the use of an algometer [2]), ultrasound measurement of synovial hypertrophy and effusion, and gait analysis (with Helen Hayes marker protocol). Inverse dynamic analysis was performed to compute the reaction forces and torques of the OA and control leg [3]. Multivariate analysis of variance was performed for the treatment, genre, age and BMI.

Results: This study was performed with the data of the 70 patients recruited to date. They are classified as shown in Table 1.

</tbody>
</table>

Only treatment factor related differences are reported. ART group present significant higher values in Wst (p=0.012), Wf (p=0.018), and PCS (p=0.018), than CNS group (Figure 1). Differences in PCS values show interaction with BMI (p=0.007) (Figure 2). Regarding the joint, number of painful sites depend on treatment and BMI group (p=0.032) (Figure 3). Finally, gait study show no direct effect of the treatment, interactions are observed in the reaction forces and torques when comparing control vs OA leg, in ART and CNS group (p=0.004 and p=0.002, respectively) (Figure 4).
Conclusion: Although both treatment groups present the same OA radiologic grade, ART group presents significant higher stiffness and functional disability. That may affect to the gait of these ART patients, altering the forces distribution and torques between both legs. Although no differences in knee pain in life situation (WP) between treatment group are reported, ART group present more painful sites in the knee with pressure stimuli. Emotional component may be playing a role in the pain and illness perception, influencing the patient decision to undergo ART surgery.

AB0814

AN EXPERT CONSENSUS ON THE APPROPRIATE USE OF ORAL SYSADOAS FOR THE TREATMENT OF THE OSTEOARTHRITIC PATIENT IN PRIMARY HEALTH CARE: A DELPHI STUDY

Jordi Monfort1, Benjamin Abacá2, Xavi Carné2, Sergio Giménez4, Ingrid Möller6, Montserrat Romera2, Marco Bibas1, Marianna Vitaloni7, Josep Verges7, Jordi Monfort3, Francisco de Abajo4, Patrick du Souich5, Jordi Monfort3, Francisco de Abajo4, Patrick du Souich5

Background: Clinical studies have demonstrated that osteoarthritis pain is linked to disability and quality of life (QoL). The therapeutic modalities in the treatment of osteoarthritis (OA) are numerous and despite the availability of evidence-based guidelines for OA management, agreement on treatments is lacking. Symptomatic Slow-Acting Drugs for OA (SYSADOAs) are natural compounds, used in OA treatment. Thus, there is disagreement about SYSADOAs use in clinical practice.

Objectives: Our objective was to prepare a consensus document on the appropriate use of oral SYSADOAs: chondroitin sulphate (CS), glucosamine (G), diacerein (D) and the combination of CS plus G for OA management in primary health care.

Methods: A two-round Delphi study was carried out to assess expert consensus on the appropriate use of SYSADOAs in primary care. The questionnaire validated by the expert committee (3 rheumatologists, 2 PC physicians, 1 clinical pharmacologist) included 24 questions. The Delphi panel was composed of 15 experts (10 PC physicians, 1 rheumatologist, 1 traumatologist, 1 rehabilitator, 1 gynaecologist and 1 clinical pharmacologist) with extensive experience in the treatment of OA and the use of oral SYSADOAs which were identified by clinical coordinator, a methodology coordinator, and four members of the Scientific Committee. Participants were asked 24 questions on SYSADOAs use. Items that reached consensus by at least 80% across both panels were included in the guidelines. The fieldwork of the study was developed for approximately 4.5 months. This study was promoted by the International Osteoarthritis Foundation (OAFI) with the support of the Spanish Ministry of Health, Social Services and Equality.

Results: Consensus statements emerged: (1) patient phenotypes affect SYSADOAs action; (2) SYSADOAs are effective in primary and secondary OA, in the three first grade of Knee OA, hand and hip; there is no evidence for erosive hands, shoulder, spine, and ankle OA; (3) CS, G and association can reduce pain, inflammation, improve QoL and functional capacity and have a chondroprotective effect; (4) CS and D can reduce synovial membrane inflammation, all oral SYSADOAs, except D, can decrease cell death and the enzymes responsible for cartilage destruction; (5) The maximum therapeutic effect is reached after 3 to 6 months; (6) SYSADOAs can be prescribed to patients having comorbidities: cardiovascular risk or disease, digestive disease, hypertension, dyslipidemia, peripheral vascular disease, type 2 diabetes, and oesophageal reflux. There is disagreement in the prescription of oral SYSADOA in patients with liver and kidney disease.

Conclusion: This study sheds light on the appropriate use of oral SYSADOAs in primary health care by providing added value to published evidence. Results based on literature evidence on efficacy and safety, the clinical experience of the panelists in OA treatment and the fact that OA patients are a chronic, elderly, with multiple diseases and polymedicated person. The diffusion of our results among primary health practitioners will contribute to improving OA patient management protocols to ensure a personalized treatment to OA patients and to ameliorate their QoL.

INDIVIDUAL AND SOCIAL FACTOR CAN INFLUENCE THE QUALITY OF LIFE OF KNEE OA PATIENTS: A SYSTEMATIC REVIEW

Josep Verges1, Marianna Vitaloni1, Marco Bibas1, Rosa Sciottrino2, Maritza Quintero2, Jordi Monfort3, Francisco de Abajo4, Patrick du Souich5, Ingrid Möller6, Elizabeth Oswald1, Marco Matucci-Cerinic7, Guy Eakin8, Angie Botto-van Bemden9, OAFI Foundation (Osteoarthritis Foundation International), Barcelona, Spain; “Universidad de los Andes, Merida, Venezuela (Bolivarian Republic)” Hospital del Mar, Barcelona, Spain; “Hospital del Mar, Barcelona, Spain; “Hospital del Mar, Barcelona, Spain; “Hospital del Mar, Barcelona, Spain; “Hospital del Mar, Barcelona, Spain; “University of Montreal, Montreal, Canada; “Institut Poal de Reumatologia, Barcelona, Spain; “University of Florence, Firenze, Italy; “ARTHritis FOUNDATION, Atlanta, United States of America

Background: Knee OA (KOA) is the most common form of chronic joint disease and bears more responsibility than any other disease for disability. It associates with remarkable functional restrictions due to pain. The limitations in activity caused by KOA seriously affect social relationships, emotional well-being, reducing the quality of life (QoL) of patients.
The identification of therapies and factors that affects and improve QoL in KOA patients may mitigate the clinical, economic, and social burden of this disease. Thus, the assessment of QoL in KOA is becoming increasingly common in both research and clinical practice. Still a general recompilation of the factors of interest as demographic features, lifestyle characteristics and comorbidity are missing.

**Objectives:** Our aim was to recapitulate the existing information on QoL in KOA patients as an international tool to raise awareness on their condition and guide future actions for patient’s management

**Methods:** We conducted a systematic review examining the breadth of the literature regarding the QoL in patients with KOA (up to 2017). We identify articles using MEDLINE, EMBASE, Cochrane, and PsycINFO using relevant keywords as KOA, QoL, and well-being and their short forms. All articles were reviewed for inclusion by 3 independent reviewers. QoL domains and items relevant to patients with KOA were extracted. Only original articles were included when containing information on QoL of patients with KOA. Inclusion criteria were QoL compared to one or more demographic factors (e.g., age, gender), lifestyle factor (e.g., functional independence), or comorbidity factor (e.g., diabetes, obesity) or a control group. The quality of included studies was assessed using a quality appraisal tool.

**Results:** We retrieved 610 articles, of which 62 articles fulfilled inclusion criteria for review. Most of the studies were carried out in Europe, American Continent and Asia. The mean of participants in these 62 studies was 561 patients and the majority of them were female, the mean age was 63 years. All the studies described a worse QoL in KOA patients when compared to a control group having women a worst QoL perception than men.

A higher BMI, a lower level of physical activity and higher energy expenditure were one of the main factors that correlated with worse QoL. Educational level and higher total mindfulness were shown to improve QoL while poverty, physiological distress, depression and having severely dysfunctional families reduce it. The delivery of a knee self-management program by health care professionals was proven to improve QoL. Finally, surgical KOA interventions generally resulted in good outcomes these results were influenced by individual factors as age, weight, and depression.

**Conclusion:** This is the first review pertaining to QoL in KOA patients. KOA has a strong impact on QoL. Individual factors (sex, weight, exercise, mental health, education) can influence QoL. These factors affect treatment outcomes and should be considered for a better patient’s management. These data are a valuable tool for health professionals, to better understand the disease and to implement more adequate standard of care.

**THE INFLUENCE OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON INFLAMMATORY SONOGRAPHIC FEATURES IN EROSIve HAND OSTEOARTHRITIS**

Xiaxia Xu1, Ruth Witteok2,3. 1Ghent University, medical student, Gent, Belgium; 2Ghent University Hospital, Rheumatology, Gent, Belgium; 3Ghent University, Internal medicine and Paediatrics, Gent, Belgium

**Background:** Erosive hand osteoarthritis (HOA) is a subtype of hand osteoarthritis affecting the interphalangeal (IP) finger joints, characterized by a more inflammatory burden. Hitherto, pharmacologic treatment options are restricted to symptomatic therapy like paracetamol and/or non-steroidal anti-inflammatory drugs (NSAIDs). The latter may affect the presence of inflammatory features on ultrasound (US), hence, assessment of this disease activity could be influenced by this treatment.

**Objectives:** To examine whether inflammatory US features (i.e. synovial proliferation (SP), effusion (EFF) and Power Doppler (PD) signal) in erosive HOA patients change when discontinuing NSAIDs intake for two weeks before the US assessment.

**Methods:** Ninety-nine patients with erosive HOA, according to American College of Rheumatology criteria (2) were enrolled. Presence of central erosions on conventional radiographs and any clinical sign of inflammatory activity (soft tissue swelling) in at least one proximal or distal IP finger joint were present. The patients were allocated to the NSAIDs or control group according to their intake before baseline (if no NSAIDs use - control group; if intake of NSAIDs on a regular base = NSAIDs group). At baseline (T0), 16 IP finger joints were examined by US. Patients in the NSAIDs group were asked to discontinue all NSAIDs intake for two weeks, when another US was performed (T1). The inflammatory features were scored at T0 and T1 using a semi-quantitative scale ranging from 0-3 (3).

Binomial mixed models with logit function were fitted for ultrasound scores SP (score=2), EFF (score=2), and PD (score=1) with a random intercept for patient and with age (in years), sex (female vs. male), duration of illness (in years), joint, side (left vs. right), anatomical phase group (N, S, J vs. E/R, R, E, F), NSAID group (NSAIDs withdrawal vs. No NSAIDs), time (T1 vs. T0), and a two-way interaction between NSAIDs group × time as fixed factors. The Odds ratios (OR, 95% confidence interval (CI)) of having an ultrasound score of at least '2' versus at most '1' for SP and EFF, and '0' vs. '1' for PD are shown.

**Results:** Forty seven patients were included in the NSAIDs group and 52 in the control group. Both groups were comparable at baseline for VAS pain, disease duration, number of radiographic affected joints and body mass index, but not for age (p=0.005). The US baseline data were comparable between both groups (all p>0.05). At T1, in the NSAIDs withdrawal group, more SP and PD was seen compared to baseline (p = 0.018 and 0.031, respectively). However, the interaction term time*NSAIDs was not found significant for any variable (table 1).

Osteoporosis

CAN STATINES IMPROVE BONE QUALITY IN POSTMENOPAUSAL OSTEOPOROSIS?

Pablo Astesana1, Paula Alba2, Carla Gobbi2, Ruth Fernandez2, Eduardo Albiero2, Marcelo Yorio3,4.
1Córdoba, Argentina; 2University of Córdoba, Córdoba, Argentina; 3Universidad Nacional de Córdoba, Córdoba, Argentina

Background: Osteoporosis (OP) is the most frequent metabolic bone disease. It has low bone mass and microarchitectural deterioration, which increases the risk of fractures. The most commonly used drugs are bisphosphonates, however statins (ST) have pleiotropic properties, and some researchers suggested their use in OP.

Objectives: To determine the effect of ST on bone mineral density (BMD) in postmenopausal osteoporotic women.

Methods: A cross-sectional study, control case where postmenopausal women with hypercholesterolemia treated with ST for a period not less than 6 months were studied for two years. The control group was postmenopausal population that did not receive statins. Exclusion criteria: Diabetes, previous treatment with estrogen, calcitonin, anabolic, steroids, bisphosphonates or vitamin D during a period of 6 months prior to enter to the study or with amenorrhea less than 12 months. We evaluated age, weight, height, BMI, personal and first degree family members’ history of fracture, use of corticosteroids, smoking, alcoholism, daily calcium intake, sedentary lifestyle, phosphophatic metabolism laboratory and Vitamin D. All patients were performed Bone Densitometry by dual-energy X-ray absorptiometry (DXA) with an Hologic equipment in right hip and lumbar spine, staging them according to WHO. The statistical analysis was performed using the Student’s test and the Fisher test for categorical variables. Values of p less than 0.05 were considered significant.

Results: 202 patients were enrolled in the ST group and 203 in the control group. Age, weight, height and BMI were 62.64; 69.6; 1.60 and 27.1 in the ST group and 58.5; 65.7; 1.59 and 26.83 in the control group respectively (p = 0.000, p = 0.001 p = 0.79, p = 0.38). There were no significant differences in risk factors for OP between groups. The average lumbar BMD was -0.87 for the ST group and -1.76 for the control group (p = 0.000), the average femur neck BMD was -1.15 for the ST group and -1.56 for control (p = 0.000), the total hip BMD was -0.32 for the ST group and -0.74 for the control group (p = 0.001), vitamin D was 25.57 for the ST group and 27.71 (p = 0.120).

Conclusion: ST can improve Bone Mineral Density in postmenopausal women, more studies are needed to confirm these results.

INCIDENCE OF FRACTURES AND ASSOCIATED RISK FACTORS DURING THE DRUG HOLIDAYS PERIOD WITH BISPHOSPHONATES

Laur Bautista1, Angel Delgado Zamorro2, Asunción Salmoral2, Inmaculada Gómez Gracia3, Ladehesa Pineda Lourdes4, Pérez Sánchez Laura5, Gómez García Ignacio5, Font Urgale Pilar2,3, María del Carmen Castro Villegas1,2,3, Alejandro Escudero Conteras1,2,3, Eduardo Collantes Estevez1,2,3,4, Reina Sofia University Hospital; Rheumatology, Cordoba, Spain; 2University of Cordoba, Cordoba, Spain; 3IMIBIC, Cordoba, Spain

Background: Biphosphonates are the most widely used treatment for osteoporosis. The optimal treatment duration, however, remains unclear. The occurrence of adverse effects, such as osteonecrosis of the jaw (ONJ) and atypical femoral fractures (AFF), has raised the issue of bisphosphonate discontinuation (“drug holiday”) after a certain treatment period.

Objectives: To assess the incidence of fractures in patients during the drug holidays period with bisphosphonates, as well as to determine the risk factors are associated to it.

Methods: Analytical, observational, longitudinal, and ambispective study of a cohort of patients with postmenopausal osteoporosis or men over 50 years of age treated with oral bisphosphonates (at least for 5 years) or intravenous (at least for 3 years) and who had been at least for one year in a drug holidays period, from 01/01/2012 to 12/31/17. Patients treated with corticosteroids and/or with diseases with effects on bone
Results: 128 patients with osteoporosis were studied, of which 19 (14.7%) suffered an osteoporotic fracture during the follow-up. Bivariate analysis showed in the group of patients with fractures a higher proportion of smoking patients (p = 0.004), osteopening treatment (p = 0.005) and a femoral neck t score lower at the beginning of the drug holidays period -2.07 (0.68) vs - 1.58 (0.63), p = 0.008.

In addition, there was a higher proportion of patients with fracture with moderate risk before the start of the drug holidays period (p = 0.007). The fracture survival curves were lower in patients older than 75 years (p = 0.04). When applying the same treatment, for each year increase, the risk of fracture was increased by 6% (p = 0.04), while, for the same age, this risk was increased 4.33 times in patients who were treated with Risedronate versus those with Alendronate (p = 0.05).

The multiple regression analysis showed that vertebral fracture was independently associated with Tabaco (HR 4.28 p=0.047).

Conclusion: Based on our results, it would be useful to follow closely those patients during drugs holidays period who are smokers, older than 75 years, with osteopening treatment, who present a low femoral neck t-score and/or have been previously treated with Risedronate.

AB0819 HANDGRIP STRENGTH PREDICTS HIGH FRACTURE RISK IN PATIENTS WITH TYPE 2 DIABETES MELLITUS
Federica Bellone1, Nunziata Morabito1, Agostino Gaudio2, Gabriella Martino1, Alberto Sardella1, Antonino Lasco1, Antonino Catalano1.
1University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy; 2University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy

Background: Accumulating evidence has revealed that the risk of osteoporosis related fractures is significantly increased in type 2 diabetes mellitus (T2DM) patients in comparison with healthy controls. Dual X-ray Absorptiometry (DXA) derived bone mineral density (BMD) is not completely useful to discriminate at risk patients.

Objectives: To find a valuable clinical tool that is helpful to identify T2DM subjects with poor bone health, finally preventing fragility fractures.

Methods: In a setting of Caucasian subjects with T2DM, anthropometric data and information about metabolic control and diabetic complications were recorded. Handgrip strength by dynamometer, FRAX derived 10-years probability of major osteoporotic fractures and hip fractures were also assessed. Bone evaluation was performed by a dual-energy X-ray absorptiometry (DXA) densitometer at the lumbar spine (L1-L4) and at the femoral neck. Based on specific software, the trabecular bone score (TBS) was calculated. Lateral scan of thoracic and lumbar spine was assessed to investigate morphometric vertebral fractures (Vfs).

Results: 29 patients (female 65%) [median age 67 (60 to 70)] with T2DM were considered. Morphometric vertebral fractures were detected by DXA in 17% of patients without any gender differences (males vs. females, p=0.6). The median ten years probability of fractures was 8.1% and 2.3% as for major osteoporotic or hip fracture respectively. Median femoral neck T-score value [-1.1 SD (-1.8 to -0.5)] was indicative of a slight osteopenia while lumbar spine T-score was even in the normal range [-0.8 SD (-1.5 to -0.1)]. The median TBS value was 1.28 (1.2 to 1.31) and TBS was positively associated with BMD at lumbar spine and femoral neck. Median handgrip strength value was 22.3 kg (18.9 to 31.3). At multiple regression analysis, handgrip strength predicted both lumbar (β=0.009, SE 0.0034, p=0.01) and femoral neck BMD values (β=0.006, SE 0.002, p=0.01) and also independently associated with TBS score, after correcting for mean HbA1c values and time since T2DM diagnosis.

Conclusion: Handgrip strength may be a reliable tool to screen for bone fragility in T2DM.

AB0820 COGNITIVE IMPULSIVITY CORRELATES WITH BONE MINERAL DENSITY

Alberto Sardella, Federica Bellone, Carmen Giulia Lasco, Gabriella Martino, Nunziata Morabito, Antonino Catalano. University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy

Background: Cognitive impairment is known to be associated with low bone mineral density (BMD) and low levels of BMD have been associated with increased rates of progression from mild cognitive impairment to Alzheimer’s disease and with the onset of episodic verbal learning deficit.

Objectives: The potential involvement of executive functions impairment on BMD is still unclear. The aim of this study was to investigate the correlations between cognitive impulsivity, BMD and fall risk.

Methods: Cognitive impulsivity was measured by Stroop Color and Word Test (SCWT) administration in a setting of 40 consecutively recruited postmenopausal women referring to a outpatient clinic for the evaluation of fracture risk. SCWT is a neuropsychological test able to assess the ability to inhibit cognitive interference: during the administration, women were required to quickly read three different tables of which two represented the “congruous condition” in which participants were invited to read names of colors printed in black ink and name different color patches. In the third table, named “incongruous condition”, color-words were printed in inconsistent color ink (e.g. the word “red” is printed in green ink) and participants were required to name the color of the ink instead of reading the word. Women with Mini Mental State Examination (MMSE) score < 24, known neurologic or psychiatric disorders, history of significant hearing or visual impairment, or significant physical disability, history of uncontrolled diabetes and abnormal thyroid function, cancer, heart, respiratory, kidney or liver failure were excluded. BMD was measured at lumbar spine and femoral site by a DXA densitometer (Hologic Discovery). History of falls in the previous 12 months was recorded.

Results: Cognitive impulsivity, as highlighted by making errors at the SCWT, was significantly associated with lumbar spine and femoral neck T-score (r=-0.39, p=0.01 and r=-0.43, p=0.008; respectively). MMSE score was not associated with T-score values, neither at lumbar spine (r=0.09, p=0.5) nor at femoral neck (r=0.2, p=0.21); differently MMSE score was significantly associated both with Stroop test error (r=-0.34, p=0.02) and time interferences (r=-0.39, p=0.01). Furthermore, time interference was positively associated with the self-reported history of falls (r=0.342; p=0.031).

Conclusion: Cognitive impulsivity was significantly associated with BMD values and higher prevalence of falls in postmenopausal women. It could be considered as a possible clinical risk factor for osteoporotic fractures.

AB0821
APPRECIATION OF OSTEOPOROTIC TREATMENT COMPLIANCE WITH ALENDRONATE 70MG ORALLY
Bhil Bengana, Abdenour Boukabous, Naima Bahalz, Salima Lefkir. University Hospital of Benimussous, Rheumatology, Algiers, Algeria

Background: Patients suffering from osteoporosis (OP) don’t have the opportunity to enjoy from an accurate and concrete parameters response to OP treatment. They therefore have no palpable evidence of the favorableness of the given therapy. Unintentional antiresorptive treatment (AT) given the silent nature of the pathology. That is way we see the non-compliance with treatment in some patients.

Objectives: It was essential to estimate the extent of the lack of compliance with AOT in order to deduce the factors related to this deficiency in order to reduce the size of the problem.

Methods: It’s a Descriptive cross study performed in all patients over 38 years for both sexes and that exhibit post menopausal or corticosteroid-induced OP justifying AOT orally (alendronate 70mg orally per week) observed over a period of at least 6 months.

Results: We collected data of 153 patients, in 9 out of 10 cases this was a woman, the mean age was 59.3 ± 8.1 years, the average duration of gain of treatment was 32.2 ± 18.2 months, 3 of 5 patients believe that treatment is for musculoskeletal pains, 1/3 of responders confess not to take their weekly treatment regularly, regular physical activity was performed by only 21% of patients, the factors related to non-compliance were: lack of education (p = 0, 032) and sedentary lifestyle (p = 0, 044).

Conclusion: OP is unfortunately underestimated by both patients and physicians, and its short- and long-term repercussions are often minimized. Our study has shown that the various measures required in its management are poorly followed by patients despite their proven effectiveness in reducing fractures. One in three patients in our sample do not follow their treatment properly. Therapeutic education seems to be the answer to overcome this lack of adherence.

AB0822
VITAMIN D (25OHD) IN PATIENTS WITH CHRONIC RHEUMATIC DISEASES RECEIVING TREATMENT WITH ADALUMAB. DESCRIPTIVE STUDY OF A COHORT
Boris Anthony Blanco Cáceres, Paula García Escudero, Javier Arostegui Lavilla, Mayra Nathali Rivas Zavaleta, Marta González Fernández. Hospital Universitario Cruces, Rheumatology, Barakaldo, Spain

Background: Patients with chronic rheumatic diseases (CRD) have lower levels of 25OHD, inverse correlation has been described and greater severity between the different CRD with 25OHD deficit. Most scientific societies recommend levels> 30 ng/mL. Patients with refractory disease to conventional therapy have a higher inflammatory load, require optimal levels of 25OHD and often need biological disease-modifying antirheumatic drugs (bDMARD) in order to prevent structural damage.

Objectives: The aim of this study was to describe the epidemiological, clinical and therapeutic characteristics of patients receiving Adalumab (ADL) in which 25OHD levels were determined in 2018.

Methods: Transversal, retrospective study in a hospital setting. We analyzed data from patients included in a study to determine levels of ADL, in whom the serum level of 25OHD was determined at least once during the last year. Among 104 patients, 74 with 25OHD determination were included.

Results: Seventy-four patients selected, 45.9% were men and 54.1% women. The mean age was 54.9 years (SD ± 13.6), 41.9% (31) had Rheumatoid Arthritis, 36.5% (27) Spondyloarthritis, 17.6% (13) Psoriatic Arthritis and 4.1% (3) Juvenile Idiopathic Arthritis. 35.1% (26) had deficit (<20 ng/mL) of 25OHD, 31.1% (23) insufficiency (20-30 ng/mL) and only 33.8% (25) optimal levels (>30 ng/mL). The 62.2% (46) of the patients received oral supplementation, of these 67.4% maintained levels >20 ng/mL and 32.6% <20 ng/mL. 37.8% (28) did not receive supplementation, despite this 60.7% within this group had levels >20 ng/mL. No statistical differences were found regarding vitamin D deficit and oral supplementation (p > 0.05).

13.5% (10) of the patients also had Osteoporosis (OP); in this group 6 had deficit of 25OHD, 1 insufficiency and only 3 optimal levels, all of them received 25OHD supplementation. No differences between the groups in relation to the DMARD treatment.

Conclusion: Vitamin D levels were determined in 71.2% of patients and not in all of them as it would be advisable. Among the patients with 25OHD determination, 62.2% received oral supplementation, however only 33.8% of the patients reached optimal levels (> 30 ng/mL) without statistical differences regarding supplementation. 13.5% of the patients who received supplementation also had OP. Despite the weakness of the study in terms of design and sample, most patients did not reached optimal levels of 25OHD; we can assume that it is necessary to obtain levels of 25OHD >30 ng/mL in all patients, with adequate supplementation if necessary due to the positive effects known in CRD.

AB0823
TRABECULAR BONE SCORE AT LUMBAR SPINE IS ASSOCIATED WITH QUANTITATIVE ULTRASOUND MEASUREMENTS AT PHALANGEAL SITE IN BREAST CANCER SURVIVORS RECEIVING AROMATASE INHIBITORS
Antonio Catalano1, Federica Bellone1, Rita Maria Agostino2, Nunzia Morabito1, Agostino Gaudio3, Antonino Lasco1. 1University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy, 2Medical Oncology Unit, Grand Metropolitan Hospital Bianchi Metacrinio Morelli, Reggio Calabria, Italy, 3University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy

Background: In breast cancer (BC) survivors, the age-related reduction in bone mineral density is exacerbated by aromatase inhibitors (AIs) treatment. AIs disrupt also bone quality and enhance fracture risk in aging women. Consequently, bone health evaluation is mandatory in BC women receiving AIs.

Objectives: Quantitative ultrasound of bone (QU5) and trabecular bone score (TBS) are recognized tools to explore bone health beyond bone mineral density (BMD). The aim of our research was to explore the association of TBS with QU5 measurements at phalangeal site in a setting of postmenopausal women taking aromatase inhibitors (AIs).

Methods: BMD at lumbar spine, femoral neck and TBS were evaluated by a DXA densitometer (Hologic Discovery). Amplitude Dependent Speed of Sound (AD-SoS), Bone Transmission Time (BTT) and Ultrasound Bone Profile Index (UBPI) were detected at phalangeal site by Bone Profiler (Igac). Results: In 102 postmenopausal women (mean age 61.64 ± 8.33 yr.) (60 AIs treated and 42 controls), at baseline examination. TBS was negatively associated with age (r= -0.39, p < 0.001) and positively related with T-score values at lumbar spine and femoral neck. After 18 months, AD-SoS, UBPI and BTT values were significantly decreased in BC women receiving AIs (-3.7%, -6.45%, -8.5%, respectively, p < 0.001 for all), but not in controls (-0.7%, -3.53%, -2.97%, respectively). Change of BMD at lumbar spine was significantly different between AIs treated women and controls (-3.7%, -6.45%, -8.5%, respectively). Change of BMD at lumbar spine was significantly different between AIs treated women and controls (-2.94% vs. -0.69%, p < 0.001) and the same result was observed as for BMD at femoral neck (-2.5% vs. -0.39%, p = 0.01). Percent change of BMD was significantly greater in AIs treated women in comparison with controls (-2.2% vs. -0.4%, respectively, p = 0.02). In AIs treated women, but not in controls, CTX levels significantly increased after 18 months 0.47 (0.36 to 0.62) vs. 0.66 (0.43 to 0.77), p = 0.0004 and the same trend was observed as for BSAP levels [14 (13.01 to 15.57) vs. 15 (13.75 to 16.75), p = 0.003]. At a multiple regression analysis, change of TBS was independently predicted by change of AD-SoS, after correcting
for BMD change at lumbar spine and femoral neck and for modification of CTX and BSAP levels (<0.037, SE= 2.44, p<0.001).

Conclusion: TBS variation was independently predicted by phalangeal OUS measurement in Al treated BC women. Phalangeal OUS may represent an alternative tool to evaluate bone health also in this setting of patients.

THE EFFECTS OF CEMENT VOLUME DISTRIBUTION OF PERCUTANEOUS KYPHOSCOPY IN OSTEOPOOROTIC VERTEBRAL FRACTURE
Keng Chen1, Ram Chaudhary2, Zhao peng Cai1, Lin Huang2, Zhongyu Xie1, Peng Wang1, Huyong Shen1. 1The Eighth Affiliated Hospital, Sun-Yat-Sen University, Orthopedic Department, Shenzhen, China; 2Sun Yat-sen Memorial Hospital, Sun-Yat-Sen University., Orthopedic Department, Guangzhou, China
Background: Osteoporotic vertebral compression fractures (OVCF) account for 45% of osteoporotic fractures. It causes severe back pain, unable to walk or even stand. Percutaneous kyphoplasty (PKP) is commonly used to treat painful OVCF, effectively relieve pain and walking ability. But there have been few clinical studies that have specifically explored the relationship of the cement volume distribution rate and clinical outcomes.
Objectives: To access the effect of the cement volume distribution pattern in percutaneous kyphoplasty.
Methods: We retrospectively reviewed 126 cases of osteoporotic compression fractures treated with percutaneous kyphoplasty from Jan 2005 to May 2015. The cement volume distribution (CVD) was measured with X-ray and CT scan. 126 thoracolumbar vertebrae were divided into two groups based on CVD ratio: 51 vertebrae in group A with CVD ratio<2; 15 in group B with CVD ratio>2. The relationships of the cement volume distribution and clinical outcomes of pain, vertebral height and kyphotic angle change between the two groups were compared.
Results: The mean duration of follow-up was 25 months (range 11-76), and the mean age was 68±8.7 years. Correlation of volume of cement distribution measured by CT scan and X-ray is 89.3% (P<0.001). The VAS improvement after kyphoplasty was no statistically significant (P = 0.651). Statistically greater height gain was observed in group B at the anterior border (4.42±2.42 VS 1.83±1.5, P = 0.035) and at the center (4.64±1.73 VS 3.01±0.41, P = 0.044). Subsequent fracture was 7 cases in group A and 4 case in group B.
Conclusion: Larger volume of cement distribution, greater correction of kyphosis. The greater distribution of the cement without leakage would be suggested when the limited volume of cement is injected.

AB0825
IMPACT OF AROMATASE INHIBITOR TREATMENT ON BONE MINERAL DENSITY AND PREVALENT VERTEBRAL FRACTURE
Cyrine Daldoul1, Nejla El Amri1, Sadok Laatoufi2, Khadija Baccouch1, Imineen Beladi3, Hela Zeglaoui1, Elyes Bouajina1, Farhat Hached Hospital, Rheumatology, Sousse, Tunisia
Background: In recent years, despite the growing incidence of breast cancer, a reduction in mortality has been observed. Adjutant therapy with aromatase inhibitors (AI) has contributed to a longer disease free survival. However these molecules induce a hyper bone remodeling, modifying the bone architecture and thus increasing the fracture risk. The new guidelines recommend indication of treatment duration up to 10 years. So special precautions must be established in order to avoid bone mineral density (BMD) decrease and to reduce fracture risk.
Objectives: The aim of this study was to evaluate the impact of AI treatment on BMD and to screen vertebral fracture (VF) in post menopausal women with breast cancer.
Methods: A clinical cross sectional study was carried between August 2016 and December 2018, including post-menopausal women with non-metastatic breast cancer. Each woman had an extensive medical history and physical examination. BMD was measured using dual energy X absorptiometry DeXa at femoral neck, total hip and at lumbar spine. We used the WHO criteria for the diagnosis of osteoporosis and osteopenia. Vertebral fractures were screened by performing a vertebral fracture (VF) image. VF grade 1 were excluded.
Results: Thirty-six post-menopausal women were examined in our rheumatology department. The mean age was 59.5±10.38 years with an average body mass index (BMI) of 30.7 kg/m².[15.81-38.28]. The average age of menopause was 45.5±5.25 years. The mean length of menopause was 14 years.[2.1-31]. The mean duration of breast cancer follow-up was 7.17 months. 22 patients underwent chemotherapy and radiotherapy.Mean femoral neck BMD was 0.805 g/cm² [0.647-1.049 g/cm²] and the vertebral BMD was 1.003 g/cm² [0.739-1.314g/cm²].According to the WHO classification, 12 women (34.6%) had osteoporosis, 15 (42.3%) had osteopenia and 9 (25.7%) had normal BMD. 9 patients showed signs of osteoporosis at femoral neck and 8 had osteoporosis at lumbar spine. 10 subjects (27.8%) had VF grade 2, 6 had VF grade 3, 3 had grade 4. No female BV were assessed. No statistically significant difference was found between women with and without VF for age, BMD value, and duration of follow-up or previous fragility fracture. We did not find a significant correlation between treatment length and BMD at either site: femoral neck (p=0.42), total hip (p=0.783) and lumbar spine (p=0.037).
Conclusion: This data has shown that approximately one-third of patients receiving AI treatment have at least one vertebral fracture, and 40% had osteoporosis. Therefore we need to screen bone mineral density and fracture in women under AI therapy.

AB0826
OSTEOEOSDIMENTOMETRIC PROFILE DURING JUVENILE CELIAC DISEASE
Cyrine Daldoul1, Nejla El Amri, Sadok Laatoufi, Khadija Baccouch, Hela Zeglaoui, Elyes Bouajina, Farhat Hached Hospital, Rheumatology, Sousse, Tunisia
Background: Bone mineralization abnormalities are often seen in children with chronic gastrointestinal disease. Among these pathologies, celiac disease (CD) is the most likely source of abnormalities of bone mineral density. These disorders are of multifactorial origin involving malabsorption, nutritional status, decreased physical activity and chronic inflammation.
Objectives: The purpose of this study was to determine the frequency and factors associated with lower bone mineral density in children with CD.
Methods: This is a retrospective study, over a period of 4 years (from January 2014 to December 2017) including children followed for CD who had a measurement of bone mineral density (BMD) by DEXA. Clinical, anthropometric and densitometry data (BMD at the femoral and vertebral site) were recorded.
Results: Thirty-six children were collected. Among them 29 were girls and 7 were boys. The average age was 11.94 years old. The average size was 137.8 cm. The average weight was 35.3 kg. The average body mass index (BMI) was 17.69 kg/m² [13.05-21.69 kg/m²]. The average vertebral BMD was 0.891 g/cm³. The average z-score was -1.08. BMD was normal in 26 cases. A decrease in bone mineral density
with respect to chronological age was observed in 10 cases. A very significant correlation was observed between BMI and vertebral BMD (r = 0.76, p < 0.000).

Conclusion: The frequency and severity of the decline in BMD in children with CD requires regular monitoring. It seems to be favored by a low BMI, which is common during CD in relation with the associated malabsorption.

IS DENOSUMAB SAFE IN HIV PATIENTS?

Isabel de la Morena1,2, Sara Velázquez, Juan Alberto Paz Solarte1, Diego Bedoya1, M José Galindo3, Hospital Clínico Universitario de Valencia, Rheumatology, Valencia, Spain; 2Hospital Clínico Universitario de Valencia, Internal Medicine, Valencia, Spain; 3Hospital Clínico Universitario de Valencia, Infectious Diseases, Valencia, Spain

Background: The survival of the infected patients by the human immunodeficiency virus (HIV) has increased in the last years, increasing the incidental comorbidities, being osteoporosis (OP) one of them, caused by traditional risk factors, by the ones associated to the infection itself and due to the specific treatments used. The denosumab is a human monoclonal antibody that acts against the link of the receptor that activates the nuclear kappa B (RANK-L), and among its secondary effects most commonly described, there are the infections, reason why its indication in HIV patients requires special caution.

Objectives: To analyze efficacy, security and compliance to denosumab in HIV patients.

Methods: Retrospective longitudinal observational study. There were included all HIV patients with OP diagnosed by bone mineral density measured by dual-energy X-ray densitometry (DEXA) or fragility fractures treated with denosumab at Infectious Diseases Unit of our Hospital from August 2014 until December 2018. There were collected clinical data, immunological status, antiretroviral therapies, fragility fractures at duration, adverse events, tolerance and compliance to denosumab treatment.

Results: There were included 14 patients, 8 females and 6 males, with a mean age of 58.35 (50-73) years old, and a mean HIV evolution of 23.78 (± 9.56) years, with a mean denosumab treatment duration at 27.07 (9-58) months. They presented a DEXA mean T-score values of -2.39 for femoral neck and -2.96 for spine. There were collected a patient with multiple vertebral fractures, and an other patient with a single vertebral fractures before started denosumab treatment and 1 distal radius fracture 9 months on denosumab treatment. There were reported adverse events in 5 of the 14 patients: 2 mild infections of the upper respiratory track, 1 injection site rash that lead to the interruption of the treatment, and 2 exits but none of them with a direct relationship with denosumab treatment: a patient with refractory small cell lung cancer history, deceased of pneumonia, and a 77 year old woman with Alzheimer disease deceased of respiratory infection. Compliance was not met in three patients, 1 because lost of follow-up, 1 caused by bad general compliance and another because indication of odontological surgery, these two last ones are waiting for re-introduction. There have not been collected jaw osteonecrosis neither atypical fractures cases. There have not been collected viral loads or CD4 changes during the follow-up period that involved a switch for the OP treatment. The antiretroviral treatment changes have been caused by intolerances to previous treatments and treatment simplifications in order to improve the compliance, but never because denosumab concommitant therapy.

Conclusion: Denosumab treatment in the HIV patients of our series is well tolerated, has adequate adherence and seems safe although perhaps it should be used with greater caution in patients with comorbidities.

RHEUMATIC PATHOLOGY AFTER SOLID ORGAN TRANSPLANTATION

Madalina Duna1, Denisa Predeteleanu2, Violeta Bojinca2, Ianos Pahomea2, Nicolae Boileac4, Radu Poenaru2, Narcis Copca3, Romania, Internal Medicine and Rheumatology, Bucharest, Romania; 2Sfânta Maria Hospital, Internal Medicine and Rheumatology, Bucharest, Romania; 3Sfânta Maria Hospital, Department of Surgery and Transplantation, Bucharest, Romania

Background: Organ transplantion has become as effective therapy for end-stage renal, hepatic, cardiac and pulmonary diseases within the past 2 decades. Osteoporosis, low level of vitamin D and hyperuricemia have emerged as frequent and sometimes devastating complications of organ solid transplantation process.

Objectives: The objective of the study was to detect the prevalence of osteoporosis, low level of vitamin D and hyperuricemia in liver and lung transplant recipients.

Methods: We evaluated a cohort of 48 patients who underwent liver and lung transplantation in a single Romanian center between July 2014 and January 2019. 44 pts undergone liver transplantation and 4 undergone lung transplantation. We have measured the level of the 25-hydroxyvitamin D and serum urate before and after the transplantation in all patients.

Results: The average age of the patients was 53.7 ± 10 years (range 32-69) with a sex ratio 1:1. 32 (66%) of patients came from urban area, 8 (16.6%) patients were excluded from this study due to recurrent HCV infection with hepatic failure in the first few months after transplantation. The final group consisted of 40 patients.

The indications of the orthotopic liver transplantation in these patients were: cirrhosis secondary chronic hepatitis B, C, D virus infection in 24 (60%) cases, autoimmune hepatitis in 7 (17.5%) patients, alcoholic liver disease in 2 (5%) patients, hepatocellular carcinoma in 1 (2.5%) patient, polycystic liver disease in 1 (2.5%) patient and nonalcoholic fatty liver disease in 1 (2.5%) patient.

In all 4 cases with lung transplantation, the reason for the lung transplantation was chronic obstructive pulmonary disease (COPD).

36 (91%) patients were receiving combination immunosuppressant therapy (tacrolimus and) and only 4 (9%) patients were receiving cyclosporine; in this situation, the association between tacrolimus and mycophenolate mofetil was preferred versus cyclosporine because of the negative effect of cyclosporine on the bone.

Post-transplant, hyperuricemia (according to local laboratory reference values >6.5 mg/dL) was presented in 28 (70%) transplant recipients but none of the hyperuricemic patients developed gout. Despite this fact, all of them were treated with allopurinol.

Vitamin D deficiency was reported in 22 (55%) transplant recipients. Also, a DXA scan of the lumbar spine and femoral neck measuring T-score of the lumbar spine and femoral neck bone mineral density (BMD) was routinely performed after a mean interval of 4-6 months post-transplant. From this group of patients, 10 (25%) patients had decreased bone mineral density (<2.5 SD) and 20% (20%) of them who complained of back pain in the early posttransplantation period, presented on x-rays vertebral fragility fractures at different sites (most frequently in the thoracic spine). The mean T-score was -2.7 and the mean BMD was 27.4 kg/m².

Conclusion: The standard care of liver and lung transplant recipients must includes, besides other lab tests, a measurement of 25-hydroxyvitamin D and serum urate. For patients with low levels of 25-hydroxyvitamin D, evaluation for osteoporosis (risk factors, x-ray, DXA scan) should be mandatory.

OSTEOGENESIS IMPERFECTA: EVOLUTION OF THE BONE MINERAL DENSITY AND EVALUATION OF FRACTURE RISK UNDER BISPHOSPHONATES

Mohamed Amine El Azzouz1, Mahbouba Jguirim, Armel Farhat, Saoussen Zrour, Ismail Beja, Mongi Tobi, Nacerre Bengaou, Fattoura Bourguiba University Hospital, Tunis, Republic of Tunisia

Background: Osteogenesis imperfecta (OI), or Lobstein's disease, also known as 'Glass bone disease' is a rare genetic disorder predisposing to low bone mass with impaired bone microarchitecture and abnormal quality of bone material, causing fracture susceptibility and bone deformities.

Objectives: The main objective of our work was to study the clinical and para-clinical characteristics, and global management, of adult patients and children with OI in a rheumatology department by comparing them with data from the literature.

The secondary objectives were to study the evolution of the bone mineral density and to evaluate the fracture incidence under treatment by Bisphosphonates.

Methods: This is a cross-sectional, observational, descriptive, analytical and monocentric study of subject with OI followed at Fattoura Bourguiba University Hospital in Monastir, Tunisia.

Results: We collected 13 patients with OI, including 5 children and 8 adults. Seven patients were female and 6 were male, including 12 patients with type IIB and one with type IIIB. Three adult patients had a family history of OI. For children, it was sporadic and the genetic survey did not reveal similar cases in the family. The mean age of clinical onset of the disease was 9 years and 3 months [0-33 years] with a mean age at diagnosis of 15 years and 7 months [14 months-40 years]. The clinical manifestations were dominated by osteo-articular symptoms. Chronic mechanical bone pain related to fractures was present in eight patients. Twelve patients had a history of fracture. These were repeated fractures without trauma or minimal trauma the majority of cases mainly in the lower limbs. The first fracture site was the femur associated with other fracture sites (there were no fractures in the pelvis, hands and skull). Deformities were observed in 7 patients, mainly in the limbs (6 patients), in the spine (2 patients) and in the thorax (1 patient).

In our study the frequency of osteoporosis and/or osteopenia regardless of the measured site and using the T-score value for women-2.5 and the Z-scores-2 for children and men was 84.62%. All patients received Aredia protocol with calcium and vitamin D supplementation. The treatment was also multidisciplinary. Bisphosphonate treatment was well tolerated for the majority of patients. There was a decrease in the number of fractures and also a densitometric gain objectively measured by Z-score of the measured site and using the T-score value for women.

Conclusion: Our results confirm the efficacy of BP in patients with OI regardless of age group. Short-term adverse effects are rare and transient.

CG AND DMARDS INDUCED BMD CHANGES IN PRE- AND POSTMENOPAUSAL WOMEN AND MAN WITH RHEUMATOID ARTHRITIS (RA)

Olona Garish, Andri Romanovski, National Scientific Center "M.D. Strazhesko Institute of Cardiology", Kiev, Ukraine

Background: Risk factors for GC-induced fracture include low bone strength at the beginning of GC treatment and the rate of decline in bone mass during treatment, which is largely determined by the dose and duration of GC use [1].

The absolute risk of future fracture in an individual is substantially influenced by demographic and other characteristics (age, race, sex and concomitant OP risk factors). For these reasons, it is important to identify differences in BMD changing depends on sex and reproductive status.

Objectives: To compare the BMD changes in man, pre- and postmenopausal women with RA depends on different treatment regiments.

Methods: The study was performed on 145 patients: 117 women (mean age 45.4±13.0 years, mean disease duration 9.7±7.7 years, 41% (n=48) postmenopausal) and 28 men (mean age 45.5±17.5 years, mean disease duration 5.7±4.8 years) with RA. Female patients were divided in two groups by menopause: premenopausal (PreM) in mean age 36.9±9.3 years and postmenopausal (PM) in the mean age 57.6±5.9 years. 68.4% women and 54.3% men received prednisolon ≤10 mg/day during 5.67±4.82 and 3.5±5.9 years respectively, 60.7% of men received MTX, 50% in combination with CGs. Among the women group 87% PreM patients received MTX, 58.3% in combination with GCs and 46.4% with biologics. 85.4% PM women took MTX, 68.8% in combination with GCs and 33.3% - with biologics. BMD was measured in 3 parts of the skeleton: hip (total and neck), lumbar spine, distal part of forearm.

Results: BMD was decreased in 44.5% of women and 42.9% of man. BMD of hip, lumbar spine, distal part of forearm were respectively decreased in 26.1%, 26.1%, 18.8% PreM women and 66.7%, 70.8%, 79.2% PM women. 39.3% of man had decrease BMD in the hip and 42.6% - in the lumbar spine. According to logistic regression in all women group the fact of CG intake was strong associated with BMD decrease in the hip (total and neck) and lumbar spine (r=0.25, p<0.05), in man no association with the fact of CG intake was found. The effect of GCs on BMD in man was cumulative dose dependent, negative correlation between treatment duration and low hip BMD (r=0.44, p<0.05) and lumbar spine BMD (r=0.5, p<0.05) was detected. In PreM women only association between CG therapy and decreased total and neck hip BMD (r=0.33, p<0.05) was detected, any relationship with cumulative dose and treatment duration wasn’t found. Only in PM patients BMD decreasing depends on average cumulative dose and treatment duration. MTX intake was negatively correlated with BMD only in PM women in total hip and lumbar spine (r=-0.37, p<0.05) and in men in the distal part of forearm (r=-2.46, p<0.05). In PM women BMD in total hip and distal part of forearm was significantly higher in MTX+BGs biologics group than without biologics (r=0.38, p<0.05).

The level of PTG was significantly higher in PM patients on GCs and was negatively correlation with cumulative dose (r=-0.77, p<0.05). In PreM women GC intake was negatively correlated with C-TP level (r=-0.37, p<0.05) and positively with RANKL level (r=0.35, p<0.05).

Conclusion: A sexual differences in BMD changes during different treatment regiments was observed in different parts of the skeleton. In man BMD lost in hip and lumbar spine depends on GCs treatment duration and on in the distal part of forearm on MTX intake. In PM women BMD decreasing was strong associated with GC and MTX cumulative dose and treatment duration.

PERSPECTIVE ON THE CLINICAL PRACTICE MANAGEMENT OF HYPOVITAMINOSIS D FROM A MEETING OF ITALIAN EXPERTS

Alessandro Gioleta, Ombretta Viapiana, Angelo Fassio, Francesco Bertoldo, Vania Teresa Braga, Maria Luisa Brandi, Stefano Calvieri, Luisella Cianferotti, Davide Gatti, Ospedale Galliera, Genova, Italy

Background: Risk factors for GC-induced fracture include low bone strength at the beginning of GC treatment and the rate of decline in bone mass during treatment, which is largely determined by the dose and duration of GC use [1].

The absolute risk of future fracture in an individual is substantially influenced by demographic and other characteristics (age, race, sex and concomitant OP risk factors). For these reasons, it is important to identify differences in BMD changing depends on sex and reproductive status.

Objectives: To compare the BMD changes in man, pre- and postmenopausal women with RA depends on different treatment regiments.

Methods: The study was performed on 145 patients: 117 women (mean age 45.4±13.0 years, mean disease duration 9.7±7.7 years, 41% (n=48) postmenopausal) and 28 men (mean age 45.5±17.5 years, mean disease duration 5.7±4.8 years) with RA. Female patients were divided in two
Background: Scientific interest in the clinical aspects surrounding vitamin D has increased exponentially in recent years. Unfortunately, this interest is not currently associated with a proportional level of consensus. Indeed, the large number of studies in this field, which are often of low quality and secondary importance has confused even experts and driven them towards controversial positions.

Objectives: To shed light on this topic, we arranged a meeting with the aim of collecting the opinions of 50 experts in different specialties (‘D. Battito Group’), including internists, endocrinologists, rheumatologists, pediatricians, geriatricians, dermatologists, gynecologists and nephrologists. This meeting dealt with specific questions regarding the management of hypovitaminosis D and aimed to investigate the opinions of Italian experts on this topic. Six key questions were addressed in the meeting.

Methods: After a short lecture and a 30 minutes discussion, all the experts expressed their opinions, which were recorded together with any specific commentary.

Results: The results of the meeting demonstrated the presence of insufficient agreement on many key questions regarding the management of vitamin D deficiency, even among clinical experts.

Conclusion: We hope that the various scientific societies will recognize and analyze the inconsistencies in their own positions and reach adequate consensus, especially on the tenets required for conducting proper and useful investigations on the topic, and that the results of these future new studies will be able to shed the needed light.

AB0832 Vertebral Pain and Physical Performance Indices in Postmenopausal Women with Vertebral Fractures Depending on Presence of Obesity

Natalia Grygoreva, Vladyaslov Povoroznyuk. Institute of Gerontology named after D. F. Chebotarev NAMS of Ukraine, Kyiv, Ukraine

Background: Vertebral fractures (VFs) are important osteoporotic fractures which manifest increased morbidity and mortality; however, their clinical features usually differ. Obesity is one of the important parameters of risk of osteoporotic fractures and vertebral pain syndrome.

Objectives: The aim of the research was to study the indices of vertebral pain (VP) and physical performance (PP) in postmenopausal women with VFs depending on presence of obesity.

Methods: We examined 87 females aged 50-89 years old with VFs in thoracic and/or lumbar spine which were divided into 3 groups: I - patients with normal weight (NW), according to WHO criteria, n=32; II - women with overweight (OW), n=37; III - females with obesity (OB), n=18. The parameters of VP in thoracic and/or lumbar spine were measured by 11-component visual analog scale (VAS), the indices of PP using static and dynamic functional tests (Thomayer, Schober tests, chest excursion, lateral trunk lean, 3-, 4-, 15-meter tests, “stand up from the chair”, static balancing). Bone mineral density (BMD) was measured by DXA (Lunar, Prodigy).

Results: We have found the significantly higher parameters of BMD of femoral neck and lumbar spine in women with VFs and OB compared to females with NW. However, we did not establish any reliable differences of VP neither in thoracic nor in lumbar spine depending on obesity presence. Also, we did not reveal the significant differences of most parameters of PP, except for the indices of chest excursion (mean parameter, of the inhalation and exhalation) which were reliably higher in patients with OB.

Conclusion: In conclusion, the indices of VP and PP do not differ in postmenopausal women depending on obesity presence, except for chest excursion that should be taken into account in rehabilitation programs for females with VFs.

Disclosure of Interests: None declared

AB0833 Bone Turnover Markers – Do They Have a Role as Predictors of Mortality and New Fracture in Patients with Fragility Hip Fracture?

Miguel Guerra1, Sara Ganha2, Francisca Aguilar3, Raquel Ferreira2, Teresa Martins-Rocha1, Ana Filipa Aguieda3, Georgina Terroso3, Carlos Vaz2,4, Lúcia Costa2,1 Centro Hospitalar de Vila Nova de Gaia/Espinho, Department of Rheumatology, Vila Nova de Gaia, Portugal;1Centro Hospitalar e Universitário de São João, Department of Rheumatology, Oporto, Portugal;2Centro Hospitalar do Baixo Vouga, Department of Rheumatology, Aveiro, Portugal;3Oporto University, Faculty of Medicine, Oporto, Portugal

Background: In Osteoporosis (OP), bone turnover markers (BTM) are potential monitors of drug adherence/efficacy as well as predictors of bone loss and fracture risk. However, without solid evidence, international guidelines still do not recommend their systematic measurement to assist treatment decision and follow-up.

Objectives: To evaluate the predictive value of baseline BTM (beta cross‐laps – bCL; osteocalcin – OC) in the outcome (death and/or new fracture) of patients that suffered a fragility hip fracture (FHF).

Methods: Patients referred to a Fracture Liaison Service from March 2015 until March 2017 with a FHF were considered for this study. Clinical/demographic variables were collected, including: age at time of fracture, sex, serum OC and serum bCL at baseline and outcome (death, new fracture, lost to follow-up) until January 2018. Cox regression analysis was used to calculate hazard ratios (HR) for values of OC and bCL; p<0.05 was considered statistically significant.

Results: From a total of 522 patients, 218 presented a baseline measurement of OC and/or bCL and were included for analysis. Table 1 summarizes clinical and demographic characteristics of the sample. Twenty seven patients died (median days until death=457, min 160, max 1049) and 18 had a new fracture (median days until fracture=343.5, min 30, max 835); 129 patients maintained follow-up. Median serum bCL was...
7.1 ng/ml (0.12-3.28, n=217) and median OC was 28.2 ng/ml (6.80-196.60, n=215). Through univariate analysis, higher bCL values predicted worse survival outcome (HR=3.09; 95% CI=1.14-8.39;p=0.026), even after adjustment for age/sex (HR=4.28; 95% CI=1.48-12.29;p=0.007); however, it did not predict higher risk of new fracture (HR=3.00;95%CI=0.85-10.68; p=0.089). Serum OC levels showed no statistically significant results, neither for mortality (HR=1.01; 95% CI=0.99-1.03;p=0.341) nor new fracture risk (HR=1.01,95%CI=0.99-1.04;p=0.057).

Abstract AB0833 Table 1

| Total (N) 215 | Age at admission, y (median, min-max) 82 (65-99) |
| Sex, female (n,%); 172, 78.9 |
| BMI (N) 195 | Underweight (n,%); 4, 2.1 |
| Normal (n,%); 90, 46.2 |
| Overweight (n,%); 66, 33.8 |
| Obesity class I (n,%); 29, 14.9 |
| Obesity class II (n,%); 5, 2.6 |
| Obesity class III (n,%); 1, 0.5 |
| Degree of dependence (N) 205 | Totally dependent (n,%); 10, 4.9 |
| Partially dependent (n,%); 53, 25.9 |
| Autonomous (n,%); 142, 69.9 |
| Type of fracture (N) 217 | Femoral neck (n,%); 90, 41.5 |
| Subtrochanteric (n,%); 16, 7.4 |
| Vertebral fracture (N) 213 | 0 (n,%); 92, 43.2 |
| > 1 fractures (n,%); 53, 24.9 |
| > 2 fractures (n,%); 68, 31.9 |
| Femur neck BMD, g/cm² (mean, SD, N) 0.66, ±0.12, 198 |
| Femur neck T score (mean, SD, N) -2.79, ±1.1, 198 |
| >2.5 (n,%); 62, 31.3 |
| ≥2.5 (n,%); 136, 67.9 |
| vD3, ng/ml (median, min-max, N) 23.24, 3-97 |

Conclusion: In this cohort, increased serum levels of bCL predicted higher mortality risk. These results support the value of BM in OP, strengthening their potential as prognostic markers, besides treatment monitors.

AB0834 FREQUENCY OF OSTEOPOROTIC HIP FRACTURE IN AN ALGERIAN HOSPITAL

Naouel Zehraoui, Narimene Saidi, Houda Hafirsou, Chafia Makhloufi-Dahou, Zehraoui Naouel Saidi Narimene Hafirsou Houda Chafia Dahou-Makhloufi, Mohamed Lamine Debaghine University Hospital, reumatology, algiers, Algeria

Background: The hip fracture is the most serious complication of osteoporosis. It is a public health issue in elderly because of its frequency, severity and economic impact. We report the result of an 18 months investigation.

Objectives: The aim of this study was to determine the frequency of osteoporotic hip fractures and identify the risk factors of osteoporosis and falls leading to these fractures.

Methods: Cross-sectional, prospective, descriptive study. We included patients with spontaneous or secondary low trauma hip fractures during 18 months, who consulted at trauma unit, Mohamed Lamine Debaghine hospital. Have been collected: patient characteristics, risk factors for osteoporosis and falls, type of treatment and length of hospital stay.

Results: 115 cases of hip fractures were recorded out of a total of 486 fractures, with a frequency of 16.8%, from all the fractures operated, it represents 22.7%. We noted a female predominance (62.6%) with a sex ratio of 0.60, the average age is 76.44 +/- 11.71 years. The associated comorbidities are: cardiovascular (55.7%), diabetes (33%), dysthyroidism (11.4%), asthma (10.4%), chronic renal failure (5.2%) prostate adenoma (4.5%). The fracture mechanism is dominated by the fall (92%), it is most often a domestic accident: slipping (30%), stumbling (26%), ablation (11%), falling on the stairs (7%),%). The risk factors for osteoporosis identified are: age more than 70 years (72.8%), female sex (62.6%), low BMI (18%), sedentary lifestyle (15.3%), corticosteroid therapy 7.2%, smoking (5.2%), history of rheumatoid arthritis in 3.4% and early menopause in 2.1% of patients. The risk factors of fracture: visual disturbances (40%) neuromuscular disorders in 11, 9%, poor health (more than 3 chronic diseases) in 9% of patients, mother’s history of hip fracture (1.7%). A personal history of osteoporotic fracture was noted in 17.4%, 7 patients presented a contralateral hip fracture. The average duration of hospitalization is 5.2 +/- 2.5 days. The treatment is surgical in 81.6% (40.8% prostheses).

Conclusion: Through this study, we found that osteoporotic hip fracture is frequent. The osteoporosis risk factors identified were female sex, advanced age, corticosteroid therapy and sedentary lifestyle. Fall risk factors were dominated by visual disturbances and neuromuscular disorders.

AB0835 BONE MINERAL LOSS DURING ULCERATIVE COLITIS : PREVALENCE AND RISK FACTORS

Hela Khiri1, Maha Mitr2,2, Dhiel Isoull2, Dhoua Chefi2,3, Rhia Kaffed4, Nadia Maamouri5,6, La Rabta Hospital, Gastroenterologie B, Tunis, Tunisia; La Rabta Hospital, Gastroenterologie B, Tunis, Tunisia; Kassab institute, Rheumatology, Tunis, Tunisia

Background: Patients with ulcerative colitis (UC) are at increased risk of bone mineral loss, leading to osteoporosis and osteopenia, Etiopathogenic factors may be divided into factors specific to the underlying inflammatory process, and factors resulting from the disease process, such as, malabsorption of nutrients vitamins and minerals,decreases in weight,and the use of bone toxic medications.

Objectives: to evaluate the prevalence and possible risk factors for bone mineral density disorders in patients with UC.

Methods: A retrospective study from January 2000 to December 2018, including all patients with UC followed in our department. Bone mineral density was determined by dual energy X-ray absorptiometry.

RESULTS: Seventy eight patients were included in our study (36 men, 26 premenopausal, and 17 postmenopausal women) with an average age of 47.5 years. Forty osteodensitometries (DXA) were performed : 17 were normal (42.5%) 13 patients had osteopenia (32.5%) and 10 suffered from osteoporosis (25%). Among the 23 patients having a bone mineral loss, the average Z-score were (-0.8 SD) in the femoral neck and (-1.78 SD) in the lumbar (L2-L4) spine whereas the average T-score were (-1.23 SD) in the femoral neck and (-2.15 SD) in the lumbar (L2-L4) spine. Osteoporotic patients included 12 men, 5 premenopausal, and 6 postmenopausal women with an average age of 53.04 years. The research of risk factors has shown that 14 patients with bone mineral loss (69.6%) underwent systemic corticosteroid treatment with an average duration of 6 months. Tobacco intoxication has been mentioned in 8 cases (34.78%) and alcoholism in 6 cases (26.08%). Otherwise, patients with bone mineral loss showed a lower body mass index (average BMI =19.46) than patients with normal bone density (average BMI = 23.64). Anemia has been reported in 11 cases with low bone density (47.82%) and low level of albumin as noted in 8 cases (34.78%). No osteoporotic fractures has been reported. Pan-ulcerative Colitis was reported in 11 cases (47.82%) and acute severe ulcerative colitis in 10 cases (43.47%).

Conclusion: Our study shows that more than half of our patients having ulcerative colitis (UC) who had an osteodensitometry presented bone demineralization (osteoporosis or osteopenia ). It seems to be associated with a low BMI, an extended and severe form of UC,and the cumulative corticoid doses.

Disclosure of Interests: None declared
Background: Rheumatoid arthritis (RA) is one of the causes of secondary osteoporosis, and steroids are often used in combination, therefore osteoporosis is highly associated with RA. Furthermore, joint disorders due to RA cause various degrees of dysfunction and ADL declines. The Steinbrocker classification is often used as the degree of dysfunction. Immobilization progresses with the progress of dysfunction, possibly causing severe osteoporosis.

Objectives: Of the 2238 cases in Akita Orthopedic Group omn Rheumatoid Arthritis (AORA) registry 2017, 101 cases simultaneously measuring bone mineral metabolism markers (TARC-Pb, NTX, urinay DPD, BAP, total P1NP) and pentosidine were involved.

Methods: Patients were divided by Steinbrocker classification into class 1,2 (group A 84 cases) and class 3, 4 (group B 17 cases), we examined whether there is a difference in bone metabolism markers in each group according to Steinbrocker classification.

Results: The average age in group B (75.9) was significantly higher than group A (66.9) (p = 0.01). DAS 28 ESR was significantly higher in group B (p < 0.01). There was no difference in eGFR representing renal function between the two groups. The urinay DPD (nM/mM · Cr) and pentosidine (µg/ml) in group B was significantly higher than group A (p <0.01).

Conclusion: Immobilization by long-term bed rest is known to enhance bone resorption. In 2002, Wakae reported DPD in urine showed a higher value in the group of not going out in femoral neck fracture cases. Based on the results of this study, urinary DPD showed a high value in RA group with high degree of dysfunction, which possibly reflected immobilization due to progress of functional disorder. Moreover, it is known that pentosidine will be higher in cases with high disease activity, severe osteoporosis will be occurred in the group with progressive functional disorder which is difficult to control.

ASSOCIATION BETWEEN BODY FAT AND BONE MINERAL DENSITY IN POSTMENOPAUSAL WOMEN THROUGH RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY

Flora Kirilova1, Nikola Kirilov2, Stoyanka Vladeva1. 1Trakia university, Stara Zagora, Bulgaria; 2Medical University of Sofia, Stara Zagora, Bulgaria

Background: Osteoporosis is characterized by reduced bone mineral density (BMD) and increased fracture risk. Age, concomitant diseases, body mass index (BMI), body composition, etc. are important risk factors that could reflect on bone density and on the increased risk of fractures.

Methods: A total of 98 women with mean age 62 ± 11 years underwent radiofrequency echographic multi spectrometry (REMS). Bioelectric impedance analysis (BIA) software was used to assess body fat percentage. Patients were divided into two groups—women body fat > 32% and women body fat < 32%. Age, BMI, lumbar spine BMD, total hip BMD and fracture risk score (FRAX) were compared between the patients with normal body fat and those with high body fat.

Results: The mean age of the women with normal body fat was 61.1 ± 14.6 years and the mean age of the women with high body fat was 63.3 ± 9.5 years. BMI of the women with body fat < 32% was significantly lower (22.5 kg/cm²) compared to the BMI of the women with body fat > 32% (30.2 kg/cm²) (p = 0.000). Bone mineral density of L1-L4 and total lumbar spine BMD did not differ between the women with normal body fat and high body fat. Femoral neck BMD, trochanteric BMD and total hip BMD of the patients with normal body fat (0.604 g/cm², 0.737 g/cm² and 0.736 g/cm² respectively) were significantly lower than those patients with high body fat (0.682 g/cm², 0.864 g/cm² and 0.838 g/cm² respectively) (p = 0.000 for femoral neck BMD and trochanteric BMD, and p = 0.001 for total hip BMD). FRAX score for 10-year probability of major osteoporotic fracture did not differ significantly between the two groups (20.8% for women with normal body fat and 16.6% for women with high body fat). FRAX score for 10-year probability of hip fracture was also not significant between the two groups, but there was a trend to statistical significance (p = 0.059) (9% for women with normal fat and 4.9% for women with high fat).

Conclusion: Postmenopausal women with body fat > 32% showed higher femoral neck BMD compared to those with body fat < 32%, but there was no significant difference in the lumbar spine BMD values between the groups. Women with high body fat did not show significantly lower FRAX score than the women with normal body fat.

REFERENCES
such as Osteopenia or even Osteoporosis. It has been reported in several studies, an incidence of fracture between 30-40% in this population.

Objectives: To evaluate the evolution of bone turnover biomarkers before and after treatment (according to 2015 NOF guidelines) and to describe the incidence of fracture after a SCI.

Methods: A prospective study was conducted, including 48 SCI patients followed during an observation period of 24 months, with visits every six months. Thirty-two patients concluded the study. In each visit patients were enquired about fractures. A blood test was also performed. In addition a dual-energy x-ray absorptiometry (DEXA) and simple x-ray of hip and spine was requested annually. Patients were also educated in lifestyle measures, such as an adequate calcium and vitamin D dietary intake. Oral supplementation was initiated in cases of low intake or deficit, respectively. In patients with bone mineral density (BMD) measured by DEXA in range of Osteopenia, pharmacological therapy was initiated (bisphosphonate or Denosumab). Statistics had been performed with mixed linear regression models.

Results: Our sample was 56.25% men with an average age of 56.08 ± 13.82 years old. In 32 patients (68.09%) low Vitamin D levels were detected. At baseline in 12 cases (25%) DEXA showed a BMD in osteoporosis range; in 12 (25%) osteopenia, plus 6 fractures (2.6 fractures per 100 years/patient). Afterwards, until the end of the study only a fracture was detected. At baseline in 12 cases (25%) DEXA showed a BMD in osteoporosis range, in 12 (25%) osteopenia, plus 6 fractures (2.6 fractures per 100 years/patient). So the fracture rate was 1.2 fractures per 100 years/patient. The evolution of the variables can be seen on the next table.

On multivariant analysis a inverse relationship between vitamin D and CTX levels was detected (p 0.05). DEXA hip measures tend to become stabilized after Bisphosphonate treatment.

Conclusion: On our cohort, bone resorption biomarkers decrease after Vitamin D restoring. Antiresorptive therapy in high risk patients stopped bone loss, especially in hip. After two years follow up, with the treatment algorithm applied, fracture incidence was lower than other series published.

POTENTIAL RISKS FOR OSTEOPOROSIS AND SARCOPENIA IN ALCOHOLIC WOMEN

Kayo Masuko1,2, Chie Iwahara3, Seiji Sakate4, Yumiko Tanaka5, Shigemi Kamiya3, Yuki Mizukami4, Medical and Addiction Center, Kanagawa, Japan

Background: Recent statistics indicated an accumulating number of patients with alcohol dependency in Japan. In particular, there had been a considerable increase in the number of alcoholic women, reaching up to 130,000 patients. Because alcoholic women often have insufficient dietary intake and physical inactivity, they may be at risk for low bone mineral density and decreased muscle power. However, these points may not be widely recognized, and the current program for the rehabilitation of alcoholism may not be sufficient to address this issue.

Objectives: To assess the risk for osteoporosis and sarcopenia in alcoholic women from a nutritional viewpoint.

Methods: Thirty-two women (mean age: 42.9 ± 7.49 years) who were admitted to the Alcohols Rehabilitation Program (ARP) for alcoholism, which was diagnosed according to International Classification of Diseases (ICD)-10, were enrolled in the study. The patients were subjected to self-answered questionnaire, nutritional assessment by expert dietitians, and measurement of body composition and grip strength.

Results: Of the 32 patients, 14 (44.0%) had a history of eating disorder, mostly anorexia. All 32 patients had elevated levels of transaminases at the time of admission. History of bone fracture was present in eight of the 32 (25.0%) patients; among them, at least three (9.4%) cases were considered to be due to a fragility fracture. The mean body mass index (BMI) was 20.4 kg/m2; 10 (31.3%) patients had BMI < 18. The average energy intake was low at 1,474.5 ± 324.3 kcal. Twenty-one (65.6%) patients were taking dietary calcium of <650 mg/day, which is the level recommended for adult women. The mean grip strength was 23.8 ± 6.5 kg, and 8 (25%) patients had grip strength of only <18 kg, which is the definition of sarcopenia in the Asian elderly.

Conclusion: Young to middle-aged alcoholic women should be treated as having high risks for osteoporosis and sarcopenia. ARP should include multidisciplinary assessment and interventions to prevent future locomotive disabilities.

AB0843

HYPOVITAMINOSIS D IN A MARFAN POPULATION

Daniele Melchiorre1, Elisa Pratelli2, Renato Colombai3, Marco Mattucci-Cerinic1, Guglielmina Pepe1,1 University of Florence, Florence, Italy; 2 AUO Careggi Hospital, Florence, Italy; 3 Department of Public Health, Pontedera, Italy

Background: Marfan syndrome is an autosomal dominant disorder of connective tissue caused by mutations in FBN1 gene on the long arm of chromosome 15. Information is often lacking regarding an increased risk of fractures and its management and prevention in patients with Marfan syndrome. In these patients reduced bone mineral density was rarely reported. A pivotal role in bone mineralization is played by Vitamin D.

Objectives: This study evaluates whether the reduction of the values of Vitamin D is present in Marfan patients.

Methods: 60 patients (pts) (28 M/32 F; age 15-75 mean age 46.2) with Marfan syndrome were studied. The patients were followed from the clinical and research regional Marfan Center in Florence, Italy. All pts met new Ghent criteria that identified ectopia lentis, thoracic aorta dilatation with Z score = or > 2 and a large group of systemic clinical features represented by cardiovascular, musculoskeletal, central nervous system (dural ectasia) pulmonary, cutaneous and ocular clinical manifestations (systemic features) reaching a score = or > 7 as major clinical criterion. Familiarity and the detection of a gene mutation (in MFS FBN1 gene displays a mutation in about 90% of patients) are also considered criteria necessary for Marfan diagnosis.

Results: 11/60 pts (18.3%) (5M/6F age 15-75 mean age 44.9) showed reduced values of Vitamin D. 6/11 pts (45.4%) (3M/5F age 15-56; mean age 34.1) showed very poor Vitamin D values (range 8.7 ng/ml – 13.17 ng/ml).

Conclusion: Our results suggests that Vitamin D may play an important role in bone metabolism in Marfan patients. These results need confirmation since further data are missing in literature.

Background: The enigma of fragility fracture with normal bone mass; Experience of a Liaison Service Fracture Unit

Objectives: To describe the characteristics of patients with fragility fracture and normal DXA treated in an FLS unit.

Methods: Prospective 6-year observational study of a FLS fracture unit. Demographic variables, FRAX items, DXA and TBS were collected. The statistical analysis was performed by means of a descriptive, comparing the normal DXA/osteopenia/osteoporosis groups by means of contingency tables, Fisher’s exact test, Student’s t test or ANOVA, as appropriate, as well as regression analysis.

Results: 1,631 patients were included, 205 with normal DXA (12.5%), 747 with osteopenia (45.8%) and 680 with osteoporosis (41.6%). Patients with normal DXA were characterized by a higher percentage of males, a younger age and a higher BMI. Hip fracture was less frequent in patients with normal DXA, while the frequency of other fractures was higher. The frequency of previous fracture, history of hip fracture of the parents and secondary osteoporosis was lower in patients with normal DXA. The TBS and FRAX values were higher in the cases of normal DXA compared to osteopenia and osteoporosis. In the multiple regression analysis, excluding TBS <1,230 as a dichotomous variable (N = 451 cases) remained significant age (OR 1.03; 1.03-1.06), sex (OR 2.48; 1.71-3.58), BMI (OR 0.91; 0.89-0.94),) and TBS, remained significant associated with abnormal DXA age (OR 1.04; 1.03-1.06), sex (OR 2.48; 1.71-3.58), BMI (OR 0.91; 0.89-0.94), and parent hip fracture (OR 1.99; 1.11-3.58). Including TBS <1,230 as a dichotomous variable (N = 451 cases) remained significant age (OR 1.03; 1.00-1.06), sex (OR 3.58; 1.81-7.10) and TBS (OR 5.23; 1.55-17.68).

Conclusion: Patients with fragility fracture and normal DXA are younger, with more frequent males and with BMI and higher TBS values. The enigma of fragility fracture with normal bone mass; Experience of a Liaison Service Fracture Unit

AB0845  EFFECTIVENESS AND SAFETY OF BISPHOSPHONATES IN THE TREATMENT OF SECONDARY OSTEOPOROSIS IN CHILDREN

Julia Ferreiro Turrión, Rocío Galindo Zavala, Esmeralda Núñez Cuadros, Gisela Diaz-Cordobes, Laura Martin Pedraz, Antonio Urda Cardona. Hospital Regional Universitario de Málaga, Málaga, Spain

Background: Prevalence of secondary osteoporosis (SO) in children is an ongoing challenge, due to the rise in life expectancy of chronic diseases and the bone toxicity medication usage. Bisphosphonates (BF) has been stated as an alternative therapy, although studies targeted children are few.

Objectives: The goal was to establish the effectiveness and safety of bisphosphonate therapy in children with SO.

Methods: A retrospective study of BF treatment in children (<16 years) with SO at a Pediatric Reumathology Unit from 2015 to 2018. Descriptive statistics were performed to examine anthropometric measurements, clinical features, diagnoses and treatment received. We measured bone mineral density by dual-energy x-ray absorptiometry and we expressed the results as adjusted for height-for-age Z-score (HAZ).

We assessed the treatment outcome by the change of HAZ after a year treatment and the decreasing fractures rate per year. Afterwards we made a bivariate analysis to identify related factors with effectiveness and safety of bisphosphonates. Values of p<0.1 were considered statistically significant.

Results: In our study 12 patients were treated with BF, three of them with two different type. Table 1 shows the descriptive data. The HAZ and the fracture rate per year after a year of treatment were significantly lower [-2.22±1.46] vs (-1.06±1.27); p=0.04, and (1 (0.5-2) vs 0 (0-0); p< 0.01, respectively].

*Due to unchance disease complications

Disclosure of Interests: Julia Ferreiro Turrión: None declared, Rocío Galindo Zavala: None declared, Esmeralda Núñez Cuadros: None declared, Gisela Diaz-Cordobes: None declared, Laura Martin Pedraz: None declared, Antonio Urda Cardona: None declared
The change at HAZ and the before treatment fractures rate per year (r=0.57; p<0.07) were directly proportional. Also, the change at HAZ was inversely proportional to the before treatment Z-score (r= -0.53; p=0.09) and the BF starting age (r=-0.35; p=0.10).

The decrement of fractures rate per year showed a statistical significant relationship with BMI percentile (r=0.48; p=0.08), the treatment starting age (r=0.53; p=0.09) and before treatment fractures rate per year (r=0.941; p<0.001).

Three patients experienced adverse effects (20%). Three related to alendronate use: two of them showed flu-like syndrome after first infusion and the other asymptomatic hypocalcemia. In another patient the treatment with alendronate was ended due to gastrointestinal intolerance.

There was not significant relationship between adverse effects and our study variables.

Two patients died during the treatment due to their underlying disease complications.

Conclusion: BF are an effective medication for SO. The treatment outcome exhibits to be better with a good nutritional status, younger age and at more severe forms of the disease. Additionally, they are safe showing just minor adverse effects often.

BMD AND MUSCLE MASS IN PATIENTS WITH ISCHEMIC HEART DISEASE
Tatiana Raskina1, Inessa Grigoreva1, Olga Barbarash2, Alexander Kokov2, Vladislava Masenko3, Tatiana Raskina1

Methods: The study included 45 patients with IHD (36 males/9 females, mean age 63.16±6.71 years) verified by coronary angiography. BMD was measured by DXA in the lumbar spine L1-L4, total hip and femoral neck. BMD was evaluated as: normal BMD (T-score ≥-1), osteopenia (T-score between -1 and -2.5) and osteoporosis (T-score of <2.5). Muscle mass was assessed using computed tomography of total psoas area (TPA) (cm²) and calculating L3 muscle index (LMI) (<52.4 cm²/m² in men; <38.5 cm²/m² in women).

Results: The results of the study indicate the presence of severe dyslipidemia in men with IHD. The frequency of patients with IHD dyslipidemia (95.7% of patients): hypercholesterolemia – 81.7%, elevated level of LDL cholesterol – 22.9% and in women – 13 (17.8%) (p = 0.1), osteoporotic fractures during 6 months after injury. The main causes of death were heart and respiratory diseases. The results of the study indicate the presence of severe dyslipidemia – 47.4% cases for women (p = 0.75). Among the dead men, 1 (4.5%) case for men and 2 (2.9%) cases for women (p = 0.75). Among the dead men, 1 (1.1%) death was caused by an infectious disease. The decline in BMD in IHD patients is associated with low BMI (<18.5) was common in 1/5 patients requiring input from the dietetics team as part of their treatment plan. Early menopause was seen in a quarter of female patients with just over 10% of these being offered HRT; undoubtedly more could have benefited from intervention at menopause. Many medical conditions associated with OP were identified with several patients being newly diagnosed (coeliac/hypothyroidism/haematological disorders especially). Treatment and lifestyle modifications are clearly essential in the management of these patients. Given the high number of patients with at least one modifiable OPFR, it is crucial that OP services are organized accordingly to identify OPFRs to intervene and modify these factors as part of the overarching management plan.

THE LIPID SPECTRUM OF BLOOD, DEPENDING OF BONE MINERAL DENSITY (BMD) IN MEN WITH CORONARY HEART DISEASE (CHD)
Tatiana Raskina1, Anna Voronkina2, Marina Leteava1, Olga Barbarash3, Vyacheslav Fanaskov4, Tatiana Raskina1

Methods: 93 men older than 50 years (mean age – 60.8±6.9 years) with coronary artery disease verified by coronary angiography were examined. The concentration of total cholesterol (OHS), triglycerides (TG), high and low density lipoprotein cholesterol (HDL and LDL cholesterol) in serum was determined by spectrophotometric method. T-criterion of the femoral neck and lumbar spine was used for the assessment of BMD, which was investigated by the method of two-energy absorptiometry (densitometer Excel XR-46, NORLAND, USA). The results of the study indicate the presence of severe dyslipidemia (95.7% of patients): hypercholesterolemia – 76.3%, elevated level of LDL cholesterol – 81.7% of the patients, hypertriglyceridemia in 49.5%, a decrease in the concentration of HDL cholesterol – 44.1% of cases. In all three groups of patients hypercholesterolemia (80, 75 and 73.7% of patients in groups I, II and III, p>0.05) and increased LDL-C concentration (83, 84.1 and 73.7% of men in groups I, II and III, p>0.05) were revealed. Reduction of HDL cholesterol level was determined in 46.7% of cases in group I, 43.2% in group II and 42.1% in group III (p>0.05). Hypertriglyceridemia was registered in 60% of patients with osteoporosis, 43.2% - with osteopenia and 47.4% – with normal BMD (p>0.05). Correlation analysis of the relationship of lipid metabolism with the T-criterion in all patients included in the study did not reveal significant relationships (p>0.05).

Conclusion: The results of the study indicate the presence of severe dyslipidemia and the absence of dependence of lipid parameters on the state of BMD in men with CHD.

AB0849

CAUSES OF EARLY MORTALITY IN PATIENTS WITH OSTEOPOROTIC HIP FRACTURES
Tatiana Raskina, Julia Averkieva, Tatiana Protasova, Inessa Grigoreva, Federal State Educational Institution of Higher Education ‘Kemerovo State Medical University’, Kemerovo, Russian Federation

Background: Osteoporosis (OP) is a skeletal disorder characterized by compromised bone strength, which predisposes the individual to an increased risk of fractures of the hip, spine, and other skeletal sites. OP, a major public health problem, is becoming increasingly prevalent with the world’s population and occupies a leading place in the structure of morbidity and mortality.

Objectives: To study the causes of mortality in patients with hip osteoporotic fractures during 6 months after injury.

Methods: 432 patients with osteoporotic hip fractures were under observation. During the study, mortality rates were assessed both in hospital and during the first 6 months after the fracture. The main causes of mortality were tracked by ICD-10 classes. Information about fractures and their outcomes was obtained from data from the archives of the trauma departments of Kemerovo, Kemerovo city registry offices, telephone interviews of patients and their relatives.

Results: In the first 6 months after injury, 96 out of 432 patients died. Overall mortality was 22.0%. In the group of deceased patients, females prevailed: 73 women (16.5%) and 22 men (5.1%) (χ² = 4.4; p <0.0001). It was established that 6 months after a hip fracture in 63 (66.3%) patients, death occurred from cardiovascular system diseases: in men - 13 (59.0%) cases and in women - 50 (68.4%) (p = 0.9). Respiratory diseases, as the cause of death, were detected in 18 (16.9%) patients (men - 5 (22.9%) cases and in women - 13 (17.8%) (p = 0.1), oncological diseases - in 10 (10.5%) men and women; 2 (9.1%) and 8 (10.9%) cases, respectively (p = 0.5). Diseases of the digestive system accounted for a small percentage of the total number of deaths (3.2%), without statistically significant differences by gender (1 (4.5%) case for men and 2 (2.9%) cases for women (p = 0.75)). Among the dead men, 1 (1.1%) death was caused by an infectious disease.

Conclusion: During all periods of observation, most of the deceased men and women had cardiovascular and respiratory diseases.

AB0851 OBESITY AND RISK OF FRACTURE: DEPENDS ON THE BODY MASS INDEX AND TYPE OF FRACTURE

Jose Rosas 1, Catalina Cano 2, Ana Pons 3, Estibaliz Ivans 4, Josué Miguel Senabre-Gallejo 5, Gregorio Santos Soler 6, Esteban Salas-Heredia 7, José Antonio Bernal-Vidal 8, José Alberto García-Gómez 9, Xavier Barber 10, AIRE-MIB. 1Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; 2Elche General University Hospital, Infectious Diseases, Elche (Alicante), Spain; 3Miguel Hernández University, Statistics, Elche (Alicante), Spain

Objectives: To know the impact of obesity on the risk of fracture.

Methods: Observational study, during 2010-2018, of patients referred for bone densitometry (BMD), to the Bone Densitometry Unit of Rheumatology.

BMD performed by Rheumatology nursing, collect several data (age, gender); osteoporosis (OP) risk factors: age of menopause, smoking and current alcohol intake, hip fracture parents, body mass index (BMI), diseases-drugs that reduce bone mass, fractures, treatment; BMD in lumbar spine (LS), femoral neck (FN); FRAX with BMD. BMI result was as WHD recommendations in kg/m²; Normal: 18.5-24.99; Obesity: ≥30; type I: 30-34.99, type II: 35-39.99, type III: ≥40.

Results: A first BMD in 6.943 postmenopausal women was done. 2.196 (32%) had normal BMI, low weight (BMI <18.5 kg/m²) 103 (1.5%) patients, overweight (BMI 25-29.99 kg/m²) 2.643 (38%) and obesity 2.001 (29%). Obesity (BMI ≥30 kg/m²) vs normal BMI are older (65±13) vs 61±13, p=0.003, lower current smokers (12% vs 27%) P <0.001, more treated for OP (37% vs 29%, P<0.002), higher percentage of fractures (44% vs 29%), especially distal radius (DR) (30% vs 11%), p<0.001 and FN (-1.1±1.5 vs -1.6 ± 1.5, p<0.0001) and lower mean T score in LS (-1.1±1.5 vs 1.8±1.5, p=0.002), lower mean T score in DR (-1.1±1.5 vs 1.8±1.5, p<0.0001) and FN (-1.1±1.5 vs -1.6 ± 1.5, p<0.0001) and lower mean FRAX hip fracture with BMD (1.9±3.6 vs 2.4±3.6, p <0.0001) and FN (-1.1±1.5 vs -1.6 ± 1.5, p<0.0001) and lower mean T score in LS (-1.1±1.5 vs 1.8±1.5, p=0.002), lower mean T score in DR (-1.1±1.5 vs 1.8±1.5, p<0.0001) and FN (-1.1±1.5 vs -1.6 ± 1.5, p<0.0001) and lower mean T score in DR (-1.1±1.5 vs 1.8±1.5, p=0.002), lower mean T score in LS (-1.1±1.5 vs 1.8±1.5, p=0.002), lower mean T score in DR (-1.1±1.5 vs 1.8±1.5, p<0.0001) and FN (-1.1±1.5 vs -1.6 ± 1.5, p<0.0001) and lower mean T score in LS (-1.1±1.5 vs 1.8±1.5, p=0.002), lower mean T score in DR (-1.1±1.5 vs 1.8±1.5, p<0.0001) and FN (-1.1±1.5 vs -1.6 ± 1.5, p<0.0001) and lower mean T score in LS (-1.1±1.5 vs 1.8±1.5, p=0.002).

Conclusion: In postmenopausal women referred for BMD, obese women vs normal BMI are 1. Older. 2. Overall, with higher percentage of fractures. 3. But, women with BMI ≥ 40 kg/m² do not have a higher overall percentage of fracture, except in DR.

AB0852 DOES INADEQUATE RESPONSE TO DENOSUMAB TREATMENT EXIST?

Clara Sanguessa, Susana Holgado Pérez, Meliana Martínez-Morillo, Jordi Camins-Fábregas, Ivette Casafont-Solé, Annika Nack, Águeda Prior-Español, Maria Aparicio Espinarr, Anahy Brandy-Garcia, Lourdes Mateo, Anne Riveros, Alejandro Olive, Laia Gifre. Hospital Germans Trias i Pujol, Badalona, Spain

Background: Denosumab (Dmab), an anti-receptor activator of nuclear factor kappa-B ligand (RANKL) monoclonal antibody, has been shown to increase bone mineral density (BMD) at lumbar spine and proximal femur, up to 21.6% and 9.1% respectively at 10 years of treatment. Additionally, Dmab has shown a marked decrease of vertebral, nonvertebral and femoral fractures during treatment. Nowadays, the existence of inadequate response to Dmab treatment remains unknown.

Objectives: to describe the clinical, analytical and densitometric characteristics of patients with an inadequate response (IR) to Dmab treatment. IR was defined as the presence of a new fragility fracture during Dmab treatment or a significant decrease in BMD (≥5% at lumbar spine or ≥4% at proximal femur) within at least 12 months of therapy.

Methods: retrospective study including patients with osteoporosis with an IR to Dmab. Therapeutic compliance was checked by clinical anamnensis and the electronic prescription. Risk factors for osteoporosis, history of fragility fractures, previous anti-osteoporotic treatment, densitometric and analytical data were collected before and at the moment when IR was diagnosed.

Results: Fourteen patients were included (12 women and 2 men) with mean age of 75 ± 9 years. The causes of osteoporosis were: postmenopausal (n=8), 57.14%, induced by glucocorticoids (n=3, 21.43%), alcoholic (n = 1, 7.14%) and multifactorial (n=2; 14.28%). Nine patients (64.28%) had been previously treated with oral or intravenous bisphosphonates for a mean of 5.8 ± 2.76 years. Nine patients (64.28%) had previous vertebral fractures (median 2, range 1-8), 2 of them had also presented a femoral fracture. During Dmab treatment, 7 patients (50%) presented a decrease in BMD (mean loss: proximal femur -3.5%, p<0.09; lumbar spine - 5.8%, p=0.046;) and 7 had incidental fractures: 5 vertebral (median 1, range 1-4), 1 humerus and 1 femur. The duration of treatment with Dmab was 3.82 ± 1.85 years in patients who sustained fragility fractures and 2.39 ± 1.4 years in patients with a BMD decrease. A multiple myeloma was diagnosed in a patient with vertebral fractures during Dmab treatment. After The identification of Dmab RI most patients maintained same treatment. Of the patients with incidental fragility fractures, 2 started combined treatment with teriparatide and Dmab, 1 changed to teriparatide and 2 maintained the same treatment. Of the 7 patients with BMD only 1 changed to zoledronic acid.

Conclusion: Most patients with IR to Dmab treatment had previous fragility fractures and had been previously treated with bisphosphonates for a mean duration of 5 years. The patients with a significant decrease in BMD had lesser duration of Dmab treatment than those who sustained fractures during Dmab treatment. Only one patient had a clinical cause for the IR development.

AB0853 BONE DENSITOMETRY IN CROHN’S DISEASE: RISK FACTORS FOR OSTEOPENIA AND OSTEOPOROSIS

Sabrine Soua 1, Dhiel Issaoua 2, Hela Kchib 2, Nouha Trad 3, Hatem Chabouni 4, Nadia Maamoun 1. 1La Rabta Hospital, Tunis, Tunisia; 2La Rabta Hospital, Tunis, Tunisia; 3La Rabta Hospital, Tunis, Tunisia

Background: Osteoporosis and osteopenia are common situations in chronic inflammatory bowel disease (IBD), particularly in crohn’s disease.

Disclosure of Interests: None declared

Objectives: The objective of our study was to determine the prevalence of these affections during crohn’s disease and to identify the risk factors for osteopenia and osteoporosis.

Methods: We conducted a descriptive monocentric retrospective study of consecutive patients with crohn’s disease who were hospitalized between January 2016 and December 2018.

Results: We included 100 patients (64 female and 36 male) with an average age of 37 years [17-68 years]. Among these patients 21% were smokers and among women 20% were in menopause. Bone densitometry was performed in 39 patients. It was found to be pathological in 53.8% of cases. The rate of osteoporosis was 17.9% (7 patients) and the rate of osteopenia was 35.9% (14 patients). Tobacco and a BMI of less than 18 had a statistically significant association with osteopenia (p=0.046; p=0.038 respectively). The presence of a family history of IBD had a statistically significant influence on a pathological bone densitometric investigation (p=0.036). An albuminemia rate of less than 35g/dl had an association at the limit of significance with bone pathology in BMD (p=0.059).

Conclusion: Osteoporosis and osteopenia are frequent during crohn’s disease. They are in the majority of cases asymptomatic. This makes bone densitometry essential, especially in the presence of a family history of IBD, smoking and malnutrition (BMI less than 18) in order to act early and avoid complications such as fractures.

Disclosure of Interests: None declared.

AB0854 PERSPECTIVES OF WOMEN WITH EXPERIENCE OF A FRAGILITY FRACTURE IN EUROPE: ATTITUDES TOWARDS FUTURE FRACTURE RISK, OSTEOPOROSIS AND PHARMACOTHERAPY

Charles Chaïne1, Peter Ray2, Jen Timoshanko2. 1AplusA, London, United Kingdom; 2UCB Pharma, Slough, United Kingdom.

Background: Fragility fractures (FF) are common in women >50 years (yrs), with 1 in 3 experiencing a fracture (Fx).1 However, the cause of these Fx is poorly recognised and measures taken to prevent future Fx are often inadequate. Recent US patient (pt) survey data suggest that awareness of osteoporosis (OP) and its contribution to Fx risk, appreciation of the benefits of OP pharmacotherapy (Rx), and discussion about OP with healthcare professionals (HCPs) are limited.2

Objectives: This study gained insight into the attitudes and experiences of post-FF women in Europe regarding future Fx risk management.

Methods: Women ≥51 yrs from Germany (DE), Spain (ES), UK, France (FR) and Italy (IT) (EUS) with self-reported experience of a FF completed a 30–min online survey (AplusA; 13–20 Feb 2018). Data are reported for EUS pts who had their first Fx at ≥50 yrs; pts whose first Fx was a hand/finger or ankle/foot/toe Fx were excluded.

Results: 199 women participated (DE: 38; ES: 36; UK: 41; FR: 34; IT:50). The most commonly experienced Fx was of the lower arm/wrist (43%). 43% reported >1 Fx (any type). Most women discussed bone health with an HCP within 6 months (mo) (70%; 42% with a GP) and HCPs were their primary source of information on OP (85%). Around a third reported taking a DEXA test within 6 mo of their first Fx (37%). Advice from HCPs to prevent Fx focused on calcium/vitamin D supplements (74%) and diet/exercise changes (54%); 46% were prescribed OP-Rx. After having a FF, around half worried about future Fx (51%) and 39% voiced concerns about their general health (Figure). A third of pts thought that OP had caused their Fx (33%), most were likely to attribute it to a fall (67%). Only 18% felt empowered to manage their bone health; 61% did not think OP-Rx reduces risk of Fx or were unsure. 97% had never joined a support group.

Conclusion: These results indicate that pts discuss future Fx risk with an HCP soon after having a FF and are concerned about future Fx. However, low levels of DEXA testing and OP-Rx, and poor awareness of the link between OP and Fx risk remain. Better education to empower women at risk of FF is critical.

REFERENCE
patients had an osteoporosis (54.8%): six cases of HCV, three cases of HBV, five cases of PBC, two cases of AIH and one case of PSC. Osteoporosis is most common in postmenopausal women with significant correlation (p<0.001). Hyperbilirubinemia and increased Gamma Glutamyl Transferase (GGT) were significantly correlated with osteoporosis (p<0.05). However, there was no significant correlation between osteoporosis and body mass index or the Child-Pugh score.

Conclusion: In our study, 54.8% of cirrhotic patients who have had a BMD, had an osteoporosis. It was more frequent among postmenopausal women with hyperbilirubinemia and increased GGT. The systematic real-

DENSITOMETRY VALUES CHANGE WHEN STOPPING DENOSUMAB
Urionaquinca Iral1, P Sandra, Chinchilla Gallo2, Sandra Hernandez Gomez1, Jose Francisco Garcia Llorente1, Izaskun Aizpurua Manso1, Nuria Vegas Reveringa1.
1GALDAKAO-USANSOLO OSPITALA, RHEUMATOLOGY, GALDAKAO-USANSOLO, Spain; 2UNIVERSITY OF THE BASQUE COUNTRY, BILBAO, Spain

Background: Denosumab (DMAB) withdrawal without subsequent bisphosphonate treatment seems to be related to a rebound effect: a rapid decrease in mineral density in bone densitometry (DEXA). However, evidence is scarce.

Objectives: To analyze DEXA values in patients who have stopped DMAB without subsequent treatment and to detect possible factors associated.

Methods: Uncentric observational study. We included patients with osteo-
porosis (OP) who attended our rheumatology clinic from May 2017 to December 2018, who had stopped DMAB without any further treatment. Demographic data, risk factors for OP (smoking, age of menopause, pre-
vious fractures, chronic corticotherapy), data related to calcium and vita-

MAINLY MEN, AND OLDER PEOPLE, WITH FRAGILITY HIP FRACTURE DO NOT RECEIVE ANTIOSTEOPOROTIC TREATMENT
Paloma Vela-Casasempere1,2,3, Marta Elvira2, Antonio Palazon Brú3, Silvia Gomez-Sabater4, Roicio Caño-Alameda5, ALICANTE UNIVERSITY GENERAL HOSPITAL, RHEUMATOLOGY, ALICANTE, Spain; 2Miguel Hernandez University, Clinical Medicine, San Juan, Spain; 3ISABIAL, Alicante, Spain

Background: Osteoporotic hip fractures have a profound impact on the physical health and psychosocial wellbeing of patients, with considerable economic implications. More than 20% of individuals experience a subse-
quent hip fracture in the following year (1,2). Although there are effective treat-
ments in the prevention of fractures, the proportion of patients who start treatment after a fragility fracture is low, having decreased in recent years (3).

Objectives: The aim of the study is to know the percentage of patients who received medical treatment for osteoporosis after a fragility hip frac-
ture in our health department. Secondary, we want to know the mortality and re-fracture rates two years after the fracture.

Methods: Cross-sectional retrospective observational study. Patients dis-
charged during 2015 with diagnosis of “Fragility Hip Fracture” were reviewed, data collected through electronic medical record. Variables: sex; age; age and date of death; treatment (calcium, vitamin D or antiosteo-
porotic drugs) before and after discharge; Fragility fracture before and after hospital discharge. Statistical methods: absolute and relative frequen-
cies for qualitative variables, means and standard deviations for quantita-
tive. Associations between variables were studied using Chi square and T-student test.
Results: A total of 320 patients were evaluated, 17 discarded (3 other fracture locations, 1 duplicate, 6 high energy trauma fractures and 8 had other pathologies than osteoporosis that justified the fracture). Mean age was 83.3 ± 7.9 years, 223 (73.6%) women. Prior to admission, 43 patients (14%) took calcium and/or vitamin D, 10 (3%) some antosteoporotic drug and 20 (7%) both. 230 patients (76%) did not receive treatment. 102 exits (33.7%) occurred in the 2 years after the fracture. In the post-discharge analysis, 30 patients were discarded (17 died during admission and 13 in the subsequent month), since it was not possible for them to be treated. After discharge, 42 patients (18%) receive Calcium and/or Vitamin D, 15 (5%) some antosteoporotic drug and 37 (14%) both, leaving 172 patients (63%) without treatment. There were 12 new hip fractures (4.0%). There is a greater proportion of deaths in men (43.8% vs. 30% in women, p = 0.026) and in patients not treated before the fracture (33.2% vs 11.6% calcium-Vit D, p <0.001, 30.5% vs 9.4%, antosteoporotic treatment p = 0.002). The multivariate analysis found a lower probability of having received treatment in men (RR 0.34 IC 95% (0.16-0.72), p = 0.005) and with more age (RR 0.95 IC 95% (0.92-0.98), p = 0.004). After correcting with age: the risk of death in men is 83% higher than in women (p = 0.035). The probability of exits increases by 10% for each additional year of life. Treatment with calcium and/or vitamin D after discharge is a protective factor against mortality from any cause (p = 0.037).

Conclusion: Percentage of patients receiving drug treatment after suffering an osteoporotic hip fracture is very low. This is accentuated in males, and at an older age, populations that also have higher mortality rates in the two years after the fracture.

THE SERUM CREATININE TO CYSTATIN C RATIO: A POSSIBLE NEW SURROGATE MARKER FOR BONE MINERAL DENSITY

Ichiro Yoshi1, Tatsumi Chijiwa2, Naoya Sawada3, 1Yoshii Hospital, Department of Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan; 2Kochi Memorial Hospital, Rheumatology, Kochi, Japan; 3Doha Osenh Hospital, Rheumatology, Matsuyma, Japan

Background: Bone mineral density (BMD) measured using dual-energy X-ray absorptiometry (DEXA) is one of the most important markers for osteoporosis diagnosis. The serum creatinine-to-cystatin C ratio (Cr/CysC) is in focus as a sarcopenia marker because it represents total muscle volume. Recently, Cr/CysC was suggested to have correlation with bone fragility fracture risk [1].

Objectives: This study aimed to assess whether Cr/CysC is correlated with BMD.

Methods: BMD at the lumbar spine (LS) and femoral neck (FN) were measured in women diagnosed with postmenopausal osteoporosis. Steroid included with antosteoporotic patients were eliminated. Cr/CysC was assessed at the time. Clinical factors, such as age, concurrent rheumatoid arthritis treatment (RA), concomitant biological drug administration (BIO), body mass index (BMI), concurrent dementia treatment (dementia), number of comorbidities other than dementia (N.Com), frailty score (FS), bone fragility fracture (BFF), and drug intervention for osteoporosis (DI), were evaluated. Multivariable linear regression (MLR) was used to assess the correlation of these factors with BMD at each part. The relationship between Cr/CysC and other parameters were statistically evaluated using MLR. Additionally, the relationships between the BMD change at each part and parameters were evaluated in the same manner.

Results: The study enrolled 207 subjects. BMD at the LS was significantly correlated with BMI and N.Com (p<0.01), whereas BMD at the FN was significantly negatively correlated with age and was positively correlated with BMI, BFF, Cr/CysC, and DI (p<0.01). Cr/CysC was significantly correlated with age, RA, BIO, dementia, FS, and BFF (p<0.01).

After effect of age was corrected, BMD at the FN demonstrated significant positive correlation with Cr/CysC (p<0.01), whereas no statistical correlation demonstrated between BMD at the LS and Cr/CysC. Both BMD at the LS and the FN demonstrated significant positive correlation with BMI (p<0.05). No parameter significantly correlated with the BMD change at both the LS and FN (p>0.01).

Conclusion: Cr/CysC represents BMD at the FN and is a candidate for BMD substitution.

RECURRENT OF VERTEBRAL FRACTURE IN PATIENTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES: RETROSPECTIVE REVIEW IN MONCLOA UNIVERSITY HOSPITAL. PRELIMINARY RESULTS

Pablo Zurita Prada1, Claudia Urrego-Laurin2, Carlos Guillén-Aste1, Luis García Rodriguez1, Rocio Queipo Matas1, 1Moncloa University Hospital. European University of Madrid, Madrid, Spain; 2European University of Madrid, Madrid, Spain

Background Current drugs for patients who suffer from stabilised osteoporosis (OP) with osteoporotic vertebral fracture (VF) have demonstrated their efficacy with different levels of evidence for secondary prevention of fractures1. In fact, this level of efficacy can be limited in real clinical practice, with pluri-pathological and previously polimmedicated patients.

Objectives Main objective of this study is to describe the percentage of patients with VF in which the therapeutic goal of avoiding new VF during their follow-up has been achieved. As a secondary objective, clinical and therapeutic differences will be analyzed among distinct groups arisen from achieving or not the therapeutic goal.

Methods Retrospective, observational, longitudinal, descriptive study of patients from Rheumatology Department in Moncloa University Hospital who have suffered a vertebral OP. Results

133 cases have been reviewed, 115 (86.5%) females and 18 males (13.5%). Average age is 72 years (+/- 7) and average follow-up time is 2.68 years (+/-3). 25 cases (18.5%) were smokers, 9 (6.8%) on oncologic treatment (73% with chronic corticotherapy and 28% (21%) with immune-mediated diseases, 81 patients (60.9%) had previous VF (0.933 fracture/patient) and 14 (10.5%) non-vertebral fracture (NVF). The average VF was 1.967/patient and 0.133/patient for NVF. 52 patients (39.1%) had received prior treatment for OP (36 Bisphosphonate, 23 Denosumab, 5 SERM, 2 strontium ranelate and 1 teriparatide) and in 39 cases (29.3%) a cementoplasty was performed. Initial treatments prescribed by Rheumatology Department were Bisphosphonates (48%), Denosumab (31%) and Teriparatide (21%). 35 patients received sequential-treatment (26.9%). 86.5 % of patients haven’t presented new VF. 18 cases (13.5%) have been registered with new VF. This group is composed by 13 females and 5 males: the average age was 75 years (+/-7.5) and the average follow-up time 2.8 years (+/- 2.46); 14 (77.8 %) patients presented previous VF and 3 (16.7 %) previous NVF. The average number of previous VF was 2.0/patient and 0.33/patient for NVF. 14 cases (78.8%) of new VF occurred during the first year of follow-up. The treatment they were receiving at the time of the new VF was in 8 cases with Denosumab (44%), 4 with Teriparatide (22%), 2 Alendronate (11%), 3 Risedronate (16%) and 1 case without treatment.

Conclusion These are preliminary data from a register for prognosis evaluation of patients who suffer VF in Moncloa University Hospital. A larger sample size is necessary to develop a strategic conclusion in this patients, pluripathological, with previous osteoporotic fractures and treatment.78 % of new VF occurred during the first year of the follow-up, 44% of them were receiving Denosumab, 77% (vs. 58% of the patients without new VF) had previous VF and 44% (vs. 37% patients without new VF) had received previous OP treatment.
Crystal diseases, metabolic bone diseases other than osteoporosis

AB0861 METHODS TO EFFICIENTLY RECRUIT MINORITY PATIENTS WITH GOUT FOR CLINIC-BASED REGISTRIES

Giovanni Adami1,2, Josh Melnick1, Jeff Foster1, Elizabeth Rahn1, Amy Mudano1, Jeffrey Curtis1, Tony Merriman3, Lou Bridges1, Kenneth Saag1.1University of Alabama at Birmingham, Birmingham, United States of America; 2University of Verona, Rheumatology Unit, Verona, Italy; 3University of Otago, Dunedin, New Zealand

Background: Gout is frequently misdiagnosed and/or miscoded, making approaches to identifying eligible patients for observational and interventional studies more challenging. Ethnic and racial minorities are underrepresented in many gout studies. Methods to better identify minorities and confirm gout diagnosis are essential to ensure studies have both validity and generalizability.

Objectives: To define efficient methods for identifying African Americans (AA) interested in participating in a gout registry and who satisfy the American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) gout classification criteria.

Methods: We identified all AA patients seen at University of Alabama at Birmingham 01/09/2017 and 31/08/2018 with an ICD 9/10 code for gout. Patients not “opted out” by their primary care provider (PCP) were invited to participate. Those interested underwent detailed medical record review followed by phone contact to determine eligibility. Those with a high likelihood of meeting diagnostic criteria for gout were invited for an in-person visit to confirm diagnosis (Abstract AB0861 Figure 1). We compared descriptive characteristics of participants enrolled in the registry and the larger potential gout populations.

Results: From 3,032 AA patients with an ICD 9/10 gout diagnosis we generated a random sample of 400 patients. 5 patients were excluded by their PCPs, thus 395 patients were preliminarily eligible and invited via e-mail (N=176) and/or letter (N=375). 1 patient (<1 %) communicated lack of interest, 19 (4.8%) were unreachable, 322 (81.5%) did not respond to the invitation, and 53 (13.4%) expressed preliminary interest and underwent medical record review. We successfully scheduled 30 subjects for a registry visit, 24 completed the visit, and 23 (86% of initial sample) satisfied 2015 ACR/EULAR gout classification criteria (see Table 1). We found no significant difference in age, sex, and the number of medical encounters in the last year between enrolled patients and the remaining population.

The mean age of the study group was 61.4 +/- 4.5 years. The radiographic findings (Eichenholtz Classification). All patients were neuroarthropathy has been assessed according to the clinical and the patient with type 2 diabetic and acute Charcot neuroarthropathy. All our A prospective 2-year follow-up study was carried out on eight radiological efficacy of Zoledronic acid in patients with diabetes and acute Charcot neuroarthropathy. The aim of this study was to investigate the clinical and involvement was bilateral in 6 patients and unilateral in the other 2. A biological inflammatory syndrome was found in 3 patients with a mean erythrocyte sedimentation rate (ESR) level at 43 mm after one hour. Foot X-rays were abnormal in all cases. The clinical outcomes at one month after Zoledronic acid infusions were the complete disappearance of acute symptoms in 6 patients and the improvement of the pain in one patient with a decreased Visual Analogue Scale (VAS) for pain by 30%. One patient had a persistence of the pain (VAS for pain at 5mm). A radiological Control was performed after 6 months for 5 patients. All of them had bone consolidation and remineralization.

Conclusion: Our study showed that the Zoledronic acid, given as a single dose, had a beneficial effect on clinical and radiological features in diabetic patients with acute Charcot neuroarthropathy. Despite our encouraging outcomes, further prospective and randomized studies are needed to confirm our preliminary results.

AB0865 GOUT IN HOSPITALISED PATIENTS FOR CARDIOVASCULAR DISEASES: PREVALENCE AND MANAGEMENT STATUS
Irene Calabuig1, Miguel Gomez-Varo2, Mariano Andrés2,1. 1Hospital General Universitario de Alicante-IBASIAL, Seccion de Reumatologia, Alicante, Spain; 2Universidad Miguel Hernandez, Alicante, Spain.

Background: Gout is an independent risk factor for cardiovascular diseases (CVDs), where the urate crystal-led inflammatory state likely has a key role. Crystal dissolution may carry with cardiovascular benefits, so optimal management of gout patients is essential, especially in high-risk individuals, such as those hospitalised for CVDs. Although the prevalence of gout in Western country adults is about 2-4% [1], the rate and characteristics in inpatients with CVDs remains to be defined.

Objectives: To determine the prevalence of gout, characteristics and management in a hospitalised population for CVDs.

Methods: Observational, descriptive, cross-sectional study. Patients admitted for CVDs in the Cardiology, Neurology and Vascular Surgery units of a tertiary centre were recruited following a non-consecutive, systematic sampling up to reaching the estimated minimum sample size. A face-to-face interview and a review of electronic health records were performed, in order to collect clinical, laboratory and management data regarding CVD and gout. Gout diagnosis was established in the interview using ACR/EULAR 2015 criteria. In addition, prior clinical or crystal-proven diagnoses at records were also registered. 95% confidence intervals (95%CI) were calculated for primary variable (gout prevalence), and comparisons were performed by Student’s t, chi-squared and Fisher’s exact tests.

Results: 299 patients were interviewed, 33 were excluded, and the final study sample was 266 participants. They were predominantly males (69.9%) and Caucasians (96.6%) with a mean age of 68 years (SD±12). The CVDs leading to admission were acute coronary syndrome (18.8%; n=50), heart failure (13.2%; n=35), stroke or transient ischemic attack (8.7%; n=23), diabetic and acute Charcot neuroarthropathy (5.5%; n=12) and peripheral artery disease (47.4%; n=126). Gout was identified in 40 individuals (prevalence 15.0%; 95%CI 10.9-19.2). Prior gout diagnosis in records was found in only two-thirds of them, mostly clinical (Table). Patients with gout were older (72±9 vs 68±13 years, p=0.026) and showed higher rates of chronic kidney disease (55.0% vs 23.0%, p=0.001) and use of diuretics (55.0% vs 38.5%, p=0.05), with no differences in other variables. The disease was long-standing though low numbers of flares and involved joints were referred (Table). Tophi were seen in about 8%. The serum urate levels were not properly controlled, both at the time of the CVD and as a median of the previous five years, and only one-third of the patients were on target (<6 mg/dl). Despite 70% of patients having been treated with urate-lowering agents at some point, at assessment only half remained treated (38.5% of them were on target). Nearly a quarter of patients used prophylactic colchicine.
Abstract AB0866 Table 1. Clinical & management of gout in inpatients for CVDs.

Data shown as n (%), unless otherwise specified.

Conclusion: Gout is prevalent in hospitalised patients for CVDs, affecting one in seven cases. The management of gout in these patients appears suboptimal, with serum uric acid levels above recommended targets and a significant percentage of no urate-lowering treatment.

AB0867 METABOLIC SYNDROME IN PATIENTS WITH GOUT ATTENDED IN A SPECIALIZED OUTPATIENT UNIT IN SPAIN. COMPARISON WITH GENERAL POPULATION AND CARDIOVASCULAR IMPLICATIONS

Enrique Calvo-Aranda, Fernando Manuel Sanchez-Aranda, Laura Cebrian, Maria Angeles Matias de la Mano, Elena Garcia-Lorenzo, Maria Teresa Navio Marco. Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain

Background: Metabolic syndrome (MS) is a cluster of interrelated components: central adiposity or higher waist circumference (WC), high values of triglycerides (TG), elevated blood pressure (BP), impaired fasting glucose and decreased HDL-cholesterol (HDL-c). It is associated with a higher incidence of developing chronic diseases (DM) as well as with other cardiovascular diseases (CVD). A direct relationship between serum uric acid (sUA) and the risk of develop MS has been reported in several studies of patients with hyperuricemia and gout.

Objectives: To study the prevalence of MS and associated CVD in patients with gout attended in a specialized outpatient unit, comparing with other local and national studies.

Methods: Retrospective observational study with consecutive patients diagnosed with gout according to EULAR/ACR criteria between August and December 2018. We analysed the presence of MS according to the 2015 International Diabetes Federation criteria (central obesity as BMI >30 kg/m² or WC >94 cm (>80 in women), with ≥2 of the following: TG ≥1.71 mmol/l, HDL-c <1.04 mmol/l (<1.3 mmol/l in women), hyperglycemia ≥5.55 mmol/l (or T2DM previously diagnosed or hypoglycaemic treatment), hypertension (HT; >130/85 mmHg or use of antihypertensive drugs).

Results: From August 2016 to December 2018, we evaluated 192 patients with hyperuricemia and gout. The MS prevalence was 64.9%; 14% diagnosed in our unit. 807%; 10.5% diagnosed in our unit. DM 22.8%. Dyslipidemia (DL: hypercholesterolemia or high levels of TG) 64.9%; 14% diagnosed in our unit. Ischemic heart disease (IHD) 14%. Stroke 24.6%. FH of CVD 24.6%. Comparing with the general population the prevalence of MS and pMS was higher (DARIOS: 31% and 24%, respectively; ENRICA: 22.7% and 16.9%; SIMETAP: 41% and 25%), as well as with the presence of CKD (11.5% in SIMETAP) and CVD (SIMETAP: HT 38%, T2DM 16%, obesity 28%, IHD 4.8% and stroke 3.8%).

Conclusion: There is a very significant percentage of MS and pMS in patients with gout compared to the general population, with important presence of CKD and CVD, sometimes underdiagnosed. Nursing guidelines were established with healthy lifestyle and periodic controls directed at all patients, with special emphasis on those newly diagnosed of HT or DL, as well as those of higher cardiovascular risk.

AB0867 DEPRESSIVE SYMPTOMS INFLUENCE SUCCESS OF ALLOPURINOL AS URATE LOWERING THERAPY

Sylvie Moug1, Catheyn Orthueta2, Elizabeth Rahm3, Kenneth Saag2, Angelo Gallo4,5,1 University of Alabama at Birmingham, Birmingham, United States of America; 2University of Alabama at Birmingham, Birmingham, United States of America; 3University of Alabama at Birmingham, Birmingham, United States of America; 4Birmingham VA Medical Center, Birmingham, United States of America

Background: Elevated levels of serum urate (sUA) is the known precursor of gout and urate lowering therapies (ULT) are the backbone of successful gout treatment. However, less is known about factors that influence the effectiveness of ULTs. Depression has shown strong relationships with treatment noncompliance, which may translate into reduced effectiveness of treatment with allopurinol. Little is known about any effects depression may produce on the observed serum urate lowering efficacy of ULTs (e.g.; allopurinol).

Objectives: To evaluate the role of depressive symptoms in the efficacy of allopurinol for lowering sUA in the context of a clinical trial.

Methods: Within a larger cross-over clinical trial of 300 daily mg of allopurinol vs. placebo for urate lowering and its effect in ambulatory blood pressure (1), 67 patients had complete data for depressive symptoms at the beginning of each treatment period, as well as sUA before and after a 4-week treatment period with allopurinol and a 4-week placebo period (order of conditions was randomized). Depressive symptoms were assessed with the Center for Epidemiologic Studies Depression Scale-10 (CESD-10) (2). Paired samples t-test evaluated change in sUA from pre- to post-treatment during active treatment and placebo. Then, linear regressions predicted change in sUA over each treatment period from pre-treatment depressive symptoms, adjusting for sex and race which were associated with baseline sUA levels.

Results: The 67 patients had average age 27.01 years (SD=6.5, range 18-40). 87% were African American, and 64% were male. Over the 4-week active treatment period, sUA levels decreased from average 5.8 mg/dL (SD=1.2) (345.7 μmol/L) to 4.4 mg/dL (SD=1.2) (261.7 μmol/L), p<.001. However, sUA did not change during the 4-week placebo condition (both 5.8 mg/dL (345.7 μmol/L), SD=1.1 and 1.3, p=0.71). Pre-treatment depressive symptoms ranged from “no symptoms” (0) to “severe symptoms” (16 or 20), with mean in the “no to mild” range (M=4.6, SD=3.1). A multiple linear regression analysis (M=6.1, SD=4.9 before placebo). After adjusting for pre-treatment sUA, sex and race, pre-treatment depressive scores predicted higher levels of sUA at the end of the active treatment period (β=0.07, beta=25, p=0.28) but not at the end of the placebo period (β=0.03, beta=11, p=0.102). After 4 weeks of allopurinol, the estimated difference in sUA between individuals with pre-treatment depressive scores of 0 vs. 16 was 1.12 mg/dL (66.6 μmol/L), which was similar to the average treatment effect of 1.4 mg/dL (88.3 μmol/L).

Conclusion: Even in the absence of clinical diagnosis of depression, depressive symptoms are associated with reduced efficacy of urate-
AB0868 ULTRASOUND MONOSODIUM URATE CRYSTAL DEPOSITS IN THE JOINTS OF GOUT PATIENTS CORRELATE WITH THE WORSENING OF THE HEART SYSTOLIC FUNCTION

Rada Gancheva1, Atanas Koundourdijiev2, Todor Kundrazhiev3, Zlatimir Kolarov4.
1University Hospital St. Ivan Rilski, Medical University, Clinic of Rheumatology, Sofia, Bulgaria; 2University Hospital St. Ivan Rilski, Medical University, Clinic of Nephrology, Sofia, Bulgaria; 3Medical Faculty, Traikia University, Department of Chemistry and Biochemistry, Stara Zagora, Bulgaria; 4Medical University, Sofia, Faculty of Public Health, Sofia, Bulgaria.

Background: The connection between gout and cardiovascular (CV) complications has been investigated a lot. Recent studies demonstrated that higher body urate load is an indicator of increased CV risk.

Objectives: To determine whether ultrasound deposits of monosodium urate (MSU) crystals in the joints of gout patients (pts) correlate with the worsening of the heart systolic function and left ventricular hypertrophy.

Methods: This was a single-center cohort-observational study including 56 consecutive gout pts. 40 males and 16 females in a mean age 58.9±13.2 years with disease duration 6.4±2.93 years. All of them underwent trans-thoracic echocardiography and ultrasound examination of the joints of the hands, elbows, knees, ankles and feet. By transthoracic echocardiography, conducted with 2.5 MHz transducer phased array working with pulse Doppler frequency of 2.5 MHz, were measured parameters which are independent predictors of CV risk: left ventricular mass index (LVMi), ejection fraction (EF), fractional shortening (FS) and systolic motion of the myocardium (Sm). Ultrasound studies of the joints were performed with a high-frequency, linear transducer, 4-15 MHz. The existence of double contour sign, tendon MSU deposits, snow storm, tophi and tophi with erosions or a combination of these ultrasound features was assessed. Examinations were done in accordance with the latest published guidelines. Data were analyzed by Kolmogorov-Smirnov, Mann-Whitney, t-test, Kruskal Wallis test and Spearman correlation.

Results: 49(87.5%) of the pts had ultrasound evidence of crystal deposits. Serum uric acid levels were equal in pts with and without MSU deposits, pts with MSU findings in one joint area and in those with crystal deposits in two or more joint areas we did not find a difference in the mean values of LVMi (means±SD; 126.86±21.95 g/m² vs 120.09 ±31.50 g/m² vs 128.63±35.19 g/m², p=0.761), FS (means±SD; 37.73 ±6.62% vs 38.25±3.51% vs 35.40±5.57%, p=0.205) and Sm (means±SD; 0.27±0.35 m/s vs 0.30 m/s vs 0.30±0.2 m/s, p=0.266). A tendency of lower EF without reaching significance was detected in subjects with crystal deposits in two or more joints, (p=0.071). The values of LVMi (p=0.295), EF (p=0.396), FS (p=0.566) and Sm (p=0.154) were similar in pts without MSU findings, subjects who had a double contour sign, those with tendon MSU deposits, pts with snow storm, individuals with tophi and in pts with tophi and erosions. However, pts with crystal deposits in the knees and in the tibiotalar joints had lower EF (p=0.047; p=0.049, respectively) and lower FS (p=0.036; p=0.016, respectively) compared to those who had no crystal deposits in these joint areas. Further a weak negative correlation was detected between the number of joints with crystal deposits and EF (r=-0.294, p=0.029) and FS (r=-0.292, p=0.030).

Regarding LVMi and Sm no correlation was established with the presence of crystal deposits in the joints (p=0.079, p=0.568 and r=-0.242, p=0.076).

Conclusion: Despite the lack of difference in serum uric acid between pts with and without MSU deposits in the joints, those with MSU findings in the knees and in the tibiotalar joints had more deteriorated systolic function of the heart in comparison to pts without crystal deposits in these joint areas. A negative correlation existed between the number of joints with crystal deposits and functional pumping indices of the heart. On the other hand, MSU deposits in the knees and in the tibiotalar joints are associated with higher urate load than deposits in the small joints. We suggest that the higher urate load is connected to the worsened pumping function of the heart.

Disclosure of Interests: None declared

AB0869 SERUM LEVELS OF ROS PRODUCTS, NO AND ASCORBATE RADICALS IN GOUT PATIENTS ARE NOT ASSOCIATED WITH ARTERIOSCLEROTIC COMMON CAROTID ARTERIES CHANGES AND USE OF XANTHINE OXIDASE INHIBITORS

Rada Gancheva1, Atanas Koundourdijiev2, Galina Nikolaeva3, Mariana Ivanova Gancheva4, Todor Kundrazhiev2, Zlatimir Kolarov1, Veselina Gadjeva1.
1University Hospital St. Ivan Rilski, Medical University, Clinic of Rheumatology, Sofia, Bulgaria; 2University Hospital St. Ivan Rilski, Medical University, Clinic of Nephrology, Sofia, Bulgaria; 3Medical Faculty, Traikia University, Department of Chemistry and Biochemistry, Stara Zagora, Bulgaria; 4Medical University, Sofia, Faculty of Public Health, Sofia, Bulgaria.

Background: Oxidative stress along with chronic inflammation and hyperuricemia links gout to arteriosclerotic vascular changes. Studies examining the connection between the level of oxidative stress and arteriosclerotic carotid arteries changes in gout patients (pts) are not enough.

Objectives: To establish the association between the serum levels of reactive oxygen species (ROS) products, nitric oxide (NO) radicals and ascorbate radicals with intima-media thickness (IMT) and common carotid artery resistive index (CCARI) in gout pts, and to find out whether the connection is more pronounced when tophi are present.

Methods: This was a cross-sectional study including 71 gout pts in a mean age 58.86±11.95 years, 61 males and 10 females (45 without tophi pts and 26 gouty tophi pts). Serum levels of ROS products, NO radicals and ascorbate radicals were determined by ex vivo electron paramagnetic resonance (EPR) study. All EPR measurements were performed on an X-band EMXmicro, spectrometer Bruker, Germany, equipped with Standard Resonator. Spectral processing was done by using Bruker WIN-EPR and Sinfonia software. By applying ultrasound of the common carotid arteries, conducted with 10 MHz linear transducer working with pulse Doppler frequency of 5 MHz, were measured IMT and CCARI. Statistical analyses were done by One-Sample Kolmogorov-Smirnov, Chi-Square, Fisher’s exact test, Mann-Whitney, t-test and Pearson correlation.

Results: Gouty arthritis without tophi and gouty tophi pts were age-matched, (p=0.309). The mean values of serum uric acid (p=0.569) and distribution of the subjects with gout attack (p=0.173), smoking (p=0.828), arterial hypertension (p=0.735), dyslipidemia (p=0.646), chronic renal failure (p=0.233) and obesity (p=0.623) was equal in the groups. In the tophi group CRP and the number of pts who had suffered a cardiovascular event were higher (p=0.048; p=0.031). Serum levels of ROS products, NO radicals and ascorbate radicals were comparable in gouty arthritis without tophi and in gouty tophi pts (p=0.783; p=0.521; p=0.651). In the groups no difference was registered in CCARI (p=0.273) but intima-media was thicker in the presence of tophi, (p=0.027). No correlation existed between ROS products, NO radicals and ascorbate radicals with IMT (r=-0.100, p=0.405; r=-0.186, p=0.121; r=0.154, p=0.201). ROS products, NO radicals and ascorbate radicals did not correlate with CCARI (r = -0.110, p=0.359; r=-0.066, p=0.587; r=0.094, p=0.436). Among treated and untreated with Allopurinol pts no difference was found in the mean values of ROS products (p=0.169), NO radicals (p=0.167), ascorbate radicals (r=0.273) and CCARI (p=0.930). Among treated and untreated with Febuxostat pts the mean values of ROS products (p=0.546), ascorbate radicals (p=0.309), IMT (p=0.842) and CCARI (p=0.100) were similar. A tendency of higher serum NO radicals was established in pts taking Febuxostat in comparison to those not treated with it (p=0.076).

Conclusion: Although between the earlier and the later stage of the disease there was no difference in the level of oxidative stress, the level of chronic inflammation was higher in gouty tophi pts. No connection was found between serum ROS products, NO radicals and ascorbate radicals with arteriosclerotic changes of the carotid arteries and use of xanthine oxidase inhibitors. We suggest that in gout pts chronic inflammation has an important role in the process of atherogenesis.
The aim of this study was to assess the incidence of gout in patients presenting to hospital with myocardial infarction (MI) or stroke (CVA). However, the incidence of gout in patients presenting to hospital with MI or CVA in Ireland has not previously been assessed. Studies have suggested gout as a risk factor in patients presenting with myocardial infarction (MI) and stroke (CVA). How-ever the incidence gout in patients presenting with CVA and MI.

Methods: The Hospital In-Patient Enquiry Scheme (HIPE) was used to identify patients admitted with stroke or myocardial infarction from 62 acute public hospitals in Ireland from January 2007 until December 2017. HIPE is a national database which records coded hospital admission and demographic, clinical and administrative data on discharges from, and deaths in, acute public hospitals nationally. Discharges are coded using the International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, Australian Modification (ICD-10-AM), Australian Classification of Health interventions (ACHI), Australian Coding Standards (ACS), 8th Edition. Age, gender and number of patient admissions with MI or CVA with gout, diabetes, hypertension, peripheral vascular disease (PVD) and hyperlipidemia were recorded.

Results: From 2007 until 2017, 64,867 were admitted with a diagnosis of CVA in Ireland. The age and gender of patients admitted with a principal diagnosis of CVA are outlined in Table 1. 70,628 patients were admitted to the stroke group (0.77%). The presence of diabetes as a risk factor (6.7%) was significantly higher compared to gout (0.5%) in patients admitted with myocardial infarction. Chart one outlines the incidence of each risk factor in patients discharge with a primary diagnosis of MI in Ireland between 2007 and 2017.

Conclusion: The incidence of gout in patients presenting with CVA or MI in Ireland was low compared to other risk factors including diabetes. In patients presenting with MI then incidence of gout is lower than in patients presenting with CVA.

Disclosure of Interests: Rada Gancheva; None declared, Atanas Konduriev; None declared, Galina Nikolova; None declared, Mariana Ivanova Goycheva Speakers bureau: Abbvie, Pfizer, UCB, Novartis, Todor Konduriev; None declared, Zlatimir Kolarov; None declared, Veselada Gjeva; None declared DOI: 10.1136/annrheumdis-2019-eular.1952

AB0870

IS THE INCIDENCE OF GOUT SIMILAR TO OTHER RISK FACTORS IN PATIENTS PRESENTING WITH STROKE OR MYOCARDIAL INFARCTION?

Aine Gorman, Gillian Fitzgerald, Finbar Barry O’shea, St. James’s Hospital, Rheumatology, Dublin, Ireland.

Background: Gout is a common form of inflammatory arthritis. The prevalence of gout in Europe is between 0.9-2.5% with rates as high as 4% reported in Ireland. Studies have suggested gout as a risk factor in patients presenting with myocardial infarction (MI) and stroke (CVA). However, the incidence gout in patients presenting to hospital with MI or CVA in Ireland has not previously been assessed.

Objectives: The aim of this study was to assess the incidence of gout in patients presenting with CVA and MI. A further objective was to explore if the incidence of gout is similar to other risk factors such as hypertension, diabetes mellitus and dyslipidemia in Irish patients presenting with CVA and MI.

Methods: The Hospital In-Patient Enquiry Scheme (HIPE) was used to identify patients admitted with stroke or myocardial infarction from 62 acute public hospitals in Ireland from January 2007 until December 2017. HIPE is a national database which records coded hospital admission and demographic, clinical and administrative data on discharges from, and deaths in, acute public hospitals nationally. Discharges are coded using the International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, Australian Modification (ICD-10-AM), Australian Classification of Health interventions (ACHI), Australian Coding Standards (ACS), 8th Edition. Age, gender and number of patient admissions with MI or CVA with gout, diabetes, hypertension, peripheral vascular disease (PVD) and hyperlipidemia were recorded.

Results: From 2007 until 2017, 64,867 were admitted with a diagnosis of CVA in Ireland. The age and gender of patients admitted with a principal diagnosis of CVA are outlined in Table 1. 70,628 patients were admitted to the stroke group (0.77%). The presence of diabetes as a risk factor (6.7%) was significantly higher compared to gout (0.5%) in patients admitted with myocardial infarction. Chart one outlines the incidence of each risk factor in patients discharge with a primary diagnosis of MI in Ireland between 2007 and 2017.

Conclusion: The incidence of gout in patients presenting with CVA or MI in Ireland was low compared to other risk factors including diabetes. In patients presenting with MI then incidence of gout is lower than in patients presenting with CVA.

ASSESSMENT OF THE KIDNEYS AND URINARY TRACT DYNSFUNCTIONS THAT INCREASE THE RISK OF DEVELOPING CHRONIC KIDNEY DISEASE IN PATIENTS WITH GOUT BASED ON COMPLEX RENAL SCINTIGRAPHY

Margarita Gromova1, Vladimir Tsurko2, Anna Kashkadayeva2, Svetlana Averinova2, Andrey Aliokhin3. 1Pirogov Russian National Research Medical University, Department of Faculty Therapy, Moscow, Russian Federation; 2N.N.Blokhin National Medical Research Center of Oncology, Laboratory of Radioisotope Diagnostics, Moscow, Russian Federation; 3Group of companies Tekon, Moscow, Russian Federation.

Background: In 40% of cases patients with gout can develop gouty nephropathy, the “kidney mask” of gout. The newest version of the technology for systemic examination of nephrological status based on complex renal scintigraphy (SENS-CRS) has been developed at the «N.N. Blokhin National Medical Research Center of Oncology». SENS-CRS at the lowest doses of radiation (0.6 mSv per adult) allows for an in-depth differential analysis of dysfunctions of the renal parenchyma, upper and lower urinary tract which increase the risk of chronic kidney disease (CKD) development.

Oxidative Stress Marker Allantoin in Patients with Systemic Autoimmune Rheumatic Diseases After Abrogation of Systemic Inflammation by TNF Inhibition

Lenka Hasikova1,2, Marketa Pavlikova3, Petr Kozlik4, Kveta Kalikova5, Blanka Stibulkova6, Jakub Zavada6,1, Institute of Rheumatology, Prague, Czech Republic

Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic; Department of Probability and Mathematical Statistics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic; Department of Analytical Chemistry, Faculty of Science, Charles University, Prague, Czech Republic; Department of Physical and Macromolecular Chemistry, Faculty of Science, Charles University, Prague, Czech Republic; Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic

Background: In patients with gout, the serum uric acid (SUA) is usually lower during acute gouty attacks than during intercritical periods. In a previous study, we have shown that abrogation of systemic inflammation by TNF inhibitors (TNFi) results in an increase in the levels of SUA in patients with systemic rheumatic diseases. We have not found any correlation between the magnitude of change of SUA and CRP or pro-inflammatory cytokines (IFN-γ, IL-6, IL-8, IL-10, IL-17a, IL-18, IL-23, TNF-α).1 Another possible mechanism for the lowering of SUA during inflammation may be consumption of circulating SUA in free radical reactions generated during systemic inflammation. Allantoin has been validated as a stable biomarker of oxidative stress in humans.2

Methods: We examined 66 patients with gout. 95% were men (average age 54±9 years). Duration of gout was 8 [4; 11] years. All patients had chronic gouty arthritis, 30% of patients had tophuses. SENS-CRS was carried out on a 2-detector γ-camera with simultaneous recording in 2 projections. In studies of the urinary system domestic radiopharmaceutical (RP) 99mTc-technetor with glomerulo- and 10-15% tubulotropic properties was used. The CRS study consisted of: 1) a basic 21-min functional study; 2) a delayed 21-min study (without the injection of RP) with a preliminary diuresis forcing to identify persistent urodynamic dysfunction.

Results: 16 patients with gout with serum creatinine level of more than 125 μmol/l had established diagnosis of chronic pyelonephritis, glomerulonephritis, urolithiasis, etc. and were allocated into a separate subgroup. In the comparative analysis of these 16 patients and other 50 patients with gout there was reliable distinction only for one indicator D (%), the rate of RP removal from a kidney parenchyma (p < 0.05). There was no significant distinctions for glomerular filtration rate by Reberg, the nuclear indicator (Grenal) of renal parenchyma concentration function, and other indicators. Renocortical parameter D (%) is one of the earliest highly sensitive markers of intrarenal developments of stagnation at development of serious morphofunctional violations in a parenchyma. In the subgroup of 16 patients the indicator accounted on average D = 48% ± 7% (range 38-55%); in subgroup of 50 patients D = 63% ± 10% (47-89%).

According to the CKD-EPI formula and SENS-CRS technology in the subgroup of 16 patients CKD stage II-III was evaluated. In addition to the standard taken rate of RP removal from a parenchyma (D) when comparing the 2 phases of CRS there was observed a steady sign of stagnation in a parenchyma and groups of upper and/or lower cups: ID = Grenal/GC < 1. Based on the water test which accelerates diuresis there was a sufficient regulation of urostasis in the renal pelvis revealed at the basic test (IP = Grenal/GP > 1.0). This indicated that the functional reserve of the outflow regulation from the kidneys was preserved at these patients.

Conclusion: This functional diagnosticizes allows one-time control of hemo-dynamics and concentration function of the parenchyma of each kidney, quantitative and qualitative signs of urodynamic delays in the intra- and post-renal urinary tract. Differentiated analysis SENS-CRS contributes to the timely therapeutic correction as well as referral for consultation to specialists (urologists, nephrologists, gynecologists, etc.).

ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH GOUT. RELATIONSHIP BETWEEN CARDIOVASCULAR RISK FACTORS

Ekaterina Ilinykh, Maxim Eliseev, Alexander Volkov. V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Patients with gout have a high risk of developing cardiovascular disease based on atherosclerosis. An early marker, and at the same time a risk factor of cardiovascular disease, is a violation of the vasoregulating endothelial activity.

Objectives: To identify the relationship between cardiovascular risk factors and endothelial dysfunction (ED) in patients with gout.

Methods: The study included 80 pts with gout. The criteria for inclusion were: 1. Male 2. Age >55 years 3. Intercritical period of arthrits 4.Absence of clinical signs of coronary artery disease 5.Absence of drug therapy. Vasoregulating endothelial activity was evaluated in all pts, 52 of them determined the carotid intima-media thickness (C-IMT). Flow-mediated (endothelium-independent) dilatation (EID) were assessed by highresolution ultrasonography (D. Celermajer). A non-invasive ultrasound technique was used to measure C-IMT. All patients were diagnosed with serum total cholesterol (CHOL), subtypes (LDL-C, HDL-C), glucose (GLU), uric acid (SUA), hsCRP. Cardiovascular risk (CVR) was calculated. Statistical analysis was conducted using the online programs package of descriptive statistics STATISTICA 12.0 (StatSoft,Inc. USA).

Results: It was found that 41 (51.25%) pts had FMD less than 8%. A correlation was found between FMD and CVR (r = -0.28, p < 0.05), age (r = -0.37, p < 0.001), Body mass index (BMI).
ANALYSIS OF LIFESTYLE AND CLINICAL FEATURES OF THE PATIENTS WITH GOUT IN MEIZHOU, GUANGDONG, CHINA

Yutong Jiang1, Yiquan Wen2, Zhongyu Liu1, Qyoun Chen3, Yetei Huang3, Yunteng Pan1, Jeruo Gu1, Junyu Gu1, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 2The Third Affiliated Hospital of Sun Yat-sen University, Yuedong Hospital, Meizhou, China.

Background: Gout is one of the most common metabolic diseases caused by purine metabolic disorder, leading to joint destruction and kidney impairment. With the improvement of living conditions, the incidence of gout is increasing year by year, especially in the developed coastal areas of China. Previous studies found that the management of gout was unsatisfactory [1]. Besides, the development of rheumatology in Meizhou, Guangdong province is extremely slow. There are only ten rheumatologists, and the general public has a limited understanding of gout.

Objectives: Our aim was to explore the lifestyle, clinical features and risk factors of recurrent gout attacks in patients with gout in Meizhou, Guangdong province.

Methods: Demographic data, lifestyle and clinical data of 188 patients with gout in Meizhou were collected. Demographic variables included age, gender, marital status, education, BMI, smoking status, drinking status, diet, daily water intake, work style, exercise habit, late sleeping habit. Smoking status includes never smoking, ever-smoking or current smoking, diet, daily water intake, work style, exercise habit, late sleeping habit.

Results: There were 249 case reports documenting non-extremity urate deposition. Urate deposition was reported in multiple organ systems including cardiovascular, renal, spine, integumentary, ocular, renal, cardiovascular, gastrointestinal, larynx, breast, middle ear, pancreas, nasal, prostate gland, liver, pulmonary, penis, nailbed, and pelvis.

Conclusion: Numerous case reports document systemic deposition of urate based on autopsy, pathology, imaging and clinical exam. Urate crystal deposition with the formation of tophi and micro-tophi involve multiple organ systems including cardiovascular, renal, spine, integumentary, prostate, bowel, pancreas, eyes, pelvic, breast, lungs, middle ear, larynx, liver, penis, nailbed, and nose. Given the strong association of gout with various comorbidities, this demonstrates a need for further studies to determine the clinical significance of systemic urate deposition with respect to ongoing subclinical inflammation and potential end-organ damage.

AB0875 GOUT, NOT JUST A DISEASE OF THE FOOT. LITERATURE REVIEW OF SYSTEMIC DEPOSITION OF URATE

Ada Kumar1, Puja Khanna2, Horizon Pharma, Lake Forest, United States of America; 1University of Michigan, Ann Arbor, United States of America

Background: Gout is the most common adult inflammatory arthropathy in the US. Although tophi in the extremities is a known source of the inflammatory cascade, urate deposition in organs throughout the body is not as well recognized. Patients with gout often have associated comorbidities including renal disease, cardiovascular disease and metabolic syndrome, however, a casual role has not been established. Direct urate deposition in these organ systems may be of interest to link the causality of these systemic disorders.

Objectives: Perform a literature review including clinical exam, autopsy, pathology, and radiology imaging results demonstrating systemic deposition of urate exclusive of the extremities.

Methods: PUBMED from 1920 to 2018 was searched to identify reports of non-extremity urate deposition. Key words included: extra-articular gout, systemic deposition of urate, ocular gout, gout nephropathy, renal tophi, gouty heart, cardiac valves and urate, urate deposition in the arteries, prostate and urate, autopsy findings in gout, cutaneous urate deposits, gouty panniculitis, auricular gout, breast and urate, gastrointestinal gout, pancreas and tophus, laryngeal tophus, and spinal gout. The reference lists from these publications were also used to identify additional articles. The literature was reviewed for organ system involvement and documented based on sites of urate deposition within an organ system.

Results: There were 249 case reports documenting non-extremity urate deposition confirmed by autopsy, biopsy, surgery, clinical exam and/or radiology imaging. Urate deposition was reported in multiple organ systems (Table 1) including the spine, integumentary, ocular, renal, cardiovascular, gastrointestinal, larynx, breast, middle ear, pancreas, nasal, prostate gland, liver, pulmonary, penis, nailbed, and pelvis.

Conclusion: Numerous case reports document systemic deposition of urate based on autopsy, pathology, imaging and clinical exam. Urate crystal deposition with the formation of tophi and micro-tophi involve multiple organ systems including cardiovascular, renal, spine, integumentary, prostate, bowel, pancreas, eyes, pelvic, breast, lungs, middle ear, larynx, liver, penis, nailbed, and nose. Given the strong association of gout with various comorbidities, this demonstrates a need for further studies to determine the clinical significance of systemic urate deposition with respect to ongoing subclinical inflammation and potential end-organ damage.

AB0876
GOUT CAUSING URATE CARDIAC VEGETATIONS:
SUMMARY OF PUBLISHED CASES
Brian LAMoreau1, Vidhya Chandrasekaran2. 1Horizon Pharma, Medical Affairs, Lake Forest, United States of America; 2Independent, Deerfield, United States of America

Background: Gout is a progressive inflammatory disease that is both widely prevalent and widely undertreated. In gout patients, urate deposition occurs in peripheral joints, the spine, and organs including the prostate, kidneys, and in atherosclerotic plaques as well as heart valves. Due to the concern of bacterial endocarditis and associated sequelae, cardiac valve vegetations are generally thoroughly evaluated even without systemic symptoms. Gout causing cardiac valvular vegetations is believed to be rare, though to date a number of case reports on this topic have been published.

Objectives: This project sought to compile and synthesize the existing published cases of proven cardiac valve urate deposition in gout patients.

Methods: Medline and google were used to search for all available published cases involving gouty valve urate deposition. The references of each publication were additionally completely examined to find any other cases that may not have been identified on previous searches. The case reports were obtained and patient, disease, and valve factors were compiled and synthesized.

Results: Eight publications were found from 1954 to 2012 reporting 9 cases of urate deposition on cardiac valves. All cases had known tophaceous gout, mean age 60.9, and 89% were male. The mean uric acid concentration of plasma ox-LDL was also closely associated with the high incidence of atherosclerotic diseases in patients with gout might be closely related to increased ox-LDL levels. However, the study about the relationship between the level of ox-LDL and the inflammatory status in gout patients are rare. The level of ox-LDL was measured using the latex enhanced immune transmission turbidimetric method. We analyzed the comparison between demographic, inflammatory markers, lipid profiles and disease subset.

Results: The primary objective of this study was to assess the oxLDL according to inflammatory status in gouty arthritis. Mean age was 50.4 year-old, 85.7% was woman, 98.9% were male, mean BMI was 25.86 and mean disease duration was 48 months. Among 174 gout patients, 61 patients (35.1%) were acute flare-up, 38 patients (21.8%) were subacute, 67 patients (38.5%) were chronic tophaceous, and 7 patients (4%) were well-controlled stable status.

Disclosure of Interests: Brian LAMoreau Shareholder of: Horizon Pharma, Employee of: Horizon Pharma, Vidhya Chandrasekaran: None declared

AB0877
OXIDIZED LOW DENSITY LIPOPROTEIN IS CORRELATED WITH INFLAMMATORY STATUS IN GOUTY ARTHRITIS
Kyuna Ann Lee1, Suyeon Park2, Bo Young Kim3, Yun Sung Kim4, Jung Ran Cho5, Hyun-Sook Kim1. 1The Soonchunhyang University Seoul Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2The Soonchunhyang University Seoul Hospital, Biostatistics, Seoul, Korea, Rep. of (South Korea); 3Gangneung Asan Hospital, Internal Medicine, Gangneung, Korea, Rep. of (South Korea); 4Chosun University Hospital, Internal Medicine, Gwangju, Korea, Rep. of (South Korea); 5Pohang St. Mary's Hospital, Internal Medicine, Pohang, Korea, Rep. of (South Korea).

Background: Lipid peroxidation and oxidized LDL (oxLDL) are hallmarks in the development of various metabolic, cardiovascular and other inflammatory diseases. Cholesterol crystals and oxLDL, which are considerably present in atherosclerotic plaques, can activate inflammamasomes. The concentration of plasma ox-LDL was also closely associated with the high incidence of atherosclerotic diseases in patients with gout might be closely related to increased ox-LDL levels. However, the study about the relationship between the level of ox-LDL and the inflammatory status in gout patients are rare.

Objectives: We aimed to the relationships between ox-LDL level, inflammatory markers and uric acid lowering agents in gout patients.

Methods: One hundred seventy four gout patients were included from the 3 institutions from 2014 to 2017. Details of demographic and clinical features along with laboratory parameters, ESR, CRP, lipid profiles, oxLDL, and disease status were noted in patients with gout. We classified inflammatory status as acute, subacute chronic tophaceous and well-controlled status. The level of ox-LDL was measured using the latex enhanced immune transmission turbidimetric method. We analyzed the comparison between demographic, inflammatory markers, lipid profiles and disease subset.

Results: The primary objective of this study was to assess the oxLDL according to inflammatory status in gouty arthritis. Mean age was 50.4 year-old, 85.7% was woman, 98.9% were male, mean BMI was 25.86 and mean disease duration was 48 months. Among 174 gout patients, 61 patients (35.1%) were acute flare-up, 38 patients (21.8%) were subacute, 67 patients (38.5%) were chronic tophaceous, and 7 patients (4%) were well-controlled stable status.

Age, sex, BMI, and accompanying disease were not statistically different in the 4 groups according to inflammatory status. However, it showed statistically significant differences in the use of glucocorticoid and uric acid lowering agents. There was no significant difference in uric acid in laboratory tests, but there was a significant difference between ESR and CRP in each disease group. Especially, oxLDL showed difference according

to inflammatory state of disease.
Conclusion: The levels of oxLDL in gout patients were significantly different according to inflammatory status. The oxLDL may be associated with inflammation process in gout patients.

CARDIOVASCULAR GOUT

Eleanor Mikhnevich1, Tatiana Pavlovich2. 1Belarusian State Medical University, Internal Medicine, Rheumatology, Minsk, Belarus; 2Belarusian State Medical University, Internal Medicine, Minsk, Belarus

Background: Gout is characterized by clinical heterogeneity and associated with comorbidities. In clinical practice, we can highlight a group of patients suffering from cardiovascular diseases (CVD) and requiring constant medication, in which the gout joins later.

Objectives: To study the group of patients with gout developing on the basis of pre-existing CVD at the gout onset.

Methods: 240 patients from our Center database with confirmed gout were included in our study. Comorbidities were registered before the gout onset, at its appearance. The study group consisted of 140 patients with CVD: hypertension with duration for 5 years and treated by medication, CHD, atrial fibrillation, CHF and stroke. The comparison group consisted of patients with gout, but without CVD (n=100).

Results: Among patients with pre-existing CVD, the gout debuted later, at the age of 60 (55-65) years (p=0.001). The most frequent comorbidity was HTN – 83.6% (n=177) (OR=7.63; 95%CI 5.33-10.93; χ² = 48.9, p = 0.001). Diabetes mellitus (OR=4.47; 95%CI 3.65-5.48; F = 0.035, p = 0.005) also dominated in this group. At the same time, BMI > 25 kg/m² was prevalent in comparison group (OR=19.46; 95%CI 2.84-133.2; χ² =15.4, p = 0.001). Alcohol abuse was considerably lower – 37.1% (n=52) (OR=54.72;95%CI 17.87-167.44; χ² =48.9, p = 0.001), but medication use was higher – diuretics in 16.4% (n=23) (OR=6.36; 95%CI 5.28-7.64; F=0.045, p = 0.001) and low-dose aspirin in 35.0% (n=49) of patients (OR=17.41; 95%CI 14.80-20.47; F=0.147, p = 0.001). In the study group, the uricemia was evidenced more often (OR=4.13; 95%CI 3.42-4.98; χ² = 12.1, p = 0.001), and the presence of CKD with GFR 60 ml/min/1.73 m² was observed in 15.0% (n=21) of patients (F=0.069, p = 0.001), but not found in the comparison group. The percentage of patients with metabolic syndrome (3 components according to ATP III) did not differ between the groups (p = 0.05).

The number of patients having a concentration of uric acid (UA) in blood 360 mkmol/l and 480 mkmol/l was similar in the both study and comparison groups (p = 0.05). At the same time, the cases of UA > 600 mkmol/l were higher in study group by 13.1% (OR=1.86; 95%CI 1.50-2.38; χ² = 5.94, p = 0.015).

Conclusion: Among our patients, the gout developing on the basis of pre-existing CVD is one of the variant of a debutting gout. The group of patients with so called “cardiovascular gout” is characterized by later gout onset, comorbidities typical for CVD, prevalence of medication (low-dose aspirin, diuretic) and renal mechanisms-triggers of gout. In these patients, the maximal concentration of UA in blood (> 600 mkmol/l) was registered more frequently than in patients with primary gout.

AB0879

INTRATENDINOUS TOPHI IN PATIENTS WITH GOUT: PERSISTENCE IN SPITE OF CLINICAL CONTROL AND SCOPE OF URICEMIA THERAPEUTIC TARGET

Carlos Guillen-Astete, Patricia Moran-Alvarez. Hospital Ramón y Cajal, MADRID, Spain

Background: The tendon affectionation of the gout consists of the deposit of uric acid in territories habitually peritendinosus causing its accumulation in the substance of the body of the tendon or occupying part of it and protruding towards zones of extension. Their presence is usually not clinically accounted for except when they obstruct tendon displacement and therefore their role as part of the clinical picture of patients with gout is often underestimated.

Objectives: The purpose of this study is to determine the ultrasound response of these tophi and the clinical activity has been controlled and the serum uricemia therapeutic target of 6.0mg/dL has been reached.

Methods: Quasi-experimental study type before after. We include 19 patients with tophaceous gout diagnosed between 2012 and 2014 and followed regularly in three rheumatology consultations through clinical, analytical and ultrasound controls. We compared the ultrasound records of static images of your Achilles, patellar and tricipital tendons at the time of diagnosis and in your last review. The longitudinal measurements of the tophi obtained were compared. The independent variable was the evaluation time (before and after) and the dependent variables were the quantification of tophi and their measurements in the longitudinal axis.

Results: All the patients were male. Mean age of 58 SD 6.8 years (Range 29-76). Mean baseline UA 480 mkmol/l. Mean follow-up time to reach therapeutic objective 18 SD 10 months (Range 9-61). Median number of intratendinous tophi (counting one for each tendon of 6 possible tendons): 2. Fashion 2 (Range 1-4). Mean longitudinal diameters: Achilles (8 cases) 18.3 SD 4.2 mm; Rotulian (11 cases) 15.3 SD 3.1 mm; Tricipital (6 cases) 9.8 SD 5.1mm. Hypouricemiant treatment administered: Allopurinol 12; Alopurinol followed by Febuxostat 7; Febuxostat only 0. In the ultrasound study, once the therapeutic objective was reached, the accounting of the intratendinous tophi Achilles and patellar tophi remained identical. One tricipital tofo disappeared completely and the rest were maintained. The longitudinal measurements of tophi that did not disappear were as follows: Achilles 18.0 SD 3.2mm (P=0.805); Rotulian 14.9 SD 3.2 (P=0.803); Tricipital 7.9 SD 3.2 (N=5, P=0.489). No differences were detected when comparing the two hypouricemiant treatment sequences.

Conclusion: Although this is a small retrospective cohort, our results show a poor ultrasound response of reduction of intratendinous tophi reaching the serum uricemia target of 6.0mg/dL. This observation raises two reflections: (1) On the one hand, and as already proposed, the therapeutic target of uricemia in our patients could require an even stricter adjustment and (2) on the other hand, it would be necessary to consider whether the inclusion of regulated ultrasound scans of certain tendons would have clinical value if they were routinely incorporated into the study of our patients with gout.

ACUTE GOUTY ARTHRITIS RELATED EMERGENCY DEPARTMENT VISITS AMONG US VETERANS: CHARACTERISTICS, PREDICTORS AND AREAS OF IMPROVEMENT

Debendra Pattanaik, Zunaira Ali, Amado Freire. University of Tennessee Health Science Center, Memphis, United States of America

Background: Gout is quite prevalent among United States veterans and many do not achieve optimal levels of uric acid (< 6 mg/dl). This suggests that there are large number of veterans who are at risk for gout flare. Therefore, utilizing health care resources such as emergency department (ED) and outpatient office visits. We investigated the ED visit patterns among veterans with history of gout and the factors contributing to ED visits.

Objectives: The objectives of the study were to identify the risk factors for ED visits by veterans for gout flare up. Future remediation of the risk factors would reduce utilization of health care resources.

Methods: This was a retrospective chart review of veterans diagnosed with gout in the ED at VA Medical Center Memphis TN between January 1st, 2011 and December 31st, 2016 using ICD-9 codes. A rheumatologist reviewed all cases and only confirmed cases of gout were included in the study. There were 2516 veterans seen for acute gout during the...
study period and of these, random selection of 10% i.e. 250 subjects were considered for the study. Baseline demographics, medical comorbidities, lab, uric acid level, medication history, and medication whether they were followed by rheumatologist or primary care physician (PCP) were extracted from electronic health record.

We used Stat view version 5.01 (SAS Institute Inc. Cary, NC) for analysis. We described data with frequency terms, continuous data by mean ± standard deviation, and categorical data by percent. Univariate analysis identified predictors of interest that were later incorporated in the best fit model with logistic regression. A p value of ≤ 0.05 was considered statistically significant.

**Results:** The mean age of subjects was 61 ±11 years, mean BMI was 32 ± 7 kg/m². 98% were males and 80% were African Americans. 26% of subjects had history of alcohol use, 89% had hypertension and 88% had chronic kidney disease (CKD stage ≥2). 86% of the subjects were followed by primary care physician (PCP), and 5% of them were followed by rheumatologist and rest of the 9% were non-compliant. 30% of subjects were receiving urate-lowering therapy and 23% of patients were on gout prophylactic therapy. 21% of patients had multiple visits (≥ 2) visits to the ED. The mean uric acid level was 8.5 ± 2.1 mg/dl for subjects with single visit compared to 9.04 ± 2.1 mg/dl for multiple visits to the ED (P = 0.09).

In the univariate analysis, CKD (stage ≥2) and higher uric acid level were associated with increased ED visits (P = 0.09) and not being on urate lowering therapy was also associated with increased frequency of ED visits (P = 0.02). On logistic regression analysis, irrespective of the type of physician follow up (PCP vs rheumatologist), being on urate-lowering therapy was associated with reduced frequency of ED visits (P =0.02).

**Conclusion:** Urate-lowering therapy (ULT) was associated with reduced ED visit irrespective of follow up care provided by PCP or rheumatologist. Given that only one third of our patients were on ULT, improving ULT dispensing by the physician and patient compliance with ULT can decrease health care utilization.

AB0881

**DESCRIPTIVE ANALYSIS OF PATIENTS WITH OSTEOPENIA IMPERFECTA IN A TERTIARY HOSPITAL IN MADRID**

**Cristina Piojo Moralla,** Maria Andreina Teran Tínez, Jose Renato Quiñones Torres. Hospital Ramón y Cajal, Reumatología, Madrid, Spain

**Background:** Osteogenesis imperfecta (OI) is an inherited connective tissue disorder with an incidence of 1 per 20,000 births. It is also called “brittle bone disease” and is most commonly caused by mutations in genes encoding type I collagen or proteins involved in its posttranslational modification. Most patients have an autosomal dominant mutation in COLA1 or COLA2. The severity of the clinical presentation depends upon the effect of the mutation that occurs, having many different phenotypic presentations. In the most severe forms, patients suffer multiple fractures with minimal or no trauma whereas mild forms may only manifest with premature osteoporosis. Attending to the clinical presentation, radiographic findings and the mutations, most OI patients can be classified in type I-III. Different types have been described: type I and III have the most prevalent and severe treatments have been studied, but none has been found to be curative. The most frequently used are bisphosphonates which try to prevent bone fragility and reduce the number of fractures but none have been approved specifically for use in either children or adults with OI.

**Objectives:** The aim of the study is to analyse the clinical characteristics of osteogenesis imperfecta (OI) patients followed in our hospital and to evaluate the different treatments used in their management.

**Methods:** A retrospective study was conducted. All patients diagnosed with OI and seen in the different departments of our hospital were included and analyzed. A database was created, including both clinical and epidemiological data and a descriptive analysis was carried out.

**Results:** 25 patients with OI are currently being followed up in our hospital and were included. Although most patients were being followed in both the Rheumatology (9) and Orthopedic units (9), 4 were being followed by pediatrics, 1 by endocrinology, 1 by internal medicine and 1 by geriatrics. 72% were female (18) with a mean age at diagnosis of 17 years (range: 1 month to 67 years). All of them had had previous fracture before the diagnosis. The number of fractures during their follow-up varied according to the different types of OI, with an average of 6 fractures (range 3-24) per patient and an average of at least 4.16 orthopedic surgeries each. 12/25 patients were diagnosed in the first ten years of life, being the ones that accumulated the highest number of fractures (96 vs. 54). Only 3 patients had family background of OI, all of them being type I. Although only 9/25 patients had undergone genetic study, all 3 cases of type III, which is the most severe, debuted in the first decade of life. Phenotypically 14/25 (56%) had short stature and 18/25 (72%) had blue sclerae, being these less frequent in those patients with debut after 20 years of age, of which 57% (4/7) had normal sclerotics. Only 4 patients suffered from dentinogenesis imperfecta (16%) and 3 from osteosclerosis and had hearing problems (12%). Regarding the treatment received, 60% of the patients (15/25) were on current treatment with oral calcium and 64% (16/25) with oral vitamin D supplements. On the other hand only 60% of the patients received bisphosphonates (4 were being treated with risedronate, 7 with pamidronate, and 4 had received both zoledronic and pamidronate during their lives).

**Conclusion:** Although a rare disease, OI has an important morbimortality in most patients. Severe cases suffer multiple fractures and undergo several orthopedic surgeries during their lifes. Given the high cost of genetic analysis, this is reserved for the most severe cases which tend to debut at younger ages and are mostly type III. Treatment for this condition is not standardized and is generally reserved for type III OI patients, which is one of the most severe types. Bisphosphonates, calcium and vitamin D are usually used in order to try to prevent new fragility fractures but in most cases fracture rates remain high despite treatment.

AB0882

**ACROMEGALY DO NOT INCREASE THE RISK OF VERTEBRAL FRACTURES: A RETROSPECTIVE AND PROSPECTIVE STUDY IN 50 PATIENTS**

Charlotte Piarot, Clairette Kochmann, Delphine Druf, Bertrand Cariou, Yves Maugars1, Benoît Le Goff, Rachel Guilhot, Nantes University Hospital, Rheumatology, Nantes, France, Nantes University Hospital, Endocrinology, Nantes, France

**Background:** Patients with acromegaly appear to be at an increased risk of vertebral fractures (VFs) despite normal bone mineral density (BMD). However, these patients could have several endocrine deficits as hypogonadism known to increase the fracture risk independently of the GH effects. The physiopathology of GH excess on bone is unclear. In addition, patients with acromegaly have radiological deformations of the spine, called Erdheim’s syndrome, which can overestimate the radiological vertebral fractures.

**Objectives:** Investigate the prevalence of VFs in our cohort of patients with acromegaly.

**Methods:** It was a monocentric, retrospective and prospective study. The rheumatologic evaluation was less than 3 years for all patients. For 40% of patients, this evaluation was prospective after the begin of the study. Acromegaly patients younger than 80 and followed at the Nantes University hospital in January 2018 were included. Patients were excluded if they had a rheumatologic or endocrinologic disease interfering with the results. The prevalence of radiological vertebral fractures was evaluated on conventional lombor and thoracic spine radiographs using Genant’s semi-quantitative assessment. We also assessed qualitative abnormalities of the spine using 3 criteria: osteophytes, disc space narrowing and cuneiform aspect of vertebrae. The X-rays were read by two rheumatologists independently. We analyzed BMD at lumbar spine and total hip, endocrine status and quality of life through 3 questionnaires (AcroQol, specific of acromegaly; Oswestry evaluating the functional impact of pain; HAQ evaluating the functional capacity).

**Results:** We included 56 patients. 6 patients were excluded : 3 declined, 1 had another endocrinologic disorder (adrenocortical and panhypopituitarism). We analyzed the prevalence of VFs in 50 patients (19 females, 31 males, median age 53, range 28-79). The average of time between the diagnosis of acromegaly and the last rheumatological evaluation was 9.1 years. 3 patients (6.1%) had a VF : 1 grade 1 and 2 grade 2 of Genant’s assessment. 28% patients were osteopenic and 12% were osteoporotic. Among fractured patients, 2 were osteoporotic and 1 osteopenic. All of them were hyponadal (100% substitu- ted), 16% had central adrenal insufficiency (100% substituted). 14 women were menopaused (74% of women). Thoracic spine was deformed in 31 patients (61%) and lumbar spine in 21 patients (43%), for at least
one of the 3 criteria. Patients with spine deformation were older (p=0.003), with higher BMI (p=0.004) and had a trend to be more hypertensive (p=0.06). Concerning quality of life, AcroQoL’s average was 70.9% (score 0 to 100, maximal quality of life =100, range 32-98), HAQ’s average was 0.18 (score 0 to 3, maximal quality of life 0, range 0-1.38) and Oswestry’s average was 9.8 (score 0 to 100, maximal quality of life 0, range 0-44).

**Conclusion:** This study shows for the first time that acromegaly patients are not at an increased risk of vertebral fractures. This result differs from the literature that reported more than 30% of VF in this population. Our study bring several points of explanation. First, the vertebral abnormalities were frequent in our patients and can overestimate the VFs without a qualitative analysis of the X-ray. Secondly, the right endocrine balance plays an important role in osteoporosis. Our patients were well supplemented, it can reduce the risk of osteoporosis. More studies are needed to confirm this new hypothesis.

**AB0883**

**SYSTEMIC INFLAMMATION AND ATHEROSCLEROSIS IN PATIENTS WITH GOUT. RESULTS FROM THE NOR-GOUT STUDY**

Silvia Rollefstad1, Till Uhlig2, Lars Fridjof Karoliussen2, Hilde Berner Hammer3, Anne Grete Semb1, 1Diakonhjemmet Hospital, Preventive Cardio-Rheuma clinic, Department of Rheumatology, Oslo, Norway; 2Diakonhjemmet Hospital, Rheumatology, Oslo, Norway

**Background:** The association between gout and cardiovascular disease (CVD) is well known,1 whereas mechanisms behind this association are poorly understood.

**Objectives:** This study aimed to evaluate factors associated with asymptomatic carotid atherosclerosis in patients with gout.

**Methods:** In this prospective study patients with crystal-proven gout were included after a recent diseaasefase, if the serum urate level was >360 μmol/L (>6 mg/dl). We analysed baseline data in patients without established CVD who were referred to a CVD risk evaluation, including ultrasound of the carotid arteries, blood pressure measurement and laboratory tests. Carotid atherosclerotic plaques were defined in the longitudinal view of the carotid arteries according to the Mannheim criteria. Lipid concentrations were measured and standardization was done for age and sex. All covariates were assessed at baseline, except age and sex.

**Results:** Of the 79 gout patients included, 10% were females, and mean (SD) age was 52.1±13.1 years. Thirty-two (40.5%) had carotid plaques (Table). Only 9.3% were current smokers, while mean (SD) body mass index was 29.1±4.7 kg/m². Systolic blood pressure was in the normal range (134±15 mmHg), although 29.1% of the patients were treated with anti-hypertensive agents. In univariate analyses, higher age, hypertension and higher erythrocyte sedimentation rate (as a marker of systemic inflammation) were significantly associated with the presence of carotid plaques (p=0.01 and p=0.04, respectively) (Figure). Serum urate levels or disease duration were not associated with carotid plaques (p=0.27 and p=0.44, respectively).

**Conclusion:** Our results indicate an association between systemic inflammation and atherosclerosis in patients with gout. To be able to efficiently prevent CVD in this patient group, prospective studies with larger sample sizes are needed to elucidate the mechanisms behind the increased risk of CVD in gout patients.

**CLINICAL AND DEMOGRAPHIC CHARACTERISTICS OF PATIENTS WITH OCHRONOTIC ARTHROPATHY**

Tuba Yüce İlnel1, Pelin Teke Kısak1, Ali Balci2, Sadettin Ulaş1, Zümrüt Arslan2, Bürro Okturk Hismi3, Nur Arslan4, Fatos Onen5, İsmail Surel6, 1Dokuz Eylul University, University of Medicine, Department Of Internal Medicine, Division Of Rheumatology, Izmir, Turkey; 2Dokuz Eylul University, Faculty of Medicine, Division Of Pediatric Metabolism and Nutrition, İzmir, Turkey; 3Dokuz Eylul University, Faculty of Medicine, Division Of Rheumatology, Izmir, Turkey; 4Tupeko Education and Research Hospital, İzmir, Turkey

**Background:** Alkaptonuria (AKU) is a metabolic disorder that causes accumulation of oxidized homogentisic acid (HGA) in the connective tissues. The excessive deposition of HGA and its metabolites can cause...
joint destruction and skeletal abnormalities which the entity is clinically referred as ochronotic arthropathy (OA) [1].

Objectives: To assess clinical, demographic features and radiographic findings in patients with OA.

Methods: Adult AKU patients registered in the database were included in the study. All patients investigated for the presence of OA and inflammatory symptoms. Patients with musculoskeletal symptoms (MSK) underwent conventional X-rays and routine laboratory evaluation. In cases suggestive of inflammatory disease additional work-up such as autoantibodies, HLA-B27 and MRI with inflammatory protocol were performed.

Results: Six out of 15 patients had symptoms compatible with OA (40%; 4 male [M], 2 female [F], median age 56 [51-62] years). The median duration of MSK symptoms was 7 (2-19) years. None of the patients had family history of rheumatologic disease. Baseline CRP were normal in all patients. The HLA-B27 test was negative in all cases. One patient had high titers of rheumatoid factor along with positive anti-CCP that were accompanying erosive arthritis on MCP joints by X-rays. Two patient had positive ANA. All patients had chronic back pain and had changes compatible with OA in their spines (narrowing of the intervertebral spaces, vacuum phenomenon and intervertebral disc calcification). Two patient had inflammatory type of pain character (IBP). Radiographic sacroilitis according to modified New York criteria was present in 2 cases. Inflammatory spine and SIJ lesions were detected by MRI in 1 patient. Extra-articular involvement including enthesis (1 patient), interstitial lung disease (1 patient) and scleritis (1 patient) was also noted. The clinical and demographic characteristics of the OA are given in Table 1.

Conclusion: There was a high prevalence of inflammatory arthritis (2 axSpA; 1 RA) in OA (50%) which contradicts with the common concept that OA is a degenerative disorder. According to our results, inflammatory disease should be carefully screened in OA patients as accumulated metabolic products may trigger inflammatory pathways.

AB0886
THE RELATIONSHIP BETWEEN METABOLIC SYNDROME SEVERITY AND THE RISK OF MORTALITY IN GOUT PATIENTS: A POPULATION-BASED STUDY
Naomi Schlesinger, Mohamed Elsaid, Vinod Rustgi. Rutgers Robert Wood Johnson Medical School, Medicine, New Brunswick, United States of America

Background: Metabolic syndrome (MetS) is common amongst gout patients. The MetS is diagnosed when a patient has at least 3 of the following 5 conditions of hyperglycemia, hypertension, hypertriglyceridemia, low high-density lipoprotein (HDL) cholesterol or abdominal obesity. Little is known about the relationship between the cumulative effects of all five metabolic syndrome conditions and the risk of mortality among adult patients with gout. Metabolic Syndrome Severity Score (MetSSS) is a new clinical prediction score that employs available components (sex, age, race, systolic blood pressure, waistline circumference, high-density lipoprotein, triglycerides and fasting blood glucose). MetSSS is a validated summary score that accounts for the combined effects of all 5 metabolic features. MetSSS allows examination of associations between MetS severity and the risk of mortality. Objectives: to use the MetSSS to examine the overall associations between MetS severity and the risk of mortality related to all-causes, cardiovascular disease and diabetes amongst United States (US) gout patients.

Methods: Mortality-linked data for 12,101 adults aged 18 to 90 years who participated in the Third National Health and Nutrition Examination Survey (NHANES III 1988-1994) was analyzed. Data from NHANES III were linked to national mortality records for all participants up to time of death or end of study (i.e. 23 years following initial recruitment). All 5 metabolic features were used to calculate gender-race/ethnicity specific MetSSS Z-scores in gout patients. The Z-score is the number of standard deviations from the mean a data point is and allows a continuous representation of all MetS conditions while accounting for gender-race/ethnicity disparities.

Results: A total of 3,381 deaths were observed, of whom 215 had gout. The prevalence of gout amongst adults was 2.59% (95% CI: 2.13%-3.05%). Moderate to high MetS severity was significantly prevalent among gout patients (47.33% vs. 21.16% no gout; P-value <0.0001). The mean MetSSS Z-score for gout patients was significantly higher than those without gout (0.71 vs. -0.04 no gout; P-value <0.0001). For gout patients, a one-unit increase in MetSSS score was associated with a significant increase in the risk of all-cause mortality Adjusted Hazard Ratio (aHR) 1.46 (95% CI: 1.13, 1.87).

In a disease-specific survival model, a one-unit increase in MetSSS score was associated with a aHR 1.62 (95% CI; 1.21, 2.15) increase in heart disease related mortality amongst gout patients. Amongst those with gout, a one-unit increase in MetSSS score was associated with increased risks of diabetes- and hypertension-related mortalities aHR 2.53 (95% CI; 1.43, 4.62), aHR 1.73 (95% CI; 1.07, 2.79), respectively.

Conclusion: The Z score calculation in our study allowed a quantification of increased diabetes- and hypertension-related mortalities, all-cause and cardiovascular mortality in patients with gout. Use of the MetSSS can provide an opportunity to identify patients at highest risk influencing patients to change their lifestyle and better comply with treatment.

AB0886
IS THE SENSE OF SMELL IMPAIRED IN GOUT PATIENTS?
Naomi Schlesinger, Mariam Alkhan, Richard Dohy. Rutgers Robert Wood Johnson Medical School, New Brunswick, United States of America; Perelman School of Medicine, University of Pennsylvania, Department of Otorhinolaryngology, Philadelphia, United States of America.

Background: The sense of smell is sensitive to hundreds of thousands of odorants. Smell disorders significantly compromise the quality of life. A National Health and Nutrition Examination Survey (NHANES) 2013-2014 survey among US population aged 40 years of age and older years found smell dysfunction in ~ 20.5 million (13.5%) of Americans (1). Prevalence increased with age. Other factors influencing the sense of smell include ethnicity, smoking, medications, head trauma, chronic sinusitis, upper respiratory tract infections; alcoholism and neurological disorders.

The University of Pennsylvania Smell Identification Test (UPSIT) (2) is a well-validated test of olfactory function that correlates with odor detection and other quantitative measures of olfaction. This test has become the ‘gold standard’ for olfactory testing and is comprised of four test booklets, each containing 10 microencapsulated (scratch & sniff) odors.

Patients with gout, the most common inflammatory arthritis, frequently have multiple associated comorbidities, affecting many organs and aspects of one’s health.

REFERENCES
Objectives: To determine whether gout patients have an impaired sense of smell.

Methods: This was a cross-sectional prospective study of gout patients seen in our rheumatology clinic. The first 30 clinic patients were recruited during the period 7/15/17-5/25/18. Each patient was administered the 40-item UPSIT. UPSIT scores were compared to age- and sex-matched controls from a normative database maintained at the University of Pennsylvania Smell and Taste Center using a paired t-test.

Results: Gout patients ranged in age from 31 - 86 years (mean: 59 years); 26 (87%) of patients were > 40 years old and included 26 men and 4 women. The duration of gout ranged from 1- 43 years (mean: 9 years), with 19 having gout for >5 years. Visible tophi were observed in 6 patients (33%). C-reactive protein was within normal range except in one gout patient. Serum urate levels ranged from 5.1-12 mg/dL (mean: 6.29 mg/dL). Two patients were current smokers; both have microsomia. No patients had head trauma, chronic sinusitis, upper respiratory tract infections, alcoholism or neurological disorders. The mean UPSIT scores of the two groups did not differ significantly [respective patient and control means (SDs) = 31.40 (5.79) and 31.80 (4.37); t 29 = -0.342, p = 0.74].

Conclusion: This is the first study to quantitatively assess smell function in patients with gout. Despite being a systemic inflammatory disease, with multiple associated comorbidities, we did not find a statistically significant effect of gout on smell function using a well validated olfactory test.

A SURVEY FOR DIAGNOSIS AND TREATMENT OF PATIENTS WITH GOUT IN KOREA
Mi Ryung Seo, Ji Na Yeo, Hee Jung Ryu, HYo-Jin Choi, Han Joo Baek. Gil Medical Center, Gachon University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Incheon, Korea, Rep. of (South Korea)

Background: The prevalence and incidence of gout has risen over the past few decades and the socioeconomic costs of gout have been increasing accordingly, but it is unclear whether proper medical care is provided for patients with gout.

Objectives: This study aims to investigate the actual status and adequacy of diagnosis and management of gout patients.

Methods: The patients with gout who visited between November 2017 and February 2018 were consecutively enrolled. Data were collected using a pre-designed questionnaire and reviews of medical records. The collected data included diagnosis and management of gout before starting a steady treatment in our clinic, and disease status at first visit to our clinic.

Results: In total, 172 gout patients were enrolled. The average age of the patients was 55 (interquartile range (IQR): 45-66) years, and 94.2% were men. The average disease duration was 8 (IQR: 4-13) years. The average age of first gout symptoms was 45 (IQR: 36-53) years. The first symptom started in the feet for 93.4% of patients. The patients in which the first symptom region was around large joints were 35.1%, and 17.3% of patients developed first gout symptoms around multiple joints. Several patients (64%) visited the hospital directly after their first acute gout attack, and 84.4% were instructed to examine gout patients were orthopedic surgery (38.2%), emergency doctors (23.6%), and rheumatologist (16%). Upon initial medical examination, 67% of patients were clinically diagnosed or suspected with gout. Monosodium urate crystals in synovial fluid or tophi were confirmed in 10.5%. Furthermore, 31% of patients had a history of pharmacology urate lowering therapy (ULT) after acute gout attack, and 84.4% were indicated for pharmacology ULT upon first visit to our clinic. Additionally, 47.6% of patients showed symptoms of chronic kidney disease, past urolithiasis, or tophi, and 52.4% suffered from ≥ 2 gout attacks/year. However, only 11.3% of patients were receiving continuous ULT before visiting our clinic.

Conclusion: Most patients were clinically diagnosed without appropriate tests for gout diagnosis, such as joint aspiration, and only a very small number of patients were receiving adequate pharmacologic ULT. The management of gout seems to be inadequate in many respects.

ULTRASOUND FEATURES IN GOUT: A COMPARATIVE ANALYSIS WITH MATCHED CONTROL
Joana Silva1, Daniela Faria1, Joana Neves1, Marcos Cerqueira1, Joana Rodrigues1, Soraia Azevedo1, Sérgio Alcino1, José Tavares-Costa1, Carmo Afonso1, Daniela Peixoto1, Filipa Teixeira1. Alto Minho, Rheumatology, Ponte de Lima, Portugal, Hospital de Braga, Rheumatology, Braga, Portugal

Background: Gout is a frequent inflammatory disease characterized by deposition of monosodium urate crystals in joints and tissues in the presence of hyperuricemia (1). Ultrasound (US) is a simple imaging technique that has gained interest in the assessment of individuals with gout due to its ability to identify inflammation and joint damage, as well as crystal deposition. The most characteristic gout US findings are the presence of intra-articular aggregates and the double contour (DC) signal, included in the 2015 ACR/EULAR classification criteria.

Objectives: To identify potential differentiating US findings between individuals with gout and matched controls.

Methods: A cross-sectional study was conducted, including 57 gout adult patients and 32 adult individuals with a normal uricemia, matched by age and gender. Sociodemographic, clinical and analytical data were collected. Bilateral US grey scale evaluation of the 1st metatarsophalangeal joint (MTP1), 2nd metacarpophalangeal joint (MCP2) and knee was performed in all participants. The following findings were assessed: intra-articular effusion, synovial hypertrophy, bone erosion, DC signal and intra-articular deposits. None of the participants presented with clinical signs of arthritis at the time of the evaluation.

Results: The mean age of gout patients and healthy individuals was 63.3 ±12.6 and 63.8±10.5 years, respectively. The majority of the gout patients were male (87.7%), 77.2% had previous history of podagra and 26.3% had tophi. Mean disease duration was 4.3 years. Mean uricemia was 6.7 ±2.0 mg/dl in gout patients and 4.9±0.9 mg/dl in the control group. At the time of the study, 31 patients (54.4%) were treated with allopurinol, 9 (15.8%) with fenbuxostat, and both allopurinol and fenbuxostat, and 16 (28%) were not on urate lowering therapy. Comparatively to the control group, in the MTP1, patients with gout presented more frequently with synovial hypertrophy (26 vs 0, p<0.001), bone erosion (19 vs 0, p<0.001), DC signal (7 vs 0, p<0.05) and intra-articular aggregates (8 vs 0, p<0.05). At the knee, patients showed more frequently with bone erosion (19 vs 2, p<0.001), synovial hypertrophy (26 vs 1, p<0.001) and DC signal (8 vs 0, p<0.05). At the MCP2, only the presence of erosion was significantly more common in the gout group (8 vs 0, p<0.05). DC signal was found in 17 patients and in none of the healthy subjects (p<0.001); this finding was more frequently observed at the knee. There was an association between previous gout crisis in the MTP1 and the presence of erosion in this joint (p<0.04). An association was found between the presence of tophi and bone erosion (p<0.001), DC signal (p<0.05) and intra-articular aggregates (p=0.006). There was no association between uricemia levels, disease duration and the different US findings.
Conclusion: In this study, the presence of synovial hypertrophy, erosions, DC signal and intra-articular deposits were the most frequent US findings in patients with gout. Moreover, these findings at the MTP1 joint allowed to distinguish between gout patients and matched control subjects. US seems to be useful to demonstrate evocative signs of crystal accumulation, inflammation or joint damage, even in the absence of overt arthropit.

AB0890 EFFECT OF DIFFERENT TYPES OF URIC ACID-LOWERING DRUGS ON GOUT ATTACK
Ya-Ling Wang1, Li Lin1, Jinhuang Tang2, Yu-Jie Tang2, Jun-Qun Lu1, Hong-Liang Zhang2, Zi-Wei Zhu1, Anhui Medical University Affiliated Provincial Hospital, Anhui Medical University Affiliated Provincial Hospital, Department of Rheumatology and Immunology, Hefei, Anhui, China;

Background: Gout is an inflammatory arthritis associated with hyperuricemia which is caused by purine metabolism disorders. General uric acid lowering treatment sometimes causes the onset of gout, but the specific cause is not clear. Our group has found that adenine nucleoside triphosphate (ATP) plays an important role in the pathogenesis of gout. It synergizes with MSU to stimulate the secretion of IL-1β, leading to the onset of gout. 1-3 The xanthine oxidase inhibitors promote the production of ATP, while the drugs that promote the excretion of uric acid does not affect ATP production. Therefore, we speculate that gout attacks induced by allopurinol and febuxostat are related to the role that ATP plays in the pathogenesis of gout.

Objectives: To compare the effects of drugs that inhibit uric acid production and promote uric acid excretion on gout.

Methods: A case-control study was used to compare the changes in serum uric acid concentration and observe whether the patients would suffer gout attacks within one month. The gout patients complied with the standard that the number of gout attacks did not exceed three times, as well as more than one time within the past six months, were selected. And patients with other chronic inflammatory and infectious diseases were excluded.

Results: A total of 148 patients with gout in the Department of Rheumatology and Immunology of Anhui Provincial Hospital were collected, all of whom were male. According to the patients taking uric acid-lowering drugs, they were divided into four groups: group A: control group (no uric acid-lowering treatment, n=38); group B: febuxostat group (40 mg Nadolol Qd, n=38); group C: allopurinol group (0.1 g Bid, n=11); group D: benzbromarone group (50mg Qd, n=38). The statistical results are as follows: (1) The levels of serum uric acid in group B, C and D were significantly decreased after uric acid-lowering treatment compared with those before treatment (B: 389.6±88.9 vs 547.5±93.0, P<0.05; D: 376.2±108.5 vs 557.3±101.8) within one month, and there was no significant difference among the three groups. (2) Comparison of gouty arthritis recurrence rates: The recurrence rate of gout patients in group B was 33.3%, and it was 18.2% in group C, which was significantly higher than that in group D (11.1%), the difference was statistically significant (P<0.05); the recurrence rate of gout patients in group A was 14.3%, and there was no significant difference compared with group D (P>0.05); the recurrence rate of gout patients treated by drugs that inhibited uric acid production (B+C group) was 31.2%, which was significantly higher than patients treated by drugs that promoted uric acid excretion (D group) 11.1%, the difference was statistically significant (P<0.05).

Conclusion: Under the same uric acid-lowering intensity, the drugs that inhibit uric acid production can induce gout attacks during the process of uric acid lowering, while the drugs that promote uric acid excretion has less effect on the recurrence of gouty arthritis.

Disclosure of Interests: None declared
Background: Hyperuricemia and gout has been described as metabolic complications in patients with more extensive Paget’s disease, with a very variable prevalence. However, there is no data about fluctuations of uric acid levels associated with its treatment and its correlation with alkaline phosphatase variations during acute gout attacks.

Objectives: To analyze the frequency of hyperuricemia and gout in patients with a diagnosis of Paget’s disease of bone (PD) and to establish the correlation between the activity of Paget’s disease and its treatment in the fluctuations of uric acid levels.

Methods: Patients with Paget’s disease and with scintigraphic uptake suggestive of activity were included. A database was created including demographic information, the presence of symptoms associated with PD, its type (monostotic or polyostotic), alkaline phosphatase (AP) and uric acid (UA) levels at diagnosis and the treatment received. AP and UA levels after treatment were also collected as well as the presence of possible hyperuricemic risk factors (HRF), history of gout and levels of AP and UA during gout attacks, if any. Finally data was analyzed using SPSS v21.

Results: A total of 95 patients were included with a mean age of 70.59 years (range 45-89), with 56% of them being women. The mean values of AP and UA at diagnosis were 178.05±82.81 mg/dL and 5.84±1.74 mg/dL, respectively. 58.9% of the patients had monostotic involvement (56/95) and only 53.12% had associated symptoms (51/95), whereas in the rest of the patients PD was an incidental finding. 70.83% did not present HRF and 56 patients (58.9%) had received treatment for their PD (41% of them with zoledronic acid). Pearson correlation between PA and UA levels was found moderately positive (0.710 with p<0.0005) and 50.52% of the patients (48/95) had UA levels above 6mg/dL at the time of diagnosis, with a mean of 7.10 mg/dl ±1.74. In 93.5% of the cases there was a decrease in UA levels after the treatment for PD, with a mean decrease of 0.78±1.3 mg/dL over the baseline value at one year of follow-up. Only 11.57% of the patients in our cohort presented gout symptoms during their follow-up, with an increase in AP levels at the time of the attack in 63.63% of the cases.

Conclusion: In our cohort, there was a moderate positive correlation between the elevation of AP and UA in patients with active Paget’s disease. Treatment for PD produced a decrease in UA levels from baseline in most patients. Similarly, during gout attacks, an increase in AP levels could be.

AB0893
WHAT IS THE CHANCE IN AN INDIVIDUAL GOUTY PATIENT THAT DISEASE WILL BE STILL ACTIVE IN A YEAR? PREDICTIVE MODELLING MIGHT COME TO AID
Nicola Ughi1, Greta Carrara2, Anna Zanetti3, Marco Amedeo Cimmino4, Maria Mariana5, Marcella Gobbi4, Fausto Salaffi6, Leonardo Puntz7, Carlomaurizio Montecucco8, Marco Mutucchi-Cerinice9, Giovanni Minisola2, Antonella Zamboni10, Carlo Alberto Scire11, THE STUDY GROUP FOR THE KICK-OFF OF THE ITALIAN NETWORK FOR GOUT STUDY, 1Italian Society for Rheumatology, Milan, Italy, 2University of Milano-Bicocca, Milan, Italy, 3University of Genoa, Genoa, Italy, 4University of Ferrara, Ferrara, Italy, 5Marche Polytechnic University, Jesi (Ancona), Italy, 6SS Giovanni e Paolo Hospital, Venice, Italy, 7IRCCS San Matteo Foundation, Pavia, Italy, 8University of Florence, Florence, Italy, 9San Camillo Hospital, Rome, Italy

Background: The treat-to-target concept is currently applied to gout [1] and a composite outcome to measure disease activity may serve as a target in clinical practice. Strategies for achieving the target are still not individualized and the ability to adjust the treatment on an individual basis using prognostic information from predictive models might help practitioners to identify patients with a high or low probability of remission or disease inactivity.

Objectives: To develop a prediction model for disease inactivity in gouty patients.

Methods: Data were retrieved from the Kick-off of the Italian Network for Gout (KING) observational cohort multicentre study on behalf of the Italian Society for Rheumatology. The gout activity score (VAS) [2,3] was used as validated outcome to define inactive disease (cut off ≤2.5) at 12 months in gouty patients with active disease at baseline and receiving the standard of care in two visits 6 months apart. Logistic regression analyses and backwards elimination of baseline predictors with bootstrap resampling were used to develop parsimonious models. Model performance and correction for optimism were assessed. Missing data were handled through multiple imputation by chained equations (50 completed datasets).

Results: Out of 446 patients enrolled from 30 rheumatology centres, 265 (59%) had active disease at baseline (mean age 63±11 years, male 91%, median disease duration 7 years, tophi 23%, urate lowering therapy 82%, mean serum urate [sUA] levels 6.7±1.6 mg/dL and a 12-month visit. In 34% (65/206) gout was inactive at 12 months. From 20 candidate predictors (complete cases n=150) disease duration, use of nonsteroidal anti-inflammatory drugs (NSAIDs), number of flares in the previous 12 months, presence of tophi, sUA >6 mg/dl, visual analogue scale (VAS) global patient, and baseline GAS were selected. The performance of the four developed models is shown in table. In the completed case analysis (n = 258) the c-statistics (95% confidence interval [CI]) of
models 1 to 4 were 0.79(0.73-0.85), 0.78(0.72-0.84), 0.76(0.70-0.82), and 0.74(0.68-0.81), respectively.

**Conclusion:** These preliminary prediction models for inactive disease showed good performance in gouty patients from a real-life secondary setting. External validation in ad-hoc studies is required to identify the best model and to search for additional predictors and increase its predictive performance.

hepatotoxicity with minor liver function abnormalities and Allopurinol induced mild skin rash was seen in 7/61 (11%) of patients. All adverse events were mild and the therapy was not changed.

Conclusion: Allopurinol increasing dose regimen was efficient in hyperuricaemia treatment, and the target goal was reached by 93.4% of patients. All adverse reactions were mild and did not influence dose regimen at the end of the 6 months period of follow-up.

Infection-related rheumatic diseases

AB0896  REINFECTION OF PROSTHETIC JOINT WITH A DIFFERENT MICROORGANISM: A PROSPECTIVE COHORT STUDY
Caroline Beal, Valerie Zeller, Younes Keremmi, Varina Meyssonnier, Beate Heym, Pascal Chazernain, Simon Marmor. Hopital de la Croix Saint-Simon, Centre de Référence des Infections Osto-Articulaires Complexes, Service de Médecine Interne et Rhumatologie, Paris, France

Background: Treatment failure of prosthetic joint infection (PJI) may be due to relapsing infection (with the same microorganism) or a new infec- tion (with a different microorganism). Data on new prosthetic joint infec- tions (NPJI) are scarce, although they represent a devastating complication and a therapeutic challenge of joint arthroplasty.

Objectives: The aim of this study was to describe epidemiological, clinical and microbiological characteristics of NPJI, their treatment and outcome.

Methods: This observational single-center cohort study was conducted in a French referral center for bone and joint infections. All patients admitted between January 2000 and December 2015 with a documented hip or knee PJs and at least 2 years of follow-up, were identified. Among those, all patients treated in our center for at least two successive PJs, involving the same joint and due to different microorganisms, were included. We compared these patients with a random selection of 124 single*PJs (72 knee and 52 hip prostheses) treated in our center and followed at least 2 years.

Results: Among 909 PJs treated during the study period, 62 patients with 70 NPJJs were included (7.7%) NPJJs developed more frequently in knee (15.7%) than in hip prostheses (4.4%) (p<0.001). Median [range] age was 70 [66-80] years old and median [range] body mass index was 28.7 [25-33] kg/m². Median [range] duration from the first to the NPJI was 70 [66-80] years old and median [range] body mass index was 28.7 [25-33] kg/m². Median [range] duration from the first to the NPJI was 70 [66-80] years old and median [range] body mass index was 28.7 [25-33] kg/m².

The radiological findings showed that 14 patients (53.8%) had abscesses. Soft tissue abscesses were detected in 7 cases with mean size of 1.3 cm [0-9cm]. Bilateral psoas abscess was recorded in one case. Epidural collection was revealed in 3 cases with an average size of 0.3 cm [0-5cm]. Paravertebral and peri-vertebral abscesses were detected in 5 cases. Intradiscal abscesses were observed in 3 cases. Cord compression and involvement of root nerve were noted in respective 6 and 1 cases. Compared to the group without abscesses, subjects with abscesses had higher ESR and the difference was statistically signif- icant (mean ESR 26.83 vs 55.9 mm) (p=0.016). There was no statisti- cally significant link between duration of symptoms or duration of hospitalization and the presence of abscesses. All patients had antibiotic treatment (cocilins and rifampicin). The evolution was favorable in all cases. Surgical intervention was required in one case (evacuation of an epidural abscess).

Conclusion: Our study showed that abscesses are frequent in osteoarticu- lar brucellosis. In spite of the low risk of complication, we have to screen it using a cross section imaging.

Disclosure of Interests: None declared

AB0897  ABSCESS DURING OSTEARTICULAR BRUCELLOSIS: A STUDY OF 26 CASES
Cyrene Daldoul1, Nejla El Amri1, Amine Kalair2, Khadja Baccouch1, Hela Zeglaoui3, Elyes Bouajila1, 1Farhat Hached Hospital, Rheumatology, Sousse, Tunisia, 2Fatrouna Bourguiba Hospital, Rehabilitation, Monastir, Tunisia

Background: Brucellosis remains an important economic and public health problem in developing countries. The osteoarticular involvement is one of the most serious complication mainly due to abscess formation.

Objectives: The aim of our study was to identify the frequency and radiological features of abscesses during osteoarticular brucellosis.

Methods: We conducted a retrospective study including 26 patients who have been hospitalized for osteoarticular brucellosis from 1998 to 2018. The diagnosis of brucellosis was made on the basis of clinical symp- toms, imaging finding (CT scan or MRI) and isolation of bruccella species in blood or tissue specimens and/or a positive Wright agglutination test.

Results: Twenty six patients were included. 15 patients were male. The mean age was 52 years [21-77] the geographical origin of the patients was rural in 80% of the cases. The average duration of symptoms pro- gression was 4.76 months [1-12]. Prominent clinical symptoms were inflammatory pain (all cases), fever (in 21 cases) and sweating (in 17 cases). Weight loss was found in 11 cases (42.8%) and hepatomegaly was found in 1 patient. The physical examination revealed a paresis of the two lower limbs in 2 cases. Brucella agglutination test was ≥1/160 in all cases (mean 1/760). Blood cultures were negative in all cases. Eryth- rocyte sedimentation rate (ESR) and serum C-reactive protein level were ranged between 30-108 mm (mean 70 mm) and 0-125 mg/l (mean 30 mg/l) respectively. Leucopenia was found in only 1 case and leucocytosis in 6 cases. The most frequent osteoarticular involvement was spondylodiscitis in 20 cases (76.9%) affecting the lumbar dorsal and cervical spine in respectively 12, 6 and 2 cases. Sacroiliitis was found in 4 cases (15.4%) and septic arthritis in 2 cases (7.7%). Biopsy was performed in 8 cases, but bacteriological examination was contributory to the diagnosis in 2 cases. The radiological findings showed that 14 patients (53.8%) had abscesses. Soft tissue abscesses were detected in 7 cases with mean size of 1.3 cm [0-9cm]. Bilateral psoas abscess was recorded in one case. Epidural collection was revealed in 3 cases with an average size of 0.3 cm [0-5cm]. Paravertebral and peri-vertebral abscesses were detected in 5 cases. Intradiscal abscesses were observed in 3 cases. Cord compression and involvement of root nerve were noted in respective 6 and 1 cases. Compared to the group without abscesses, subjects with abscesses had higher ESR and the difference was statistically signif- icant (mean ESR 26.83 vs 55.9 mm) (p<0.016). There was no statisti- cally significant link between duration of symptoms or duration of hospitalization and the presence of abscesses. All patients had antibiotic treatment (cocilins and rifampicin). The evolution was favorable in all cases. Surgical intervention was required in one case (evacuation of an epidural abscess).

Conclusion: Our study showed that abscesses are frequent in osteoarticu- lar brucellosis. In spite of the low risk of complication, we have to screen it using a cross section imaging.

AB0898  HIV AND RHUMATOLOGICAL DISEASES. MISDIAGNOSIS OR CONSEQUENCE!
Fatma fayed, Mai Morsy, Marwa Elkhalifa. Alexandria university, rheumatology and immunology unit, Alexandria, Egypt

Background: Human immunodeficiency virus (HIV) infection is pandemic nowadays, more than 35 million people are infected with HIV, with two thirds being resident in Africa.1 The incidence of rheumatic manifesta- tions in HIV infection was reported in about 4 to 71.3% cases in differ- ent studies depending on the stage of the disease and musculoskeletal involvement.2-5

Objectives: The aim of these study to scope the light on HIV associated rheumatic syndromes. Rheumatic disease were a misdiagnosis or not?

Methods: Cross sectional study of patients admitted to rheumatology unit in Alexandria University with a previous diagnosis of autoimmune rheumatic diseases, resistant to treatment, were screened for HIV.

Results: Three patients found to be HIV positive with low CD4+ less than 200 cells mm³ among 130 screened patients. Two patients were diagnosed as beehot disease due to recurrent oral and genital ulcers.
The first one, also had recurrent skin infections associated with bilateral anterior and posterior ulcers. The second one admitted by recurrent oral and genital ulcers associated with severe oral candidiasis, arthritis, erythema nodosum and positive pearly test, The third one diagnosed as peripheral spondyloarthritides admitted with low-grade fever, palmpantar psoriasis as well as acute extensive anterior and posterior ulcers in left eye and chronic anterior and posterior ulcers in right eye with CMV positive.

Conclusion: HIV infection might be misdiagnosed as a rheumatic disease. It is important to screen patients with inflammatory autoimmune rheumatic manifestations for HIV infection for its implications in the diagnosis and management.

AB0899 COMPUTER TOMOGRAPHY GUIDED BIOPSY YIELD IN PYOGENIC VERTEBRAL OSTEOMYELITIS. AN EXAMINATION OF INFLUENCING FACTORS

Jorge Juan Fraga-Quiñó, Paula Gimenez Catala, Roxana Gonzalez Mazaror, Jose Ivorra Cortés, Francisco Miguel Ortiz Sanjuan, Elena Grau Garcia, Cristobal Pérez Perales, Marta De la Rubia Navarro, Inmaculada Chalmeta Verdejo, Luis Gonzalez Puig, Isabel Martinez Cordelila, Rosa Negueroles Albuixech, Cristina Alcañiz Escandell, Jose Eloy Ollor Rodriguez, Elvira Vicens Bernabeu, Carmen Najera Herranz, Ines Canovas Olmos, Maria Tasias Pitarch, Eva Calabuig Muñoz, Miguel Salvart Liét, Jose Andres Roman Ivorra.

Background: Vertebral Osteomyelitis (VO) is an infectious disease that could involve intervertebral space (discitis), which it is avascular in adults, VO and disitis may occur together or independently. Both are frequently the result of a spreading of a distant focus, such as infectious endocarditis or soft tissue infection. Due to the lack of direct blood supply, reliability of blood cultures is low, so biopsy is highly encouraged by current guidelines. Treatment includes long term antibiotic (ATB), that should be initiated after biopsy (if possible) and sometimes, further surgery is needed.

Objectives: To analyze which factors influence the result of a CT-guided biopsy in patients with VO.

Methods: Retrospective observational study including adult patients diagnosed of VO based on the combination of clinical presentation with either a definitive bacteriologic diagnosis and/or imaging studies, who underwent CT-guided biopsy from January 2010 to January 2019. Demographic features, concurrent diseases, clinical history (length of pain and fever prior to admission), laboratory findings, microbiological diagnosis and radiological data were compiled. Days until biopsy from admission, prior antibiotic exposure was also collected. We considered as immuno-suppressed patients those who had rheumatic or inflammatory bowel disease (IBD) or were undergoing immunomodulatory drugs, solid organ transplantation, and patients with an active malignancy or Human Immunodeficiency Virus (HIV) infected. Clinical and radiological history of lumbar stenosis or disc herniation was considered as prior spine pathology. We considered deaths attributable to PVO those which were directly caused by the infectious picture and/or its complications during the next year after diagnosis.

Results: Seventy-two of 109 patients with VO underwent biopsy (66.0%). Thirty-nine brought a positive culture (54.2%). Basal demographic and clinical features are exposed in table 1. Positive cultures included 33 cases (84.61%) of Gram+ infection (23 Staphylococcus and 6 Streptococcus) and 6 (15.39%) by Gram- bacilli (3 cases of Pseudomona aeruginosa, 2 Escherichia coli and 1 Brevundimona spp).

Conclusion: In our population, it has been observed that not a single variable collected showed influence on culture result, although a negative tendency is observed in cases of prior antibiotic exposure, with no significant difference. Since CT guided biopsy is a safe technique, offering an acceptable reliability, our results support its use even in those cases that empirical antibiotic had been already initiated.

AB0900 ACUTE PARAPARESIS AS CLINICAL PRESENTATION OF VERTEBRAL OSTEOMYELITIS

Jorge Juan Fraga-Quiñó, Roxana Gonzalez Mazaror, Jose Ivorra Cortés, Francisco Miguel Ortiz Sanjuan, Elena Grau Garcia, Cristobal Pérez Perales, Marta De la Rubia Navarro, Inmaculada Chalmeta Verdejo, Luis Gonzalez Puig, Isabel Martinez Cordelila, Rosa Negueroles Albuixech, Cristina Alcañiz Escandell, Jose Eloy Ollor Rodriguez, Elvira Vicens Bernabeu, Carmen Najera Herranz, Ines Canovas Olmos, Maria Tasias Pitarch, Eva Calabuig Muñoz, Miguel Salvart Liét, Jose Andres Roman Ivorra.

Background: Vertebral Osteomyelitis (VO) is an infectious disease that could produces neurologic complications such as paresthesia, limb weakness or even acute paraparesis (AP). Objectives: To analyze the clinical characteristics of patients with VO with AP as clinical presentation.

Methods: Single center retrospective observational study including adult patients diagnosed of VO based on the combination of clinical presentation with either a definitive bacteriologic diagnosis and/or imaging studies, who had a clinical examination at diagnosis compatible with AP, from January 2010 to January 2019. ASIA score (American Spinal Injury Association) was registered at diagnosis and one year after. Clinical and radiological history of lumbar stenosis or disc herniation was considered as prior spine pathology. We considered deaths attributable to PVO those which were directly caused by the infectious picture and/or its complications during the next year after diagnosis.

Figure 1

Results: In 15 of 122 patients with VO (18.30%), AP was described on physical examination at admission. Basal demographic and clinical features are exposed in table 1. ASIA scores at diagnosis and 1 year after are showed in chart 1. Duration of pain prior to diagnosis had a median of 24 days (7.5, 55), C reactive protein showed a median value of
AB0001

TWO TYPES OF SYSTEMIC AMYLOIDOSIS IN A SINGLE PATIENT

Riccardo Papa1, Janet A. Gilbertson2, Nigel Rendell2, Ashutosh Wechalekar2, Julian D. Gillmore2, Philip N. Hawkins3, Helen J. Lachmann2, 1IRCCS Istituto Giannina Gaslini, Clinica Pediatrica e Reumatologia, Genova, Italy; 2University College London Medical School, Royal Free Hospital Campus, National Amyloidosis Centre, London, United Kingdom

Background: The systemic amyloidoses are a group of rare diseases, in which extracellular deposition of a variety of proteins in an abnormal fibrillar confirmation results in life-threatening organ dysfunction. Acquired and hereditary amyloidoses differ in their precursor proteins and predilection for specific organ involvement.

Objectives: To describe the history of two types of amyloidosis developing consecutively in a single individual.

Methods: Targeted biopsies were used to confirm the presence of amyloid by Congo red staining viewed under polarized light, while immunohistochemistry and mass spectrometry were used to characterize the amyloid fibril type. 125I labeled serum amyloid P component (SAP) scintigraphy was performed to map the distribution of amyloid deposits.

Results: We report a woman of Sudanese origin who presented aged 31 with dysuria and haematuria. She was found to have an estimated Glo- merular Filtration Rate of 38 ml/min and no proteinuria, and a renal biopsy demonstrated AA amyloid deposition. An I-123 labelled SAP scan demonstrated a small amount of amyloid confined to the kidneys. She had no overt underlying inflammatory disease, an infectious diseases work up, including blood borne viruses, was negative and serial measure- ment of serum amyloid A protein showed no significant elevation with a median of 5 mg/L. Management was blood pressure control only, and work up, including blood borne viruses, was negative and serial measure-

Conclusion: Despite of being a well-known condition, VO is still an issue since 1-2 out 10 patients have a severe complication at diagnosis, such as AP. None of the basal characteristics analyzed acted as a risk factor, since 1-2 out 10 patients have a serious complication at diagnosis, such as AP. None of the basal characteristics analyzed acted as a risk factor.

AB0002

RHEUMATIC LYME DISEASE SYMPTOMS BASED ON EPIDEMIOLOGICAL DATA IN HIGH ENDEMIC AREA

Agne Petruoliaienė1, Daiva Radzilaukiene2, Anydas Ambrozaitis2, Saulius Čaplinskas3, Aigimantas Paulauskas2, Algirdas Venalis1,2, 1 Clinic of Rheumatology, Orthopaedics Traumatology and Reconstructive Surgery, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 2Center for Communicable Diseases and AIDS, Vilnius, Lithuania; 3Mykolas Romeris University, Vilnius, Lithuania

Background: Lyme disease is a tick born infectious disease caused by different genospecies of Borrelia bacteria (B. burgdorferi sensu strictu (ss), B. afzelii and B. garinii). The signs and symptoms of Lyme disease vary, they usually appear in stages, but the stages can overlap. In early stage skin rash (erythema migrans) appears, which may be accompanied by fever, chill, fatigue, body aches, headache, neck stiffness, and swollen lymph nodes. Later signs and symptoms can be these: joint pain and inflammation, neurological problems or other less common syndromes - heart problems, eye inflammation, and liver inflammation. Lyme disease is very common disease in the world, approximately 300,000 people get Lyme disease each year in the United States (Centers for disease con- trol and prevention US), in Lithuania disease frequency is 101.6 cases per 100 000 population (Center for Communicable Diseases and AIDS, Lithuania, 2016 year).

Objectives: To investigate the frequency of rheumatic symptoms between Lyme diagnosed persons in Lithuania, based on epidemiological data.
Methods: We have analyzed data of Center for Communicable Diseases and AIDS of Lithuania about Lyme diagnosed patients from 2014 to 2016 years.

Results: Total number of cases was 7425, 2791 males, 4633 females, age range 1 - 91 years, median age 52 years. 996 patients found out as symptomatic. The rest were either asymptomatic either information about clinical disease manifestation was not known. Among symptomatic patients two rheumatic symptoms were observed: arthralgia (220 cases, 22.1%), 140 females, 80 males, age range 12 – 84 years, median age 58 years, and myalgia (79 cases, 7.8%), 44 females, 34 males, age range 15-80, median age 56. Other symptoms were erythema migrants (75.6%), headache (15.2%), general weakness (12.4%), fever (10, 1%), and head dizziness (6.4%).

Conclusion: In total, almost 30 percentages (29, 91%) of symptoms were rheumatic. To conclude, joint pain and/or muscle pain can lead not only to systemic rheumatic diseases, but to infection diseases as well (for example: Lyme disease).

LYME ARTHRITIS IN HIGH LYME DISEASE ENDEMIC EUROPE ZONE

Agne Petronioniené1, Daiva Radzilauskienė2, Anvydas Ambrazaitis2, Saulius Čaplinskis3,4, Algimantas Paulauskas3, Algirdas Venals3,4, Clinic of Rheumatology, Orthopaedics Traumatology and Reconstructive Surgery, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania;2Center of Communicable Diseases and AIDS, Vilnius, Lithuania;3Mykolas Romeris University, Vilnius, Lithuania;4Vytautas Magnus University, Kaunas, Lithuania;5State research Institute Center for Innovative Medicine, Vilnius, Lithuania

Background: Lyme disease is a tick born infectious disease caused by different genospecies of Borrelia bacteria (B. burgdorferi sensu strictu, B. afzelii and B. garinii). Disease clinical manifestation varies and belongs to different genospecies of Borrelia bacteria. In America Lyme arthritis dominates, which is caused by B.burgdorferi, while in Europe Lyme disease is caused by Borrelia afzelii or Borrelia garinii (less commonly by Borrelia burgdorferi) leading to usual disease manifestation as erythema migrans or neuroborreliosis. Lyme disease is very common disease in the world, approximately 300,000 people get Lyme disease each year in the United States (Centers for disease control and prevention US), in Lithuania disease frequency is 101.6 cases per 100 000 population (Center for Communicable Diseases and AIDS, Lithuania, 2016 year).

Objectives: To investigate the frequency of Lyme arthritis in high disease endemic European country Lithuania. To find out with joint was most frequently affected.

Methods: A retrospective, single center study was performed. We have analyzed the medical documents of adult patients, who were hospitalized to Infectious disease center (Vilnius, Lithuania), due to severe Lyme disease clinical manifestation, in 2014-2017 years.

Results: 88 patients were enrolled (57 females, 31 males, age range 18-90 years, median age 57 years). Patients were divided into four groups according disease clinical manifestation: erythema migrans, neuroborreliosis, Lyme arthritis and carditis (atrophicventricular block). The most frequently erythema migrants was observed (53 cases, 62, 35 percentages (%)), than neuroborreliosis (27 cases, 31, 76 percentages), following by Lyme arthritis (3 cases, 3, 53 percentages) and Lyme carditis (2 cases, 2, 35 percentages). Between Lyme arthritis patients inflamed joints were these: knee (one case), ankle (one case) and both - knee and ankle (one case). In two cases high laboratory markers (ESR 116, 23 mm, CRP 125, 50 mg/l) and high body temperature (38, 2; 39, 5 t) was documented.

Conclusion: 2.35% of hospitalized Lyme infected patients reveal as Lyme arthritis. Inflamed joint were knee (50%) and ankle (50%). Despite the fact that it is used to think that Lyme arthritis occurs only (mostly) in America we can find it in Europe too, though its incidence is low.

AB0904
EFFECTIVENESS AND SAFETY OF RITUXIMAB IN SYSTEMIC AUTOIMMUNE DISEASES: A CASE SERIES

Milagros Suárez, Ana Argibay, Clara Portela, Olalla Lima, Lorena María Rodríguez Ferreiras, Meliana Estevez, Brenda Maure, Cantina Vázquez Trifán, Beatriz Gimena, Rut Lorenzo, Julian Fernandez, Alberto Rivera, Systemic Autoimmune diseases and Thrombosis Unit, University Hospital of Vigo, Spain, Hospital Álvaro Cunqueiro, Vigo, Spain

Background: Rituximab (RTX) is a drug composed of chimeric monoclonal antibodies against the CD20 protein, producing a depletion of B lymphocytes. Nowadays, it is used to treat severe and refractory systemic autoimmune diseases (SAD).

Objectives: Analysing the effectiveness and safety of RTX in patients with SAD in clinical practice.

Methods: We conducted a retrospective analysis of patients with SAD treated at least once with RTX in the autoimmune diseases unit of our hospital in the last 3 years. We evaluated demographic, clinical and serological variables as well as the presence of adverse events (AE).

Results: Twenty two patients have been included (13 women and 9 men, mean age 63 ±15 years). The diagnosis were ANCA-associated vasculitis (31.8%), cryoglobulinemic vasculitis (18.2%), autoimmune hemolytic anemia (13.6%), systemic lupus erythematosus (9.1%), immune thrombocytopenia in antiphospholipid syndrome (9.1%) and one each of: Felty syndrome, IgG4-related disease, necrotizing myopathy and systemic sclerosis. Indications for treatment were renal disease in 36.4% of the cases, haematological manifestations in 27.3%, skin involvement in 13.6%, neurologic manifestations in 9.1% and other different reasons in the remaining 15.6%. RTX was used after therapeutic failure with previous treatments in 81.8% and as first line treatment in only 18.1% of the cases. RTX dose was 375 mg/m2 once weekly for 4 doses (54,5%) and 1000 mg on days 1 and 15 (45.5%). After rituximab, 77.3% of patients had complete response, 9.1% partial response, and 13.7% non-responding. There were 14 AE reported in 10 of the 22 patients (45,5%). (See table). Three severe infections were found: 2 patients with invasive pulmonary aspergillosis and 1 patient with invasive cryptococcosis. All of them died within the next month after beginning RTX. One of those who were diagnosed of argepliosis had never received steroids. The other two were treated with high dose of steroids for several months. One patient had a nonischemic cardiomyopathy (NIC) with systolic dysfunction that resolved 4 months after RTX discontinuation.

Conclusion: As far as we are concern, RTX is a useful and pretty safe biological agent in the treatment of refractory SAD. However, we must be aware of rare adverse effects such as NIC. In addition, given the potential severity of the infections found (although not totally attributable to RTX), we must closely follow up these patients for early diagnosis, treatment and even starting profilaxis in high risk patients.
MAY CHRONIC CONSTIPATION-INDUCED CHRONIC INFLAMMATION AFFECT THE ONSET AND SEVERITY OF FIBROMYALGIA SYMPTOMS?

Baspak Mansız-Kaplan, University of Health Sciences, Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey.

Background: Up to 70% of fibromyalgia patients have functional bowel disorders as irritable bowel syndrome (IBS), constipation and diarrhea. Patients with chronic constipation may feature changes in microflora of large bowel, which are characterized by a relative decrease in obligate pathogens and an increase in enteric bacteria and fungi. This condition causes chronic low-grade inflammation. It has been reported that as a result of chronic constipation, altered microbiota of large bowel, which are characterized by a relative decrease in obligate pathogens and an increase in enteric bacteria and fungi, may cause low-grade chronic inflammation which may affect the onset and severity of fibromyalgia.

Methods: The cross-sectional study was designed as two groups: fibromyalgia patients, who is diagnosed according to the ACR 2016 revised classification criteria, and healthy population. All study participants were included in this study. The demographic and clinical characteristics of the participants such as age, height, weight, body mass index (BMI), occupations, exercise habits were recorded. In semi-standing position with isokinetic dynamometer (BIODEX) at 60° ~90° ~120° /second (s) angular velocities, trunk flexor and extensor muscle performances were evaluated. Flexor (flex) peak torque (PT), extensor (ext) PT values and flex/ext PT values were calculated. The flexor PT values also were lower in FMS group but no statistically significance in flexor PT values between the groups (p>0.05). As a result of isokinetic measurements of trunk muscles, extensor PT values were found significantly lower in women with FMS than C group at all three angular velocities (p<0.05). The flexor PT values also were lower in FMS group but no statistically significance in flexor PT values between the groups (p>0.05). As a result of isokinetic measurements of trunk muscles, extensor PT values were found significantly lower in women with FMS than C group at all three angular velocities (p<0.05).

Results: The mean age was 43.9 ± 8.1 years in FMS group and 43.7 ± 7.6 in control group. The mean BMI was 27.5 ± 4.19 in FMS group and 27.4 ± 4.58 in control group. The mean duration of constipation was 20.1 ± 8.9 and the mean duration of fibromyalgia symptoms was 16.0 ± 10.2 years. Fibromyalgia symptoms started in 16 of 18 patients after constipation (Mean year: 4.1 ± 5.3). Compared with constipated and non-constipated fibromyalgia patients, symptom duration and FIQ were significantly higher in constipated fibromyalgia patients (p<0.01). The duration of constipation was correlated with duration of fibromyalgia symptom (r² = 0.65, p = 0.00), PACQLQ (r² = 0.71, p = 0.001) and CSI (r² = 0.59, p = 0.01). There was a correlation between FIQ and CSI (r² = 0.96, p = 0.00) and PACQLQ (r² = 0.62, p = 0.006).

Conclusion: The frequency of gastrointestinal symptoms increased in patients with fibromyalgia. As the severity of constipation increases, the symptoms of fibromyalgia are exacerbated. The presence of constipation findings before fibromyalgia suggests that low-grade chronic inflammation caused by constipation may have an effect on the onset of fibromyalgia. There is a need for a prospective cohort study to clarify this cause and effect relationship.

AB0906 RELATIONSHIP BETWEEN FIBROMYALGIA AND TRUNK MUSCLE PERFORMANCE

Cevvibe Müködül, Sühan Tağgün, Seçil Vural, Baspak Mansız-Kaplan, Hakan Genç, Ankara Training and Research Hospital, Ankara, Turkey.

Background: Muscle performance is adversely affected by pain, fatigue and low aerobic capacity in fibromyalgia syndrome (FMS).

Objectives: We compared trunk muscle performance of women with FMS and healthy individuals who have similar age and body mass index (BMI).

Methods: A total of 37 women with FMS and 32 healthy women were included in this study. The demographic and clinical characteristics of the participants such as age, height, weight, body mass index (BMI), occupations, exercise habits were recorded. In semi-standing position with isokinetic dynamometer (BIODEX) at 60° ~90° ~120° /second (s) angular velocities, trunk flexor and extensor muscle performances were evaluated. Flexor (flex) peak torque (PT), extensor (ext) PT values and flex/ext PT values were calculated.

Results: The mean age was 43.9 ± 8.1 years in FMS group and 43.7 ± 6.7 in control group. The mean BMI was 27.5 ± 4.19 in FMS group and 26.4 ± 4.08 in control group. There was no significant difference between the groups in terms of age and BMI (p>0.05). As a result of isokinetic measurements of trunk muscles, extensor PT values were found significantly lower in women with FMS than C group at all three angular velocities (p<0.05). The flexor PT values also were lower in FMS group but no statistically significance in flexor PT values between the groups (p>0.05). When flexor/ extensor PT ratio was compared, it was seen that this ratio increased in the FMS group.

Conclusion: There are many studies in the literature assessing upper and lower extremity muscle performances in FMS (1-2). To our knowledge, we first evaluated trunk muscle performances of patients with FMS and we found that trunk muscles, especially extensors, were significantly weaker in FMS group. As a result, in treatment of FMS, there is a need for more comprehensive randomized controlled studies showing the importance of strengthening exercises to improve trunk muscle performance.

REFERENCES
Background: Dysautonomia describes a group of conditions associated with a malfunction of the autonomic nervous system. Symptoms of dysautonomia and inflammation have been described in Fibromyalgia (FM) and Myalgic encephalomyelitis (ME)/Chronic Fatigue Syndrome (CFS) [1–4]. Symptoms include increased disabling fatigue, pain, dizziness and digestive problems.

Objectives: This ongoing study investigates, for the first time, how a sympathetically mediated challenge and induced systemic inflammatory state impact on mood, pain, fatigue, and autonomic function.

Methods: In a randomized, double-blind, placebo-controlled study, 25 participants with FM and/or ME/CFS underwent an autonomic- and inflammatory challenge during three visits. Outcome measures included a range of questionnaires including the Profile of Mood States (POMS), Pain visual analogue scales (VAS), measures of heart rate (HR), Pressure Pain Threshold (PPT), alongside subjective pain and fatigue measures. Autonomic function was assessed using a passive non-invasive tilt-test (upright tilt of 60°) and active-stand (AS) with beat-to-beat HR and blood pressure monitoring. Remaining visits involved an inflammatory challenge using intramuscular typhoid- and saline (placebo) injection.

Results: Tilt-table test was positive in 20% participants and AS in 92% participants indicated by HR rise >30 bpm or a sustained HR of 120 bpm. Overall fatigue correlated with peak HR during tilt (r=−0.465, p=0.025, n=23). There was a positive correlation between the average HR during AS under typhoid after controlling for placebo and average HR during tilt (r=−0.517, p=0.049, n=15). Scores on the Wide Spread Pain Index (WPI) at screening correlated with the change in POMS pre- and post-typhoid after controlling for placebo (r=−0.479, p=0.049, n=18). Scores on the Fibromyalgia Severity Scale correlated with the change in physical fatigue pre- and post-typhoid after controlling for placebo (r=−0.582, p=0.047, n=12). Mean change in heart rate pre-post active stand correlated with a change in pain VAS pre- and post-typhoid after controlling for placebo (r=0.382, p=0.023). There was a positive correlation between the average HR during AS under typhoid after controlling for placebo and average HR during tilt (r=−0.517, p=0.049, n=15). Scores on the Fibromyalgia Severity Scale correlated with the change in physical fatigue pre- and post-typhoid after controlling for placebo (r=−0.582, p=0.047, n=12).

Conclusion: Preliminary findings suggest that dysautonomia and induced inflammation significantly impacts on pain, fatigue, and autonomic function in FM and ME/CFS. On-going data collection of 100 participants (25 controls) will allow extended analyses to test how autonomic function in FM and ME/CFS impact symptom domains that impact on quality of life.

AB0909  
Efficacy and safety of ultrasound guided aspiration and intralesional corticosteroids injection of ruptured Baker’s cyst

Mohammed A. Mortada, Yourna A. Amer. Faculty of Medicine. Zagazig University, Rheumatology and Rehabilitation, Zagazig, Egypt

Background: Baker’s cyst is the most common mass in the popliteal fossa and results from fluid distension of the gastrocnemio-semimembranosus bursa. The most common complication of Baker’s cyst is the rupture or dissection of fluid into the adjacent proximal gastrocnemius muscle belly, which results in a pseudothrombophlebitis syndrome mimicking symptoms of DVT.

Treatment of ruptured Baker cysts ranged from conservative management to surgical resection.

Ultrasound guided aspiration and corticosteroids injection may be an effective and easy method of management of these cases.

Up to the best of our knowledge, this is the first study to detect the efficacy and safety of ultrasonographic guided aspiration and injections of ruptured Baker cysts.

Objective: To evaluate the efficacy and safety of ultrasonographic guided aspiration and local corticosteroids of ruptured Baker cysts based on follow-up clinical and sonographic results.

Methods: A retrospective study was conducted on 42 patients (12 males and 30 females, mean age 36 +/- 10 SD years) affected by a ruptured Baker cysts associated to knee joint disorders in the period between January 2013 to January 2019. The diagnosis was done by clinical presentation of acute calf pain, swelling, tenderness at the calf muscles and ultrasonographic evidences of ruptured backer cysts in the form of free fluid collection in the calf connected to a well defined cyst at the back of knee.

All cases were treated by ultrasonographic guided aspiration and intralesional injection of corticosteroids once or twice a week one part. Follow up was done on a weekly basis until complete resolution of symptoms then 3 months later. Visual analogue scale (VAS) for calf pain and Rauschning-Lindgren and Lysholm Knee Scoring Scales were used to assess pre/post-injection knee function.

Results: The primary diagnoses to patients presented with ruptured Baker cyst in this study were as follow: 18 (42.8%) cases with rheumatoid arthritis; 15 (35.7%) cases with osteoarthritis and 9 (21.4%) cases with psoriatic arthritis.

Clinical parameters (VAS for calf pain and Rauschning-Lindgren score) improved significantly in all patients at post injection evaluation visits.

Rauschning-Lindgren score was significantly lower after US guided injections (mean, 0; range, 0-1) than at baseline (mean, 2; range, 1-2); p < 0.001 (table1).

VAS for calf pain also significantly lower after US guided injections (mean,0.5; range, 0-1) than at baseline (mean, 9.5; range, 0-10); p < 0.001.

Ultrasoundographic features improved significantly with complete disappearance of free fluid at the calf in 35 (83.3%) cases one week after the injection.

As regards Baker cyst only 5 (11%) cases showed complete disappearance of the backer cyst and in the majority of cases 37 (88%) there were persistent Baker cysts.

No side effects were reported in all cases.

AB0910  
Effective restoring motion and effective treatment of myofascial and neuropathic low back pain by targeted dry needling using ultrasound guidance

Rostyslav Bubnov1,2, Lev Kalika3. 1Zabolotny Institute of Microbiology and Virology, NAS of Ukraine, Kyiv, Ukraine; 2Clinical Hospital “Pheophania” of State Affairs Department, Ultrasound, Kyiv, Ukraine; 3NYDNIRheab: Chiropractic and Physical Therapy Clinic NYC, New York, New York, United States of America

Background: Low back pain (LBP) involves both myofascial and neuropathic components of pain. Neuropathic pain is a widespread problem, require continuous consumption of medications. Muscle spasticity might evoke nerve compression, dry needling (DN) of myofascial trigger points (MTP) under ultrasound (US) guidance is effective method for treatment myofascial pain [1,2] restoring posture [3] and can be effective for neuropathic pain.

Objectives: The aim was to evaluate efficacy of dry needling under US guidance for treatment myofascial and neuropathic components of LBP.

Methods: We included 52 patients, 37 females, aged 18-64 years (the average was 55 years) low back pain was diagnosed chronic low back pain with neuropathic component with clinically diagnosed low back pain over 3 month with neuropathic component and reduced motility in spine, pelvis and lower extremity. All patients had symptoms over 3 month, underwent general exam, including MRI, laboratory, neurologic, orthopedic tests. We conducted precise physical tests and neuromuscular ultrasound using M-mode and evaluated nerves and motion in intervertebral spaces, pelvis, intrinsic foot and leg muscles. We conducted ultrasound survey at the levels of predicted nerve injury. Patients received DN of MTP under US guidance according to approach by R.Bubnov [1,2], considering nerve entrapment area. Visual analogue scale (VAS, 0-10) and Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) scores were measured before, immediately after, 24 hours, and 7 days after intervention.

Results: After 7 days, VAS scores showed pain improvement from 7.4 to 2.2; LANSS scores improved from 16 to 4. In diabetic and postherpetic neuropathy cases we obtained similar results as in rest of patients (p < 0.05). US demonstrated improvement nerve structure, increasing motility, contractility (muscle contracted/rested thickness) on M-mode during functional tests and walking in all levels. Improvement of neuropathy signs as decrease of fascicles diameter from 2 to 0.9 mm measured on US in sciatic nerve, both in tibial, peroneal portions, data correlated with self-assessment pain decrease (r > 0.8). Preferably MTP were identification in supinators muscle (wrist pain); rotator muscles (infraepatins, supraspinatus, subscapularis and teres minor muscles); scalene muscles; obliques capitis muscles, and also in fascial tissue.

Conclusion: Dry needling under US guidance efficiently reduce myofascial pain, ameliorate symptoms of neuropathy and local muscle hypomotility in low back pain. Further research needed for development US patterns and study causation in chain spasticity-contractility-motion-neuropathic pain.

REFRACTORY LOW BACK PAIN AND LUMBAR CT-GUIDED STEROID INFLTRATION. STUDY OF 582 PROCEDURES FROM THE SAME CENTER

I. Calvo1, O. Ibariguengolita1, D. Montero1, L. Vega1, L. María1, M. E. Ruiz1, I. Torres1, F. Diez2, C. Morandeira1, Iñigo Gorostiza3, E. Galindez1.

1Basurto University Hospital, Research Unit, Bilbao, Spain; 2Basurto University Hospital, Radiodiagnostic, Bilbao, Spain; 3Basurto University Hospital, Research Unit, Bilbao, Spain

Background: Mechanical low back pain which is refractory to analgesic and rehabilitative treatment is an important cause of disability. The primary objective of corticosteroid (CS) lumbar infiltration is to accelerate the recovery process and to avoid surgery. However, its use is not without controversy.

Objectives: To review the indications, efficacy and complications of lumbar computed tomography (CT)-guided CS infiltration.

Methods: Retrospective study (January 2012 - April 2018) of lumbar CT-guided CS infiltrations performed in a single center. The epidemiological variables, underlying pathologies, approach of injection, used CS (dexamethasone during the whole period and triamcinolone until February 2015), efficacy after 1 and after 3 months and complications were registered. In addition, a comparative study of the efficacy according to indication, type of CS and approach of injection was performed.

Frequencies and percentages were used in qualitative variables, mean ±SD in quantitative and for the comparison between groups Chi2 test or Fisher test was used in categorical variables and Student T test or U of Mann-Whitney in quantitative. Statistical analysis was performed with IBM SPSS v.23.

Results: 582 procedures were performed in 445 patients (1 infiltration in 445 patients, 2 in 106, 3 in 23, 4 in 7 and 5 in 1). The mean age±SD was 58.6±14.8 years with a male/female ratio of 224/221. Traumatology was the service with highest demand (88.8%) followed by rheumatology (14.8%) and orthopedics (36.4%), postoperative fibrosis (14.8%), spondyloarthrosis (2.7%) and degenerative disc (2.7%). The mean ±SD follow-up period was 32.4±24.9 months. The indication was the service with highest demand (88.8%) followed by rheumatology (14.8%) and orthopedics (36.4%).

Only 21% required surgery. Triamcinolone (although its use is currently discouraged because it is a particulate CS), foraminal infiltration and lateral recess proved to be more effective for pain control. In this study, lumbar CT-guided CS infiltration in patients with refractory low back pain is an accessible, minimally invasive, safe and effective procedure in long term.

EXTRACORPOREAL SHOCKWAVE VERSUS MUSCULOSKELETAL MESOTHERAPY FOR ACHILLES TENDINOPATHY IN ATHLETES

Reem Elmalakh1, Enas Elattar1, 1Faculty of medicine Ain Shams University, Assistant Professor of Physical Medicine, Rheumatology and Rehabilitation, Cairo, Egypt; 2Faculty of Medicine. Ain Shams University, Assistant Professor of Physical Medicine, Rheumatology and Rehabilitation, Cairo, Egypt

Background: Achilles tendinopathy (AT) is considered as one of the common tendon pathologies, which occurs mainly in athletes. Different conservative treatment options have been introduced and used for symptoms relief of AT but with short-term effect.1 Extracorporeal shockwave treatment (ESWT) provides longer effects and could be used in cases fail to respond to conservative treatments.2 Mesotherapy is widely practiced in sports medicine as multiple injections, often of anti-inflammatory medications into the subcutaneous fat overlying a region of musculoskeletal pain. The effect appears unclear but may be due to localized tissue uptake of anti-inflammatory medication which may provide symptomatic relief especially in insertional Achilles tendinopathy 3

Objectives: In this study, we aimed to evaluate the effect of extracorporeal shockwave treatment (ESWT) and mesotherapy on chronic Achilles tendinopathy in athletes.

Methods: 40 patients with chronic AT were diagnosed clinically & using high resolution ultrasound (US) according to the Eular guide lines and randomly allocated in two groups, first receive ESWT, other group underwent mesotherapy (MT) one session once a week for 4 weeks to the 2 groups. Pain, ankle-hindfoot scale of the American Orthopedic Foot and Ankle Society (AOFAS) 4 & US were recorded at baseline, 4 and 12 weeks after intervention.

Results: Both groups improved during the treatment and follow-up period. The mean VAS score decreased from 7.55 to 3 in the ESWT group and from 7.70 to 4.30 in MT group. There was no significant difference in terms of AOFAS and VAS scores between both groups at 4 weeks follow-up while Mean AOFAS & VAS scores were significantly different between ESWT and MT groups at 12 weeks of follow-up (P = 0.013) (P = 0.47). US assessment significantly improved after 12 weeks in ESWT group as regards tendon thickness, calcifications(figure1,2) and doppler signal.

Conclusion: ESWT showed improvement of pain and inflammation of AT than MT injections which was documented by the decreased VAS, increased AOFAS scores as well as US improved findings shortly after the treatment as well as on late follow up.

THE ROLE OF BISPHOSPHONATES IN THE MANAGEMENT OF SPONTANEOUS OSTEONECROSIS OF THE KNEE (SONK)

Mark Ford, Roshan Amarasena. The Robert Jones and Agnes Hunt Orthopaedic Hospital NHS Foundation Trust, Gobowen, United Kingdom

Background: Spontaneous osteonecrosis of the knee (SONK) was first described by Arhlück, Bauer and Bohnein in 1968 when they identified 39 patients with radiolucent lesions of subchondral bone in the medial femoral condyle which represented a manifestation of osteonecrosis. The aetiology and pathogenesis of SONK remains unclear with possibilities including microvascular compromise, reduced bone mineral density, and mechanical disruption within the knee. The treatment compromises of conservative, medical and surgical options depending on the severity of osteonecrosis identified on imaging. Lai et al (2005) demonstrated the beneficial effect of alendronate in the prevention of early collapse of the femoral head in patients with nontraumatic osteonecrosis: a randomized clinical study. 

Methods: A literature search was conducted to identify studies reporting the effect of bisphosphonates in the treatment of SONK and the usefulness and validity of their conclusions was subsequently assessed.

Results: We have identified one randomised controlled trial and four case series investigating the use of a bisphosphate on the clinical and radiological outcome in patients with osteonecrosis of the knee. All four case series showed improvements with bisphosphonates on patient visual analogue scale (VAS) and radiological outcome. However, the sole randomised controlled trial reported that bisphosphonates had no additional benefit over conservative measures and anti-inflammatory medications after 24 or 48 weeks both functionally and radiographically. These studies had a small number of participants and the size of the osteonecrotic lesion was either small, which traditionally is managed conservatively, or not interpreted in the context of the results.

Conclusion: The role of bisphosphonates in the treatment of SONK remains unclear. Further randomised controlled trials would be beneficial in these patients with emphasis on the symptom duration and the size of the osteonecrotic lesion.

EFFECT OF VITAMIN D SERUM CONCENTRATION ON ARTHRALGIA INDUCED BY ADJUVANT THERAPY WITH AROMATASE INHIBITORS IN NON METASTATIC BREAST CANCERS SURVIVORS

Emanuele Gotelli, Carlotta Schenone, Francesco Cattelan, Elisa Alessandri, Federica Goegan, Massimo Patanè, Massimo Ghio, Maurizio Cutolo, Sabrina Paolino. IRCCS San Martino Polyclinic Hospital, Genoa, Italy, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, genoa, Italy

Background: Hand arthralgia is often reported by breast cancer patients treated with adjuvant hormonal therapy. Aromatase inhibitors (AIs) improve survival in postmenopausal women with hormone-sensitive breast cancer, but can cause joint pain and stiffness (2). Low concentration of vitamin D in adults can cause musculoskeletal pain and joint discomfort (1). No data are available to date, on serum concentrations of (25-hydroxyvitamin D) [25 (OH) D3] vitamin D in AI-treated patients and possible relationship with arthralgia.

Objectives: To evaluate possible correlation between different 25 (OH) D3 serum concentrations and hand arthralgia in patients with breast cancer treated with AIs.

Methods: All patients that during the AIs therapy develop arthralgia referred to the rheumatologist; they reported the pain following the VAS (visual analog scale) and contemporary performed a sample blood for dosage of vitamin D as well as biomarkers for inflammation and autoimmunity to exclude concomitant immune/inflammatory rheumatic musculoskeletal causes.

Results: In a group of 63 women taking AIs (mean age 62.3±9.8years; disease duration from first assumption of AIs 10.6±3.2 months) 81% reported hand arthralgia and stiffness within the first year of follow-up; the most prevalent site of pain localization was bilateral hands (85%). Symptom was associated with minimal increase of serum parameters of inflammation (the mean value of C-reactive protein was 7.1±3.0 mg/L (normal value 0-5) but negative autoimmune profile (negative rheumatoid factor and anticollagen type II antibody). The mean 25(OH)2D3 serum concentration was 18.4±5.9 ng/mL. Only 9% of women had an adequate (> 30 ng/ml) [25 (OH) D3] vitamin D serum levels; 70% were insufficient (> 10 < 20 ng/mL), and 21% were severely deficient (< 10 ng/mL). 55% of patients started AIs after chemotherapy. From the group that received AIs after chemotherapy 77% patients with arthralgia were found during the first years of hormonal therapy, in the group that previously did not take chemotherapy 88% of patients referred arthralgia. There was any
difference on vitamin D serum levels between patients previously treated or not treated with chemotheraphy (17.8 ± 7.8 vs. 19.3 ± 9.7 p = 0.6). After subdivision of patients that referred hand arthralgia according to the different type of AIs used: 22% have been treated with tamoxifen, 30%, anastrozole and 48% letrozole. Therefore, the baseline serum vitamin D concentrations did not significantly predict arthralgia in the overall group (P = 0.70) or separately in the single AIs group (anastrozole (P = 0.60) or tamoxifen(>P=0.30) or letrozole (P = 0.60, respectively).

Conclusion: Vitamin D serum concentration in women treated with AIs are at lowest ranges in the majority of the patients analysed, but no apparent interference with musculoskeletal symptoms was found related to the different concentrations; the cause of arthralgia might be better related to estrogen deficiency induced by AIs their self.

AB0916 INVESTIGATION OF PAIN AND DEPRESSION IN CANCER OUTPATIENTS RECEIVING CHEMOTHERAPY
Fulya IFEK, Vesile Yildiz Kabak, Songül Atasavun Uysal, Tulin Duger. Hacettepe University, Physiotherapy and Rehabilitation, Ankara, Turkey

Background: Cancer treatments such as chemotherapy contribute to the development of depression and pain (1). Prevalence of pain ranges from 14% to 100% and depressed symptoms occur 1-42% in cancer patients (2). The empirical evidence indicates that pain is often untreated and may induce depression in cancer patients (1,2) and depression affects the management of symptoms such as pain (3). Therefore, depression and pain have interrelated effects with each other. Pain and depression in cancer patients lead to discontinuation of therapy, difficulties in controlling symptoms and negative treatment compliance (4). Studies report the need for more research on pain and depression associated with cancer treatment (2).

Objectives: The objectives of this study are to: 1) compare the depression levels of painful and painless cancer patients who received outpatient chemotherapy; and 2) investigate the relationship between pain and depression in these patients.

Methods: This study was carried out in outpatient chemotherapy unit of Hacettepe Oncology Hospital based in Ankara, the capital city of Turkey. The visual analog scale (VAS) was used to investigate if the patients may have had pain. The Brief Pain Inventory (BPI) was applied to evaluate the pain frequency and pain interference on the function of patients while the Beck Depression Inventory (BDI) was applied to evaluate depression.

Results: The study findings are based on the outcomes of 27 cancer outpatients receiving chemotherapy. Their mean age was 56.89±11.08 years (age range; 31-73). Almost half of the of patients had pain (48.15%). There was a difference between the depression scores of the patients who had pain and the other patients without pain but this is not statistically significant (p=0.07). The depression scores of painful patients and non-painful patients were 13 and 6, respectively. There was a moderate association between scores of pain severity and depression (r=0.4, p=0.04). Moreover, there was a high association between the score of depression and pain interference on function (r=0.61, p=0.016).

Conclusion: This study shows that pain is related with depression in cancer outpatients receiving chemotherapy. Depression may occur more frequently in patients who have experienced pain than in patients with no pain and also depression is likely to increase pain in cancer patients. Therefore, the addition of emotional and psychosocial components for treatment procedures and effective pain management may have positive effects on the treatment of cancer outpatients receiving chemotherapy.

**PATTERN OF SERUM CHOLECALCIFEROL (VITAMIN D3) LEVEL AMONG THE FEMALE IN RELATION TO CLOTHING'S**

Mohammad Abdur Razzaque 1, Mirza Nural Karim 2, Rajat Sanker Roy Biswas 3, Nazul Islam 4, Satyajit Mallick 4, Chittagong Medical College, Medicine, Chittagong, Bangladesh; 5Chittagong Medical College, Medicine, Chittagong, Bangladesh; 6Chittagong Maa O Shisu Medical College, Medicine, Chittagong, Bangladesh; 7BSMMU, Rheumatology, Dhaka, Bangladesh.

**Background:** Both clinical and subclinical low level vitamin D is common. Various kinds of health hazard including musculoskeletal symptoms are frequently seen among the Vitamin D deficients. It is also uncommon even in a sunny country. Lack of sun exposure, particularly female using veil may be an important cause.

**Objectives:** To assess the relationship between using veil and serum vitamin D3 (cholecalciferol) level

**Methods:** This prospective cross-sectional descriptive study was conducted during July 2017 to June 2018. Patients with common complaints related to lack of Vitamin D (muscle cramp, myalgia, fatigue, bone pain, generalized weakness, difficulty in getting up, climbing stairs and pain in weight bearing joints) were enrolled. Patient having other disease were excluded from study. Serum cholecalciferol was measured for each patient. Race, occupation, educational status, skin complexion, body mass index, sunlight exposure, covering of body with clothing and use of sunscreen were taken under consideration in final analysis. Correlation of serum cholecalciferol level with different types of veils (Burkha, halve sleeve, full sleeve, quarter sleeve and Hijab) of individual’s was analyzed.

**Results:** A total 79 female patients were enrolled after screening 108. All of them were of multi-ethnic Asian origin. Age distribution of them is 17 to 39 years 34.2%, 40 to 50 years 38%, 50 to 70 years 26.6% and above 70 years 1.3%. Maximum (93.7%) of them were house wife. 91.1% had no adequate sun exposure and 81% had no skin exposure to sunlight. Among clothing 79.7% used Burkha, 5.1% halve sleeve, 2.5% full sleeve and 12.7% quarter sleeve. Among Burkha 28.6% (18), 55.6% (35 & 15.9% (10) and among quarter sleeve 50% (5), 40% (4) & 10% (1) had deficient, insufficient & sufficient vitamin D level respectively while 2 (100%) female with full sleeve and 4 (100%) female with halve sleeve had deficient and insufficient vitamin D level respectively. The cholecalciferol level among the users of veil is shown in Table-1. There was no significant difference between different types of clothing’s (Table: 2).

</tbody>
</table>

Conclusion: Main source of Vitamin D is sunlight. Proper exposure to sunlight is essential for adequate vitamin D level even in a sunny country. Receiving in vitamin D3 absorption from sunlight, there may be no difference between Burkha and other covered dressings. Further study needed to have a conclusion.

**CELCIVAL INSTABILITY AND VISUAL PATHWAYS COMPROMISE IN PATIENTS WITH JOINT LAXITY**

sharareh Roshanzamir 1, Aida Askarian 2. 1Shiraz University of Medical Sciences, Shiraz, Iran (Islamic Republic of); 2Shiraz University of Medical Sciences, Shiraz, Iran (Islamic Republic of)

**Background:** Cervical spine stability is to a great extent dependent on the capsular ligaments, laxity of which would lead to extensive movements of the vertebrae. This instability of the cervical spine, particularly in the upper segments (C0-C2) would be a major source of vertebrobasilar insufficiacy. The resultant brain posterior circulation compromise would then make the foundation of white matter changes and cause many neurological signs and symptoms. Occipital lobe and visual pathways are certainly in danger in these circumstances. How and to what extent could the visual pathways be involved in patients with joint laxity is not well studied yet.

**Objectives:** This study was designed to find whether the visual evoked potential parameters (latency and amplitude) of the patients with generalized joint laxity differs from that of the normal population.

**Methods:** In this cross-sectional comparative study, 90 consecutive patients with generalized lax joints and 90 normal individuals were enrolled and underwent the visual evoked potential test by pattern reversal. The latency and amplitude of P100 were determined for all the participants and data from the 2 groups were compared statistically.

**Results:** The results demonstrated that although none of the VEP parameters fell in the abnormal range, there was significant difference between P100 latency in patients with generalized lax joints (mean:110.23 ms) versus normal population (100.18 ms) (P<0.001) with longer latency in patients with generalized lax joints. But the amplitude was not significantly different across the groups (P > 0.05).

**Conclusion:** It can be concluded from this study that although the VEP parameters of the patients with generalized joint laxity don’t exceed the normal range limits, P100 latency in these patients is significantly more prolonged than in normal population. This finding is valuable from two points of view, first P100 latency at the verge of abnormality (upper limit of normal range) in these patients is a warning sign implying the visual pathway involvement, and second VEP could be invaluable in differentiating the signs and symptoms that are produced by vertebrobasilar insufficiency secondary to the joint laxity from multiple sclerosis, which can be mimicked both clinically and in MRI findings by many vascular problems but shows a great percent of VEP abnormality as a particular feature.

AB0919 EFFECTS OF ALEXITHYMIA ON ACTIVITY PAIN, UPPER EXTREMITY FUNCTION, SYMPTOM AND DEPRESSION LEVELS IN PATIENTS WITH THORACIC OUTLET SYNDROME

Yasin Tunç1, Nur Banu Karaca1, Tüzün Firtalı, Ayten Kaya Ganger1. Hacettepe University, Ankara, Turkey; Ankara University, Ankara, Turkey

Background: Presentation of the most common changes in the thoracic outlet syndrome causing functional disorders of the upper limb (1). The majority of the studies published on TOS highlight physiotherapy strengthening exercises and postural reeducational drills as being the mainstay of any conservative management programme for TOS (2). However, in the literature, the effect of emotional state on progression in treatment programs has not been investigated. Alexithymia, which refers to deficiencies in the self-awareness of emotional states, has been reported to be associated with poor ability in various aspects of social cognition (3). The ability of TOS patients to express themselves and their emotions will affect the success of the treatment.

Objectives: The aim of this study was to investigate the effect of alexithymia on upper extremity functions, symptoms, pain level, depression and anxiety in patient with Thoracic Outlet Syndrome.

Methods: Forty-three TOS patients (36.67±13.99 years; 38 women, 5 men) were enrolled to the study. Alexithymia was assessed with Toronto Alexithymia Scale (TAS-20). The patients were divided into two groups as non-alexithymia group and alexithymia group according to 51 points. TAS-20 cut-off score. Pain levels at rest and activity were assessed with visual analogue scale; upper extremity function was assessed with Disabilities of the Arm, Shoulder, and Hand (DASH) questionnaire, and upper extremity symptom was assessed with using Servical Brachial Symptom Questionnaire. Mann-Whitney U test was used for data analyses.

Results: Activity pain level and depression in alexithymia group was higher than the non-alexithymia group, p=0.008 and p=0.007, respectively. Also, functional level and symptoms were worst in alexithymia patients, p=0.041 and p=0.05, respectively. No difference was found between groups anxiety and resting pain level.

Conclusion: Thoracic outlet syndrome patients who have alexithymia show worse pain, symptoms, function, and depression. Emotion should be considered in physiotherapy programs. Because the progression of alexithymia patients are worst than non-alexithymia patients.

Pediatric rheumatology

AB0921 JUVENILE-ONSET LUPUS WITH SECONDARY CMV-INDUCED MACROPHAGE ACTIVATION SYNDROME (CASE REPORT)

Hanan Abd El-Lateef, Ain Shams University, Pediatric Rheumatology Immunology Unit, Cairo, Egypt

Background: Juvenile-onset lupus (JSLE) is a complex illness with an aggressive course and higher chances of morbidity and mortality. JSLE is extremely rare before the age of 5 years. A sole disease criterion may precede long time before others, making diagnosis rather challenging.

Objectives: Identifying JSLE and its subsequent complications

Methods: A three and half years old female patient presented with an established diagnosis of idiopathic thrombocytopenia (ITP) of one year duration. One month ago, the patient developed an acute onset of high grade persistent fever, bilateral knee swelling and significant weight loss.

Results: On physical examination, patient was emaciated and pale with multiple ecchymotic patches allow her body, Vital data showed normal blood pressure and apical heart rate ranges for age. Systemic examination revealed multiple oral ulcers, hepatosplenomegaly, bilateral knee arthritic and bilateral below knee painless pitting lower limb edema. Neurological examination was free. Laboratory evaluation showed a CBC with TLC 1.800/mm³ NE 0.5/mm³, HB 7.9 g/mdl, PLT 79 x10³/μL.ESR 120 mm/1st hr and CRP 96 mg/dl. Routine chemistry showed elevated liver enzymes (ALT 137 IU/L & AST 280 IU/L), LDH 960 IU/L, serum albumin 2.5 gd/l, normal renal functions. The history of chronic ITP together with evolution of other autoimmune manifestations raised the suspicion of an underlying Connective tissue disorder. Immunological profile showed positive immune markers (ANA 1/320 speckled and positive Anti-DNA), positive lupus anticoagulant and antiphospholipid IgM.C3 was consumed(49 mg/dl). Secondary Macrophage activation syndrome (MAS)

AB0923 EFFECTS OF EXON 10 MUTATIONS VS NON-EXON 10 MUTATIONS ON FMF PHENOTYPE AND RESPONSE TO TREATMENT
Hatice Adiguzel Dundar, Ozge Altug Guçenmez, Ceyhun Acari, Serkan Turkucar, Balahan Makay, Erbil Unsal.

Dr. Behcet Uz Childrens Hospital, Childrens Department, Izmir, Turkey

Disclosure of Interests: None declared
exon 10 involvement or non-exon 10 mutations. Genotype-phenotype features and response to treatment were compared.

Results: There were exon 10 mutations in 631 (67.5%) patients and non-exon 10 mutations in 304 (32.5%) patients. The follow-up period was 50 (26-83.2) months. The age of symptoms onset was significantly lower in group with exon 10 positive than compared group with non-exon 10 mutation. There was no difference between the age of diagnosis and colchicine onset and the diagnosis delay time. The symptoms of fever, chest pain, and arthritis were significantly higher in the exon 10 mutation group than compared other group. Biological agent need was statistically higher in exon 10 mutation group (4.8%) than group with non-exon 10 mutation (1.3%) (Table 1).

Conclusion: In our study, it was observed that cases with exon 10 mutation have early symptoms of disease. Fever, chest pain and joint findings were more prominent in cases with exon 10 mutation than cases with non-exon 10 mutation. Additionally, colchicine resistance should be kept in mind in cases with exon 10 mutation.

AB0924 EVALUATION OF PERIPHERAL NERVOUS SYSTEM INVOLVEMENT IN PATIENTS WITH JUVENILE SYSTEMIC SCLEOROSIS AND JUVENILE SYSTEMIC LUPUS ERYSHEMATOSUS

Nuran Burcu Alkali1, Amra Adrovic2, Sezgin Sahin2, Mehrmet Yildiz2, Oya Koker2, Kenan Barut2, Nurten Uzungudatpe2, Ozgur Kasapoglu2, Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Neurology, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Rheumatology, Istanbul, Turkey

Background: Juvenile systemic sclerosis (JSS) and juvenile systemic lupus erythematosus (JSLE) are rare connective tissue disorder characterized by multisystemic involvement, including gastrointestinal, cardiovascular, respiratory and nervous system complications. According to data from literature, peripheral nervous system (PNS) involvement is seen in 86.7% of adult patients with systemic sclerosis. Frequency of PNS disorders is reported as 10-86.7% in adult patients. Data on PNS involvement in patients with JSS and JSLE are scarce.

Objectives: We aimed to evaluate PNS involvement in patients with JSS and JSLE. Consequently, we sought to detect patients with PNS disorders, in order to enable early diagnosis and timely intervention.

Methods: Patients with JSS and JSLE were included in a cross-sectional study. Demographic and clinical data of patients were recorded during clinical visits. All of patients were evaluated and examined for signs of PNS involvement. In order to examine mononeuropathy, polynueropathy and trigemino-facial involvement, all patients underwent routine nerve conduction studies (NCS), blink reflex (BR) and sympathetic skin responses (SSR) evaluation.

Results: Twenty JSS (15 [75%] female) and 18 (15 [83%] female) JSLE patients were initially included. All of JSS and JSLE patients had normal neurologic examination. NCS was normal in all JSS (20/20) and JSLE (18/18) patients. SSR was not recorded in 1 (5%) JSS and in 3 (16.67%) JSLE patients. BR was recorded in all JSS (18/18) and JSLE patients and in majority of JSS patients (19/20, 95%). According to SSR, mean latency of hand and foot was similar in both patients' groups. Amplitude of foot response was lower in JSS patients, comparing to JSLE (Table 1). Among JSLE patients, amplitude of hand response was lower than amplitudes of foot response.

According to BR, R1, R2, R2K duration and latency were not different between right and left eyes in both patients' groups. R3 was absent in 2 (10%) bilaterally and in 1 (5%) JSS patients unilaterally (right). R3 was absent in 4 (22.2%) bilaterally and in 2 (11%) JSLE patients unilaterally. Absence of R3 was more prominent in JSLE patients, comparing to JSS. (Table 2)

Conclusion: BR could be considered as a potential indicator of neuropathy in JSLE and JSS patients. Data on SSR need to be evaluated in studies with higher number of patients with juvenile-onset connective tissue disorders.

AB0925  TOCLIZUMAB AS A TREATMENT OPTION FOR PATIENTS WITH JUVENILE SYSTEMIC SCLEROSIS

Amra Adrovic1, Sezgin Sahin2, Mehmet Yildiz1, Oya Koker1, Kenan Barut1, Ozgur Kasapcopur1, 1Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Rheumatology, İstanbul, Turkey, 2Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Rheumatology, Istanbul, Turkey

Background: Juvenile systemic sclerosis (JSS) is a rare autoimmune disease characterized by skin stiffness and fibrosis of internal organs (eg. lung, heart, gastrointestinal system). The efficacy and safety of tocilizumab (TCZ), an interleukin 6 receptor-inhibitor, in adult patients have been studied in a few recent studies. Reports on its efficacy among children have been reported among patients with localized disease form. This is a first report on treatment of JSS patients with TCZ.

Objectives: We aimed to evaluate efficacy of tocilizumab as a treatment option for patients with juvenile systemic sclerosis. Consequently, we sought to explore its influences on internal organ involvement, skin stiffness and patient global assessment score.

Methods: We retrospectively evaluated patients diagnosed with JSS according to EULAR criteria. Among 30 patients diagnosed with JSS, 7 (23%) were treated with TCZ. Demographic data are taken from patients’ charts. Data on clinical characteristics and treatment outcome are recorded during the patients’ last visit.

Results: Seven patients treated with TCZ were analyzed: 6 (85.71%) girls, one boy. Median age of patients was 17.5 years (range:11-12 years), at disease onset 10 years (range 6-15 years) and at diagnosis 11 years (range 7.5-17 years). Median disease duration was 8 years (min. 3-max.11 years). Median duration of TCZ treatment was 10 months (min. 1-max. 21 months). One (14.28%) patient had gastro-intestinal involvement, 4 (57.14%) patients had lung involvement and 2 (28.57%) patients had both gastro-intestinal and lung involvement. Improvement in mRSS was detected in 5 (71.43%) patients. DLCO improved in 4 (57.14%) patients. Four (57.14%) patients had radiologically confirmed improvement in lung findings. Data on radiological findings of one patient treated with TCZ for 6 mos were not available. Five patients (71.43%) reported improvement in patient global assessment (PGA) score after the TCZ treatment. PGA score of two remaining patients were not applicable due to short treatment duration (Table 1). None of 7 patients had recorded adverse effect of TCZ treatment.

AB0926  JUVENILE SYSTEMIC SCLEROSIS AND MUCINOUS ADENOCARCINOMA OF THE LUNG IN PATIENT WITH CYSTIC ADENOID MALFORMATION-PARANEOPLASTIC SYNDROME OR JUST A COINCIDENCE?

Amra Adrovic, Kenan Barut, Mehmet Yildiz, Oya Koker, Sezgin Sahin, Ozgur Kasapcopur, Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Rheumatology, Istanbul, Turkey

Background: Juvenile systemic sclerosis (JSS) is a rare auto-immune condition characterized by skin stiffness and internal organ fibrosis. In adult patients, systemic sclerosis has been related to an increased risk of malignancy with lung cancer being most prevalent. Up-to-date, we haven’t found any report on lung cancer in patient with JSS.

Objectives: Herein, we aimed to present a case with juvenile systemic sclerosis and coincidentally detected cystic adenoid malformation complicated by the mucinous adenocarcinoma of the lung.

Methods: Data on disease history are taken from patient’s chart. Clinical and laboratory findings are recorded during the last visit at our outpatient department.

Results: A 14 years old previously healthy female patient, admitted to our outpatient department due to puffy fingers, Raynaud’s phenomenon and stiffness of the skin proximally to metacarpalphalangeal joints. Her anti-nuclear antibody was positive (1/80) but the other auto-antibodies (including Anti Sc 70, anti-centromere antibody) were negative. Patient was diagnosed as progressive systemic sclerosis and the prednisolone, methotrexate and nifedipine were started. Routinely performed echocardiography was normal. Respiratory function tests were appropriate for the age and hemoglobin level: FVC 80%, DLCO 92%. Surprisingly, thorax HRCT revealed cystic adenoid malformation on the left lower lobe of the lung so pediatric surgery department has been consulted. The decision for surgical intervention has been made and the lesion has been removed. Tissue sample has been sent to the pathological investigation and the result was consistent with mucinous adenocarcinoma of the lung. There were 2 focus (0.4 cm in diameter) of the adenocarcinoma in the cystic adenoid malformation without invasion to the local perineural, lymphatic or vascular tissues, with positive KRAS (KRAS12-612C, 612S) mutation. Cranial MRI and PET-CT show no residual, relapse nor the metastatic lesions. Clinical follow-up has been suggested, without need for further oncological treatment.

Conclusion: Juvenile systemic sclerosis is a rare disease characterized with multorgan involvement. The paraneoplastic syndrome with clinical presentation of systemic sclerosis should be kept on mind among adolescents, especially those with negative auto-antibodies.

Disclosure of Interests: None declared
Background: Juvenile idiopathic arthritis (JIA) is a complex entity and is the most common rheumatologic disease of the children with the knee being the most frequently affected joint. Extensive proliferation of the synovial cells, synovial thickening and inflammation are the hallmark pathological processes ongoing in the affected joints. The traditional methods in assessing the disease activity involve investigating tenderness, pain, and swelling of the relevant joint on physical examination in addition to biochemical markers; however, the psychical examination may yield equivocal results in some patients. Sonographic modalities are being increasingly used as a complementary method in the assessment of the joints in JIA and Power Doppler ultrasound (PDUS) is the current reference sonographic method in assessing the inflammation by measuring the vascularity in the synovium. SMI is a novel Doppler technique using advanced filtering algorithms with an ability to detect even subtle and slow blood flow signals.

Objectives: We aimed to investigate the efficiency of Superb Microvascular imaging (SMI) in assessing inflammation of synovium in the knee of patients with JIA compared with PDUS.

Methods: Both knees of the patients with a diagnosis of clinically active JIA were examined using gray-scale US. The knees with positive US and physical examination findings included in group A while the knees with positive US findings despite negative physical examination findings included in group B. The observers calculated vascularity index (VI) by manually drawing a region of interest (ROI) onto the thickest part of the synovium using PDUS and SMI.

Results: A total of 41 knees with both clinical and sonographic positive findings constituted group A and 14 knees with sonographic positive findings and normal physical examination categorized as group B in the final cohort. The median SMI-VI (observer 1 = 4.9%, IQR 3.6; observer 2 = 4.1%, IQR 4.6) was exceeded the median PDUS-VI (observer 1 = 1.5%, IQR 1.8; observer 2 = 1.5, IQR 1.9) (P < 0.0001). In group B, the median SMI-VI (observer 1 = 2.85%, IQR 8; observer 2 = 3.1%, IQR 6.3) were exceeded the median VI PDUS-VI (observer 1 = 0.5%, IQR 2; observer 2 = 0.55, IQR 2.3) (P = 0.002 and P = 0.001 for observer 1 and observer 2, respectively). No significant differences were observed between groups concerning PDUS-VI and SMI-VI (P = 0.05). In all of the patients in group A, SMI was able to identify the presence of vascularity for both observers while no blood flow was detected (VI = 0%) using PDUS in 6 patients (14.6%) for observer 1 and 7 patients (17.1%) for observer 2. In all of the patients in group B, SMI was also able to identify the presence of vascularity for both observers while no blood flow was detected (VI = 0%) using PDUS in 5 patients (%35.7) for each observers.

Conclusion: SMI-VI obtained from the hypertrophied synovium of both clinically active and inactive knee joints were substantially higher compared with PDUS-VI in JIA patients. Furthermore, SMI detected the presence of blood flow in patients in whom PDUS could not be able to identify any blood flow. The findings of the present work indicate that SMI seems to a promising tool and a valuable adjunct to conventional US in assessing the inflammation of the synovial tissue in JIA patients.

ACUTE RHEUMATIC FEVER: IS PROLONGED CORTICOSTEROID TREATMENT ASSOCIATED TO A BETTER CARDIAC OUTCOME?
Dariya Vankova1, Alexandra Chomahidze1, Ivan Kriulin1, Alina Alshevskaya3, Ekaterina Alexeeva1,2, Tatyana Dvoryakovskaya1,2, Ksenia Isaeva1,2, Policlinico Giovanni Battista Rossi, Reumatology, Verona, Italy 1Azienda Ospedaliera Universitaria Integrata Verona, Paediatric, Verona, Italy 2Policlinico Giovanni Battista Rossi, Reumatology, Verona, Italy 3Azienda Ospedaliera Universitaria Integrata Verona, Cardiology, Verona, Italy

Background: Acute rheumatic fever (ARF) is a nonsuppurative sequela that can occur two to four weeks after group A beta-hemolytic Streptococcus pharyngitis. Despite its decline in incidence in modern countries, ARF still represents worldwide a serious healthcare concern. The most common manifestations are arthritis and carditis, followed by chorea, erythema marginatum, and subcutaneous nodules. The diagnosis of ARF is clinical and requires satisfaction of revised Jones criteria as well as evidence of a recent streptococcal infection.

Carditis and chorea both need systemic corticosteroid treatment (prednisone, 1 mg/kg) but with different treatment courses: 2-3 weeks prednisone treatment course in carditis is generally undertaken compared to a longer prednisone treatment period in chorea (at least 2 months).

Objectives: The aim of this study was to investigate if the longer corticosteroid treatment used for patients with chorea and carditis is related to a better regression of cardiac damage compared to the shorter course of corticosteroid treatment used in patients with only carditis.

Methods: Data regard 14 patients were retrospectively revised (8 males, 6 females): 7 ARF patients with both cardiac and neurological involvement treated with systemic prednisone for 2 months; 7 ARF patients with only cardiac involvement treated with systemic prednisone for 2 weeks. The regression of cardiac damage in the two different groups was evaluated in relation to the different duration of corticosteroid treatment comparing ultrasound echocardiography (cardiac-US) performed at ARF onset and during a 2-3 year follow-up. The trend of the grade of aortic and mitral valves insufficiencies was chosen as indicator of the ARF cardiac damage evolution.

Patients with a similar grade of cardiac damage at disease onset were identified; then pairs were created according to the presence of chorea (so one patient was affected only by carditis and the other one of the same pair, according to the similar cardiac damage, had both carditis and chorea). Cardiac-US damage regression of the 7 pairs was assessed in order to evaluate if the grade of regression was higher in the patients with only carditis compared with the ones with both carditis and chorea.

Results: in 3 pairs a better regression of the cardiac damage was evident in the patients with only carditis; in other 3 a better regression was noticed in the patients with both carditis and chorea; finally no difference was detected in the last pair. No significant cardiac-US difference according to patient pairs appeared in relation to the steroid time treatment course (2-3 weeks vs 2-3 months); however in 85% of the cases (12 patients) steroid therapy did achieve regression on ARF cardiac damage.

Conclusion: This retrospective study does not reveal any significant difference between steroid duration therapies in ARF complicated by carditis; limits of the study are the size sample as well as the intra/inter observer variation during cardiac-US (all exams were achieved in a high level experience paediatric cardiac service); this study underlines the established importance of the use of corticosteroid in ARF carditis.

AB0930
EFFICACY OF TOCILIZUMAB IN TREATMENT OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN PATIENTS WITH MACROPHAGE ACTIVATION SYNDROME
Ekaterina Alexeeva1,2, Tatjana Dvoryakovskaya1,2, Ksenia Iseaeva1, Rina Denisova1, Margarita Soboshenko1, Anna Fetsiova1, Anna Mamutova1, Dariya Vankova1, Alexandre Chomahidze1, Ivan Kriulin1, Alina Alshevskaya1, Andrey Moskaliev1,1 National Medical Research Center of Children’s Health, Moscow, Russian Federation 1M. Sechenov First Moscow State Medical University, Moscow, Russian Federation 2Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation

Background: Macrophage activation syndrome (MAS) is a rare and severe complication of juvenile idiopathic arthritis (JIA) that most typically develops in patients with its systemic form (sJIA). Tocilizumab proved to be efficacious for treatment of both systemic JIA and polyarthritis. Nevertheless, the question regarding the effect of MAS on efficacy of TOC therapy in patients with sJIA is still to be solved.

Objectives: To evaluate the efficacy of tocilizumab therapy in patients having sJIA and MAS versus the patients without MAS.

Methods: Throughout the period between 2009 and 2018, 251 children with the acute phase of sJIA started to be treated with TOC at the Rheumatology Department of the National Medical Research Center of Children’s Health (Moscow, Russia). Of those, 69 patients had active MAS at initiation of TOC therapy. Patients were diagnosed with MAS according to the preliminary diagnostic guidelines for MAS complicating sJIA [1]. Treatment efficacy was evaluated according to the dynamics of clinical and laboratory signs using the ACRPedri criteria. The Wallace criteria were used to evaluate whether or not remission had been achieved.

Results: At initiation of TOC therapy, patients with and without MAS were comparable in terms of their sex and age characteristics, as well as the overall severity of arthritis (the percentage of women, 56.6% (intergroup p=0.396); the median age, 7.83 (4.39-11.3) years (intergroup p=0.640); and JADAS-71, 17.4 (13.7-22.8) (intergroup p=0.055)). Nevertheless, patients differed in terms of severity of certain clinical manifestations and prior history of the disease. The group with MAS was characterized by such parameters as shorter disease duration, shorter duration morning stiffness, and smaller number of affected joints but higher activity and severity score (Patient/Parent and Physician VAS score).

After treatment initiation, TOC was discontinued after treatment for 4-12 weeks only in 2 out of 69 (2.9%) patients because of persistent MAS or MAS flare. The patients successfully achieved remission after therapy switching. No intergroup differences were observed for the rate of treatment discontinuation within the first year of therapy: the drug was discontinued in 5 (7.2%) patients in the MAS+sJIA group (2 MAS flares + 3 cases of poor efficacy) and in 25 (13.7%) patients in the sJIA group (4 SAEs + 21 cases of poor efficacy).

One-year treatment with TOC proved that this drug is highly efficacious to treat sJIA regardless of whether or not patients had MAS at treatment initiation (Figure).

No deaths were reported throughout the entire treatment period. We attributed this to early diagnosis and high efficacy of treatment of JIA patients.

Conclusion: Tocilizumab therapy in patients with sJIA in the presence of MAS is as efficacious as in patients without MAS and does not aggravate the course of MAS.

TRANSLATION AND VALIDATION OF THE MTX INTOLERANCE SEVERITY SCORE QUESTIONNAIRE FOR PORTUGUESE VERSION IN BRAZIL IN JUVENILE IDIOPATHIC ARTHRITIS

Ana Carolina Londe, Roberto Marini, Simone Appenzeller. University of Capinas, Campinas, Brazil

Background: Methotrexate (MTX) is the first-choice disease-modifying anti-rheumatic drug (DMARD) for the treatment of juvenile idiopathic arthritis (JIA). During therapy, there are frequent reports of discontinuation of MTX, either by physicians or patient’s own conduct. Through the MTX Intolerance Severity Score questionnaire (MISS), we determined the prevalence of MTX intolerance.

Objectives: Translate and validate the MTX Intolerance Severity Score questionnaire (MISS) to Portuguese.

Methods: The MISS was translated into Portuguese following the “Guidelines for the process of cross-cultural adaptation of self-report measures”. The MISS consists of 4 domains: stomachache, nausea, vomiting, and behavioral complaints. Each domain includes three to four items, and for every item, four answers are possible: no complaints (0), mild complaints (1), moderate complaints (2 points), and severe complaints (3 points). The points are summed to give a total score from 0 to 36. Statistically analysis was performed on the SPSS version 21, the psychometric properties were analyzed according to the Consensus based Standards for the Selection of Health Measurement Instruments (COSMIN), analyzing acceptability for each item, internal consistency using Cronbach’s alpha coefficient and reproducibility assessed by Kappa. We plot the ROC curve to evaluate the discriminant validity of the MISS compared to gold standard (clinical interview) and cut-off score was determined.

Results: We included 220 subjects, 144 patients with JIA in use for less than 3 months of MTX and 76 parents. The median age of patients were 18.3 SD±8.7 years. Seventy-three (73%) patients were females and the JIA subtype most frequently observed was polyarticular. Routes of administration of MTX were subcutaneous (81%) and oral (19%). All the subjects answered the MISS with less than 5 minutes. The internal consistency of MISS had a Cronbach’s alpha = 0.851 (patients) and 0.805 (parents), considered good (>=0.8). The reproducibility between the test (40 patients) and the retest done after 15 days (36 patients) was almost perfect (kappa=0.8). Reliability between patients and parents was almost perfect (kappa=0.8), except stomachache (anticipatory with kappa = 0.30); considered weak (κ = 0.2 - 0.4) and stomachache by association (κ = 0.54); considered moderate (κ = 0.4 - 0.6). A cut-off scores of 3 showed the best sensitivity (93%) and specificity (71%). Using this cut-off we observed 78 (54.2%) patients intolerant.

Conclusion: MISS is a good tool for physicians, because it can not only measure the intolerance, but also explore the different forms in which it manifests. Although MTX has a great therapeutic index, the adverse reactions are still seen as a major form of abandonment of this pharmacological treatment. Therefore a careful history is essential to identify side effects and adequate treatment to increase adherence.

PREDICTORS OF FLARE FOLLOWING ETANEOCTETE WITHDRAWAL IN PATIENTS WITH RHEUMATOID FACTOR NEGATIVE JUVENILE IDIOPATHIC ARTHRITIS DURING 48 MONTHS OF FOLLOW-UP

Angela Aquilani1, Denise Pires Maranon2, Andreni Uva1, Hanan Jadoun1, Fabio Basta1, Rebecca Nicolai1, Fabrizio De Benedetti1, Silvia Magni-Manzoni1.

1IRCCS Ospedale Gaslini, Division of Rheumatology, Genoa, Italy; 2Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Intermediate Pediatric Care Unit, Milan, Italy

Background: Little is known about the risk of flare after etanercept (ETN) withdrawal in children with Juvenile Idiopathic Arthritis (JIA). Recently we conducted a retrospective chart review of 110 patients with JIA who discontinued ETN due to persistent clinically inactive disease (CID) on medication and were followed up to 12 months after ETN withdrawal. We showed that 60% of patients flared with arthritis. Male gender, presence of ANA and elevated CRP at baseline were associated with a higher risk of flare.

Objectives: To evaluate frequency and timing of flares during 48 months of follow-up after withdrawal of ETN first course in patients with JIA who attained clinical remission on medication and to identify predictors of early flares (<12 months after withdrawal of ETN first course) and predictors of repeated flares (>2).

Methods: The 110 patients enrolled in the previous study with oligo (o-JIA) and RF-negative polyarticular JIA (p-JIA) who received a first course of ETN for at least 18 months and maintained clinically inactive disease (CID) for at least 6 months on treatment, were followed for 48 months after withdrawal of first course of ETN. We excluded patients that switched or swapped to other biologics or with limited follow-up. Demographic and clinical features at onset, at baseline (initiation of ETN) and at time of disease flares were collected.

Results: Among the cohort of the study, 10 patients (9%) were lost to follow-up and 18 (16%) switched/swapped to other biologics during 48 months of follow-up after withdrawal of ETN first course. Of the 82 patients included in the analysis, 55 (67%) were treated with only one course of ETN, while 27 (33%) received more than one course of ETN. The median age at disease onset was 3.6 years (IQR 1.9-8.5) and 72% of patients were female, ANA positive patients had a younger age at onset and were more frequently o-JIA. After withdrawal of ETN first course, 70 of the 82 (85%) patients enrolled flared with arthritis, without evident differences between o-JIA and p-JIA. Disease duration at diagnosis and at ETN start, total number of joints involved and total MTX treatment duration were not associated with flare. Patients who flared were more frequently males (p=0.017) and ANA positive (p=0.026), presented higher levels of CRP (p=0.029) at baseline and had longer total ETN treatment duration (p=0.0046). Higher values of CRP were associated with a higher risk of repeated flares (p=0.0094). No predictors of early flares were identified in this group.

When we analysed the 55 patients treated with one course of ETN, 48 (87%) flared during follow-up. Patients who flared were more frequently ANA positive (p=0.015), presented higher CRP levels (p=0.042) at baseline and concomitant MTX at ETN withdrawal (p=0.009). Higher levels of CRP was also associated with higher numbers of repeated flares (p=0.049). No predictors of early flares were identified in this subgroup.

Conclusion: Our results show that almost 90% of patients with JIA experience at least one flare after ETN withdrawal during 48 months of follow-up. Our findings confirmed that male gender, positive ANA and elevated CRP at baseline are associated with a higher risk of flare. Higher CRP levels at baseline resulted also associated with a higher risk of repeated flares.

ANALYSIS OF THE STATE OF IMMUNITY IN PATIENTS WITH JIA IN TREATMENT

Inmaculada Concepcion Aranda-Valera1,2, Ladeheasa Pineda Lourdes3, Font Ugalde Pilar2, Fernandez de la Puebla Lechuga Elena2, Copete Marín Sara4, Eduardo Collantes Estevez1,2, Roldán Molina Rosa1, Reina Sofia University Hospital, Rheumatology Service, Córdoba, Spain; 2University Of Córdoba (UCO), Medicine, Córdoba, Spain; 3Reina Sofia University Hospital, Pediatric, Córdoba, Spain; 4University Of Córdoba Regional Hospital, Rheumatology Service, Córdoba, Spain

Background: The correct indication of the suspension of treatment with FAMES and biological therapy in pediatric patients, in the presence of a mild infectious disease or vaccination is a common problem in children’s rheumatology. In patients with juvenile idiopathic arthritis (JIA), joint or extra-articular clinical reactivation during these “pauses” is not uncommon,
however, there are not enough studies in the pediatric population to show the influence of treatments on the immune system, and therefore, that justify this clinical practice.

Objectives: To analyze the levels of T, B and NK lymphocyte subpopulations in patients diagnosed with JIA treated with FAMES and biological therapy.

Methods: A descriptive and cross-sectional study in which 39 patients from the Pediatric Rheumatology Unit of the Reina Sofia University Hospital were recruited, diagnosed with JIA according to the ILAR 2001 criteria. The patients were divided into four groups: 8 controls in clinical remission without treatment, 17 in treatment with DMARD in monotherapy, 7 in biological treatment in monotherapy and 7 in treatment with DMARD-biological. Patients with systemic JIA were excluded because they had a pathogenic mechanism different from the rest of the JIA categories. By flow cytometry, the levels of CD3, CD4, CD8 and CD19 cells were measured for acquired immunity and from NK for innate, the CD4/CD8 index was also calculated.

Results: The mean age of the 39 patients was 10 ± 5.7 years, 29 were girls (74.3%), 4 patients had arthritis related to enthesitis, 16 patients had oligoarticular involvement ANA+e, 6 subjects polyarticular involvement FR- and 13 they were psoriatic arthritis. Although no statistically significant differences were found when contracting cellular levels among the 4 groups evaluated, it was observed that the group treated with DMARD monotherapy had the highest percentage of children with alterations in cellular levels CD3, CD4, CD8 and CD19 (41.17% of the patients of the group); the group treated in monotherapy with biological treatment (28%) presented an alteration in the levels of CD3 and CD8 and CD19 and the group treated in combination of DMARD and biological (14.28%) in CD19. On the other hand, the NK cells and the CD4/CD8 index were not altered in any of the groups. Only 6 cases of serious infections were registered in patients in combination therapy (DMARD-biological) who had received corticosteroids by clinical activity. There were no statistical differences between patients who had received corticosteroids and those who did not.

Conclusion: Patients in treatment with DMARD monotherapy had a tendency to decrease cellular levels. On the other hand, alterations in innate immunity or CD4/CD8 index were not observed.

AB0934

IL-6 AND ALLELIC POLYMORPHISM OF ITS GENE IN JUVENILE IDIOPATHIC ARTHRITIS

Aizar Artsymovich, Olena Oshilianska, Shupyk National Medical Academy of Postgraduate Education, Paediatrics N61, Kyiv, Ukraine

Background: The development and maintenance of inflammation in juvenile idiopathic arthritis (JIA) is mediated by cytokine imbalance; interleukin 6 (IL-6) plays a leading role among pro-inflammatory cytokines. Its pathological synthesis has a negative impact on all organs and system. It is not excluded that its effector ability depends on genetic structures of IL-6 gene. It has not been studied whether the allelic polymorphism of the IL-6-174CG gene affects the effectiveness of targeted biological therapy. Objectives: To assess the IL-6 dynamics level in serum of patients with ineffective JIA-treatment.

Methods: The level of IL6 in the serum of JIA patients 1-18y.o. was determined using ECLIA method, debut of the disease (54) and treatment failure (36; 6 oJIA, 14 pJIA, 10 enthJIA, 6 sJIA). In patients with JIA, allelic polymorphism of the IL-6-174CG gene was studied by PCR-method using allele-specific primers. A correlation analysis of clinical and laboratory parameters was made.

Results: Among patients with ineffective treatment of JIA, the duration of the disease was 39.5±35.8 months, 62.9% were girls. 27 patients received GC (<1mg/kg), 30-DMTX(10-15mg/m2), 3-leflunomide, 1-AZA, 10-TZ, 16-ADA/ETA, 1-TFC, 5 were switched from antiTNF for antiIL6. The levels of IL6 in the serum of JIA patients with treatment ineffectiveness was higher than at the beginning of disease (sJIA 52.40±37.84±24.4±1.7 (p <0.05); pJIA 36.19±8.58±6.23±20.25± <0.05); oJIA 6.99±5.27±0±1±0.1; enthJIA 90.55±63.3±4±29.9±p/ml). There was no increase in IL6 level in patients with an unfavorable course of the RFpos-pJIA (4±7±3.5±p/ml) and with uveitis (5.59±4.9±p/ml) (norm.1–5±7±p/ml). In 57.1% of cases of RFneg-JIA IL6 was elevated, in 3 children it was the highest (79.77; 218.7±p/ml), they had anemia and osteoporosis. A high (51-484.6±p/ml) level was observed in 4 patients with enthJIA, in 1-inadequate therapy was performed, in 3 patients there was a fever, a lag in physical development, the highest CRP (up to 300 mg/ml). The correlation between the level of IL6 in the blood of children with JIA and the presence of lymphadenopathy in the debut of the disease (r=0.53), the child’s age at the debut of the disease (r=0.63), examination (r=0.74), and the patient’s weight (r=0.87), the duration from the onset of the disease to the initiation of biological therapy (r=0.44), the number of exacerbations in the first years of the disease (r=0.66-0.69), the formation of contractions and the limitation of movement in the joints (r=0.75), radiological progression in the 1st year from the debut (r=0.54), ESR (r=0.48), CRP (r=0.40), doctor’s estimate of disease activity (r=0.79), ALT (r=0.69), AST (r=0.99), LDH (r=0.73) was found. There was no correlation with the number of affected joints (r=0.28), heart rate (r=0.48), metabolic abnormalities on the ECG (r=0.39). In children with an adverse course of JIA, IL6 correlated backward with TNF (r=−1), which was not observed in children at the onset of the disease (r=0.19).

Analysis of the results of genetic examination showed that among children with treatment failure, 23% had GG allele, and 27,3% had CC allele, and 23,7% had GC allele.

Conclusion: Treatment of JIA leads to changes in cytokine profile. The IL6-174CG gene has a high level of IL6 in the blood. The longer the duration of the disease and the time before the start of treatment with biological DMARDs, the greater the likelihood of an increase of IL-6 level in serum. In cases of even short-term enminia in JIA, subclinical activity with IL-6 can be suggested. In case of presence of some signs (hyperthermia, osteoporosis, anemia) in patients with antiTNF, it is advisable to determine the level of IL-6 in blood serum.

ANTI-TF-1-AntIBODIES IN JUVENILE DERMATOMYOSITIS ARE ASSOCIATED WITH VARIOUS CLINICAL PHENOTYPES

Brigitte Bader-Meunier1, Cyril Gitiaux2, Jean-Luc Charuel2, Nicole Fabien2, Isabelle Melki2, Pierre Quartier2, Alexandre Belot7, Nathalie Streichenberger4, Christine Bodemer1, Audrey Aussay6, Olivier Boyer2, Hospital Necker, Pediatrics, Paris, France, Hospital Necker, Pediatrics, Paris, France, Hospital Necker, Pediatrics, Paris, France, Hospital La Pitié, Immunology, Paris, France, HCL, Lyon, France, Hôpital R. Debré, Paris, France, Hospital Necker, Paris, France, HFM, Lyon, France, Rouen University Hospital, Rouen, France

Background: Juvenile dermatomyositis (JDM) is a rare heterogeneous autoimmune disease. The identification of myositis specific antibodies (MSAs) has allowed the characterization of subgroups of JDM patients who each have specific phenotypes. Antibody (Ab) against transcriptional intermediary factor-1-γ (TIF-1-γ) or p155/140 is the most common MSA in JDM. In the American and English JDM cohorts, anti-TF-1-γ associated JDM is classically associated with a larger proportion of caucasians, mild or moderate severity with typical cutaneous manifestations (Gottron’s papules and heliotrope rash), and subclinical activity, and a chronic disease course with a low mortality. The frequency of skin ulcerations and lipoatrophy differs between the two cohorts.

Objectives: To report the clinical and muscle histology associations of anti-TF-1-γ Ab in a series of patients with JDM followed in the French referral center for rare pediatric systemic autoimmune diseases.

Methods: Retrospective study of patients with JDM (according to the EULAR/ACR criteria) associated with anti-TF-1-γ autoantibodies and included in our CEMARA database approved by the French National Committee on Informatics and Liberty.

Results: Thirteen patients were included (males: 5, females: 8; Caucasians: 6, Black Africans: 2, North Africans: 5). Age at diagnosis ranged from 1.5 to 11 years. Serum creatine kinase was elevated in 12 patients (range: 180-43 000 IU/L). Three different phenotypes were identified according to the severity and course. In group 1 (n=4), 3 patients had a moderate JDM: classical cutaneous manifestations and moderate muscle involvement; relapsing course, which remitted under methotrexate/corticosteroids; an additional 2-year-old girl had an amyopathic JDM. In group 2 (n=7), patients had ulcerating skin lesions, severe muscle involvement, dysphagia, gastrointestinal vasculitis and/or requirement to an intensive care unit, and required more than two lines of treatment. In this group, 2/7 patients died from refractory JDM, comparing to a mortality rate of 2% in the remaining JDM patients tested for MSA and negative for anti-TF-1-γ. Only 2/5 patients achieved a complete remission under treatment. Group 3 comprised two patients with severe muscle atrophy, calcinosis and lipodystrophy and a chronic course; one of them had a very-early-onset JDM at 1.5 year-old and the other an inherited neurological involvement, potentially suggestive of a genetic predisposing condition to JDM. None of the patients developed lung involvement or malignancy. Six patients underwent a muscle biopsy which was
AB0936
A NATIONAL SURVEY OF CLINICAL PRACTICE OF CORTICOSTEROID USE IN NEWLY DIAGNOSED OR FLARING CASES OF JUVENILE IDIOPATHIC ARTHRITIS ACROSS THE UK
Eileen Baildam1, Ashley Jones2, Dannii Claydon2, Gloria Nkoma3, Matthew Peak1, Athimalaipet Ramanan3, Madeleine Rooney4, Helen Foster5, Simon Stones6, Flora McErlane7, Tracy Moitt8, Louise Roper9, Bridget Young1, Frances Sherratt1, Michael Beresford9, Alder Hey Children’s Hospital – Liverpool, Paediatric Rheumatology, Liverpool, United Kingdom; 2University of Liverpool, Clinical Trials Unit, Liverpool, United Kingdom; 3Bristol Royal Hospital for Children, Paediatric Rheumatology, Bristol, United Kingdom; 4Royal Belfast Hospital for Sick Children, Paediatric Rheumatology, Belfast, United Kingdom; 5University of Newcastle upon Tyne, Paediatric Rheumatology, Newcastle upon Tyne, United Kingdom; 6University of Leeds, School of Healthcare, Leeds, United Kingdom; 7Great North Children's Hospital, Paediatric Rheumatology, Newcastle upon Tyne, United Kingdom; 8University of Liverpool, Institute of Population Health Sciences, Liverpool, United Kingdom; 9University of Liverpool, Department of Translational Medicine, Liverpool, United Kingdom

Background: Corticosteroids (CS) are widely used for rapid-action or induction treatment in children and young people (CYP) with juvenile idiopathic arthritis (JIA). Given a lack of evidence base on CS induction regimens for CYP with JIA, and since criteria for choosing CS are based on healthcare professional (HCP) preference, further research is needed (1).

Objectives: To establish the opinions of HCPs regarding the clinical criteria for commencing CS treatment.

Methods: A national electronic survey was undertaken among HCPs across the UK as part of the steroid induction regimen for juvenile idiopathic arthritis (SIRJIA) study.

Results: A total of 39 (24%) responses were received from 162 HCPs. These included 22 (56%) NHS consultants, five (13%) grid trainees, eight (21%) clinical nurse specialists and four other HCPs (10%). The most common treatments in CYP with newly diagnosed JIA or a disease flare were intra-articular (IA) CS or a combination of DMARDs and IAAS (except for systemic JIA and oligoarticular JIA). The majority of HCPs 17 would treat new and flaring CYP the same in terms of a CS remission induction regime, with 53% choosing a different regime or not answering. The key criteria that HCPs used for commencing CS and choosing the route of administration were rapid induction of remission (31 (89%)), severity of systemic JIA (20 (56%)) and level of inflammation (28 (80%)) Table 1. The number one determinant of route of administration of CS was disease severity followed by disease subtype.

The majority of HCPs (52-72% depending on role) would consider entering CYP with JIA into a trial randomising to the various modes of administration.

Conclusion: The results from this national survey of clinical practice showed varying practices in the management of new CYP with JIA and those that are flaring. The majority of HCPs who completed this survey, indicated that they would be prepared to consider entering CYP into a trial that randomised to the four CS delivery methods.

IDENTIFYING THE PRIMARY OUTCOME MEASURE AND PROTOCOL COMPONENTS FOR A PROSPECTIVE FEASIBILITY STUDY OF CORTICOSTEROID REGIMENS FOR CHILDREN AND YOUNG PEOPLE WITH JUVENILE IDIOPATHIC ARTHRITIS USING CONSENSUS METHODS WITH YOUNG PEOPLE, FAMILIES AND PROFESSIONALS
Simon Stones1, Heather Bagley2, Ashley Jones3, Flora Mcerlane3, Tracy Moitt1, Gloria Nkoma2, Frances Sherratt1, Bridget Young4, Michael Beresford5,6
Eileen Baildam1, SIRJIA Trial Management Group. 1University of Leeds, School of Healthcare, Leeds, United Kingdom; 2University of Liverpool, Institute of Translational Medicine, Liverpool, United Kingdom; 3Newcastle Hospitals NHS Foundation Trust, Great North Children’s Hospital, Newcastle upon Tyne, United Kingdom; 4University of Liverpool, Institute of Population Health Sciences, Liverpool, United Kingdom; 5Alder Hey Children’s NHS Foundation Trust, Liverpool, United Kingdom

Background: Juvenile idiopathic arthritis (JIA) is an umbrella term for seven relapsing-remitting inflammatory conditions in children and young people (CYP). Early, intensive treatment can prevent long-term damage; however, established drugs exhibit a delayed response, prompting the need for rapid-onset treatment in the form of corticosteroids. Given a lack of consensus as to which corticosteroid induction regimen should be used for CYP with JIA, a feasibility trial of different regimens is needed.
EFFICACY AND SAFETY OF BIOLOGICAL THERAPY WITH ETA NERCEPT IN A CASE OF SEVERE POLIARTHRITIS ASSOCIATED TO HARLEQUIN ICHTIOSIS

Francesco Baldo, Simone Carbogno, Sofia Torreggiani, Carlo Virgilio Agostoni, Larni Stefano, Francesca Minola, Giovanni Filocamo. Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Pediatria Media Intensità di Cura, Milano, Italy.

Background: Harlequin Ichthiosis (HI) is a rare autosomal recessive congenital disease, due to mutations of gene ABCA12. The estimated incidence is approximately 1 in 300,000 births, and approximately 200 cases have been reported worldwide. Typical manifestations of the disease at birth are the presence of hyperkeratotic plates with erythematous fissures, ectropion (eversion of the lower eyelids) and eclabium (eversion of the lips), rudimentary ears and nasal hypoplasia, and articular contractures. Babies who survive into infancy tend to lose hyperkeratotic plaques in favour of generalized scaling and erythroderma. Mental retardation is present in about 2/3 of cases. The association between HI and inflammatory joint involvement has been reported only in few patients since now.

Methods: We report clinical and laboratory findings, treatment choices and outcomes of young boy with HI who developed polyarthritis.

Results: A 6 years old kid with HI (the genetic test showed homozigous mutation of ABCA12) came to our attention with an history of chronic arthritis. Since he was 4, he developed bilateral knee arthritis. At first, he was treated with antimicrobial drugs, without improvement, in suspect of septic arthritis. In the following two years, he developed severe chronic polyarthritis. At the first visit in our center, he showed the classical clinical feature of HI (severe ectropion, contracture and generalized erythroderma), and had history of multiple severe infections and sepsis. Arthritis affected both hips, knees, ankles, wrists, elbows, shoulders and all the feet joints. He lost the ability to walk since the onset of arthritis. Laboratorial features showed negative anti nuclear antibodies (ANA) and anti- extractable nuclear antigen antibodies (ENA), anti celic citrullinated peptide and rheumatoid factor. No signs of uveitis were present at ophthalmological evaluation.

The patient was treated with intraarticular corticosteroid injections (IAI) into knees, wrists, elbows and ankles, and then oral methotrexate (MTX) was started. The clinical response was initially good, with partial recovery of deambulation in the 4 months following the intraarticular injection treatment. After 7 months ankles and wrists showed swelling and tenderness, and IAI were repeated, with clinical improvement.

AB0938

Efficacy and Safety of Biological Therapy With Etanercept in a Case of Severe Poliarthritis Associated to Harlequin Ichthiosis

Francesco Baldo, Simone Carbogno, Sofia Torreggiani, Carlo Virgilio Agostoni, Larni Stefano, Francesca Minola, Giovanni Filocamo. Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Pediatria Media Intensità di Cura, Milano, Italy.

Background: Harlequin Ichthiosis (HI) is a rare autosomal recessive congenital disease, due to mutations of gene ABCA12. The estimated incidence is approximately 1 in 300,000 births, and approximately 200 cases have been reported worldwide. Typical manifestations of the disease at birth are the presence of hyperkeratotic plates with erythematous fissures, ectropion (eversion of the lower eyelids) and eclabium (eversion of the lips), rudimentary ears and nasal hypoplasia, and articular contractures. Babies who survive into infancy tend to lose hyperkeratotic plaques in favour of generalized scaling and erythroderma. Mental retardation is present in about 2/3 of cases. The association between HI and inflammatory joint involvement has been reported only in few patients since now.

Methods: We are describing the case of a 6 years old kid with HI that at the age of 4 developed arthritis with severe impact on his quality of life.

Results: A 6 years old kid with HI (the genetic test showed homozigous mutation of ABCA12) came to our attention with an history of chronic arthritis.

Conclusion: It is feasible to include CYP, families and HCPs in synthesising complex concepts to agree by consensus the design components of clinical research. The primary outcome measure for inclusion in a prospective feasibility study of corticosteroids regimens in CYP with JIA was co-prioritised, with CYP and families taking a leading role in the ultimate selection of an appropriate outcome measure and other study protocol components. Using consensus methods with CYP, families and HCPs is a systematic and rigorous way in which to select outcome measures that are both meaningful and relevant to everyone involved in the care and treatment of CYP with JIA.

Disclosure of Interests: Simon Stones Consultant for: SS has provided consultancy services to Envision Pharma Group, though this is not related to the contents of this abstract., Speakers bureau: SS has undertaken speaking engagements for Actelion, eyeforpharma, Four Health, Janssen and Roche, though these are not related to the contents of this abstract., Heather Bagley: None declared, Ashley Jones: None declared, Flora McErlane: None declared, Tracy Moitt: None declared, Gloria Nkhoma: None declared, Frances Sherratt: None declared, Bridget You: None declared, Michael Beresford: None declared, Eileen Baildam Consultant for: EB has received one paid consultancy for Pfizer in the last 12 months, but this was not related to this study.

Methods: A cross-sectional descriptive study in which 34 patients were recruited sequentially and randomly, 15 with JDM and 19 with JIA, from the Rheumatology department of Niño Jesus Hospital between September-November (2018). Demographic, clinical, analytical data, presence and subtype of calcinosis, active treatment, HAQ, patient and physician global assessment (PGA), cutaneous assessment tool (CAT) and manual muscle testing (MMT8) validated for JDM were collected. One observer performed blindly, both for clinic and diagnosis, a NFC initially using a videodermatoscope in order to obtain a wide view of the vascular bed and then with a videocapillaroscope (x3000), which recorded 2-4 images per finger (except thumbs) to be analyzed far ahead. The presence of a decreased nailfold capillary density (NCD, capillary n°/mm²), architectural derangement (disorganization), neoangiogenesis, giant capillaries (ø>50µm, pathological if ≥1), enlarged loops (ø20-50µm) and microhaemorrhages, both pathological present in ≥2 fingers were evaluated. Neovascular pattern was defined as the sum of NCD, disorganization and neoangiogenesis with frequent haemorrhages and giants (active and late scleroderma pattern).

Results: The descriptive analysis of the main variables is shown in Table 1. Patients with JIA: all received active treatment, 95% MTX (33% concomitant with anti-TNF; 1 TCZ and 16% CE) and 1 anti-TNF. 26% active uveitis. Two patients presented morphological abnormalities: 1 neoangiogenesis and another enlarged loops. Patients with JDM: 73% received MTX (18% concomitant with CE, 73% Igs and 1 RTX). Three patients had active calcinosis: 2 mixed (circumscribed and cutis) and 1 calcinosis cutis. 2 had previous calcinosis (both circumscribed); 87% presented for the first-time weakness but none had current weakness (MMT8 40). 67% presented morphological abnormalities: NCD 33%, disorganization 40%, neoangiogenesis 53%, enlarged loops 27%, giants 20% and microhaemorrhages 13%. All patients with calcinosis (active or previous) presented disorganization and neoangiogenesis, NCD 80%, giants 60%, enlarged loops and microhaemorrhages 40%. 50% of patients with JDM had a neovascular pattern, of which 80% had a previous or current history of calcinosis.

Conclusion: Patients with JDM presented more abnormalities in NFC compared to patients with JIA. Neovascular pattern was observed in half of patients, who have previous or current history of calcinosis. Consequently, NFC could be a useful imaging technique in routine clinical practice to evaluate skin activity in patients with JDM.

AB0939 NAILFOLD CAPILLAROSCOPY IN JUVENILE DERMATOMYOSITIS: DESCRIPTION OF ABNORMALITIES IN A SERIES OF PATIENTS
Laura Barrio Nogal1, Agustina Sharruf2, Sonia Peña Montelongo3, Daniel Clemente4, J.C. López Robledillo5, 1Hospital Universitario Príncipe de Asturias, Madrid, Spain; 2Hospital Niño Jesús, Tucumán, Argentina; 3Hospital Universitario de Canarias, Tenerife, Spain; 4Hospital Universitario Niño Jesús, Madrid, Spain

Background: Juvenile dermatomyositis (JDM) is characterized by the presence of microangiopathy which can be assessed by nailfold capillaroscopy (NFC), a simple and noninvasive imaging technique. Morphological abnormalities in scleroderma NFC are well described, but it is known that they may be present in other autoimmune diseases, such as JDM.

Objectives: To describe the capillary morphological abnormalities assessed by NFC in a series of patients diagnosed with JDM in contrast with patients diagnosed with juvenile idiopathic arthritis (JIA).

Results: The descriptive analysis of the main variables is shown in Table 1. Patients with JIA: all received active treatment, 95% MTX (33% concomitant with anti-TNF; 1 TCZ and 16% CE) and 1 anti-TNF. 26% active uveitis. Two patients presented morphological abnormalities: 1 neoangiogenesis and another enlarged loops. Patients with JDM: 73% received MTX (18% concomitant with CE, 73% Igs and 1 RTX). Three patients had active calcinosis: 2 mixed (circumscribed and cutis) and 1 calcinosis cutis. 2 had previous calcinosis (both circumscribed); 87% presented for the first-time weakness but none had current weakness (MMT8 40). 67% presented morphological abnormalities: NCD 33%, disorganization 40%, neoangiogenesis 53%, enlarged loops 27%, giants 20% and microhaemorrhages 13%. All patients with calcinosis (active or previous) presented disorganization and neoangiogenesis, NCD 80%, giants 60%, enlarged loops and microhaemorrhages 40%. 50% of patients with JDM had a neovascular pattern, of which 80% had a previous or current history of calcinosis.

Conclusion: Patients with JDM presented more abnormalities in NFC compared to patients with JIA. Neovascular pattern was observed in half of patients, who have previous or current history of calcinosis. Consequently, NFC could be a useful imaging technique in routine clinical practice to evaluate skin activity in patients with JDM.

AB0940 OBESITY AND NUMBER OF ACTIVE JOINTS AT TUMOR NECROSIS FACTOR-INHIBITOR START ARE ASSOCIATED WITH SHORTER REMISSION DURATION AFTER WITHDRAWAL IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: PRELIMINARY RESULTS FROM A MONOCENTRIC COHORT
Fabio Basta, Hanan Jadoun, Maria Isabella Petrone, Angela Aquirani, Andrea Uva, Rebecca Nicolai, Fabrizio De Benedetti, Silvia Magni-Manzoni. Ospedale Pediatrico Bambino Gesù, IRCCS, Division of Rheumatology, Rome, Italy

Background: No recommendations on appropriate withdrawal of tumor necrosis factor-inhibitors (TNFi), once remission status has been achieved

Disclosure of Interests: None declared 
in patients with juvenile idiopathic arthritis (JIA), are currently available. With regards to possible predictors of flare, the role of obesity has not been investigated yet.

**Objectives:** To investigate to role of obesity at start of TNFi therapy on remission duration and flare rate after TNFi withdrawal in JIA patients.

**Methods:** The charts of JIA patients followed at the study center and treated with TNFi as first biologic from 2009 to 2015, who reached remission and with at least one year of follow up after withdrawal, were retrospectively reviewed. Exclusion criteria were: systemic JIA and pJIA RF-positive. Demographic and clinical features were registered, including: ILAR JIA subtype, occurrence of uveitis, ANA status, number of active and clinical manifestations of SLE in patients younger than 6 years old in our series are similar to those described in the literature: arthritis and seizures, as well as neurological and neuropsychiatric manifestations; We present the demographic and clinical characteristics of SLE in patients under 6 years old with a diagnosis of SLE based on the 1997 ACR criteria at the Federico Gomez Children’s Hospital of Mexico from June 2017 to January 2019.

**Background:** Systemic lupus erythematosus (SLE) is a rare entity in patients under 5 years old, depending on the ethnic group it has a prevalence of 3.3 to 24 per 100,000 children. Before puberty no difference in prevalence associated with gender was observed. In the pediatric age, SLE has a more aggressive course.

**Objective:** To describe the demographic and clinical characteristics of 6 patients under 6 years old diagnosed with SLE.

**Methods:** To describe the demographic and clinical characteristics of 6 patients under 6 years old with a diagnosis of SLE.

**Results:** The diagnosis of SLE in patients under 5 years old is rare, the literature describes that in these patients there is greater renal, hematological and neuropsychiatric manifestations; We present the demographic and clinical characteristics of 6 patients under 6 years old with a diagnosis of SLE based on the 1997 ACR criteria at the Federico Gomez Children’s Hospital of Mexico from June 2017 to January 2019.

Table N°1. Demographic and clinical characteristics of patients under 6 years of age diagnosed with SLE.
Background: A challenge with the present classification of JIA is the evolution of the disease over time. One category that is especially difficult to classify is enthesitis-related JIA (ERA). Objectives: To longitudinally study radiologically diagnosed sacroiliitis (Si) developed during the first 18 years in an aim to gain knowledge about classification challenges posed by the Si category, nosoclassification (Martin-Atencia A et al. J Rheumatol. 2018 Oct; Epub ahead of print).

Methods: 510 consecutive cases of JIA with disease onset 1997 to 2000 were prospectively included in a Nordic, longitudinal, close to population-based 18-year follow-up study, and 434 (85%) had at least two follow-up visits during disease course. At the 18-year follow-up visit; 329 (76%) attended a clinical visit, and 105 (24%) a telephone interview. The follow-up period was 17.5 ± 1.7 years (mean ± SD) after onset. Mean age of the study participants was 24.0 ± 4.4 years. Clinical data, collected at one, eight and 18 years after disease onset, were evaluated regarding variables for enthesis/spondylitis-related arthritis compared to the other JIA categories.

Results: In 376 participants evaluated for Si, radiology was performed on clinical suspicion. 26 (16%) males and 10 (28%) females developed radiologically verified sacroiliitis (rad-Si) during the first 18 years of disease. Age at onset was significantly higher in this group compared to the other participants, median 9.9 (IQR 6.4-12.0) vs. 5.6 (IQR 2.6-9.5) years, (p=0.001). Only 3/26 had rad-Si at eight-year follow-up.

Using the ILAR criteria 12/26 with rad-Si were classified as ERA after median 7 (IQR 6-10.2) months, 1/26 as juvenile psoriatic arthritis, 5/26 as undifferentiated JIA because of psoriasis-related variables, the remaining had oligo- or polyarticular arthritis. At 18-year follow-up, 18/26 fulfilled criteria for ERA, 2/26 juvenile psoriatic arthritis, and 3/26 the undifferentiated category because of psoriasis-related variables, 3/26 had polyarticular RF negative or oligoarticular extended disease. Enthesitis, inflammatory back pain, and morning stiffness were more common with rad-Si (p=0.001; p=0.001; p=0.001), also HLA-B27, 1/26 vs. 62/351 (p=0.001), but not 1st degree heredity for ankylosing spondylitis. Uveitis developed in 10/26 (38.5%). Two participants developed IBD.

Conclusion: The majority of variables involved in the new proposed classification of enthesitis/spondylitis-related JIA were significantly more common during the first 18 years of disease in those that developed rad-Si. Psoriasis-related variables, no longer exclusion criteria for ERA, should be further evaluated as possible inclusion criteria, as well as higher age at onset.

RADIOLOGICAL SACROILIITIS AFTER 18 YEARS OF FOLLOW-UP IN THE POPULATION-BASED NORWEGIAN JUVENILE IDIOPATHIC ARTHRITIS (JIA) COHORT

AB0944

SJÖGREN’S SYNDROME IN CHILDREN: A CASE SERIES

Masa Biniak, Štefan Blazina, Tina Vesel Tajnišek, Tadej Avčin, Nataša Toplak. University Children's Hospital, University Medical Centre Ljubljana, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia

Background: The symptoms of pediatric Sjögren’s syndrome (SS) are different in adults. There are currently no validated pediatric diagnostic criteria or treatment guidelines for SS. In most cases adult criteria are used, but they apply poorly to children.

Objectives: To present pediatric patients with primary SS who were treated at University Children’s Hospital (UCH) Ljubljana in the past 10 years.

Methods: Eight children with primary SS were identified. Demographic data, clinical and laboratory findings and therapy were analysed by retrospective review of medical records at UCH Ljubljana.

Results: Six girls and 2 boys were evaluated. The mean age at disease onset was 12.3 years (range 6.5 – 17) and mean age at diagnosis was 13.8 years (range 7.5 – 17.5). The mean follow-up duration was 2.8 years (range 0.5 – 8.5). Four patients presented with recurrent bilateral parotitis, two with rash, one with arthralgia and fatigue and one with acute central nervous system vasculitis. The latter patient presented with rheumatic fever at the same time. During disease course arthritis and/or xerothalmia, which compromises exocrine glands causing inflammatory response that leads to glandular hypossecretion. SS is probably underdiagnosed in pediatric range due to differences in presentation regarding adults with this condition, causing low recognition of the disease in children.

Objectives: The authors describe demographic, clinical, laboratory and therapeutic profiles of a cohort of children with primary SS attended at a university center.

Methods: Retrospective analysis of 30 selected patients’ medical records between 2005 and 2017 allowed collection of various data. Laboratory and additional investigations included documentation of ocular dryness (Schirmer test, Rose-Bengal stain); evidence of parotid involvement (scintiscan, sialometry); and histological evidence of lymphocytic infiltration of the minor salivary glands or other organs.

Results: 30 patients diagnosed with juvenile SS were selected: 22 girls (73%) and 8 boys (27%) with an average age of 11 years. The clinical characteristics were: parotid enlargement as the initial manifestation of the disease in 11 patients (37%), and recurrent episode in 4 patients (13.3%). 12 patients (40%) had xerostomia and 17 (57%) xerophthalmia. One patient (3.3%) presented with leukocytoclastic vasculitis in lower limbs as first manifestation of the disease in association to recurrent parotid swelling. Two (6.6%) patients presented neurological symptoms (1 peripheral sensory neuropathy and 1 with dysautonomic manifestations).

Positive Schirmer test was observed in 11 patients (37%), Rose Bengal stain in 10 (33%). 76% of patients had abnormal salivary glands scintigraphy. In 8 patients (30%) the salivary gland biopsy revealed compatible with juvenile Sjögren syndrome clinical picture (30%) presented positive RF, 14 patients (46%) anti-Ro/SSA, 10 patients (33%) anti-La/SSB, 28 patients (93%) had +ve ANA. 50% received glucocorticoid. Hydroxychloroquine was the drug most often used in 25 patients (83%), followed by methotrexate in 12 patients (40%), azathioprine in 4 patients (13%) and cyclophosphamide in 3 patients (10%). Only one patient required the use of human immunoglobulin and one leflunomide (3.3%). Two patients (6.6%) received rituximab.

Conclusion: The present study demonstrated the demographic, clinical aspects and laboratory and treatment in a series of patients with primary juvenile Sjögren’s syndrome, a relatively rare condition, presenting an overview of this particular patient population.

AB0943

CLINICAL AND LABORATORY PRESENTATION OF JUVENILE SJÖGREN’S SYNDROME IN A COHORT OF 30 PATIENTS

Blanca Bica, Fernanda Zonis. UNIVERSIDADE FEDERAL DO RIO DE JANEIRO, INTERNAL MEDICINE, RIO DE JANEIRO, Brazil

Background: Sjögren’s Syndrome (SS) is a chronic autoimmune disease, rare in childhood and adolescence, characterized mainly by xeroesthesia and and xerophthalmia, which compromises exocrine glands causing inflammation of enthesitis/spondylitis-related arthritis compared to the other JIA categories.

REFERENCES

Scientific Abstracts
arthralgia was present in 5/8, parotitis in 4/8, oral symptoms in 4/8, rash in 4/8, fatigue in 3/8 and ocular symptoms in 2/8 patients. One patient developed superficial calcifications on fingers. All patients had high titre of antinuclear antibodies, 7/8 were positive for anti-Ro and 5/8 for anti-La antibodies. Three patients were tested for rheumatoid factor and all were positive. 6/8 patients had elevated ESR and hypergammaglobulinemia. 4/8 patients had elevated serum amylase.

Biopsy of salivary glands was performed in 5 patients and foci of lymphocytic infiltration were shown in all of them. Further 2 patients had salivary gland changes on MRI and/or US. On ophtalmologic evaluation 3 patients had positive Schirmer test and one had unstable tear film. One patient had CNS vasculitis and two decreased diffusing capacity of the lungs. Other patients showed no signs of internal organ involvement.

4/8 patients were treated with NSAIDs, 7/8 patients with hydroxychloroquine, 2/8 also received corticosteroids and one patient MMF. At this point the patient with CNS vasculitis has stable changes on head MRI without clinical symptoms. Other patients have no signs of internal organ damage. Calcifications that appeared on fingers in one patient are not progressing.

Conclusion: Most common symptoms in our cohort were arthritis and/or arthralgia, parotitis, oral symptoms and rash. Half of the children presented with recurrent parotitis. One child developed calcifications on fingers, which have not yet been described in patients with SS. Pediatric SS differs from adult SS and specific pediatric diagnostic criteria would improve management of these patients.

CO-MORBID AFFections in CHILDren WITH SYSTEMIC LUPUs ERYThEMATOSUS

Lyudmila Bohmati 1, Natalia Shevchenko1,2, Irina Bessonova1,2, 1 Institute of Children and Adolescents Health Care, Department of cardiology, Kharkiv, Ukraine; 2 V.N. Karazin National University, Department of pediatrics, Kharkiv, Ukraine; 3 V.N. Karazin National University, Department of pediatrics N2 2, Kharkiv, Ukraine

Background: In children with systemic lupus erythematosus (SLE) due to the cascade of immune-inflammatory reactions there is a development of systemic vascular endothelium lesion, which causes not only clinical manifestations of the main process, but also leads to the damage of vital organs and systems, the development of metabolic disorders. Extensive damage aggravates more the course of the disease, worsens its prognosis, complicates the response to therapy and reduces the quality of life of patients.

Objectives: The aim of study was to determine the frequency and variants of comorbid conditions in children depending on the duration and activity of the disease and features of the therapeutic complex.

Methods: A survey was conducted on 41 patients with SLE: 37 girls (90.2%), 4 boys (9.8%); the duration of the disease is up to 3 years in 20 patients (48.8%) and more than 3 years in 21 (51.2%). Presence of comorbid conditions determines as the cardiovascular system, kidney, liver and lungs functions changes. General clinical trials included autoantibodies, disease activity and drugs assessment. Total cholesterol, triglycerides, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, apolipoprotein B, ApoA-I and lipoprotein-α were evaluated. The state of the blood coagulation system was also studied: fibrinogen of the blood, prothrombin index, thrombin time, active partial thrombin time, D-dimer, international normalized ratio. Bone mineral density was determined.

Results: In 74.3% of children with SLE, the presence of comorbid conditions characterized by pathology of the cardiovascular system, kidneys, liver, the organ of vision, pulmonary system is established. Besides, atherogenic dislipoproteinemia has been detected in 60.0%, disorders in the hemostasis system were in 25.0% of patients and 43.0% persons have osteopenia. Children with SLE and the presence of comorbid conditions, especially with the involvement of the liver and kidneys and the long-term preservation of the disease activity (SRP, ANA, anti-DNA), are more likely to develop atherogenic dislipoproteinemia and hypercoagulation (increase in the prothrombin index, fibrinogen and D-dimer). The values of the comorbidity index in patients with SLE increased while maintaining the activity of the process and using high doses of glucocorticosteroids (GCS) including pulse therapy. Comorbidity index was 2.9 ± 0.5 points in the patients who received the GCS pulse therapy: 2.5 ± 0.3 in the cases of treatment by combination GCS + azathioprine; 2.0 ± 0.6 in the children without GCS; p<0.05). ANA-positivity was also accompanied by higher values of the comorbidity index (2.8 ± 0.3 vs. 1.4±0.5, p<0.05).

Conclusion: Children with SLE in the long-term course of the disease and maintaining the activity of the pathologic process (ANA, DNA antibodies high level) have a formation of lesions of systems and organs, the lipids metabolism disorders, prolonged hypercoagulation and the development of osteopenia. Aggressive therapy for reducing the activity of the autoimmune process helps to prevent the formation of comorbid states and persistent metabolic disorders.

QUALITY IMPROVEMENT IN PEDIATRIC RHEUMATOLOGY: A NEW APPROACH TO CARE IN QATAR
Sharon Bou-Tabaku, Sidra Medicine, Pediatric Rheumatology, Doha, Qatar

Background: Quality improvement (QI) projects have been established in many pediatric and adult rheumatology centers around the world to enable real time improvement of health delivery and outcomes. QI has been driven by the Institute of Medicine, patients, professional organizations and the providers. Notably, another driver is the discrepancy between the availability of better and targeted therapies and poor disease outcomes. QI projects for healthcare teams are designed to improve the efficiency and effectiveness of patient care by addressing gaps in care and implement these goals in sustainable ways, evaluate the impact and start a new cycle of improvement. In so doing, teams collaborate, learn from each other, and improve variability in a short time frame. In small practices with limited resources, effective QI projects allow for understanding the gaps in the processes, data collection and several process improvements to be done by different team members, in short cycles that allow for real time data evaluation and fine tuning processes.

Objectives: We describe the chosen quality measures, implementation of processes and first 6 months of data at a newly opened Children’s Hospital in Doha, Qatar.

Methods: We chose quality measures that have been proposed in the literature and have been implemented in large learning collaboratives. We worked with the informatics team to build measures that are accurately captured and retrievable from the electronic medical record. Additionally we worked with our Ophthalmology clinic to ensure a smooth referral pathway that is coordinated by nursing staff. Our EMR measures were chosen to screen for drug toxicity among patients receiving methotrexate or leflunomide within 3-4 week of receiving Methotrexate 2) the time between referral to and visit in Ophthalmology, to screen for toxicity among patients receiving hydroxychloroquine 3) time between referral and visit in Ophthalmology, to screen for uveitis in children diagnosed with juvenile idiopathic arthritis.

Our nursing teams developed a manual joint injection log 1) to capture the time between referral for procedure and procedure date occurred within 2 weeks, and monitor side effects. We examined data between June to December 2018 from the pediatric rheumatology patient population of 420 unique patients.

Results: 96% of children receiving methotrexate or leflunomide were screened for methotrexate toxicity within 3-4 months of the medicine being dispensed. 50% of children receiving hydroxychloroquine were seen by Ophthalmology within 4 months of the referral. 71% of children with JIA were seen by Ophthalmology within 1 month of the referral. 100% of children had joint injections performed within 14 days of the referral.

Conclusion: We described the development, implementation and results of our pediatric rheumatology QI projects. To our knowledge it is the first of a kind in Qatar and in the area. For our growing practice of 600 patient visits our data shows areas of great performance and poor performance, specifically in eye care for our patients. Barriers included education of teams about QI measures and processes, collaborating with other services on negotiating best patient practices. Successful implementation in our processes underlines the need for further data collection and additional improvement cycles. Additionally, in resource poor areas, it is essential to make good use of the EMR and
work in collaborative teams to ensure participation and sustainability of processes. Next steps would be to add additional quality and disease outcome measures.

TREATMENT WITH SIMULTANEOUS BIOLOGICAL AGENTS IN JUVENILE IDIOPATHIC ARTHRITIS: SINGLE-CENTER CASE SERIES AND REVIEW OF LITERATURE

Natalia Cabrera1, Pauline Nakhlieb2, Marine Desjouquères2, Jean-Paul Larbre2, Alexandre Belot2, Jean-Christophe Lega1, 1Claude Bernard University Lyon 1, UMR-CNRS 5558 Laboratoire de Biométrie et Biologie Humaine (LBBE), Villeurbanne, France; 2Hospital Woman Mère Enfant – Hcl, Paediatric Rheumatology, Bron, France; 1Lyon Sud Hospital Center, Rheumatology, Pierre-Bénite, France

Background: Several therapeutic choices are currently available for juvenile idiopathic arthritis (JIA) patients. The classical first line therapies are NSAIDs and corticosteroids (CTCs) and the second line encompasses synthetic and biological DMARDs. The clinical efficacy of DMARDs (alone or in combination) has been well demonstrated in RCTs and the treatment is often tailored on an individual basis. Combination of bDMARDs has not been formally evaluated in rheumatology and few publications are available concerning the combination of bDMARDs in patients with severe active forms of JIA, mainly systemic (SpJIA) and polyarticular (Pa) categories.

Objectives: To describe efficacy and safety of JIA patients resistant to MTX and bDMARDs requiring a simultaneous bDMARDs treatment.

Methods: Retrospective analysis of 7 (4.7 ± 2.1 years, male sex 75%) patients with JIA of a single tertiary center. A systematic review of literature was made to search observational studies from MEDLINE database (January 1946 to January 2019).

Results: All patients in the Paediatric Rheumatology Department (Lyon University Hospital) receiving combination therapy with bDMARDs were eligible. Seven patients with JIA diagnosis (4 SpJIA and 3 PA) were included. Genetic studies were performed in three patients, with positive LAC3C1 mutation in one. The exposure to the bDMARDs of the whole cohort was 79 patient-years (PY), including 16.5 PY of combination with simultaneous bDMARDs. The delay between the date of diagnosis and the first prescription of a combination of simultaneous bDMARDs treatment was 8.3 ± 4.8 years. Nine bDMARDs drugs were prescribed: anti-TNFs, tocilizumab and rituximab (nine times each). Ten co-prescriptions of the bDMARDs were administrated with 5 possible types of combinations between them, the most frequent associating tocilizumab/rituximab. Rituximab was used most frequently in combination with another bDMARD. The rituximab schedule was different between patients. Disease activity decreased for all patients, primarily at the biological level without reaching complete clinical remission.

In general, the clinical tolerance to the co-prescription of bDMARDs was acceptable. One patient (P2) experienced a severe hepatitis event in adulthood attributed to the treatment (tocilizumab), dropping the bDMARDs combination. During the exposure time, the most frequent adverse events were infections: repeated otitis media (P1), persisting vaginitis and fungal urinary infection (P3) not requiring hospitalization. One patient (P6) had 2 episodes of purpuric rash on the days of the canakinumab injection requiring oral CTC treatment. No severe acute reactions were found and no patients died.

The systematic review found a publication: retrospective series of 4 patients (SpJIA) combining abatacept and canakinumab (2).

Conclusion: Severe forms of JIA that are refractory to the current therapeutic options could benefit from the combination of bDMARDs. The combination of bDMARDs may be an alternative therapy to explore in this group of patients.

PARADOXICAL TINEA AMIANTACEA IN A PATIENT WITH JUVENILE IDIOPATHIC ARTHRITIS RECEIVING ADALIMUMAB

Maria Costanza Caparella1, Francesca Tirelli1, Gabriele Simonini1, Rolando Cimaz2, Teresa Giani3,2, AOU Meyer, Rheumatology, Florence, Italy; 1University of Siena, Siena, Italy

Background: Tinea amiantacea is a papulo-squamous condition of the scalp that can lead to scalp fibrosis and subsequent permanent hair loss. It is thought to represent a reaction pattern to inflammatory skin disease as psoriasis or seborrheic dermatitis (1).

Objectives: To highlight an adverse reaction which involved the skin in the disease course of a young JIA (juvenile idiopathic arthritis) patient, during treatment with adalimumab.

Methods: A 16-month-old female patient presented to our clinic with a 4-week history of knee swelling, associated with functional limitation and morning stiffness. Family history was unremarkable, while past medical history revealed atopic dermatitis in the first year of life. The baby was initially treated with NSAIDs, but one month later, due the persistence of arthritis and the appearance of uveitis, subcutaneous methotrexate was started (15 mg/m²/weekly). However 5 months later, given the persistence of uveitis and the onset of a severe hypertensinamiasemia, methotrexate was interrupted and adalimumab (24 mg/m² every 2 weeks) was introduced with a prompt and stable control of ocular and articular disease and a gradual normalization of transaminases. One year later the patient developed dry, itchy, and cracked skin behind her ears, with fissurizing the lower attachment of the ear lobe, and presented right parietal yellowish scalp lesions which were pruriginous, thick, and scaly, attached both to the scalp and to the proximal hair shafts. A first diagnosis of pityriasis amiantacea secondary to atopic dermatitis was made. A paradoxical cutaneous reaction to the anti-TNF therapy was later hypothesized (2), and 7 months later adalimumab was interrupted with quick resolution of the dermatologic lesions. However, both arthritis and uveitis rapidly reappeared, showing an inadequate response to a six month cycle of abatacept treatment (10 mg/kg/month). Adalimumab was than reintroduced with a rapid improvement.

Results: Currently, after 16 months of adalimumab treatment, the patient still shows complete disease control, without any new dermatologic lesions up to now.

Conclusion: TNF antagonist-induced tinea amiantacea is a rare adverse reaction that may require the drug discontinuation. Although the exact pathogenetic mechanism is unclear, an imbalance in the cytokine milieu with a selective overexpression of type I interferon has been hypothesized.

AB0949
IS PEDIATRIC ONSET LUPUS MORE SEVERE IN BOYS? OUR EXPERIENCE AT A TERTIARY CARE CENTER IN NORTH-WEST INDIA

Himanshi Chaudhary, Pandiarajan Vignesh, Arnuk Jindal, Deepi Suri, Anju Gupta, Amit Rawat, Surjilt Singh. Post Graduate Institute of Medical Education and Research, Chandigarh, allergy immunology unit, Chandigarh, India

Background: There is diversity in clinical presentation of pediatric onset SLE (pSLE) and the manifestations are more severe as compared to
adults. Males comprise 4-22% of all SLE patients. Gender distribution of pSLE is 4:5.5: 1 (female-to-male) as opposed to 9:10: 1 (female-to-male) in the adult population. However male patients have been known to have a more severe disease with higher morbidity, especially due to renal causes.

**Objectives:** To evaluate clinical and immunological profile and outcomes in a follow up series of males with pediatric onset SLE

**Methods:** We analyzed the clinical and immunological profile and outcome of male patients diagnosed with SLE at less than 18 years of age. These children were followed-up in Pediatric Rheumatology Clinic, Advanced Pediatrics Centre, Postgraduate Institute of Medical education and research, Chandigarh, India. Details on demographic data, clinical presentation, laboratory findings, immunological profile, treatment regimens and outcomes of these children were retrieved from clinic files.

**Results:** Forty-three patients were diagnosed to have SLE between January 1998 to December 2018. Mean age at presentation was 9.7 years (range: 9 months-12 years). Total patient years of follow up was 192 years. The most common clinical presentation was fever in 38 (88%) patients; rash in 27(63%); pallor in 21(49%); edema with urinary abnormalities in 17(40%) and photosensitivity in 16 (37%). A diagnosis of lupus nephritis was made in 25 (58%) patients out of which 17 (39.5%) had nephritis at presentation. Renal biopsies were performed in 18 patients; 11 had class IV disease, 2 had class 5 disease, 2 had class IV/V. Neuropsychiatric manifestations were seen in 11 (26%) patients - 7 of these had symptoms at presentation. Seizures were the predominant manifestation in 9 patients (21%)-6 of these had MRI changes consistent with posterior reversible encephalopathy syndrome while 3 had cerebral infarcts. Other central nervous system abnormalities included psychosis (1 patient) and chorea (1 patient). We also noted a family history of lupus like illness in 4 patients and 3 (6.9%) were found to have early complement deficiencies. Antiphospholipid antibodies (aPLA) were detected in 8 (18.6%)patients - antiphospholipid antibody was positive in 8 and lupus anti-coagulant was positive in 6. Dual aPLA positive was seen in 6(13.9%) and triple positive was positive in none. Infections were seen in 16 (37%) patients during follow-up. All patients received steroids in gradually tapering doses along with hydroxychloroquine following a diagnosis of SLE. Cyclophosphamide was given for induction in 13 patients who had severe forms of lupus nephritis. Remission was maintained through aza-thioprine in 8 patients and 8 required Mycophenolate mofetil. Ten patients (23%) had a relapse on therapy -1 had CNS relapse, 3 had renal relapse, 2 had muco-cutaneous relapse and 4 had hematological relapse. Six fatalities (14%) were recorded during follow-up -1 with severe disease activity and neuropsychiatric manifestations, 1 had disseminated tuberculosis, 1 had CNS flare with status epilepticus, 4 had sepsis.

**Conclusion:** This is one of the largest series on boys with pediatric onset SLE from a developing country. It appears that while the severity of lupus nephritis in boys is different from that in girls, neurological disease is more severe in the former. Further, boys appeared to have earlier onset of neuropsychiatric lupus as compared to girls. The incidence of complement deficiency lupus was also more in boys. Mortality in boys with SLE appears to be comparable to our previously published mortality data on pSLE(1).

**CORRELATION OF QUANTITATIVE MAGNETIC RESONANCE IMAGING BIOMARKERS AND AXIAL PAIN IN ENTHESIS-RELATED ARTHRITIS PATIENTS**

Varvara Choida1,2, Tim Bray1,3, Anna Radziszewska1,2, Corinne Fisher1,2, Cozianna Ciurtin1,2, Debajit Sen3, Margaret Hall-Craggs1,2. 1University College London, London, United Kingdom; 2Arthritis Research UK Centre for Adolescent Rheumatology, London, United Kingdom; 3UCL Centre for Medical Imaging, London, United Kingdom

**Background:** Magnetic resonance imaging is increasingly used to diagnose, stratify and monitor inflammation in patients with spondyloarthropathies. Magnetic resonance imaging (MRI) has the potential to provide more accurate assessment of disease activity and outcomes. In patients with enthesis-related arthritis (ERA), inflammation is often assessed by visual scoring, diffusion-weighted imaging (DWI) and fat fraction (FF) mapping. The correlation of ADCmean, which increases with increased inflammation, and T1mean, which decreases with inflammation, and outcomes of these children were retrieved from clinic files.

**Objectives:** To analyse the relationships between quantitative imaging biomarkers (QIBs), axial pain and serum biomarkers – including ‘inflammatory’ biomarkers and those reflecting bone turnover - in a cohort of ERA patients.

**Methods:** 28 patients with ERA were prospectively recruited. The hips, sacroiliac joints and lumbar spine were assessed with chemical shift-encoded MRI and diffusion weighted imaging. Quantitative MRI parameters, such as the apparent diffusion coefficient (ADC) and fat fraction (FF) were measured in the sacroiliac joints. Visual scores for inflammation and fat metaplasia were also reported. BASDAI questionnaires were completed. Serum cytokines and bone markers were measured via multiplex bead-based immunoassays (Luminex) and results were available for 14 patients with ERA.

**Results:** The mean visual analogue score for spinal and hip pain (BASDAI Q2) was 3.9 (Table 1). There was a correlation between ADCmean and spinal and hip pain (rs=0.393, P=0.043). There was also a negative correlation between FFmean and the above pain score (rs = -0.378, P=0.047). There was a positive correlation between matrix metalloproteinase-3 (MMP-3) levels and FFmean (n=14, rs=0.698, P=0.006). However, the correlation did not reach statistical significance when corrected for multiple testing.

**Conclusion:** The correlation of ADCmean, which increases with increased tissue water/inflammation, with spinal and hip pain suggests that BASDAI Q2 relates to pain of active inflammation. Similarly the inverse correlation of FFmean, which increases with bone healing and reduced inflammation, and BASDAI Q2, would also support this relationship.

**REFERENCES**

Objectives: Describe two brothers affected by MCTO highlighting the importance of a genetic diagnosis.

Methods: B1 (20 years) presented age 3 years with swollen painful feet and restricted movement in his fingers and wrists and was diagnosed with polyarticular juvenile idiopathic arthritis (JIA). After no response to steroid treatment he developed rapid onset fixed flexion deformity of both elbows. He had mild learning difficulties. Based on clinical and radiological findings he was diagnosed with carpotarsal osteolysis age 4 years. Bisphosphonates and vitamin D replacement did not halt progressive bony destruction. Consistent with the literature osteolysis stabilised in the teenage years. Renal function remains normal.

B2 (5 years) is a dizygotic twin and younger sibling of B1. All other family members: parents (non-consanguineous), twin sister, sister, brother and half-brother are healthy. B2 presented aged 21 months with bilateral painful swollen wrists and reduced range of movement. His development was normal and comparable to his twin. Clinical presentation was similar to B1 who was yet to receive a genetic diagnosis. Plain films were not diagnostic as carpi unossified. Regular monitoring of renal function was advised although it was noted the nephropathy associated with MCTO does not normally manifest until the second decade.

At genetic review an autosomal recessive form of carpotarsal osteolysis was considered most likely. The elbow contractures in B1 were consistent with this phenotype although subcutaneous nodules were absent. Genetic testing for MAFB gene alterations identified an identical mutation in B1 and B2 (MFAB – c176c>Tp(Pro59leu) confirming the autosomal dominant MCTO. B2 developed hypertension, heavy proteinuria and hypoalbuminemia at 3 years, responding to tacrolimus.

Results: Two brothers with clinical features of MCTO and identical mutations in MAFB gene are described. The phenotype varied significantly with early renal disease in one and mild learning difficulties in the other. Inheritance of this autosomal dominant condition in these two brothers with unaffected parents could result from either gonadal mosaicism or incomplete penetrance. There is a case of incomplete penetrance in MCTO described in the literature. [2]

Conclusion: Individually skeletal dysplasias are rare yet as a group they represent an important differential to JIA requiring different management. Pursuing a genetic diagnosis in carpotarsal osteolysis is important not only for prediction of recurrence risk. It allows a definitive diagnosis to be made earlier than is possible clinically/radiologically. Significantly different phenotypes yet the same genetic mutation lends weight to the possibility of modifier genes or other epigenetic mechanisms/environmental factors affecting disease penetrance as proposed by Dworschak et al. [2]. A greater understanding of these may enable prediction of renal involvement and aid development and stratification of new therapies.

AB0952 RETROSPECTIVE STUDY OF PROCEDURAL PAIN ANALYSIS DURING JOINT INFLTRATION IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Emanuele Cocchiara1, Claudia Ferrat2, Michela Cappella2, Carlo Salvarani3, Alessandro De Fanti1, 1Policlinico di Modena University Hospital of Modena, Rheumatology, Modena, Italy; 2Arcispedale Santa Maria Nuova, Rheumatology, Reggio Emilia, Italy; 3Arcispedale Santa Maria Nuova, Pediatrics, Reggio Emilia, Italy

Background: Juvenile Idiopathic Arthritis (JIA) is the rheumatic disease more common in childhood. Intra-articular corticosteroid injections (IAC) are a mainstay in the treatment of this disease, unfortunately it is often associated with pain and anxiety, for this reason is extremely important to pay attention both to procedural analgesia and to the reduction of anticipatory anxiety.

Objectives: The primary aim was evaluate the impact of the our analgesic procedure on the perception of infiltration pain; the secondary aims were stratify the results according to the demographic characteristics, number of joints infiltrated for each patient.

Methods: 30 patients (pt) studied between August 2016 and August 2017 (1 year) received a IAC [F/M=25/15, age 8.63 ± 3.41 yrs, weight 32.1 ± 13.9 kg; monarticular JIA 7 pt (17.5%), oligoarticular 19 (47.5%), polyarticular 14 (35%). 27/40 (67.5%) pt infiltrated in one joint, 13/40 (22.5%) in two or more joints]. One hour earlier of the procedure for each pt was applied 1% prilocaine cream and 30 minuts before administered Midazolam orally at a dose of 0.5 mg/kg (maximum 15 mg), 50% nitrogen protoxide mixture dispursed with a mask, in spontaneous breathing and continuous flow. In 25/40 (62.5%) pt distraction techniques were performed during IAC and in 24/40 (60%) was also applied ice spray before IAC. To monitor pain, before and after IAC, appropriate scales have been used, stratified by age: CHIPPS scale (pt ≤ 5 yrs), Wong-Baker scale for ages 6 to 10, numerical scale analog visualVAS (pt ≥ 8 yrs), CHIPPS and VAS scales:4 indicative of mild pain. For each pt pain assessment was performed before and after IAC.

Results: VAS before IAC = 0.90 ± 1.67/Median (M) = 0, after IAC = 1.07 ± 1.56/NI = 0, CHIPPS before IAC = 0.82 ± 1.88/M = 0, during IAC = 2.75 ± 3.01/M = 2. No significant correlation between VAS scale scores and after IAC and of CHIPPS both before and during IAC and respectively of age, weight, sex, application of ice spray, application of distraction techniques before the execution of the procedure, number of infiltrated joints. Significant correlation between VAS before and after IAC (RHO Spearman 0.397, p = 0.018), CHIPPS before and during IAC (RHO Spearman 0.599, p ≤ 0.0001). Highly significant correlation coefficient between VAS and CHIPPS before IAC (RHO Spearman 0.6, p = 0.0001) and between CHIPPS during IAC and VAS after IAC (RHO Spearman 0.403, p <0.05). Significant difference between CHIPPS before and after IAC (Wilcoxon Ranks Signed Test, R = 85, p <0.0001), not between VAS before and after IAC (R = 83, p = 0.62).

Conclusion: In our study the intensity of pain would seem exclusively subjective, in fact it does not depend: on age, number of IAC, on the application of distraction techniques and application of ice spray. Anyway the protocol that we used seems to be effective on pain control (VAS and CHIPPS scale respectively and after and during IAC: m ± sd and M. <4 points) and it can be performed on outpatients safely without an anesthetic procedure. Our results encourage to expand the series with a future prospective trial.

AB0953 EAR INVOLVEMENT IN PATIENTS AFFECTED BY JUVENILE IDIOPATHIC ARTHRITIS

Giovanni Conti1, Giulia La Barbera1, Carmela Visalli1, Giuseppe Alberti1, Paola De Pasquale2, Francesco Borgia1, Francesco Ciodaro3, 1AOI Policlinic G Martino, University of Messina, Pediatric Rheumatologic Unit, Messina, Italy; 2AOI Policlinic G Martino, University of Messina, Radiology Unit, Messina, Italy; 3AOI Policlinic G Martino, University of Messina, Otolaryngology Unit, Messina, Italy; 4AOI Policlinic G Martino, University of Messina, Dermatology Unit, Messina, Italy

Background: Few clinical studies in pediatric patients have shown a possible link between hearing loss and Juvenile idiopathic arthritis (JIA). It could be related to the involvement of the joints of the ossicular chain as a result of the autoimmune inflammatory process in the middle and inner ear.

Objectives: The aim of this study was to assess the frequency of hearing impairment in patients affected by JIA versus a healthy control group.

Methods: We studied 64 ears of 32 JIA patients (25 girls and 7 boys, mean age 15 years, age range 8-19 years) from June to December 2018. The mean disease duration was 7 years (+/- 4 DS). Polyarticular JIA was diagnosed in 6 patients, oligoarthritis JIA in 19; 5 patients had psoriatic arthritis and 2 spondyloarthritis. The control group consisted of 60 ears of 30 healthy children, sex and age-matched. Patients with previous otitis media at least 3 months and/or ear surgery were excluded. The study was approved by the local ethics committee and parents and/or patients signed their informed consent. All subjects underwent
audiological examination involving otomicroscopy, audiometry, tympanometry and stapedius reflex. Rheumatologic evaluation included joint examination with application of a measure of functional ability (disability) using the Childhood Health Assessment Questionnaire (CHAQ). The investigators were blinded about JIA type, severity, duration, and treatments of the patients.

Results: 11/32 (34%) JIA patients had abnormal audiological exam. Hypoacusia was significantly more frequent (p<0.05) in JIA patients (15/64 ears=23%) respect to the control group. In particular, hypoacusia was associated to psoriatic arthritis (6/15 ears). Conductive hearing loss was detected in 12/15 involved ears, while sensorineural type in 3/15. In the JIA group, according to the Jerger classification for tympanometry, abnormal findings were observed in 7 ears. The stapedius reflexes were absent in only one patient (3%). JIA patients with hypoacusia had a greater CHAQ (0.4+/-0.3) than JIA patients with normal audiometry (0.18+/-0.29).

Conclusion: The presence of hearing impairment and/or abnormal tympanogram suggests early involvement of the tympanic-ossicular complex, especially in patients with psoriatic arthritis. These findings could be a marker of the JIA activity. Therefore, it is advisable that JIA patients perform periodic audiological examination to early detect eventual hearing impairment, in order to prevent hearing loss in adult age.

AB0954 PEDIATRIC RHUPUS A RARE OVERLAP SYNDROME: CASE SERIES OF MEXICAN CHILDREN’S HOSPITAL FEDERICO GOMEZ

Velka Cortez, Merari Gomez Cortez, Edith Adriana Benitez Vazquez, Enrique Fauquier Fuentes. CHILDREN S HOSPITAL OF MEXICO FEDERICO GOMEZ, PEDIATRIC RHEUMATOLOGY, Mexico, Mexico

Background: Rhupus is an overlap syndrome of rheumatoid arthritis and systemic lupus erythematosus (SLE) in adult patients. Its pediatric presentation is very rare, the presentation of both juvenile idiopathic arthritis (JIA) and SLE as a clinical manifestation of the same patient has aroused different theories being the most accepted a true overlap between SLE and JIA. To diagnosis a patient with Rhupus present with clinical symptoms of JIA and SLE with positive ANA, antiDNA or antiSm, associated with clinical symptoms of JIA.

Objectives: To describe disease features and adherence to the follow-up and visits. To describe disease features and adherence to the follow-up and visits.

Methods: We present a case series of 4 patients diagnosed with Rhupus. We describe the demographic characteristics, clinical presentation, serological finding, the criteria for the diagnosis of SLE (ACR 1997) and JIA (ILAR 2001) and the treatment installed

Results: We describe four patients with Rhupus, the medium age at diagnosis was 12.5 years, and it was more common in female 3:1.

Three presented joints manifestations, integrating an initial JIA diagnosis. The evolution to an overlap syndrome took an average time of 19 months. The main symptom at diagnosis was erosive arthritis, polyarticular, morning stiffness and decreased joint range of motion. Three patients met 6 classification ACR 1997 criteria for SLE. All of the patients met ILAR 2001 criteria for JIA diagnosis. The four patients were treated with multitarget treatment. Joint manifestations were treated with methotrexate, and kidney and neurological manifestations with MFM and IV CFM. One patient required etanercept therapy for persistent joint disease.

AB0955 TRANSITIONAL CARE: A SINGLE CENTER ITALIAN EXPERIENCE

Francesco Crisafulli, Marco Catalini, Francesca Rizzo, Giada Malfeisi, Franco Franceschini, Angela Tincani, Milco Frassà, ASST Spedali Civili di Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2 University of Brescia, Brescia, Italy; 3 ASST Spedali Civili di Brescia, Paediatric Clinic, Brescia, Italy

Background: Transitional care from paediatrics to adults is an important step in the growth of the adolescent patients. One of the final goals is to guarantee the continuity of healthcare, increasing compliance in treatment and visits.

Objectives: To describe disease features and adherence to the follow-up in rheumatic patients that were transferred from Paediatric Clinic to our adult department.

Methods: From May 2016 to May 2018 the transition has been performed with a visit in presence of both specialists and 28 patients were evaluated. For juvenile Idiopathic Arthritis (JIA) we registered: category of
Table 1 Cutoff of disease activity: JADAS10* and DAS28-CRP**

<tr>
<td>High activity</td>
<td>&gt;4</td>
<td>&gt;8.5</td>
</tr>
</tbody>
</table>

Results: Between May 2016 and May 2018, 28 patients were enrolled (6 male, 22 female); mean age at diagnosis was 8.1 years (range 1-6 years); mean age at transition was 18.5 years (range 17-21 years). Twenty patients had a diagnosis of JIA, 3 of Undifferentiated Connective Tissue Disease, 1 Dermatomyositis, 1 Systemic Lupus Erythematosus, 1 Takayasu Arteritis, 1 Morphea, 1 Raynaud’s phenomenon.

Among JIA, 6 (30%) were Persistent Oligoarthritis, 4 (20%) Extended Oligoarthritis, 8 (40%) Polyarthritis (RF negative), 1 (5%) Psoriatic Arthritis, 1 (5%) Enthesitis Related Arthritis. Five patients (25%) had history of uveitis. Treatment during the paediatric follow-up period are summarized in table 2. At the time of first evaluation in adult department, 2 patients (10%) were on treatment with systemic steroids (5mg/day), 6 (30%) with methotrexate, 2 (10%) sulfasalazine, 1 (5%) with hydroxychloroquine, 1 (5%) leflunomide; 10 patients (50%) were on treatment with bDMARDs (6 adalimumab, 3 etanercept, 1 infliximab). Mean JADAS10-CRP was 3.8 (range 0-17, SD 5.8) as mean DAS28-CRP was 1.65 (range 0.96-3.44, SD 0.72). In 7 patients, disease activity assessed with JADAS10 was moderate-high as it resulted low-absent using DAS28-CRP. The rate of patients classified as having moderate-high activity was significantly different using the two index (35% using JADAS10 vs 5% using DAS28-CRP, p-value 0.044).

Until 2016, 6 of 44 (11%) patients were lost to follow-up while in the period between May 2016 and May 2018 no patients were lost (11% vs 0; p-value 0.042).

Conclusion: Disease activity seems to be underestimated using DAS28-CRP as compared with JADAS10-CRP. This could be due to the more frequent involvement of ankles and feet (that are not included in DAS28-CRP) in JIA. The adherence to follow up was greater in patients whose transition was performed in presence of the two Specialists.

Disclosure of Interests: Francesca Crisafulli: None declared, Marco Cattalin: None declared, Francesca Ricci: None declared, Giada Maffeis: None declared, Franco Franceschini: None declared, Angela Tincani Consultant for: UCB, Pfizer, Abbvie, BMS, Sanofi, Roche, GSK, AlphaSigma, Lilly, Jannsen, Cellgene, Novartis, Micul Frassi: None declared

She is the first born of a 51-year-old father and 40-year-old mother, non-consanguineous parents, at full term, and has a history of early hypotonía, psychomotor developmental delay and failure to thrive. Physical exam revealed arthritis of both ankles, the right knee and the MCP joint of the left thumb. We noted loose joints, high-arched palate and facial dysmorphism (hypertelorism, large protruding ears, flat nose and short philtrum). Body weight and height were at -3SD. Intellectual disability was mild. Laboratory tests showed slightly increased ESR (35mm at first hour) with positive ANA (+1/1000) and negative RF and anti-CCP. Karyotype is 46XX with deletion of the short arm of chromosome 18. Both parents had normal Karyotypes. MRI of the brain showed cortical atrophy and periventricular leucomalacia.

Ophthalmic screening detected bilateral anterior uveitis.

The patient was treated by AINS and methotrexate along with topical ophthalmic steroids. 6 months after treatment, the child had complete regression of uveitis and arthritis.

Results: This case of de-novo 18p deletion is associated to oligoarticular JIA with uveitis. According to our knowledge, there have only been 2 published cases of juvenile inflammatory arthritis with 18p deletion although 5 other cases were reported in association to other chromosome 18 abnormalities (deletion of long arm and ring). Few reports of adult-onset arthritis with monosomy 18p are available.

The exact explanation of this association is still unclear. As gene loss is a major factor in the pathogenesis of inflammation, this presentation might be related to deletion of PTPN2, a gene that has been associated to rheumatoid arthritis. PTPN2 encodes Protein Tyrosine Phosphatase Non-receptor type 2 and is located in the short arm of chromosome 18. PTPN2-deficiency stimulates T follicular helper cell and B cell responses, thus promoting autoimmune reaction. Of the 67 genes in 18p, only around 12 (of which PTPN-2) are responsible of a phenotype when hemizygous. Further genetic studies are needed to better elucidate the role of all involved genes in the pathogenesis of inflammation in monosomy 18p.

Conclusion: In addition to skeletal deformities such as kyphosis and feet deformities, children with 18p deletion should be screened for inflammatory arthritis.

ATYPICAL PRESENTATION AND EARLY RECURRENCE OF KAWASAKI DISEASE IN A FEMALE INFANT: CASE REPORT

Rodrigo del Toro Rosas, Patricia Javier Flores Lopez, Luis Fernandez Sané Espino, Cesar Adrian Martinez Longoria, Hector Enrique Valdes Garza. Instituto Tecnológico y de Estudios Superiores de Monterrey, TecSalud Pediatría, San Pedro Garza Garcia, Mexico

Background: Kawasaki Disease (KD) is the second most common vasculitis in the pediatric population and the leading cause for pediatric acquired heart disease in developed countries. It is commonly diagnosed in the Mexican pediatric population, epidemiology in this country is not established, since cases are not usually reported to the healthcare system. The clinical features are quite variable, but diagnosis and prompt treatment will decrease morbidity and mortality. Coronary artery aneurysms are the most common complication, which represent the leading cause of acute coronary syndrome before 40 years of age. Recurrence of KD is estimated to be around 3% in Japanese patients and 1% in the United States, nevertheless, this data in Latin-American children is unknown. It usually affects patients before reaching 3 years old and within 2 years of the initial attack, presenting with an abrupt onset and higher complication rates, requiring aggressive workup, treatment and follow-up.

Objectives: To review an atypical presentation of KD and early recurrence in a 7-month-old female.

Methods: We present a 7-month-old female diagnosed with KD at 48 days old. She presented to the emergency unit with irritability, high and persistent fever and acholia. During workup, she was found with cholestasis and gallbladder hydrops. Negative CSF, blood and urine cultures were documented, and the patient was hospitalized, and fulfilled the KD criteria. The cardiac ultrasound revealed coronary abnormalities: a RCA of 2.8mm (Z-SCORE +4.79), LCA of 3.3mm (Z-SCORE +5.69) and LAD of 2.4mm (Z-SCORE +4.25), which fit into classification 3 and 4, as small and medium aneurysms, according to AHA 2017. Immunoglobulin (2g/kg) and aspirin (80mg/kg) were administered and she was discharged 36 hours after the IVIg infusion, without fever and normal ESR. 30 days later the coronary abnormalities showed RCA of 2.0mm (Z-SCORE +2.3), LCA of 3.0mm (Z-SCORE +6), LAD 2.3mm (Z-SCORE +2.9). Six months later, she presented fever for 6 days, irritability and polymorphous rash. On physical exam BCGilis, normal-suppurative conjunctivitis and pallor in hands and feet, elevated CRP and ESR, leukocytosis, thrombocytosis and sterile leukocyturia. Echocardiography reported RCA od 2.4mm (Z-SCORE +4.8), LCA of 3.1 (Z-SCORE +4.2) and LAD of 2.3mm (Z-SCORE +3.2), diagnosing KD recurrence, admitting the patient for IVIg and aspirin administration.

Results: The patient was treated with IVIg and aspirin. Follow-up by Cardiology determined improvement of Z-Scores. Recurrence occurred with worsening of the cardiac abnormalities. Cardiac prognosis is importantly affected due to the atypical age, vascular abnormalities and repeated vasculitic process. Rheumatologic consult should be considered since disease like Takayasu Arteritis, Polyanarteritis Nosa and ADA2 deficiency need to be ruled out.

Conclusion: KD needs prompt diagnosis and treatment due to the potential consequences when delayed. Clinical suspicion is important due to the possible atypical presentation. As with this patient, age, gender and presentation are not exclusive. Despite adequate treatment, recurrence and worsening of the cardiac abnormalities occurred. Both KD events before 1 year old and with atypical presentations. Rheumatologic and cardiac follow-up need to be stringent through lifetime, to determine pharmacologic treatment, as well as physical activity and reproductive counseling.

PEdiatric BEChEt’s Disease wIth sinuUs venous thromboSIs: thRee CenTer experIence From tUrkey

Sezcan Demir1, Ceyhun Acar2, Özge Basaran2, Erdal Sag3, Kader Karlı Oğuz4, Yelda Bilginer4, Erdal Unsal4, Seza Özen3, 1Hacettepe University Faculty of Medicine, Pediatric Rheumatology, Ankara, Turkey; 2Dokuz Eylül University Faculty of Medicine, Pediatric Rheumatology, Ankara, Turkey; 3Ankara Child Health and Disease Hematology Oncology Training and Research Hospital, University of Health Sciences, Pediatric Rheumatology, Ankara, Turkey; 4Hacettepe University Faculty of Medicine, Radiology, Ankara, Turkey

Background: Behçet’s disease (BD) is an autoinflammatory disorder which may present with multi-systemic involvements including the vascular, cutaneous, articualar, gastrointestinal, and/or central nervous systems (CNS). CNS involvement appears in two main groups: parenchymal or non-parenchymal. Neurological symptoms in children and adolescents can be confused with many other disorders and may be the initial symptom of BD.

Objectives: To report our experiences of the juvenile Behçet’s Disease patients with cerebral venous sinus thrombosis (CVST) and to review previous studies reporting the clinical characteristics and outcomes of Juvenile Behçet’s Disease with CVST.

Methods: The patients who met Pediatric Behçet’s Disease (PDBD) classification criteria for juvenile Behçet’s Disease from 3 referral centers in Turkey were reviewed retrospectively. Disease activity was assessed by BD current activity form (BDCAF). A systematic review of literature of all published data was conducted.
Results: The study group consisted of 12 juvenile BD patients with CVST. At the time of CVST diagnosis, the most common symptom was headache (75%), followed by vomiting (25%), blurred vised (16.6%), and disturbances in eye movements (16.7%). Six (50%) patients presented with sinuses venous thrombosis as an initial symptom. Transverse sinus was the most frequently affected sinus (9/12, 75%) followed by superior sagittal sinus (8/12, 66.6%) and sigmoid sinus (1/12, 8.3%). The median (minimum-maximum) BDCAF was 6 (5-8). Four children (33.3%) had another venous thrombosis apart from CVST. All patients received pulse methylprednisolone for three consecutive days continued with oral prednisolone. Steroid treatment was tapered and discontinued minimum in six months. Eleven patients received azathioprine concomitant to steroid treatment at the time of CVST. All the patients received anticoagulant therapy concomitantly. Only one patient had relapse. Median (min-max) follow-up period was 4 years (1-10). In the literature review, we identified nine articles, describing 35 pediatric CVST patients associated with BD. Thirty patients achieved remission, while five patients had residual neurologic deficit.

Conclusion: Further multicenter studies with more patients and prospective follow-up may help us to understand the whole spectrum in these patients.

AB0959

EXEMPLARY RESPONSE TO TOCILIZUMAB IN PEDIATRIC ONSET RAPTORARY TAKAYASU ARTERITIS: CASE SERIES OF THREE PATIENT

Ferhat Demir, Betül Sözeri, University of Health Sciences, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Takayasu arteritis (TA) is a idiopathic and rarely seen chronic systemic vasculitis that affect the aorta and its major branches. Stenosis, occlusion and aneurysms may develop in large arteries in the setting of granulomatous arteritis (1). The first purpose in patients with TA after diagnosis is to prevent the progression of vascular lesions with medical treatment. Used as a first choice in medical treatment, steroids and steroid-sparing immunosuppressive agents, may sometimes fail to prevent to progression of the disease. Interleukin (IL)-6, which synthesize from activated dendritic cells, is one of the main cytokine in the development of panarteritis in TA. Tocilizumab (TCZ), an anti-IL-6 receptor antibody, has been shown to be used as an effective treatment in many refractory adult TA patients (2).

Objectives: We have presented our experience with TCZ treatment in three children with refractory TA.

Methods: We reviewed three cases of childhood TA diagnosed between 2016-2018. These patients were successfully treated with TCZ that started due to refractory disease.

Results: The first patient, 15 year-old girl, presented with fever, headache and abdominal pain. Physical examination showed sputum murmur in interscapular area and abdominal tenderness. The C-reactive protein (CRP) level was 4.7 mg/dL (n: <0.5 mg/dL) and the erythrocyte sedimentation rate (ESR) was 78 mm/h (n: <20 mm/h). Doppler ultrasound imaging showed wall thickening in bilateral carotid arteries. The angi-Ct imaging revealed that 70% stenosis in the bilateral renal arteries and partial stenosis in the mesenteric artery. Methylprednisolone treatment was started (30 mg/kg/d x 3 days). Maintenance treatment consisted of prednisone (1 mg/kg/d), methotrexate and azathioprine. Her complaints improved rapidly and the acute phase reactants decreased. However, the patient relapsed while tapering the corticosteroids.

The second patient was diagnosed with TA in 2012 after the complain of chest pain and finding of hypertension. MRI angiography revealed wall irregularities and stenosis in the descending aorta and dilatation in the ascending aorta. CRP and ESR levels found high. The patient was followed up with glucocorticoid and azathioprine treatment. After four years of follow-up, relapse of the disease was observed with symptoms of fever, chest and back pain.

The third patient presented with fever, abdominal pain, arthralgia in the left elbow and arthritis of the left knee, and was diagnosed with TA two years ago. His CRP and ESR levels were found elevated. The angi-Ct imaging revealed that 70% stenosis in the 4 cm segment of the abdominal aorta, 70% stenosis in the right renal artery, 50% stenosis in the left renal artery and 90% stenosis in the origin of celiac trunk and superior mesenteric artery. Despite the given bolus methylprednisolone and methotrexate therapy, there had not seen any improvement in disease activity. Tocilizumab was started at 8 mg/kg monthly in all three patient and they achieved complete clinical and laboratory remission.

Conclusion: These cases demonstrate that the TCZ treatment has been shown to be successful option in TA patients resistant to conventional immunosuppressive therapies.

Disclosures: The authors have declared no conflicts of interest. Informed consent form was obtained from patients and their legal guardians.

THE HELIOS (HACETTEPE UNIVERSITY ELECTRONIC RESEARCH FORMS) REGISTRY: USE OF BIOLOGIC DRUGS IN AUTOINFLAMMATORY DISEASES

Selcan Demir1, Ezgi Deniz Batu1, Fuat Akalı2, Erdal Sag3, Ummusen Kaya Akca1, Elif Anılangoğlu2, Emli Aliyev3, Kübra Yüksel2, Armağan Keskin2, Yelda Bilginer1, Seza Özen1,1Hacettepe University Faculty of Medicine, Pediatric Rheumatology, Ankara, Turkey, 2Hacettepe University Faculty of Engineering, Computer Engineering, Ankara, Turkey, 3Hacettepe University Faculty of Medicine, Pediatrics, Ankara, Turkey

Background: Autoinflammatory diseases (AID) are characterized by a dysregulation of innate immunity leading to uncontrolled inflammation. The treatment in AID is critical to control the disease activity, to prevent complications, and to improve the health-related quality of life. Biologic drugs have revolutionized the treatment and outcomes in AID.

Objectives: Herein we aim to present the clinical characteristics of children to whom biologic drug therapy was initiated for the management of AID.

Methods: A web-based registry called the Helios Registry (Hacettepe university electron Research forms) has been formed to evaluate the data of all children on biologic treatment. We have been enrolling patients since August 2018 retrospectively and prospectively. We have analyzed the data about the general characteristics of the patients, treatment, the biologic drug used, and adverse effects. Only the patients with the following diagnoses were included: systemic juvenile idiopathic arthritis (SJIA), familial Mediterranean fever (FMF), cryopyrin associated periodic syndrome (CAPS), and chronic recurrent multifocal osteomyelitis (CRMO).

Results: Of 60 patients included, 19 had FMF (31.7%), 24 had SJIA (40%), 10 had CAPS (16.7%), and 7 had CRMO (11.7%). Their mean age was 10.7 (2-20) years old and disease duration was 2.8 (0-6) years, at the time of biologic drug initiation. 58.3% were currently on canakinumab, 20% anakinra, 10% tocilizumab, 10% etanercept, and 1% adalimumab. 63.3% of our patients had previously used at least one other biologic drug. The rate of glucocorticoid use before biologic treatment was 56.6%. The median duration of glucocorticoid treatment after initiating biologic drugs was 7.4 months. 56 (93%) patients achieved remission on biologic therapy. There were 15 patients (25%) who received tuberculosis prophylaxis due to positive tuberculin skin test (diameter≥10 mm) and there was no QuantiFeron test positivity. Thirteen adverse events (AE) had been noted. 2 of them were serious events as anaphylaxis due to tocilizumab infusions. The rest of the adverse events were mild thrombocytopenia (n=2), varicella infection (n=1), and local side effects (n=8).

The median number of the infections per year was one and there were cytopenia (n=2), varicella infection (n=1), and local side effects (n=8). 2 of them were serious events as anaphylaxis due to tocilizumab infusions. The rest of the adverse events were mild thromboctopenia (n=2), varicella infection (n=1), and local side effects (n=8).

There was no Quantiferon test positivity. Thirteen adverse events (AE) had been noted. 2 of them were serious events as anaphylaxis due to tocilizumab infusions. The rest of the adverse events were mild thromboctopenia (n=2), varicella infection (n=1), and local side effects (n=8).
Conclusion: The most commonly prescribed biologic drugs were IL-1 inhibitors especially for patients with IL-1-mediated AID (RMF, CAPS, and SJIA). The biologic treatment in AID is effective and there were no serious side effects.

AB0961 ADVERSE EVENTS ASSOCIATED WITH ANTI-TNF-ALPHA THERAPY IN PEDIATRIC RHEUMATIC DISEASES
Betül Sozeri1, Ferhat Demir2, Deniz Çakır3, Fatma Ciftci1, Duygu Kurtulus2,1 University of Health Sciences, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 2University of Health Sciences, Umraniye Training and Research Hospital, Pediatric Infectious Diseases, Istanbul, Turkey; 3University of Health Sciences, Umraniye Training and Research Hospital, Physical therapy and rehabilitation, Istanbul, Turkey

Background: In recent years, the biologic drugs has led to a dramatic change in the management of rheumatic diseases. The most commonly used molecules are TNF-α antagonists among biologic treatments in pediatric age (1). The anti-TNF-α agents used in childhood are; etanercept (a fusion protein of the TNF-α receptor), infliximab (a chimeric monoclonal antibody) and adalimumab (completely human monoclonal antibody). As a result of the increasing use of anti-TNF-α agents in recent years, adverse events reports have also increased (2). We assessed the prevalence of adverse events (AEs) in a single pediatric referral center for chronic rheumatic diseases.

Objectives: The aim of this study was to evaluate the adverse events that associated with anti-TNF-α therapy in children with rheumatic disease.

Methods: This was cross-sectional study conducted University of Health Sciences, Umraniye Training and Research Hospital, Department of Pediatric Rheumatology, in Turkey. We retrospectively reviewed the patients with a diagnosis any of pediatric rheumatic disease whom treated at least 3 months with an anti-TNF-alpha agents (etanercept, infliximab, adalimumab), between June 2016 and January 2019. Adverse events that develop after anti-TNF-α therapy are recorded. AEs were categorized and graded based on the Common Terminology criteria for AEs (CTCAE). Grades 3-5 were considered severe AEs.

Results: We evaluated 131 patients who were treated with anti-TNF-α drugs; 110 with juvenile idiopathic arthritis (JIA)(27 of with uveitis) 7%, 5 with Behçet disease; 110 with juvenile idiopathic arthritis (JIA)(27 of with uveitis) 83%, 10 with idiopathic uveitis 4%, 4 with adeno-sine deaminase deficiency%3, and 2 with juvenile sarcoidosis%. The study included 74 females and 57 males (FM: 1.29:1) and the mean age of the patients was 12.8 years. Of the patients, 106 had used only 1, 21 had two different and 4 had 3 different anti-TNF-alpha biologic treatments. A total of 160 different anti-TNF-alpha experiences had in 131 patients.

A total of 333.4 patient-years (PYs) were included: 136 PYs-63 patients for etanercept (2.15 patient/year), 134 PYs-68 patients for adalimumab (1.97 p/y) and 63.4 PYs- 29 patients for infliximab (2.18 p/y). During follow-up, 44 patients (33.5%) experienced at least one AEs. 14 of them (10%) were recorded as SAEs. 17 of the AEs were show up after adalimumab, 16 were etanercept and 11 were infliximab. The most common AEs were found; local reactions, increased infection frequency and PPD positivity in follow up, respectively. The SAEs that observed were; anaphylactoid reactions (n=5), uveitis (n=3), pneumonia (n=3), TAILS (n = 2) and vasculitis (n=1).

Conclusion: Here in, we presented safety data of anti-TNF-alpha drugs in pediatric patients. Although the high prevalence of AEs was observed, when anti-TNF-α discontinuation, AEs were mostly not persistent and not mortal.

AB0962 UPDATE FOR THE CLINICAL PRACTICE: INTEGRATED, EVIDENCE-BASED APPROACH FOR THE MANAGEMENT OF JUVENILE SPONDYLOARTHROPATHIES
Mervat Elissä1, yasser El Miedany2, Waleed Hassan3, Dalia Mekkawy2, Mohammed A. Mortada4, Samah Ismail Nasef5, Mahaa El Gastany6, Hala Lotfy7, Yomna Farag8, Ghada El Deriny9, Mohammed Hassan Abu-Zaedi10, Yosra Atef11, Nadia El Anossy12, PRINTO Egypt, 1 Cairo University, Faculty Of Medicine, Kasr Al Ainy, Rheumatology and Rehabilitation, Cairo, Egypt; 2 Ain Shams University Faculty Of Medicine, Rheumatology and Rehabilitation, Cairo, Egypt; 3Faculty Of Medicine – Benha University, Rheumatology and Rehabilitation, Benha, Egypt; 4Zagazig University school of medicine, Rheumatology and Rehabilitation, Zagazig, Egypt; 5Suez canal University school of medicine, Rheumatology and Rehabilitation, Ismailia, Egypt; 6 Ain Shams University faculty of medicine, Community and Public Health, Cairo, Egypt, 7 Cairo University, Faculty Of Medicine, Kasr Al Ainy, Pediatrics, Cairo, Egypt; 8Alexandria Faculty of Medicine, Pediatrics, Alexandria, Egypt; 9Faculty Of Medicine – Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; 10Assiut University, Faculty of Medicine., Rheumatology and Rehabilitation, Assiut, Egypt

Background: Juvenile onset spondyloarthropathis (SpA) is a heterogeneous group of human leucocyte antigen (HLA) –B27 associated inflammatory syndromes that affect children and adolescents under the age of 16 years No specific recommendations for the treatment of juvenile spondyloarthritis have been established. Important differences exist between spondyloarthritids in children and adults, supporting the need for pediatric-specific recommendations.

Objectives: To set recommendations for the management of children and adolescents with spondyloarthritids.

Methods: Searching Medline for Juvenile spondyloarthritids management was done. A systematic literature search was conducted to collect the existing recommendations. The studies involved line of treatment for Juvenile SpA & adult SpA. These included 2011 ACR recommendations for the treatment of JIA and the 2016 update of the ASAS-EULAR management recommendations for axial spondyloarthritids.

Results: NSAIDs have been shown to improve symptoms, reduce inflammatory lesions and may slow spinal radiographs progression with continuos use. Glucocorticoid injections directed to the local site of musculoskeletal inflammation may be considered. Sulfasalazine may be considered in patients with peripheral arthritis. Initiation of a (tumor necrosis factor inhibitor (TNFi) was recommended for patients with active saccroiliac arthritis who have received an adequate trial of NSAIDs. Also, it should be initiated to those who fail to respond to synthetic disease modifying anti-rheumatic drugs (DMARD). If TNFi therapy fails, switching to another TNFi should be done. If a patient is in sustained remission, tapering of a biological DMARD can be considered.

Conclusion: These guidelines provide up-to-date guidance on the management of patients with juvenile SpA, based on combining evidence and expert opinion.

AB0963 ROLE OF THYROID HORMONES IN JUVENILE IDIOPATHIC ARTHRITIS
Nilor Revenco, Rodica Eremeruici, State University of Medicine and Pharmacy "Nicolea Testemitanu", Pediatric Department, Chisinau, Moldova, Republic of

Background: The frequency of autoimmune thyroid disease have been reported in adults with systemic autoimmune diseases. However, little is
known about the association between those diseases and rheumatic disorders during childhood, such as juvenile idiopathic arthritis (JIA).

**Objectives:** Our objective was to evaluate the correlation between the thyroid function and the clinical presentation in children with juvenile idiopathic arthritis.

**Methods:** Case series of 7 pts (5 boys, 2 girls) with initial rheumatologic symptoms. Therefore, there in 5 pts, and systemic onset JIA onset of first symptoms until 10 years. The time-interval from the onset of first symptoms until diagnosis was 4 years. Mean age at CD onset was 12.7 ± 3.98 yrs, varying from 5 to 17 yrs.

**Results:** Fifty-one of the cases were classified as oligoarticular, thirty-one as seronegative polyarticular, two as seropositive polyarticular, eleven as systemic, and two as enthesis related- juvenile idiopathic arthritis.

No cases of overt clinical and biochemical hypothyroidism were found among children with juvenile idiopathic arthritis. On opposite, mean thyroid free T3 levels were higher in 36.4% of cases and free T4 in 29.7% cases.

**Conclusion:** These data seem to suggest careful monitoring of thyroid function and thyroid autoantibodies just in children with juvenile idiopathic arthritis presenting clinical symptoms of thyroid involvement.

**REFERENCES**

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.7974
Conclusion: Manifestations of sarcoidosis vary significantly across the paediatric age spectrum. While EOS is a known juvenile idiopathic arthritis mimicking condition, it is important to recognize the diagnostic difficulties that prolonged the diagnosis by years in 4/7 patients.

PROPOSAL OF OUTCOME MEASURES TO BE USED ON A 12-MONTH OPEN LABEL DRUG TRIAL IN JUVENILE SYSTEMIC SCLERODERMA: RESULTS OF THE 3RD CONSENSUS MEETING IN HAMBURG DECEMBER 2018

Ivan Foeldvari1, Kathlyn Tokor1, Lusine Ambartsumyan2, Jordi Anton2, Christian Beyer2, Michael Blakley2, Tamas Constantin2, Patricia Costa Reis2, Dragana Lazarevic3, Kirsten Minden2, Susan Nielsen3, Farzana Nuruzzaman3, Anjali Patwardhan4, Yosel Uziel5, Nicolette Helmus6, 1Hamburger Zentrum für Kinder- und Jugendrheumatologie, Hamburg, Germany; 2Participant of the Hamburg Outcome measure consensus process, Hamburg, Germany

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease, associated with high morbidity and mortality. New treatment strategies are much needed. To develop an open label drug trial for the treatment of jSSc patients, it is necessary to clearly define how to evaluate outcomes in this disease, which are currently not existing. A group of experts in jSSc has met annually and worked to develop an index to evaluate outcomes in this disease.

Objectives: The aim of our third consensus meeting was to establish the domains and the items that should be assessed in a clinical drug trial in jSSc.

Methods: In the consensus meeting 26 jSSc international experts with various specialties participated (22 voted). In a nominal group technic, moderated by DEF, was used to develop the outcome measures. Agreement was defined if 80% or more of the participants approved an item.

Results: Domains and items suggested in the 2017 consensus meeting were reconsidered and selected or rejected during the 2018 meeting, as were additional domains/items (Table).

AB0967

IS THERE A DIFFERENCE IN PRESENTATION OF FEMALE AND MALE PATIENTS WITH JUVENILE SYSTEMIC SCLERODERMA. AN UPDATE FROM THE JUVENILE SYSTEMIC SCLERODERMA INCEPTION COHORT. WWW.JUVENILE-SCLERODERMA.COM

Ivan Foeldvari1, Jens Klotsche2, Ozgur Kasacopur3, Amira Adrovici4, Kathlyn Tokor1, Valda Stanevich5, Khalid O. R. Sztajnbok6, Ana Paula Sakamoto7, Ekaterina Alexeieva8, Jordi Anton9, Maria Katsikas10, Vanessa Smith11, Tadej Avorn12, Rolando Cimaz13, Mikhail Kostik14, Thomas Lehman15, Walter Alberti Silente16, Giraldo17, Simone Appenzeller18, Lillemor Berntson19, Blanca Bica20, Juergen Brunner21, Patricia Costa Reis22, Despina Eleftheriou23, Liora Harel24, Gerd Horneff25, Tilmann Kallinich26, None declared

Methods: The JSSIC is a prospective multicentre registry of patients with jSSc, who fulfill the adult classification criteria (2), and presented the first non-Raynaud symptoms before 16 years old and were younger than 18 years old at the time of inclusion in the cohort. Patients characteristics at time of inclusion in the cohort were evaluated.

Results: As of 15th of December 2018 120 patients are included in JSSIC. The great majority are female (80%). There were more female patients with CK elevation (29% vs 22%) and more female patients with Gottron papule (25% vs 12%). The mean modified skin score was higher in males (18.6 vs 13.9).

Scleractyly was more frequent in males (90% vs 76%). Active ulceration was present in 33% of males compared to 14% of females (p=0.026). FVC<80% occurred more often in males with 47% compared with 24% in females (p=0.018). Pulmonary hypertension was more

Hoffmann-La Roche, Genentech

common in females with 7% compared to 4% in males. Urine sediment changes were more common in males (8% vs 4%). Gastrointestinal involvement was more common in females (37% vs 29%). Contractions occurred more often in males with 62% compared with 46% in females. Tendon friction rub was observed in 21% of males and 3% of females (p=0.001). Physician global scores of disease activity and damage were higher in males with 48 for both assessments compared to 36 and 30 in females.

Conclusion: Male patients with JSSc have a higher severity of disease, as it has been reported in adults.

AB0967 INTEGRATED RHEUMATOLOGY AND OPHTHALMOLOGY CARE IN PEDIATRIC AUTOIMUNE UVEITIS – OUTCOME AND EFFECTIVENESS

Milena Foizer Leite1, Luana Coelho Benevides1, Francisco Hugo Rodrigues Gomes1, Rafael Esteves de Angelis2, Virginia Ferranti3, João Marcelo Fortes Furtado4, Iuliana Martins de Carvalho5, Ribeirão Preto Medical School, University of São Paulo, Department of Pediatrics, Division of Pediatric Rheumatology, Ribeirão Preto, Brazil, Ribeirão Preto Medical School, University of São Paulo, Department of Ophthalmology, Otorhinolaryngology and Head and Neck Surgery, Ribeirão Preto, Brazil

Background: Uveitis is an ocular inflammatory disease that may lead to irreversible blindness if not treated early and properly. May be induced by infectious and non-infectious diseases (autoimmune diseases, especially juvenile idiopathic arthritis), or ‘masquerade’ causes. Some uveits are termed “idiopathic”, although autoinflammatory evidence. Treatment effectiveness depends on the accuracy of the ophthalmologic evaluation and the appropriate management, especially when immunosuppressive medications are necessary. (1, 2)

Objectives: To describe the first year experience of the Integrated Ophthalmology and Pediatric Rheumatology Outpatient Clinic in the management of pediatric patients with autoimmune uveitis.

Methods: Retrospective chart review study of twenty-four patients followed up from June 2017 to October 2018. The patients clinical evolution at 0, 3, 6, 9 and 12 months was analyzed.

Results: In this group, 62% were female, and mean age at first appointment and at symptoms onset were 11.7 (2.9 to 17.5) and 7.3 (1.1 to 12) years, respectively. Anterior uveitis was present in 70.8% of the cases, and in 65.6% it was bilateral; cataract or glaucoma was observed in 20.5%. The identified diagnosis during follow-up were: idiopathic autoimmune uveitis in 45.8%, juvenile idiopathic arthritis in 41.6% (20.8% oligoarticular, 16.6% polyarticular, 4.1% associated with enthesitis) and juvenile systemic lupus erythematosus, Kawasaki Disease and Vogt-Koyanagi-Harada syndrome one case of each. Antinuclear antibodies were present in 41% and inflammatory markers in 28.7% patients. At first appointment, 20.5% presented ocular inflammatory activity and 53.3% had sequelae when examined in slit lamp or indirect ophthalmoscopy. Medica-tions used were: topical corticosteroids (61.6%), topical mydriatic (49.2%), oral corticosteroid (41%), methotrexate (41%), etanercept (12.3%), adalimumab (28.7%) and periccular injections of triamcinolone, cyclosporin, tocilizumab, azathioprine (4.1% each). The comparison of the data at inclusion and during follow-up is reported in Table:

At inclusion 3 months 6 months 9 months 12 months
Ocular inflammation(%) 20.5 24.6 12.3 12.3 12.3
Topical Corticosteroids(%) 61.6 32.8 16.4 8.2 20.5
Topical Mydriatic (%) 41 24.6 28.7 20.5 20.5
Oral Corticosteroid (%) 73.8 20.5 12.3 12.3 20.5
Etanercept (%) 12.3 53.3 49.2 36.9 28.7
Adalimumab (%) 20.5 20.5 16.4 16.4 16.4
Others (%) 12.3 4.1 4.1 4.1 4.1
No medication (%) 4.1 8.2 8.2 4.1 4.1

At the end of 12 months, only 12.3% of the patients still had active uveitis. We have also observed a reducing in 66.6% of topical cortico-steroids and 72.2% of oral corticosteroids use during the treatment of uveitis over 12 months.

Conclusion: Considering that before the inclusion, patients were followed independently in each clinic, there was optimization of the treatment and reduction in number of medical appointments after the creation of the integrated outpatient clinic. The interprofessional management teams should be the standard of care for pediatric patients with autoimmune uveitis.

We report the case of idiopathic calcinosis cutis in a young girl.

**Background:**

Calcinosis includes a rare group of disorders characterized by abnormal intracutaneous, subcutaneous, fascial or intramuscular calcium deposits. Idiopathic calcinosis is diagnosed after the exclusion of secondary forms related to trauma, abnormal calcium/phosphorus metabolic disorders, inflammatory processes, neoplasms, connective tissue diseases or renal insufficiency. There are very few cases reported, especially in childhood.

**Objectives:**

We report the case of idiopathic calcinosis cuts in a young girl.

**Methods:**

A 15-year-old female presented an abrupt onset of 2 painful swollen lesions on the left trochanteric region and over the posterior side (76.4% versus 58.4%, $p = 0.001$), although sensitivities were similar at both times. EU LAR/ ACR criteria score $\geq 10$ exhibited greater sensitivity than ACR 1997 (67.4% versus 70.5%, $p < 0.001$) at first visit, but comparable at 1-year, whereas specificity was lower at first visit (67.4% versus 83.2%, $p = 0.004$) and 1-year (58.4% versus 76.4%, $p = 0.002$). A EU LAR/ ACR score $\geq 13$ against a score $\geq 10$, resulted in higher specificity, positive predictive value, and cut-off point accuracy. Compared to SLICC, a EU LAR/ ACR score $\geq 13$ resulted in lower sensitivity at first visit (76.2% versus 89.3%, $p < 0.001$) and 1-year (91% versus 97.5%, $p < 0.008$), but similar specificities at both periods. When compared to ACR 1997, a EU LAR/ ACR total score $\geq 13$, resulted in no differences in sensitivity and specificity at both times.

**Conclusion:**

In this cSLE population, SLICC criteria performed best at first visit and 1-year follow-up. The adoption of a EU LAR/ ACR total score $\geq 13$, against the initially proposed $\geq 10$ score, was most appropriate to classify cSLE in our study. Further studies are necessary to address if SLICC might allow cSLE classification earlier in disease course and be more inclusive of cSLE subjects for clinical studies.

of her right elbow. The patient denied any trauma or associated symptoms such as muscle weakness or joint stiffness. On physical examination, a large hard mass was present over her left trochanteric region, with hyperemic skin, and a similar one was palpable over her right elbow.

**Results:** Radiographs of the two sites showed well-defined calcified masses, one (9x5 cm) over the trochanteric region, and the other (3x2 cm) over the posterior aspect of the distal end of the humerus extending up to the elbow. MRI confirmed the presence of calcified intramuscular lesions (Figure 1). Serologic evaluation showed increased levels of CRP and ESR, while autoimmune screening was negative. Calcium/phosphorus metabolism, creatinine kinase, aldolase and ferritin levels were within the normal limits. Therefore, a clinical diagnosis of idiopathic calcinosis was made. After 3 months, the lesion on the elbow had spontaneously reabsorbed, while the other one kept on growing, with 3-4 episodes per month of febrile painful swelling. A CT-guided biopsy was then performed, confirming the diagnosis of calcinosis. No infectious causes were detected. One year later, since there was no local amelioration, the lesion was surgically removed with apparent complete local remission. No other new lesions were detected during the 3 months follow-up period.

**Conclusion:** Idiopathic calcinosis is very rare and no specific medical therapies are available. In our patient no causative factors were identified and thus the diagnosis of idiopathic calcinosis was made. Prognosis seems to be variable, since one lesion resolved spontaneously while the other needed surgical excision.

**ARTEFACTUAL SKIN LESIONS: A TRAP FOR RHEUMATOLOGISTS**

Lisa Gamalero1,2, Ilaria Pagnini2, Gabriele Simonini2, Rolando Cimaz2, Teresa Giani2,3. 1University of Udine, Pediatrics, Udine, Italy; 2Meyer Children’s University Hospital of Florence, Pediatric rheumatology Unit, Florence, Italy; 3University of Siena, Siena, Italy

**Background:** Dermatitis artefacta (DA) refers to deliberate and conscious self-inflicted skin lesions to satisfy an unconscious psychological or emotional need. It is an unusual condition often described in women, and rarely reported in children. The disorder is often misdiagnosed and needs to be distinguished from organic illness, Munchausen’s by proxy syndrome, and from illicit, nontherapeutic drugs or overdose of medications.

**Objectives:** We report three paediatric cases with a long medical history characterized by many laboratory and radiological exams, and mistaken etiologies.

**Methods:** Case 1. An 11-year-old female was referred to our Rheumatology Department for a second opinion about a suspicion of Behcet’s disease based on her cutaneous manifestations. Clinical examination was unremarkable except for bluish ecchymoses, and linear cutaneous abrasions and scars located in accessible areas of her skin (Figure 1, Figure 2 and Figure 3). Extensive laboratory tests and radiological exams were normal.

Case 2. A 14-year-old female was admitted to our pediatric hospital for a 1 month history of fever, malaise and multiple purpuric lesions. The patient referred a 3 year history of similar recurrent episodes characterized by abrupt onset of fever, arthralgia and purpuric lesions for which she already received the diagnosis of urticarial vasculitis. The girl was in good general conditions, without fever. Violaceous ecchymotic lesions were evident on her left forearm. Exhaustive laboratory tests, chest X-ray, and abdomen ultrasound were within normal limits.

Case 3. A 14-year-old female was referred to our Pediatric Rheumatology department for a 6 month history of musculoskeletal pain, recurrent shoulder and hip dislocations, and spontaneous ecchymosis on her neck and face. Except for joint hypermobility (Beighton score 7/9), physical examination was normal. At a careful orthopedic evaluation and after shoulder and hip imaging the history of dislocations appeared to be inconsistent. Blood and radiologic tests, cardiological and genetic evaluations for Ehler-Danlos syndrome were negative.

**Results:** In Case 1, dermatitis artefacta was suspected and the patient was referred to our mental health colleagues that confirmed a severe psychological stress in a basal condition of psychiatric disorder. In Case 2, an in-depth psychological evaluation highlighted a depressive status for personal and familiar suffering. The patient was therefore referred to our mental health department for assessment and management. In Case 3, eventually a psychiatric interview oriented the diagnosis to a major depressive disorder.

**Conclusion:** DA is a rare condition that should be evaluated in the differential diagnosis, in the presence of unexplained cutaneous lesions without an apparent identifiable cause. Association with various psychological disturbances is the mainstay for this diagnosis, and a careful psychiatric history represents the essential diagnostic key to identify this disorder.

ATYPICAL KAWASAKI DISEASE SHOCK SYNDROME

Present and discuss a rare case of KDSS in an adolescent.

Kawasaki Disease Shock Syndrome (KDSS) was introduced in 2009 after reports of hemodynamic instability during the acute phase of the illness.

**Background:** Kawasaki disease (KD) is an acute, self-limited vasculitis of unknown etiology with peak incidence at 9-12 months of age. The term Kawasaki disease shock syndrome (KDSS) was introduced in 2009 after reports of hemodynamic instability during the acute phase of the illness.

**Objectives:** Present and discuss a rare case of KDSS in an adolescent patient.

**Methods:** Review of patient’s clinical records and scientific literature.

**Results:** A 12-year-old boy was admitted in the pediatric intensive care unit (ICU) with a 5-day history of high persistent fever, abdominal pain, vomiting and headaches. On examination, he looked ill, was tachycardic and hypotensive with delayed capillary refill, had non-exsudative oropharyngeal erythema, cracked lips, terminal nuchal rigidity, jaundice and small palpable supraventricular lymph nodes. On day 3 a generalized morbilliform rash and diffuse swelling of the hands became apparent. Blood gas showed metabolic acidosis. He had decreased platelet count of 72,000/mm3, AST 122 UI, ALT 192 UI, LDH 366 UI/L, triglycerides 207 mg/dl, total bilirubin 85.5 μmol (direct 68.4). Renal function, urinalysis and fibroscan were normal. ESR was 42 mm/h, CRP was markedly high (286 mg/l) and ferritin 544 ng/ml. Lumbar puncture revealed mild sterile pleocytosis. Due to progressive hemodynamic instability he required fluid resuscitation, inotropic drugs and mechanical ventilation. Broad-spectrum antibiotic therapy was started due to suspected septic shock/streptococcal toxic shock syndrome. IVIG was empirically started 24h later due to non-response. Viral screening, all blood and urine cultures and ASO titers were negative. Myelogram revealed no signs of hemophagocytosis, neoplastic changes or growth of microorganisms in culture. Fine needle biopsy of a supraclavicular lymph node showed nonspecific inflammatory changes. Thoracoabdominal scan revealed moderate bilateral pleural effusion, mild hepatosplenomegaly, retroperitoneal/mesenteric lymphadenopathy. Brain MRI and echocardiogram were normal as well as ophthalmologic evaluation. In the presence of prolonged fevers, mucosal changes, extremity edema and non-specific rash in a severely-ill adolescent with no response to broad spectrum antibiotics and negative cultures, the possibility of KD was raised.

Due to ongoing fevers and inflammation after 36h of first IVIG, he received a second IVIG dose 2g/Kg, methylprednisolone IV pulses for 3 days and aspirin, with rapid clinical and laboratorial improvement. Within 24h the patient was off inotropic support, 48h off mechanical ventilation and 3 days later he was discharged from the ICU. His general condition continued to improve gradually, with increased platelet counts, normalization of liver function and CRP. In this phase, skin desquamation (buttocks/perineal region) was noted. At follow-up, thoracoabdominal angioMRI and serial ecocardiograms were normal. He was weaned off corticosteroids and aspirin without recurrence of symptoms.

**Conclusion:** In this case, despite the atypical age and lack of some classical signs/symptoms, broad-spectrum antibiotic refractoriness and the described clinical presentation raised the hypothesis of KSDD. Diagnosis can be difficult, especially if shock occurs in incomplete forms of KD, but must be suspected early and treatment promptly started in order to ensure a good prognosis. Clinicians should be aware that thrombocytopenia and hepatitis are risk factors for refractory severe KD. MAS must always be excluded in cases of hemodynamic instability.

Renal function, urinalysis and fibroscan were normal. ESR was 42 mm/h, CRP was markedly high (286 mg/l) and ferritin 544 ng/ml. Lumbar puncture revealed mild sterile pleocytosis. Due to progressive hemodynamic instability he required fluid resuscitation, inotropic drugs and mechanical ventilation. Broad-spectrum antibiotic therapy was started due to suspected septic shock/streptococcal toxic shock syndrome. IVIG was empirically started 24h later due to non-response. Viral screening, all blood and urine cultures and ASO titers were negative. Myelogram revealed no signs of hemophagocytosis, neoplastic changes or growth of microorganisms in culture. Fine needle biopsy of a supraclavicular lymph node showed nonspecific inflammatory changes. Thoracoabdominal scan revealed moderate bilateral pleural effusion, mild hepatosplenomegaly, retroperitoneal/mesenteric lymphadenopathy. Brain MRI and echocardiogram were normal as well as ophthalmologic evaluation. In the presence of prolonged fevers, mucosal changes, extremity edema and non-specific rash in a severely-ill adolescent with no response to broad spectrum antibiotics and negative cultures, the possibility of KD was raised.

Due to ongoing fevers and inflammation after 36h of first IVIG, he received a second IVIG dose 2g/Kg, methylprednisolone IV pulses for 3 days and aspirin, with rapid clinical and laboratorial improvement. Within 24h the patient was off inotropic support, 48h off mechanical ventilation and 3 days later he was discharged from the ICU. His general condition continued to improve gradually, with increased platelet counts, normalization of liver function and CRP. In this phase, skin desquamation (buttocks/perineal region) was noted. At follow-up, thoracoabdominal angioMRI and serial ecocardiograms were normal. He was weaned off corticosteroids and aspirin without recurrence of symptoms.

**Conclusion:** In this case, despite the atypical age and lack of some classical signs/symptoms, broad-spectrum antibiotic refractoriness and the described clinical presentation raised the hypothesis of KSDD. Diagnosis can be difficult, especially if shock occurs in incomplete forms of KD, but must be suspected early and treatment promptly started in order to ensure a good prognosis. Clinicians should be aware that thrombocytopenia and hepatitis are risk factors for refractory severe KD. MAS must always be excluded in cases of hemodynamic instability.

**A CASE OF ADENOSINE DEAMINASE 2 DEFICIENCY (DADA2) WITH AN UNCOMMON CLINICAL PRESENTATION AND RESPONSE TO IV IG**

Francesca Garbarino1, Roberta Caorsi2, Stefano Volpi2, Alice Grossi3, Isabella Ceccherini1, Marco Gattorno3, Università degli studi di Genova, Genova, Italy; IRCCS Istituto Giannina Gaslini, Clinica Pediatrica e Reumatologia, USOSD Malattie Autoinflammatorie-Immunodeficienze, Genova, Italy; IRCCS Istituto Giannina Gaslini, UOC Genetica Medica e USOSD Genetica e Genomica delle Malattie Rare, Genova, Italy

**Background:** DADA2 is an autoinflammatory disease with autosomal recessive inheritance characterized by a heterogeneous clinical phenotype ranging from multisystemic inflammation (fever, polyarthritides nodosa, cerebral stroke, livedo reticularis etc.) to immune-dysregulation and immunodeficiency.

**Objectives:** To extend the clinical spectrum of DADA2 reporting a case of isolated nonspecific systemic inflammatory syndrome associated with signs of immune-dysregulation in a patient with a novel ADA2 mutation.

**Methods:** In a patient with nonspecific inflammatory phenotype associated to susceptibility to viral infections, Next Generation Sequencing (NGS) panel was performed; mutations detected were confirmed by Sanger analysis. ADA2 enzymatic activity was analyzed in monocyte isolated from the patient and incubated with adenosine and an ADA1 inhibitor.

**Results:** The girl, adopted and of Asian origin, began to suffer from non-specific systemic inflammatory syndrome associated with signs of immune-dysregulation in a patient with a novel ADA2 mutation.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.7039
substitution dosage, the patient experienced Herpes Zoster virus reactiva-
tion (requiring prolonged antiviral treatment), followed by the reappearance of
the inflammatory phenotype complicated by HLH with neurological
involvement (iritis and lethargy), responsive to HD steroids and IG. A
later cerebral MRI evidenced a small gliotic area in left Centrum Ovale.
After steroids suspension, monthly HD IV IgG administrations maintained
clinical remission. Further immunological studies confirmed a reduction of
NK cells with normal function. Hereditary HLH, Autoimmune Lympho-Prolif-
erative Syndrome (ALPS) and main primary immunodeficiencies were ruled out.
Given the clinical picture, a large NGS diagnostic panel (courtesy by
K. Botrug, Vienna) for autoinflammatory diseases and immunodeficiencies
was performed revealing the homozygous LEU141PRO ADA2 mutation,
confirmed by Sanger analysis. Being this mutation novel, an ADA2 enzyme-
atic activity test was performed revealing a complete loss of ADA2 activ-
ity. The parents refused anti-TNF treatment and the patient is still on
monthly HD IG with a complete wellbeing after 3 years of follow-up.
Conclusion: The current report enlarges the clinical spectrum associated
with ADA2 to a persistent unspecific inflammatory syndrome, complicated by
HLH. This case further emphasizes the possibility that NGS could unravel
unusual phenotypes of already known inflammatory syndromes. Even if fur-
ther reports are required, the response to HD IG observed in the present
case is of interest. Even if anti-TNF is the treatment of choice in HD IG
could be a possible treatment in DADA2, especially during the acute phase.

AB0975 INITIAL BIOLOGICAL THERAPY RESPONSE IN PATIENTS WITH SUSPECTED AUTOINFLAMMATORY DISEASE

Laura Fernández Silvera1, María Isabel García Ruiz-Santa Quitèria1, Marisol Camacho Lovillo1, Paula Sánchez Moreno1, Marco Antonio Montes Canto1, Jose Manuel Lucena Solo1, Jose Bernabeu Witter2, Beatriz Muñoz Cabello1, Julia Fijo López-Viola1, Olaf Neth1, لا كرة a. Sevilla, Spain. 1Hospital Universitario Virgen del Rocio,
Pediatrician, Sevilla, Spain; 2Hospital Universitario Virgen del Rocio, Immunologist, Sevilla, Spain; 3Hospital Universitario Virgen del Rocio, Dermatology, Sevilla, Spain

Background: The choice of the initial biological therapy for patients with
suspected autoinflammatory diseases and not conclusive genetic test remains challenging.
Objectives: To assess the clinical response to the initial biological ther-
apy in pediatric patients with suspected autoinflammatory disease with no
genetic diagnosis.
Methods: We retrospectively reviewed the clinical charts of patients followed in our clinic who started empirical biological therapy after being diagnosed
with suspected autoinflammatory disease(sAID) due to the intensity of their
symptoms and no response to colchicine or FAMEs. Next generation sequencing using an immune deficiency/dysregulation(115 genes) and autoin-
flammatory panel(12 genes) was negative/inconclusive in all patients.

Results: We identified 9 patients(6/9) were male, median age at fever
onset 1.33 years old (IQR(0.46-4), age at diagnosis of sAID 3.8 years old
(IQR(1.75-7)). Clinical presentation included fever(9/9), abdominal pain and
arthromyalgia(7/9), aphthous(6/9), headache, rash and adenopathy(5/9),
delayed growth(4/9), tonsilitis and pericarditis(3/9) as well as diarrhea and
pleuritis(2/9). One patient presented with stroke, cutaneous lesions, vas-
culopathy and haemolytic uraemic syndrome and 1 patient with amyloido-
sis and secondary hepatosplenomegaly. None of the children suffered
from uveitis or meningitis. The flares lasted a median of 14 days(IQR 8-
20). Two patients had persistent symptoms. Their mean/median lab val-
ues are shown at table. 4/9 patients had homozygous mutations with
uncertain significance, heterozygous mutations or polymorphism but their
symptoms or familiar study was not suggestive of the corresponding AID.
One patient had a heterozygous mutation in MEFv (p.P369p.m.R408q) and also a CECR1 heterozygous mutation with uncertain significance,
one patient had p.R92Q heterozygous mutation in TNFRSF1A, one patient had
MEFv p.R202Q homozygous mutation, other patient had a NOD-2 heterozygous mutation and the patient with amyloidos had
NOB0 deficiency and a NOD2 mutation (p.A918D). All patients responded to steroid therapy; subsequently 8/9 received anti IL-1Recep-
tor kineret as first biological therapy and 1/9 with suspected vasculopathy
received anti-TNF. Response to IL-1R antagonist was complete in 3/8 and partial in 4/8 children;1/8 showed no response. 2/8 patients
were switched to anti-TNF. One each to etanercept and Infliximab with
good response. The patient with amyloidos was changed to anti IL-6R
with incomplete response but clear improvement compared to anti IL-1R
response. The patient with suspected vasculopathy and initial anti-TNF
treatment had partial response with no recurrent stroke but persistent
symptoms.

Conclusion: An important group of patients with sAID lack genetic confir-
more. Empirical use of IL-1R antagonist is promising but not effective in all patients as it was observed in our case series,where 5/8 children
showed partial or no response.3/5 needing a second biologic treatment in
form of anti-TNF due to persistent moderate-severe symptoms.
A model to predict the response to different therapeutic strategies, based
on clinical features and immunological profile (including inflammatory cyto-
kines) might help to choose the most appropriate immunomodulatory

AB0976 PSYCHIATRIC DISORDERS DURING TRANSITION CARE IN ADOLESCENTS WITH RHEUMATIC DISEASES

Background: Chronic rheumatic diseases (CRD) have a strong
psychosocial development of adolescents. There are several factors
associated with psychiatric disorders (PD) in these children; physical
disability, complex treatments, long-term follow-up, and flares are the
most cited in literature. Juvenile Idiopathic Arthritis (JIA) is the first cause of disability in children with
CRD, on the other hand, Major Depressive Disorder (MDD) and Dysthymia are the third cause. Some PD, mostly MDD, appear as a
consequence of disability caused by CRD, but immune pathways might be
implicated in pathogenesis as well.
Adolescents with CRD need to transition to an adult-centered care while
deal with emotional and physical changes. This implies a difficult situation
in which patients could be in higher risk for develop PD. There are
a lack of information on how this process affects emotional health in this
population.
Objectives: The aim of the study is to calculate the prevalence of PD
in adolescents with CRD during transitional care and their relationship with
clinical and social factors.
Methods: Patients older than 16 years with an established CRD, who
were in transitional care during the period between July 2017 and January
2019 were included in this transversal study. We used MINI KID assessment tool to characterize PD in our patients. Each patient performs an interview with both a clinical psychologist and
a pediatric psychiatrist to confirm psychiatric/emotional diagnosis. Clinical, social and demographic data were collected from medical records. Descriptive statistics with frequencies or measures of central tendency and dispersion, depending on variable characteristics were used. Comparisons and correlations were performed with parametric and non-parametric tests as appropriate.

Results: Forty patients were recruited during study period, aged 18 (IQR 16 - 19) years old, 31 female, and most diagnosed with JIA (22, 55%) and Systemic Lupus Erythematosus (SLE, 7, 17.5%). Time since diagnosis was 5.5 (IQR 0.5 - 13) years and half of the patients presented with an active disease. After psychiatric evaluation, 24 (60%) patients presented an active disease, while 16 (40%) were identified with MDD, and minor disorders (specific phobia and anxiety) were noticed in 11 (27.5%). Two patients presented alcohol dependence, and 11 (27.5%) were diagnosed with more than one PD. PD were more frequent in patients with SLE (71%) and in those with active disease regardless underlying diagnosis (54% vs 45%, P = .490). Other significant factors related with more prevalence of PD were female gender (66% vs 44%, P < .001), having a couple (90% vs 57%, P < .001), have a single parent (83% vs 60%, P = .005), and sex activity (71% vs 61%, P = .002).

Conclusion: We found a higher prevalence of PD in adolescents during transitional care, especially in those with active disease. It is priority to involve a multidisciplinary team to transition adolescents from pediatric to adulthood care to prevent and detect PD in this population.

ULTRASOUND MEASUREMENT OF JOINT CARTILAGE THICKNESS IN HEALTHY ASIAN SCHOOL-AGED CHILDREN

Chun-chun Gau, Chao-Yi Wu. Division of Allergy, Asthma, and Rheumatology, Department of Pediatrics, Chang Gung Memorial Hospital at Linkou and Chang Gung University, Taiwan, Taoyuan, Taiwan, Republic of China

Background: Degeneration of the osteocartilaginous structures due to synovial inflammatory process is a feature of juvenile idiopathic arthritis (JIA)1. While anthropometry difference has been reported between Asian and Caucasian2, Asian specific age- and gender-related normal standard reference values should be established before ultrasound (US) measurement of cartilage thickness (Cth) becomes standard procedure in the clinic.

Objectives: The standard cartilage thickness in Asian children population

Methods: A cross-sectional study was performed in 100 healthy Asian children (including 48 girls and 52 boys, age between 5 to 12 years-old). Bilateral knees, ankles, wrists, second metacarpophalangeals (MCPs) and proximal interphalangeals (PIPs) were measured using US. Children’s body weight and body height were also recorded for later adjustment.

Results: We observed no difference in the Cth between right and left knees, ankles and wrists but MCPs and PIPs. Cartilage thickness in the large joints such as ankles and knees differed between sexes (p>0.001), and the boys had thicker cartilage than those of the girls. Cartilage thickness decreases with increasing age after weight, height and BMI adjustment. A formula for calculating sex-specific cartilage thickness at different ages in childhood is suggested.

Conclusion: Cartilage thickness measurement with US in small joints may be biased. A standard reference of Cth for Asians in the knee, ankle and wrist joints between age 5- to 12 have been proposed.

CORTICOSTEROID TREATMENT IN PEDIATRIC RHEUMATIC DISEASES AND SUPPRESSION OF THE HYPOTHALAMIC-PITUITARY AXIS

Teresa Gianì1,2, Francesca Falorni1, Rolando Cimaz2. 1Pediatric Rheumatology, Meyer Children’s University Hospital of Florence, Florence, Italy, 2Department of Medical Biotechnology University of Siena, Siena, Italy; 3Pediatric Rheumatology, Meyer Children’s University Hospital of Florence, Florence, Italy

Background: Corticosteroids are the mainstay in the treatment of several chronic inflammatory diseases. Long-term treatment may lead to suppression of hypothalamic-pituitary-adrenal axis, which in turn can be dangerous in stress situations such as after surgical interventions. Oral replacement therapy may be needed in some cases. Data on pediatric populations are scanty.

Objectives: The aim of our study has been to evaluate hypothalamic-pituitary-adrenal function during corticosteroid tapering by measuring serum cortisol.

Methods: During long term corticosteroid treatment, serum cortisol levels were evaluated when oral prednisone dose was decreased to 7.5 mg/day and also after 4-6 weeks, and if below range ACTH levels were also determined.

All patients aged < 18 years seen in our center during the last 6 months who were on corticosteroid treatment for > 1 month were included. Serum cortisol levels were considered normal in the range of 5-25 μg/dL in a morning fasting blood drawing, while ACTH levels were considered normal in between 6 and 55 ng/L (with chemiluminescent method). Clinical and demographic data were recorded from clinical charts in a customized database.

Results: We have included in this preliminary study 12 patients (7F, 5M) affected by uveitis (n=4), JIA (n=4), scleroderma (n=3), lupus (n=1). The mean age (at the time of sampling) was 11.5 years, with a median of 10 and a range of 8-17. Prednisone starting dose was 1 mg/kg/day. Four out of 12 patients had decreased cortisol levels. Characteristics of these four patients (none of whom had additional steroid pulses) are detailed in the table.

Conclusion: One third of our patients had decreased cortisol levels, after three months of prednisone treatment. In one case, who showed persistently low levels, oral supplementation with hydrocortisone 20 mg/day for two months was needed. Our study is ongoing and results could help in identifying patients at risk for adrenal crisis.

Efficacy of Etaenertcept Treatment for Children With Kawasaki Disease Intractable to Intravenous Immunoglobulin Therapy in Russian Children

Anastasiya Glazyrina1,2, Seda Kurbanoval,2 Marina Kantemirova1,2, Yuliya Novikova1,2, Dmitry Ovsyannikov1,2, Elena Zholobova1, Saniya Valevaa, Elena Petroyakina1,3, Morozovskaya children’s city clinical hospital, Moscow, Russian Federation; 2RUDN-University, Moscow, Russian Federation

Background: Kawasaki disease (KD) is recognized in developed countries as a fundamental reason of acquired heart diseases in children nowadays. The main treatment is infusion of intravenous immunoglobulin (IVIG) at a dose of 2 g/kg. However for about 10-30% of children is reported the development of resistance to standard therapy: continuation of fever >38.0°C or recurrence of fever after 36 hours of afebrile period (Tc37.5°C), but not later than on the 7th day after completion of the IVIG infusion at a dose of 2 g/kg. Until now there are no unified recommendations for treatment of such patients. As alternative therapy researchers empirically apply second infusion of IVIG (77%), high doses of glucocorticoids (16%), blockers of tumor necrosis factor α (3%) and interleukin-1, cyclosporine and other cytostatic drugs.

Objectives: Efficacy evaluation of therapy by inhibitor of TNF-alpha (Etanercept) in treatment of KD immunoglobulin -resistant forms according to the data from Morozovskaya Children’s City Clinical Hospital.Moscow.

Methods: There were examined 152 patients (boys:girls = 2:1, median age = 21 months – 21 months [10;36] with KD hospitalized in Morozovskaya Children’s City Clinical Hospital in 2014-2018. The frequency of complete form of KD was 80.6%. All children had a standard therapy – IVIG. Efficacy evaluation was based on normalization of body temperature, decrease of neutrocytosis, decrease of C-reactive protein (CRP) level. In case of ineffectiveness of therapy the second infusion of IVIG, pulse-therapy and inhibitor of TNF-alpha (Etanercept) were used.

Results: The resistance to standard IVIG therapy was revealed in 16 children (10.5%), mostly in boys (4:3.1) at the age of Me = 21.5 months [9.5; 34]. Complete form of KD was diagnosed in 11 patients (88.8%), incomplete form - in 5 children (31.2%). Cardiovascular lesions were noted in 14 children (87.5%): pericarditis - in 2 (12.2%), coronary arteries (CA) lesions – in 12 (75%), with formation of aneurysms in 8 (50%), including the giant ones in 3 children (18%); peripheral arteries damages were noted in 2 children (12.5%), thrombosis and thromboembolism – in 4 children (25%).

To all of children was made the second IVIG infusion, 13 of those children (81.2%) had a positive effect:11 children with complete form of KD, 2 children with incomplete form of KD. For 3 children (18.7%) with incomplete form of KD and significant cardiovascular changes (pericarditis, giant aneurysms of coronary and peripheral arteries,thrombosis and thromboembolism) it was needed an additional therapy. As a second-line therapy the methylprednisolone pulse-therapy was used in 2 children(12.5%) at a dose of 10 mg/kg, without sufficient effect. For these three patients (3) as a third-line therapy was applied Etanercept at a dose of 0.8 mg/ kg/week subcutaneous. In all children normalization of body temperature, decrease of leukocytosis by factor of 1:5-3 and decrease of CRP by factor of 10-15 occurred after three injections of Etanercept. However, for 1 child it was needed the additional fourth injection of Etanercept because of repeated fever, increased laboratory parameters, development of thrombosis of the left coronary artery after 2 weeks upon discharge.

Conclusion: The frequency of immunoglobulin-resistant forms was 10. 5%. The first-line therapy of resistance (second IVIG-infusion) was effective in 13 children (81.2%). Methylprednisolone pulse therapy was ineffective. The use of 3 subcutaneous injections of Etanercept at a dose of 0.8 mg/kg/week resulted in decrease of intensity of inflammatory changes and in fever relief, but it did not prevent the development of dyspnea and thrombosis of coronary arteries.

Disclosure of Interests: : Anastasiya Glazyrina: None declared, Seda Kurbanoval: None declared, Marina Kantemirova: None declared, Yuliya Novikova: None declared, Dmitry Ovsyannikov: None declared, Elena Zholobova Grant/research support from: Roche, Pfizer, Novartis, Consultants for: Pfizer, AbbVie, Roche, CMS, Novartis, MSD, Speakers bureau:
Background: Juvenile idiopathic arthritis (JIA) in recent decades has changed its course, thanks to the use of genetically engineered biological drugs. If therapy with methotrexate is inefficient etanercept is the drug of choice for JIA treatment. Etanercept has been used in Chelyabinsk regional pediatric hospital during 10 years.

Methods: 51 children aged from 3 to 17 (mean age 10,0 years) diagnosed with JIA were under monitoring (12 boys, 39 girls). Disease duration was from 2 to 15 years (mean duration 5,4 years). JIA was diagnosed based on ILAR diagnostic criteria. Oligo arthritis was diagnosed in 9 children, mono- dimensional disease in 24, polyarticular disease in 17. 3 patients had systemic JIA (without active systemic presentations), 5 children had enthesitic JIA. X-ray stage 1-2 was observed in 45 children and stage 3-4 in 5. Enhancement antigens HLA B 27 were found in 11 children. In all children methotrexate was ineffective in dose of 15 mg/m² during 6-12 months. Etanercept was introduced in dose of 0.8 mg/ KW. Therapy duration was from 3 months to 8 years (mean duration 29 months).

Assessment of disease activity and therapy efficiency was conducted in accordance with ACR pedi criteria. Nonparametric statistical methods were used to compare results.

Results: Prior to etanercept use high disease activity was observed in all children. Mean number of joints with active arthritis was 8 [4, 10] (Me;25;75%). Mean number of joints with functional impairments – 4 [2;10]. Mean ESR (according to Panchenkov) – 23 [10;35] mm/h, CRP 12,0 [5,7;32] g/L. Assessment of functional activity according to CHAQ questionnaire – 1,25 [1;2]. Activity assessment according to VAS by doctor – 70 [60;70]. Assessment of parents/patients according to VAS 70 [10;90]. No active systemic presentations and eye lesions were found in children under monitoring.

On the background of etanercept therapy a decrease in disease activity was observed in 50 patients. Mean number of joints with active arthritis was 0 [0;2] (Me;0;0001). Mean number of joints with functional impairments – 0 [0;2] (P=0,0001). Mean ESR was 5 [3,6] mm/h (P=0,0001), CRP 3 [2;4] g/L (P=0,0001). Assessment of functional activity according to CHAQ questionnaire was 0,125 [0,0;0,5] (P=0,0001). Activity assessment according to VAS by doctor – 10 [5;20] (P=0,0001). Assessment of parents according to VAS 10 [5;20] (P=0,0001).

Clinical disease remission (according to ACR pedi criteria >90%) was observed in 32 patients after 6-12 months of treatment. Remission duration up to now is from 1 to 7 years. Efficient according to ACR pedi criteria is 70% in 11 children, 50% in 5, 30% in 2.

Etanercept was well-tolerated. Drug was cancelled in 9 patients. 6 patient (11,8%) developed bilateral uveitis, one patient had an allergic reaction (rash), one - systemic manifestations, one - urinary tract infection. There were no cases of tuberculosis.

Conclusion: Etanercept therapy was highly effective and safe in patients with JIA. Clinical remission was achieved in 62,7% children. Decrease in disease activity was observed in 98% of children. 11,8% patient developed uveitis, on average, after a year of using etanercept.

REFERENCES
PTX3 is known to have an interesting role in regulation of innate immunity and it is a key player in regulation of many inflammatory reactions [1].

Objectives: This study aimed to measure serum and synovial fluid (SF) levels of PTX3 in juvenile idiopathic arthritis (JIA) patients and to correlate them with different clinical, laboratory and musculoskeletal ultrasound parameters of disease activity.

Methods: We measured PTX3 in the serum (n=57) and SF samples (n=18) from 57 JIA patients and in the serum from twenty healthy controls. Disease activity was calculated using the Juvenile Arthritis Disease Activity Score in 27 joints (JADAS27) and musculoskeletal ultrasound examination (MSUS) was performed using grey scale (GS) and power Doppler (PD) 10-joint score (bilateral knee, ankle, wrist, elbow and the 2nd metacarpophalangeal (MCP) joints)[3]; Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) levels, serum ferritin, rheumatoid factor (RF) titre were measured and the Juvenile arthritis multidimensional assessment report (JAMAR) was documented.

Results: Serum PTX3 level was significantly higher in JIA patients (3.59±2.38 ng/mL) compared to serum level in the healthy controls (1.5 ± 0.9 ng/mL) (p=0.001). There was no significant difference between SF PTX3 level (4.73 ± 2.62 ng/mL) and its level in paired serum samples(4.23±2.93 ng/mL) (p=0.59). JIA patients with systemic onset subtype (n=13) had higher PTX3 serum levels (5.57±2.52 ng/mL) compared to serum level in the oligoarticular (n=25) and polyarticular (n=19) subtypes (2.88±2.13 ng/mL and 3.18±1.92 ng/mL respectively) (p=0.001 and 0.005 respectively). In JIA patients, serum PTX3 level significantly correlated with JADAS27 (r=0.52, p<0.05), CRP titres (r=n.46, p<0.05) and serum ferritin (r=0.48, p<0.05). Both serum and SF PTX3 levels significantly correlated with PD score (r=0.51 and 0.48 respectively, p<0.05). SF PTX3 (p =0.001) was shown to be superior to serum PTX3(p =0.02), ESR (p =0.07) and comparable to CRP (p =0.001) at predicting PD synovitis score.

Conclusion: JIA patients have significantly increased serum and synovial fluid levels of Pentraxin 3 that remarkably correlated with the JADAS27 and MSUS parameters of inflammations suggesting that it could be a useful marker to reflect JIA disease activity.

AB0984 INTERSTITIAL LUNG DISEASE IN CHINESE JIA PATIENTS

Assunta Ho, Kate Chan, Li Albert. Prince of Wales Hospital, The Chinese University of Hong Kong, Paediatrics, Hong Kong, Hong Kong (SAR)

Background: Rheumatic diseases and or medications (for example methotrexate) used to treat the underlying condition are associated with the development of interstitial lung disease (ILD). Development of ILD in subjects with juvenile idiopathic arthritis (JIA) is assumed to be rare, however, severe respiratory complications are increasingly reported in JIA patients.

Objectives: To describe the prevalence of respiratory diagnoses and ILD in a group of Chinese JIA patients at a tertiary center.

Methods: Retrospective chart review of JIA patients attending rheumatology clinic during 2012 to 2019.

Results: Fifty-eight cases of JIA were identified. Thirty-three (57%) received DMARDs, majority were on methotrexate (MTx, 24, 73%) and sulfasalazine (SSZ, 14, 42%). Eleven (19%) were currently or previously on biologics (adalimumab 5, etanercept 5, anakinra 1, previous exposure: infliximab 1, etanercept and anakinra 1). Respiratory diagnosis was made in 11 (19%) patients. There were 2 (3.4%) cases of ILD diagnosed during the study period (see below). The rest were asthmatics. Among them, 9 were on DMARDs [MTx (8/9%), SSZ 4(44%), leflunomide 2(LEF), hydroxychloroquine 1(HCQ)] or biologics [Etanercept 3(33%), adalimumab 1, tocilizumab and anakinra 1(sequential use)]. Four subjects were on combination DMARDs [MTx+SSZ in 2, 1 each for MTx+LEF+HCQ+SSZ, MTx+LEF]. Three received combination DMARDs and biologics (1 each for MTx+adalimumab, MTx+etanercept & MTx+anakinra).

Cases of ILD

One was a SJIA patient diagnosed at 2 years old. She failed methotrexate, etanercept & tocilizumab (infusion reaction). She was on low dose prednisolone, methotrexate and anakinra when she presented to us with acute right heart failure requiring ICU care 3 years after diagnosis. Advanced clubbing was noted (fig 1). HRCT thorax on presentation showed severe interstitial lung disease with marked fibrosis and traction bronchiectasis (fig 2). She was diagnosed acute on chronic cor pulmonale and pulmonary hypertension secondary to ILD.

The other was an oligoarticular JIA patient, diagnosed at 2 years old. She was refractory to intra-articular steroid injections and combination DMARDs including MTx, SSZ, LEF & HCQ. Arthritis was controlled by Etanercept. At 12 years of age, she started to have chest pain. Lung function test showed restrictive lung pattern. HRCT thorax showed pulmonary fibrosis.

Conclusion: From this Chinese cohort we identified 2 cases of ILD. They did not present with any symptoms until advanced stage or when complications set in. Both were very young at diagnosis and were difficult to control, as evidenced by the use of multiple DMARDs and biologics including methotrexate, IL6 and IL1 blockade. The causes of ILD are believed to be multifactorial. For severe case, prognosis is poor[2]. Although rare, methotrexate induced pneumonitis do occur. Symptoms of ILD may not be obvious until late stage. Clinical examination alone is not sensitive enough to detect disease progression. Asthma is common, as in this cohort, and may further complicated the assessment. It is recommended in the recent SHARE initiative on JSLE to screen for lung disease[3]. We believe it should be performed in JIA patients as well. 6 minute walk test is a noninvasive way to assess cardiopulmonary functional status and is validated in children[4]. Patients with unexplained chest symptoms or impaired lung function should be referred to pulmonologist for further assessment.

EVALUATION OF SERUM CALPROTECTIN (MRP-8/MRP-14) LEVEL IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Tetiana Marushko1, Yulia Holubovska1, Yuriy Marushko2, Shupyk National Medical Academy of Postgraduate Education, Pediatrics N02, Kyiv, Ukraine; Bogomolets National Medical University, Pediatrics postgraduate education, Kyiv, Ukraine.

Disclosure of Interests: None declared

Background: Evaluation of inflammatory activity is an important element in the management of patients with juvenile idiopathic arthritis (JIA), for which C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are traditionally used. However, they might be uninformative in case of subclinical inflammation. The serum level of calprotectin MRP-8/MRP-14 (sCal) correlates well with arthritis activity, as it is produced by activated cells directly in synovia.

Objectives: We evaluate the level of sCal in patients with JIA depending on the type of therapy in order to assess comprehensively the disease activity for further treatment correction.

Methods: 74 patients with JIA were examined, 18 of them had oligoarticular disease subtype, 39 – polyarticular, 17 – systemic. The mean age was 11.3 ± 0.4 years; the disease duration was 5.2 ± 0.4 years. Among them, there were 49 (66%) females and 25 (34%) males. All patients were divided into 2 groups depending on the therapy type. Group I consisted of 33 children treated with methotrexate, while 11 of them were in a state of clinical remission. Group II included 41 children treated with biologic DMARDs (adalimumab, etanercept, tocilizumab), while 14 of them achieved clinical remission. All children had normal levels of CRP and ESR. Quantitative indicators distribution is given as a median [5th; 95th percentile], the calculations were carried out using the Mann-Whitney U test.

Results: Level of sCal in the active disease stage in children of Group I was 8,750 ng/ml [3,700; 17,100], while sCal level in Group II was 2,900 ng/ml [1,200; 24,900]; sCal level in children of Group I which achieved clinical remission – 3,400 ng/ml [1,200; 6,000], and the same indicator in Group II – 1,000 ng/ml [100; 2,800]. sCal level was significantly higher in the group of patients who did not receive biologic DMARDs, both in the active stage of disease (p = 0.000006, U = 71.5) and in the stage of clinical remission (p = 0.00034, U = 11). sCal level is 5,800 ng/ml less in patients with active stage of disease and 2,400 ng/ml less in patients with clinical remission, both treated with biologic DMARDs. In addition, the level of sCal is 5.5 times higher in our patients (3,300 ng/ml) compared with healthy children (600 ng/ml) (p = 0.015). The moderate positive correlation of sCal and JADAS-27 activity index (r-Spearman’s r = 0.58) was credibly established.

Conclusion: The level of sCal can reflect the degree of inflammatory activity in JIA, it is significantly higher in the group of patients who did not receive biologic DMARDs in the treatment regimen, both in the active disease stage (p = 0.000006, U = 71.5) and in the stage of clinical remission (p = 0.00034, U = 11), which indicates the effectiveness of biologic DMARDs in the treatment of JIA. We assume that it would be appropriate to estimate the serum calprotectin level in the comprehensive analysis of clinical status in JIA patients for the further correction of therapy.

AB0986 VITAMIN D LEVEL AND BONE MINERAL DENSITY IN PATIENTS WITH JUVENILE RHEUMATOID ARTHRITIS

Tetiana Marushko1, Yulia Holubovska1, Yuriy Marushko2, Shupyk National Medical Academy of Postgraduate Education, Pediatrics N02, Kyiv, Ukraine; Bogomolets National Medical University, Pediatrics postgraduate education, Kyiv, Ukraine.

Background: An impaired bone metabolism is observed in patients with juvenile idiopathic arthritis (JIA), associated both with the activation of pro-inflammatory cytokines and use of steroid medications. The majority of children with JIA have low vitamin D level, which may complicate the disease course. We regard the monitoring of bone mineral density (BMD) in patients with juvenile rheumatoid arthritis (JRA) should be complemented with an additional assessment of calcidiol (25(OH)D) serum level as an indicator of BMD and a criterion of successful therapy.

Objectives: To evaluate the bone densitometry data and calcidiol level in patients with JRA in order to estimate the osteopenic syndrome and the advisability of prescribing the vitamin D additional doses.

Methods: The calcidiol level and BMD data in 65 patients with JIA were assessed (41 girls and 24 boys). All children were divided into 2 groups, depending on the therapy type. Group I consisted of patients who received methotrexate (n = 37), Group II – patients who received the biological DMARDs (n = 28), namely tocilizumab (6 patients), adalimumab (20 patients) and etanercept (2 patients). At the time of the study, 14 children of the Group II were prescribed the biological DMARDs only, while the 12 patients were in the state of clinical remission unlike the 7 patients of Group I. It should be mentioned that the majority of children in the Group II had high disease activity degrees before the start of treatment with biological DMARDs. In order to show the correlation between BMD and disease activity, cJADAS-27 score result for the last 6 months was estimated. The data were processed using Pearson’s chi-squared test and Spearman’s Rank correlation coefficient.

Results: The study revealed, 60 children (92% of all patients) showed vitamin D insufficiency, that mainly manifested by decreased calcidiol level (from 21 to 29 ng/ml), only 8 children (12%) showed calcidiol level deficiency (<20 ng/ml). A significant difference was found in the BMD results depending on the therapy type (χ² = 10.05; p < 0.01) using Pearson’s chi-squared test. As a result, children who received biological DMARDs, demonstrated significantly better results according to BMD assessment data. A direct association of moderate strength was found (the correlation coefficient (r-Spearman’s ) is 0.39). The strong negative association (r-Spearman’s was -0.72) was observed between BMD assessment data and cJADAS-27 score result, which confirmed our statement – high disease activity affects the bone tissue mineralization. There was a weak negative association between 25(OH)D level and cJADAS-27 score result (r-Spearman’s was -0.15).

Conclusion: There was a paucity of vitamin D level in 92% of patients with JRA, in 80% secondary osteoporotic syndrome. It was revealed that patients, who receive biological DMARDs in integrated treatment, demonstrate significantly better results according to BMD assessment data. Calcidiol level has a moderate effect on BMD, while BMD strongly depends on disease activity degree according to the Spearman’s Rank correlation coefficient.

AB0987 CHOICE AND SWITCH BETWEEN BIOLOGICAL AGENTS IN NON-SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (JIA)

Anna Ignatova1, Nina Seylanova1, Elena Zholobova2, I.M. Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation; I.M. Sechenov First Moscow State Medical University (Sechenov University), Paediatric Rheumatology, Moscow, Russian Federation.

Background: Over the past few decades, biologic therapy has significantly improved the prognosis in children with JIA. The issue of optimal and personalised biologics prescription and the problem of switching between drugs are relevant questions of modern paediatric rheumatology.

Disclosure of Interests: None declared
Objectives: The aim of our retrospective observation was to describe trends in the biologics prescription in first and subsequent lines for the treatment of non-systemic JIA.

Methods: We recruited 252 patients with non-systemic JIA, who received medical treatment with biologics at the Department of Paediatric Rheumatology of Sechenov University from January 2015 to December 2017. 18% of them (n=46) had chronic anterior uveitis at the moment of biologic therapy initiation. Eye involvement influenced treatment decisions in these patients, and therefore they were excluded from the analysis. 206 children with non-systemic JIA and without uveitis were included in a study group.

Patients' characteristics: 128 girls and 78 boys (1.6/1). Mean age 13.5 ± 3.8 years, age of disease onset 7.8 ± 4.2 years; mean disease duration before biologic therapy initiation 3.3 ± 3.4 years. JIA categories: 135 (85.5%) had polyarticular RF, 29 (14.1%) - oligoarticular, 26 (12.6%) - enthesitis-related, 9 (4.4%) - polyarticular RF, and 7 (3.4%) - psoriatic subtype. At baseline, 204 patients (99%) received concomitant therapy with conventional DMARDs: 175 children (85.0%) received Methotrexate (MTX), 3 (1.5%) - combination of MTX and sulfasalazin (SSZ), 9 (4.4%) - SSZ, 9 (4.4%) - leflunomid, 4 (1.9%) - combination of MTX and leflunomid. 4 (1.9%) - cyclosporine A. Two children (1%) received biologics as monotherapy.

Results: As a first biologic abatacept was used in 26 patients, adalimumab in 14, tocilizumab in 6 and infliximab in 4. Etanercept was pre-scribed to 156 patients (75.7%;± 3.5) without non-systemic JIA, which was significantly more frequently than other biologics together - 50 (24.3%;± 6.2) (t=7.7; P<99.97). Later 24 children (11.7%) were switched from the first to a second biologic agent. The main reason for switching (n=14) was inefficacy of the first-line drug. When etanercept was ineffective, abatacept (n=3) and adalimumab (n=5) were prescribed as second-line biologics. Etanercept was used as a second-line biologic in 6 children, who were initially treated with other biologic agents. The other reason for switching was the appearance of chronic anterior uveitis (n=7); 6 of these children were initially treated with etanetepic, 1 with abatacept; they were switched to adalimumab (n=6) and abatacept (n=1). In 2 cases adverse events were observed - one episode of intrathoracic lymphatic nodes tuberculosis in a patient receiving etanercept, and one allergic reaction (rash, asphyxia) after the infliximab injection. At the end of our observa-tion etanercept was chosen as treatment for 148 (71.8%) patients with non-systemic JIA.

Conclusion: Thus, etanercept was preferred biologic agent in the treat-ment of non-systemic JIA. The presence of uveitis requires a different treatment approach.

PATIENTS' AND CAREGIVERS' ASSESSMENT OF A DEDICATED OUTPATIENT SERVICE FOR INTRAARTICULAR GLUCOCORTICOID INJECTIONS IN JUVENILE IDIOPATHIC ARTHRITIS

Hanan Jadoun1, Aurora Pucacco1, Angela Aquilani1, Andrea Uva2, Fabio Basta1, Rebecca Nicolai1, Fabrizio De Benedetti1, Silvia Magni-Manzoni2, Bambino Gesù Children's Hospital, Rheumatology, Rome, Italy; 2Sapienza University of Rome, Rome, Italy

Background: Patients with juvenile idiopathic arthritis (JIA) may require several hospital admissions over the disease course, due to flares or persistently active arthritis, with a negative impact on the patients’ and family’s daily life. To provide timely intervention and support the patients and families’ quality of life, in 2018 an afternoon outpatient service for intraarticular glucocorticoid injections (IAGI) in JIA has been created at the study center.

Objectives: To evaluate the patients’ and caregivers’ assessment of the outpatient service for IAGI in JIA; to investigate demographic and clinical features of patients entering the service.

Methods: All consecutive JIA patients and their caregivers seen at the IAGI outpatient service from February 2018 to January 2019 completed a satisfactory questionnaire just after the IAGI procedure. The patient’s part included: satisfaction on the overall service and on dedicated personnel (yes/no, why), procedure pain assessment (VAS 0-10, 0–none; 10 worst); whereas the caregiver’s part: satisfaction on the overall service (yes/no, why), facilitation of family burden (yes/no, why). Descriptive analysis was performed on 102 completed questionnaires. No answers were synthesized in items.
Results: All of the 46 JIA patients seen at the IAGI outpatient service and their caregivers completed the questionnaire. Patients were mostly females (78%) with early disease onset (median 4.8 years) and positive ANA status (61%). The majority (52%) had persistent oligo-JIA, followed by extended oligo-JIA (26%), RF-negative polyarthritis (17%), ERA and systemic JIA (2%, respectively). The median age at IAGI was 14.7 years (IQ 11.3-19.5). Forty patients (87%) had previous hospitalization for IAGI, mostly under general sedation (64%). All patients, except a 12 year old girl (0.02%) with uncontrolled needle phobia and previous IAGI, were treated with the IAGI outpatient service. In Table 1 reasons of satisfaction are detailed in items. Procedural pain was median rated 3 (IQ 2-6). Most of the families came from the city or province of the study center (76%); 17% from other provinces of the same geographical region; 7% from other regions.

Abstract AB0989 Table 1. Frequency of specific reasons of satisfaction on the IAGI outpatient service, synthesized in items, during the 56 procedures of the study.

</table>

Conclusion: The results outline the afternoon IAGI outpatient service foster the management of flares or persistently active arthritis in JIA patients, particularly at older ages, with high rate of satisfaction and lower impact on patients’ and family burden compared to hospital admission and, of note, despite moderate pain rating and multiple site injections. This supports the development of Diagnostic Therapeutic Care Pathways for JIA patients, in the view of improving patients’ quality of life and also towards resource optimization.

AB0990

FINAL DIAGNOSIS OF THE PATIENTS WITH MUSCULOSKELETAL COMPLAINTS: PRELIMINARY RESULTS OF ONE-YEAR STUDY
Nuray Aktyay Ayaz, Hafize Emine Sonmez, Serife Gül Karadaş, Aysė Tanatar.
University of Health Science, Kanuni Sultan Süleyman Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Musculoskeletal (MS) complaints are one of the most common reason for administration to outpatient clinics. Objectives: The study aimed to summarize the final diagnosis of the patients who suffered from musculoskeletal (MS) findings. Methods: We prospectively evaluated the patients who were referred with the complaints of MS systems in a year period. Results: A total of 940 patients with the complaint of musculoskeletal systems were examined. Among them, 577 patients suffered from arthralgia, 234 had arthritis, 39 had low-back pain, 26 had limb pain, and 64 had other symptoms such as myalgia, heel pain, hip and neck pain. A diagnosis of rheumatic disease was made in 430 of patients, whereas 510 had non-rheumatic conditions. Final rheumatological disease diagnoses were as follows: juvenile idiopathic arthritis (n=195), familial Mediterranean fever (n=101), reactive arthritis (n=46), acute rheumatic fever (n=39), toxic synovitis (n=17), psoriasis (n=8), Raynaud’s phenomenon (n=6), chronic recurrent multifocal osteomyelitis (n=5), vasculitis (n=5), systemic lupus erythematosus (n=4), juvenile dermatomyositis (n=2) and juvenile scleroderma (n=1). Among patients with non-rheumatic conditions, most of them had vitamin D deficiency, infections, mechanic-orthopedic conditions, and growing pains. Conclusion: Evaluation of a child presenting with MS findings requires a comprehensive, multidisciplinary, and systematic approach. As a busy pediatric rheumatology center, we demonstrated the final diagnosis of referred patients with MS symptoms and only less than half of the patients were diagnosed as a rheumatological condition. Whilst pediatric rheumatology centers are limited in number, our results put forth the need of formulating recommendations for clinicians in order to prevent unnecessary referrals

AB0991

PRELIMINARY RESULTS OF REFERRALS TO A TERTIARY PEDIATRIC RHEUMATOLOGY OUTPATIENT CLINIC: A YEAR IN REVIEW
Serife Gül Karadaş, Aysė Tanatar, Hafize Emine Sonmez, Nuray Aktyay Ayaz. Health Sciences University Kanuni Sultan Süleyman Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Previously, the profile of pediatric rheumatology practice was demonstrated from several countries[1,2]. However, there is not a
documented data about the pediatric rheumatology clinic population in our country.

**Objectives:** To evaluate and define the patient population referred to a tertiary pediatric rheumatology outpatient clinic in Turkey.

**Methods:** We prospectively evaluated the patients who were initially referred to our department with suspicion of rheumatic diseases in a year period. These findings cover only ten months results as a preliminary study.

**Results:** A total of 2317 new patients (1142 male 1175 female) were seen. Among them, most of patients(n=1445) were referred from pediatric outpatient clinics, pediatric emergency units(n=168) and orthopedic surgeons(n=91). Of these 48.9% had a final diagnosis of a rheumatic disease. 37.9% had non-rheumatic conditions, and 13.2% had no definitive diagnosis yet. Most of them were periodic fever syndromes(n=553), juvenile idiopathic arthritis(n=207) and vasculitis(n=160) (Table 1). Other than rheumatological diseases, non-rheumatic conditions were mostly vitamin D deficiency, infections, mechanic-orthopedic conditions, and growing pains (Table 2).

**Conclusion:** Both in our country and all over the world, there are limited number of pediatric rheumatology centers and experienced pediatric rheumatologists, and it is clearly known that diagnosing a rheumatic disease requires a careful evaluation and a high index of suspicion. As our study implies, a vast majority of referrals are composed of non-rheumatic conditions, so specifying the algorithms before referring the patients to pediatric rheumatology centers will be cost-effective and time for evaluation of patients with rheumatic diseases will be satisfactory.

**AB0992 HEPATITIS A VIRUS VACCINATION IN AUTOINFLAMMATORY DISEASES UNDER CANAKINUMAB AND TOCILIZUMAB TREATMENT**

Kenan Barut, 1, Adna Adrovic, 1, Sezgin Sahin, 1, Mehmet Yildiz, 1, Oya Koker, 1, Gamze Yalın, 1, Omer Faruk Beser, 1, Bekir Kocaceybejek, 1, Pelin Yüksel, 1, Omer Kasapoglu, 1, Istanbul University Cerrahpasa, Pediatric Rheumatology, Istanbul, Turkey; 2, Okmeydani Education and Training Hospital, Istanbul, Turkey; 3, Istanbul University Cerrahpasa, Microbiology, Istanbul, Turkey

**Background:** Autoimmune, autoinflammatory mechanism and drugs used in treatment increase the risk of liver disease in patients with chronic rheumatic diseases. Hepatitis A vaccine is a highly effective vaccine that prevents both the formation and spread of clinical hepatitis. The risk of various infections increases with the immunosuppressive effect of both the disease and the drugs. Therefore, vaccination of these diseases is of high importance for the prevention of infectious diseases. Systemic juvenile idiopathic arthritis (SJIA) arthritis is a juvenile idiopathic arthritis (JIA) subtype with autoinflammatory pathogenesis. Steroid, methotrexate and anti-interleukin 1 and 6 are used for the SJIA treatment. Anti-interleukin 1 treatments are also used in the treatment of Cryopyrin-associated periodic syndromes (CAPS), which is also characterized with autoinflammatory pathogenesis.

**Objectives:** The aim of this study was to investigate the efficacy and safety of hepatitis A vaccine in patients with autoinflammatory disease on anti-interleukin 1 and 6 treatment.

**Methods:** In this study a total of 39 patients with autoinflammatory diseases on anti IL-1 and IL-6 therapy were initially evaluated but 25 of them were excluded due to anti-HAV IgG positivity. At the end, 24 patients with autoinflammatory diseases on anti IL-1, anti IL-6 therapy and 39 healthy participants who were seronegative for hepatitis A received two doses of the hepatitis A vaccine in a 0 and 6 month schedule. Hepatitis A virus (HAV) IgG antibodies were measured before vaccination and one month after last dose of the vaccine. Anti-HAV IgG titer as S/CO:1.1, IU/L was considered positive and protective.

**Results:** Total 24 patients with autoinflammatory condition (13 females, 11 males) and 39 healthy controls (16 female, 21 male) were included in the study. Among patients with diagnosis of autoinflammatory disease, 19 were SJIA and 5 were CAPS patients. The mean age was 14.1±3.7 and 12.2±3.3 years respectively. Canakinumab was used in 15 (62.5%) and tocilizumab in 9 (37.5%) all patients. Among all SJIA patients, 10 (52.6%) were treated with canakinumab and 9 (47.4%) were treated with tocilizumab. All patients with CAPS (n: 5) were using canakinumab. Among SJIA cases, 15 (75%) were also using methotrexate and 14 (70%) prednisolone. Anti-HAV IgG concentrations were measured one month after the last dose of hepatitis A vaccine. There was statistically significant difference between patients with autoinflammatory condition and healthy controls regarding the anti-HAV IgG titer (mean 5.3±1.5 IU/L) versus (10.5±7 IU/L) p<0.05. The rate of anti-HAV IgG seropositivity (cut-off 1.1 IU/L) in autoinflammatory disease (24/24 (100%)) was significantly different comparing to healthy controls (33/39, 84.6%) (p=0.04). There was no disease flare of disease nor the adverse event detected in any patients after vaccination.

**Conclusion:** Anti-HAV IgG seroconversion was detected in patients with autoinflammatory disease on anti-IL1 and anti -IL6 therapy 1 month after the last dose of hepatitis A vaccine. The response to vaccine did not differ between healthy children and patients with autoinflammatory disease under canakinumab and tocilizumab. In this study hepatitis A vaccine was found to be safe in autoinflammatory diseases with canakinumab and tocilizumab treatment.

COMORBIDITIES IN FAMILIAL MEDITERRANEAN FEVER

The relationship between vitamin D and disease activity was analyzed based on juvenile arthritis disease activity score (JADAS27).

Objectives:
The aim of this study was to examine the status of vitamin D in children with JIA depending on the peculiarities of the disease and the season.

Methods:
92 patients with JIA were examined. The median age of them was 10.5±2.17 years, from 1.8 to 17.6 years (55 female, 37 male). The serum level of vitamin D was measured through blood test by chemiluminescence method. The relationship between the level of vitamin D and disease activity was analyzed based on juvenile arthritis disease activity score (JADAS27).

Results:
The average level of vitamin D was 22.75±1.97 ng/ml (corresponded to an insufficient level). It was not found relationship between the level of vitamin D deficiency and gender. Vitamin D status changed throughout the year from lowest value 19.52±1.61 ng/ml (in May) till the greatest value 29.62±2.49 ng/ml (in September). Significantly higher level of vitamin D was in September compared to most months (January, p=0.04; February, p=0.04; March, p=0.01; April, p=0.02; May, p=0.01; October, p=0.03; November, p=0.03; December, p=0.01).

The geographical location of Kharkiv (Ukraine) is at 50° latitude. It was proved that UVB radiation above the 33° latitude is not intense enough for the synthesis of vitamin D during the whole year [3]. At the same time there was no significant relationship between the low level of vitamin D in serum and disease activity.

Conclusion:
A decrease of vitamin D status were observed throughout the year. Despite the fact that in September was the highest level of vitamin D, the normal concentration was not reached. Seasons should be taken into account, but patients with JIA need supplementation of vitamin D all around the year.

EXPLORING UVETIS IN EARLY ONSET ANA POSITIVE JIA

Natasja Kiler1, Mihovil Hrgovic1, Mario Sestan1, Sanja Perić2, Damagaj Kiler1, Marijan Kralj1, Kristina Potocki4, Nenad Vukojevic2, Marija Jelusic1, University Hospital Centre Zagreb, University of Zagreb School of Medicine, Department of Paediatrics, Zagreb, Croatia; University Hospital Centre Zagreb, University of Zagreb School of Medicine, Department of Ophthalmology, Zagreb, Croatia; Faculty of Pharmacy and Biochemistry, University of Zagreb, Department of Biophysics, Zagreb, Croatia; University Hospital Centre Zagreb, University of Zagreb School of Medicine, Diagnostic and Interventional Radiology Department, Zagreb, Croatia.

Background: Juvenile idiopathic arthritis (JIA) is the most frequent childhood systemic disease associated with uveitis, where uveitis occurs in 10–13% of the patients, frequently causing long lasting consequences when unrecognized, untimely or incorrectly treated.

Objectives: To explore correlations between age, gender, ANA, RF titer in patients with JIA, occurrence of ocular manifestations and its complications. To examine similarities and differences between patients with different subtypes of JIA and uveitis.

Methods: The retrospective study included 31 children treated for JIA and uveitis in the period 2009-2017 at the Department of Paediatrics, UHC Zagreb. The SUN working group classification and grading system were used to evaluate ocular manifestations. Data analysis was executed using R programming language.

Results: We followed 31 patients (81% female) suffering from JIA with ocular manifestations. Median age at JIA onset in girls was 2.5 (1-14.5) years and in boys 8.6 (11-14.5) years, while girls had median age 4.25 (1-14) years at first ocular manifestation and boys 8.25 (4 -13.5) years. All patients were RF negative. 61% of patients was ANA positive, out of
which 88% had onset of JIA before the age of 6 (all girls). Complete remission of uveitis was achieved in two patients treated with topical corticosteroids, with non-steroidal anti-inflammatory medication and methotrexate used in one of the patients. Inactive uveitis was most frequently achieved with a combined therapy which included biologics. A patient suffering from uveitis and JIA was found to be significantly more likely to suffer from oligoarticular subtype (64.5%, CI 45.4-80.8%, p<0.001). We determined that a positive ANA titer occurred statistically more frequently in females (OR int., CI 3.18-int., p=0.001). No significant statistical difference in ANA titer was found between groups of patients who were diagnosed with rheumatologic or ocular disease before and after the age of 6 (OR 1.85, CI 0.12-29.57, p=0.6111) nor between different subtypes of JIA. There was no difference in time passed between the occurrence of rheumatologic and ocular manifestations (median difference =1.75 years, W=131, p=0.2597), nor between ANA titer (OR 0.57, CI 0.09-3.12, p=0.4775) between groups with and without ocular complications. Patients who first presented with ocular manifestations did not have a greater likelihood to develop ocular complications (OR 5.59, CI 0.51-299.98, p=0.175).

Conclusion: A group of female patients suffering from RF negative subtypes of JIA and uveitis, with onset occurring before the age of 6 and positive ANA was prominent. These patients were traditionally classified as different subtypes of JIA, but together, they are best described as “early onset ANA positive JIA”, concuring the need for reclassification of JIA. Limited by a small number of patients, this was partly confirmed with significant statistical findings, a recurrent positive ANA titer in females with JIA and uveitis and a more frequent occurrence of uveitis in oligoarthrits. The occurrence of ocular complications was not dependent upon ANA titer, nor upon the time difference between rheumatic and ocular symptoms or their order of appearance.

APPLICATION OF YAMAGUCHI CRITERIA FOR CLASSIFICATION OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS
Kwang Nam Kim1, Jong Gyun Ahn2, Young Dae Kim2. 1Hallym University Sacred Heart Hospital, Pediatrics, Anyang, Korea, Rep. of (South Korea); 2Severance Child’s Hospital, Yonsei University, Pediatrics, Seoul, Korea, Rep. of (South Korea); 3Ilsan Paik Hospital, Inje University, Pediatrics, Goyang, Korea, Rep. of (South Korea)

Background: The ILAR criteria require the presence of arthritis to classify a patient as having sJIA. The sJIA patients prior to the onset of arthritis (suspected sJIA) appeared clinically similar to patients fulfilling the ILAR criteria for sJIA.

Objectives: Children with sJIA may have a delayed onset of arthritis and it fail to fulfill the ILAR criteria for sJIA. This study was undertaken to determine whether the Yamaguchi criteria is useful in classification of child with sJIA particularly in pre-arthetic phase of illness.

Methods: Retrospective chart review all patients with a diagnosis of sJIA in Hallym University Medical Center from Feb. 2002 through April 2016.

Results: Total 73 patients were diagnosed by ILAR classification criteria, 38 boys and 35 girls formed the study cohort. There are only 20 patients who are fulfilled of ILAR criteria in sJIA. Characteristics sJIA (n=20) suspected (n=53) Total (n=73)

Evanescent Rash 19 24
Sore throat 1 5
Lymphadenopathy 2 11
Hepatomegaly 1 11
Splenomegaly 4 10

37 patients were diagnosed with suspected sJIA due to have not an arthritis. 36 patients were presented the arthritis at the onset of sJIA. The Yamaguchi criteria was fulfilled in a higher number of patients in the study (n=44) as compared to the ILAR criteria (n=20). Among the patients with the absence of arthritis (n=37), 25 patients fulfilled the Yamaguchi criteria. (67.5%).

ILAR criteria Yamaguchi criteria
Yamaguchi criteria fulfilled 16 28
Yamaguchi criteria not fulfilled 4 25
Total cohort 20 53

Conclusion: Overall the Yamaguchi criteria was fulfilled in a higher number of patients in the study (60.2%) as compared to the ILAR criteria (27.3%). The failure of ILAR criteria was mainly due to the absence of arthritis. The Yamaguchi criteria is more helpful to diagnosis of sJIA. The Yamaguchi criteria may be useful on early diagnosis and treatment for patient with delayed onset arthritis at onset of disease.

AB0097 MATCHED CONTROLLED SURVEILLANCE OF TOCILIZUMAB TREATMENT FOR POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS–AN INTERIM ANALYSIS
Arane Kleen, Dennis Conzelmann, Toni Hospach, Frank Weiler-Heinemann, Sandra Hansmann, Jasmin Kuemmerle-Deschner, Michael Borte, Kirsten Minden, Ivan Foeldvari, Christoph Rietzschel, Gerd Ganser, Ralf Trauzeddel, Markus Hufnagel, Dirk Foell, Rainer Berendes, Gudula Boeschow, Prasad Commen, Angelika Thon, Gerd Homett, BIKER-Registry, BIKER-Registry, Sankt Augustin, Germany

Background: Tocilizumab (TOC) is approved for treatment of polyarticular juvenile idiopathic arthritis (pJIA). Real world data are limited.

Objectives: Long-term surveillance of patients newly initiating tocilizumab treatment for at least five years using TOC and a control cohort using alternative biologics.

Methods: Baseline demographics, clinical characteristics and disease activity parameters as well as efficacy and safety parameters were compared between patients using TOC and a control cohort using alternative biologics. The cohorts were matched for region and date of therapy start. Efficacy outcome variables were JADAS10 and joint counts. Functional status was determined with the Childhood Health Assessment Questionnaire disability-index (CHAQ-DI). Safety assessments were based on adverse events (AE) reports.

Results: Patients starting on TOC had a longer disease duration (5.2y vs. 2.9 y; p= 0.0001) and had TOC significantly more often as second line biologic than patients in the comparator group (80% vs 14%, p< 0.0001). No differences could be observed regarding disease activity parameters (JADAS 10 14.7 +/- 6.4 vs 15.8 +/- 6.0) or disability (CHAQ DI 0.65 +/- 0.63 vs 0.66 +/- 0.66) at baseline. Patients treated with TOC showed a substantial response to treatment with a significant reduction in JADAS 10 from 14.7 to 5.4 (p<0.0001). After 6 months of TOC treatment, 40% of patients had reached JADAS minimal disease activity (MDA), 22% of patients had reached JADAS remission. Tolerability was comparable between the two cohorts, with 31 in the TOC versus 34 patients in the control cohort experiencing AE; serious AE (SAE) were documented in 3 patients in the TOC and one patient in the control cohort. The SAE in the TOC cohort were medication intoxication with suicidal intent, JIA flare, gastrointestinal infection and abdominal pain in 1 patient each. In the control cohort there were JIA flare in 2 patients and gastrointestinal infection in 1 patient. No significant differences regarding infectious AEs, cytopenias or elevated transaminases were observed. No other AE were reported more than once; no deaths occurred.

Conclusion: Comparability of efficacy was limited due to the fact that patients in the TOC cohort had longer disease duration and were more often second line biologic users. Tolerability was comparable in both cohorts. Long-term observation is ongoing.
Severe IGA Vasculitis: Cyclophosphamide in Treatment Follow-up After Transition from Paediatric to Adult Rheumatology Care

Background: Cyclophosphamide (CYC) has been a mainstay in the treatment of severe childhood primary systemic vasculitis. Although major organ involvement is rare in Iga vasculitis (IgAV), CYC is among therapeautical options in moderate and severe IgAV nephritis. No specific recommendations are available for severe vasculitis of IgAV.

Objectives: To describe disease course and treatment response in 2 patients with severe IgAV with CNS and renal involvement.

Methods: Case reports with disease assessments using Paediatric Vasculitis Activity Score (PVAS).

Results: Both children were Caucasian boys with unremarkable previous history aged 4 (Patient 1) and 8 (Patient 2) years. In both cases the initial typical presentation included purpura and abdominal pain in both, arthritis in Patient 1 and haematuria in Patient 2. After 2 weeks of prednisone therapy for severe gastrointestinal (GIT) symptoms Patient 1 was admitted for right-sided weakness and facial palsy. His brain MRI revealed an ischaemic lesion. His PVAS reached 21/63 for skin, abdominal, renal (haematuria) and CNS systems. When Patient 2 was admitted for abdominal symptoms he developed a focal epileptic paroxysm. His brain MRI was compatible with cerebral vasculitis. His nephritic-nephrotic syndrome prompted renal biopsy showing mesangio proliferative nephritis with IgA deposits. His PVAS was 27/63 for skin, abdominal, renal (hyper tension, haematuria, proteinuria) and CNS systems. Both patients received 3 doses of intravenous methylprednisolone 30 mg/kg followed by oral prednisone 1 mg/kg with subsequent tapering and 3 doses of CYC 500mg/m² (monthly i.v.). At follow-up 3 months after the 1st CYC dose both patients fully recovered neurologically. Patient 2 was on prednisone (0.2 mg/kg) and ACE inhibitor and his urine was negative for the first time. PVAS=0. Patient 1 had been developing significant proteinuria during prednisone withdrawal and his PVAS counted 10/63 for renal disease. Prednisone was re-instituted and ACE inhibitor added while renal biopsy has been pending.

Conclusion: In both cases therapy with corticosteroids and CYC led to the full recovery of CNS disease but did not prevent progression of nephritis in Patient 1. Response of Patient 2 nephritis to CYC appeared satisfactory at 3 months visit but would require confirmation after full prednisone withdrawal. Although generally benign, when IgAV presents with major organ involvement its treatment is challenging. Further research is needed in order to gather better evidence to support treatment recommendations.

Treatment Follow-up after Transition from Paediatric to Adult Rheumatology Care

Briqita Koreg, Majma Tomazin, Vojko Berc, Artur Pahor, Iztok Holc. University Medical Centre Maribor, Maribor, Slovenia

Background: Many juvenile onset rheumatic diseases continue to have activity in adulthood. Therefore, a continuous uninterrupted healthcare of these patients is needed.

Objectives: To determine whether and how therapy has changed in patients after transition from paediatric to adult rheumatology service in our medical centre.

Methods: A retrospective single centre study was performed. Patients seen at least once at both paediatric and adult rheumatology outpatient service were enrolled. Data was collected from patients medical records.

Results: A total of 50 patients were included. Most of them were female (82%). Average age at transition was 19.6 years (range 18-27 years). Mean time of follow up was 44 months (range 2-119 months). Juvenile idiopathic arthritis (JIA) was the most common juvenile onset chronic rheumatic disease. The medications used either as monotherapy or in combination before transition at last visit at paediatric rheumatology
outpatient unit were nonsteroidal anti-inflammatory drugs (NSAIDs) (14%), corticosteroids (6%), synthetic disease modifying antirheumatic drugs (DMARDs) (18%), biologic DMARDs (2%). After transition 34% of patients used NSAIDs, 16% corticosteroids, 24% synthetic DMARDs, 8% biologic DMARDs. Without any medication before and after transition were 66% and 48% of patients, respectively. After transition 36% of patients had their therapy changed. 30% needed escalation of therapy because their disease was still active or they experienced exacerbation.

Most changes in therapy occurred in the first year after transition. 

Conclusion: We confirmed that many patients with juvenile onset rheumatic disease had changes in their therapy after transition, especially escalations of therapy. Most changes occurred in the first year after transition which is a vulnerable period in a young adult life.

**THE SURVIVAL OF METHOTREXATE IN JUVENILE IDIOPATHIC ARTHRITIS CHILDREN AFTER DURING FIRST BIOLOGIC TREATMENT**

Rinat Raupov1, Lubov Sorokina1, Yuri Korin2, Ilya Avrusin1, Elizaveta Orlova1, Ekatерина Гайдар1, Margarita Dubko1, Vera Masalова1, Tatiana Лихачева1, Ludmila Снегирева1, Eugenia Испова1, Tatiana Кормшина1, Olga Kalashникова1, Mikhail Костик1.

1Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation; 2Peter the Great St.Petersburg Polytechnic University, Saint-Petersburg, Russian Federation; 3Pediatric Research and Clinical Center for Infection Diseases, Saint-Petersburg, Russian Federation

Background: Methotrexate (MTX) is a gold standard for treatment of juvenile idiopathic arthritis (JIA) patients. The main adverse events (AE) related to the MTX are intolerance, increased rate of infections, elevation of the liver enzymes, hematological abnormalities and stomatitis, which required to stop the MTX therapy [1]. In children without remission who tolerated MTX often the second-line treatment is the biologics, which may use alone or in the combination with MTX.

Objectives: The aim of our study was to evaluate the main reasons of MTX discontinuation in JIA children who started first biologic.

Methods: In the study were included 173 non-systemic JIA patients, whom biologic therapy was prescribed firstly to previous MTX treatment. We evaluate the main reasons of MTX discontinuation after the starting of the biologic treatment, duration of MTX treatment (all and after biologic start), achievement the remission, according C. Wallace criteria and time to remission, flare of JIA. We compared two groups: i) patients with biologics with ongoing methotrexate and ii) patients with biologics alone, whom MTX was discontinued or not prescribed.

Results: During the trial MTX discontinued 40 (23.1%) patients: due to intolerance (n=11), other adverse events (AE) (n=10), except intolerance (mainly, frequent infection and transaminitis) and remission of JIA (n=19). Patients with onset age of JIA <4.4 years were in the risk of developing MTX intolerance (LogRank test, p=0.000001), but the younger patients usually developed other AE. Compare of the three subgroups of patients, who discontinued MTX we have not yet found any differences, except the onset age and frequency of remission, which was higher in patients who discontinued MTX due to other AE than due to intolerance.

Conclusion: The main factor, associated with MTX discontinuation in JIA patients, who received first biologic was the disease onset age. Eldest age was related to higher risk of developing the MTX intolerance.

ARE ANY DIFFERENCES IN THE LOCATION OF BONE LESIONS BETWEEN BONE MALIGNANT TUMORS AND INFLAMMATORY OSTEOPATHIES?

Vyacheslav Silkov1,2, Nikita Suvorov2, Mikhail Kroutk1, Olga Kopchak2, Alexei Malayev1, Vyacheslav Zorn1, Alexander Malakhin1. 1Saint-Petersburg clinical scientific and practical center for special types of medical care (oncology-oriented), Saint-Petersburg, Russian Federation; 2Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation; 3Kirov’s regional children’s hospital, Kirov, Russian Federation; 4Science research Institute of Phthisiopulmonology, Saint-Petersburg, Russian Federation

**Background:** Different pediatric bone destructive diseases may have similar radiological findings but have their typical localizations [1].

**Objectives:** The aim of our study was to differences in the bone lesions location in various pediatric bone destructive diseases.

**Methods:** Our cohort (n=204) consists of four main subtypes: i) chronic non-bacterial osteomyelitis (CNO, n=91), ii) hematogenous osteomyelitis (HO, n=47); iii) tuberculosis osteomyelitis (TBO, n=33), and iv) malignant bone tumors (MBT, n=33) - osteosarcoma and Ewing’s sarcoma.

**Results:** All bone destructive diseases have the similar frequency of femur and humerus involvement. MBT patients compare to others had the highest onset age, and higher frequency of pelvic involvement, and comparatively rare the involvement of spine, tibia, foot bones, sternum, the bones of forearm and hand (table).

**Conclusion:** Patients with bone destructive process with femur, humerus and pelvic involvement have to be under high level of consideration about all type of osteopathy, especially MBT.

IMMUNOGLOBULIN G4 RELATED DISEASE IN A 10 YEAR-OLD GIRL WITH MULTISYSTEM INVOLVEMENT

Özgü Kul Çınar1, Muthana Al-Obiali2, Neil Sebire3, Parichat Khaosut4, Despina Eleftheriou5,6. 1Great Ormond Street Hospital NHS Foundation Trust, Paediatric Rheumatology, London, United Kingdom; 2Great Ormond Street Hospital NHS Foundation Trust, Paediatric Rheumatology, London, United Kingdom; 3UCL Great Ormond Street Institute of Child Health, Histopathology, London, United Kingdom; 4King Chulalongkorn Memorial Hospital, Paediatric Rheumatology, Bangkok, United Kingdom; 5UCL Institute of Child Health and Great Ormond Street Hospital NHS Foundation Trust, Paediatric and Adolescent Rheumatology, London, United Kingdom; 6Aruk Centre for Paediatric and Adolescent Rheumatology, Paediatric and Adolescent Rheumatology, London, United Kingdom

**Background:** IgG4-related disease (IgG4RD) is an immune-mediated fibroinflammatory condition characterized by the infiltration of IgG4-carrying plasma cells and storiform fibrosis in most of the tissues. The condition is reported to cause multisystem involvement, however salivary gland is the most commonly affected organ with IgG4-related sialadenitis. Raised IgG4 concentrations in the serum and prominent infiltration by plasma-cytes expressing IgG4 in the lacrimal and salivary glands have been confirmed.

**Objectives:** IgG4-RD has mostly been described in adult population and therefore generally not well-known among paediatricians. To the best of our knowledge, this patient is one of the rare paediatric cases in literature diagnosed with IgG4-RD. We intended to emphasize that IgG4RD should be kept in mind for differential diagnosis of the patients presenting with enlarged parotid, lacrimal and submandibular glands and sicca symptoms.

**Methods:** We extracted patient’s clinical, laboratory and imaging data from our database and reviewed literature to reveal different manifestations of the IgG4RD.

**Results:** 10 year-old-girl presented with lacrimal and salivary gland swelling, sicca symptoms and fatigue. Ultrasound scan (US) neck revealed multiple small lymph nodes and enlargement of both submandibular glands. Salivary glands also appeared bulky and heterogenous with multiple small hypoechoic foci. Appearances were likely to represent sialoadenitis and there was no convincing evidence of malignancy or lymphoma. USS abdomen showed no abnormality. Full blood count, routine biochemistry and urine microscopy were normal. Autoantibodies came back as negative (ANA/Negative, ANCA: negative, Anti-Ro and Anti-La: negative, RF:Negative, thyroid autoantibodies: negative). Anti-Cardiolipin IgG was weakly positive on the first visit, however repeated analyses were negative. IgG level was elevated in repeated samples. IgA, IgM and IgE levels remained normal. IgG subclasses were performed which revealed significantly elevated IgG4 levels (21.49 Normal range: 0-1.1) IgG1, IgG2 and IgG3 levels were slightly elevated. The biopsy of salivary gland showed chronic inflammation with IgG4 staining and was suggestive of IgG4 related disorder. The patient was diagnosed with IgG4 related disease and treatment was started with intravenous methylprednisolone followed by Anti-CD20 (Rituximab) therapy and a weaning plan for steroids was given. Mycophenolate motefilk was commenced for the maintenance therapy. Patient has been in remission on maintenance therapy.

**Conclusion:** IgG4RD is a rare condition which can cause multisystem involvement with the infiltration of IgG4-bearing plasma cells in the tissues. We wanted to emphasize that this condition could also be seen in the paediatric population. Steroids are the cornerstone of the treatment, however Anti-CD20 medication (Rituximab) and steroid sparing agents such as mycophenolate motefilk could be the choice for maintenance therapy.

AB1003  DELAY IN DIAGNOSIS OF KAWASAKI DISEASE IS THE COMMONEST PROXIMATE REASON FOR DEVELOPMENT OF GIANT CORONARY ARTERY ANEURYSMS- OUR EXPERIENCE AT CHANDIGARH, NORTH INDIA

KUMAR RAKESH1, Ankur Jindal1, Anju Gupta1, Deepi Suri1, Manphool Singh2, Surjit Singh1. 1 Post Graduate Institute of Medical Education and Research, Chandigarh, Allergy Immunology Unit, Department of Pediatrics, Chandigarh, India; 2 Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Radiodiagnosis and Imaging, Chandigarh, India

Background: Long-term effects of Kawasaki disease (KD) depend primarily on development of coronary artery abnormalities. Giant coronary aneurysm (GCA) is one of the most severe sequelae in KD. Regression of giant aneurysm is rare. Data from Indian subcontinent is limited. In this study we review patients with KD who had GCA.

Objectives: To describe the profile of patients with KD who developed GCA from a cohort of KD patients at Advanced Pediatric Centre, Post-graduate Institute of Medical Education and Research (PGIMER), Chandigarh.

Methods: Records of all children diagnosed to have KD during 1994-2017 were analysed. Out of the 680 patients with KD, clinical details of 17 (2.5%) children with GCA were retrieved.

Results: Diagnosis of GCA was based on coronary artery diameter >8 mm or >10 z score. Six of 17 children (boys 13: girls 4) with GCA had incomplete KD. Diagnosis of KD was made at a mean of 17.2±12.2 days of fever. Eighty (47%) children were <1 year. Median age of diagnosis was 18 months (range 1.5 months-12 years). Left anterior descending (LAD) coronary artery was affected in 82% followed by right coronary artery (RCA) in 59%. Multiple GCA >1 were seen in 65% patients. All patients had received first line therapy as IVig. Median day of IVig administration was 15.5 days. Twelve patients received additional therapy with infliximab. Thromboses developed in 4 (23.5%) and most common coronary artery affected was LAD. All patients were started on anticoagulation therapy and there were no significant complications related to anticoagulation.

Conclusion: Results of this study suggest that GCA develop more commonly in infants and young children. Delay in diagnosis and consequent administration of IVig appears to be the commonest proximate cause of development of GCA.

AB1004  LUPUS LIKE SYNDROME ASSOCIATED WITH INFlixIMAB TREATMENT IN CHILDHOOD: CASE SERIES OF TWO PATIENT

Duygu Kurtulus1, Ferhat Demir2, Betül Sözeri2. 1 University of Health Sciences, Umraniye Training and Research Hospital, Physical medicine and rehabilitation, İstanbul, Turkey; 2 University of Health Sciences, Umraniye Training and Research Hospital, Pediatric Rheumatology, İstanbul, Turkey

Background: Drug-induced lupus (DIL) caused by medication is a form of lupus erythematosus. When the medication is stopped, disease symptoms generally disappear in 4 days or months. Infliximab is an anti-TNF chimeric antibody widely used and approved for the treatment of many diseases. TNF-α antagonist induced lupus-like syndrome (TAILS) is among the uncommon side effects of infliximab. TAILS is a clinical syndrome with features similar to SLE, but with some differences in laboratory and clinical findings.

Objectives: We have presented our experience with lupus like syndrome emerge after infliximab treatment in two children.

Methods: We evaluated the clinical properties of 2 patients who were monitored with diagnoses of juvenile idiopathic arthritis and uveitis symptoms and developed TAILS after infliximab treatment.

Results: First patient applied to our pediatric rheumatology outpatient clinic with a complaint of swelling in the left knee continuing for 1 month. During the physical examination, we found arthritis on the left knee. During the eye examination, it was discovered that he had bilateral pars planitas. Anti-nuclear antibodies were found positive at 1/320 titration, and anti-dsDNA was negative. Following JIA and accompanying uveitis diagnoses, methylprednisolone and methotrexate treatment was started for the patient. After treatment, the patient’s joint and eye symptoms started to regress, was subjected to lesser dose of methylprednisolone, but the uveitis attack of the patient started to occur again. We added infliximab treatment to its treatment that was resistant to uveitis. At the 6-month of infliximab treatment, there was no uveitis attack observed. During remission, after 6. dose of infliximab treatment, there were complaints of tiredness and polyarthralgia. It was observed that the patient had arthritis in several joints. After the re-studied laboratory tests, there was anti-dsDNA antibody positivity. We thought the patient developed TAILS, and stopped the infliximab treatment. After stopping the treatment, the complaints of tiredness and polyarthralgia, as well as arthritis symptoms were improved, and anti-dsDNA antibody levels returned back to normal. The second, 15-year-old patient was being monitored by pediatric rheumatologist outpatient clinic with oiliaric JIA diagnosis since the age of 1. The patient had also uveitis on the right eye since the age of 6. During methylprednisolone, methotrexate, and azathioprine treatment, there were uveitis attacks that developed at different periods. We started infliximab treatment for uveitis of the patient. After 2. dose of infliximab, the patient started to complain about migraine style headaches that occurred once or twice a week. In re-done laboratory tests, ANA (at 1/320 titration), anti-cardiolipin antibody, and anti-beta2 glyco-protein antibody were found positive. There was also low levels of C3 and C4 detected. The infliximab treatment was stopped for the patient who was diagnosed with TAILS. After stopping treatment, the headache complaints regressed, and auto-antibody positivity’s turned back to normal.

Conclusion: Although the development of ANA anti- dsDNA antibodies during infliximab therapy is common, TAILS is rare, especially in the pediatric population. In patients develop SLE findings under infliximab infusion, TAILS must be considered and the drug should be discontinued.

AB1005  THE UNUSUAL ADVERSE EVENTS INCLUDING MULTIPLE SCLEROSIS DEVELOPED UNDER ABATACEPT THERAPY IN A PATIENT WITH JIA

Alia Latylova, Anna Shapovalenko, Irina Nikishina. V.A.Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation

Background: Biological therapy in patients with pediatric rheumatology disease may be associated with adverse events up to demyelinating lesion of CNS including multiple sclerosis (MS). It is a rare condition in the pediatric practice.

Objectives: to describe the clinical case of newly diagnosed psoriasis arthritis and subsequently developing of multiple sclerosis in pediatric patient revealed in JIA who has been followed-up in Pediatric department of V. A, Nasonova Research Institute of Rheumatology for 8 years.

Methods: Description of clinical case of 13 y.o. male Caucasian pts presented with polyarthritis variant of juvenile idiopathic arthritis (JIA) since 2006.

Results: The first symptoms (at the age of 1.5) were polyarthritics with fever, morning stiffness and inflammatory activity in laboratory tests in chronological link of DTP – re-vaccination. The patient admitted to the regional hospital where JIA was diagnosed and he received traditional therapy including NSAIDS, methotrexate, numerous of intrarticular injections, methylprednisolone pulse therapy with initial response. By the 2012 the child deteriorated with progressive polyarthritics, deformation of wrist joints, bilateral camptodactylia with progressive destruction on X-ray. Under the administration of abatacept therapy in our clinic in 2012 the significant improvement (70-90% ACR response) was achieved. 2 years later the plaque psoriasis developed. The cutaneous changes were impaired by the regular local application of GC so infusions of abatacept were continued. In 4th years of regular therapy (in the age of 13) sudden neurological symptoms such as headache, loss of sensitivity, ataxia, visual field defect appeared. He was admitted to neurological clinic. Multiple sclerosis was diagnosed based on the presenting signs and symptoms supporting cranial MRI – multiple focal areas of demyelination.

Conclusion: We presented a patient with JIA who developed two different immunological related adverse events under long-term abatacept using:
psoriasis “de novo” appeared as a native origin of juvenile arthritis and CNS – multiple sclerosis. This is the first case of developing MS under the abatacept therapy, confirming the 1118 pts (2002-2018) who receive biological therapy in our clinic.

AB1006 THE CLINICAL SPECTRUM OF TWO HETEROZYGOUS MUTATIONS IN THE MVK GENE CONFIRMING HYPERIMMUNOGLOBULIN D SYNDROME

Dragana Lazarevic1, Jelena Vojnovic2, 3Clinical Center Niš, Clinic of Pediatrics, Niš, Serbia; “University of Niš, Faculty of Medicine, Niš, Serbia

Background: Autoinflammatory syndromes represent the wide spectrum of rare diseases (associated with genetic disturbances) characterized by the presence of chronic or recurrent systemic inflammation with diverse clinical presentation.

Objectives: We report a case report of child with confirmed two heterozygous mutations in the MVK gene with clinical features associated hyperimmunoglobulin D syndrome.

Results: We present girl with clinical symptoms starting just after birth when in the first days of life she was examined at gastroenterology department in Belgrade due to elevated parameters of inflammation, anemia, direct hyperbilirubinaemia, abdominal bloating and hepatosplenomegaly. Breastfeeding was discontinued due to galactosuria and lactose free diet was advised. Due to the maintenance of hepatomegaly, a detailed hematological, virusological and gastroenterological diagnostic testing was performed. Since liver biopsy has shown portal and lobular hepatitis with cholestasis without fibrosis she was on ursosulfate treatment with partial response. At five months of age she started to have recurrent episodes of fever every month for few days with no associated infection, but always followed with digestive symptomatology (abdominal pain and abdominal flatulence) and elevation of inflammatory parameters. Despite antibiotics, episodes of fever continued to repeat twice monthly with accompanying occurrence of hypersalivation, small ulcers in the mouth, skin rash, cervical lymphadenopathy, hepatosplenomegaly, abdominal pain and abdominal bloating with elevated inflammatory markers. One year later she was admitted for the first time at our department and detailed differential diagnostic testing was performed. Clinical spectrum of presenting symptoms with specific phenotypic aspect (hypertelorismus and frontal bossing) were enough to suspect on autoinflammatory disease background (hyper IgD syndrome), but without IgG increase. Genetic testing have revealed presence of two heterozygous mutations ( heterozygous variant c.790del p.Leu264Serfs*2) and heterozygous variant c.1129G>A p.Val377Ile) in the mevalonate kinase deficiency gene (MVK gene) confirming hyperimmunoglobulin D syndrome. Introduction of nonsteroidal antiinflammatory drugs and corticosteroids have led to complete or partial remission during a fever episodes. As fever episodes continued on every two weeks we are about to start with donated fully-humanized protein interleukin-1 beta cytokine.

Conclusion: Diverse clinical manifestations of some patients with autoinflammatory syndromes can provoke differential diagnostic and treatment dilemmas. Genetic testing is of great importance for establishing the final diagnosis and starting accurate treatment in order to prevent potential serious complications seen in these patients.

AB1007 PREVALENCE AND CHARACTERISTICS OF TEMPOROMANDIBULAR JOINT (TMJ) INVOLVEMENT IN A COHORT OF YOUNG ADULT PATIENTS WITH DIAGNOSIS OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) AND NON-JIA CHRONIC INFLAMMATORY ARTHROPATHIES

Adriano Lercara1, Gloria Crepaldi1, Francesco Licciardi2, Marco Davico3, Stefano Cintio4, Sarah Marouen5, Enrica Vandelli4, Yves-Marie Pers4, Adriano Lercara1, Gloria Crepaldi1, Francesco Licciardi2, Marco Davico3, Stefano Cintio4, Sarah Marouen5, Enrica Vandelli4, Yves-Marie Pers4

Objectives: To investigate the prevalence of TMJ involvement in young adults with JIA and young adults with non-JIA inflammatory rheumatism.

Methods: Patients were recruited prospectively in 2 clinical centers. Inclusion criteria were: patients <35 years diagnosed with JIA who had undergone transition from the pediatric to the adult rheumatologist, and patients diagnosed with non-JIA inflammatory arthropathies. All patients were assessed for joint count, clinical examination for TMJs (tenderness to palpation, swelling, signs of damage such as joint crepitations, lateral deviation, retrogaththis, and decreased mouth opening), evaluation of global disease activity with composite indexes and underwent MRI of the TMJs to detect inflammation (bone marrow edema, effusion, synovial thickening) or damage (condylar flattening, erosions, disk abnormalities); MRIs with either inflammation or damage were considered pathological. Demographic and clinical characteristics were described using frequency or median and interquartile range (IQR), depending on the distribution of the variable. Differences between groups were analyzed using the Mann-Whitney U test and the χ² test when appropriate. The significance was set at p-value ≤ 0.05.

Results: 19 patients were included in the JIA group and 8 patients in the non-JIA group. Patients' demographic and disease characteristics were reported in Table 1.

There are no statistically significant differences between groups for the presence of inflammation on MRI, while damage (in particular, disk abnormalities) is more likely in JIA rather than non-JIA patients (p < 0.02). Joint effusion is more likely to be mild rather than moderate/severe in JIA patients (p = 0.04).

Conclusion: It was found that it is more likely to find damage on MRI in patients of both groups rather than inflammation. Both groups show the same frequency of TMJ involvement, suggesting that TMJ involvement must be sought by the adult rheumatologist as it not only affects JIA patients, but also those with adult-onset inflammatory arthropathies.

Abstract AB1007 Table 2

There are no statistically significant differences between groups for the presence of inflammation on MRI, while damage (in particular, disk abnormalities) is more likely in JIA rather than non-JIA patients (p = 0.02). Joint effusion is more likely to be mild rather than moderate/severe in JIA patients (p = 0.04).

Conclusion: It was found that it is more likely to find damage on MRI in patients of both groups rather than inflammation. Both groups show the same frequency of TMJ involvement, suggesting that TMJ involvement must be sought by the adult rheumatologist as it not only affects JIA patients, but also those with adult-onset inflammatory arthropathies.
**AB1008**

**AGE DEPENDENT SAFETY AND EFFICACY OF COLCHICINE TREATMENT FOR FAMILIAL MEDITERRANEAN FEVER IN CHILDREN**

Voel Levinsky1,2, Orli Goldberg1,2, Orit Peled1,2, Gideon Koren1,2, Lora Harel1,2, Gil Amarilyo1,2, Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; Sacker Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

**Background:** Colchicine has been found to be highly effective for the treatment of familial Mediterranean fever (FMF). However, it is FDA-approved only for children older than 4 years owing to the lack of studies in younger children.

**Objectives:** Our tertiary pediatric rheumatology department routinely uses colchicine even in very young children with FMF. The aim of the study was to evaluate its safety and efficacy in children with FMF ≤4 years old.

**Methods:** The departmental database was searched for all children diagnosed with FMF between 2010-2018. Those who started treatment with colchicine before age 4 years were identified and matched by MEFV variant to children who started treatment at age ≥4 years. Drug efficacy was assessed by the improvement in the frequency and duration of attacks. Adverse events were assessed according to the Rheumatology Common Toxicity Criteria ver. 2.0.

**Results:** The cohort included 89 patients with FMF: 41 first treated before age 4 years, and 48 first treated at age ≥4 years. Rates of complete response to colchicine were 61% in the younger group and 60.4% in the older group. Corresponding rates of partial remission were 24.4% and 29.2%, respectively (p=0.77). The most frequent adverse event was diarrhea, with a prevalence of 24.4% in the younger group and 22.9% in the older group (p=0.87). There were no significant between-group differences in other adverse events.

**Conclusion:** Colchicine is equally effective and safe for use in patients with FMF under 4 years old, with no difference in response from older pediatric patients.

**CLINICAL FEATURES PREDICTIVE OF RENAL AND GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH HENOCH-SCHÖNLEIN PURPURA**

Chun-Hua Liao, Li-Chieh Wang, Bor-Luen Chiang. National Taiwan University Children’s Hospital, Department of pediatrics, Taipei, Taiwan, Republic of China

**Background:** Henoch-Schönlein purpura (HSP), the most common form of vasculitis in children, predominantly involves the small vessels of the skin, the gastrointestinal (GI) tract, joints, and kidneys. GI involvement is the most severe short-term complication, in contrast, renal disease is the most troublesome long-term complication. Meanwhile, although the disease course of HSP is usually benign in children, recurrence still occurs in a subset of patients. Studies documenting the incidence and predictive factors of recurrent HSP, and biomarkers of the various manifestations of HSP are limited.

**Objectives:** We aimed to delineate characteristics and biomarkers of HSP patients with GI or renal involvement, and hoped to clarify the incidence and predictive markers of recurrent HSP.

**Methods:** We retrospectively reviewed the medical records of 40 patients admitted in one tertiary medical center in Taipei, Taiwan over a 5-year period with a diagnosis of Henoch-Schönlein purpura. Incidence and risk factors for GI involvement, renal involvement, and recurrent HSP were analyzed. The Mann-Whitney U test and Fisher exact test were utilized for statistical assessment.

**Results:** From January 1, 2005 to December 31, 2010, 40 HSP patients aged ≤18 years were identified. The mean onset age was 8.35±3.3 years. Among them, 45.1%(18/40) of the patients were male. Ten patients had more than 2 HSP episodes (recurrence rate 25%). Renal involvement was noted in 17.5% (7/40) of the patients, and it was found to occur more frequently in children with later onset age (with renal involvement: 11.43±4.33 years; without renal involvement: 7.73±2.72 years; p=0.03). Recurrent HSP was found to occur more frequently in patients with renal involvement, though without statistical significance (odds ratio: 6; 95% confidence interval: 1.05-34.14; p=0.051). Renal involvement was not associated with GI involvement (p=0.69). GI involvement was noted in 47.5% (19/40) of the patients, and it was found to occur more frequently in patients with higher segmented neutrophil percentage as assessed by complete blood count (with GI involvement: 74.16±13.31%; without GI involvement: 61.84±17.22%; p=0.051). GI involvement was not associated with relapse of HSP. Fourteen patients (35%) had arthritis or arthralgia, and it was found to occur more frequently in children with earlier onset age (with arthralgia/arthritis: 7.26±2.55 years; without arthralgia/arthritis: 10.39±3.63 years; p<0.01).

**Conclusion:** HSP patients with GI involvement had higher segmented neutrophil percentage, consistent with previous studies proposing neutrophil-lymphocyte ratio as a biomarker for GI involvement. Patients with renal involvement had a later age of onset, and the relapse rate was higher in this subpopulation but not statistically significant.
Macrophage activation syndrome (MAS) is a severe complication of several rheumatologic diseases, being of special relevance systemic lupus erythematous (SLE) and systemic juvenile idiopathic arthritis (sJIA). Its characterized by an excessive activation of the immune system due to various mechanisms, including hyperactivation of macrophages and a failure in downregulation activity by NK and cytotoxic lymphocytes. There are various criteria for its diagnosis, highlighting secondary lymphohistocytosis syndrome (HLH) criteria from 2004 and provisional secondary MAS criteria for JIA proposed by Ravelli in 2016.

In our case series rash and fever were more frequent among sJIA patients, the rest of the clinical manifestations were more common in SLE group. Analytical measures were more altered in SLE group except for ferritin and ALT. Mortality was 33.33% in SLE group vs 0% in sJIA group, probably due to early diagnosis and treatment in these patients.

MACROPHAGE ACTIVATION SYNDROME: A CASE SERIES OF 16 PATIENTS

Jesús Loarce-Martos, Fernando López Gutiérrez, Jose Renato Quiñones Torres, Alina Boteanu, M. Ángeles Bilázquez, Mónica Vázquez Díaz. HU Ramón y Cajal, Madrid, Spain

Background: Macrophage activation syndrome (MAS) is a severe complication of several rheumatologic diseases, being of special relevance systemic lupus erythematous (SLE) and systemic juvenile idiopathic arthritis (sJIA). Its characterized by an excessive activation of the immune system due to various mechanisms, including hyperactivation of macrophages and a failure in downregulation activity by NK and cytotoxic lymphocytes. There are various criteria for its diagnosis, highlighting secondary lymphohistocytosis syndrome (HLH) criteria from 2004 and provisional secondary MAS criteria for JIA proposed by Ravelli in 2016.

Objectives: To describe a case series of patients with MAS.

Methods: This is a retrospective case series of 16 patients with MAS secondary to systemic autoimmune diseases diagnosed in Ramón y Cajal University Hospital between April 2009 and September 2018.

Results: The baseline pathology was sJIA in 8 patients (2 cases with 2 episodes) and SLE in the other 6 patients. Mean age at diagnosis was 17.44 years for sJIA and 37.5 years for SLE. Mean time from diagnosis of the baseline disease to MAS episode was 11.31 years, with 3 cases being the initial manifestation of their systemic disease. 43.8% of patients were treated with corticosteroids previously to MAS episode, and 50% were being treated with DMARDs/biologic agents (SLE: 3 patients with hydroxychloroquine and 1 patient with mycophenolate and hydroxychloroquine; sJIA: 2 patients with Anakinra, 1 patient with tocilizumab and 1 patient with etanercept). Clinical and analytical characteristics of the patients are presented in table 1 and table 2, respectively. In SLE group, only 2 patients (33.3%) had high anti-DNA titers during the MAS episode, 5 patients (83.3%) had increased C3 consumption and 4 patients (66.6%) had increased C4 consumption. As severe manifestations, 4 SLE patients had increased C4 consumption. As severe manifestations, 4 SLE patients had increased C4 consumption. Infection was confirmed as a trigger in 3 patients with SLE (50%) and 4 patients with JIA (40%). Prednisone at high doses was prescribed to 11 patients, cyclosporine in 4 patients (86.6%) with SLE and 9 patients (90%) with sJIA. Additionally, anakinra was prescribed in 4 patients (40%) with sJIA, 4 patients (66.6%) with SLE met secondary HLH criteria and 9 patients (90%) with sJIA met secondary MAS criteria. Bone marrow biopsy was performed in all patients with SLE and in 9 patients with sJIA, demonstrating hemophagocytosis in 5 patients (83.3%) with LES and 5 (50%) patients with sJIA. Only 2 patients in the SLE group died because of MAS.

APPLICATION OF AUTOINFLAMMATORY DISEASE DAMAGE INDEX (ADDI) TO AUTOINFLAMMATORY DISEASES IN A TERTIARY REFERRAL HOSPITAL

Mireia Lopez Corbeto, Estefania Moreno Ruzafa. Hospital Universitari Vall d’Hebron, Rheumatology, Barcelona, Spain

Background: Autoinflammatory diseases (AIDs) cause chronic systemic inflammation that can damage multiple organs. Recently, the autoinflammatory disease damage index (ADDI) has been developed and validated in the four most common monogenic AIDs, Cryopyrin-associated Periodic Syndrome (CAPS), Familial Mediterranean Fever (FMF), Mevalonate Kinase Deficiency (MKD) and Tumor Necrosis Factor Receptor-associated Periodic Fever Syndrome (TRAPS). The use of ADDI index could also be of great value in other AIDs.

Objectives: The aim of this study is to assess the application of ADDI in patients with the four most common monogenic diseases and other AIDs. To accomplish this objective a detailed cohort of patients with different AIDs is presented.

Methods: All patients with AIDs followed in the Pediatric Rheumatology Unit comprising the Translational Care and specialized AIDs outpatient clinics from Hospital Universitari Vall d’Hebron were identified. A cross-sectional, descriptive study was performed applying ADDI by two pediatric rheumatologists (EM, ML). Laboratory test including C-reactive protein (CRP) mg/dL, amyloid protein (AP) mg/L, erythrocyte sedimentation rate (ESR) mm/h and protein/creatinine ratio (mg/g Cr) were performed at the moment ADDI was applied. Variables related with disease duration, current treatment and accumulated corticosteroids treatment were assessed. The continuous variables are presented as mean and standard deviation (mean ± SD) and categorical variables are presented by percentages.

Results: A total of 41 patients with AIDs were included, 61% were female, with a median age of 20 ± 11.9 years at inclusion. Disease duration was 11 ± 8.2 years. AIDs included were 11 patients with FMF (26.8%), TRAPS n=4 (9.8%), MKD n=3 (7.3%), CAPS n= 2 (4.9%), Blau

Table 2. Analytical measures. Hb=haemoglobin(g/dl), Nt=neutrophils (10^9/mm3), Pla=platelets (10^9/mm3), Cr=creatinine (mg/dl), Brb=bilirubin (mg/dl), AST (U/L), ALT (U/L), Fe=ferritine (ng/ml), Tg-triglycerides (mg/dl), Fb=fibrinogen (mg/dl), INR (International Normalized Ratio).

HENOCH-SCHÖNLEIN PURPURA AND UVEITIS, AN CHILDREN IN RISK OF LOW BONE MASS HAVE MORE

Florence, Italy

We describe a 6-year-old female patient who presented HSP have been reported so far. Ment. To our knowledge only 4 cases of HSP with ocular involvement hood vasculitis characterized by cutaneous palpable purpura predominantly Henoch-Schönlein purpura (HSP) is the most common child-

A 6-year-old female, previously in good health, received the Describe a case report.

Methods:

nephrological and articular involvement. Prednisone was then gradually

sone (2 mg/kg/day), with a progressive improvement of the ocular, skin, ANA, ANCA, ASCA, LAC, HLA B27 and B51 were all negative. Chest X tious work-up for viral, bacterial and parasitic infections was negative. played mild hematuria and proteinuria. Immunoglobulin levels were slightly

increased values of CRP (1.92 mg/dl) and ESR (69 mm/h) with normal

Conclusion: ADDI is a feasible index suitable to measure damage in a single patient. Despite it was performed to the four most common AIDs it could be applied to other diseases. In our cohort the mean ADDI index was low and musculoskeletal item has the highest score. This result could be explained by the tight control of the disease and successful targeted therapy. Laboratory tests also support this finding. Nevertheless, some organ systems are not assessed like respiratory, cardiovascular or cutaneous damage, important in some syndromes. Knowing the difficulties of applying an unified index for all diseases, ADDI may be supportive in other AIDs and longitudinal cohorts.

AB1013 CHILDREN IN RISK OF LOW BONE MASS HAVE MORE THAN 2 RISK FACTORS

Berta Paula Magnolfi Lépiz1, Dacia Corda2, Jocelyn Betsunour2, Gloria Frag1, Estefania Quesada-Masachs4, Mireia López-Corbel3, Montserrat Torrent2, Ana Maria Marín5, Silvia Herrera3, Jordi Casademont5, Hector Corominas1, Jorge Malouf6, 1 Santa Creu i Sant Pau Hospital, Rheumatology, Barcelona, Spain; 2 Moises Brogi Hospital, Rheumatology, Barcelona, Spain; 3 Santa Creu i Sant Pau Hospital, Pediatrics, Barcelona, Spain; 4 Vall d’Hebron Hospital, Pediatric Rheumatology, Barcelona, Spain; 5 Santa Creu i Sant Pau Hospital, Bone Metabolism Unit, Internal Medicine, Barcelona, Spain; 6 Santa Creu i Sant Pau Hospital, Internal Medicine, Barcelona, Spain Background: Low Bone Mass (LBM)/Infantile Osteoporosis (IOP) require an active evaluation for its diagnosis and prevention. Therefore, its inci-

dance is unknown and could be undertreated. The systematic collection of risk factors associated with LBM/IOP could help identify the population at risk of presenting it

Objectives: To assess the prevalence and number of risk factors (RF) in the pediatric population at risk of developing LBM/IOP. Assess its influ-

ence on Bone Mineral Density

Methods: Demographic and clinical data were prospectively collected from patients from 2 to 20 years of age, who had at least one risk factor for LBM/IOP, among them: chronic diseases, treatment with immunosuppres-

sants and/or corticosteroids and insufficient calcium intake. Cacemcia, cal-

ciuria, and Vitamin D were determined in blood samples, and whole body and lumbar DXA were performed. The calcium intake, the number of previous fractures and other RF were collected

Results: Data were collected from 103 patients, with an average age of 9.8 years, 52.4% women, and 80%Caucasians. Of these, 9 were pre-
schoolers (2-3 years old), 33 schoolchildren (4-9y), 55 teenagers (10-17y) and 6 young people (18-20y) The most frequent diagnoses were: Malabsorption/Food allergies: 46.6%, JIA: 17.5%, Nephropathies: 17.8%, Hematological diseases: 6.8%, and Vasculitis and connective tissue diseases: 3.9% each

The frequency of RFs can be observed in Table 1

% Insufficient calcium intake in the diet 84.5 Association of a second chronic diagnosis 4.9 Hypovitaminosis D in blood (<30 nmol/L) 8.1 Sedentary lifestyle (PAQ test <2) 13.6 History of long bone or vertebral fractures 12.6 24-hour urine hypercalciuria 3.1 Proteinuria >0.20 g/l in 24-hour urine 17 Drugs with osteopening potential (non-corticosteroid immunosuppressants) 31.1 Corticosteroids at the time of inclusion 19.4 Corticosteroids prior to inclusion in the study 18.4 The average dose of current corticoids was 0.21 mg/kg/day of prednisone with a total cumulative average dose of: 7 gr, with an exposure of 1 to

44 months 43.3% of the sample had an isolated RF, 38% had 2 RF, 31% 3, 15% 4, and 12% 5 or more 87% of the sample presented a LBM and 4.8% met criteria for Opi for vertebral fractures, 3 of them asymptomatic and discovered by morphometry

In the multiple linear regression analysis: age, Latin ethnicity, gender, and hypovitaminosis D were the main RFs related to lumbar BMD. Likewise,
age, latin ethnicity and sedentary lifestyle were the RF related to the BMD of the whole body without head (BMDwbwh).

In lumbar BMD, these 4 FR explained up to 85% of the BMD variation, where the age adds 0.036 per year gained, the male sex subtracts 0.061, the hypovitaminosis D sum 0.077 and the latin ethnicity subtracts 0.070.

Up to a 90.8% variation of BMDwbwh is explained by these 3 RF: age adds 0.036 per year gained, sedentary life subtracts 0.084 and latin ethnicity subtracts 0.055.

Conclusion: The child population at risk of LBM/IOP associates 2 or more risk factors 8.7% of children with risk factors have LBM and 4.8% IOP.

The RFs related to changes in BMD are: age, sex, sedentary lifestyle and ethnicity. Hypovitaminosis D correlated positively with lumbar BMD.

**USE OF ETANERCEPT BIOSIMILAR IN JIA: PRELIMINARY EXPERIENCE USING REAL WORLD DATA**

Marco Marini1, Achille Marino1, Gabriele Simonini1, Rolando CIMAZ1, Teresa GIANI1,2, 1Meyer Children's University Hospital of Florence, Florence, Italy; 2University of Siena, Siena, Italy

Background: Biosimilars are biological medical drugs that are almost an identical copy of an original drug, manufactured by a different company. Since last year regional regulations have imposed a non-medical switch from reference etanercept (ETN) originator to biosimilar (SB4).

We compared treatment survival on SB4 to reference etanercept, assessing efficacy and safety data in our cohort of patients with JIA.

Objectives: To review clinical charts of JIA patients, including efficacy and safety of ETN biosimilars after transition from originator. Compliance was also assessed.

Methods: This was a retrospective observational study of patients with JIA who switched from reference etanercept to SB4 during 2018 in our Pediatric Reumatology Department. Clinical and demographic data were collected from charts and inserted into a dedicated database. Relevant data included: age at disease onset, age at first administration and duration of treatment, if patients had remission of disease with etanercept therapy or if there were any relapses, ESR and CRP values before and after etanercept therapy, assessing remission.

Results: A total of 14 patients (13F, 1M) were identified. Age at diagnosis ranged from 1 to 12 years. Before ETN, all had received methotrexate. ETN was added for disease activity persistence, and induced remission in all cases but one. SB4 treatment duration ranged from 1 to 11 months. After switch to SB4 no disease recurrence was observed. ESR and CRP values before and after switching to SB4 were collected. Global assessment of patient satisfaction with the clinical management plan. Paediatric care is family oriented and relies on significant modifications that patients have to face in an adult medical environment may affect the compliance with the management plan. Paediatric care is family oriented and relies on significant modifications that patients have to face in an adult medical environment may affect the compliance with the management plan. **OUTCOME OF TRANSITION OF CARE IN YOUNG ADULTS WITH JUVENILE ONSET CHRONIC RHEUMATIC DISEASES**

Patricia Martins1,2, Sofia C. Bameire1,2, Ana Teresa Melo1,2, Raquel Campanhão-Marques1,2, João Euciro Fonseca1,2, Filipa Oliveira-Ramos1,2.

1Serviço de Reumatologia e Doenças Ósseas Metabólicas, Hospital de Santa Maria, CHULN, Centro Hospitalar Universitário Lisboa Norte, Portugal, Lisbon, Portugal; 2Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Portugal, Lisboa, Portugal

Background: The transition process of adolescent care from a paediatric to an adult medical environment may affect the compliance with the management plan. Paediatric care is family oriented and relies on significant parental involvement in decision-making. On the contrary, adult care is patient-specific and requires autonomy and independent skills.

Objectives: The aim of this study was to evaluate the transition of care at our centre, namely the adherence to clinical appointments, modification of disease activity and patient satisfaction.

Methods: All consecutive patients with juvenile onset of rheumatic chronic diseases followed in a young adult clinic were included. Disease activity was evaluated at the last appointment in the paediatric unit and up to 2 years after transition of care, according to validated scores for each rheumatic disease. Dropout was defined as not attending the clinic for 2 consecutive visits. Global assessment of patient satisfaction with the clinical

Disclosure of Interests: None declared.

**REFERENCES**

appointments before and after transition of care was evaluated in a scale of 0 to 10. Variables were analysed as means, medians and frequencies as appropriate. Univariate analysis was performed with student t-test and Qui-square.

Results: 126 patients were included. Of these, 77 (61.1%) had juvenile idiopathic arthritis (JIA, see table I for list of diagnosis), 78 (61%) were female with a mean age of 23.1±3.2 years and a mean disease duration of 12.7±5.3 years. During the transition of care, 92 patients were treated with conventional disease modifying antirheumatic drugs (73%) and 35 with biologic therapy (27.8%). 69 patients (54.7%) missed at least one clinical appointment with a dropout rate of 9%. This was associated with longer disease duration (15.9 vs 12.3 years, p=0.024). 11 patients (8.7%) had worsened clinical activity: 5 patients with polyarticular JIA with arthritis flare (ΔDAS28 2.14 ± 0.83); 4 patients with oligoarticular JIA with new onset of disease; and 2 patients with juvenile systemic lupus erythematosus with a SLEDAI increase from 5 to 16 points. 4 patients abandoned DMARDs. Regarding patient satisfaction questionnaire, paediatric rheumatology appointments had a median evaluation of 9 (7-10), adult rheumatology appointments of 8 (5-10) and the transition process had an evaluation of 8 (5-10). The majority of patients reported the longer appointment waiting time as the major negative aspect after transition.

Conclusion: In our centre the transition of care had a small percentage of dropping out from the clinic, which was associated with longer disease duration, a slight worsening of disease activity and a 10% decrease in patient satisfaction.

AB1017 WHAT IS THE CURRENT SITUATION OF THE PAEDIATIC RHEUMATOLOGY TRANSITION CARE UNITS?
José-Luis Martín-Varillas1, Daniel Clemente2, J.C. López Robledillo2, Belén Serrano Benavente3, Indalecio Montenegro4, Juan Carlos Nieto1.
1H.U.M. Valdecilla, Santander, Spain; 2H.U. Niño Jesús, Madrid, Spain; 3H.G.U. Gregorio Marañón, Madrid, Spain

Background: Switching from paediatric rheumatology to the adult rheumatology care units has a negative impact on disease control and adherence in young patients with juvenile idiopathic arthritis (JIA) but also in other chronic diseases. Transitional care services provide the opportunity of being followed-up by an adult rheumatologist specialized in juvenile rheumatic diseases.

Objectives: In our study we report the current situation of a rheumatology transition care unit (RTCU).

Methods: We set up an observational and retrospective study of patients followed in our unit between September 2015 and December 2018. We included those patients with a disease beginning at 16 years or younger and those patients who were attended on RTCU for the first time before age 25. Clinical and demographic data and all treatments received by the patients before and after the first visit in the transition care unit were also collected.

Results: 119 patients were attended in our RTCU. After applying the exclusion criteria, 110 patients remained: 78 female/32 male (70.9/29.1%) with a median age of 17.9 (17.9-19.8) years at the first visit. No significant differences in age at the first visit were found between the first (September-2015 to September-2017) and the second stage (October-2017 to December-2018), 18.7 (17.8-20.2) vs. 18.2 (17.9-18.6) years respectively. The most frequent diagnoses are included in the table 1.

Of the 75 patients with JIA, 54 were women (72%) with a median age at the disease onset of 6.88 [2.5-12.7] and 21.3% of patients had chronic anterior uveits. 22 patients (29.3%) presented joint or ocular inflammatory activity or flare at the time of transition first visit but only 1 patient maintained inflammatory activity during the 3 years of follow-up. A total of 64 patients (85.3%) with JIA diagnosis were under treatment with synthetic DMARD, mostly methotrexate (61) or leflunomide (7). In addition, 43 patients (57.3%) required biological DMARD in the past, and 8 of them (10.7%) required more than one. The most frequently used drugs were: etanercept (ETN) (29 patients) and adalimumab (ADA) (19 patients). Tocilizumab (TCZ) (4), abatacept (1) and infliximab (1) were also used.

Of these patients, at the time of the first visit on RTCU, 24 (32%) had no treatment, 42 patients (56%) had synthetic DMARD and 34 patients (43.3%) had biologic therapy in monotherapy or combined with DMARDs (19 ETN, 12 ADA, and 3 TCZ).

Conclusion: RTCU assessed mainly patients with JIA and connective tissue diseases. Most patients were inactive during the transfer to the adult unit due to the existence of patients that were still active and/or needed treatment with synthetic and/or biological DMARD reaffirms the need for close control in this period.

AB1018 CONE BEAM CT IN JUVENILE IDIOPATHIC ARTHRITIS: ROLE OF IMAGING DIAGNOSTIC TOOL WITH MINIMAL X-RAY EXPOSURE IN THE FREQUENT, SUBTLE AND INDOLENT TEMPROMANDIBULAR JOINT INVOLVEMENT
Maddalena Maschio1, Sara Pieropan1, Giulia Aiello1, Giulia Melotti1, Elisa Tadiotto1, Erica Giacomelli1, Antonio D’agostino2, Lorenzo Trevisiol1, Giorgio Piacentini2, 1Azienda Ospedaliera Universitaria Integrata Verona, Pediatric, Verona, Italy; 2Azienda Ospedaliera Universitaria Integrata Verona, Maxillo Facial Surgery, Verona, Italy

Background: The prevalence of the temporomandibular joint (TMJ) involvement in patients affected by juvenile idiopathic arthritis (JIA) ranges from 17% to 87% depending on population. TMJ is frequently the first and unique joint involved in the arthritic process. Unfortunately detection of TMJ arthritis in children with JIA is difficult as early signs and symptoms are missing in most patients. Therefore failure to diagnose and treat TMJ arthritis may have severe consequences on masticatory function, like

**Results:** CBCT is a useful tool to improve the diagnostic and therapeutic iter of TMJ involvement in JIA; in fact on one hand it highlights the unsuccessful and palliative role of IACI and on the other hand it can reveal significant impairment of the joint bone components in frequent asymptomatic patients; systemic therapy from the early phase of TMJ involvement could prevents the irreversible modification of the mandibular growth process of undertreated inflammation.

**Conclusion:** CBCT is a useful tool to improve the diagnostic and therapeutic iter of TMJ involvement in JIA; in fact on one hand it highlights the unsuccessful and palliative role of IACI and on the other hand it can reveal significant impairment of the joint bone components in frequent asymptomatic patients; systemic therapy from the early phase of TMJ involvement could prevent the irreversible modification of the mandibular growth process of undertreated inflammation.

**THE EFFECT OF TREATMENT REGIMEN ON HEALTH-RELATED QUALITY OF LIFE AND FUNCTIONING IN CHILDREN WITH UVEITIS**

**Joseph McDonald1,** Virginia Utz2, Theresa Hennard1, Najima Mwash3, Joseph Lipscomb1, Amy Cassidy1, Sheila Angeles-Han1, 1Cincinnati Children’s Hospital Medical Center, Pediatric Rheumatology, Cincinnati, United States of America; 2Cincinnati Children’s Hospital Medical Center, Pediatric Ophthalmology, Cincinnati, United States of America; 3Cincinnati Children’s Hospital Medical Center, Biostatistics and Epidemiology, Cincinnati, United States of America; 4Cincinnati Children’s Hospital Medical Center, Pediatric Dermatology, Cincinnati, United States of America; 5Ribeirão Preto Medical School, University of São Paulo, of Radiology, RIBEIRÃO PRETO, Brazil

**Background:** Pediatric non-infectious uveitis can lead to ocular complications and blindness. Complex treatment regimens are often needed and consist of frequent topical treatments (glucocorticoids, mydriatics, glaucoma medications) and systemic immunosuppression.

**Objectives:** To examine the impact of topical and systemic treatment on health-related quality of life (HRQOL), mental health, and uveitis-related quality of life (UQL) in children with uveitis.

**Methods:** We reviewed records of 40 children with uveitis (22 JIA-associated uveitis (JIA-U), 18 other uveitis types). Patients and parents completed questionnaires on general QOL (Pediatric Quality of Life Inventory–PedsQL), depression and anxiety (Revised Children’s Anxiety and Depression Scale–RCADS), physical functioning (Childhood Health Assessment Questionnaire–CPHQ), and visual function and uveitis-related QOL (Effect of Youngsters’ Eyesight on QOL-EYE-Q). We used ANOVA and T-Test to compare treatment groups: 1) topical only vs. systemic only vs. combined topical and systemic treatment; 2) topical vs. no topical treatment.

*p<0.05

**Conclusion:** The parents of children with uveitis who need topical treatments as part of their therapy regimen report worse uveitis-related QOL. This is likely secondary to parental responsibility for instilling topical therapy. Additionally, visual function scores were also lower in the topical treatment group and could reflect disease activity or use of mydriatics which can affect vision. Other measures including the PedsQL, CHAQ, and RCADS did not appreciate differences based on treatment regimen. Our findings demonstrate the importance of including uveitis-specific disease measures in the assessment of the impact of uveitis. The burden of medication use, specifically eye drops, that can sting, require frequent application, or affect vision, needs further study as this can affect medication adherence and patient outcomes.

**DISEASE ACTIVITY INDEX IS ASSOCIATED WITH SUBCLINICAL ATHEROSCLEROSIS IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS**

**Priscila Medeiros1,** Roberta Garcia Salomão2, Diane Meyre Rassi2, Luciana Rodrigues Roberts2, Sara Reis Teixeira3, Priscila Giacomo Fassini3, Rita de Cássia Tostes3, Jacqueline Pontes Monteiro2, Virginia Fertani2, Luciana Martins de Carvalho1, 1Ribeirão Preto Medical School, University of São Paulo, of Pediatrics; Division of Pediatric Rheumatology, RIBEIRÃO PRETO, Brazil; 2Ribeirão Preto Medical School, University of São Paulo, of Pediatrics, Division of Nurtology, RIBEIRÃO PRETO, Brazil; 3Ribeirão Preto Medical School, University of São Paulo, Department of Internal Medicine and Department of Pharmacology, RIBEIRÃO PRETO, Brazil; 4Ribeirão Preto Medical School, University of São Paulo, of Pediatrics, RIBEIRÃO PRETO, Brazil; 5Ribeirão Preto Medical School, University of São Paulo, of Radiology, RIBEIRÃO PRETO, Brazil

**Background:** Systemic lupus erythematosus (SLE) is considered an independent risk factor for cardiovascular events in association with traditional risk factors. Therefore, it is important to recognize and to identify the specific risk factors for atherosclerotic disease in these patients for the prevention and early treatment of cardiovascular diseases, aiming to provide a better quality of life with long-term morbidity reduction.

**Objectives:** To determine the prevalence of subclinical atherosclerosis by the measurement of carotid intima-media thickness (CIMT) in patients with childhood-onset systemic lupus erythematosus (SLE) younger than 21 years. To check for associations between sex, age, race, body mass...
index, medications in use, cumulative dose of corticosteroid, traditional and nontraditional risk factors for artherosclerosis, laboratory tests, including plasma cytine levels, clinical disease activity score (SLE Disease Activity Index - SLEDAI-2K) and cumulative damage index (Cumulative Organ Damage of the SLE International Collaborating Clinics - SLICC/ACR damage index) with CIMT.

Methods: This was a cross-sectional study. Clinical and laboratory data were collected based on chart review and laboratory testing; present clinical and laboratory data were performed during interviews and CIMT was evaluated by ultrasound carried out by an expert radiologist. Associations were estimated using univariate analysis (Fisher and Wilcoxon-Mann-Whitney tests) and multivariate analyses (linear and log binominal regression).

Results: Twenty-eight patients, aged 13.9 ± 3 years, were enrolled in the study. In children with subclinical atherosclerosis was 32.14% (95% CI: 14.8, 49.4) and the mean carotid intima-media thickness (CIMT) was 0.43 ± 0.035 mm. Most common traditional risk factors observed were dyslipidemia in 89.3%; uncontrolled hypertension in 66.6%; overweight or obesity in 32% and poor diet in 78.6%. Nontraditional risk factors observed were duration of disease of 2.4 ± 2.12 years; mean SLEDAI-2K of 7.8 ± 6.0; SLICC/ACR damage index scored ≥ 1 in 25%; high levels of ultra-sensitive C-reactive protein in 25% and nephritis and neuropsychiatric involvement in 75% and 28.5% of the patients, respectively. Cumulative dose of corticosteroids was 0.48 ± 0.83 mg/kg/day and 60.7% of patients were using immunosuppressive drugs. Univariate analysis showed that uncontrolled hypertension, proteinuria, estimated glomerular filtration rate < 75 ml/min/1.73 m2 and SLEDAI-2K ≥ 5 were associated with subclinical atherosclerosis. The association of CIMT with SLEDAI-2K > 5 was maintained after adjusting for control variables (cumulative corticosteroid dose, duration of disease, levels of cholesterol fractions, hypertension and renal disease).

Conclusion: This study demonstrated that subclinical atherosclerosis was frequently observed in cSLE, mainly in patients with moderate to severe disease activity (SLEDAI-2K greater than 5).

Background: Appointment of modern methods of treatment led to a modification of the course of juvenile idiopathic arthritis (JIA). In Ukraine, the basic preparation for treatment prescribed at JIA since 1984, then the biological was registered only in 2011.

Objectives: To evaluate the effect of treatment changes on activity indicators, functional disorders and physical development of patients with JIA.

Methods: retrospective analysis of medical records of 67 patients in 2018 who were admitted to the Rheumatology Unit of Verona were evaluated. For each child the following data were analyzed: JIA subtype, ANA positivity, anti-DFS positivity, presence of uveitis diagnosed by a pediatric ophthalmologist and the finding of markers of uveitis is still a challenge. In adults anti-DFS70, the role of these antibodies in children remains yet not established even though but it has also been reported that anti-DFS70, particularly asymptomatic and can lead to blindness if misdiagnosed. To date the finding of markers of uveitis is still a challenge. In adults anti-DFS70, which have indirect immunofluorescence pattern described as dense fine speckles (DFS pattern) and bind a 70kDa protein in immunoblot or immunofluoresence, and are associated with subclinical atherosclerosis.

Results: In the first 6 mo. from the debut (JADAS 6.6±1.2- 5.5±1.7) than DMARDs + ADA (4.0± 2.3 - 0.0) and DMARDs + TOCY (5.2±1.2 - 3.6 ±1.3). The max. JADI were in RF-JUA (3.0±1,3). In general, JADI increased with age (>65 0,55±0,3; >10y 1.7±0,9), JADI didn’t depend on the onset age (<r=0,12), disease duration (<r=0,16), ANA detection (1.8 ±1,1; >r=0,18), the RF (1.2±0,5; >r=0,07); HLA B27 0,5±0,3 (<r=0,1); sero-negative (1.0±0,4; =r=0,07). In patients last years of FL III-II-II cen. marked with a higher frequency of 35.9%. A smaller proportion of patients with high disease activity, the combination of DMARDS and sCS was worse than in previous yrs. (10.4 vs 49%). The delay in linear growth with JIA is -1.7±0.06SD now, the degree of growth retardation depends on the duration of the disease (up to 3y -1.2 ±0,1, 8-13y 1.6±0,7) and the variant of the course (the max. growth retardation rate observed in sJIA (78% to -1.2SD; 11% -1SD). The DMARDS+sCS+T2Z in high activity JIA and growth retardation was better for normalizing the growth (0.9±4.0±0.4SD after 2y) compared to DMARDS+sCS+ADA (-1.3±0.4). On average BMI at JIA did not differ from the age norm (17±8,0; 48% cases with overweight in last). DMARDS in higher doses was better for the normalization of BMI (MTX 15 mg/m² 17±1±12; 10 mg/m² 19±2,19). The use of ADA in patients with malnutrition resulted in 6 mo. to normalization of the BMI (18,55±1,5) in contrast to the use of ETA (16,5±2,0).

Conclusion: The results obtained showed that the overall activity of JIA is significantly reduced today. Improvement of the course of JIA and the degree of functional impairment is explained by the introduction of modern methods of pathogenetic therapy into the clinical practice.

Disclosure of Interests: None declared

AB1022 UVEITIS AND ANTI-DFS70 ANTIBODIES IN JUVENILE IDIOPATHIC ARTHRITIS: AN OBSERVATIONAL RETROSPECTIVE STUDY

Gilia Melito1, Sara Pieropan1, Elisa Tedottot, Maddalena Maschio1, Giulia Agnelli1, Federica Martinis2, Federico Caldonazzi3, Giorgio Piccinent, Caterina Mansoldo1, 1Azienda Ospedaliera Universitaria Integrata Verona, Paediatric, Verona, Italy, 2 Policlinico Giovanni Battista Rossi, Reumatology, Verona, Italy, 3 Hospital Santa Maria Dei Caminiti, Paediatric, Rovereto, Italy, 4Azienda Ospedaliera Universitaria Integrata Verona, Ophthalmology, Verona, Italy

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in childhood and uveitis is one its major extra-articular manifestation. Children with JIA and a positive antinuclear antibodies (ANA) are known to be at risk to develop severe uveits, which is usually asymptomatic and can lead to blindness if misdiagnosed. To date the finding of markers of uveitis is still a challenge. In adults anti-DFS70, which have indirect immunofluorescence pattern described as dense fine speckles (DFS pattern) and bind a 70kDa protein in immunoblot or immunofluoresence, and are associated with subclinical atherosclerosis and atherosclerosis. In adults anti-DFS70, which have indirect immunofluorescence pattern described as dense fine speckles (DFS pattern) and bind a 70kDa protein in immunoblot or immunofluoresence, and are associated with subclinical and subclinical atherosclerosis. In adults anti-DFS70, which have indirect immunofluorescence pattern described as dense fine speckles (DFS pattern) and bind a 70kDa protein in immunoblot or immunofluoresence, and are associated with subclinical atherosclerosis. Anti-DFS70 which are known to be associated with subclinical atherosclerosis and can lead to blindness if misdiagnosed. To date the finding of markers of uveitis is still a challenge. In adults anti-DFS70, which have indirect immunofluorescence pattern described as dense fine speckles (DFS pattern) and bind a 70kDa protein in immunoblot or immuno-
guide ophthalmologic screening in JIA patients in order to identify children likely to develop uveitis.

AB1023
PHYSICAL ACTIVITY LEVEL IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS FROM THE GERMAN NATIONAL PAEDIATRIC RHEUMATOLOGY DATABASE: A COMPARISON WITH THE GENERAL POPULATION

Florian Milatz1, Martina Nieweth1, Jana Hörstemann2, Nils Geisemeyer2, Peter Haas3, Gerd Hornett4, Tilman Kallinich5, Matthias Hartmann6, Joachim Peitz7, Josephine Merker8, Kirsten Minden9,10. German Rheumatism Research Centre, Epidemiology, Berlin, Germany; 2German Rheumatism Research Centre, Berlin, Germany; 3German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany; 4Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany; 5University Medicine Charité Berlin, Department of Pediatrics, Division of Pneumonology and Immunology with intensive Medicine, Berlin, Germany; 6Asklepios Clinic, Sankt Augustin, Germany; 7Technische Universität München, Department of Biomechanics in Sports, München, Germany; 8University Medicine Charité Berlin, Berlin, Germany

Background: Insights in pathogenesis and the availability of new biologic drugs have created requirements and an increasing interest for encouragement of physical activity (PA) as long-term treatment option in patients with juvenile idiopathic arthritis (JIA). A low level of PA in healthy individuals is related to a higher incidence of overweight and hypertension in later life. This low level of PA might even be more dangerous for children with JIA, as they also have elevated inflammatory parameters, perhaps increasing the risk of future cardiovascular diseases.

Objectives: Since children and adolescents with physical disabilities may have an increased risk for developing a sedentary lifestyle, the objective was to investigate if encouragement of PA in most German medical care settings has led to PA levels in JIA similar to that of healthy counterparts.

Methods: Data from children and adolescents with JIA recorded in the German National Paediatric Rheumatologic Database (NPRD) in the year 2017 were considered for the analyses. In accordance with the methodology used in the general population survey [1], the achievement of the WHO recommendations on PA for health was determined on the basis of self-reported outcomes in individuals aged 3 to 17 years. Patients met the WHO criteria if they stated to be physically active for at least 60 minutes per day.

Results: In 2017, the data from 5,918 patients (mean age 11.2 ± 4.1 years, female 67%, disease duration 4.6 ± 3.7 years, persistent oligoarthritis 42%) were available for evaluation. Almost 35% of patients aged 3 to 17 years met the recommended physical activity level (72% aged 3 to 6; 47% aged 7 to 10; 27% aged 11 to 13; 16% aged 14 to 17). In the general population, 26% fulfilled the WHO recommendations on PA for health determined on the basis of self-reported outcomes in individuals aged 3 to 17 years. Patients met the WHO criteria if they stated to be physically active for at least 60 minutes per day.

AB1024
USE, EFFICACY AND LONG TERM SAFETY OF RITUXIMAB IN PEDIATRIC RHEUMATIC DISEASES: SINGLE CENTER EXPERIENCE FROM NORTH INDIA

Suzumita Mittal, Manjari Agarwal, Sujata Sawhney, SIR GANGA RAM HOSPITAL, PEDIATRIC RHEUMATOLOGY, DELHI, India

Background: Rituximab (RTX) is used in pediatric rheumatic diseases as an off label indication. There is paucity of data on safety and long term efficacy in countries with high burden of infectious diseases.

Objectives: 1. To study the use and safety of RTX in pediatric rheumatic diseases
   2. To assess the long term efficacy of RTX in pediatric systemic lupus erythematosus (pSLE).

Methods: Data of all children who received RTX was collected on standardized collection forms. This data set was reviewed.

Results: USE: Rituximab was given to 4 children with polyarticular juvenile idiopathic arthritis (PJA) (4/14=2.7%) and 17 children with pSLE (17/122=7.5%). In children with PJA, RTX was used as third line treatment, who failed methotrexate and TNF inhibitor therapy. In pSLE, lupus nephritis was the primary indication for RTX (96%), vasculitis (17%), neuropyschiatric SLE and refractory cytopenia (12%) and aggressive polyarthritis with steroid dependence (5%).

SafetY: Pre-biologic screen for HIV, Hepatitis B and C and tuberculosis was negative. Total immunoglobulin G level was assayed prior to RTX for all children. CMV PCR was done in 11/17 pSLE patients. No immediate or delayed anaphylaxis was noted. No child had reactivation of herpes zoster. There was no mortality in this cohort.

Efficacy: Studied in 17 children with pSLE over 21 episodes of RTX (2 received 3 cycles of RTX over 5 years); Median age at RTX use was 13.66 years (range 6.58-21.66 years). Median duration of follow up was 48 months (range 3-120 months). During long term follow up 14 patients did not have any disease flare. Three (17.6%) flared and required cyclophosphamide/second cycle of RTX. Mean dose of prednisolone prior to RTX was 0.7mg/kg/day while that at 1 year post RTX was 0.05mg/kg/d by 0.001) and at 2 years was 0.05mg/kg/d by 0.001). Mean SLE disease activity index 2K (SLEDAI-2K) prior to RTX was 16.25 while that at 1 year post RTX was 12.5(p value 0.004), at 2 years was 2(p value 0.004) and at 3 years was 0.85(p value 0.028).

Conclusion: We conclude that RTX is efficacious for use in severe spectrum of pSLE and is relatively safe to use even in a developing country like ours with huge infectious disease burden.

AB1025 HARMONIZING JAPANESE VERSION OF THE CHILDHOOD HEALTH ASSESSMENT QUESTIONNAIRE (CHAQ) WITH CHAQ
Takako Miyamae1,2, Yumi Tanii, Takayuki Kishi, Hisashi Yamanaka, Gurkarpal Singh3,4.
1Tokyo Women’s Medical University, Pediatric Rheumatology, Institute of Rheumatology, Tokyo, Japan; 2Tokyo Women’s Medical University, Department of Pediatrics, Tokyo, Japan; 3Tokyo Women’s Medical University, Institute of Rheumatology, Tokyo, Japan; 4Stanford University, Division of Gastroenterology and Hepatology, Stanford, CA, United States of America; 5Institute of Clinical Outcomes Research and Education, Woodside, CA, United States of America

Background: Juvenile idiopathic arthritis (JIA) is one of the most common rheumatic diseases of childhood. The Childhood Health Assessment Questionnaire (CHAQ) is one of the most widely-used self-report questionnaires to measure patient disability and discomfort (1). The American English version of the CHAQ was previously translated into Japanese, cross-culturally adapted and validated in a cohort of healthy Japanese children and Japanese patients with JA (2).

Objectives: To revise the Japanese version of the CHAQ (JCHAQ) to meet requirements of clinical international trials that pool data from various centers in different countries which need the same number of questions in each functional area of the CHAQ and to validate the harmonized JCHAQ with JIA patients.

Methods: The questionnaire in the JCHAQ consisted of 36 items, measuring 6 different functional areas: dressing and grooming, arising, eating, walking, hygiene, reach, grip, and activities, was changed to 30 items of questionnaire as each functional area has same number of questions as the original American English version after a conference among pediatric rheumatologists in US and Japan. The revised version was professionally translated from English to Japanese and reviewed by rheumatologists for accuracy. Then, it was validated with Japanese JIA patients.

Results: A total of 42 JIA patients were enrolled in the validation: 7 systemic, 30 polyarticular/oligoarticular and 5 enthesitis related. Most patients were well controlled and the median disability index (DI) scores was 0.0, however, significant correlation was seen with VAS (Visual Analog Scale) of pain, VAS overall well-being, physician VAS, DAS (Disease Activity Score)28-ESR, and JADAS (Juvenile Arthritis Disease Activity Score)-27. All variables in the questionnaire were shown to be significant (P<0.001).

In comparison of two groups of disease activity, remission/mild vs. moderate/severe, both DAS28-ESR and JADAS27 showed significant correlation with DI.

Conclusion: The Harmonized JCHAQ was a reliable and valid tool for the functional assessment of children with JIA. It is more suitable for international comparison.

Background: The transition from pediatric to adult healthcare systems has recently received worldwide attention, and it is “the purposeful, planned movement of adolescents and young adults with chronic physical and medical conditions from child-centered to adult-oriented healthcare systems.” In Japan, 1,000 patients with childhood-onset chronic disease reach adulthood every year, and many of them will suffer from serious sequelae or disabilities. The Japan Pediatric Society convened a committee of healthcare transition, summarized their statements, and the working group launched its activities in 2013.

Objectives: A clinical practice guidance for the transitional care of young people with childhood-onset rheumatic disorders has been established in Japan.

Methods: The guidance was designed to support pediatric and non-pediatric rheumatologic health care professionals make decisions about appropriate transitional health care for childhood-onset rheumatic disorders. It offered statements and recommendations addressing key clinical questions regarding transitional care proposed by leading pediatric and non-pediatric rheumatology medical experts and consisted of general core and disease-specific guidance.

Results: Category of clinical questions in the general core guidance involved the following: (1) initial statement of transitional care in rheumatology; (2) management of social life environment and public funded health care; (3) issues specific to adolescence; (4) risk management in childhood-onset rheumatic disorders; and (5) decision-making, privacy and consent, access to information, adherence to care, and preferred methods of communication, including attending to health literacy needs. In the disease-specific guidance, issues focused on each rheumatic disorder such as juvenile idiopathic arthritis, childhood-onset systemic lupus erythematosus, juvenile dermatomyositis, and Sjögren’s syndrome were brought up.

Conclusion: The guidance informs policy and strategies to reach optimal outcomes in transitional care for both pediatric and non-pediatric rheumatologists based on available evidence and expert opinion.

MYOCARDITIS IN PEDIATRIC LUPUS: A CLINICAL CONUNDRUM

Johnson Nameirakpam, Anjani Gummadi, Rakesh Kumar, Deepi Suri, Amit Rawat, Sunjti Singh. Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Myocarditis in pediatric lupus is uncommon but carry a significant morbidity and mortality.

Objectives: To study the clinical profile and outcome of children with lupus myocarditis.

Methods: We reviewed our cohort of children with lupus registered between January 1993 to November 2018. Of the 140 lupus patients that were diagnosed during this time, 3 had myocarditis.

Results: Patient 1 was an 11-year-old girl who presented with fever, rash and generalized body swelling for 3 months. Physical examinations revealed heart rate 148/min, respiratory rate 30/min, and blood pressure (BP) 100/80 mmHg. She had pallor, malar rash, hepatomegaly and gallop rhythm. Investigations are detailed in the table. She received intravenous immunoglobulin and initiated on pulse methylprednisolone and followed by pulse intravenous cyclophosphamide. She was discharged on oral prednisolone and subsequently tapered. Patient 2 was a 9-year-old girl presented with fever and rash for 3 months with lethargy for 1 day. She had pallor, malar rash, hepatomegaly. Physical examinations revealed heart rate 132/min, respiratory rate 32/min, feeble peripheral pulses and BP 100/80 mmHg. She received intravenous cyclophosphamide monthly for 6 months along with oral prednisolone in tapering dose. Patient 3 was a 12-year-old girl, who was known to have SLE for 2 months, presented with fever, malar rash, gallop rhythm and tender hepatomegaly. She was given pulse methylprednisolone and furosemide therapy followed by oral prednisolone in gradually tapering dose.

Conclusion: Myocarditis in lupus is uncommon but carries a significant morbidities. The presence of global hypokinesia with a low ejection fraction on two dimensional echocardiography (2DE) is a strong pointer towards the diagnosis. Immunosuppressants drugs with supportive therapy remain the preferred treatment. Early diagnosis and prompt treatment may be very rewarding.

DEVELOPMENT OF A NOVEL DIAGNOSTIC METHOD FOR ATYPICAL AND TREATMENT-REFRACTORY KAWASAKI DISEASE USING NEWLY IDENTIFIED PROTEINS AS BIOMARKERS

Masaaki Mori, Katsumasa Yanagimachi. Tokyo Medical and Dental University, Tokyo, Japan

Background: Kawasaki disease (KD) is a representative acute inflammatory disease of the children mainly under 4 years old. There were more than 15,000 onset cases per year in Japan. KD without proper treatment can lead to cardiovascular complications such as coronary artery lesions (CALs). We are still missing about an etiology and the onset mechanism of KD. Therefore, the diagnosis of KD depends on its clinical features. There are also no specific biomarkers for therapy effectiveness in clinical settings. By using proteomic analysis, we found that the serum expression of lipopolysaccharide binding protein (LBP) and leucine rich alpha 2 glycoprotein 1(LRG1) at the acute phase of KD were significantly high, compared with that of healthy control or patients with autoimmune diseases and biomarkers such as LRG1 and LBP. This study contains more cases and biomarkers such as LBP and LRG1 for grouping of KD patients using clustering analysis based on clinical features and biomarkers.

Methods: The research strategy is composed of clinical phenotype subgrouping of KD patients using clustering analysis based on clinical features and biomarkers such as LRG1 and LBP. This study contains more than 350 KD patients’ data sets including clinical characteristics and laboratory parameters including those of Biomarkers.

Results: According to these results of study, we can objectively diagnose KD without depending on only clinical manifestations.

Conclusion: These two biomarkers may be added in a new KD diagnostic criteria, resulting in quality enhancement of KD diagnosis and may have the potential of proper clinical examination for KD without consequence of CALs.

FIBRODYSPLASIA OSSIFICANS PROGRESSIVA: A CHALLENGE TO DIAGNOSE AND TO TREAT

Mohammed Nashawi, Jan Henje Döring, Markus Bettendorf, Stefan Kölker, Georg Hoffmann, Andreas Ziegler. University Hospital Heidelberg, Center for Pediatrics and Adolescent Medicine, Heidelberg, Germany

Background: Fibrodysplasia ossificans progressiva (FOP) caused by mutations in the ACVR1 gene, which codes for activin receptor IA, a type I receptor of the bone morphogenetic protein (BMP) pathway. FOP is a very rare disease which usually begins in the first decade of life and characterized by congenital bilateral hallux valgus in combination with progressive heterotopic ossification in specific anatomical patterns preceded by inflammatory responses and soft tissue swelling.

Objectives: Our objective is to expand the differential diagnosis of recurrent swelling without trauma by presenting a case of Infant suffering from recurrent swelling and diagnosed to have FOP.

Methods: We used standard laboratory assessment and ultrasound to exclude other diseases. To confirm the diagnosis we used next generation sequencing to identify ACVR1 variants.

Results: A full-term male infant from non-consanguine parents delivered spontaneously after uncomplicated pregnancy. Initially bilateral hallux valgus, as well as limited motility in the metacarpophalangeal joint of D1 of the right hand was noted. At the age of 1.5 months, a severe swelling appeared on the left head without trauma. The further investigation showed no signs of retinal hemorrhage or intracranial injury. The swelling resolved spontaneously, but he readmitted to the hospital due to swellings of different localization in the head area. At the beginning a child abuse had been discussed with the family, although there was no concrete evidence.

At the age of 7 months he presented to our center with renewed swelling in the area of the forehead. Due to the characteristic symptom constellation, a genetic analysis was performed on ACVR1, which confirmed a de novo mutation c.617G> A, p.R206H.

We started a combined therapy with Montelukast 4 mg oral daily for specific inhibition of mast cell activation, Neridronat (Bisphosphonate) 2 mg/kg as i.v. every 3 months for the modification of secondary ossification. As well as Prednisolone for 3 days 20 mg/kg i.v. in the flare up.

At the beginning there were a significant reduction in the frequency and severity of new swellings, however after 9 Months he had frequent flare up with limitation of head movement. At that point we decided to start an off-label therapy with Imatinib. He responded well to the current therapy and the medication is well tolerated.

Conclusion: FOP is a very rare and important differential diagnosis of child abuse. With the characteristic symptom of congenital bilateral hallux valgus and unclear swellings, the diagnosis can be genetically secured.

An early specific treatment concept for the avoidance of trauma as well as drug-based anti-inflammatory therapy are crucial for the clinical course and subsequent impairment of the patient. New targeted treatment approaches offer a promising option for the long-term improvement of disease progression and associated quality of life like Imatinib, which is a tyrosine kinase inhibitor used in the treatment of chronic myeloid leukaemia in adult and children. A recent article showed that it decreased the flare up in 6 out of 7 patients with FOP.

Fibrodysplasia ossificans progressiva: a neuropsychiatric manifestation in childhood-onset systemic lupus erythematosus: retrospective study in one single center

Maria Kaleda, Iraja Nkoshia, Svetlana Glukhova, V. A. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation

Background: Systemic lupus erythematosus is a complex autoimmune disorder characterized by multisystem involvement, including the nervous system, which elevate damage and mortality. The investigation of neuropsychiatric involvement in childhood-onset SLE (cSLE) is important in real clinical practice to improve the prognosis.

Objectives: The study included this was to assess neuropsychiatric manifestations (NM) in cSLE in one single center.

Methods: The study included all pts with cSLE who undergoing in-patient treatment in our center from 1992 to 2017 y. Diagnosis of SLE was reviewed based on 2012 SLICC criteria. Data including sex, age at the time of onset, age at the time of diagnosis, physical examination, laboratory review, and neuropsychiatric inventory were extracted from our database. Classification of NM of SLE was according to the 1999 American College of Rheumatology (ACR) neuropsychiatric manifestations of SLE case definitions.

Results: We included 218 consecutive pts with cSLE, of which 45 pts (20.6%) had neuropsychiatric involvement at the time of diagnosis (Tab.1).

Abstract AB1030 Table 1. Clinical and demographic characteristics of patients.

</table>

Neuropsychiatric manifestations were significantly more frequently detected during the acute development of SLE (46.7% of patients, p = 0.003). Among immunologic disorders, patients with NM often had antibodies to RNP (p = 0.073) in the absence of any differences in other immunological parameters. Of the clinical manifestations in patients with NM, chronic skin lesions were recorded more often (p = 0.076), while arthritis was detected relatively less frequently (p = 0.028). Serositis and nephritis were diagnosed significantly more often in the group of patients with NM (p = 0.003, 0.003, respectively). Of the hematological disorders, NM was relatively more frequently accompanied by leuko/lymphopenia (p = 0.087) and thrombocytopenia (p = 0.077). In general, the group of patients with NM was characterized by a higher degree of multiorgan involvement (the number of clinical manifestations was on average 5.6 and 3.7, respectively, p <0.0001), but both groups were comparable for number of immunological disorders (p = 0.49).

As early signs of NM, all patients had mood disorders and impaired school adaptation. In the structure of NM, central nervous system involvement prevailed (89%), 15 pts (33.3%) had experienced more than one NM. Headaches, cognitive dysfunction and cerebrovascular disease were the most common (28.9%, 28.9% and 24.4%, respectively). Other NM included distal polyneuropathy – 20%, episody – 15.5%, acute confusional state – 11.1%, anxiety disorder – 11.1%, psychosis – 8.9%, pare-sis – 6.7%, chorea – 4.4%.

Conclusion: Acute onset, multiorgan lesions, mood disorders, impairment of学校 adaptation in a patient with suspected SLE should prompt investigations into diagnosis of the primary nervous system involvement. Patients with neuropsychiatric disorders require earlier complex aggressive therapy due to greater disease activity and poor prognosis.

Disclosure of Interests: None declared

ETANERCEPT-INDUCED LUPUS-LIKE SYNDROME IN THE BOY WITH IDIOPATHIC DERMATOMYOSITIS OR DEFACTO MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS?

Maria Kaleza, Irina Nikishina, V. A. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation

Background: Treatment of juvenile onset rheumatic diseases (RD) is an ongoing problem because of the more aggressive disease course and more various clinical manifestations than adult-onset RD. Since the main clinical symptoms may overlap between well-known various RD, in some cases the path to diagnosis and the search for optimal therapy takes longer, especially in patients of pre-adolescence and adolescence.

Objectives: We described a rare case of one boy with RD who presented initially with severe dermatomyositis with sequential evolution to systemic lupus erythematosus.

Methods: Case report.

Results: A 8 yo male patient with normal physical, psychosocial and cognitive development experienced muscle weakness, periorbital edema, Gottron symptom, dysphagia in September 2015 y, which developed after infection. When he was admitted to hospital, increased levels of muscle-derived enzymes and positivity of ANA 1:640 were found. He was diagnosed as having juvenile dermatomyositis and was treated with prednisolone (Pr) for 3 years (IV courses repeated and per os constantly, max dose 1.5 mg/kg/day, min dose 0.5 mg/g/day), IVIG courses repeated and sequentially methotrexate, hydroxychloroquine, cyclosporine with short time of remission. Muscle weakness disappeared after the treatment, but in October 2015 y he experienced new eruptions on his face, heavy arthropathies, lymphadenopathy, distal polyneuropathy, weight loss without strong effect after increase the dose of Pr, IVIG courses repeated, cyclosporine and added of abatacept during 6 months. Because the response to this treatment was low, etanercept was started in June 2016 y, but after two injections he had flare of disease: bright rash on the face, scalp and legs, hard aphthosis stomatitis, cheilitis, cognitive disorders, diffuse alopecia. He received IV course of Pr without significant stable effect. We reviewed diagnosis as systemic lupus erythematosus and changed therapy in November of 2016. Because he had steroid’s osteoporosis with spondylopathy, this combination that made us initiate treatment with mycophenolate mofetil and repeating courses of rituximab (5 courses in total) without increased dose of Pr. Clinical features gradually improved and now he feel good and receive mycophenolate mofetil and Pr 5 mg/day.

Conclusion: This clinical observation can be considered as a course of overlap-syndrome with a successive phase change that could be triggered by anti-TNF therapy, or as an unusual course of SLE in a male patient with a predominance of myositis at onset. Treatment strategy, including Pr, mycophenolate mofetil and rituximab in a young patient proved successful for treatment and seems to be justified in similar cases.

FACTORS TO AID IN EARLY DIAGNOSIS OF KIKUCHI’S DISEASE IN ASIAN CHILDREN

Poh Lin Pauline Chan Ng, Lee Kean Lim, Elizabeth Ang, Pei Ling Ooi, National University Hospital, Khoo Teck Puat-National University Children’s Medical Institute, Singapore, Singapore

Background: The diagnosis of Kikuchi’s Disease (KD), also known as histiocytic necrotizing lymphadenitis, is often delayed as patients often undergo multiple investigations to exclude other causes of cervical lymphadenopathy, such as infection and malignancy1.

Objectives: To describe the clinical features and treatment response of pediatric patients diagnosed with KD in our institution to aid early recognition.

Methods: A retrospective study was conducted on patients < 18 years old diagnosed with KD in National University Hospital, Singapore, from Jan 2006 – Dec 2018. Demographics, clinical characteristics and treatment information were collected.

Results: 14 patients were diagnosed with KD. All were Asian and majority were Chinese (64.2%). 57.1% were male and the age of presentation ranged between 2.8 to 17.9 years old. Fever duration at diagnosis ranged between 8 - 50 days. Median height of temperature was 39.8°C (IQR: 39.4 – 40.0) deg C. This was frequently associated with neck pain and swelling (57.1%) and constitutional symptoms (71.4%) such as anorexia and weight loss. Other symptoms include abdominal symptoms of pain, vomiting or diarrhea (57.1%), rash (35.7%) and oral ulcers (28.6%).

All patients had cervical lymphadenopathy either in the anterior cervical triangle or both anterior and posterior triangles, but not in the posterior triangle alone. This was usually multiple (92.9%), measuring ≥2cm in diameter (100%), tender (95.7%), and tended to be unilateral (64.3%); none had overlying warmth or skin changes. 14.3% had isolated hepatomegaly while 14.3% had hepatosplenomegaly. Common lab abnormalities included cytopenia (50% bicytopenia, 28.6% leucopenia, 7.1% anaemia), elevated inflammatory markers C-reactive protein (CRP) (range: 12 – 117 mg/L), erythrocyte sedimentation rate (ESR) (range 15 – 116 mm/h) and lactate dehydrogenase (range: 490–1514 U/L). Only 3/14 had mild transaminis. Interestingly, almost half had low alkaline phosphatase (ALP). All patients had normal to low complements and were negative for anti-dsDNA antibodies. Ultrasound of the neck typically revealed non-specific findings of reactive lymphadenopathy while 1 showed suspicious features of thickened cortex and loss of fatty hilum. 10/14 patients underwent excision biopsy which confirmed the diagnosis of Kikuchi Disease on histology. 3/14 did not have excision biopsy as they responded promptly to non-steroidal anti-inflammatory drugs (NSAIDs), one declined excision biopsy. All patients had received empiric antibiotics with no response. 84.3% required treatment with NSAIDs for an average of 2-4 weeks. Of the 4 patients who required steroid therapy, one was started at the diagnosis of KD, while the other 3 received steroids upon failure of NSAIDs. Response to either NSAIDs or prednisolone, if effective, was usually prompt, within 24 hours.

Conclusion: Prolonged high grade fever with multiple tender cervical lymphadenopathy ≥ 2cm without warmth or redness and non-response to antibiotics should raise concerns for KD. The presence of cytopenia with moderately elevated inflammatory markers and LDH, coupled with low ALP, may be considered supporting biochemical features of KD. Prompt response to a trial of NSAIDs can help with the diagnosis of KD and potentially avoid excision biopsy of the lymph node. More research needs to be done to determine a clinical and biochemical diagnostic criteria for Kikuchi’s Disease so as to aid early diagnosis and potentially avoid invasive excision biopsy of the lymph nodes.

MEASUREMENT OF DISEASE ACTIVITY LEVEL OVER TIME IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS UNDER BIOLOGIC TREATMENT, USING THE JUVENILE DISEASE ACTIVITY SCORE HUNGARIAN DATA FROM THE JUVENILE IDIOPATHIC ARTHRITIS REGISTRY OF THE NATIONAL INSTITUTE OF RHEUMATOLOGY AND PHYSIOTHERAPY

Ilona Orbán1, Krisztina Sevcic1, Emese Virág Kiss1, Gyula Póó2, 1National Institute of Rheumatology and Physiotherapy, Department of Clinical Immunology, Adult and Paediatric Rheumatology, Budapest, Hungary; 2National Institute of Rheumatology and Physiotherapy, 1st Department of Rheumatology, Budapest, Hungary

Background: A wide variety of measures are currently available to monitor disease course over time in children with JIA. The Juvenile Disease Activity Score JADAS71 version was validated for 71 joints, global score for the JADAS71 is: 0-101.

Objectives: To report the changes of disease activity in JIA patients under biological treatment at age 18, using the JADAS 71 score for the extended oligoarticular and seropositive/seronegative polyarticular form of JIA.

Methods: The Hungarian Biologics JIA Registry of National Institute of Rheumatology and Physiotherapy, Budapest is a longitudinal, unicenter, observational study, that has been maintained since 2002. JIA-ILAR criteria were used for the diagnosis.

Patients with polyarticular course, who failed to respond or did not tolerate methotrexate and were treated with biological agents at the Paediatric Rheumatologic Centre of the National Institute of Rheumatology and Physiotherapy, Budapest, Hungary from 2002 to 25th January,019, were enrolled in an open label observational study and have been monitored prospectively in the registry. At baseline patients and disease characteristics were registered such as, patients’
history, demographic characteristics, and previous DMARDs treatments. Adverse events (AEs), reason for the discontinuation of the biologic treatment, or switch to another biological treatment were documented. The study was approved by the Institutional Review Board. Written informed consent was obtained from parents of the patients and the study was conducted in accordance with the Declaration of Helsinki.

**Results:** In this study 64, 18-year-old Caucasian JIA patients were evaluated from the day of entrance into the registry, who had JADAS 71 results at age 18, from the 347 patients treated with biologics at the submission. Demographic data and disease related variables by descriptive statistics:

- **Gender:** Female: N(%) = 49 (77%)
- **Subtypes of JIA:**
  - Extended oligoarticular form: 11 patients, Polyarticular form: 53 patients (5 RF positive, 48 negative)
- **Median age:** 8 (range: 4-17) years.
- **Mean disease duration:** 3592 days.
- **Mean time on biological treatment:** 1030 days.
- **The first JADAS 71 summation at the entry into the registry:** Median: 18.65 (range: 14.4, 55.4).

**Methods:**

- **Anti-HBs antibody positivity and titers were compared between healthy controls.**
- **Background:** Biologic disease-modifying antirheumatic drugs (DMARDs) use in JIA can reduce and might contribute to the development of renal disease. Although ACE inhibitors could potentially slow down the progression of kidney dysfunction, other treatments would be welcome. Furthermore, a slight proteinuria reduction in a patient with MCTO treated with cyclosporine has been reported. MABF-deficient mice develop systemic lupus erythematosus-like autoimmune disease by inhibited C1q production and effecrocytosis. In the human, monoallelic mutations in MABF result in MCTO.

**Objective:** To investigate whether C1q levels in patients with MCTO are associated with poorly controlled structural kidney damage that usually requires kidney transplantation in adulthood. Because ACE-inhibitors could potentially slow down the progression of kidney dysfunction, other treatments would be welcome. Furthermore, a slight proteinuria reduction in a patient with MCTO treated with cyclosporine has been reported. MABF-deficient mice develop systemic lupus erythematosus-like autoimmune disease by inhibited C1q production and effectorcytosis. In the human, monoallelic mutations in MABF result in MCTO.

**Methods:**

- **Objectives:** To investigate whether C1q levels in patients with MCTO are associated with poorly controlled structural kidney damage that usually requires kidney transplantation in adulthood. Because ACE-inhibitors could potentially slow down the progression of kidney dysfunction, other treatments would be welcome. Furthermore, a slight proteinuria reduction in a patient with MCTO treated with cyclosporine has been reported. MABF-deficient mice develop systemic lupus erythematosus-like autoimmune disease by inhibited C1q production and effectorcytosis. In the human, monoallelic mutations in MABF result in MCTO.

**Results:** Three patients with MCTO were enrolled (table 1). Patient A presented recurrent urinary tract infections since 18 months of life, for a third-degree vesicoureteral reflux. Despite correction surgery, he displayed proteinuria after one year, and kidney biopsy did not reveal significant lesions. After two years, he displayed bilateral tarsal malformations requiring orthopedic surgery. At the age of 6, a pathological fracture of the right wrist occurred, and local X-ray revealed osteolysis of carpal bones. - Because of a suspected juvenile idiopathic arthritis of the right wrist, patient B was treated with intra-articular steroid injection and subsequentous methotrexate for one year without benefit. After one year, he developed proteinuria and kidney biopsy revealed focal segmental glomerular lesions with tubular fibrosis and renal vasa sub-intimal delamination. C3 and C4 positive mesangial deposits were also present. - Patient C was referred to us for suspected juvenile idiopathic arthritis of the right wrist. No inflammatory signs were present at the ultrasound examination. Sequencing of the MABF gene revealed in all the patients a novel heterozygous mutation. Although specific variants have not been reported before, the nature and position of the variants associated with the clinical features of the patients strongly argued in favor of their pathogenic role. The serum C1q concentration was normal in all the patients.

**Conclusion:** It appears from our study that at age 18, 72.3% JIA patients with extended oligoarticular subtype and 26.4% with polyarticular subtypes report a JADAS71 high disease activity sum, so, these young adults will need transitional care.

**AB1034 NO DIFFERENCES IN HEPATITIS B ANTIBODY POSITIVITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS ON BIOLOGICAL THERAPY**

**OCEK SUMEYRA OZDEMIR1, Nihal Sahin1, Aysenur Pac Kisaarslan1, Meda Kondolot2, Zubeyde Gunduz3, Muammer Hakan Poyrazoglu1, Ruhan Düsünsel1. 1Erciyes University Faculty of Medicine, Pediatric Rheumatology, Kayseri, Turkey; 2Erciyes University Faculty of Medicine, Social Pediatrics, Kayseri, Turkey; 3Acibadem Hospital, Pediatric Rheumatology, Kayseri, Turkey.

**Background:** Biologic disease-modifying antirheumatic drugs (DMARDs) are frequently used in the treatment of juvenile idiopathic arthritis (JIA) resistant to nonbiologic DMARDs recently. There is a concern for their reducing the effectiveness of vaccines due to immunosuppressive effects. Objectives: To evaluate hepatitis B antibody (anti-HBs) positivity and antibody titer between JIA patients on biologic DMARDs therapy and healthy controls.

**Methods:** Anti-HBs antibody positivity and titers were compared between 88 patients with JIA on biologic DMARDs therapy followed in our clinic and 91 healthy controls aged 2-19 years. All participants were vaccinated according to the routine vaccination schedule in our country.

**Results:** Eighty-eight JIA patients included and fifty five (62.5%) patients were female. The median age of patients was 13.31 (4.07-18.08) years. The JIA subtypes were systemic JIA (10.2%), oligoarticular JIA (33%), polyarticular JIA (29%), enthesitis related arthritis (26.1%), psoriatic JIA (3.4%), and undifferentiated JIA (2.3%). The median duration of biologic DMARDs was 31.995 (1.33-115) months. 54 patients were treated only with one anti-TNF (34 etanercept, 17 adalimumab), 16 patients were treated more than one different group biologic DMARDs, and 7 of them had more than two biologic DMARD due to disease activity. Anti-HBs positivity was 67% in the JIA group and 54.9% in the control group, and no significant difference detected between the two groups (p=0.097). The anti-HBs titer was 12.95 (min: max: 2-1000) in the controls and 22.44 (2-1000) in the biologic DMARDs.

**Conclusion:** Patients with JIA on biologic DMARDs had not lower anti-HBs positivity than healthy controls in our study. Further studies are required to understand the effects of biologic DMARDs on protective anti-HBs antibody levels.

**Disclosure of Interests:** None declared

**AB1035 MABF-VARIANTS IN MULTICEUTRIC CARPOTARSAL OSTEOLYSIS WITH NEPHROPATHY DO NOT SEEM TO AFFECT SERUM C1Q CONCENTRATION**

**Riccardo Papa1, Annalisa Madoz2, Stefano Volpi1, Roberta Caorsi1, Giancarlo Barbano1, Marina Botto1, Belinda Campos-Xavier5, Andrea Superni-Furga5, Marco Gattorno1, Maja Di Rococo1, Paolo Picco2,1, IRCCS Istututo Giannina Gaslini, Clinica Pediatrica e Reumatologia, Genova, Italy; 2IRCCS Istituto Giannina Gaslini, Malattie Rare, Genova, Italy; 3IRCCS Istituto Giannina Gaslini, Malattie Rare, Genova, Italy; 4IRCCS Istituto Giannina Gaslini, Malattie Rare, Genova, Italy; 5Centre Hospitalier Universitaire Vaudois, Division of Genetic Medicine, Lausanne, Switzerland.

**Background:** Multicentric carpotarsal osteolysis syndrome (MCTO)-associated progressive nephropathy is an orphan disease associated with well-known structural kidney damage that usually requires kidney transplantation in adulthood. Although ACE inhibitors could potentially slow down the progression of kidney dysfunction, other treatments would be welcome. Furthermore, a slight proteinuria reduction in a patient with MCTO treated with cyclosporine has been reported. MABF-deficient mice develop systemic lupus erythematosus-like autoimmune disease by inhibited C1q production and effecrocytosis. In the human, monoallelic mutations in MABF result in MCTO.

**Objectives:** To investigate whether C1q levels in patients with MCTO are reduced and might contribute to the development of renal disease. Methods: In three individuals with clinical and radiographic signs of MCTO, the MABF gene was sequenced. The serum C1q concentration was determined with a commercial laboratory kit.

**Results:** Three patients with MCTO were enrolled (table 1). Patient A presented recurrent urinary tract infections since 18 months of life, for a third-degree vesicoureteral reflux. Despite correction surgery, he displayed proteinuria after one year, and kidney biopsy did not reveal significant lesions. After two years, he displayed bilateral tarsal malformations requiring orthopedic surgery. At the age of 6, a pathological fracture of the right wrist occurred, and local X-ray revealed osteolysis of carpal bones. Because of a suspected juvenile idiopathic arthritis of the right wrist, patient B was treated with intra-articular steroid injection and subsequentous methotrexate for one year without benefit. After one year, he developed proteinuria and kidney biopsy revealed focal segmental glomerular lesions with tubular fibrosis and renal vasa sub-intimal delamination. C3 and C4 positive mesangial deposits were also present. Patient C was referred to us for suspected juvenile idiopathic arthritis of the right wrist.

No inflammatory signs were present at the ultrasound examination. Sequencing of the MABF gene revealed in all the patients a novel heterozygous mutation. Although specific variants have not been reported before, the nature and position of the variants associated with the clinical features of the patients strongly argued in favor of their pathogenic role. The serum C1q concentration was normal in all the patients.

Conclusion: C1q plasma levels in our patients were normal, suggesting that MCTO-associated genetic variants do not play a role in MafB-dependent regulation of complement component C1q production in humans. Further studies are necessary to exclude a role of complement system in the progressive nephropathy of patients with MCTO.

AB1036
AN UNSOLVED CASE: IS THIS A CANDLE-LIKE SYNDROME?

Alessia Pinis1, Alessia Tesser2, Flavio Faletra2, Alberto Tommasini2, Serena Pastore2, Andrea Taddio1,2,1University of Trieste, Trieste, Italy; 2Institute for Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy

Background: Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated Temperature (CANDLE) syndrome is a complex autoinflammatory disorder arising from inborn defects in immunoproteasome. Several genes can be involved and cases with digenic inheritance have been described. However, many cases remain without the identification of a specific genetic defect. A positive interferon signature is typically found in patients and may serve as a diagnostic clue.

Methods: We performed Whole Exome Sequencing (WES) on 10 family members. Moreover, we assessed RNA-seq on three samples from the proband, collected during acute phases of disease (samples positive to class I interferon signature (IS)) (1), and her parents. Results of RNA sequencing (RNA-seq) were compared with specimens from healthy controls.

Differentially expressed genes (DEGs) were filtered by fold change > 2 and padj < 0.05. DEGs enrichment were performed using different R packages, such as pathfinder.

Results: We describe the case of a 20 years old girl with clinical and biological data supportive of CANDLE syndrome. At the age of 3 years, she started presenting a clinical picture reminiscent of amyopathic dermatomyositis, with skin rash, lipodystrophy, subcutaneous panniculitis nodules, and more recently with chilblains, skin ulcerations, polyarticular arthritis and alopecia. Her pedigree includes several relatives with rheumatic disorders, but none has a clinical picture as complex and severe as our patient. This girl was found to have a strongly positive class I IS in peripheral blood cells. After several unsuccessful therapeutic attempts with antirheumatic drugs and biologics, the girl showed a dramatic clinical response to JAK inhibitors tofacitinib.

Conclusion: Our results suggest that our family may present a multigenic form of CANDLE, with a complete clinical picture only in the proband, whilst other relatives may only present partial or incomplete forms of the disease.

SEROLOGICAL PHENOTYPES, UVEITIS AND DISEASE ACTIVITY INTO ADULTHOOD: LONG TERM OUTCOME IN A COHORT OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Martina Priori1, Tilde Manetta2, Simone Parisi1, Maria Chiara Ditto1, Silvia Sanna1, Richard Borrelli2, Enrico Fusaro2, A.O.U. Città della Salute e della Scienza, Rheumatology, Turin, Italy; A.O.U. Città della Salute e della Scienza, Clinical Chemistry Laboratory, Turin, Italy

Background: Deepening the long-term study in adulthood of Juvenile Idiopathic Arthritis (JIA) is fundamental in order to expand knowledge of the pathogenesis, optimize the therapeutic choices, favour a more active communication between paediatric and adult care specialists.

Objectives: To present the results of a follow-up of adult patients affected by JIA.

Methods: The present study aimed to follow-up patients with JIA for a period ranging from 20 to 30 years.

Results: The main objectives were those of: analyse the serological profile (rheumatoid factor –RF- IgM, ACPA IgG, ANA) of such patients to investigate possible seroconversions in adulthood compared to the diagnosis in paediatric age; investigate whether correlations between antibodies (Ab) and diagnostic subgroups persist in adulthood; evaluate the association between Ab and disease activity; investigate the association between the presence of uveitis in the medical history and specific Ab, diagnostic subgroups and disease activity.

Conclusion: The prevalence of RF and ACPA remained unchanged in adulthood, whereas the positivity for ANA in adulthood was 45.6% of patients with ANA positivity in adulthood 13.2%. The difference was statistically significant. The Ab profile of both RF and ACPA remains unchanged in adulthood, whereas the positivity for ANA in adulthood was 13.2%. The presence of uveitis was not correlated either with the presence of ANA in paediatric age, nor in adulthood, but it is instead associated with the presence of specific Ab, diagnostic subgroups and disease activity.

AB1038 JUVENILE IDIOPATHIC ARTHRITIS INTO ADULTHOOD: HOW DO WE ASSESS DISEASE ACTIVITY?

Marta Priora, Clara Lisa Peroni, Angela Laganà, Richard Borrelli, Enrico Fusaro, A. O. U. Città della Salute e della Scienza, Rheumatology, Turin, Italy

Background: Deepening the long-term study of Juvenile Idiopathic Arthritis (JIA) in adulthood is essential to increase the pathogenetic knowledge of the disease, to optimize the therapeutic choices accordingly, as well as to promote a more active communication between paediatric care and adult care specialists.

Objectives: The present project, created as part of the “transition of care”, aims to compare clinimetric scores of wide use for adult inflammatory rheumatisms of the adult (DAS28, CDAI and SDAI) with the JADAS27 score, which has been validated and widely used in order to quantify JIA’s activities in the paediatric field. As of today, adult patients with JIA are usually evaluated with clinimetric scores developed for adult chronic rheumatic diseases (DAS28, CDAI, SDAI) and there is no consensus concerning which of these scores doctors should favour, so that the choice is quite autonomous and varies from centre to centre. It is therefore of interest to verify whether among these indices of purely rheumatological use of adults there is one that is more appropriate than JADAS27 which can be useful in monitoring adult patients with JIA.

Methods: The relevant clinical data were collected from 68 adult patients with JIA. A correlation analysis was performed between the clinimetric scores according to McNemar test and Kappa by Cohen.

Results: The results obtained suggest that none of the clinimetric scale commonly used in the rheumatological clinical practice of adult patients can completely replace JADAS27. DAS28 is the score that goes further from an acceptable correlation with JADAS. Since both CDAI and SDAI are calculated with formulas that are similar to the one used for JADAS (algebraic sums of affected joints, subjective outcomes reported by the patient, clinical judgment of the physician), they happen to be a method of quantification of disease activity quite closer to JADAS itself. The analyses outlined a scenario in which a much larger portion of patients are classified in remission stages or in low disease activity when using CDAI and SDAI compared to JADAS27.

Conclusion: This element inspired us to consider how in paediatric age a more “demanding” attitude towards the disease led to the validation of both a score and its very stringent cut-offs which are functional to a treat to target characterized by a complete remission whose main goal is to avoid long-term sequelae. SDAI was found to be the scale of common use in the adult care that more properly approaches the clinometry validated for the paediatric population (JADAS27). Although clinical common sense should not distract from assessing disease activity in this specific patient population from a global perspective, such a study could suggest using SDAI as clinimetric score of choice in adult patients with JIA. Further checks in larger population samples are obviously necessary.

ADA2 DEFICIENCY PRESENTING AS INFANTILE POLYARTERITIS NODOSA

Graça Loureiro1, Diana Oliveira2, Sara Ganhão3, Francisca Aguiar3, Mariana Rodrigues3, Iva Brito3, 1Centro Hospitalar de Entre Douro e Vouga, Paediatrics, Santa Maria da Feira, Portugal; 2Hospital de Braga, Paediatrics, Braga, Portugal; 3Hospital São João, Porto, Portugal

Background: Polyarteritis nodosa (PAN) is a rare form of primary systemic vasculitis with heterogeneous presentations, treatments and disease course. There have been improvements in understanding of certain causes of PAN such as the association of the monogenic disorder Deficiency of Adenosine Deaminase 2 (DADA2) with a PAN phenotype. This described autoinflammatory disease is caused by loss-of-function homozygous or compound heterozygous mutations in CECR1 and can be characterised by an early onset vasculopathy with clinical and histopathological features of PAN associated with haemorrhagic and ischemic strokes.

Objectives: We report a case of a 14-year-old boy, with a prenatal diagnosis of Klinefelter syndrome, whose parents are first cousins.

Methods: Review of patient’s clinical records and scientific literature.

Results: During his first two years of age, he suffered two small strokes, was investigated in another Hospital and no diagnosis was made. At 4 years of age he was admitted to another hospital for prolonged fever and arthralgia. At age 5 he was admitted to our hospital for fever, arthralgia and myalgia. He later developed a modular stroke and arterial hypertension. Due to suspected PAN he underwent a renal angiogram which confirmed our suspicion.

He completed induction treatment with IV cyclophosphamide (6 months), steroids, and arthralgia. At age 5 he was admitted to our hospital for fever, arthralgia and myalgia. He later developed a modular stroke and arterial hypertension. Due to suspected PAN he underwent a renal angiogram which confirmed our suspicion.

He maintained follow-up, with no sequelae to his strokes and apparent clinical remission.

Conclusion: The purpose of this study is to describe five cases with pediatric SS in order to better clarify the characteristics of the disease in the childhood.

Methods: We retrospectively reviewed medical records of patients with pediatric SS referring to our center (ASST-PINI-CTO, University of Milan) from November 2008 to December 2018. No adequate childhood SS-specific criteria exist. Therefore we select our pts according to a combination of clinical, serological, histopathological findings. For the assessment of systemic disease activity we applied ESSDAI (EULAR Sjögren’s syndrome disease activity index). We calculated ESSDAI at diagnosis, at the peak disease activity and at the last follow up visit.

Results: We collected data on 5 pts (4 females). The mean of age at onset is 8.4 yrs (range 4.8-11.2). The mean of age at diagnosis is 10.8 (range 6.5-13.3). The follow up period varied from 1.2 to 9.3 yrs (mean 6.3). The most common manifestations were parotid/salivary glands swelling (5/5 pts) and articular involvement (5/5 pts) with arthritis in 2 pts and arthralgia in the others. Nobody of our pts presented dryness of eyes. Xerostomia was found in 2/5 pts. Fever and fatigue occurred in 2/5 and 3/5 pts respectively. We also recorded 2 cases of abdominal pain, 1 case of glomerular proteinuria, 2 cases of purpura and 1 case of erythema nodosum. ANA, anti-SSA, anti-SSB, RF, elevation of ERS and hypergammaglobulinemia (1.6 – 8.04 g/dl) were present in all cases. Minor salivary gland biopsy was performed in 4 pts resulting in histological evidence of focal lymphocytic sialadenitis (one of them showed chronic sialadenitis with a focus score <1/4mm2). Ultrasound studies of salivary glands were positive in 5/5 cases. Mean ESSDAI scores at diagnosis, peak activity and the last follow up visit were 8 (range 5-11), 13.2 (9-20), 4.8 (0-9). The most frequently involved domains at the peak activity were biological (5/5), parotid/salivary glands swelling (5/5) and articular (5/5). No major complications have been observed. With regard to treatment, all patient received corticosteroids and DMARDs (5/5 hydroxychloroquine, 3/5 methotrexate, 1/5 azathioprine, 1/5 leflunomide); one patient needed plasmapheresis and immunosuppressive therapy with cyclophosphamide. Biological therapy was administered to 2 patients; 1 received belimumab and then rituximab, while the other patient received rituximab.

Conclusion: Xerostomia and keratoconjunctivitis sicca are not a common features in children, on the other hand juvenile SS has higher incidence of recurrent parotid swellings than adults [2, 3]. All pts had laboratory abnormalities. The long-term prognosis of pediatric SS is unknown, in our series only 2 patients were inactive (ESSDAI score <5, according to the definition by EULAR) at last evaluation, 3 were moderately active with a minimal clinically important improvement (MCII) observed in all of them [4].

PREVALENCE OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) SUBGROUPS AND JIA-ASSOCIATED UVEITIS AMONG JIA PATIENTS ADMITTED TO REFERRAL PEDIATRIC RHEUMATOLOGY CLINICS IN TURKEY: A RETROSPECTIVE STUDY, JUPITER

Sezgin Sahin1, Ceyhun Acar2, Hafize Emine Sonmez3, Fatma Zehra Kilic1, Erdal Sag1, Hatice Adiguzel Dundur2, Amra Adrovic1, Selcan Demir1, Kenan Barut1, Yelda Bilginer4, Betül Sözeri5, Erbil Unsal2, Seza Özen6, O zgur Kasapcoppur1, Istanbul University Cerrahpasa, Cerrahpasa School of Medicine, Department of Pediatric Rheumatology, Istanbul, Turkey; 1Dokuz Eylul University, School of Medicine, Department of Pediatric Rheumatology, Izmir, Turkey, 2Hacettepe University, School of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey, 3Umraniye Training and Research Hospital, Department of Pediatric Rheumatology, Istanbul, Turkey

Background: Juvenile Idiopathic Arthritis (JIA) is a chronic childhood arthritis with onset before age of 16 and has a significant degree of morbidity that negatively affects quality of life. Uveitis, which is defined as the inflammation of the iris, ciliary body and choroid, is the most common cause of morbidity of JIA. This study was planned to collect data from a Turkish cohort to provide the initial national prevalence data of patients with JIA.

Objectives: The objective of this study was to determine the frequency of JIA subtypes in Turkey. We also aimed to assess the frequency and characteristics of eye involvement in JIA.

Methods: This national, non-interventional, multicenter, observational study was conducted in a retrospective manner in four study centers which were main referral pediatric rheumatology clinics across Turkey. Data on patient demography, medical history, JIA disease characteristics, laboratory data, cases of JIA-associated uveitis, JIA treatment history and data on other comorbidities were collected from a cohort of 500 patients.

Results: Oligoarthritis (n=194, 38.8%) was the most common JIA disease characteristic in this study cohort. The frequency of the subgroups was as follows: Enthesis-Related Arthritis (ERA) in 23.2% (n=116), polyarthritis in 15.6% (n=78), systemic arthritis in 12.2% (n=61), psoriatic arthritis in 5.2% (n=26), idiopathic arthritis in 2.8% (n=14) and polyarthritis (RF−) in 2.2% (n=11) of patients were identified. The most frequently prescribed treatment for JIA was methotrexate (n=384, 76.8%). A total of 85 comorbidities were reported, and the most frequently reported comorbidity was Familial Mediterranean Fever (FMF) (n=63, 12.6%). The number of patients with JIA-associated uveitis diagnosis was 34 (6.8%), and the mean duration of uveitis was 3.2 (±2.3) years. The mean duration between the initial JIA diagnosis and diagnosis of uveitis was 1.8 (±1.0) years. Among 34 patients with uveitis, 45 eye involvement were identified; left eye, right eye and both eyes were affected in 5, 8 and 16 patients, respectively. Five patients (14.7%) had uveitis-related complications that required surgical intervention.

Conclusion: The main difference from the European Caucasian population is the lower frequency of oligoarticular JIA and higher frequency of ERA in Turkish JIA patients. Uveitis was also somewhat lower than expected. It is the lower frequency of oligoarticular JIA and higher frequency of ERA in Turkish JIA patients. Uveitis was also somewhat lower than expected.

THE EFFECT OF INTRA-ARTICULAR STEROID INJECTION ON THE CARTILAGE THICKNESS IN JUVENILE IDIOPATHIC ARTHRITIS

Nihat Sahin1, Sumeyra Ozdemir Cicek1, Ayseynur Pac Kisacali1, Muammer Hakan Poyrazoglu1, Ruhan Dusunsel1, Erciyes University, Pediatric Rheumatology, Kayseri, Turkey

Background: Intra-articular corticosteroid injection is a choice in the treatment of juvenile idiopathic arthritis (JIA), especially in large and few joints involvement. Intra-articular steroid injection provides relief in active synovitis but its effects on cartilage are controversial.

Objectives: The aim of this study is to evaluate the effect of intra-articular steroid injection on distal femoral cartilage thickness in patients with JIA by ultrasonography.

Methods: Distal femoral cartilage thicknesses were measured before the procedure and 6 months later by ultrasonography in the patients that were injected an intra-articular steroid to the knee.

Results: The mean age of the patients was 12.1±4.8 years. Nine of patients were girls and 2 were boys. The mean disease duration was 5.1±4.2 years. Ten patients had left knee arthritis and one patient had enthesis-related arthritis. The number of patients injected to the right knee was 3, the left knee was 5 and both the knee was 3. The femoral cartilage thickness before the procedure was 3.0 mm [min-max 2.0-3.65 mm], 6 months after the procedure was 2.95 mm [min-max 2.0-3.55 mm] and there was no statistical difference (p<0.05).

Conclusion: In this study, no effect of intra-articular steroid treatment on cartilage was observed. However, the number of patients is lacks. Therefore, we planned a comprehensive study with more patients.

CLINICAL OUTCOMES OF ANTI-NUCLEAR ANTIBODY POSITIVENESS IN THE 0-18 AGE GROUP: SINGLE-CENTER REAL-WORLD EXPERIENCE

Nihat Sahin1, Ayseynur Pac Kisacali1, Sumeyra Ozdemir Cicek1, Nesilhan Guna2, Aysel Seda Pinarbası2, Sibel Yeşil, Ismail Dursun2, Muammer Hakan Poyrazoglu1, Hüseyin Kilic1, Ruhan Dusunsel1, Erciyes University, Pediatric Rheumatology, Kayseri, Turkey; Erciyes University, Pediatric Nephrology, Kayseri, Turkey; Erciyes University, Medical Microbiology, Kayseri, Turkey

Background: Anti-nuclear antibody (ANA) assay is important in the diagnosis of autoimmune diseases. However, it has a poor positive predictive value and is detected positive in 10% of general population. In this study, the children that ANA assay was performed in a tertiary pediatric clinic, was evaluated and was aimed to investigate the clinical outcomes in positives.

Objectives: In this study, the children that ANA assay was performed in a tertiary pediatric clinic, was evaluated and was aimed to investigate the clinical outcomes in positives.

Methods: 0-18 age group patients that ANA assay was requested in the various clinics of Erciyes University were included. The patients with positive ANA assay and access to hospital records were retrospectively examined. Patients with and without autoimmune disease were identified as group 1 and group 2, respectively.

Results: The number of patients who required ANA assay in pediatric clinics was 3812. There was a positive ANA assay in 1010 of these patients. The medical records of 909 patients were reached. There were 345 (38%) patients in group 1 and 564 (62%) in group 2. In group 1, female gender was higher compared to group 2 (p <0.05).
Musculoskeletal, hematologic, enterohematic, and ocular findings as initial findings were significantly high in group 1 (p<0.05). Pediatric Rheumatology, general pediatrics and pediatric neurology are the three clinics which the assay was requested most common. The patients who were examined in pediatric rheumatology, pediatric hematology-oncology, pediatric gastroenterology departments had a higher incidence of autoimmune disease (p<0.05). In patients with autoimmune disease, >1/1000 ANA titer and homogenous staining were frequent (p<0.05).

Conclusion: In our center, which is a tertiary health center, the autoimmune disease was not detected in most of the patients whose ANA assay was positive. The proportion of patients with autoimmune disease was low in most of the commonly requested departments. The ANA assay should be requested after the patient’s clinical findings are evaluated in detail.

AB1044 CYTOKINE PROFILE OF MACROPHAGE ACTIVATION SYNDROME ASSOCIATED WITH KAWASAKI DISEASE
Nao S Nakamura, Masaki Shimizu, Azumi Jinkawa, Hitoshi Iwabu, Maiko Takakura, Natsumi Inoue, Mao Mizuta, Akihito Yachie. Graduate School of Medical Sciences, Kanazawa University, Department of Pediatrics, Kanazawa, Japan

Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening complication of childhood systemic inflammatory disorders. MAS occurs most often in children with systemic juvenile idiopathic arthritis and less commonly in children with Kawasaki disease (KD). Objectives: Our study aimed to assess the kinetics of cytokine release and compare the accuracy of serum biomarkers for diagnosis of MAS, including neopterin, IL-18, IL-6 and soluble TNF receptor type I (sTNFR-I) and sTNFR-II levels, we analysed these levels in patients with KD, including those with MAS, and compared them to the clinical features of KD and MAS.

Methods: Serum neopterin, interleukin (IL)-18, IL-6 and soluble tumour necrosis factor receptor type I (sTNFR-I) and sTNFR-II levels were determined using enzyme-linked immunosorbent assay in 78 patients with KD, including five with MAS. Results were compared to the clinical features of MAS.

Results: Serum neopterin, IL-18, sTNFR-II levels and sTNFR-II/I ratio were significantly elevated in KD patients with MAS compared to those in the acute phase. Receiver operating characteristic curve analysis revealed areas under the curve and cutoff values of neopterin, IL-18, sTNFR-II levels and sTNFR-II/I ratio were 0.975 ± 0.03 nmol/L, 0.981 ± 0.1165 ng/ml, 0.9969 ± 0.600 µg/ml and 0.9975 ± 0.04 4.75, respectively. Serum sTNFR-II levels correlated positively with disease activity.

Conclusion: These findings indicate that interferon (IFN)–γ and tumour necrosis factor-α (TNF-α) are closely associated with the pathogenesis of MAS associated with KD. Serum sTNFR-II levels might be a useful marker to diagnose the transition to MAS.

AB1046 PHYSICAL ACTIVITY ASSESSMENT IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS COMPARED TO CONTROLS
Alia Fazaaz, Meemir Sallami, Saousen Miladi, Kmar Quenchiene, Leila Souabni, Selma Kassab, Selma Chekili, Leith Zakroui, Kawther Ben Abdelghani, Ahmed Latar. Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Physical activity (PA), known to maintain optimal metabolic function and normal development could be impaired during Juvenile Idiopathic Arthritis (JIA).

Objectives: The aim of our study was to assess PA in children and adolescents with JIA compared to healthy peers using the physical activity questionnaire for children (cPAQ) and adolescents (aPAQ).

Methods: This is a cross-sectional study of measured level of PA in children and adolescents with JIA, compared to age and gender-matched healthy Tunisian schoolchildren. PA was estimated by cPAQ and aPAQ filled by the patient group and the reference group. If the child is unable or unsure to answer the questions we have helped with the parents’ response. The PAQ scores 2 as ‘low activity,’ >2 and ≤3 as ‘moderate activity,’ and >3 as ‘high to vigorous activity.’

Results: A total of 55 patients (38 boys and 17 girls) with JIA and 60 healthy control schoolchildren were included. No significant difference in demographic background was found between the two groups. The mean age was 8.5 ± 4.12 years in the JIA group and 9.2 ± 3.51 years in the control group. Thirty-one patients (53%) had persistent oligoarthritis JIA, 15 (27%) had polyarticular JIA, 5 patients (9%) had systemic JIA, and 4 (7%) had enthesis-related arthritis. The median disease duration was 3.2 ± 2.8 years. The mean cPAQ was 2.101 ± 0.722 in the JIA group and 4.112 ± 0.644 in the control group (p=0.0001). Children and adolescents with JIA had a significantly lower levels of PA compared with their healthy peers as assessed by cPAQ/aPAQ (p=0.012). The time spent in watching television <2 and ≥2 hours/week, p=0.001), and after school activities (0.5 ± 0.5 versus 2.5 ± 0.8 hours/week, p=0.001), and after school activities (0.5 ± 0.5 versus 2.5 ± 0.8 hours/week, p=0.001). Seventy six percent of the JIA group spent the day on the two lowest PA categories: sleeping and sitting, which was significantly higher compared with the reference group (p=0.001 and p=0.055, respectively).

Conclusion: In our study, children and adolescents with JIA were less physically active than the healthy peers as assessed by the PAQ. More objective methods are needed to better evaluate and quantify the PA.

DYNAMICS OF GROWTH AND BONE AGE IN CHILDREN WITH JIA DURING BIOLOGICAL THERAPY

Valentia Serayia, I.M.Sehenov First Moscow State Medical University, children’s rheumatology, Moscow, Russian Federation

Background: In children with severe juvenile idiopathic arthritis (JIA), growth impairment is often accompanied by retardation of bone age. Dynamics of growth and bone during biological therapy is an important criterion for the effectiveness of treatment.

Objectives: To assess the effect of biological therapy on growth and bone age in children with JIA.

Methods: The study included 45 patients with JIA and (30 boys and 15 girls, mean age 12.2 ± 2.7 years; disease duration before the start of biological therapy 6.5 ± 3.3 years, 18 children with systemic JIA and 27 with polyarticular JIA). All children due to the ineffectiveness of standard therapy were transferred to biological therapy with TNF-α and IL-6 inhibitors. The study assessed growth SDS and bone age (according to x-ray imaging) before starting biological therapy (initially) and after 24 months of therapy.

Results: Of the 45 children, the initial growth retardation marked in 13 children, all with systemic JIA (growth SDS -3.19 ± 0.36 (-6.67; -2.04)). All these children also showed a lag of bone age from the passport by 2.9 ± 0.5 years, which corresponded to growth retardation. During biological therapy, the growth retardation decreased within 24 months: growth SDS -2.73 ± 0.34 (-5.87; -1.17). The lag of bone age was maintained at 2.3 ± 1.5 years, which is comparable to the baseline (p = 0.053). In 32 children, the initial growth was within the normal range (growth SDS 0.12 ± 1.07 (-1.97; 1.76)); 8 children with sJIA, 24 with polyarticular JIA. In all these children, the lagging of bone age from the passport at the time of the start of biological therapy was not detected (deviation from the passport age at most 1 year). During biological therapy for 24 months, growth rates remained normal: growth SDS was 0.22 ± 0.99 (-1.56; 1.67). Indicators of bone age in all children were corresponding passport age.

Conclusion: In children with severe JIA and normal growth, the bone age is more likely to correspond to the passport age; during therapy with TNF-α and IL-6 inhibitors, there is no significant change in bone age in these children. In children with severe JIA, growth impairment and bone age may be observed, most likely in children with systemic JIA. During biological therapy, there is an improvement in growth, while the lagging of bone age from the passport remains, which indicates the preservation of growth potential and the possibility of achieving higher final growth.

SYSTEMIC LUPUS ERYTHEMATOUS WITH UNUSUAL PRESENTATION : SINGLE CENTRE EXPERIENCE FROM NORTH INDIA

yamini sharma, Ranbir Jaswal, Piyush Gautam, Jyoti Sharma, Sanjeev Chaudhary, Avinash Sharma. dr RPGMC, PEDIATRICS, kangra, India

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease. Presentation can range from constellation of non specific constitutional symptoms to definitive signs and symptoms. Systemic Lupus International Collaborating Clinics(SLICC) criteria help in making a diagnosis of SLE. SLE mimics many clinical entities and diagnosis may become difficult at times, especially if presentation is atypical. We describe children who presented with unusual manifestations and were finally diagnosed to have pediatric SLE.

Objectives: To highlight unusual presentation of pediatric SLE.

Methods: Retrospective case review of all children diagnosed as SLE from July 2017–November 2018 at a single tertiary care hospital in north India was done. We here describe 5 children who presented with unusual manifestations.

CASE 1: 8 years, girl, presented with fever for 1 month and bilateral pleural effusion. She had had 2 hospitalizations in the past. Once with fever, epistaxis and haemorrhagic shock and subsequently with fever, hepatitis, proteinuria and bicytopenia and was managed as tropical infections at both times. She was evaluated this time and was diagnosed to have SLE and managed for the same.

CASE 2: 11 years, boy, presented with arthritis in multiple small and large joints of body. No other features of SLE were seen. On evaluation ANA and anti dsDNA were found to be positive and he fulfilled criteria for SLE. He was started on subcutaneous, weekly methotrexate and responded to treatment. However, he developed lupus nephritis during disease course after 6 months of diagnosis. Renal biopsy revealed Class Ⅲ-V lupus nephritis. Intravenous Cyclophosphamide pulses were started for induction along with tapering doses of corticosteroids.

CASE 3: 8 years, girl, presented with early morning periobital puffiness and abdominal distention. She also had a history of photosensitivity and Raynaud phenomenon. Urine routine examination revealed nephrotic range proteinuria with no hematuria. Clinical possibility of nephrotic syndrome secondary to SLE was kept. Renal biopsy revealed Class V lupus nephritis. She was started on oral prednisolone and enalapril.

CASE 4: 15 years old, girl, presented with non-specific generalized body pains with n joint pains associated with low grade fever. There were no other complaints. Examination was unremarkable. Investigations, however, were suggestive of SLE.

CASE 5: 17 years old, girl, presented with high grade fever and pain in bilateral knee joints and malar rash. Investigation were suggestive of SLE with MAS (macrophage activation syndrome). Child was started on iv antibiotics and iv immunoglobulins but died during the disease process.

ANA positivity, hypocomplementemia and Anti ds DNA positivity were seen in all the 5 cases. Results: out of 11 children diagnosed to have SLE, 5 presented with unusual manifestations as described above. All patients were initiated on hydroxychloroquine and photoprotection other drugs used were prednisolone, naproxen, subcutaneous weekly methotrexate, cyclophosphamide and Azathioprine.

Conclusion: In this report we present unusual presentations as the predominant manifestation of SLE and emphasize the fact that early recognition and awareness of unusual presentation of SLE help institute timely initiation of appropriate treatment.

CO-MORBIDITY INDEX IN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Ljudmila Bohmal1,2, Irina Bessonova1,2, Natalia Shevchenko1,3, Elmira Kzhazharsiantz1,2, Tetiana Holovko1, Institute of Children and Adolescents Health Care, Department of cardiorheumatology, Kharkiv, Ukraine; V.N. Karazin National University, Department of pediatrics, Kharkiv, Ukraine; V.N. Karazin National University, Department of pediatrics № 2; Kharkiv, Ukraine

Background: Comorbid conditions in patients with rheumatic diseases (RD) aggravate the course of diseases, worsen the prognosis, impede the response to therapy, and reduce the quality of life of patients. Initial manifestations of comorbid lesions of organs and systems are already manifested in childhood and adolescence, and in the future are the causes of persistent morphologic and functional disorders, disability and mortality of patients.

Objectives: The purpose was to identify comorbid conditions in children with systemic lupus erythematosus (SLE), followed by an assessment of the comorbidity index (CI).

Methods: 41 patients with SLE aged 7-18 years were examined. The average duration of the disease at the time of the survey was 44.5± 2.9 months, 20 persons (48.78%) had a period of illness up to 3 years, 21 (51.22%) – over 3 years. Among the patients female subjects predominated (79.09%). The comorbidity index (CI) was determined by the total score (points) of the disturbances in all systems of the organism without specific diagnoses.
Results: Pathological changes of the one or two systems were noted in 19.51% of patients, between three and four systems - in 24.4%, and in six systems - in 14.6% of patients. The mean values of CI among patients with SLE were 2.6±0.3 points and did not differ significantly depending on the duration of the disease (2.5±0.7 points before 3 years and 2.4±0.3 points after 3 years; p>0.05), as well as did not differ in female and male patients (2.6±0.3 and 2.8±0.5 respectively, p=0.05). The CI was higher in the cases of development of SLE before the age of 7 years than in older patients (3.6±0.5 vs 2.4±0.3 respectively, p<0.05).

The activity of the pathological process significantly influenced the indicators of the CI: 2.4±0.4 with its minimal activity; 2.7±0.4 with an average degree of activity and 3.0±0.6 with a high degree (p<0.05). The frequency of the smallest CI (0 or 1) turned out to be associated with the earliest activity of the disease. The CI with ANA-positivity association was defined: 2.8±0.3 points among patients with ANA that has twice exceeded the CI of ANA-negative patients (1.4±0.5), p<0.05. Its highest level (like 4, 5 and 6 points) was registered only among the ANA-positive patients.

In patients with SLE with high CI, changes in the system of coagulation due to elevated fibrinogen levels predominated (3.7±0.4 g/l vs 2.8±0.3 g/l (p>0.05)). Similar changes were recorded with the atherogenic coefficient increased (2.7±0.7 vs 1.3±0.5; p<0.05).

Conclusion: According to the research, it was found that in children and adolescents with SLE the formation of lesions of systems and organs occurs while maintaining the activity of the process, especially immunologic and ANA-positive association of lipid metabolism and blood coagulation were associated with the formation of comorbid states.

AB1050

Tocilizumab modifies clinical manifestations and laboratory features of systemic juvenile idiopathic arthritis (s-JIA) associated with macrophage activation syndrome (MAS) could be modified in patients treated with tocilizumab (TCZ). Objectives: To clarify whether TCZ modifies clinical manifestations and atypical MAS, or early treatment that prevented fulminant MAS. Methods: A combination of expert consensus and analysis of real patient data was conducted by a panel of 15 pediatric rheumatologists. Clinical manifestations and laboratory features of s-JIA associated MAS while treated with TCZ and 18 patients not treated with TCZ were evaluated. Possible MAS was defined as having characteristic laboratory features but lack of clinical features of MAS, or atypical MAS, or early treatment that prevented fulminant MAS.

Results: Among 12 patients while treated with TCZ, only 2 patients were diagnosed with definite MAS, and other 10 patients were diagnosed with possible MAS. On the other hand, among 18 patients not treated with TCZ, 10 patients were diagnosed with definite MAS, and other 8 patients were diagnosed with possible MAS. MAS classification criteria could classify the patients diagnosed with definite MAS while treated with TCZ as well as the patients not treated with TCZ (100% and 75%, respectively).

Furthermore, the patients with possible MAS while treated with TCZ were less likely febrile and significantly less often had rash, and had notably lower ferritin levels (587 ± 8518 ng/ml; P=0.0021), compared to the patients with possible MAS not treated with TCZ. Other laboratory features of MAS including lower platelet counts, lower fibrinogen were more pronounced in patients treated with TCZ.

Conclusion: These findings show TCZ could modify clinical manifestations and laboratory features of s-JIA associated MAS. When evaluating s-JIA patients while treated with TCZ, care must be taken to not underdiagnose MAS based on MAS classification criteria.

Transition care in a new pediatric rheumatology center in Brazil: caring for adolescence beyond rheumatism

Larissa Finho, Marco Felipe Silva, Ana Paula Pessoa, Carlos Nobre Rabelo Junior.

Hospital Geral de Fortaleza, Pediatric Rheumatology Unit, Fortaleza, Brazil

Background: Transition care is the planned transfer of adolescents with chronic health conditions from children-centered to adult-oriented health systems. Its challenges include gaps in continuity of care, poor adherence, delays in adult services attendance, differences between pediatric and adult centers, difficulties in autonomy over care and unstable medical conditions. EULAR/PRES recently published recommendations, standards and quality indicators on transition care for young people with rheumatic diseases, which serve as a guide for transitional outpatient clinics. In Brazil, few centers focus on transition from pediatric to adult rheumatology. The Pediatric Rheumatology Unit of Hospital Geral de Fortaleza is a reference in North and Northeast of the country, intending to be pioneer in transitional medicine in region.

Objectives: To evaluate the adolescents and their families’ perception regarding follow-up and autonomy in health care, as well as to identify the main risks inherent to this age group.

Methods: A longitudinal and descriptive study was carried out through interviews, questionnaires and medical records analyzes. Adolescents between 15 and 18 years old, regularly followed, who had at least three planned visits/year were included. Patients with cognitive impairment or without definite diagnosis were excluded. Epidemiological and clinical data were collected; self-management and health care utilization skills were evaluated by Transitional Readiness Assessment Questionnaire (TRAQ), a self-administered questionnaire.

Results: Eighty two patients were recruited into the transitional service (61 female [74.4%]). Patients’ ages ranged from 15.0 to 18.7 years (median 16.9). Regarding religion, 41 patients (54.7%) were Catholic and 27 were Protestant (36%). Concerning to ethnicity, most of them declared themselves white (61%) or white (22%). Fifty-nine adolescents (72%), considered themselves able to take care of their own follow-up, whereas 39 relatives (50%) considered the patient capable of doing so. The most frequent diseases were juvenile idiopathic arthritis (31.7%) and systemic lupus erythematosus (29.3%), of which 37 (45.1%) were in remission. Medical disease duration and follow-up were 48.5 (5 - 175) months, respectively. The median TRAQ value was 3.27 (1.61 - 4.55). There were 191 transitional visits (median 2.0 visits/patient). Fifty three patients had 2 or more visits, out of which 42 (79.2%) had at least one visit in which the patient and/or the family was confident in their own role.
least one risk identified. The most prevalent risks were: overweight or obesity (31.7%), sedentarism (26.4%), anxiety (22.6%), changes in family structure (22.6%), school problems (20.8%), depression (18.9%), suicidal ideation/self-mutilation (18.9%), low self-esteem (15.1%). Risks related to psychiatric diseases were identified in 23 patients (43.4%).

Conclusion: This is one of the first studies on transition care in Brazil focused on risks identification in adolescence. Transition care allows improvement survival and quality of life due to advances in preventive medicine and treatment of chronic rheumatological diseases. The identification of inherent risks, especially psychiatric disorders, plays a fundamental role in the long-term follow-up, making it possible to deliver multidisciplinary and rehabilitation of adolescents.

SYSTEMIC LUPUS ERYTHEMATOSUS IN CONTEXT OF HUMAN IMMUNODEFICIENCY VIRUS INFECTION: A CLINICAL CONUNDRUM

Ankita Singh1, Anjani Gummadi1, Laxmi Makam2, Deepit Sur1, Anju Gupta1, Pandiarajan Vignesh1, Ankur Jindal1, Amrit Rawat1, Sunjit Singh1. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Advanced Pediatrics Centre, Allergy Immunology Unit, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Advanced Pediatrics Centre, Chandigarh, India

Background: Systemic lupus erythematosus (SLE) and Human immunodeficiency virus (HIV) infection can occasionally coexist in a patient. Also, in rare scenarios, the clinical symptomatology and laboratory tests of these diseases can masquerade each other.

Objectives: To describe diagnostic and therapeutic dilemmas of coexistent SLE and HIV

Methods: We analyzed case records of 2 patients with childhood SLE who had the clinical conundrum of HIV infection as well

Results: Case 1- An 11-year-old girl with fever and respiratory distress for 4 days. On examination he had pallor, oral thrush, and onycomycosis. A malar rash was also noted. Systemic examination revealed consolidation in right lung and hepatosplenomegaly. Investigations showed severe anemia and lymphopenia. HIV serology was reactive of HIV serology was false positive. Subsequently she was given intravenous immunoglobulin following which she improved.

Conclusion: This child had the dual diagnosis of HIV infection and SLE which she transiently responded however she developed acute intracranial bleed during hospital stay and died.

MACROPHAGE ACTIVATION SYNDROME AS A PRESENTATION IN PEDIATRIC LUPUS: A RETROSPECTIVE STUDY OF 3 CASES

Ankita Singh1, Anjani Gummadi1, Rakesh Kumar, Sandesh Guleria, Johnson Nameirakpam, Pandiarajan Vignesh, Ankur Jindal, Amrit Rawat, Sunjit Singh. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Advanced Pediatrics Centre, Chandigarh, India

Background: Macrophage activation syndrome (MAS) can, at times, be the presentation of pediatric lupus and diagnosis requires high index of suspicion.

Objectives: To report children who had MAS as a presenting manifestation in our cohort of childhood lupus

Methods: We retrospectively studied 140 pediatric lupus patients from January 1993- November 2018 and collected clinical and laboratory data of patients (3) who had MAS as presenting manifestation.

Results: Case 1 was 11-year-old girl with fever for 4 months associated with rash and generalized body swelling for 1 month. Examination revealed rash over malar area and ear lobules, anasarca, hepatomegaly, bilateral pleural and pericardial effusion. In view of multisystem involvement a possibility of lupus was considered which was confirmed by investigations (table 1). She had elevated ferritin and low fibrinogen. A clinical possibility of lupus with associated MAS was considered. She received pulses of methylprednisolone, one dose of intravenous immunoglobulin following which she improved. In view of nephrotic range proteinuria she was started on induction regimen with cyclophosphamide and shifted to mycophenolate in maintenance. Her initial SLEDAI-2k was 32- this decreased to 4 at 3 year follow up.

Case 2 was a 9-year-old girl with fever, rash, generalized body swelling for 1 month and altered sensorium for 4 days. Examination revealed palmar erythema, oral ulcers and hepatomegaly. She was in shock at presentation. In view of multisystem involvement a possibility of lupus was considered which was confirmed by investigations (table 1). She had pericardial effusion and low ejection fraction (25%). A possibility of MAS was considered and investigations revealed hyperferritinemia, elevated triglyceride and hypoalbuminemia. She was given methylprednisolone pulses and continued on oral prednisolone, mycophenolate and hydroxychloroquine. Her initial SLEDAI-2k was 17- this decreased to 0 at 3 year follow up.

Case 3 was an 8-year-old girl who had fever, rash and body swelling for 15 days. On examination she had tachycardia, tachypnea, pallor, anasarca, subconjunctival bleed and frontal alopecia. She had pleural and pericardial effusion. In view of multisystem involvement a possibility of lupus was considered which was confirmed by investigations (table 1). She had high ferritin and triglyceride. So a possibility of MAS was considered and she received pulse methyl prednisolone and intravenous immunoglobulin. She also had hematuria and proteinuria (renal biopsy could not be performed as she was sick and had thrombocytopenia) so was given pulse cyclophosphamide followed by mycophenolate. Her initial SLEDAI-2k was 25- this decreased to 0 at 2 year follow up.

Conclusion: MAS can be the presenting manifestation of pediatric lupus and may contribute to disease severity and requires aggressive management.

Hepatic involvement as a presentation in pediatric lupus: A retrospective study of 3 cases

Ankita Singh1, Anjani Gummadi1, Rakesh Kumar Pilania1, Pandisarjan Vignesh1, Ankur Jindal1, Deepthi Suri1, Amit Rawat2, Surjit Singh1.
1. Allergy Immunology Unit, Chandigarh, India
2. Department of Pediatrics, Guru Nanak Dev Hospital, Chandigarh, India

Background: Though abnormal liver tests can be seen during the course of disease in lupus, liver involvement as a presenting manifestation is uncommon in children with lupus (1).

Objectives: We report on 3 children with lupus who had predominant liver involvement at presentation.

Methods: We retrospectively studied 140 pediatric lupus patients from January 1993 to November 2018 and collected clinical and laboratory data of patients who had liver involvement as presenting manifestation.

Results: Case 1 was 13-year-old girl with fever and joint pain for 7 months associated with rash and yellow discoloration of eyes and body for 1 month. She also had altered behavior for 3 days. Examination revealed malar rash, jaundice, bilateral knee arthritis and hepatosplenomegaly. Investigations revealed anemia, thrombocytopenia and lymphopenia. She had conjugated hyperbilirubinemia. Transaminases were elevated. Further investigations confirmed diagnosis of lupus (table 1). Markers for autoimmune hepatitis (SMA; LKM) were negative. She received pulse methylprednisolone followed by tapering doses of oral prednisolone. In view of neurological involvement she also received cyclophosphamide and shifted to azathioprine later. Her initial SLEDAI-2k was 18, that decreased to 12 in follow-up. Her initial SLEDAI-2k was 18, that decreased to 12 in follow-up.

Conclusion: Hepatic involvement at presentation in lupus can be multifaceted and poses challenge in diagnosis.

The Experiences of Biological Therapies in Children with Juvenile Idiopathic Arthritis Associated Uveitis: Single Center Study

Background: Juvenile idiopathic arthritis (JIA) is the most common systemic disease causing uveitis in childhood, with a prevalence of 10 per 100,000 persons. JIA-associated uveitis is estimated to have a poor prognosis and a high rate of complications. JIA-associated uveitis can manifest in various forms, depending on the location and severity of the ocular inflammation, as well as on the type of arthritis. The most of JIA patients with uveitis have oligoarthritis. Therefore, other types of JIA are rarely accompanied by uveitis. Topical corticosteroids are the first-line therapy, and disease conventional and biologic modifying anti-rheumatic drugs (DMARDs) are used.

Objectives: The purpose of the present study was to report on the clinical characteristics, ocular complications, treatment, and visual outcome in children with JIA-associated uveitis who were examined in recent years at a single tertiary pediatric rheumatology and ophthalmology center in Turkey.

Methods: We retrospectively analyzed the data of 41 JIA patients (14 males, 27 females).

The duration between the initial evaluation and the final visit was recorded as follow-up time. Juvenile idiopathic arthritis was defined according to the International League of Associations for Rheumatology (ILAR) classification criteria. Uveitis was classified according to the SUN classification.

Two approaches were utilized to evaluate the change of visual acuity (VA) during the disease course: (i) VA was measured on Snellen chart. The equivalent logarithm of the minimum angle of resolution acuity (logMAR) was calculated and used for analysis.

Results: The study included 31 patients (57 eyes) of whom 22 (71%) were females. Mean age (+SD) at uveitis diagnosis was 8.42 (+4.13) years (median 8, range: 34 months–17 years) and there was no significant difference between genders. The mean age of patients with diagnosed uveitis was 4.42 (+4.7), respectively. Nine patients were <7 years of age at the time of JIA diagnosis. Anterior uveitis (AU) was the most common type, diagnosed in 57 (76%) eyes. All patients had methotrexate, therefore biologic therapy was used in 29/31 patients (93.5%) at the follow up time (infliximab in 12, adalimumab in seven, and tocilizumab in three patients) and 9 patients (31%) required ≥2 biologics over the follow up period. Thirteen patients switched between infliximab and adalimumab (10 patients switched from infliximab). The reason for treatment switch included treatment failure and treatment-related side-effects (n=3). Systemic and topical steroids treatment were gradually tapered and discontinued in all patients after initiation of biologics. Of the all affected eyes, posterior synchiae (16 eyes, 7.5%) was the most frequent complication on follow-up. During the follow-up period new complications were seen in 11 eyes (13%). Posterior synchiae (6 eyes, 7.5%) was the most frequent complication observed followed by cataract (3 eyes, 3%) and glaucoma (2 eyes, 2.5%) Improvement or preservation of visual acuity (VA) was noted in 77 eyes (94.3) at the last visit.

Conclusion: We report a large cohort of children with JIA uveitis managed in a Turkey tertiary unit. Low complication rates and favorable visual outcomes are found in the present study. The high rate of biologic use, and close monitoring of affected children with pediatric rheumatology and uveitis clinic may have contributed to our improved outcomes.

Difficulties in the Diagnosis of the PFAPA Syndrome in the Real Clinical Pediatric Practice

Anna Spivakovskaya, Yuri Spivakovskiy, Yuri Cnemenkov, Aoiya Dushanova.

Saratov State Medical University named after V. I. Razumovsky, Saratov, Russian Federation

Background: Symptom complex of PFAPA syndrome is characterized by a rather diverse clinical picture, including recurrent fever, aphthous stomatitis, pharyngitis, adenitis. The annual incidence of PFAPA syndrome does not exceed 0.2%. [1], but it is believed that this disease is much more common than diagnosed [2]. The absence of specific genetic and biochemical markers of this syndrome determine the complexity of timely diagnosis and treatment of this auto-inflammatory disease.

Objectives: The objective reaction is of importance is that the time of diagnosis of PFAPA syndrome is a clinical practice of a pediatrician.

Methods: We conducted a follow-up analysis of the medical documentation of patients with verified PFAPA syndrome who were examined and treated at the hospital pediatrics department of the university clinic for the period from 2015 to 2019 year. A survey of pediatricians and pediatric rheumatologists was carried out on the knowledge of diagnostic criteria, protocol for the management and treatment of patients with PFAPA syndrome.

Results: During this period, in the department of PFAPA syndrome was diagnosed in 7 patients. Among patients with a diagnosis of PFAPA syndrome, there were 4 boys and 3 girls, the average age of children at the time of diagnosis was 1.4 ± 0.7 years. Before the diagnosis was verified, all patients were observed by a pediatrician or otorhinolaryngologist regarding repeated manifestations of tonsillitis and received antibacterial therapy at each episode of exacerbation of the disease. The average period from the first manifestations of the disease to the verification of the diagnosis was 1.4 ± 0.5 years. Diagnostic algorithm for verification of the diagnosis was completed by setting prednisolone test. According to the results of this test, in 100% of cases it was possible to completely arrest the phenomena of the inflammatory process (fever, tonsillitis, pharyngitis, stomatitis) and to normalize biochemical markers of inflammation (CRP) without the use of antibacterial therapy. With further observation, two of 7 patients recorded a decrease in the effectiveness of glucocorticoid therapy, which required a tonsillectomy, and one of them noted the temporary effectiveness of colchicine. According to the results of a questionnaire survey of pediatricians and children’s otorhinolaryngologists of the outpatient service, a low level of knowledge was revealed on the issues of the clinic, diagnosis and therapy of auto-inflammatory diseases. Only 40% of respondents were able to specify the diagnostic criteria for setting PFAPA syndrome and determine the further routing of these patients. It should be noted that more than half of the respondents (57%) had a clear idea about the methods of rational therapy of patients with PFAPA syndrome.

Conclusion: Thus, the complexity of the primary diagnosis of PFAPA syndrome is associated both with the clinical features of the disease and the insufficient level of knowledge of primary outpatient specialists on this issue, which is largely due to the low incidence of PFAPA syndrome. This conclusion was the reason for the inclusion of additional topics in the educational course of pediatricians.

Co-designing a Comparative Randomised Controlled Clinical Trial of Corticosteroid Regimens with Children, Young People and Parents Living with Juvenile Idiopathic Arthritis

Simon Stones1, Heather Bagley2, Frances Sherratt3, Louise Roper2, Eileen Bailey2, SIRUA Trial Management Group.

1University of Leeds, School of Healthcare, Leeds, United Kingdom; 2University of Liverpool, Institute of Translational Medicine, Liverpool, United Kingdom; 3University of Liverpool, Institute of Population Health Sciences, Liverpool, United Kingdom; 4Alder Hey Children’s NHS Foundation Trust, Paediatric Rheumatology, Liverpool, United Kingdom

Background: Previous research has identified the need for a randomised controlled trial (RCT) evaluating the most appropriate corticosteroid induction regimen to be used for children and young people (CYP) with juvenile idiopathic arthritis (JIA). A recent qualitative study found that parents and CYP understood trial concepts and were able to identify potential flaws in a proposed RCT. This confirms the need to involve parents and CYP in co-designing RCTs to best meet the needs of future trial participants (2).

AB1059 CLINICAL MANIFESTATIONS OF CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PRESENTING WITH CYTOPENIA

Woosuk Suh, Ky Hwan Kim, Jung Woo Rhim, Soo Young Lee, Seung Beom Han, Nack Gun Chung, Dae Chul Jeong, Woosuck Suh, Ki Hwan Kim, Jung Woo Rhim, Soo Young Lee, Seung Beom Han, Nack Gun Chung, Dae Chul Jeong, Woosuck Suh, Ki Hwan Kim, Jung Woo Rhim, Soo Young Lee, Seung Beom Han, Nack Gun Chung, Dae Chul Jeong, Woosuck Suh, Ki Hwan Kim, Jung Woo Rhim, Soo Young Lee, Seung Beom Han

AB1060 BONE MARROW OEDEMA IN CHILDREN: THE ROLE OF VITAMIN D

Elsa Tadikott1, Sara Pieropan1, Maddalena Maschio1, Giulia Aiello1, Giulia Melo1, Federica Martinis1, Erica Giaconelli1, Giorgio Piacentini2, Azienda Ospedaliera Universitaria Integrata Verona, Paediatric, Verona, Italy; Policlinico G. B. Rossi, Ospedale Borgo Roma, Reumatologia, Verona, Italy

Background: Bone marrow oedema (BMO) in children is a rare clinical condition characterized by joint and bone extremity pain, out of proportion to the clinical findings, exacerbated by weight bearing, in the absence of a known etiologic cause. It is associated with typical increased signal intensity on T2-weighted MRI. Management is still under debate. Treatment has mostly been reported in adult case series encompassing analgesic drugs, a variety of pharmacological treatments (corticosteroids, bisphosphonates, vasodilators), physiotherapy, reduction of weight-bearing, or core decompression. No treatment guidelines for children are to date available.

Objectives: Recently it has become evident that BMO is associated by an increase in bone turnover, in which vitamin D plays a pivotal role. In literature association between hypovitaminosis D and BMO of the foot and ankle in adult patients is reported. No data are reported in cohorts of children. The purpose of this study is to investigate the incidence of hypovitaminosis D in a paediatric population with primary bone BMO of the foot and the role of a vitamin D supplementation therapy.

Methods: A retrospective study involving 12 paediatric patients (range age 8-14 years) referred to our Rheumatologic Paediatric Clinic of Verona University in the period 2015-2018 with persistent foot pain and MRI compatible with BMO of the foot has been performed. They had all been diagnosed in other institutions as affected by algodystrophy or complex regional pain syndrome. Data collection included sex, age, medical and surgical history, recent or remote trauma history, symptoms at presentation, clinical examination, laboratory bone turnover markers, vitamin D levels, MRI, treatment and outcome.

Results: 2/12 patients are male and 10/12 female (male to female ratio: 1:5). 2/12 had a previous diagnosis of juvenile idiopathic arthritis ANA + with the disease in remission at the moment of evaluation. 10/12 were previously healthy.

In all cases history of minor ankle strain or recurrent microtraumas of feet prior to symptom onset had been reported. Joint hypermobility was observed in 75% of cases. One child had been previously treated with bisphosphonates and 5 with limb immobilization, without any improvement.

Objectives: To co-design components of an RCT of corticosteroid regimens with CYP and parents living with JIA.

Methods: A focus group was conducted with CYP with JIA and parents as part of a wider consensus and discussion group meeting within the Steroid Induction Regimen for Juvenile Idiopathic Arthritis (SIRJIA) study in December 2018. The discussion focused on two components of the RCT design: i) Discussing the most appropriate treatment protocols; and ii) Addressing practicalities associated with an RCT.

Results: Two RCT protocol options, chosen through an online survey by a critical majority out of a possible eight protocols, were discussed and critiqued: i) Protocol A (intravenous vs intraarticular corticosteroid delivery); and ii) Protocol B (intravenous vs intraarticular vs intramuscular vs oral corticosteroid delivery). Several issues pertaining to both protocols were raised, related to the influence of age and past experience, routes of administration and concerns over randomisation. Participants emphasised the importance of clinicians/researchers discussing all of the potential risks with them. Participants also wanted enough information to make an informed choice. Participants emphasised the usefulness of combining trial visits with regular follow-up appointments to minimise the burden of taking part in an RCT and had a preference for their usual hospital being the site they visited. Some participants remarked that videos could be a useful way of conveying information beyond traditional participant information sheets. Some also felt that awareness of research opportunities is not equally accessible to them either, depending on where they lived in the country. Participants would want to be kept regularly updated about the progress of the RCT and felt that incentives were a good way of keeping people engaged, although some were trepidatious to hear negative treatment results. With regards to dissemination, participants felt that study results should be readily available to them in an accessible format, should they wish to view them.

Conclusion: CYP and parents have a considerable amount of knowledge and experience which can shape the design of RCTs. With adequate support, complex concepts such as treatment protocols can be discussed and critiqued. Involving CYP and parents at the design stage of an RCT has been shown to eliminate some potential challenges in the future.

DISCLOSURE OF INTERESTS
None declared

Physical examination revealed weight bearing pain of foot or ankle in all patients. No other sensory, vasomotor, trophic ore neurological signs and symptoms were detected. Vitamin D deficiency was found in all cases (range 10 to 22 ng/ml). All patients were thus treated with adequate vita- 
min D daily intake. Pain relief was achieved with paracetamol, low dose ibuprofen, or a short course of oral prednisone. Rest from intense physi- 
cal activity and physical therapy, avoiding detrimental feet and ankle 
immobilization were recommended. All children (100%) fully recovered in 
3-month lag period. 

Conclusion: BMO in children is a cause of disability and it is often mis- 
diagnosed and incorrectly treated. Environmental factors, such as underes- 
timated articular or bone microtraumasms, as well as joint hyper 
mobility, typical of paediatric age, in a bone turnover milieu of vitamin D 
deficiency could be the cause of the clinical conditions. Adequate vitamin D 
supplementation, associated with physical and analgesic therapy, are crucial in the management of BMO. We highlight the importance of sup- 
plementing vitamin D as recommended in the current guidelines, in order to 
avoid its deficiency and prevent invalidating clinical complaints.

AB1061 SHORT TERM FOLLOW-UP RESULTS OF CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER AFTER CESSATION OF COLCHICINE: IS IT POSSIBLE TO QUIT?

Aysë Tanatar1, Şente Gü Kardakjian1, Hafize Emine Sonmez1, Mustafa Çakan1, Nuray Akşy Ayaz1,1 University of Health Science, Karuni Sultan Suleyman Research and Training Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background Familial Mediterranean Fever (FMF) is considered as the prototype of autoinflammatory diseases, and colchicine is the main treatment option for FMF. However, the data on cessation of colchicine treatment in FMF patients is limited.

Objectives To define the characteristics of children with familial Mediterranean fever (FMF) whose colchicine treatment was discontinued and then to compare these features of the patients whose colchicine was restarted with the ones not restarted.

Methods Sixty-four out of 1786 children with FMF whom colchicine was stopped by the physician or patients/parents own decision were enrolled. These patients were grouped into two as: group 1; children whose colchicine was re-started and group 2; children whose colchicine was not re-started. The demographic, clinical and genetic data were collected and compared between group1 and group 2.

Results Colchicine was stopped in 59.4% (38/64) by the physician and 40.6% (26/64) of them had stopped colchicine by patients/parents will. Colchicine was ceased at a median of 10.5 (2.120.5) years of age, and attack- and inflammation-free periods of 18.2 (6-148) months. The median follow-up of 64 patients after col- 
chicine cessation was 37.4 (6.145.7) months. It was re-started in seventeen patients due to attacks (n=11) or elevated acute phase reactants (n=6), while remaining 47 patients did not require colchicine. The age at cessation of the col- 
chicine was lower (p=0.04) and duration of colchicine treatment until its cessation was shorter (p= 0.007) in group 1 than group 2.

Conclusion Even though the results of our study are not satisfactory enough to endorse the hypothesis that colchicine may be discontinued by close follow-up; older age and long duration of colchicine treatment before cessation may be two important features that should be considered in the future studies.

AB1062 INTER-LABORATORY COMPARISON OF TYPE I INTERFERON SIGNATURE ANALYSES: PAVING THE WAY TO SHARE RECOMMENDATIONS.

Alessandra Tesser1, Gian Marco Moneta1, Antonella Insalaco1, Rebecca Nicolai2, Claudia Braccaglia1, Valentina Moressa3, Serena Pastore4, Andrea Taddio4, Alberto Tommasini1, Paola Bocca5, Marco Gattorno5, Fabrizio De Benedetti6, Volpi Stefano6,7.1 Institute for Maternal and Child Health IRCCS “Burlo Garofolo”; Trieste, Italy; 2IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy; 3University of Trieste, Trieste, Italy; 4IRCCS Istituto Giannina Gaslini, Genova, Italy

Background Interferon (IFN) signature analysis is currently used to classify pathological conditions characterized by a type I IFN dysregulation (i.e. mono- 
genic interferonopathies, dermatomyositis, systemic lupus erythematosus), and to formulate targeted therapy approaches. Indeed, IFN signature is used to differ- 
entiate patients with IFN-related inflammation from conditions predominantly 
mediated by other cytokines (e.g. JIA and periodic fevers), through the calculation of an IFN score (IS). However, at the moment, there is not a shared threshold able to 
discriminate among different inflammatory conditions.

Objectives To characterize the IS in different inflammatory diseases and evalu- 
ate the concordance of IFN signature results among the laboratories of the three 
Italian Hospitals.

Methods Assessment of the expression in peripheral blood of six IFN-induced genes (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1) in Real Time PCR, refer- 
ring to a calibrator sample (healthy controls). Calculation of the “interferon score” (IS) for each patient using the median fold change of the six relative 
quantifications.

50 patients with different inflammatory disorders considered not related to IFN (e. 
g. Crohn, JIA, hereditary periodic fevers) were compared with established type I 
IFN-related diseases (SLE, monogenic interferonopathies, dermatomyositis). We 
avalised the concordance of the clinical classification of different inflammatory 
diseases and the IS results. To assess the inter-laboratory variability, twenty 
patients with different degree of type I IFN inflammation were analysed at three 
different laboratories.

Results Despite the IFN signature showed a similar and comparable trend, the IS 
was not consistent between different laboratories, in particular for samples with 
higher IS score. Thus, the concordance between clinical classification and IS 
could be assessed only separately for each laboratory. Although in each series 
IFN-related disorders showed a IS significantly higher than other kind of inflamma-
tory disorders, preliminary results suggest there is no clear threshold able to differ- 
entiate among these groups.

Conclusion Analysis of type I IFN activation in peripheral blood showed a rele-
vant inter-laboratory variability between our three centers, limiting the possibility 
of identifying a shared defined threshold to differentiate inflammatory syndromes, 
and suggesting the need to determine reproducible calibrator samples. Coopera-
tion between different institutes could facilitate the collection of clinical and labora-
tory data in a common database, to exchange expertise in type I IFN-mediated 
diseases, and provide practical advices for IFN signature assessment and inter-
pretation in the clinical practice.

AB1063 INTERSTITIAL LUNG DISEASE IN A NEWBORN AFFECTED BY MEVALONIC ACIDURIA

Sofia Torreggiani1,2, Carlo Pietrasanta1,3,4, Francesca Minoia1, Giovanni Filocamo1, Andrea Ronchi1,2, Stefano Volpi2, Roberta Caorsi2, Marco Gattorno3, Francesco Caroli4, Alice Grossi4, Isabella Ceccherini4, Lorenza Pugni4, Fabio Mosca5,6,7.1 Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Pediatra Medica Intensità di Cura, Milano, Italy; 1Università di Milano, Milano, Italy; 2Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, NICU, Milano, Italy; 3University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy; 4Istituto Giannina Gaslini, Clinica Pediatria e Reumatologia, Genova, Italy; 5Istituto Giannina Gaslini, UOC Genetica Medica, Genova, Italy

Background Mevalonic aciduria (MA) is the most severe phenotype of mevalonate-kinase deficiency (MKD), with early onset and poor prognosis. Given its rarity and its unspecific symptoms, MA diagnosis may be
challenging in the newborn. To our knowledge, interstitial lung involvement has never been described as onset feature in MKD.

Objectives: We report a new case of a newborn affected by MKD characterized by interstitial lung disease.

Methods: The patient underwent laboratory and radiology evaluation as clinically indicated. Direct Sanger sequencing was used to screen the 10 exons of the MVK gene.

Results: A female neonate born at term from consanguineous parents was referred to our hospital at 16 days of life (DOL) for mild hypotonia and persistent raised inflammatory markers despite antibiotic therapy. Infectious work-up was negative. Chest x-ray revealed bilateral perihilar peribronchial thickening. Electroencephalography reported moderate diffuse anomalies of background activity without major abnormalities. On DOL 20 the first episode of fever was recorded. Due to worsening tachypnea and persistent abnormal chest x-ray, a pulmonary CT scan was performed and showed diffuse groundglass bilateral infiltrates consistent with alveolar-interstitial lung disease. On DOL 22 a maculopapular skin rash appeared on feet and hands, vanishing spontaneously 24 hours later. Bone marrow examination and levels of perforins, neuron-specific enolase and urinary catabolites of catecholamines were normal. A total body MRI was normal except for a mild cerebellar hypoplasia and the known interstitial lung disease. The patient kept presenting hypotonia, relapsing episodes of fever and skin rashes, developed severe anemia and failure to thrive. Type-I IFN signature was negative. A genetic test was requested, as well as quantification of urinary levels of mevalonic acid, which were markedly elevated. Direct Sanger sequencing allowed to detect a homozygous c.709A>T missense mutation in the exon 8 of the MVK gene, coding for a protein substitution p.T237S. Classified as pathogenic in the INFEVERS database and therefore consistent with the diagnosis of MKD. Both parents and her sister were heterozygous carriers of the same mutation. On DOL 38 treatment with anakinra was started, with prompt regression of fever and skin rash, decrease in inflammatory markers, increase in reticulocytes count and weight gain. Hypotonia improved but persisted. The patient was discharged from hospital on DOL 56 in good clinical conditions, with acute phase reactants within the normal range and mild hypotonia. She is now 4 months old, still on anakinra treatment without adverse events.

Conclusion: Autoinflammatory diseases in the neonatal period are a diagnostic challenge. Clinical suspicion is crucial in order to perform specific laboratory and genetic testing and start appropriate treatment. Interstitial lung involvement may be present in MKD and, together with increased inflammatory markers, could be the first manifestation of the disease.

AB1064
LONG-TERM SAFETY AND EFFICACY OF ADAHILUMAB IN GREEK ADULTS WITH JIA OR NON-INFECTIONOUS UVEITIS AT THE TRANSITION PERIOD
Artemis Koutsoukou1, Despoina Dimopoulou, Maria Trachana1, Vassiliki Sgouropoulou, Polyonera Pratidou-Gerti1, Alexandros Garyfalias2, Pediatric Immunology and Rheumatology Referral Center, 1st Dept of Pediatrics, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2Rheumatology Unit, 4th Dept of Internal Medicine, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Our previous publication on Juvenile Idiopathic Arthritis (JIA) revealed that half of the pts had flare in adulthood and the need for administration of several anti-TNFs.

Objectives: a. To describe the long-term outcome of adults with JIA or non-infectious uveitis (NIU), exposed to Adalimumab (ADA) as the single or last biologic during the transition period. b. To evaluate our model of transition in a subgroup of refractory to conventional DMARDs JIA or NIU pts, in the 1st Greek Transition Clinic for Pediatric Rheumatic Diseases.

Methods: Retrospective cohort analysis of Greek adults with JIA or NIU between 2004 and 2018. The JIA activity state was assessed by 2 quantitative tools: the Juvenile Arthritis Disease Activity Score-10 (JADAS-10, Clinical Remission [CR]), Low, Moderate and High Disease Activity [LDA, MDA, HDA, respectively] and Wallace criteria (CR on/off ADA). Baseline was defined as the 1st ADA dose.

Results: 28 pts were enrolled: 24 JIA pts (female 18), aged 20.6±3.1 yrs, for a f/u of 6.5±3 years (Group-A) and 4 female pts with active uveitis (2 with JIA-associated and 2 with NIU, mean aged: 18.9 yrs, f/u: 2.3 yrs) (Group-B). The age at baseline was 14.1±3.2 yrs in Group-A and 16.7±3.2 yrs in Group-B. The lag time from JIA onset to baseline was 5.3±3.8 yrs and the JIA subtypes were: 37.5% polyarthritis RF neg, 33.3% extended oligoarthritis, 20.8% enthesis-related arthritis, 4.2% persistent oligoarthritis, 4.2% psoriatic arthritis. 11/24 (45.8%) pts (Group-A) and 3/4 pts (Group-B) were ANA positive, 5/24 JIA-pts had a history of uveitis (20.8%). Naive to anti-TNF drugs were 18 pts (75%) of Group-A and 4/4 from Group-B. The baseline JADAS-10 was 13.9±5.9. The ADA yr-administration was 5.3±2.3 in Group-A and 2 in Group-B. Compliance to ADA had 17/24 (70.8%) pts in Group-A and all from Group-B. Regarding safety, 4/28 patients (14.3%) experienced Events of Special Interest (1/33.6 patient-years), herpes zoster (n=1), anorexia nervosa (n=1), breast fibroadenoma (n=1) and uveitis (n=1). Among the Group-A pts: 4/24 (16%) pts continued ADA due to inefficacy and 1/24 due to pregnancy planning, 6/24 pts (25%) achieved CR and discontinued ADA after 5.3±1.6 yrs. CR off ADA lasted 15.5±9.8 mo. The rest 13/24 continued ADA at the last f/u. In Group-B, 3/4 were still on ADA and 1 pt discontinued ADA due to NIU remission after 4.2 yrs and sustained CR 16 mo off ADA. The median CR remission on ADA total administration period was 75% in Group-A and 100% in Group-B. Among the ongoing receivers: a) the JIA activity state at the last assessment was: CR 84.6%, LDA 7.7% MDA 7.7% (median JADAS: 0, Group-A), b) 100% were in remission in Group-B.

Conclusion: 86% of adult pts with JIA or NIU tolerate ADA well. Pts exposed to ADA achieved CR on/off medication in 75% and 25%, respectively.

AB1065
THE UTILISATION OF S100 PROTEINS TESTING IN PEDIATRIC RHEUMATOLOGY PATIENTS IN A TERTIARY CARE INSTITUTION AND IMPLICATIONS FOR CARE
Elena Tronconi, Najla Aljaberi, Angela Merritt, Jennifer Huggins, Michael Henriksson, Hermine Brunner. Cincinnati Children’s Hospital Medical Center, Division of Rheumatology, Cincinnati, United States of America

Background: S100 proteins are calcium-binding proteins of increasing value as biomarkers in various inflammatory conditions. They are considered sensitive biomarkers of disease activity in rheumatologic disorders such as rheumatoid arthritis (1) and juvenile idiopathic arthritis (2). They are considered more accurate than conventional inflammatory indices such as the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) (3).

Objectives: To evaluate the utilization of S100 proteins in the clinical setting as supportive diagnostic tools as well as their performance in evaluating disease activity.

Methods: Patients seen at the hospital’s specialty clinics who had S100 proteins tested during their care from April 2017 to August 2018. A retrospective chart review was performed to collect data on serum S100 protein levels, other inflammatory markers as CRP and disease activity measured as active joint count (AUC) in JIA patients and the presence of systemic symptoms in systemic JIA (sJIA) patients. Graphpad Prism Version 7.05 was used for data analyses. Descriptive statistics were calculated for all variables. Comparisons were done by the Mann-Whitney U test and the Kruskal-Wallis test. Spearman correlation were calculated to assess association between S100 proteins and other numerical variables.
Results: A total of 164 patients were included. All 164 patients had S100A8/9 collected but only 151 had S100A12 samples. Patients with sJIA had higher levels of S100A8/9 and S100A12 compared to patients with non-systemic JIA (nsJIA) and periodic fever syndrome (PFS). CRP levels were not statistically different among diagnosis while S100 proteins were. Both S100A8/9 and S100A12 showed a good ability to differentiate sJIA from PFS (AUC=0.76 for both) compared to AUC=0.6 for CRP. At a cut-off value of 164 ng/ml, S100A12 was 71% sensitive and 73% specific in differentiating between sJIA and PFS (Figure 1). In JIA there was no correlation between S100 protein levels and AJC. either sJIA or nsJIA patients. S100A8/9 and S100A12 were significantly elevated in active sJIA patients compared to inactive ones while CRP levels were not different. S100 proteins levels where significantly higher during a flare of PFS compared to inactive disease, as well as CRP. There was no difference in S100 proteins and CRP in patients with or without tocilizumab treatment.

Conclusion: S100A8/9 and S100A12 are particularly elevated in sJIA compared to nsJIA and PFS. They are useful in distinguishing sJIA from other diagnoses with similar presentations, such as PFS. S100 proteins were significantly higher in active disease status of patients with sJIA and PFS compared to inactive status and their levels were closer associated with sJIA disease activity than CRP. The S100 proteins could provide valuable data in the work-up of patients with autoinflammatory conditions and monitoring disease activity in sJIA and PFS patients.

Methods: Results: A 15 years old girl presented with acute lower limb flaccid paralysis. Neurologic exam showed peripheral deficit of the VII cranial nerve, absent motor activity at lower limbs with sensitive deficit. At physical examination she had marked and diffuse livedo reticularis. She underwent a brain and spinal magnetic resonance imaging (MRI) revealing multiple areas of signal abnormalities (T2 hyperintensity) in both thalamus and basal ganglia, small area in the spinal cord at C2-C3, at D10-D11 and L1 levels; these images were related to vascular damage. Blood exams showed high blood counts and inflammatory markers (C-reactive protein 16.76 mg/dl). Coagulation was normal, antiphospholipid and antinuclear antibodies were negative. Immunochemical work-up showed normal immunoglobulin level, T and B phenotype. She received intravenous steroid and high-dose intravenous immunoglobulin. The constellation of findings led to clinical suspicion for ADA2, which was confirmed by low plasma ADA2 activity. For the presence of microhematuria, worsening proteinuria and hypertension, vascular ultrasound was performed with no evidence of renal artery stenosis. She underwent renal biopsy negative for glomerulonephritis, renal vasculitis and amyloidosis. Following the diagnosis of ADA2, she was initiated on etanercept 50 mg once weekly and she was able to taper steroid with normalization of inflammatory markers and improvement of skin rash.

The girl is the second of 3 children, born from consanguineous parents of Italian origin. By the age of 1 she started suffering from fever, arthritis, pericarditis with elevated inflammatory markers and was diagnosed with systemic juvenile idiopathic arthritis (sJIA) and chronic disease anemia. At that time, she already presented livedo reticularis. She was treated with short term oral steroid and methotrexate with remission of fever and articlar symptoms. At the age of 2 she had a convulsive crisis. polysomnography and brain MRI were performed with no evidence of sleep disorders. One year later she presented a convulsive status epilepticus, brain MRI was repeated and resulted negative. She was started on topiramate with no further crisis, treatment was stopped 2 years later. When she was 9, she was admitted for pancytopenia and she was diagnosed of Leishmania infection. The two siblings of the girl were tested for plasma ADA2 activity and both resulted deficient. The boy is 12 years old with mild developmental delay and a previous diagnosis of sJIA when he was 5. He was treated with steroid and Methotrexate with remission of arthritis. The older sister is now 19 years old and she had an episode of erythema nodosum. Genetic test for pancytopenia and she was diagnosed of Leishmania infection. The two siblings of the girl were tested for plasma ADA2 activity and both resulted deficient. The boy is 12 years old with mild developmental delay and a previous diagnosis of sJIA when he was 5. He was treated with steroid and Methotrexate with remission of arthritis. The older sister is now 19 years old and she had an episode of erythema nodosum. Genetic test for pancytopenia and she was diagnosed of Leishmania infection. The two siblings of the girl were tested for plasma ADA2 activity and both resulted deficient. The boy is 12 years old with mild developmental delay and a previous diagnosis of sJIA when he was 5. He was treated with steroid and Methotrexate with remission of arthritis. The older sister is now 19 years old and she had an episode of erythema nodosum. Genetic test for pancytopenia and she was diagnosed of Leishmania infection.

Conclusion: Given the important morbidity, especially in consanguineous families, high index of suspicion is required for early diagnosis and precocious intervention, before persistent neurologic damage has been established. We report our data for the first time a new neurological presentation as acute transverse myelitis in a patient with ADA2.

THE IMPACT OF ACUTE RHEUMATIC FEVER IN A PROVINCE OF CENTRAL-NORTH ITALY

Elena Tronconi1, Erika Miglioni1, Andrea Doni2, Andrea Pession1, Angela Miniaci1, Sant’Orsola-Malpighi Hospital, University of Bologna, Department of Pediatrics, Bologna, Italy; 2Sant’Orsola-Malpighi Hospital, Pediatric Cardiology and Adult Congenital Heart Disease Program, Bologna, Italy

Background: Acute rheumatic fever (ARF) is a multisystem complication of group A streptococcal (GAS) infection. The incidence of ARF varies greatly in different geographic areas, with the highest incidence in Asia, Eastern Europe, and Australia (10-350 out of 100 000 per year) (1) and greatly in different geographic areas, with the highest incidence in Asia, Eastern Europe, and Australia (10-350 out of 100 000 per year) (1) and lowest (0.5-3 out of 100 000) in the US and Western Europe. In 2015 the latest version of Jones Criteria has been published (2), incidence less than 2 out of 100.000 per year was established to define low-risk (LR) population. Due to the lack of nationwide epidemiologic data in Italy, it is difficult to define the correct population Jones criteria’s category to use.

Objectives: To estimate the incidence of ARF in a metropolitan area of Central-North Italy and to study the clinical characteristics of the disease in a developed country.

Methods: We retrospectively analyzed the data of all patients with ARF aged 5-14 years old, diagnosed according to the classical and now LR Jones criteria (2), referred to Sant’Orsola-Malpighi Hospital of Bologna from January 2012 to December 2017 living in the province of Bologna.

Results: We identified a total of 24 patients diagnosed by ARF. In the province of Bologna, the inhabitants between 5 and 14 years of age varied from 82,967 in 2012 to 89,699 in 2017. Every year the annual incidence of ARF was above 2 out of 100,000. The highest incidence was reported in 2013 with 8 new diagnosis (incidence of 9.3 out of 100 000 per year). Carditis was present in 20 patients (83.3% of cases), chorea in 8 children (33.3%). Only 3 patients presented polyarthritis at diagnosis while 9 had polyartralgia and 3 presented with monarthrosis. In 6 patients the diagnosis followed the onset of chorea and no joint involvement was recorded. In 5 patients the diagnosis of ARF was made after the detection of classical cardiac findings without other major criteria. Cardiac involvement was characterized by mitral regurgitation in 17 cases and aortic regurgitation in 10 (8 patients with mitral aortic involvement). Five patients presented with fever (>38.5°C), 11 children had elevated inflammatory markers as erythrocyte sedimentation rate (ESR) > 60 mm/h and/or C-reactive protein (CRP) >3.0 mg/dL. Only 5 patients had positive swab for GAS. Twelve patients (50%) were treated with steroid. Fourteen patients received secondary prophylaxis every 28 days, two of them switched to every 21 days.

Conclusion: Our study confirms the previous published data of Breda et al. (3) and Liciardi et al. (4) in other Italian areas supporting the evidence for high risk (HR) in our region. Furthermore, this study shows that in our population only few patients had the classical polyarthritis presentation. It is important to consider the new HR criteria for arthritis in order not to miss diagnosis. A careful clinical history is needed because the demonstration of GAS infection is often difficult. These data may strengthen the hypothesis to consider our whole country as a HR area for ARF. A nationwide study is mandatory.

AB1068 CLINICAL FEATURES IN TURKISH CHILDREN WITH CHRONIC NON-BACTERIAL OSTEOMYELITIS

Ceyhun Acar1, Elif Çoşak2, Süleyman Şeşenk2, Serkan Turuçar2, Hatice Adıgüzel Dundar1, Sara Şenbenedik Kılıç3, Sema Akman1, Ercel Unsal3, Dokuz Eylül University Faculty of Medicine, Department of Pediatrics, Balıkesir, Turkey; 2Akdeniz University Faculty of Medicine, Department of Pediatrics, Antalya, Turkey; 3Ülger University Faculty of Medicine, Department of Pediatrics, Bursa, Turkey

Background: Chronic non-bacterial osteomyelitis (CNO) is a rare bone disease of autoinflammatory origin. CNO patients present with bone, joint pain and swelling. Other autoinflammatory disorders such as palmoplantar pustulosis, psoriasis and inflammatory bowel disease may accompany CNO.

Objectives: Our aim is to determine demographic, clinical and radiological characteristics of Turkish children with CNO.

Methods: Clinical, laboratory features and imaging findings were retrospectively analyzed in 28 CNO Turkish patients from three pediatric rheumatology centers. Clinical findings, radiological data, treatments and outcome were evaluated.

Results: Of the 28 CNO patients, 10 (35.7%) female and 18 (64.3%) were male. Mean age at diagnosis was 9.54 (3-16.5) year. The lag time between symptoms and diagnosis was 6.5 (0-60) months. The median follow-up time was 18.5 (1-107) months. At the time of admission, symptoms were arthralgia (75.0%), bone pain (64.3%), limping (32.1%), swelling (28.6%), weakness (10.7%), and fever (3.6%). Two patients had inflammatory bowel disease (IBD) and six had familial Mediterranean fever (FMF). The bone lesions were mostly multifocal (%96.4), pelvic bones (32.2%). The patients had mildly elevated CRP and ESH levels. HLA B27 association was 25%, ANA was positive in 5%. All patients were RF negative. Six patients had mutations in the MEFV gene, all of them had M694V allele. The most common finding in Histopathological examination (n=9) demonstrated sterile mixed cell infiltration composed of lymphocyte and neutrophils. MRI results were mostly defined as bone marrow edema, and bone scan findings showed increased osteoblastic activity. All of patients received NSAIDs. Other drugs were methotrexate (46.4%) sulfasalazine (39%), steroids (25%), anti-TNF drugs (32%), and pamidronate (25%). Response to treatment was partial in 32.1%, whereas 39.3% patients had complete remission. There was no response in 8 patients (28%).

Conclusion: CNO was first described by Giedion in 1972 as multifocal bone lesions of inflammatory origin.1 There are 500 CNO patients reported in the literature as individual or case series.2 The laboratory findings are nonspecific and the diagnosis is mostly clinical and radiological. MRI and bone scan are the most commonly used imaging modalities. Histopathological results are non-specific, and may be necessary to exclude infection and malignancy. NSAIDs, sulfasalazine and methotrexate are mostly used in the treatment. Steroids, biological drugs and pamidronate are other options. There is still need for further treatment options, because there are significant number of resistant patients.

AB1069 HYPERZINCÆMIA AND HYPERCALPROTECTINÆMIA SYNDROME: MORE THAN JUST AUTOINFLAMMATION?
Andrea Uva1,2, Claudia Bracaglia1, Silvia Federici1, Camilla Celani1, Manuela Pardeo1, Christoph Kessel2, Fabrizio De Benedetti1, Antonella Insalaco1.
1IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy; 2University Children’s Hospital, Department of Pediatric Rheumatology and Immunology, muenster, Germany

Background: Hyperzincaemia and hypercalprotectinæmia (HandH) syndrome has been described as a new rare entity characterized by recurrent infections, dermatological involvement, increased inflammatory markers, hepatosplenomegaly and anemia. Little is known about its heterogeneous presentation, pathophysiology and treatment.

Objectives: To describe three cases with HandH syndrome

Methods: Serum calprotectin (MRP8/14) was measured according to Buehlmann assay (ELISA) and plasmatic zinc by atomic absorption spectrometry

Results: Three patients were referred to our centre because an history characterized by recurrent episodes of skin rash, severe oral aphthosis and increased level of serum amyloid A (SAA). Patient 1 presented, since the age of ten years, with recurrent episodes of fever and rash; skin biopsy showed a picture consistent with a lymphocytic lichenoid vasculitis resembling erythema multiforme. Patient 2 presented at birth, with hemolitic anemia and thrombocytopenia. At the age of 5 she was admitted to another hospital due to EBV related hemophagocytic lymphohistiocytosis (HLH). At the age of 8, she was first seen at our center because of a persistent desquamant erythematous rash with recurrent abdominal pain and recurrent arthritis. Intestinal biopsy showed small intestine inflammation (erosions in the digiurnum). Patient 3 presented with recurrent episodes of fever, rash, two episodes of transient hip synovitis and musculoskeletal pain. A bone scintigraphy was performed resulting normal. Patients 1 and 2 suffered from recurrent infections (pneumonia, otitis, skin abscesses). Immunological studies revealed in patient 2 a reduction of memory B cells and a reduced response to Toll like receptor 9 agonist. Of note, all the patients presented in their medical history at least one episode of vasculitis: patients 1 and 3 suffered from Schonlein-Henoch’s purpura at the age of 11 and 3 respectively and patient 2 had at the age of 2 years an undelineated vasculitis (evaluated elsewhere). Laboratory tests showed in all patients elevated inflammatory markers, zincemia and serum calprotectin (table)

Figure 1

Conclusion: We report three patients with high serum levels of calprotectinæmia and zinc presenting with a clinical phenotype consistent with previously reported cases. The presence of vasculitis in all of the patients suggest that it may represent the first symptom of this condition. Vasculitis could lead to an increase of serum calprotectin already proposed as a marker of vascular impairment. Moreover, considering the immunological defect detected in one of our patient, we speculate that recurrent infections described in this syndrome may underline an immune-dysregulation process in which the role of zinc metabolism needs to be assessed

AB1070 MICROVASCULAR NAILFOLD ALTERATIONS BY VIDEOCAPILLAROSCOPY IN PATIENTS WITH RHEUMATOLOGICAL SYMPTOMS WITH JUVENILE INFLAMMATORY BOWEL DISEASE
1Hospital Universitario “Dr. José Eleuterio González”, Pediatrics, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González”, Pediatrics, Monterrey, Mexico; 3Hospital Universitario “Dr. José E. González”, Pediatrics, Monterrey, Mexico; 4Hospital Zambrano Hellon TEC salud, Pediatrics, Monterrey, Mexico

Background: Juvenile Inflammatory Bowel Disease (jIBD) is a chronic relapsing inflammatory condition of the gastrointestinal system that includes Crohn’s disease (CD) and Ulcerative Colitis (UC) and develops during childhood or adolescence in up to 25% of patients and affects the patients and patient s quality of life. Endothelial dysfunction is considered one of the etiological factors of jIBD. Nailfold videocapillaroscopy is one of the best and safest diagnostic non-invasive imaging techniques to analyze microvascular abnormalities. Previous studies describe the involvement of the microvasculature in the pathogenesis of these diseases, suggested that chronic mesenteric vasculitis is a pathogenetic mechanism in CD. Nailfold abnormalities found are similar to those observed in some systemic vasculitides. Subapillary venous plexus dropout and low vessel density were previously reported.

Objectives: In this abstract we describe nailfold videocapillaroscopy findings in patients with jIBD and their correlation with disease activity.

Methods: This is a prospective and analytical study thad recruited pediatric patients between 2 and 18 years with jIBD. A single cross-sectional 8-finger nailfold videocapillaroscopy was performed using a 200x optical probe videocapillaroscope. The images were collected, encoded and stored using the Optipix™ software. Qualitative, quantitative and semi-quantitative assessment for architecture were scored following the international definitions for the capillary abnormalities Blood chemistry, C-reactive Protein, erythrocyte sedimentation rate, antineutrophil cytoplasmic antibiotic, and calprotectin were performed. Sociodemographic data, clinical evaluation, confirmation of IBD criteria, disease history, and activity evaluation were collected from patients clinical records. Statistics were performed using Spearman correlation to evaluate the correction coefficient between the variables under study.

Results: 10 patients with jIBD were included 60% male, 50% Ulcerative Colitis and 50% Crohn’s Disease. 20% had severe disease according the Pediatric Ulcerative Colitis Activity index, Pediatric Crohn’s Disease activity index showed mild activity in just one patient. Rheumatological manifestations were found in 40%, 4 had arthritis, systemic vasculitides in 2 and 10% hematologial manifestations. Abnormal endoscopy in 60% showing pancolitis. Normal microvasculature pattern were only found in 3 patients (25%), microangiopathy was found in 75%, edema of the nailfold bed was present in n=6 patients, a low capillary density was found in 100% of the patients with disease activity. A statistical negative correlation between the number of capillarities per millimeter and disease activity was found (coefficient -0.936, p=0.001).

Conclusion: Previous data showed that low capillary density was find in patients with jIBD, the data in this pilot study are consistent with those findings. The assessment of the microvasculature through the use of videocapillaroscopy could be useful in this diseases.

AUTO-IMMUNE AND INFLAMMATORY DISEASES IN CHILDREN WITH SICKLE CELL DISEASE: DIAGNOSTIC AND THERAPEUTIC ISSUES

Caroline Vint1, Corinne Guillon2, Patricia Benhaim1, Florence Missud3, Mariane De Montalembert1, Lahoueri Amor1, Cécile Arnaud2, Oussama Charara3, Vincent Gajdos1, Véronique Hentgen3, Annie Kamdem4, Sylvie Nathanson4, Brigitte Bader-Meunier1, Isabelle Melki1, Isabelle Koné-Paut2, Pierre Quartier4, Loïc De Pontual1, Luu-Ly Pham1,1,1, J.Verdier hospital, Bondy, France, 2Béclère hospital, Créteil, France, 3R. Debré hospital, Paris, France, 4Necker hospital, Paris, France, 5CHIC, Créteil, France, 6A. Mignot Hospital, Versailles, France, 7A. Béclère Hospital, Clamart, France

Background: Coexistent auto-immune and inflammatory diseases (AID) and sickle cell disease (SCD) have been recently described in adults and children, however its frequency and physiopathology remain unclear (1–6).

Objectives: The aim of this study is the analysis of clinical and biological characteristics at AID diagnosis and the evolution under treatment in children with SCD.

Methods: Between May 1991 and March 2018, 35 of 3,800 SCD children diagnosed with AID in seven hospitals in Paris and suburb were analyzed in a retrospective survey.

Results: Thirty-five patients reported 44 AID: autoimmune liver disease (AILD, n=13), inflammatory bowel disease (IBD, n=7), juvenile idiopathic arthritis (JIA, n=6), systemic lupus erythematosus (n=5), autoimmune hemolytic anemia (n=3), Sjögren’s syndrome (n=2), histiocytic necrotizing lymphadenitis (n=2), vasculitis (n=2), myasthenia gravis (n=2), sarcoidosis (n=2), inflammatory uveitis (n=1), scleroderma/juvenile dermatomyositis (n=1). Median age at diagnosis was 10 [2–18] years. The mean delay between first symptom and diagnosis was 15.5 ± 29 months. The time of diagnosis was significantly longer for patients with JIA compared to other AID (63 versus 10 days, p=0.004). Sixteen patients (45.7%) had hypergammaglobulinemia > 20 g/L at diagnosis. AILD had a hypergammaglobulinemia at the time of diagnosis (30.0±L), with a statically significant decrease at the end of follow-up (18.2±L, p=0.0048). Among 21 patients (60%) treated with systemic steroids, it triggered vaso-occlusive crisis in 14 (66.7%), one acute chest syndrome, one transient ischemic attack. Thirteen of 35 patients (37.1%) were managed with biotherapy for AILD, well tolerated. Three patients (8.6%) underwent stem cell transplantation, one died of a cortico-resistant and multipolar graft versus host reaction, two were cured of both AILD and SCD. Nine severe infections were reported, four under steroids, five under biotherapy.

Conclusion: Diagnosis and therapeutic care of coexistent auto-immune and inflammatory diseases are difficult and challenging in children with SCD. Annual monitoring of inflammatory markers could be recommended to detect AILD earlier and prevent diagnostic delay in case of high ascension in SCD patients.

UVEITIS IN PEDIATRIC RHEUMATOLOGY: TERTIARY CENTER EXPERIENCE IN TURKEY

Zahide Ekiici Tekin1, Gulcin Otar Yener1, Ebru Nevin Çetin2, Selen Akbulut3, Selcuk Yüksel3,1 Pamukkale University Faculty of Medicine, Pediatric Rheumatology, Denizli, Turkey, 2Pamukkale University Faculty of Medicine, Ophthalmology, Denizli, Turkey

Background: Since pediatric uveitis is generally asymptomatic, the diagnosis and treatment may be mostly delayed. Severe complications and visual loss may be observed even at the initial visit. Pediatric uveitis is tend to be chronic, persistent, recurrent, and the management may be complex (1).

Objectives: The aim of this study is to report epidemiology, etiology, clinical features, management and the outcomes of non infectious pediatric uveitis at a tertiary pediatric rheumatology center in Turkey.

Methods: The clinical records of the patients with non infectious uveitis who were followed up by department of pediatric rheumatology and ophthalmology were reviewed, from January 2013 to June 2018, retrospectively. The inclusion criteria were as follows being age ≤ 16 years, following up at least 6 months in both the ophthalmology and pediatric rheumatology clinics. Uveitis was categorized anatomically according to the Standardization of Uveitis Nomenclature criteria (2).

Results: Of 37 patients (67 eyes), 45.9% were female. Mean age of onset was 8, 5 ± 4, 4 years (1.6 - 15.6), mean follow-up was 60 ± 42 months (6 - 191). The general features of uveitis were anterior, idiopathic, rare and bilateral in this study similar to literature (Table 1). The most common systemic diseases associated with uveitis were juvenile idiopathic arthritis (JIA). Two patients improved with local medications, while the remaining 35 patients required systemic treatments such as short-time (oral/i.v) corticosteroids (CS) in 94.5% of them, methotrexate (MTX) in 86.4%, azathioprine (AZA) in 5.4%, adalimumab (ADA) in 67.5%, tocilizumab (TCB) in 2.7%. In 26.1% of patients receiving ADA who did not respond to standard dose of ADA, we had to shorten the dosage intervals of ADA from every 2 weeks to every week. At least 1 ocular complication was observed in 83.7% of the patients, such as cataract, glaucoma, band keratopathy, synechiae, macular edema and retinal detachment. Four (10.8%) patients had moderate visual loss and 6 (16.2%) patients severe visual loss (3). The prevalence of surgery in our study was 18.9% for cataract and glaucoma treatment.

Conclusion: Diagnosis and management of uveitis in childhood is complicated. Despite the new medication options, the advancements in diagnosis and surgical techniques, the complications are still high. Usage of shorter dose interval of ADA may be an alternative to control of the disease in patients with unresponsive to standard dosage of ADA. However, large-scale clinical trials are required to assess the efficacy and safety of this treatment.

AB1072B
THE CONSEQUENCES OF THE PROVISIONAL PAEDIATRIC RHEUMATOLOGY INTERNATIONAL ORGANISATIONS JUVENILE IDIOPATHIC ARTHRITIS CLASSIFICATION CRITERIA

Vera Mars1, Joost F. Swart2, Gabriella Giancane3, Sytze De Roock2, Anne Estmann1, Marija Jelusic1, Etiestania Moreno Ruizaf, Jaime de Inocencio2, Jelena Vojinovic2, Agustin Remesala3, M Laday4, Rolando Cimaza2, A V. Cochino2, Inmaculada Calvo2, M Harjacek3, Nico Wulffraat2, Nicolino Ruperto3.

Background
Last year the International League of Associations for Rheumatology (ILAR) classification criteria for juvenile idiopathic arthritis (JIA), [1] were challenged by the provisional Paediatric Rheumatology International Trials Organisation (PRINTO) classification criteria.[2] Four disorders were proposed: (a) systemic JIA; (b) rheumatoid factor (RF)-positive JIA; (c) enthesitis/spondylitis-related JIA; and (d) early-onset antinuclear antibody (ANA)-positive JIA. Early-onset ANA-positive JIA is defined by: arthritis for ≥ 6 weeks, and early-onset (≤ 6 yrs), and presence of 2 positive ANA tests with a titre ≥ 1/160 at least 6 months apart with the exclusions of having systemic JIA, RF-positive arthritis, or enthesitis/spondylitis-related JIA.

Objectives
To evaluate the shifts from the original subtypes of JIA in the new disorder of early-onset ANA-positive JIA.

Methods
This study used data from the international PRINTO based registry regarding pharmacovigilance in JIA called Pharmachild.[3] For this analysis we used the data of 4,165 patients completely categorized following the ILAR’s category and therefore were not categorized as early onset ANA-positive JIA. This study used data from the international PRINTO based registry called Pharmachild. Of these 957, 2 patients were RF-positive, which is an exclusion criterion for early onset ANA-positive JIA.

Results
Table 1 shows the characteristics of all 4,165 patients according to the ILAR criteria. Of this final set of 4,165 patients, 1279 (30.7%) were ANA-positive and 957 (74.8%) classified into the PRINTO ‘early onset ANA-positive JIA’ category. Of these 957, 2 patients were RF-positive, which is an exclusion criterion for the ‘early onset ANA-positive JIA’ category and therefore were not categorized as early onset ANA-positive JIA. The female proportion was higher than in any ILAR subtype being 83.0%. This new category consists largely of 3 ILAR subtypes: persistent oligoarthritis (34%), extended oligoarthritis (25%) and RF negative polyarthritis (28%). Further studies on these provisional criteria are ongoing.

AB1072C
CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS. THE CORRELATION BETWEEN CAROTID INTIMA-MEDIA THICKNESS AND MARKERS OF INFLAMMATION TO DETERMINE PRE-CLINICAL ATHEROSCLEROSIS

Mustafa Armut1, Ruhan Düşündürtu1, Aysevur Pac Kisaarslan2, Gonca Kon2, Betül Sözen2, Ferhan Elmas3, Muammer Hakan Poyrazoglu4, Zubeyde Gunduz2.

1Erciyes University Faculty of Medicine, Pediatrics, Kayseri, Turkey; 2Erciyes University Faculty of Medicine, Pediatric Rheumatology, Kayseri, Turkey; 3Erciyes University Faculty of Medicine, Pediatric Radiology, Kayseri, Turkey; 4Zümrüt Kaplanoğlu Celebi University, Biostatistics, Izmir, Turkey

Background
Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. JIA is a heterogeneous group of disorders with different disease progression and prognosis. Cardiovascular...
moribidity and mortality are becoming major health concerns for children with inflammatory rheumatic diseases. Inflammation has been suggested to play an important role in the pathogenesis of both atherosclerosis and JIA.

Objectives: objective of this study was to determine carotid intima-media thickness (cIMT) in children with JIA and their correlation with JIA sub-type and markers of inflammation.

Methods: We included 112 patients (50 boys and 62 girls) with diagnosis of JIA for at least 6 months and 54 healthy control subjects (32 girls and 22 males). All children were had normal body mass index, blood pressure, lipids and blood glucose levels to exclude conventional risk factors.

Carotid ultrasound for evaluation of cIMT was performed by same radiologist who was blinded to the participants’ clinical and laboratory data. Patients datas were collected. We compared all cIMT values of patients and controls and investigated the relationship between inflammatory markers, disease status, periods and therapies.

Results: Our study showed that children with JIA had more increased cIMT values than controls. There was no correlation between disease subgroups, activity status, ANA, HLA-B27, RF positivity, WBC, ESR and CRP with cIMT. The cIMT values were not differences between patients used steroid, DMARD and biologic agents and non used. An increased active disease and total disease periods, decreased in mean platelet volume were determined as independent risk factors at increased of cIMT.

Conclusion: The study showed that the patients with JIA had more risks than healthy controls for cardiovascular diseases.

A RETROSPECTIVE COHORT STUDY OF IgG4-RELATED DISEASE IN IRISH PATIENTS

Aadil Al Ghaifi1,2, Aurelie Fabre3, Eamonn S. Molloy1, Al Nahda Hospital, Department of Medicine/Rheumatology, Muscat, Oman; 2St Vincent’s University Hospital, Rheumatology, Dublin, Ireland

Background: Immunoglobulin (Ig) G4-related disease (IgG4RD) is a novel clinical entity characterized by elevated serum IgG4 concentration and tissue orifice or tissue infiltration by IgG4-positive plasma cells.

Objectives: To describe the clinical presentations, laboratory features, imaging manifestations, histopathologic characteristics and treatments in a cohort of 38 patients with IgG4RD.

Methods: A retrospective study was performed at St. Vincent’s University Hospital. Clinical, laboratory, imaging and histopathologic data was retrieved from electronic records. All data were assessed using SPSS 24.0.

Results: Median age was 59 years with M:F ratio= 2.2:1. 29 patients (76.3%) had received steroid therapy and 19 (50.0%) had a commonest histopathologic pattern reported in 29 (76.3%) patients. Lymphoplasmacytic infiltration + Storiform fibrosis + Phlebitis without obliteration was the most frequently involved organ (17/38, (44.7%)). 55.3% had a systemic complaints that could be categorized as possible category. GI manifestations (followed by pancreatic) were the most frequent clinical presentation.

Conclusion: IgG4RD is a rare entity in Ireland and an inadequately understood condition overall. Further research is required to better understand the pathophysiology, clinical course and optimal treatment for IgG4RD.

REFERENCES

site preceded distant or systemic manifestations. Abnormal blood tests were common. Localised inflammatory nodules and paucinulitis in 88.88% especially in autoimmune disorders, vs. 90% systemic juvenile rheumatoid arthritis, 90.9% idiopathic orbital pseudotumor. 90% systemic lupus erythematosus, 90% sarcoidosis, human adjuvant disease, vasculitis, inflammatory bowel syndrome and inflammatory polyarthritis. 11.11% cases presented primarily with systemic autoimmune disorders.

**Conclusion**: Biomaterials and prostheses can provoke late-onset systemic autoimmune disorders fulfilling ASIA criteria, or present primarily local/regional inflammatory reactions that may eventually evolve into systemic autoimmune and/or granulomatous disorders which fall under ASIA.

**IDIOPATHIC ORBITAL PSEUDOTUMOUR: A CASE SERIES AND LITERATURE REVIEW**

Edna Amaya Cabrera, Sergio Corpas-Cruz, Veronica Gonzalez-Diaz, Gloria Martinez-Bonilla, Sergio Gutierrez-Ureña, Marisol Iniguez Soto. Hospital Civil Fray Antonio Alcalde, Reumatología, Mexico, Mexico

**Background**: Idiopathic orbital pseudotumor (IOP), also known as idiopathic orbital inflammatory syndrome is a benign, non-infective, inflammatory condition of the orbit without identifiable local or systemic causes. After Grave’s disease and lymphoproliferative disorders, orbital pseudotumor is the 3rd most common ophthalmologic disease of the orbit and account for approximately 8-11% of all the orbital tumors. Pathogenesis of orbital pseudotumor remains elusive but several lines of evidence point to immune-mediated processes as the likely underlying ocular mechanism. The etiology of orbital pseudotumor is unknown, but infection, autoimmune disorder, and aberrant wound healings have been put forward as possibilities. The ocular manifestations of orbital pseudotumor may include periorbital edema, erythema, proptosis, ptosis, diplopia and pain with eye movements.

**Objectives**: Describe clinical and demographic characteristics, most frequent diagnoses, immunological serology and treatments in patients with Orbital Pseudotumor.

**Methods**: We performed a retrospective cohort study of adult and pediatric patients with orbital pseudotumor diagnosis referred to the Department of Rheumatology of the Fray Antonio Alcalde Civil Hospital in Guadalajara, Jalisco, Mexico, from 2012-2018. We collected data that included demographic data of the patient, symptoms, laboratory data that included antibodies, management plans and results.

**Results**: A total of 20 patients diagnosed with orbital pseudotumor, with a mean age of 42±18.5 years, 3 pediatric patients and 65% women. Clinical manifestations were: 90% unilateral, 90% lacrimal gland involvement, 75% ptosis/proptosis, 40% conjunctival hyperemia, 55% ocular pain, 20% decreased visual acuity, 15% headache and no optic nerve involvement. The findings were similar between adults and children. The most common diagnoses were: 40% idiopathic, 10% orbital cellulitis, 10% granulomatosis with polyangitis and 5% each of the following: systemic lupus erythematosus, Sjögren’s syndrome, dacrocyoadenitis and myositis due to IgG4, Kimura’s disease, Mikulicz, meningioma and cavernous sinus aneurysm. All patients underwent excisional biopsy, and the histopathological report showed the following findings: 40% non-specific chronic inflammation, 30% non-specific chronic dacryoadenitis, 5% granulomatous inflammation/vasculitis, 10% chronic sclerosing inflammation-IgG4 and 15% others. Only 9 of the 20 patients underwent immunological serology, finding positivity in: 15% for c-ANCA, 10% PR3, 5% p-ANCA, 10% MPO, 5% ANAs and 10% elevated blood levels of IgG4. Regarding treatment, 100% received glucocorticoids, and received immunomodulatory therapy: 20% received azathioprine, 5% mycophenolate mofetil, 20% methotrexate, 15% cyclophosphamide IV, 15% rituximab and 25% received no other medication.

**Conclusion**: The orbital pseudotumor might be the first manifestation of an autoimmune or inflammatory disease, the early and correct diagnosis is necessary to avoid permanent sequelae.

**TREATMENT REVIEW OF ADULT-ONSET STILL’S DISEASE IN A TERTIARY HOSPITAL**

María Dolores Arvia Duran, Clara Aguila Clos, Lara Mendez, Isabel Madronal García, Marina Gomez Vargas, Alberto Ruiz Roman, Esteban Rubio Romero, Juan Povedano Gomez. Hospital Universitario Virgen del Rocio, Sevilla, Spain

**Background**: Adult-onset Still’s disease (AOSD) is a rare systemic inflammatory disorder of unknown aetiology, and approximately 60% or 70% of the patients can develop a chronic polyphasic form of the disease or a chronic polyarthritis. Due to the rarity of this disease, the treatment of AOSD is not based on a controlled study, but in the experience based on real cases.

**Objectives**: Describe the different treatments employed in a patient cohort diagnosed with adult-onset Still’s disease (AOSD).

**Methods**: Descriptive, retrospective study of patients treated in our Hospital (2008-2018), diagnosed with AOSD according to the classification criteria of Yamaguchi. The data were achieved by the review of the clinical records.

**Results**: Twenty-four patients (15 women), average age of 41±13 years, were included. Two women, with presentation on the symptoms at 8 and 3 years old, first diagnosed with systemic juvenile idiopathic arthritis (S-JIA), and then with AOSD. The initial treatment was based in non-steroidal anti-inflammatory drugs (96%) and glucocorticoids (0.5-1 mg/kg/day) (96%) for symptom control, with the necessity to add oral or subcutaneous methotrexate at a dose of 15 mg per week in 13 patients (54%). Only two patients used acetylsalicylic acid as initial treatment, with no improvement.

Five patients used also biological treatments with a standard doses, with the necessity to add oral or subcutaneous methotrexate at a dose of 15 mg per week in 13 patients (54%).
inhibitors (baricitinib and tofacitinib, respectively), one patient with anti-TNF (infliximab) and another one with anti-CD20 (rituximab).

**Conclusion:** In general, our results match what is published in the literature.

For the treatment of AOSD has been used high doses of ASA (4g/day) or NSAID. However, the required doses (with their respective adverse effects), its limited responses and the frequent relapses after its suppression make difficult to maintain it. Nowadays, the systemic glucocorticoids are our first choice (0.5 to 1 mg/kg/day). A high average of our patients have a positive response with it, but in a 54% of the cases were necessary to add methotrexate or others DMARDs because of a partial response with steroids.

In the physiopathology of the AOSD there is an increase of pro-inflammatory cytokines, as the tumor necrosis factor, IL-1 e IL-6. The use of therapies that inhibit these molecules (anti-TNF, anakinra or canakinumab as a diliy, or tocilizumab or sarilumab as anti IL-6) is being a progress.

The inhibitors of IL-1 can be more effective for systemic manifestations, while the inhibitors of IL-6 are for articular and systemic affection. The TNF inhibitors should be used for the articular affection only. In our patient cohort there is no patient with anti-IL1, a patient in clinical remission with anti-TNF and another one with anti-IL-6. Prospective studies with a higher number of patients is necessary to define better the AOSD treatment.

IDIVAL: Rheumatology and Ophthalmology, Santander, Spain

**Background:** Graves’ orbitopathy (GO) is the most common and important extrathyroidal manifestation of Graves’ disease. Corticosteroids and conventional immunosuppressors are not always effective or well tolerated. The IL-6 receptor antibody tocilizumab (TCZ) has demonstrated efficacy in the treatment of this pathology.

**Objectives:** To assess the efficacy of TCZ in refractory thyroid associated orbitopathy (TAO) due to Grave’s disease.

**Methods:** Multicenter study of 46 patients with TAO refractory to conventional immunosuppressive therapy.

**Results:** We studied 46 patients (85 eyes) (37 women/9 men); mean age at diagnosis 49.2±11.8 years. Besides oral corticosteroids, before the onset of TCOZ patients had been treated with pulses of iv methylprednisolone (42), radioactive iodine (4), methotrexate (2) and other drugs (selenium in 11 cases, methimazole in 8, lefumodine in 1 and azathioprine in 1). 7 patients underwent ocular urgent decompressive surgery.

According to the classification of severity of the EUGOGO group (European Group on Graves’ Orbitopathy) using the clinical activity score (CAS), before TCZ onset patients whose data were available had severe (27 eyes) or moderate (34 eyes) disease. Moreover, patients presented exophthalmos (53 eyes), strabismus (37 eyes), muscle fibrosis (38 eyes) and dysthyroid optic neuropathy (10 eyes). TCZ was used in monotherapy (43) or combined with methotrexate (2) or azathioprine (1) at 8 mg/kg iv/w (41) or 162 mg/sc/w (5). TCZ yielded rapid and maintained improvement in all ocular parameters as shown in Figures.

**Conclusion:** TCZ appears to be a useful and secure option in GO treatment.

**AB1078**

**RED CELL DISTRIBUTION WIDTH (RDW) – A NEW POSSIBLE DISEASE ACTIVITY PREDICTOR IN RELAPSING POLYCHONDRITIS**

Bianca Balan1, Roxana Ioana Gutu2, Felicia Mustătea3, Ioana Felea3, Ileana Filipescu1, Cristina Pântilî1, Liliana Bene2, Simona Rednic1, Laura Dăian1, County Emergency Hospital Cluj-Napoca, Rheumatology, Cluj-Napoca, Cluj, Romania; County Emergency Hospital Cluj-Napoca, Immunology, Cluj-Napoca, Cluj, Romania

**Background:** Relapsing polychondritis (RP) is a rare condition defined by recurrent inflammation of cartilaginous tissue and systemic manifestations. Biomarkers for RP diagnosis and assessment of disease activity, damage and prognostic in clinical practice are currently lacking. Red blood cell distribution width (RDW) is an index of erythrocyte size variation depicting...
anizocytosis. RDW is routinely assessed, is not influenced by infections and its standard deviation (RDW-SD) does not depend on medium corpuscular volume. Recent studies showed an increased RDW in various autoimmune diseases (systemic lupus erythematosus, Sjogren’s syndrome, rheumatoid arthritis, systemic vasculitis), correlating with inflammatory markers and disease activity. Also, the RDW seen in solid tumors and hematological cancers has prognostic value.

**Objectives:** To assess the RDW-SD in RP patients, its relation with the disease activity and with the presence of neoplasia

**Methods:** We performed a retrospective study on the patients diagnosed with RP in a tertiary Rheumatology department between January 2017 and January 2019, using the Atlasmed data management system of the institution. The concomitant diseases and the inflammation parameters were recorded. The RP activity was measured using RPDAl (relapsing polychondritis disease activity index). The correlation between variables were calculated using GraphPad Prism.

**Results:** We identified 20 patients, median age 59.04 years (range 38-81), with a male-to-female ratio of 1:5.66. An associated autoimmune disease (Sjogren syndrome, Hashimoto thyroiditis, systemic lupus erythematosus, rheumatoid arthritis, psoriatic arthritis) was found in 85% of patients. Moreover, 40% of the patients had various types of solid or hematologic neoplasia, including myelodysplastic syndrome. An elevated RDW-SD was seen in 90% of RP patients. The average RPDAl was 10.6 points. RDW-SD significantly correlated to RPDAl (p=0.0012). Of the inflammatory parameters, RDW-SD was not found to be related to ESR and CRP. RDW-SD increased with age, but no correlation was found between RPDAl and age. All patients with neoplasia had abnormally high RDW-SD. Nevertheless, RDW-SD was not significantly different in RP patients with or without neoplasia (Mann-Whitney test, p=0.56).

**Conclusion:** RP was frequently associated with other autoimmune diseases, but also with neoplasia. The positive correlation of RDW-SD and RPDAl in RP suggests a possible new, clinically employable, biomarker of disease activity.

**AB1079 CHECKPOINT INHIBITOR-ASSOCIATED ARTHRITIS: PHENOTYPES AND CYTOKINE ASSOCIATIONS**

Karmela Kim Chan1,2, Gregory Vitone1, Sara Shanaj3, Aidan Tirpack1, Jackie Finik1, Laura Donlin4, Deepak Rao5, Caroline Benson1, Vivian Bykerk1,2, Karmela Kim Chan1,2, Gregory Vitone1, Sara Shanaj3, Aidan Tirpack1, Jackie Finik1, Laura Donlin4, Deepak Rao5, Caroline Benson1, Vivian Bykerk1,2, Dana Orange2, Michael Brenner4, Susan Goodman1,2, Anne Bass1,2, 1Hospital for Special Surgery, Rheumatology, New York, United States of America; 2Weill Cornell Medical College, Medicine, New York, United States of America; 3Hospital for Special Surgery, Research Institute, New York, United States of America; 4Bristan and Women’s Hospital, Rheumatology, Boston, United States of America; 5The Rockefeller University, New York, United States of America

**Background:** Immune checkpoint inhibitors (CI) have revolutionized cancer management, but can also cause immune-related adverse events. Five percent of CI-treated patients develop inflammatory arthritis, but it is poorly defined phenotypically and immunologically.

**Objectives:** To characterize phenotypes of CI-associated arthritis, and compare cytokine levels in these patients to rheumatoid arthritis (RA) and osteoarthritis (OA) controls.

**Methods:** Patients referred for CI-associated arthralgia or arthritis were prospectively enrolled in an institutional registry. Serum was collected when patients underwent phlebotomy for a clinical indication. We used a Luminex Human Magnetic Assay to measure levels of IL-1β, IL-2, IL-6, IL-8, IL-10, IL-12, IL-17, TNF, IFN-γ, PD-L1, CCL2, CXCL2, CXCL13, OSM, CCL20, GM-CSF, CXCL11 in CI-treated patients, and in stored serum from 7 RA patients (matched for medication, age, sex, CDAI) and 4 OA patients (age, sex matched). All comparisons were planned a priori.

**Results:** Thirty-six patients were enrolled 5/1/18-1/25/19. Median [IQR] age was 67[58-78], 18(50%) were female, 14(39%) were smokers and 13 (36%) had melanoma. Twenty-two (61%) were on anti-PD1 or PD-L1 monotherapy, and the remainder were on combination CI. Phenotypes included 1. Small joint involvement in 17(47%), 2. Exclusively large joint involvement in 6(17%), 3. Arthralgia without arthritis in 9(25%), and 4. Polymyalgia rheumatica in 4(11%). In all, 7(19%) had concomitant tenosynovitis or enthesitis, mostly accompanying large joint arthritis or arthralgia.

TOCILIZUMAB FOR REFRACTORY DYSTHYROID MYOPATHY (RDM) : A MONOCENTER OBSERVATIONAL STUDY OF 8 PATIENTS

Philip Bielefeld1, Florian Baudin2, Julie Blanc2, Alain Brion2, Suzanne Mories-Martin1, Romain Bouvet1, Hervé Devillers1, ‘University Hospital, internal medicine and systemic diseases, Dijon, France; 2University Hospital, ophthalmology, Dijon, France

Background: Dysthyroid myopathy (DM) refers to Graves’ ophthalmopathy (GO) in 90% of the cases but can also be observed with hypothyroidism, and is responsible for orbital fat and muscles inflammation. In those patients with euthyroidism and no thyroid receptor antibody, a strong argument for DM can be the aspect of the extra ocular muscles. In myosit- is of other causes, muscle insertions are increased in size. In DM, the insertions are respected and not increased in volume in magnetic reso- nance imaging. This was the case of our eight patients.

Objectives: To describe the efficacy of Tocilizumab (TCZ) in RDM in 8 patients.

Methods: We conducted a monocenter study of 8 patients with RDM refractory to conventional treatment scheme

All patients have been treated following the EUGOGO (European Group on Graves’ Orbitopathy) scheme, which consists in weekly infusions of 300 mg prednisolone (4 to 6) followed by weekly infusions of 250 mg (4 to 6). One patient had received before oral prednisolone, which is known to be less effective and no other immunosuppressive therapy.

The aim was to reduce the clinical activity score (CAS) of the disease to be less effective and no other immunosuppressive therapy.

Results: We studied 8 female patients (16 eyes); mean age at diagnosis 50.2±10.9 years and the mean disease duration was 5.4±6.4 years.

All patients had normal thyroid function at diagnosis. Three patients had a mean age at diagnosis 64,37±9,37 years.

We studied 8 female patients (16 eyes); mean age at diagnosis 64,37±9,37 years.

All patients had normal thyroid function at diagnosis. Three patients had a mean age at diagnosis 64,37±9,37 years.

After a mean of 4 pulses (extremes 1 to 7), all patients experienced improvement with TCZ withdrawal in all due to complete remission in 3 and regression in ocular inflammation in 5. Unfortunately, one patient relapsed two months after the 6th TCZ infusion, despite of initial com- plete remission and was treated with 4 weekly infusions of rituximab at 375 mg/m 2 with a very good response three months later. Only one

patient experienced a severe anal abscess after the first TCZ infusion leading to treatment interruption, but with a good improvement of DM. Improvement of ocular parameters with TCZ therapy. Data are expressed as mean±SD or median [IQR]. (VA : visual acuity; IOP : intra ocular pressure; CAS : clinical activity score)

Before tocilizumab after tocilizumab

VA 0.7 (0,3-1) 0.9 (0,7-1)

IOP 26.5 +/-7.7 21,1 +/-13

CAS 4.25 +/- 1.28

Conclusion: TCZ seems to be effective in RDM, as previously reported. In case of ineffectiveness or relapse, rituximab may be effective as well. This questions us about a new treatment scheme, which patients could benefit from biotherapies alone for a better and quicker efficiency?

A COMPARATIVE STUDY ON THE FEATURES OF THE SPINAL INVOLVEMENT IN SAPHO SYNDROME

Xiaodi Deng1, Shuang Gao2, Lihua Zhang3, Le Song3, 1Peking University Third Hospital, Department of Rheumatology and Immunology, Beijing, China; 2Peking University Third Hospital, Beijing, China; 3Peking University Third Hospital, Department of Radiology, Beijing, China

Background: SAPHO syndrome is a rare disease with the typical involve- ment of the anterior chest wall. The spinal involvement is more often than we thought and less understood by us.

Objectives: To assess the clinical and imaging features of the spinal involvement in SAPHO syndrome.

Methods: Patients diagnosed with SAPHO syndrome in Peking University Third Hospital from 2006 to 2018 were recruited. Patients were divided into spinal involvement group and non-spinal involvement group. Patients with AS (ankylosing spondylitis) were recruited as control group. Their clinical data, laboratory data and imaging data (CT, MRI and radionuclide imaging) were collected and were compared. All the patients with SAPHO syndrome were followed up regularly.

Results: Totally 46 SAPHO patients were included (17 male and 29 female) and 34 patients (73.9%) had spinal involvement. The mean age was 50.2±10.9 years and the mean disease duration was 5.4±6.4 years. 50 patients with AS were also included. Compared with non-spinal involvement group, the age at disease onset in spinal involvement group was older, the disease duration was longer; the CRP elevation was more often and the anterior chest wall involve- ment was less often (table 1).

In spinal involvement group, the thoracic spine was most commonly involved and the vertebral inflammatory changes including bone marrow edema were often seen. These patients were more likely to suffer from cervical spine involvement, endplate inflammation and spondyloiscits (table 2).

All the SAPHO patients with spinal involvement were followed up. 30 patients received NSAIDs plus DMARDS/biologics and the symptoms improved. Reexamined imaging data of 10 patients were available and the spinal involvement became better.

Conclusion: 73.9% of SAPHO patients had spinal involvement and they were more likely to suffer from cervical spine involvement, endplate inflammation and spondylodiscitis. The combination of NSAIDs and biologics/DMARDs were helpful to improve the symptoms.

IATROGENIC INFECTIOUS SPONDYLODISCITIS: 6 CASES

nim dhahir, Maroua Slouma, Leila Metoui, Souha Hannachi, Imen Gharsallah, Bassem Louzir. Military Hospital of Tunis Tunisia, Internal Medicine, Tunis, Tunisia

Background: The increasing proportion of iatrogenic spondylodiscitis (SD) is a prominent feature of infectious DS in recent decades

Objectives: To describe iatrogenic clinical, aetiological and evolutive SD features.

Methods: We report 6 cases of iatrogenic DS collected in our department in 2001-2012 period.

Results: All patients were male. The average age was of 49 (35 to 68 years). Four cases of SD were caused by direct inoculation (surgical in 3 cases, chemonucleolysis in 1 case) and 2 cases of hematogenous SD from an initial outbreak. The seat of infection is lumbar in all cases. Spinal pain is almost constant. The admission examination noted arexia in 5 cases. A biological inflammatory syndrome was present in 5 cases and hyperleucocytosis in 2 cases. The bacteriological investigation was able to isolate a methicillin-sensitive Staphylococcus aureus (SAMS) and a proteus mirabilis in one patient and SAMS in another. The radiological assessment made it possible to objectify a para vertebral abscess in 5 cases and an epileptis in 1 case. The evolution was favorable in all cases under antibiotic therapy of average duration of 4.5 months and immobilization of the spine by corset.

Conclusion: The detection of an anaerobic germ causing infectious spondylodiscitis should search for an iatrogenic portal chronologically and anatomically close to the vertebral disc infection.

IN A FAMILIAL MEDITERRANEAN FEVER PREVALENT REGION, ARE FAMILIAL MEDITERRANEAN FEVER AND BEHÇET’S DISEASE ASSOCIATED?

Ozgur Alparslan1, Bugra Har Efe2, Yeltekin Derriie2, Sedral Ugurlu2, Gaziosmanpasa University, Tokat, Turkey; 1University of Istanbul-Cerrahpasa, Istanbul, Turkey; 2Sivas Cumhuriyet University, Sivas, Turkey

Background: The co-existence of Familial Mediterranean Fever (FMF) and Behçet’s disease (BD) has been questioned. There have been a variety of claims on a common pathogenesis.

Objectives: We intended to report the prevalence of Familial Mediterranean Fever (FMF) and Behçet’s disease (BD) and comorbidity ratio of these two diseases in Sivas, Turkey, a city where FMF is known to be very high.

Methods: Seventy-two primary schools in the center of Sivas participated in the study. A total of 14881 randomized sample children from 6th, 7th, and 8th grades, and also 985 of them with their parents (n: 978) were interviewed. During these interviews, the family tree up to second degree relatives was drawn. The presence of a diagnosis of FMF or BD was questioned. The ones who have a diagnosis were confirmed by contacting the medical centers. The ones who were suspected of a disease were further investigated at Sivas Cumhuriyet University Medical Faculty, Family Medicine Outpatient unit. For each disease a disease related history, physical examination, eye examination and pa rethery test for BD were performed when needed.

Results: 985 students, 978 mothers, 953 fathers and 1876 relatives (4792 in total) were included in the study. Only 30 (0.6%) of the sample was diagnosed with FMF, and 3 (%0.06) was diagnosed with BD. One of them had concomitant FMF diagnosis.

Table. FMF symptoms within the last year

<table>
<thead>
<tr>
<th>Symptoms</th>
<th>N</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abdominal Pain</td>
<td>20</td>
<td>66.7</td>
</tr>
<tr>
<td>Fever</td>
<td>23</td>
<td>76.7</td>
</tr>
<tr>
<td>Joint Pain</td>
<td>8</td>
<td>26.7</td>
</tr>
<tr>
<td>Chest Pain</td>
<td>10</td>
<td>33.3</td>
</tr>
<tr>
<td>Muscle Pain</td>
<td>7</td>
<td>23.3</td>
</tr>
<tr>
<td>Erythema like erysipealae</td>
<td>5</td>
<td>16.7</td>
</tr>
</tbody>
</table>

Conclusion: The prevalence of FMF in Sivas is higher than Turkey’s prevalence; however, BD prevalence was found very low. According to these findings, it is not easy to conclude that these two diseases share a similar background of pathogenesis.

PECULIARITIES OF ERYTHEMA NODOSUM ASSOCIATED WITH SARCOIDOSIS AND BACTERIAL-VIRAL INFECTION IN RHEUMATOLOGIST PRACTICE

Oltu Egorova, Boris Belov, Svetlana Glukhova, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Erythema nodosum (EN) is a nonspecific immune inflammatory syndrome, which is a septal panniculitis without vasculitis. Often EN acts as one of the symptoms of systemic pathology, which can cause late diagnosis and, accordingly, the appointment of adequate therapy. Objectives: to study clinical, laboratory and radiological data in EN in the acute form of sarcoidosis (SAR) and EN associated with bacterial and viral infection in patients sent to the rheumatology center.

Methods: The study included 312 patients (61 men and 251 women, age 35.4 ± 8.2 years) who applied to the clinic with a referral diagnosis of FMF and EN associated with bacterial and viral infection in patients sent to the rheumatology center.

Results: The study included 312 patients (61 men and 251 women, age 35.4 ± 8.2 years) who applied to the clinic with a referral diagnosis of FMF and EN associated with bacterial and viral infection in patients sent to the rheumatology center.

Conclusion: The prevalence of FMF in Sivas is higher than Turkey’s prevalence; however, BD prevalence was found very low. According to these findings, it is not easy to conclude that these two diseases share a similar background of pathogenesis.

OSTEO-ARTICULAR MANIFESTATIONS OF ADULT ONSET STILL'S DISEASE: EXPERIENCE OF THE RHEUMATOLOGY DEPARTMENT OF THE UNIVERSITY HOSPITAL OF CASABLANCA

Zakaria El Ouafi, Saadia Janani, Kawtar Nassar, Ouafa Niknisi. CHU Ibn Rochd, Department of Rheumatology, Casablanca, Morocco

Background: Adult onset Still's disease (AOSD) is a rare condition characterized by four cardinal signs: fever, arthralgia/arthritis, rash, and neutrophil leukocytosis. The absence of specific criteria is currently compensated by pathophysiological advances, leading to the introduction of a promising new therapeutic arsenal represented by biotherapies.

Objectives: The aim of this study was to compare the profiles of this disease in our latitudes with data from foreign literature; and to study the most recent data concerning the pathophysiology and treatment of this disease.

Methods: We conducted a retrospective study of hospital files from January 1993 to October 2018. The diagnosis is retained according to Yamaguchi criteria. Analysis was performed using IPSS.

Results: 17 patients were selected. The sex ratio was 0.54, and the average age was 31.5 years. At the time of diagnosis, fever was found in 94% of cases, arthralgia/arthritis in 100% of cases, and rash in 65% of cases. Concerning rheumatic features, the most frequently affected joints were: wrists (87%), knees (73%), shoulders (67%), proximal interphalangeal (62%), elbows and ankles (60%), hips (47%). The involvement of the hands is dominated by the proximal interphalangeal and metacarpophalangeal (45%). Distal interphalangeal involvement is observed in 23% of cases. Cervical spine involvement is noted in 50% of cases. Biologically, 88% of patients had neutrophil leukocytosis. Ferritinemia was increased in 79% of patients. The glycosylated fraction of ferritin was measured at diagnosis in 47% of patients, of whom 63% had a fraction ≤ 20%. Elevated transaminases were found in 47% of cases. Therapeutically, 100% of patients received corticosteroids; 65% methotrexate; and 29% biotherapies (tocilizumab,akinlimab, infliximab, adalimumab). The evolutionary profile was exploitable in 13 patients, of whom 10 were in complete remission.

Conclusion: Our data are consistent with those in the literature. Some peculiarities emerge concerning the articular features. From 3 series of literature and ours, totaling 135 cases, it appears that the most frequent locations are: wrist (82%), knees (70%), elbows (46%), ankles (45%), proximal interphalangeal (44%),shoulders (42%) and metacarpophalangeal (42%). The pathogenesis of AOSD seems to lie at the crossroads between auto-inflammatory diseases and lymphohistiocyte activation, resulting from a multifactorial predisposition. The central role of innate immunity, the clinical presentation, and the efficacy of blocking the IL-1 pathway comparable to that observed in "monogenic inflammasomopathies" justify the reclassification of AOSD among polygenic auto-inflammatory syndromes.

OSTEO-ARTICULAR MANIFESTATIONS OF SARCOIDOSIS: ABOUT 13 CASES

ACHEK Mohamed Amine EL, Khadjia Baccouche, Amel Farhat, Nejla El Amri, Hela Zeglaoui, Elyes Bouajina. Farhat Hached University Hospital, Rheumatology, Sousse, Tunisia

Background: Sarcoidosis is a systemic disorder of unknown etiology, affecting the respiratory tract and the lymphatic system with predilection. It is an ubiquitous condition whose clinical phenotype is very diverse.

Objectives: To detail the epidemiological, clinico-biological, therapeutic and evolutionary features of osteoarticular forms of sarcoidosis.

Methods: This is a monocentric, descriptive retrospective study conducted over a 17-years period [2002-2018] involving 13 patients diagnosed with sarcoidosis with osteoarticular manifestations at the department of Rheumatology at Farhat Hached University Hospital in Sousse.

Results: 13 patients with osteoarticular manifestations were studied; this is indicative of the disease in 8 cases (61.5%). The sex ratio was 0.23 with a mean age of 42.38 years and a diagnostic delay of 12 months. In 77% of cases, inflammatory arthralgia was noted, Löfgren syndrome (30.7%), chronic polyarthitis (30.7%), phalanges cystoid ostitis (15.4%) and no cases of monoarthritis. The extra articular manifestations found were: Adenomegaly (92.3%), lung (77%), cutaneous (38.5%) (including 80% erythema nodosum), neurological (30.7%) (Aseptic meningitis and convulsion), ocular (23%) (chorioretinitis, keratoconjunctivitis and retro-bulbar optic neuritis), cardiac (15.4%), and biological hepatitis (7.7%). In the biology, a biological inflammatory syndrome was found in 30.7% with a mean sedimentation rate of 31.07 in the 1st hour, an average CRP of 9 mg/L, cholestasis and cytolysis found in 15.4% and 7.7% respectively. No Hypercalcemia was noted. The value of the conversion enzyme was high in 5 out of 6 patients who were dosed with an average of 71 µL. In imaging, sarcoidosis was destructive in 4 cases; A multifocal osteonecrosis, Algodystrophy of the two hips and two cases of bullos cystoid ostitis of phalanges.

Conclusion: The osteo-articular involvement of sarcoidosis is polymorphic, which can reveal the disease or enamel its evolution.

Disclosure of Interests: None declared
Background: Familial Mediterranean fever (FMF) is the most common hereditary inflammatory disease characterized by recurrent attacks of fever and serositis. The most devastating complication of FMF is amyloidosis, leading to chronic renal failure (CRF). The amyloid protein may accumulate in many tissues including the cartilage, particularly in the kidneys. Sonographic femoral cartilage thicknesses (FCT) was evaluated in many chronic rheumatic diseases and was shown to be thinner than healthy individuals.

Objectives: The aim of this study was to determine FCT in FMF patients and healthy individuals and to assess the relationship of FCT with the development of amyloidosis and clinical features.

Methods: Patients diagnosed with FMF according to the Tel-Hashomer criteria were included in the study. Patients with trauma and other inflammatory disease and patients with a history of knee operation were excluded. Femoral cartilage thickness of both knees was measured with a 7-12 MHz linear probe in maximum knee flexion. Three mid-point measurement were obtained from each knees: lateral femoral condyle (LFC), intercondylar area (ICA) and medial femoral condyle (MFC). Clinical characteristics of the patients including disease duration, medications, comorbid conditions, amyloidosis, CRF, FMF gene mutation, arthritis, sarcroilitis, PRAS score and physical activity scores were recorded. Descriptive analysis was performed for all parameters. The Mann-Whitney U test and Spearman’s correlation coefficient were used in statistical analysis.

Results: A total of 45 patients with FMF (35 women, 10 men) and 20 age-sex-BMI matched controls (14 women, 6 men) were enrolled in this study. The mean age of the patients and controls were 38.2 (SD:12.2) and 37.5 (SD:8.5) years, respectively. Amyloidosis occurred in 7 patients (15.6%), CRF in 3 (6.7%), sarcroilitis in 10 (22.2%) and arthritis in 16 (35.6%). Disease activity was mild in 48.9%, moderate in 20% and severe 22.2% of the patients. The mean FCT in centimeters values in the FMF and control groups were as follows: on the right side LFC 0.19 (SD:0.03) and 0.22 (SD:0.05), ICA 0.23 (SD:0.05) and 0.24 (SD:0.06), MFC 0.20 (SD:0.04) and 0.24 (SD:0.06); on the left side LFC 0.19 (SD:0.03) and 0.21 (SD:0.03), ICA 0.22 (SD:0.05) and 0.24 (SD:0.06), MFC 0.19 (SD:0.03) and 0.22 (SD:0.04). Patients with FMF had decreased cartilage thickness at the lateral condyle of both knees (p<0.05) and medial condyle of the left knee (p<0.05) compared with controls. FCT measurements were similar in patients with or without arthritis, sarcroilitis, amyloidosis and CRF. Physical activity scores were significantly correlated with the left LFC (r=0.309). Total protein in 24-hour urine showed a highly negative correlation with left LFC (r=-0.718).

Conclusion: These findings suggest that patients with FMF have decreased FCT compared with controls. There is no significant relationship between the FCT and amyloidosis, it has significant relation with proteinuria level.

Disclosure of Interests: Halise Hande Gezer: None declared. Didem Erdem: None declared, Sevtap Acer Kasman: None declared, Hatte Sule Bakiçloglu: None declared, Mehmet Tuncay Duruž Grant/research support from: Abvie, Speakers bureau: Novartis, AMGEN, Abdi Ibrahim, liko

Background: Familial Mediterranean fever (FMF) is known as the most common monogenic autoinflammatory disease. Its prevalence is reported high from the eastern Mediterranean areas (1). The disease is characterized by episodes of fever, serositis, arthritis, renal complications and other different clinical manifestations (2).

Objectives: Here, we aimed to present our data of our 139 FMF patients for demonstrating the demographic and clinical features of the study group from North-western part of Turkey.

Methods: A total of 139 FMF patients who were diagnosed and treated in the department of Internal medicine/Rheumatology, Sakarya University (North-western area of Turkey) were included in the study and the demographic and clinical characteristics of the patients were examined.

Results: The mean age of the patients was 39.02 ± 11.3. Male gender was 42 (30.2%) and female gender was 97 (69.8%), 107 (77%) of patients had fever and 32 (23%) had no history of fever. 127 (91.1%) patients complained about peritonitis, 27 (19.4%) patients had pleuritic pain, 19 (13.7%) patients had erysipelas like erythema and 53 (38.1%) patients had arthritis attack. 34 (24.5%) patients also had sacroiliitis. The ratio of resistance of treatment response to colchicine drugs that can be available in Turkey (Colchicum disper t.), 6 (4.3%) was determined. Interestingly these patients responded to the colchicine drugs available from some other countries from Europe (as Colchicine-opocalcium and Colchicina-lirca®). None of our patients needed anti-IL1 therapies. The rate of amyloidosis was 5 (3.6%).

Conclusion: FMF is a disease with high morbidity and mortality, 95.7% of the patients in our region have response to colchicine drugs which is available in our country. The remaining patients have also responded to colchicine available from some other countries. None of our patients had anti-IL1 therapies.

Background: Deficiency of adenosine deaminase 2 (DADA2) is a recently identified cause of early onset polyarteritis nodosa and stroke: a multicentre international study. Ann Rheum Dis 2017; 76:

Results: There was no statistically significant difference between the two groups in terms of age or sex (respectively p=0.189 and p=0.585). There was no difference between the Behçet’s patients and healthy volunteers in the qualitative analysis on capillary density, capillary visibility, aneurism, hypocapillagomulbinema and cytopenia.

Objectives: To present the clinical cases of two Brazilian siblings with early stroke episodes carrying a homozygous CECR1/ADA2 mutation.

Methods: Chart review of clinical data, laboratory tests and mutation analysis.

Results: The index case is a 7-year-old boy who presented to the emergency unit with right lower limb weakness, rhyme deviation and palpebral ptosis, associated with recurrent and intermittent fever, mood change and hypertension. The physical exam revealed drowsiness, lateral and vertical ocular paresis, diplopia, facial palsy, and bilateral ataxia. The brain MRI showed acute left mesencephalic small vessel lacunar stroke, previous right mesencephalic subacute stroke, and cerebellar cavity related with anterior cerebellar artery segmental narrowing. Laboratory tests revealed increased inflammatory markers and anemia. Autoantibodies and viral screening were negative. Renal ultrasound showed a pattern of low resistance in the intrarenal arteries bilaterally. At this time, he was diagnosed as polyarteritis nodosa (PAN). Despite of adequate treatment (cyclophosphamide and corticosteroids), two new stroke episodes occurred at left head of caudate and right thalamus. His brother, a 9-year-old healthy boy at that time, had a previous history of ischemic stroke when he was 4 years old, after receiving a vaccine, with complete recovery.

Conclusion: ADA2 should be suspected in patients with PAN-like phenotype and history suggestive of an inherited disease (e.g.: affected siblings and consanguineous parents) or resistance to conventional treatment.

---

Background: Behçet’s disease is a chronic, recurrent and systemic vasculitis that may affect veins and arteries at all diameters. Small vessel involvement is responsible for most of its pathological signs.

Objectives: We aimed to compare the nailfold capillaroscopy findings of Behçet’s patients to a healthy control group and examine the relationships, as well as revealing the relationships with the sub-type, activity and other characteristics of Behçet’s disease.

Methods: We conducted a cross-sectional analysis of 153 patients with Behçet’s disease and 165 healthy volunteers in a single center. The capillaroscopic findings of the 2nd-5th fingers of both hands of the participants in the Behçet’s patients and control groups were included in the analysis. Capillaroscopic findings were evaluated by two different experts who were experienced in this field by using the scoring at Atlas of Capillaroscopy in Rheumatic diseases by Maurizio Cutolo.

Results: There was no statistically significant difference between the two groups in terms of age or sex (respectively p=0.189 and p=0.585). There was no difference between the Behçet’s patients and healthy volunteers in the qualitative analysis on capillary density, capillary visibility, aneurism, hypocapillagomulbinema, cytopenia, capillary tortuosity, capillary enlargement and presence of avascular areas (p values respectively: 0.610, 0.147, 0.481, 0.057, 0.514 and 0.110). In the Behçet’s patients, bushy capillaries (24.2%, 37/153), capillary dilatation (32%, 49/153) and microhemorrhage (39.2%, 60/153) rates were significantly higher than those in the healthy control group (p<0.001). In the quantitative analysis, total capillaroscopy score was significantly higher in the Behçet’s patients than those in the healthy control group (p<0.001) (Table 1). No statistically significant relationship was found between the presence of clinical signs and capillaroscopy scores, except for erythema nodosum.

Conclusion: the Behçet’s patients had significantly higher total capillaroscopy scores in comparison to those in the healthy control group. Based on these data, we believe that the capillaroscopic changes found in Behçet’s patients, though unspecific, may support clinical diagnosis in uncertain cases where Behçet’s disease is considered as a probability. There is a need for well planned prospective studies to support this our thought.

INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES: A SINGLE CENTER EXPERIENCE AND THE IMPORTANCE OF A MULTIDISCIPLINARY APPROACH

Carina Lopes1,2, Lúcia Costa3, Hélder Novais Bastos4,5, Patrícia Mota4,5, Natália Melo6, Susana Guimarães6,6, Conceição Moura7,8, José Pereira7,8, António Morais7,8, CedOC, NOVA Medical School | Faculdade de Ciências Médicas, Universidade NOVA de Lisboa, Lisbon, Portugal; 9Hospital de Egas Moniz, CHLCO, Rheumatology Department, Lisbon, Portugal; Centro Hospitalar e Universitário de São João, Radiology Department, Oporto, Portugal; Centro Hospitalar e Universitário de São João, Pulmonology Department, Oporto, Portugal; Centro Hospitalar e Universitário de São João, Pulmonology Department, Oporto, Portugal; Centro Hospitalar e Universitário de São João, Radiology Department, Oporto, Portugal;

Background: Interstitial lung disease (ILD) remains a significant cause of morbidity and mortality in patients with connective tissue diseases (CTD). Interstitial pneumonia with autoimmune features (IPAF) is a subset of ILD with clinical features suggestive of but not definitive for a CTD. IPAF is a new concept relatively unknown to rheumatologists. A multidisciplinary approach to diagnosis and management of IPAF patients is essential, involving close interaction between pulmonologists, rheumatologists, radiologists and pathologists.

Objectives: Revision of ILD patients followed at a specialized tertiary hospital’s ILD department and description of their clinical characteristics and multidisciplinary approach.

Methods: The study was conducted according to the declaration of Helsinki. All patients who met the Fischer criteria for IPAF in 2000–2018 were identified. Clinical characteristics, comorbidities, ILD subtype, pulmonary function tests, baseline serologies and treatment strategies were collected. The consents from a multidisciplinary meeting and Rheumatology referral and evaluation were also recorded.

Results: We identified 8 cases fulfilling classification criteria for IPAF (4 [50%] female); mean age 64.9 years (range 34–83); past smoking was referred in 5 (62.5%) patients with an average of 54.15 smoking pack years. Overall, 4 (50%) patients were exposed to organic dusts and 2 (25%) to inorganic dusts. Arterial hypertension was the most frequently recorded comorbidity (50%). Among the 8 patients, 6 (75%) had at least 1 feature from the serologic and morphologic domains, 1 patient had at least 1 feature from clinical and serologic domains and 1 patient had at least 1 feature from all 3 domains. From those meeting ‘suggestive radiology pattern based on high resolution chest CT (HRCT)’, 2 had nonspecific interstitial pneumonia (NSIP) and 1 had organizing pneumonia (OP). Biopsy (3 transbranchnial biopsies and 1 transthoracic biopsy) were conclusive in 4 patients (2 NSIP, 1 lymphoid interstitial pneumonia and 1 OP). Usual interstitial pneumonia (UIP) pattern was observed in two patients. Antinuclear antibodies were positive in 5 (62.5%) patients. Overall, 5 (62.5%) clinical cases were discussed in a multidisciplinary meeting including revision of imaging and biopsies. A Rheumatology appointment was requested in 5 patients to investigate a possible CTD diagnosis. Six (75%) patients had pulmonary function tests (PFT) and diffusing capacity of the lung for carbon monoxide (DLCCO) results recorded at baseline: 4 patients had a DlCCO below 70% (33.8 – 61.8%), 3 patients had normal PFT, 1 had restriction pattern and 2 had small airways obstruction. During a median of 2.7 years of follow-up, none of the patients progressed to a definitive diagnosis of CTD. Pharmacological treatment was prescribed in 6 patients, including corticosteroids (5), DMARDs (3), antibiotic therapy (2) and azithromycin (2).

ARTERIOSCLEROSIS MAY AFFECT PERIAORTIC/PERIARTERIAL LESIONS AND THEIR ANEURYSMAL CHANGES IN PATIENTS WITH IGG4-RELATED PERARTERITIS/PERIARTERITIS

Ichiro Mizushima, Masahiro Koriishi, Hajime Sanada, Kazuyuki Suzuki, Aki Takeji, Satoshi Hara, Kiyoki Ito, Hiroshi Fuji, Kazunori Yamada, Mitsuhiro Kawano, Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan

Background: IgG4-related periarthritis/periarteritis (IgG4-PA) is a major organ manifestation of IgG4-related disease (IgG4-RD) [1]. In the affected aorta/artery, arteriosclerotic changes are frequently observed [2]. However, the influence of arteriosclerosis on IgG4-PA and aneurysmal changes of the affected lesions has not been well evaluated.

Objectives: This study aimed to clarify the relationship of arteriosclerosis with periarteric/periarterial lesions and their aneurysmal changes.

Methods: We retrospectively investigated the medical data, including the presence of IgG4-PA at diagnosis, new development of IgG4-PA during the clinical course, arteriosclerotic and aneurysmal changes of the affected lesions, and classic risk factors for arteriosclerosis in 130 patients with IgG4-RD at a single center in Japan. The relationship of arteriosclerosis with the periarteric/periarterial lesions and their aneurysmal changes was statistically analyzed.

Results: Of the 130 patients with IgG4-RA, 44 comprising 39 men and 5 women (mean age 67.4 years) were diagnosed with IgG4-PA. The mean follow-up period was 72.8 months, and the mean serum IgG4 level at diagnosis was 851 mg/dL. The proportions of males (86.6% vs. 55.8%, P=0.004) and positive smoking history (81.4% vs. 47.6%, P<0.001), and history of malignancy (36.4% vs. 14.0%, P=0.006) were significantly higher in the 44 patients with IgG4-PA than in the 86 without it. Arterial wall calcification and/or mural thrombus in the affected lesions were detected in 86.0% of the IgG4-PA patients, some of whom had had these arteriosclerotic changes before the development of periarteric/periarterial lesions.

Conclusion: The present study suggests that arteriosclerotic changes and the classic risk factors for arteriosclerosis may be related to periarteric/periarterial lesions and their aneurysmal changes in IgG4-PA.
the appearance of symptoms caused by the involvement of other non-cartilaginous tissues and the presence of systemic symptoms.

**Objectives:** To describe the clinical characteristics and treatment of patients diagnosed with RP in a tertiary level university hospital.

**Methods:** Data from RP patients were obtained from the computerized medical history of our center, including demographics, disease phenotype, treatment, laboratory and imaging studies.

**Results:** A total of 12 patients were included; 66.7% were women, age at diagnosis was 36 [34-52.5] years (median [p25-p75]). The main manifestation observed was auricular involvement (75%) followed by nasal (66.7%), joint (66.7%), and laryngo-tracheo-bronchial disease (50%). All patients were on DMARD’s treatment and two thirds of the patients were receiving biological therapy at the time of analysis. Infliximab was the first biological line in all the cases (100%). Other biological therapies used, in order of frequency, were: adalimumab (25%), rituximab (25%) and tocilizumab (12.5%). 50% of the patients associated another autoimmune disease diagnosed before or during RP follow-up: Crohn’s disease, epidermolysis bullosa, primary biliary cholangitis, autoimmune hypothyroidism, systemic lupus erythematosus, granulomatosis with polyangiitis and ulcerative colitis. Only one patient (8.33%) associated hemolytic disease (myelodyplastic syndrome) and another one died during follow-up.

**Conclusion:** RP is a rare disease with a broad spectrum of clinical expression, which often requires intensive management to control its manifestations, potentially serious when there is involvement of the tracheo-bronchial tree or is associated with other autoimmune diseases. A large part of our patients require biological therapy at some point in their evolution.

**DOI:** 10.1136/annrheumdis-2019-eular.4797
Objectives: We evaluated iRPF cases of a single institution cohort to describe the features of patients (pts) with iRPF.

Methods: Twenty-eight iRPF patients who were being followed in our outpatient clinic between 2009 and 2018 were reviewed retrospectively. The demographic characteristics, clinical and radiologic findings, medical and interventional therapies were retrospectively collected and reported.

Results: We evaluated the data of 28 patients (17M/11F). The mean age at the time of diagnosis was 53±10.57, median follow-up was 46 (IQR:23-67) months. Fifteen (%50) patients were presented with abdominal-pain which was the most common initial complaint; 9 (32%) flank pain, 1 anuria, 1 nocturia, and 2 had nausea. Twenty-one patients had hydronephrosis (11 bilateral hydronephrosis, 5 right and 5 left hydronephrosis) at initial visit and one patient diagnosed while on temporary hemodialysis therapy. Laboratory tests showed that ESR was elevated in 15 of 23 cases in which it was available (65.2%), with a median value of 39 mm/h (IQR:17-88); CRP was elevated in 19 of 28 patients (68%), with median value 11 (IQR:5,5-46,5). Mean serum creatinine level was 1,14 mg/dl IQR (0,83-1,9). Tissue involvement was detected with computed tomography in 25 (89%) patients. The remaining 3 patients’ involvement was located with 18 F-fluorodeoxyglucose positron emission tomography (18 F-FDG-PET). 18 F-FDG-PET has been performed in 19 patients and 16 of them (84%) revealed tissue involvement of iRPF. Histopathological samples were available for further analysis in 8 cases and 5pts’ findings were consistent with iRPF (storiform fibrosis and dense lymphoplasmacytic infiltration were observed) and of these 5 pts, 2 of them were classified as IgG4-related subtype. The remaining 3 pts were diagnosed with positive radiologic findings. Medical and interventional therapies are presented in Table 1. The mean initial oral prednisone dose was 45,5±13,8 mg/day. Prednisone was discontinued in 4 patients after remission and for the remaining 23 pts; 12 pts’ prednisone was tapered <5 mg/day at mean 9 (IQR:6,7-22,5) months. One patient diagnosed AML-M2 during the follow-up and had allogenic stem cell transplantation. Rheumatoid factor (RF) and anticitrullinated protein antibodies (ACPA) were determined in all patients. Subjects were classified by each of the three different criteria.

Conclusion: Steroids are the mainstay treatment for iRPF and steroid resistant cases could be treated with rituximab rescue therapy. Prompt interventional approaches are valuable bridging therapies for pts who presented with hydronephrosis. Imaging modalities add great value on the interventional approaches are valuable bridging therapies for pts who presented with hydronephrosis. Imaging modalities add great value on the intervention approach.

COMPARISON OF THE PERFORMANCE OF CLASSIFICATION/DIAGNOSTIC CRITERIA FOR POLYMYALGIA RHEUMATICA. SINGLE CENTERSTUDY OF 100 PATIENTS

D. Prieto-Peña, Monica Calderón-Goercke, Miguel A. González-Gay, Ricardo Blanco. Marqués de Valdecilla University Hospital, Santander, Spain

Background: Polymyalgia rheumatica (PMR) diagnosis is based on the combination of shoulder and pelvic girdle pain associated with elevated acute phase reactants. Traditionally, Bird et al.1 and Chuang et al.2 criteria have been used for establishing PMR diagnosis. In 2012 an international working group developed new European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) classification criteria for PMR.3

Objectives: a) To compare the performance of Bird et al., Chuang et al. and 2012 EULAR/ACR classification criteria for PMR in a single-center study. b) To describe the characteristics of the patients excluded by these criteria.

Methods: We included 100 patients with new-onset PMR who were consecutively diagnosed over a 7-year period by experienced rheumatologists from a single center. PMR diagnosis was confirmed during a prospective 24-months follow-up after excluding other mimicking conditions. Rheumatoid factor (RF) and anticitrullinated protein antibodies (ACPA) were determined in all patients. Subjects were classified by each of the three different criteria.

Results: We studied 100 patients (61 women/39 men); mean age 67.1 ± 10.2 years. 96% of the patients fulfilled Bird et al criteria, 94% fulfilled Chuang et al criteria and 84% of the patients fulfilled 2012 EULAR/ACR criteria. We assessed the characteristics of the 16 patients who did not fulfilled 2012 EULAR/ACR criteria: 6 of them were under 50 years of age (range age 43-48 years). Another 10 patients did not complain of pain/stiffness in the shoulder girdle at any time. However, they had typical inflammatory pain involving the pelvic girdle and elevated acute phase reactants.

Conclusion: In our single-center experience we found that 2012 EULAR/ACR criteria classified most of our patients. However, patients who presented predominant pelvic girdle affection and those who were under 50 years old despite showing all the rest of clinical and analytical required criteria were excluded. Some of these patients did fulfill Bird and/or Chuang criteria.

Chagas Disease Reactivation in the Rheumatologic Immunosuppressed Patient. Is It No Longer an Orphan Disease?

**Background:** Chagas' disease (CD) is an endemic and neglected infection in Latin America. Due to international human migration, it has become a worldwide issue. Scarcely evidence is published regarding its behavior in rheumatic diseases (RD) with rheumatologic treatments (RT).

**Objectives:** To screen and follow up patients with CD under RT. To detect clinical and serological reactivation.

**Methods:** A systematic screening was conducted between January 2018 and January 2019 in a third-level Hospital in Argentina. Patients with CD and concomitant RD under RT were included. Assessments were done before and after RT. A direct (Strout) and indirect method (Polymerase chain reaction-PCR) were performed in order to detect parasitemia, levels of antibodies were evaluated by three techniques. Clinical, infectological and cardiological features were examined. Everything was assessed in, at least, two opportunities, separated by a minimum of one month. If treatment was modified or clinical condition changed, all the evaluations were repeated as before. In case of reactivation, specific treatment was indicated and follow up controls were stricter.

**Results:** 38 patients were identified. RD: Rheumatoid Arthritis: 22 (57,9%), Systemic lupus erythematosus: 4 (10,5%), Systemic Sclerosis: 3 (7,9%), Vasculitis: 2 (5,3%), Psoriatic Arthritis: 1 (2,6%), others: 6 (15,8%). RT: classic, synthetic and biological disease-modifying antirheumatic drugs, cyclophosphamide and corticosteroids.

Two reactivations were detected with both direct and indirect methods, with a significant title antibody increment and consistent clinical signs and symptoms. Cardiological abnormalities were found. A 64-years old lady with Microscopic Polyangiitis, under prednisone 60 mg/day, and a 57-years old lady with Systemic Lupus Erythematosus under hydroxychloroquine and prednisone 40 mg/day, who happen to be sisters. They did not have other treatments. Both of them developed high fever, myalgias, arthralgias and asthenia. Other infections were ruled out. They received Benzimidazole and Nitritomix respectively. After one-week treatment, Strout and PCR became negative and antibodies decreased, with remarkable clinical improvement.

**Conclusion:** Two patients with parasitemia and concomitant symptoms were detected, after high doses of corticosteroids. Because they were sisters, a genetic background would also play a role. Parasite's screening before starting immunosuppression and its follow-up during treatment in search of reactivation should be integrated to rheumatology daily practice in endemic countries. It should also be taken into account in patients from non-endemic countries that have an epidemiological nexus. CD specific antibodies determination, Strout and PCR are economic and practical techniques, although they require qualified personnel and equipment. In areas with high prevalence of CD, the benefits of this measures would outweigh costs. A more advanced study should be performed to extend our knowledge.

ANA SUBSETS ANTIBODY PROFILE OF EARLY UNDIFFERENTIATED ARTHRITIS (UA) IN PAKISTAN
Syed Hussain Azhar Rizvi, Tariq Gazdar1, Aneela Pasha, Mohammad Saeed.
Immunocure, Karachi, Pakistan

Background: Undifferentiated Arthritis (UA) is a group of inflammatory disorders where early synovitis (duration less than 12 months) is present, however patients do not meet criteria for established rheumatologic disorders such as Rheumatoid arthritis, Lupus or Spondyloarthritides (1). On long term follow up, a subpopulation of UA patients converge into definitive Rheumatologic disorders. Up to 50% of early arthritis in European cohorts has been reported to be UA (1, 2).

Objectives: Identify Anti-nuclear antibody (ANA) Subset antibodies in patients presenting with early UA.

Methods: Over a 1-year period (2017-18) patients with early UA were prospectively evaluated. This included clinical exam, routine laboratory investigations including ESR and CRP, RF and anti-CCP as well as Musculoskeletal ultrasound (MSKUS) (3). These patients underwent further testing for ANA Subset antibodies. ANA subsets (17 antibodies) were performed using standard immunoblot assays (EUROIMMUN) at our clinic laboratory (4).

Results: 110 UA patients were found to have positive ANA subsets. The most frequent antibodies were Ku (77.3%) and M2 (73.6%) followed by dsDNA (30%) and Nucleosome antibody (29%) (Figure 1). Low frequency antibodies included Sm (n=1), Ribosomal-P and PCNA (n=2 each), Jo-1 (n=3), PM-Scl100 (n=4) and SSB (n=5), whereas Scl70 antibodies were absent. SSA (n=9) and Ro-52 (n=14) together constituted 21% frequency. These antibodies had high signal intensities (mean ± SD SSA = 52±35 and Ro-52 = 46±25). Ku (17±11) and M2 (22±15) had modest signal intensities (Figure 2). Clinically 42 patients were classified as RA (RF+ = 33%; anti-CCP+ = 14%) and 41 patients met ACR criteria for SLE while 2 patients met criteria for both and were classified as Rhepus. ANA subset antibody frequencies did not statistically differ between the RA and SLE groups signifying that the clinically classified RA patients in fact had early Rhupus which did not meet ACR criteria for SLE.

Conclusion: Early UA is difficult to categorize clinically, sometimes even after long term follow up, though a substantial portion converge into RA. This study shows that there is a significant portion of early Rhupus in the RA group whose steroid discontinuation leads to a disease flare. ANA Subset antibody profile in such patients may help in their more accurate diagnoses and treatment.

NEUROLOGICAL IMPAIRMENT DURING SARCOIDOSIS
sameh sayhi1, Rim Dhahi1, Najah Boussetta1, Bibel Arfaoui1, Feida Laajili2, Bassem Louzir1, Hajar Derbal1, Linda Mrisa1, Rida Mrisa1. 1Military Hospital of Tunis Tunisia, Internal Medicine, Tunis, Tunisia; 2Military Hospital of Tunis Tunisia, Autoimmune Diseases Unit Research UR171002, Tunis, Tunisia; 3Military Hospital of Tunis Tunisia, Neurology, Tunis, Tunisia

Background:
Objectives: To describe neurological impairment characteristics in sarcoidosis.
Methods: This was a descriptive and retrospective study including 65 patients with sarcoidosis, followed in the departments of internal medicine and neurology at the Military Hospital of Tunis over a period of 20 years from 1997 to 2017.
Results: A total of 65 patient files have been selected, of which 38 have neurological involvement. Thirty-eight patients met the inclusion criteria for Neurosarcoidosis. According to Zajicek’s criteria, the diagnosis of neurosarcoidosis was certain in 2 cases, probable in 18 cases and possible in 18 cases. Neurological disorders were symptomatic in 58.5% of the studied population. Neurological signs were inaugural in 9 patients (14% of cases). A central neurological involvement was demonstrated in 33 patients (86.8%), of whom 23 presented with cranial nerve involvement and 10 patients (26.3%) had both central and peripheral impairment. Neurological involvement was significantly associated with cardiac, renal extra-thoracic, ophthalmologic, articular and cutaneous involvement (p <0.05). Neurogenotype of the conversion enzyme and HLA typing did not show any particular pattern of neurosarcoidosis in comparison with patients without neurological signs.

Conclusion: Neurological impairment was frequently observed in our series. It was also significantly associated with multivisceral involvement without particular genetic pattern.

GENETIC ASPECTS OF SARCOIDOSIS IN A TUNISIAN POPULATION
sameh sayhi1, Rim Dhahi1, Najah Boussetta1, Souha Hannachi1, Feida Laajili2, Bassem Louzir1, Hajar Derbal1, Linda Mrisa1, Rida Mrisa1. 1Military Hospital of Tunis Tunisia, Internal Medicine, Tunis, Tunisia; 2Military Hospital of Tunis Tunisia, Autoimmune Diseases Unit Research UR171002, Tunis, Tunisia

Background:
Objectives: To determine the frequencies of the HLA alleles and genotypes of the ACE gene.
Methods: This is a cross sectional study of 65 patients with sarcoidosis, followed in the departments of internal medicine and neurology at the Military Hospital of Tunis. The genetic study involved 50 patients. DNA extraction was performed to determine the frequencies of the HLA alleles and genotypes of the ACE gene.
Results: 1. HLA typing
The analysis of HLA typing allowed us to estimate the different frequencies of alleles in patients. The calculation of the allelic frequency found that the most frequent alleles are HLA-DRB1*1501 alleles with a frequency of 38% and HLA-DRB1*0301 of 28%. Other alleles are at lower frequencies (Table1).

2. Genotyping of the ECA gene
Genotyping of the polymorphism of the angiotensin converting enzyme (ACE) involved 50 patients. Genotypic frequencies (II, ID and DD) and allele frequencies (I and D) were estimated in order to evaluate the frequencies of each genotype and the 2 alleles for this pathology. The genotypic and allelic frequency results were summarized in Table 2.

Conclusion: The most frequent alleles in Tunisian patients with sarcoidosis are HLA-DRB1*1501 with a frequency of 38% and HLA-DRB1*0301 of 28%. The genotypic and allelic results showed that genotypic ID was the most frequent with 48% with a predominance of the D allele in 54%.

A NOVEL AUTOINFLAMMATORY AND LYMPHOPROLIFERATIVE SYNDROME ASSOCIATED WITH PIM1 MUTATIONS
Giovanna Ferrara1, Silvio Polizzi2, Erica Valencic3, Annalisa Chiochietti4, Josef Vuch1, Alessia Pin1, Elisa Piscian1, Diego Vozi1, Serena Pastore5, Paola Tomietto5, Andrea Teddi6, Flavio Faletta7, Umberto Dianzani8, Alberto Tommasini9, University of Trieste, Trieste, Italy; 1Institute of Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy; 2Universita’ del Piemonte Orientale, Novara, Italy; 3Azienda Sanitaria Universitaria Integrita Trieste, Cattinara Teaching Hospital, Trieste, Italy; 4Institute of Maternal and Child Health, IRCCS Burlo Garofolo and University of Trieste, Trieste, Italy

Background: Whole exome sequencing can allow genetic diagnosis in subjects with long lasting clinical stories not supporting any well-defined disorder. A 35-year-old man was referred to ophthalmologist’s evaluation for blurry vision in his left eye. The fundus examination showed choroidal lesions in both eyes. His past medical history was relevant for celiac disease, recurrent episodes of fever and skin rashes with leukocytoclastic vasculitis, inflammatory lesions of the osteoarticular and muscular system, one episode of aseptic meningitis, an intracranial granuloma and two episodes of anterior uveitis. He had also splenomegaly with non-caseating granulomas. Brain TC founded multiple lytic and sclerotic skull lesions. He was diagnosed with atypical sarcoidosis and treated with oral steroid and methotrexate. Laboratory data always showed elevated erythrocyte sedimentation rate, strong positive C-reactive protein and polycyonal gammopathy.

Objectives: To describe functional and genetic data supporting the role of a PIM1 mutation in the multisystemic inflammation and lymphoproliferation of the patient.

Methods: Whole exome sequencing (WES) analysis. Flow-cytometry to evaluate Pim1 expression, Bad phosphorylation (target of Pim1 kinase) and the effect of PIM inhibitor on peripheral blood mononuclear cell (PBMC) viability. RNAseq was on primary fibroblasts from the patient and
from healthy donors. Cloning of the mutated gene in a vector for further functional studies.

Results: WES analysis revealed the de novo heterozygous missense variation c.C1132A (p.H378N) in PIM1 gene. This variation was never described in on-line database and was predicted as damaging by various bioinformatic tools. Preliminary functional investigations in fibroblasts showed normal expression of Pim1, but higher phosphorylation of BAD protein was measured in cells from the patient. Moreover, PBMC from the patient displayed a lower sensitivity to the PIM inhibitor PIM447. RNAseq showed an altered expression profile in genes involved in the extracellular matrix organization.

Conclusion: PIM1 is an oncogene that encodes a protein kinase and, indeed, somatic gain of function mutations can be found in cancers. Preliminary data obtained from our patient suggest a gain of function effect of the p.H378N variant. The lymphoproliferative disorder may be sustained by the anti-apoptotic action of phosphorylated BAD. Recent data correlated hyperactive PIM1 in tumors with high degree of inflammatory infiltration accompanied by NFAT and mTOR activation and IL6 expression. A role of this cytokine also in our patient was coherent with a good clinical response to a treatment with tocilizumab, targeting IL-6.

Although these results are supportive of a role of mutated PIM1 in the observed phenotype, we cannot still claim that this is causative of a novel syndrome. The detection of further cases and functional studies on cells transfected with mutated PIM1 will help shedding more light on this inflammatory and lymphoproliferative disorder.

PREVALENCE AND EPIDEMIOLOGY OF FAMILIAL MEDITERRANEAN FEVER AND TUMOR NECROSIS FACTORRECEPTOR-ASSOCIATED PERIODIC SYNDROME: RESULTS FROM AN ITALIAN CENTER
Rossella Talotta1, Lorena Mosca2, Francesco Ruco3, Antonio Brucato3, Fabiola Atzeni4, Carlo Federico Perno4, Francesco Scaglione5, Carlo Federico Perno5, Francesco Scaglione6, Ugo Cavallari2.
1University of Milan, Postgraduate School of Clinical Pharmacology and Toxicology, Milan, Italy; 2ASST Grande Ospedale Metropolitano Niguarda, Medical Genetics Unit, Department of Laboratory Medicine, Milan, Italy; 3Papa Giovanni XXIII Hospital, Internal Medicine Unit, Bergamo, Italy; 4University of Messina, Rheumatology Unit, Messina, Italy; 5ASST Grande Ospedale Metropolitano Niguarda, Chemical-Clinical Analysis and Microbiology, Department of Laboratory Medicine, Milan, Italy; 6University of Milan, Department of Oncology and Onco-Hematology, Milan, Italy

Background: Familial Mediterranean fever (FMF) and tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) represent two forms of periodic monogenic autoinflammatory diseases, characterized by recurrent and auto-limiting attacks of fever and systemic inflammation. Both the diseases are due to the aberrant activation of inflammasome platforms. Several variants in the Mediterranean Fever (MEFV) gene and TNF Receptor Superfamily Member 1A (TNFRS1A) gene are respectively at the basis of FMF and TRAPS.

Objectives: The aim of this study is to report the genotype and phenotype prevalence of a cohort of patients referring to our laboratory with a suspicious diagnosis of FMF or TRAPS.

Methods: We retrospectively collected genetic and demographic data of patients undergoing MEFV (NM_000243) and TNFRS1A (NM_001065) genetic test at our laboratory. Both genes were analysed by direct sequencing on both strands. Data were statistically analysed for descriptive and inferential purposes.

Results: A total of 168 cases were collected, most of which were Caucasian subjects (88.0%). The most common clinical manifestation was periodic fever, occurring in 121 cases, with musculoskeletal, intestinal and cutaneous symptoms, polyserositis and lymphadenopathy occurring at variable rates. Several variants in the Mediterranean Fever (MEFV) gene and TNF Receptor Superfamily Member 1A (TNFRS1A) gene were respectively identified in our cohort. The most prevalent variant in the MEFV gene was p.Ala744Ser (37.1%), associated with different geographic provenience and symptoms. According to Eurofever scoring system, the MEFV variant p.Ala744Ser was significantly associated to the likelihood of having FMF and to the severity of the disease. A higher prevalence of MEFV pathogenic variants was observed in Egyptians and patients living in Southern Italy.

Analysis of TNFRS1A gene in 80 subjects revealed the presence of the pathogenic variant p.Cys102Tyr in 3 patients (3.75%).

According to Eurofever scoring system, the MEFV variant p.Ala744Ser was significantly associated to the likelihood of having FMF and to the severity of the disease. A higher prevalence of MEFV pathogenic variants was observed in Egyptians and patients living in Southern Italy.
### COMPLEMENTARY AND ALTERNATIVE MEDICINE USAGE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

Seda Cokal1, Emre Tekeaga2, Fatma Ilkuc Cinar1, Sedat Yilmaz2, Muhammet Çınar1, 2
1University of Health Sciences, Gulhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2University of Health Sciences, Gulhane Faculty of Nursing, Department of Internal Medicine Nursing, Ankara, Turkey

#### Background: Familial Mediterranean Fever (FMF) is the most common hereditary, chronic autoinflammatory disease. Colchicine is the mainstay of treatment, which reduces frequency of attacks and amyloidosis risk. Complementary and alternative medicine (CAM) therapies can be a non-mainstream treatment choice in chronic diseases. Frequency of use of CAM therapies among patients with FMF is not established yet.

#### Objectives: In the current study, we aimed to identify the prevalence of the patients using CAM therapies and the factors associated with CAM usage among the patients with FMF.

#### Methods: One hundred and sixty-five patients were included in the study. Data regarding demographic, social and clinical characteristics were obtained from the patients. The patients were asked whether they were using any type of CAM and if they had suffered harm and/or benefit. The treatment adherence of the patients was assessed using by Morisky Green Levine Scale (MGLS). The Beliefs About Medicines Questionnaire (BMQ-T) was used to assess patient’s beliefs about medicines.

#### Results: Fifty-six (33.9%) patients declared to use at least one CAM. The mean age of the patients was 34.1 ±12.7 years and the mean disease duration was 16.8±10.8 years. The mean dose of colchicine was 1.4±0.4 mg/day. Patients with concomitant disease and positive history of FMF in relatives had higher rates of using of CAM (p=0.011 and p=0.014 respectively). There was no statistically significance between age, sex, marital, socioeconomic and working status, difficulty of access to the treatment center, dose of colchicine, adverse events related to colchicine, attack frequency and disease severity of the patients and frequency of CAM using (p>0.05). The most frequently chosen types of CAM modalities were massage therapy (12.1%), imagining (9.7%), relaxation techniques (9.1%), cupping (9.1%) and natural products (9.1%). It is found that 42 (75.0%) of patients reported that they had suffered benefit from CAM. The mean duration of the using of CAM was 7.9 ±6.4 years. According to the BMQ-T, there was higher rate of concern about colchicine among patients that were using CAM (p=0.035) (Table 1). There was no statistically significance between compliance with colchicine treatment and using of CAM (p=0.313).

#### Conclusion: Colchicine is the gold standard of treatment because of the known effect of colchicine treatment on the severity and frequency of FMF attacks and the risk of development of amyloidosis. Approximately one third of patients with FMF were using at least one of the CAM modalities in the current study. Concerns about colchicine treatment may have increased the tendency to use CAM therapies. On the other hand, patients should be informed that CAM therapies should not be an alternative to colchicine.

### Coexistence of Sarcoidosis and Chronic Inflammatory Rheumatic Diseases

Marta Veilés Roc1, Merrit��al Sàlles Lizarzaburu2, Sonia Minguéz Blasco2, Elisabet García Casares3, Elena Riera Alonso4, Vera Ortiz-Santamaria3, Clara Sangués4, Alejandro Olive5, 61Hospital de Figueres, Rheumatology, Figueres, Spain; 2Althaia, Xarxa Assistencial Universitària de Manresa, Rheumatology, Manresa, Spain; 3Hospital Germans Trias i Pujol, Badalona, Spain

#### Background: Sarcoidosis is a systemic granulomatous disease of unknown etiology, mediated by Th1 lymphocytes, characterized by bilateral hilar adenopathies, pulmonary infiltrates, ocular, articular and cutaneous involvement and histologically by noncaseating granulomas. Sarcoidosis can simulate many chronic rheumatic diseases but can also coexist with them, so there are doubts about whether there is a true association or is incidental. Likewise, the occurrence of sarcoidosis has been described as a paradoxical effect during treatment with biological drugs, especially with tumor necrosis factor antagonists possibly due to a dysregulation in the compensatory proinflammatory cascade related of TNF blockade. The association between sarcoidosis and Sjögren’s syndrome, systemic lupus...
Characterization of Patients with Interstitial Pneumonia with Autoimmune Features (IPAF) and Its Comparison with Patients with Scleroderma-Related Interstitial Lung Disease and with Idiopathic Fibrosis

Karen Vergara1, Silvana Saavedra1, Felipe Reyes2, Annelise Goecke1, Caterina Chesta1, Sebastian Chavez2, Hospital Clínico Universidad de Chile, Reumatología, Santiago, Chile; 3Hospital Clínico Universidad de Chile, Neumología, Santiago, Chile; 4Hospital Clínico Universidad de Chile, Medicina Interna, Santiago, Chile; 5Hospital Clínico Universidad de Chile, Medicina Interna, Santiago, Chile, 6Hospital Clínico Universidad de Chile, Medicina Interna, Santiago, Chile, 7Hospital Clínico Universidad de Chile, Medicina Interna, Santiago, Chile

Background: Diffuse parenchymal pulmonary diseases, called interstitial lung diseases, are a heterogeneous group of disorders that are classified together due to clinical, radiographic, physiological or similar pathological manifestations. The diagnosis of idiopathic interstitial pneumonias requires the exclusion of known causes of interstitial pneumonia. Identifying an underlying etiology is important for clinical perspectives because it impacts prognosis and treatment. A recent number of studies has shown that many patients diagnosed as idiopathic interstitial pneumonia have clinical elements that suggest an underlying autoimmune process without meeting established diagnostic criteria for connective tissue disease.

Objectives: Our objectives were characterize the clinical findings of patients who meet the IPAF criteria and compare them with the clinical characteristics of patients with scleroderma-related interstitial lung disease and patients with idiopathic pulmonary fibrosis.

Methods: We retrospectively reviewed 254 patients hospitalized at the Hospital Clínico de La Universidad de Chile between January 2012 and June 2018 who had ICD-10 diagnosis of J.84 (Other respiratory diseases principally affecting the interstitium) and J99.1 (Respiratory disorders in other diffuse connective tissue disorders). The electronic medical record was reviewed retrospectively to extract pertinent data. We applied IPAF criteria to this 254 patients. We then characterized the clinical, serological and morphological features of the IPAF cohort and compared outcomes to other ILD cohorts: scleroderma-related interstitial lung disease and idiopathic pulmonary fibrosis (IPF).

Results: Of 254 patients screened, 17 patients met the IPAF criteria. Mean age was 60 years with a female predominance. The most frequent pattern by high-resolution computed tomography was NSIP present in 72% of the cases. The trend in survival was worse than Scleroderma cohort and better than the IPF cohort. Further prospective studies should be conducted for a more comprehensive evaluation of the evolution of these diseases and the impact of the treatments used.

AUTOINFLAMMATORY DISORDERS ARE COMMON IN PATIENTS WITH MYELODYSPLASTIC SYNDROME AND LINKED TO KARYOTYPE ABNORMALITY AND SOMATIC MUTATIONS STATUS AND A WORSE PROGNOSIS

Abdulla Watad1, Mark Kacar2, Nicola Luigi Bragazzi2, Qiao Zhou2

Objectives: We tested the hypothesis that autoinflammatory disease is common in MDS cohorts and we further theorised that MDS with somatic mutations and karyotypic abnormalities were associated with autoinflammation.

Methods: 140 MDS patients referred to St. James’s University Hospital in Leeds during the period 2012-2018 were systematically and retrospectively recruited with karyotypes and somatic mutations status being performed. Patients with autoinflammation were classified as well-defined autoinflammatory disease or poorly defined “autoinflammatory state” (non-infection related elevated CRP over 10.0 mg/L in 5 consecutive times, taken at separate occasions based on their final diagnosis and compared in terms of demographic, clinical, laboratory, cytogenetics charts, and outcomes.

Results: The average age was 77.08±11 years (median 79 years), with (n=91, 65.0%) male. 72 (51%) patients had an autoinflammatory state and were younger (75.15±11.23 versus 79.15±11.92, p<0.05), and had more frequent arthritis (n=25, 34.7%, versus n=12, 17.6%, p=0.0225), arthralgia (n=32, 44.4%, versus n=18, 26.5%, p=0.0271), skin rash (n=22, 30.6%, versus n=10, 14.7%, p=0.0261), pleuritis (16, 22.2%, versus n=3, 4.4%, p=0.0022). 26.3% of MDS patients with autoinflammatory state had a well-defined autoinflammatory disorder (neutrophilic dermatosis, and poly-myalgia rheumatic being the commonest). Mutations affecting the transcription factors pathway (NPM1, RUNX1, BCOR, WTI, TP53, MYD88) (OR 3.15 [95%CI 1.04 to 9.56], p=0.0426) and deletion of chromosome 5 and chromosome 7 were independent predictors for well-defined autoinflammatory disorder and poorly-defined autoinflammatory state, respectively. Furthermore, acute leukaemia transformation was more frequent in MDS patients with autoinflammatory status (n=25, 34.7%, versus n=8, 11.8%, p=0.0002).

Conclusion: Both well-defined and poorly defined autoinflammatory diseases are common in MDS. Transcription factors pathway somatic mutations and abnormal karyotype are associated with the risk of autoinflammation. Autoinflammation is linked to a worse prognosis which may be linked to the higher risk of malignant transformation.

RELATIONSHIP BETWEEN SERUM ADENOSINE DEAMINASE LEVELS AND DISEASE ACTIVITY IN AUTOIMMUNE HEPATITIS

Jing Xie1, Hua Wei1, Xiaoqing Xiang2, 1Dalian Medical University, Dalian, China; 2Northern Jiangsu People’s Hospital, Yangzhou, China

Background: Autoimmune hepatitis (AIH) is a chronic liver inflammation mediated by autoimmune response, characterized by serum autoantibodies, high immunoglobulin G(IgG), and interface hepatitis histology, which can develop into cirrhosis and liver failure. Adenosine deaminase(ADA) is an enzyme involved in purine metabolism, which can catalyze the irreversible conversion from deoxyadenosine to deoxyinosine. As adenosine is an important immunoregulatory factor in the physiological microenvironment, ADA plays an important role in regulating the balance of the human immune system. Previous studies have reported the associations between ADA and disease activity in a variety of autoimmune diseases, such as systemic lupus erythematosus, rheumatoid arthritis and juvenile idiopathic arthritis.

Objectives: To investigate the relationship between serum adenosine deaminase levels and disease activity in patients with autoimmune hepatitis.

Methods: Thirty patients with autoimmune hepatitis and 30 healthy individuals were included in the study. We enrolled 30 patients who met the simplified criteria suggested by the International Autoimmune Hepatitis Group. All of the cases had been diagnosed with AIH between 2013-2018 at Northern Jiangsu People’s Hospital, Department of Gastroenterology or Rheumatology, and the diagnosis was confirmed by liver biopsy. Serum adenosine deaminase levels were measured by enzyme-coupled assay, and >25U/L were determined to be high level 25U/L.

Results: The mean serum ADA levels were significantly higher in AIH patients than those in healthy controls (29.13 ± 8.70 U/L vs 14.50 ± 4.63 U/L, P < 0.001). Serum ADA levels were > 25 U/L in 70% AIH patients and in 0% healthy controls (P < 0.001). Mean serum ADA levels were significantly increased in each stage of disease activity: 26.32 ± 8.78 U/L for mild patients, 31.33 ± 4.23 U/L for moderate patients and
37.20 ± 7.36 U/L for severe patients (P = 0.03). Correlation analysis showed that there was a positive association between serum ADA levels and disease activity (r = 0.43, P = 0.02). Receiver operating characteristic analysis showed that 38.5 U/L was the optimum cut-off point of ADA level for severe disease activity (sensitivity 60%, specificity 92%, area under the curve: 0.81).

Conclusion: The evaluation of serum adenosine deaminase level in patients with autoimmune hepatitis should be considered a useful biomarker in the monitoring of their disease activity.

RELATION BETWEEN RESTRICTIVE PULMONARY FUNCTION TESTS AND ULTRASONOGRAPHIC CHANGES OF ASYMPTOMATIC ANTERIOR CHEST WALL JOINTS IN RHEUMATOID ARTHRITIS PATIENTS

Fatma Ibrahim Abdelrahman1, Mohammed A. Mortada2, Amal Abdul-Sattar2, 1Zagazig University, Rheumatology and Rehabilitation, zagazig, Egypt, 2Zagazig University, Rheumatology and Rehabilitation, zagazig, Egypt

Background: Ultrasonography can detect different changes in anterior chest wall (ACW) joints in patients with Rheumatoid Arthritis (RA) even before being clinically manifested.1 Pulmonary functions may be affected during the course of RA due to interstitial lung problem or chest wall problem.2 All studies usually demonstrate the interstitial pulmonary affection in RA but the chest wall joints is usually underestimated by the rheumatology community. Up to the best of our knowledge, there are no previous studies about the relationship between ultrasound detected subclinical changes in ACW and the pulmonary functions in RA patients.

Objectives: To detect the relation between ultrasonographic changes of asymptomatic ACW joints and pulmonary function tests (PFTs) in patients with RA.

Methods: The study included 44 subjects (22 RA and 22 control) in whom 88 sternoclavicular joints (SCJ) and 44 manibrusternal joints (MSJ) were studied. None of the participants had a history of respiratory complaints such as dyspnea, chronic cough, or chest pain. High resolution Computed Tomography (HRCT) was done on the chest to exclude interstitial lung problem that may affect chest expansion and PFTs. Ultrasound (US) assessments were performed to detect synovitis, erosions, ankylosis, osteophytes, or Doppler signals. Chest expansion was measured. PFTs were done and included measurement of the forced expiratory volume in 1 s (FEV1), forced vital capacity (FVC), and the ratio of forced expiratory volume in 1 s to the forced vital capacity(FEV1/FVC). In RA group, DAS28 and Health Assessment Questionnaire Disability Index (HAQDI) were recorded.

Results: US detected subclinical changes of ACW joints in (74.2%) of RA patient with significant difference between total US changes in RA (74.2%) and control (21.2%) (p<0.001). MSJ ankylosing and erosions were highly associated with limited chest expansion in RA group (p<0.001). PFTs were found to be restrictive in 13 RA patient (59.1%) with mean of FVC (65.5±5.5%), FEV1 (70.4±9.1%), FEV1/FVC (80.1±2.6) with significant difference to control with mean of FVC (93.6±2.7%), FEV1 (94.3±4.5%), FEV1/FVC (95.3±2.4). These restrictive PFTs were associated with SCJ synovitis (p=0.04), SCJ PD activity (p<0.04), SCJ erosions (p=0.02) and highly associated with MSJ ankylosing and erosions (p=0.001). All RA patients (100%) with MS ankylosing and erosions and SCJ PD activity by US had limited chest expansion and restrictive PFTs. Restrictive PFTs were associated also with limited chest expansion with mean of (2.3±0.5) with significant difference (p=0.001) to non-restrictive PFTs in RA with mean of (5.2±1.4).

Conclusion: Our study demonstrated that ultrasonographic subclinical changes in ACW joints is associated with restrictive pattern of PFTs and limited chest expansion in RA patients.

**CALPROTECTIN IN SERUM AND SYNOVIAL FLUID AS A BIOMARKER IN ACUTE ARTHRITIS**

Martí Aguilar-Zamora1, L Montolio-Chiva, Isabel de la Morena, José María López Ortega, Carlos Feced Olmos, Ana V. Crenes Vera, I Vázquez-Gómez, Elia Valls-Pascual, D Ybáñez-García, À Martínez-Ferrer, A Sendra-García, I Torner-Hernández, V Núñez-Monje, Juanjo J. Alegre-Sancheo, Hospital Universitario Dr. Peset, Rheumatology, Valencia, Spain; 2Hospital Universitario de Fuenlabrada, Unit of Rheumatology, Fuenlabrada, Spain; 3Hospital Universitario Central de la Defensa, Rheumatology Service, Madrid, Spain; 4Hospital Universitario de Fuenlabrada, Internal Medicine, Fuenlabrada, Spain

**Background:** There are increasingly data about the usefulness of calprotectin levels in chronic inflammatory arthritis and its relationship with prognostic factors. However, few data are available on its role in the diagnosis of acute arthritis.

**Objectives:** To evaluate the possible usefulness of testing plasma and synovial fluid (SF) calprotectin levels as a predictor of the final diagnosis behind an acute mono or oligoarthritis.

**Methods:** Longitudinal observational study. We included non-consecutive patients referred to the rheumatology emergency department with suspected mono or acute oligoarthritis for a period of 23 months. Patients with a previous diagnosis of inflammatory, infectious or neoplastic disease were excluded. All of them underwent diagnostic arthrocentesis and blood extraction simultaneously. The SF was evaluated under optical microscopy immediately for the study of microcrystals. Samples of SF were also routinely sent to microbiological culture, and calprotectin levels (SFC) and cell count were determined. In blood, the calprotectin level (SC), CRP and ESR were determined. The calprotectin level in plasma was determined by an automated fluoroenzyme-immunoassay technique on an ImmunoCAP250 analyzer (Thermo Fisher). All patients were followed until diagnostic confirmation. The statistical analysis was performed with the SPSS 22.0 program.

**Results:** 41 patients were collected, 28 men (68.3%) and 13 women (31.7%) with a mean age of 56.2 years (SD 17.6). The patients presented an average of 6.5 days of symptoms duration (SD 7), manifested as monoarticular in 80.5% of the cases, with the knee being the most frequently affected joint (92.5%). In all patients, SF culture was negative. The most frequent diagnosis was microcrystalline arthritis in 21 patients (13 gout and 8 pseudogout), followed by the forms of onset of different chronic inflammatory arthropathies (9). Another 8 patients presented a mechanical joint effusion, in 1 patient the final diagnosis was not collected and there were 2 patients who presented other diagnoses (viral oligoarthritis, pigmented villonodular synovitis).

Calprotectin values were higher in SF than in serum (mean 73,058 vs 824.75 μg/L). A high positive correlation was found between the SC and the CRP (p<0.05, r=0.7) whereas the correlation with the number of leukocytes in SF (p<0.05, r=0.47) and with the ESR (<0.05, r=0.5) was moderate. The SFC was correlated with the CRP (p<0.05, r=0.45) and with the leukocyte cell count in SF (p<0.05, r=0.6), but not with the ESR. Regarding the different diagnoses, SC was numerically higher in microcrystalline arthritis (1157 μg/L) compared to non-microcrystalline arthritis (862 μg/L), although these differences were not significant due to the low number of patients in each group.

**Conclusion:** Our preliminary results suggest that the analysis of SC could complement the information provided by a conventional analysis in the differential diagnosis of acute arthritis in situations in which an arthrocentesis is not possible. Studies with a greater number of patients and that include patients with septic arthritis are necessary.

**AB1115**

**OBESITY AND FLAT VERTEBREAS**

María Del Pilar Ahijado Guzmán1, Raül Maria Veiga Cabello2, Miguel Cantalejo Moreira3, Justo Ruiz Ruiz4, Antonio Zapatero Gavilán3, 1Hospital Universitario de Fuenlabrada, Unit of Rheumatology, Fuenlabrada, Spain; 2Hospital Universitario Central de la Defensa, Rheumatology Service, Madrid, Spain; 3Hospital Universitario de Fuenlabrada, Internal Medicine, Fuenlabrada, Spain

**Background:** Spine is a mechanical structure, in a young and healthy individual, under a radiological focus, disposes their vertebral bodies in harmony with their stature, and progressively increasing in magnitude from the cervical to the lumbar spine, in a range of vertical growth that it can exceed the horizontal (1).

It is postulated that the important obesity in the early stages of life, could modify the vertebral parameters by skeletal overloads, but the problem is that the current vertebral indexes do not measure a relation of the person height with his vertebra (2).

**Objectives:** Thus, to check whether the childhood obesity could modify the vertebral parameters, or it is accepted that it entails a loss of equivalent stature, and in this case would be necessary a study comparative of average height, or whether the harmony of the individual is accepted, it would be necessary to create an index that combine these variables to objectively if its value is a constant, and thus, eliminate the ambiguity of the observer.

As variables, sex, age, body mass index (BMI), and with a chest lateral plate, not rotated, and in the eighth dorsal vertebra, we calculate his height (LVD8) and his height (HVD8), measured in mm. Figure 1.

Finally, we applied a comparative study of average of height and vertebral index (VI) results: VI = 10 x LVD8/(HVD8 x stature)

**Results:** 90 patients were analyzed. 20 patients in the study group (22.2%): 48.1% female, 48.6 years old, 38.2 BMI, and VI 11.6 Meters-1 and 70 patients in the control group (77.8%): 51.1% females 45.15 yers old, 26.2 BMI, and VI 11.2 Meters-1.

The comparative analysis of averages does not show any significant differences in the index or in the stature of these patients.

**Conclusion:** It is a small study, and according to height or the created index, it does not seem that obesity in development modifies the overall height or the vertebral parameters. In addition, the index gives a stable value regarding the sex of both populations in the eighth dorsal vertebra.

CORRELATION BETWEEN SERUM RESISTIN AND CAROTID INTIMA-MEDIA THICKNESS AS A MARKER OF SUBCLINICAL Atherosclerosis IN SYSTEMIC LUPUS Erythematosus

Omnia Ahmed1, Mona Abdel Mageed2, Mohamed Barakat2, Dalia Eliney1, Ahmed Shabana3, faculty of medicine, Alexandria university, Rheumatology and internal medicine, Alexandria, Egypt; 2, faculty of medicine, Alexandria university, rheumatology and internal medicine, Alexandria, Egypt; 3, faculty of medicine, Alexandria university, university, radiodiagnosis, Alexandria, Egypt; 4, faculty of medicine, Alexandria university, chemical and clinical pathology, Alexandria, Egypt; 5, faculty of medicine alexandria university, rheumatology and internal medicine, alexandria, Egypt

Background: Although SLE management has improved markedly in the last few decades, cardiovascular disease (CVD) is still one of the most important leading cause of death. Subclinical atherosclerosis is increased in patients with SLE and it is not fully explained by traditional cardiovascular risk factors. Evidences suggest that resistin is involved in pathological processes leading to CVD including: inflammation, endothelial dysfunction, thrombosis, angiogenesis and smooth muscle cell dysfunction.

Objectives: to determine the relation between serum resistin level and carotid intima-media thickness by doppler technique as a marker of premature or subclinical atherosclerosis in SLE patients.

Methods: this is a cross-sectional study, carried on thirty Egyptian SLE patients who fulfilled the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria. All patients had metabolic syndrome were excluded. Twenty healthy individuals, non smokers, matched for age and sex as controls. All patients were subjected to detailed history taking, a complete clinical examination. Laboratory investigations were done included serum resistin and HOMA was calculated, also the SLE disease activity index (SLEDAI 2K) and SLE disease damage index (SLEDDI) were applied and the scores were estimated. The carotid intima media thickness (CIMT) was assessed by carotid doppler ultrasonography.

Results: There was no statistically significant difference in serum resistin between SLE patients and healthy individuals (p=0.804). As regards the correlation with disease parameters Serum resistin show statistically significant correlation correlation with hs-CRP (r=0.027), HDL (p<0.001), and correlation with disease parameters Serum resistin show statistically significant correlation with SLEDAI 2K and SLEDDI were highest in rheumatoid factor (RF)-positive polyarticular JIA (n=8, 6.67%), followed by systemic JIA (n=3, 3.4%) and oligoarticular JIA (n=3, 2.2%). The sensitivity and specificity of anti-CCP antibodies in all JIA patients were 4.7% and 99.4%.

Conclusion: Anti-CCP antibodies have high specificity for JIA, but its sensitivity is low. Therefore, it can provide additional help for diagnosis of JIA with its high specificity. In particular, anti-CCP antibodies have the highest sensitivity in RF-positive polyarticular JIA than other subgroups, so it can be a more effective diagnostic tool in the subtype.

THE ROLE OF ANGIOPOETHIN-LIKE PROTEIN 4 TYPE IN PROGRESSION OF INFLAMMATORY CHANGES IN RHEUMATOID ARTHRITIS

Vladislav Aleksandrov1,2, Ludmila Shilova1, Inna Alekhina2, Nina Aleksandrova2, Andrey Aleksandrov1,2, Natalia Nikitina2, Andrey Aleksandrov1,2, Ludmila Shilova1, Irina Alekhina3, Ninel Aleksandrova2, Vladislav Aleksandrov1,2, Ludmila Shilova1, Irina Alekhina3, Ninel Aleksandrova2, Vladislav Aleksandrov1,2

Background: Angiopoietin-like protein 4 (ANGPTL4) is actively involved in the processes associated with inflammation, angiogenesis and lipid metabolism in rheumatoid arthritis (RA).

Objectives: To study of the effect of ANGPTL4 on the features of the inflammatory process in RA.

Methods: The study included 36 RA patients (aged from 33 to 64 years old), 28 patients with osteoarthritis (OA) aged 48 to 70 years and 14 people with ankylosing spondylitis (AS) aged 39 to 62 years. Levels of ANGPTL4 in serum were determined by the enzyme immunoassay using the commercial test systems «Human Angiopoietin-like Protein 4 ELISA» from «Bio Vendor» (Czech Republic), Serum C-reactive protein (CRP) levels, erythrocyte sedimentation rates (ESR), rheumatoid factor (RF) titers, and anti-cyclic citrullinated peptide antibody (anti-CCP) were also measured in patients with RA.

Results: The following results were obtained: the level of ANGPTL4 was significantly higher in patients with RA than in patients with OA, AS, and healthy individuals (p = 0.04, p = 0.021, p = 0.038, respectively). A strong positive correlation was found between the level of ANGPTL4 and the activity of RA according to DAS28 (r = 0.71, p = 0.002). There is no reliable association between ANGPTL4 and anti-CCP (p> 0.05). The ANGPTL4 level in the serum was correlated with levels of ESR (r = 0.49, p = 0.019, CRP (r = 0.49, p = 0.007) and the Sharp score of radiologic change (r = 0.39, p = 0.045) in RA. Hypervascularization rates were significantly correlated with ANGPTL4 in patients with RA (r = 0.38, p = 0.002) according to Doppler data. ANGPTL4 can activate proliferation processes in the synovial membrane by binding to integrin-ovvl3. Besides,

DIAGNOSTIC VALUE OF ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODIES FOR JUVENILE IDIOPATHIC ARTHRITIS IN KOREA

Jong Guen Ahn1, Kwang Nam Kim2, 1, Severance Children’s Hospital, Yonsei University College of Medicine, Department of Pediatrics, Seoul, Korea, Rep. or (South Korea); 2, Yonsei University Sacred Heart Hospital, Department of Pediatrics, Anyang, Korea, Rep. of (South Korea)

Background: Anti-cyclic citrullinated peptide (CCP) antibodies are considered to have specificity for rheumatoid arthritis (RA). However, the diagnostic value of anti-CCP antibody has not been proved in juvenile idiopathic arthritis (JIA).

Objectives: The purpose of this study was to access the prevalence of anti-CCP antibodies in Korean children with JIA, and to investigate the diagnostic accuracy of anti-CCP antibodies according to JIA subgroup.

Methods: JIA patients were recruited from Severance Children’s Hospital, Seoul, Korea from 2004 to 2018. Diagnosis of JIA was made by pediatricians according to the International League of Associations for Rheumatology (ILAR) classification. Control group consisted of healthy children with anti-CCP antibodies test, who had visited the outpatient clinic of the hospital for JIA suspected symptoms, but diagnosed as not JIA. Enzyme-linked immunosorbent assay (ELISA) was used for detection and quantification of anti-CCP antibodies.

Results: Study subjects included 295 JIA patients and 165 controls. Among the JIA children, 14 (8.6%) patients were found to be positive for anti-CCP antibodies. 1 (0.6%) of the control group was positive for anti-CCP antibodies. The prevalence rates of anti-CCP were highest in rheumatoid factor (RF)-positive polyarticular JIA (n=8, 66.7%), followed by systemic JIA (n=3, 3.4%) and oligoarticular JIA (n=3, 2.2%). The sensitivity and specificity of anti-CCP antibodies in all JIA patients were 4.7% and 99.4%.

Conclusion: Anti-CCP antibodies have high specificity for JIA, but its sensitivity is low. Therefore, it can provide additional help for diagnosis of JIA with its high specificity. In particular, anti-CCP antibodies have the highest sensitivity in RF-positive polyarticular JIA than other subgroups, so it can be a more effective diagnostic tool in the subtype.

AB1119 THE PRESENCE OF SYNOVITIS IS THE MAIN FACTOR INFLUENCING THE DEVELOPMENT OF PAIN SYNDROME IN ARTHRITIS OF THE KNEE Joint

Ninel Aleksandrova1, Natalia Nikitina1, Vladislav Aleksandrov1,2, Ludmila Shilova1, Andrei Aleksandrov1,2.

1Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russian Federation; 2Volgograd State Medical University, Hospital Therapy, Volgograd, Russian Federation

Background: Dysfunctions and pain syndrome in lesions of the knee joint can significantly discomfort a sick person and lead to a persistent decrease in physical activity and disability. Often pain syndrome precedes radiographic appearance of the structural changes in the joint and is accompanied by an increase in number of different changes in the synovium according to ultrasound investigation.

Objectives: To investigate the clinical significance of ultrasound criteria of changes in the synovial membrane of the knee joint cavity and its role in the assessment of pain in gonarthrosis.

Methods: 30 people aged 30 to 50 years with osteoarthritis of the knee joint were under observation; assessment of the severity of pain in the knee when walking was at least 40 mm on a visual analogue scale (VAS). Ultrasound examination of the knee joint was carried out according to standard procedure using a linear sensor with a frequency of 0.5, 12 MHz in an ultrasonic diagnosis system Accuvix V10 (Samsung Medison, Korea).

Results: The evaluation of ultrasound changes was performed in the upper inversion of the knee joint according to the following criteria: the severity of intraarticular effusion, synovial proliferation, local vascularization of the synovial membrane by power doppler. All patients were divided into three groups, according to the severity of pain in the knee joint: group I (12 people) - 41–59 mm, group II (10 people) - 60–79 mm, group III (8 people) - 80–100 mm on the VAS scale. By comparing changes in the knee joint by ultrasound data in patients of different groups, the following results were obtained: group I: severity of intraarticular effusion - 10 people (minimal changes in 60%, moderate in 20%, expressed in 20%), synovial proliferation - 4 people (moderate changes in 50%, expressed in 50%), local vascularization of synovium - 6 people (minimal changes in 66.7%, moderate in 16.7%, expressed in 16.6%); group II: severity of intraarticular effusion - 9 people (55.6%, 22.2% and 22.2%), synovial proliferation - 3 people (0%, 33.3% and 66.7%), local vascularization of the synovial membrane - 4 people (25%, 25% and 50%, respectively); group III: severity of intraarticular effusion - 8 people (62.5%, 12.5% and 25%), synovial proliferation - 5 people (20%, 40% and 40%), local vascularization of the synovial membrane - 3 people (per 33.3%, respectively).

Conclusion: The use of ultrasound in the diagnosis of diseases of the knee joints allows to reliably determine the structural and functional changes in all components of the knee joint. The severity of pain in gonarthrosis is most associated with the presence of synovitis in the joint.

AB1121 EFFICACY AND SAFETY OF ULTRASOUND GUIDED ASPIRATION AND INTRA-LESIONAL CORTICOSTEROIDS INJECTION OF RUPTURED BAKER CYST

Mohammed A. Mortada1, Yoomna A. Amer2. 1Faculty of medicine, Zagazig University, Reumatology and Rehabilitation, Zagazig, Egypt; 2Faculty of medicine zagazig university, Rheumatology and rehabilitation, Zagazig, Egypt

Background: Baker’s cyst is the most common mass in the popliteal fossa and results from fluid distension of the gastrocnemio-semimembranosus bursa. The most common complication of Baker’s cyst is the rupture or dissection of fluid into the adjacent proximal gastrocnemius muscle belly, which results in a pseudothrombophlebitis syndrome mimicking symptoms of DVT. Treatment of ruptured Baker cysts ranged from conservative management to surgical resection.

Ultrasound guided aspiration and corticosteroids injection may be an effective and easy method of management of these cases. Up to the best of our knowledge, this is the first study to detect the efficacy and safety of ultrasonographic guided aspiration and injections of ruptured Baker cysts.

Objectives: To evaluate the efficacy and safety of ultrasonographic guided aspiration and local corticosteroids of ruptured Baker cysts based on follow-up clinical and sonographic results.

Methods: A retrospective study was conducted on 42 patients (12 males and 30 females, mean age 36 +/- 10 SD years) affected by a ruptured Baker cysts associated to knee joint disorders in the period between January 2013 to January 2019. The diagnosis was done by clinical presentation of acute calf pain, swelling, tenderness at the calf muscles and ultrasonographic evidences of ruptured backer cysts in the form of free fluid collection in the calf connected to a well defined cyst at the back of knee. All cases were treated by ultrasonographic guided aspiration and intralesional injection of corticosteroids once or twice one week a part. Follow up were done on a weekly basis until complete resolution of symptoms then 3 months later. Visual analogue scale (VAS) for calf pain and Rauschning-Lindgren and Lysholm Knee Scoring Scales were used to assess pre/post-injection knee functions.

Results: The primary diagnoses to patients presented with ruptured Baker cyst in this study were as follow: 18 (42.8%) cases with rheumatoid

AB1120 DIAGNOSTIC ROLE OF NEUROMUSCULAR ULTRASOUND IN CUBITAL TUNNEL SYNDROME

Fatma Ab1, Mona Nasr1, Ahmed Hafez2, Adham Khalil2. 1Minia university, Reumatology and Rehabilitation, Minia, Egypt; 2Minia university, Reumatology and Rehabilitation, Minia, Egypt; New Cairo El Ein El Teaching Hospital, Cairo University, Cairo, Egypt

Background: Cubital tunnel syndrome (CuTS) is the second most common compressive neuropathy of the upper limb following carpal tunnel syndrome and is the most common site for entrapment for the ulnar nerve.

Objectives: Our aim is to evaluate the role of ultrasonography (US) as a diagnostic tool for Cubital tunnel syndrome (CuTS) in comparison with nerve conduction study (NCS).

Methods: twenty elbows with CuTS and twenty asymptomatic controls were assessed by NCS and underwent ultrasonography of elbows. Data from patients and controls were compared to determine the diagnostic relations in patients with CuTS and the grade of severity

Results: There was a high degree of correlation between NCS of the ulnar nerve, clinical parameters and variable US measurements. The CSA of the ulnar nerve was the most sensitive parameter and a cut-off point of 9.5 mm2 behind medial epicondyle was found to be 100% sensitive and 80% specific. The ulnar nerve ratio (UNR) had a diagnostic accuracy of 95% with 85% specificity.

Conclusion: Ultrasonographic measurements of the ulnar nerve CSA and UNR have a comparable diagnostic value as a non-invasive and an alternative modality for the evaluation of CuTS

Disclosure of Interests: None declared

arthritis, 15 (37.5%) cases with osteoarthritis and 9 (21.4%) cases with psoriatic arthritis.
Clinical parameters (VAS for calf pain and Rauschning-Lindgren score) improved significantly in all patients at both post injection evaluation visits. Rauschning-Lindgren score was significantly lower after US guided injections (mean, 0; range, 0-1) than at baseline (mean, 2; range, 1–2); \( p < 0.001 \) (table1).
VAS for calf pain also significantly lower after US guided injections (mean,0.5; range, 0-1) than at baseline (mean, 9.5; range, 0-10); \( p < 0.001 \).
Ultrasoundographic features improved significantly with complete disappearance of free fluid at the calf in 35 (83.3%) cases one week after the injection.
As regards Baker cyst only 5 (11%) cases showed complete disappearance of the backer cyst and in the majority of cases 37 (88%) there were persistent Baker cysts.
No side effects were reported in all cases.

### PREDICTION OF THE UTILITY OF ULTRASOUND EVALUATION IN RHEUMATOID ARTHRITIS BY THE CLINICAL FACTORS

**Background:** It is known that ultrasound detects synovitis with higher sensitivity than physical examination in rheumatoid arthritis (RA), and the residual inflammation detected by ultrasound even in the patient achieving clinically remission well correlates with progression of erosion. It is impossible to perform ultrasound evaluation on all the joints in all the patients in terms of time and human resource. Therefore, ultrasound use in RA should be more focused on situations when the physical findings and ultrasound findings likely to dissociate.

**Objectives:** To investigate the factors that can predict dissociation between clinical and ultrasound-detected synovitis in the patient with rheumatoid arthritis.

**Methods:** Patients aged 18 years or older who satisfied ACR/EULAR 2010 criteria who visited St. Luke’s International Hospital from June 1, 2018 to November 9, 2018 and were performed ultrasound on PIP, MCP, and wrist joint. We retrospectively reviewed the electronic medical chart and ultrasound data, and analyzed the dissociation of clinical synovitis defined as existence of swelling or tenderness and ultrasound-detected synovitis defined as both of power doppler grade and gray scale grade 1 or gray scale grade 2. Clinical evaluation was done by the attending physician who ordered the ultrasound evaluation. Ultrasound evaluation was done using standard scan technic by the sonographers who are blinded to the clinical evaluation.

The correlation between patient’s characteristics and dissociation was analyzed using \( \chi^2 \) test, Mann-Whitney U test and logistic regression analysis.

**Results:** 51 joints in 32 patients (4 males, 28 females) were included in the study. Among the 32 patients, 18 was classified in the dissociation group (DG) and 14 in the non-dissociated group (NDG). No significant difference was observed in the patient’s characteristics of DG and NDG. In the univariate analysis, the absence of swelling in the target joint had tendency to be the risk of dissociation. The same tendency was preserved in the multivariate analysis with the presence of tenderness in the target joint assigned as a covariate (OR 3.68, 95% CI = 0.85 - 15.90, \( p < 0.08 \)).

**Conclusion:** There was a numerical tendency that no swelling on the joint is a risk factor for the dissociation between clinical synovitis and ultrasound-detected synovitis. Future study with increased number of participants may identify more sensitive risk factors for dissociation, and enable to make an effective indication of ultrasound evaluation in the care of RA.

### SHOULDER PAIN: ARE THERE PREDICTIVE FACTORS OF RESPONSE TO TREATMENT AND OF ULTRASOUND FINDINGS?

Sorin Anveda\(^1\), Joana Rodrigues\(^1\), Daniela Farai\(^1\), Joana Neves\(^1\), Joana Silva\(^1\), Daniela Pires\(^2\), Sérgio Alcino\(^1\), José Tavares-Costa\(^1\), Armando Abravanel\(^1\), Filipa Teixeira\(^1\), \(^1\)Unidade Local de Saúde do Alto Minho, Rheumatology department, Porto de Lima, Portugal, \(^2\)Hospital de Braga, Rheumatology department, Braga, Portugal

**Background:** Shoulder pain is a common cause of consultation in Primary Health Care, and may correspond to up to 30% of the reasons for consultation. Pathology of the rotator cuff is the most common cause of pain. Ultrasound is a valuable diagnostic tool in assessing shoulder disorders; it can be as effective as magnetic resonance imaging.

**Objectives:** To determine the predictive factors of response to treatment and ultrasound findings in shoulder pain.

**Methods:** We performed an analysis of the patients’ cases sent to rheumatology consultation with shoulder pain, every patients had an echography shoulder evaluation, and the rheumatologist decided treatment based on the guidelines for the treatment of shoulder tendinopathies. The use of nonsteroidal anti-inflammatory drug (NSAIDs) and muscle relaxant medications as well as the following techniques: corticosteroids local injection, barbotage, capsular distension and physiotherapy programs were some of the variables assessed. Posteriorly, the patients were clinically assessed in a follow-up visit.

**Results:** A total of 119 patients were evaluated. Men presented a higher risk of distension of the subscapular bursa. There was a statistically significant relationship between the time from the beginning of the symptomatic and treatment response. Diabetes mellitus, arterial hypertension and dyslipidemia were statistically significantly associated with some rotator cuff lesions and distention of the subscapular bursa.

**Conclusion:** In patients with shoulder pain, early intervention positively influences the response to treatment. Thus, it is important that these patients are evaluated more promptly. Some comorbidities seem to be associated with a higher risk of specific rotator cuff lesions.

**No relationship was found between response to treatment and age, sex, occupation, previous treatments or type of therapy selected. The association found in this study seem to have clinical implications. Prevention of rotator cuff disease is a matter of major relevance as well as early institution of treatment.**

[10] Aisha Ben Tekaya1, Lobna Ben Ammar 1, Olfa Saidane1, Rawdha Tekaya1, Mohammed Ben Hammania2, Ines Mahmoud3, Leila Abdelmoula1, 1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; 2Charles Nicolle Hospital, Cardiovascular Surgery, Tunis, Tunisia

Background: Spondylodiscitis is a potentially life-threatening infection burdened by high morbidity rates. MRI remains the key examination in the diagnosis of infectious spondylodiscitis. The microbiological diagnosis is the main driver for successful treatment.

Objectives: To evaluate the MRI characteristics associated with the detection of microbial pathogens by computed tomography (CT) guided biopsy in case of suspicion of infectious spondylodiscitis.

Methods: Retrospective study including all patients hospitalized in our department between 1999 and 2019 who underwent CT and/or MRI-guided biopsy (CT-guided biopsy + CT). The CT-guided biopsy was performed in 92 patients, including 53 men and 39 women, aged 16-86 years (mean age 56 years; 16-86 years). The median delay of consultation was 3 months. Inflammatory back pain was reported in 78% of cases. Neurologic deficiency was noticed in 19.5% of cases. The lumbar spine was involved more than 50% of cases. Spinal MRI was performed to all patients and showed paravertebral abscess in 64.6%, epidural abscesses in 62.1%, intradiscal abscesses in 3.6%, spinal cord compression 10.9%, and vertebral osteolysis in 6.09% of cases. The causative microorganism was mycobacterium tuberculosis in 53.6%, brucella in 24.3%, and pyogenic germs in 15.8% of cases. The presence of spinal cord compression, intradiscal abscess and vertebral osteolysis was more frequent in group 2, but with no statistically significant difference (p = 0.65, 1 and 0.56, respectively). In addition, there was no significant difference in the presence of paravertebral abscesses and epiduritis (p = 0.41 and 0.53, respectively).

Conclusion: Spondylodiscitis is an emergency which must be diagnosed on time to avoid life threatening complications, neurological sequelae and spinal deformities.

Disclosure of Interests: None declared

Results: The “before” ultrasounds were performed between 2012 and 2016 and the “after” ultrasounds between 2015 and 2018. The time fashion between the two ultrasounds for each patient was 2 years. Thirty-three subjects were included, with an average age of 47.5 SD 7.6 years. Proportion of women 66.6%. Proportion of dominant shoulders (51.1%). As shown in table 1, the most significant changes were the thickness of the tendon measured at the height of the middle of the longitudinal axis of the TSE had been previously diagnosed in an ultrasound study. DEMographic data and static images from the ultrasound studies of each patient were compared. The explanatory variable was time (before-after) and the response variables in image were: (1) Increased tendon thickness measured at 30mm from the deep edge of the acromion (GRO- SORB), (2) Increased tendon thickness measured at the height of the middle of the longitudinal axis of the calcification (GROSORC), (3) Longitudinal axis of the calcification (LONGC), (4) Thickness or height of the calcification, when this was measurable (ALTC), and (5) Distance between the calcification and the deep end of the acromion (DISTC). In addition, two indices were determined: (a) Increased tendon thickness in the calcification zone (GROSORC/GROSORB) and (b) proportion of tendon thickness occupied by calcification (ALTC/GRO- GOSC). The measurements were carried out using the software of the equipment in which the original and subsequent study was made (GE Logiq e; Toshiba Nemo XG).

Variables measured by ultrasound measurement Before measurements After measurements t Student (paired data)

Conclusion: The most important factor that explains the development of an SS associated with calcification is the increase in tendon thickness at the height of the calcification itself and, at the same time, this measure increases when the calcification is more lateralized and the more elongated its longitudinal diameter. These modifications could have implications when deciding the therapeutic management of these processes.

AB1127 ULTRASOUND INTER-READER RELIABILITY OF INFLAMMATORY FINDINGS IN PATIENTS WITH POLYARTHRITIS

Luisa Bredes,1 Mariana Santiago,2,3 João Rovisco,2,3 João Dinis de Freitas,4 José Antonio P. Da Silva,2,4 Inês Silva,2 Filipa Teixeira,1 Daniela Faria,4 Cândida G. Silva,2,5 Sandra Falcão,1,3,7 Centre Hospitalar e Universitário de Coimbra, Coimbra, Portugal,2 Faculdade de Medicina de Coimbra, Coimbra, Portugal,2 Hospital Egas Moniz, Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal,4 Unidade Local de Saúde do Alto Minho, Serviço de Reumatologia, Ponte de Lima, Portugal,5 Higher School of Health Sciences, Polytechnic Institute of Leiria, Leiria, Portugal,6 Centro de Quimica da Universidade de Coimbra, Coimbra, Portugal,2 Faculdade de Ciências Médicas da Universidade Nova de Lisboa, Lisbon, Portugal

Background: Ultrasonography is an imaging technique that allows rheumatologists to visualise structural and inflammatory changes within a joint. Objectives: The objective of this study was to assess the inter-reader reliability of interpretation of inflammatory and destructive changes in a wide range of joints in patients with polyarthritides.

Methods: This study was divided in two parts: 1) consensus process and 2) reliability exercise. For the first part, a written questionnaire was sent by email to 6 sonographers from 3 portuguese hospitals with the highest level of competence (EULAR competency assessment level 2). The questionnaire included 17 questions divided in two groups: 1) elementary components in B-mode and Doppler assessment (effusion, synovial hypertrophy (SH), power Doppler (PD), erosions and synovitis definition) and 2) approach at the joint level (the definition of which plan and recess will be assessed in each joint). The participants were asked to rate their level of agreement/disagreement for each statement using a 1-5 Likert scale (1=strongly disagree to 5=strongly agree). For the reliability exercise, video clips of US examinations of 40 joints (wrist, metacarpophalangeal (MCP) from 1 to 5, elbow and shoulder) and metatarsophalangeal (MTP) joints from 1 to 5, knee, tibiotarsal (TT) and metatarsalphalangeal (MTP) joints from 1 to 5, elbow and shoulder) from each of 15 patients were collected (showing a multiplanar bilateral ultrasound approach). Each joint in each video was scored by individual ultrasonographers for the presence/absence of elementary components: effusion (Yes/No), SH (No/Grade 1 to 3), PD (No/ Grade 1 to 3) and erosions (Yes/No). Inter-reader agreement analysis was assessed through Fleiss’ kappa coefficient and classified according to Landis and Koch[8]: κ values ≤ 0 were considered poor, 0.20 slight, 0.21-0.40 fair, 0.41-0.60 moderate, 0.61-0.80 good and 0.81-1.00 excellent. Statistical significance was defined as p<0.05. Statistical analysis was performed using STATA V.14.

Results: Thirty seven joints of the 600 joints were excluded due to dislocation of the joint or presence of objects (rings/catheters) and the videos of a total of 563 joints were analysed by the 6 ultrasound experts. Inter-reader agreement was superior for TT joints and inferior for wrist; the identification of the erosions had the better agreement in the elementary components (Table 1).

SENSITIVITY AND SPECIFICITY OF THE AUTOMATED SQUEEZE TEST (GAENSLEN’S MANEUVER) FOR IDENTIFYING METACARPOPHALANGEAL SYNOVITIS BY MAGNETIC RESONANCE IMAGING

Diana Daniela Cañadía Martínez, David Vega Morales, Jorge Antonio Esquivel Valerio, Mario Alberto Garza Elizondo, Brenda Roxana Vázquez Fuentes, Dionicio Ángel Galarra-Delgado. Hospital Universitario "Dr. José Eleuterio González" Universidad Autónoma de Nuevo León, Servicio de Reumatología, Monterrey, Mexico

Background: It is well known that an early diagnosis and treatment for Rheumatoid Arthritis (RA) prevents its complications, therefore there are many efforts to identify individuals at risk to develop RA. The Squeeze test has been used to detect synovitis in metacarpophalangeal joints, even though it is used in daily practice, there is a great variability in their performance among rheumatologists. [2]

Objectives: The aim of this study is to determine the diagnostic performance of the automated squeeze test (AST) on the metacarpophalangeal (MCP) joints to detect the presence of synovitis, edema, or erosions by magnetic resonance imaging (MRI) using the rheumatoid arthritis magnetic resonance imaging score (RAMRIS) in first-degree relatives (FDR) of RA patients, of whom clinically suspect arthralgia (CSA) in hands was suspected, as well as in RA patients.

Methods: It is an observational and cross-sectional study for a diagnostic test. A total of 60 patients, older than 18 years, were included and divided in three groups: CSA group, 22 with less than 1 year with arthralgia and required to be FDR of RA patients; early RA group: 22 patients who met ACR/EULAR 2010 Classification Criteria with less than 1 year with the disease; and late RA group: 16 patients who met ACR/EULAR 2010 Classification Criteria, with more than 1 year with the disease. The AST was performed in the 60 participants’ dominant hand. The device was evaluated by MRI, which examined the same hand in the 60 patients.

Results: A total of 240 MCP joints were evaluated. The AUC for the total RAMRIS score >10 was [0.480 (95% CI 0.301-0.617) P=0.597]; for synovitis RAMRIS score >7 was [0.459 (95% CI 0.331-0.669) P=0.791]; and for the presence of any synovitis by RAMRIS was [0.575 (95% CI 0.428-0.723) P=0.331]. For the RAMRIS synovitis score, the most sensitive and specific cut-off of the force by AST was 4.645 kg with a 66.7%-sensitivity and 50% specificity.

ULTRASOUND MEASUREMENT OF MUSCLE THICKNESS AT THE PROXIMAL FOREARM: VALIDITY ISSUES

Sonia Castell1, Gianluca Smerilli2, Edoardio Cipolletta2, Fausto Salafi2, Emilio Filippucci2, Walter Grassi2. 1Hospital del Mar, Rheumatology, Barcelona, Spain; 2Università Politecnica delle Marche, Rheumatology Unit, Ancona, Italy

Background: The term sarcopenia defines the muscle strength loss and muscle mass loss due to aging, and it is one out of three criteria for the diagnosis of frailty in the elderly. A number of studies have related the handgrip strength with muscle thickness (MT) in the forearm measured by ultrasound (US)1, but a standardized scanning protocol has not been described and its interobserver reliability has not been investigated yet.

Objectives: The aims of this study were to provide detailed description of the scanning protocol to measure the MT in the forearm and to test its feasibility and interobserver reliability.

Methods: A total of 27 consecutive subjects were enrolled at Ospedale “Carlo Urbanii”, in Jesi (Ancona, Italy): 2 healthy volunteers recruited from among our staff, and 25 patients referred to the Rheumatology Department affected by rheumatoid arthritis (5), psoriatic arthritis (4), spondyloarthritides (3), polymyalgia rheumatica (3), systemic sclerosis (1), overlap SLE/SSc (1), Sjögren syndrome (1), anti-synthetase syndrome (1), undifferentiated connective tissue disease (1), osteoporosis (1), small vessels vasculitides (2) and fibromyalgia (2). The female to male ratio was 19:27, the mean age was 52.1 years (SD ±13.7), and the mean Body Mass Index was 27.4 Kg/m2 (SD ±4.2). Four rheumatologists (SC, EC, GS, EF) trained in musculoskeletal US, with a different degree of expertise, performed the examinations using a MyLab ClassC (Esaote SpA) equipped with a broadband linear probe (frequency range 4-13 MHz). All subjects sat in front of the sonographer with their hands supinated and the forearm resting on the examining table. First, the coronoid process was imaged according to the “longitudinal scan of the coronoid recess” as indicated by the 2017 EULAR US guidelines. Then the probe was moved distally following bony cortex until the ulnar tuberosity was identified. Immediately distally to the ulnar tuberosity the bone turns flat and hyperechoic and this was taken as the anatomical reference for the measurement. Afterwards the probe orientation was changed to obtain a transverse view. During the rotation, the proximal third of the diaphysis of the radius was imaged. Two MT were measured, the ulnar MT (UMT) and the radial MT (RMT), between the subcutaneous tissue-muscle interface and the muscle-bone interface of each bone respectively. The measurement of UMT and RMT of both arms were registered, as well as the scanning time of all the examiners.

Results: We found an excellent interobserver reliability of this scanning protocol, with and interclass correlation coefficient (ICC) among the four sonographers of 0.975 (CI 0.955 - 0.987) for the right UMT, an ICC of 0.968 (CI 0.942 - 0.984) for the left UMT, an ICC of 0.932 (CI 0.878 - 0.966) for the right RMT and an ICC of 0.949 (CI 0.908 - 0.974) for the left RMT. The mean time required to acquire all measurements in each subject was less than five minutes (SC 4.4 min; EC 4 min; GS 4.2 min; EF 4.5 min).

Conclusion: The results of this study provide evidence in favour of both feasibility and interobserver reliability of US measurement of the forearm MT.

RELIABILITY OF ULTRASOUND MEASUREMENT OF HYALINE CARTILAGE THICKNESS IN RHEUMATOID ARTHRITIS

Eduardo Cipolletta, Emilio Filippucci, Andrea Di Matteo, Marco Di Carlo, Walter Grassi. Politecnico University of Marche, Rheumatology Unit, “Carlo Urbani” Hospital, Jesi, Italy

Background: Only few studies investigated the role of ultrasound (US) in the assessment of hyaline cartilage in rheumatoid arthritis (RA).

Recently, a positive correlation was found between the US measurement of the metacarpal head cartilage thickness (MCT) and both the anatomical MCT and the radiographic joint space width1.

Objectives: To evaluate inter- and intra-observer reliability in the assessment of MCT in RA patients and healthy subjects; to compare the agreement of the sonographers in the assessment of the MCT using different methods (i.e. semiquantitative and quantitative); to determine the inter-observer smallest detectable difference (SDD) of MCT measured by US.

Methods: US assessment was performed by two rheumatologists on 160 metacarpophalangeal (MCP) joints of 10 healthy subjects and 10 patients with RA (according to 2010 ACR/EULAR classification criteria) using a MyLab Twice (Esaote Biomedica, Genoa, Italy) equipped with a linear very high frequency probe (i.e. 10-22 MHz).

To assess inter-observer reliability, the hyaline cartilage of metacarpal head from II to V digits of both hands were examined independently on the same day by two rheumatologists (an experienced musculoskeletal sonographer and an investigator with limited US training).

To assess intra-observer reliability, all the subjects were rescanned using the same scanning protocol and the same US setting by one sonographer after a week.

Hands were scanned with the MCP joints in maximal flexion (approximately 90°). The hyaline cartilage of all the metacarpal heads was scanned in longitudinal and transverse views in the central portion of the metacarpal head. Particular attention was paid on maintaining the probe in a position providing an angle of 90° between the direction of the US beam and the cartilage surface2.

MCT was scored both semi-quantitatively (using a five-grade scoring system3) and quantitatively (using the average value of the longitudinal and transverse measurements).

The inter- and intra-observer agreements for assessing the MCT with the semiquantitative scoring system were calculated using Cohen’s kappa and interpreted according to Landis and Koch.

The inter- and intra-observer agreements for assessing the MCT with the quantitative scoring system were calculated using intraclass correlation coefficients (ICC) and their 95% confidence intervals (95%CI).

The SDD was determined using Bland-Altmann 95% limits of agreement method.

Results: The inter- and intra-observer agreements for the semiquantitative assessment of the MCT were moderate [κ=0.59 (95% CI: 0.35-0.83) and κ=0.63 (95% CI: 0.39-0.87), respectively].

Considering all the measurements, a substantial inter-observer [ICC= 0.88 (95% CI: 0.82-0.92)] and intra-observer [ICC= 0.88 (95% CI: 0.87-0.94)] agreements for the quantitative assessment of MCT were found.

The SDD of the MCT measurement was: 0.11 mm for both longitudinal and transverse scans and 0.09 mm for the average of the two measures.

Conclusion: This study provides evidence in favor of the reliability of semiquantitative and quantitative US methods for assessing MCT in RA.

Further studies are required to determine standard reference values of MCT by US in healthy subjects.

HIGH-RESOLUTION ULTRASOUND ASSESSMENT OF CARTILAGE THINNING IN RHEUMATOID ARTHRITIS

Eduardo Cipolletta, Emilio Filippucci, Andrea Di Matteo, Marco Di Carlo, Fausto Salaffi, Walter Grassi. Politecnico University of Marche, Rheumatology Department, “Carlo Urbani” Hospital, Jesi, Italy

Background: Conventional radiography is the standard imaging modality to detect joint damage in rheumatoid arthritis (RA). Ultrasound (US) allows for a direct visualization of hyaline cartilage. To date, only few studies investigated the role of US in the assessment of cartilage damage in RA.

Objectives: To compare US qualitative and quantitative assessments of cartilage thinning at metacarpal head (MH) in RA patients and in an age-, sex- and height-matched healthy controls (H). To correlate cartilage damage and clinical parameters in RA.

Methods: US examination was performed on 318 metacarpophalangeal (MCP) joints of 40 consecutive RA patients and on 320 MCP joints of 40 age-, height- and sex-matched H using a MyLab Twice (Esaote Biomedica, Genoa, Italy), equipped with a high frequency linear probe (up to 22 MHz).

RA patients were enrolled according to the 2010 RA classification criteria. The hyaline cartilage of MH from II to V digits of both hands was examined with the MCP joints in maximal flexion.

Each MH was scanned in longitudinal and transverse views. Particular attention was paid on maintaining the probe in a position providing an angle of 90° between the direction of the US beam and the cartilage surface.

Cartilage thickness (CT) was assessed both semi-quantitatively (using a reliable qualitative five-grade scoring system3) and quantitatively (using the mean value of longitudinal and transverse measurements of the CT). Finally, association between cartilage damage and clinical parameters was assessed.

Results: Semiquantitative score: Cartilage thinning (grade 2, 3 and 4) was found in at least one MH in 23 RA patients (57.5%) and in 4 H (10.0%) (p<0.01). A significantly higher prevalence of cartilage damage (grade 2, 3 and 4) at joint level was found in RA patients (86 MCP joints, 27.0%) in comparison with H (13 MCP joints, 4.1%) (p<0.01).

Quantitative assessment: CT of the MH ranged from 0.0 to 1.10 mm (0.60±0.26 mm, mean±SD) in RA patients and from 0.41 to 1.08 mm (0.67±0.12 mm, mean±SD) in H. Male had a thicker hyaline cartilage than female, both in RA patients (p<0.01) and in H (p<0.01). No significant difference was found between left and right side, both for RA patients (p=0.48) and healthy subjects (p=0.94).

Detailed quantitative measurements of CT of MH are reported in table 2.

Abstract AB1131 Table 2. US cartilage thickness measurement for each digit in RA patients and healthy controls.

95% CI: 95% confidence interval; L: left; MH: metacarpal head; R: right; RA: rheumatoid arthritis; SD: standard deviation; US: ultrasound.

A significant association was found between the CT value and age (r=0.528, p<0.001), disease duration (r=0.376, p=0.005) and grade of the semiquantitative scoring system (r=0.80, p<0.001). No association was found between CT and BMI, weight, ACPA positivity and RF positivity.

Conclusion: This study demonstrated that a significantly higher prevalence of cartilage damage was found in RA patients using both the semiquantitative score and the quantitative assessment. In particular, in RA patients the hyaline cartilage of II and III MH is thinner in comparison with H. Finally, a significant association was found between the CT values and disease duration and age.

THE ROLE OF PET/CT IN THE MANAGEMENT OF GIANT CELL ARTERITIS
Alessandro Crono1, 2, Mattea Bellain2, 3, Roberta Pedrazzoli1, Daniele Sola1, Enrico Perrotta, OA Mascia, as a member of the Imaging - Radiology and Nuclear Medicine Division, Immunorheumatology Unit, Novara, Italy, 1Università del Piemonte Orientale – UPO, Department of Translational Medicine, Novara, Italy, 2IRCAD – Interdisciplinary center of autoimmune diseases, Novara, Italy; 3A.O.U. Maggiore della carità, Nuclear Medicine, Novara, Italy

Background: Giant cell arteritis (GCA) is a large vessel vasculitis that affects the aorta and/or its major branches including the superficial temporal artery. Together to cranial symptoms such as headache and visual disturbances, extra cranial manifestations have been widely reported, sometimes as unique clinical presentation. Several imaging modalities are available to evaluate aortic involvement including fluorodeoxyglucose (FDG) positron emission tomography (PET), however there are few reports that analyzed the impact of the findings of this advanced imaging in predicting outcomes of the disease.

Objectives: To assess the utility of PET in disease extension assessment to predict, together to clinical manifestations, the disease evolution.

Methods: We retrospectively reviewed all the clinical records of patients receiving a diagnosis of large vessel vasculitis from 1st January 2010 to 1st January 2016 at a tertiary immunorheumatology clinic of a university Hospital, who underwent a PET. Clinical, laboratory, and imaging data were collected. Non-parametric analysis was performed.

Results: We recruited 19 patients (10 females, 52.6%). The median age was 74.0 [65.5-76.0]; at the diagnosis, the median erythrocyte sedimentation rate (ESR) was 65.5 [49.0-86.0], while C-reactive protein (CRP) was 8.5 [5.5-14.0]. 12 patients showed a typical cranial GCA (63.2%), while 7 (36.8%) were diagnosed with extracranial GCA. The two groups were comparable at diagnosis for age, gender, median ESR and CRP. Interestingly, the PET was significant for aortitis not only in the 7 patients with extracranial involvement, but also in 7/12 patients with cranial GCA (58.3%). Along a median follow-up of 15 months [4.5-26.5], 4 relapses were reported. Notably, all the relapses were males and showed both aortic and cranial involvement. In a multivariate model, male gender was the only predictor of relapse (p=0.02), while age at onset, clinical subsets (cranial vs. extracranial) and steroid dose did not fit the model

Conclusion: The use of PET in GCA is relevant in the assessment of extension of disease since a significant number of patients without cranial symptoms in the end resulted to have large vessel involvement. In addition, PET is useful in identifying patients with cranial involvement that have also aortic inflammation since they seem to have worse prognosis.

IMPRESSING THE STANDARDISATION OF DIAGNOSTIC LABORATORY TESTS FOR RF AND ACPA THROUGH THE ESTABLISHMENT OF A NEW INTERNATIONAL REFERENCE MATERIAL
Luis de Jesus Saravia1, Peter Piggy2, Lucy Studholm1, National Institute for Biological Standards and Control, Biopharmaceutics, Potters Bar, United Kingdom; 2National Institute for Biological Standards and Control, Biostatistics, Potters Bar, United Kingdom

Background: Rheumatoid arthritis is a debilitating chronic inflammatory disease. Its laboratory diagnosis relies mainly on testing for the presence of two groups of autoantibodies in patient’s serum: rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA). Most RF assays are standardised against W1066, the WHO international standard rheumatoid arthritis serum established in 1968, or 64/002, the British Standard rheumatoid arthritis serum, which is the same material. Stocks of W1066 are becoming exhausted which triggered a decision by NIBSC and WHO to prepare a new standard preparation intended to replace W1066.

Objectives: Primarily, we have a responsibility to ensure the continuity of W1066 as a calibrator in RF agglutination-based assays. However, science has progressed and ACPA are now recognised as equally important to RF in the diagnosis of rheumatoid arthritis which is reflected in the ACR/EULAR 2010 classification guidelines. Therefore, we intend to assign the new standard values in international units to both RF and ACPA. In order to do this, a new international reference material (IgG-RF and IgA-RF). In addition, some assays look at isotype-specific RF, so we will assess the new standard values in international units to both RF and ACPA. In order to do this, a new international reference material (IgG-RF and IgA-RF).

Methods: A pool of rheumatoid arthritis serum was prepared and dispensed into ampoules, lyophilised and sealed under an inert nitrogen atmosphere. An international collaborative study was organised with expert laboratories, including commercial kit manufacturers and medical

Disclosure of Interests: None declared
laboratories, to assess the suitability of the new candidate standard and calibrate it against W1066.

Results: The results of the collaborative study will be used to propose a new standard, to the new candidate standard in RF and ACPA for consideration at the WHO Expert Committee for Biological Standardisation.

Conclusion: Standardisation of diagnostic laboratory tests involves the development of a physical sample for each analyte. The use of these international reference standards as primary calibrators promotes the harmonisation of test results between different assays. Because the assays use a similar scale, their results are easily understood, which ultimately increases the impact of published research and clinical findings on our knowledge of the disease.

CD26: A POTENTIAL NOVEL HISTOLOGICAL MARKER OF IDIOPATHIC INFLAMMATORY MYOPATHIES

Rebecca De Lorenzo1, Clara Scialor1, Antonella Monno1, Francesco Bonom0, Silvia Cavali2, Antonio Francesco Di Naro2, Stefano Prevalti1, Patrizia Rovero-Querini1, San Raffaele Scientific Institute, Laboratory of Innate Immunity and Tissue Remodelling, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy; Adienne Pharma and Biotech, Lugano, Switzerland; San Raffaele Scientific Institute, Experimental Neurology Institute (INSPE), Milan, Italy

Background: Idiopathic inflammatory myopathies (IMM) are a heterogeneous group of acquired skeletal muscle disorders including polymyositis (PM), dermatomyositis (DM), inclusion body myositis (IBM) and immune-mediated necrotizing myopathy (IMNM), characterized by immune-mediated muscle damage. Activated T cells are the predominant inflammatory infiltrates in muscle biopsies of PM and DM patients and the lack of T regulatory cells (Treg) has been implicated in the persistence of muscle damage. CD26 is an intracellular membrane glycoprotein and a serine exopeptidase involved in the activation of T lymphocytes and amplification of inflammatory cytokines production. The enzymatically active form of CD26 is selectively expressed by activated T cells and has been described as a negative selection marker for human Treg.

Objectives: The aim of this study was to evaluate the expression of CD26 in muscle biopsies of IMM patients and to correlate it with patients’ clinical and histological features.

Methods: Immunofluorescence was used to evaluate CD26 expression and co-localization with CD3 and CD15 in biopsies of immune inflammatory myopathies. Immunofluorescence was used to evaluate CD26 expression in muscle biopsies of IMM patients and to correlate it with patients’ clinical and histological features.

Results: We found that CD26 is preferentially expressed in muscle biopsies of IMM patients with respect to controls and that its level of expression is higher in DM patients. In muscle biopsies of IMM patients, CD26 is distributed not only in the extracellular matrix surrounding myofibers and infiltrating leukocytes, but also at the level of T cell membranes and endothelial cells. Specifically, CD26 co-localization with CD31 is more prominent in DM muscle biopsies. We could not find any association between vessel morphology in terms of size and shape and CD26 endothelial expression, suggesting that CD26 is expressed at the perivascular level independently of the degree of vessel dysfunction. With regard to clinical features, we found that CD26 is more expressed in patients presenting the typical DM rash. Moreover, CD26 expression was found not to be significantly associated with the degree of muscle weakness nor with the presence of interstitial lung disease, dysphagia, myalgias or mechanic’s hands. As for histological data, higher levels of CD26 expression were found in biopsies with perivascular inflammatory infiltrates, especially T lymphocytes and macrophages.

Conclusion: Our data suggest that CD26 may represent a suitable marker for the diagnosis of IMM and a potential novel target for selective immune-therapies.

AB1137 QUANTIFYING KNEE JOINT EFFUSIONS WITH CLINICAL TESTS, MUSCULOSKELETAL ULTRASOUND AND SYNOVIAL FLUID ASPIRATION: A PROSPECTIVE COHORT STUDY

Thilinie De Silva1, Chris Pham2, Adam Rischin2, Kim Le Marshall1,3, Sara Vogrin4, Albert Leung1,3, Keith Lim5.
1,3Western Health, Melbourne, Australia; 2Western Health, Melbourne, Australia; 3Western Clinical School, University of Melbourne, Melbourne, Australia; 4University of Melbourne, Statistics, Melbourne, Australia; 5Australian Institute for Musculoskeletal Science, Melbourne, Australia

Background: Aspiration of knee joint effusions is an integral diagnostic and therapeutic intervention in many rheumatologic diseases. Clinical examination has traditionally involved tests including the "patella tap" or "bulge test". The accuracy of these tests for determining effusion presence and size is not well established. Musculoskeletal ultrasound (MUS) is considered better for identification and quantification of knee effusions.

Objectives: To investigate the correlation between both clinical examination and MUS to aspirated knee effusion volume.

Methods: We performed a prospective cohort study of 37 osteoarthritis and therapeutic intervention patients with symptomatic knee effusions. Clinical assessment with patella tap, bulge test and knee circumference measurement were carried out. MUS was used to measure effusion depth in the suprapatellar, lateral and medial parapatellar views. All knee effusion aspirations were performed by the same experienced clinician using a consistent, lateral approach. Linear regression analysis was used to assess correlations between clinical tests, MUS and aspiration volume.

Results: In patients with >3ml of fluid aspirated, patella tap and bulge test were positive in 67% and 80% respectively. The positive predictive value for bulge test was 80%. Where larger volumes were aspirated (i.e. >10ml), patella tap and bulge test were only positive in 52% and 65% respectively. There was a significant correlation between the measured circumference of the index and non-index knee and aspiration of fluid (coefficient=5.6, p=0.007). The relationship between fluid depth on MUS and aspirated volume showed a trend towards statistical significance, with a depth of 1mm equating to 1.57 ml of fluid (coefficient=1.57, p=0.06).

Conclusion: This pilot study demonstrates that a positive patella tap or bulge test is moderately predictive of knee effusion volume. However, this association is weaker when larger knee effusions are present. MUS showed promise at accurately predicting knee effusion volume. A larger study is underway to assess this relationship further.

AB1138 BONE SARCOIDOSIS: USEFULNESS OF 18F-FDG PET/CT

Lucie Demaria, Raphael Borle, Khalidia Benali, Marine Forien, Philippe Dieudé, Bruno Crestani, Sebastien Ottaviani, Bichat-Claude Bernard Hospital, Paris, France

Background: Bone sarcoidosis is usually rare but more sensitive imaging procedures such as 18F-fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (18F-FDG PET/CT) allow a better characterization of such lesions. We aimed to describe bone sarcoidosis involvement using 18F-FDG PET/CT.

Methods: We performed an observational retrospective study of patients with pulmonary sarcoidosis having a 18F-FDG PET/CT. As stated by ATS/ERS/WASOG criteria, diagnosis of sarcoidosis was established on the presence of clinical symptoms and/or imaging features of sarcoidosis, and evidence of non-caseating epithelioid granuloma in a biopsy sample after exclusion of other known etiology of granuloma. We assessed clinical and 18F-FDG PET/CT characteristics.

Results: A total of 85 patients (56.5% of female, median age 47 years) with sarcoidosis were analyzed. The median of disease follow-up was 4 years. Sarcoidosis occurred in more than three organs among 66% of cases. Using ATS/ERS/WASOG criteria, bone sarcoidosis was diagnosed in 12 (14%) patients. Spine was the most commonly affected bone (92%), followed by pelvis (67%), sternum (33%), humerus (25%) and fingers (17%). Only peripheral adenopathy was associated with bone lesions (p=0.04). Seven patients have benefited from a follow-up 18F-FDG PET/CT, which in 100% of cases showed an improvement of lesions.

Conclusion: Bone sarcoidosis occurred in 14% of patients, affecting multiple bones and mostly the axial skeleton. 18F-FDG PET/CT appears to be a sensitive imaging for diagnosis and follow-up of bone sarcoidosis.

Abstract AB1137 Figure 1. Relationship between aspirated volume and USS detected knee effusion depth
CONTRIBUTION OF CERVICAL SPINE IMAGING IN RHEUMATOID ARTHRITIS

ACHEK Mohamed Amine EL1, Amel Farhat1, Chakib Kraiem2,3, Fattouma Bourguiba University Hospital, Rheumatology, Monastir, Tunisia; 2Ennahma Polyclinique, Radiology, Mahdia, Tunisia

Background: Cervical involvement in rheumatoid arthritis (RA) ranks third after erosive lesions of the hands and feet. The evolution is unpredictable and imposes regular radio-clinical surveillance because of the frequency of asymptomatic forms and of its seriousness, especially the neurological involvement could threaten functional and vital prognosis.

Objectives: To specify the contribution of imaging means in the diagnosis of rheumatoid cervical involvement and perform a comparison of these different imaging means to establish an exploration strategy.

Methods: This is a cross-sectional and descriptive retrospective study of 55 patients with RA which evolves since more than two years. All patients were explored by standard radiographs. CT and/or cervical MRI were performed according to the radiological findings.

Results: The mean age of the patients was 57.55 ± 13.59 years with a female predominance (72.7%). Functional signs were dominated by neck pain (87.3%). The stiffness of the cervical spine was the most recovered physical sign (69.1%). In imaging, cervical involvement was dominated by antlodo-axiodal subluxations (AAS) in 50.9% and pannus of C1-C2 (14.54%). Among AAS, anterior AAS was the most common (40%) followed by vertical AAS (7.27%) then lateral and rotary (both in 1.81%). Subaxial subluxation was found in 14.54% of cases. Standard radiographs detected 38.2% of previous AAS versus 20% on MRI. CT allowed a better study of rotary and lateral subluxations. MRI detected pannus of C1-C2 and assessed the neurological impact of the various cervical rheumatoid lesions.

Conclusion: Clinical examination alone remains insufficient in the evaluation of the rheumatoid cervical spine. Imaging has thus emerged as a key examination in exploration and therapeutic orientation. The standard radiography with its different incidences is the first-line examination. CT and MRI will be discussed as second-line. CT essentially detects atypical subluxations and bone lesions. MRI is the exam of choice for the study of pannus and neurological repercussions.

ROLE OF ULTRASOUND IN ASSESSMENT OF JOINT PAIN AMONG HEMO DIALYSIS PATIENTS

Ahmed Fahmy, Ahmed Al-Ashkar Mohammed Sabhy Abdullameed Abdulhalikhal, Al azhar university in cairo, rheumatology, cairo, Egypt

Background: Few studies including limited number of patients assessed the rheumatologic effects of hemodialysis (HD) on joints using ultrasonography. Joint ultrasound has been emerged as a cheap noninvasive tool for assessment of joint pain among HD patients. This was the aim of our study to make use of such tool in such life quality threatening complaints

Objectives: to determine the role of ultrasound in evaluation of joint pain and its causes among patients on regular HD

Methods: One hundred and four patients with end stage renal disease (ESRD) who were regular on HD three sessions per week four hours per session were subjected to history taking, complete physical examination stressing on musculoskeletal examination and ultrasonography of painful joints.

Results: Dialysis related arthropathy (DRA) was not the only cause of joint pain among HD patients but there were diverse causes in different joints. As regard affected joints, knee was the most affected one then came wrist, shoulder, ankle and elbow respectively. As regard causes of joint pain, DRA was the commonest one then came osteoarthritis, Nonspecific ultrasonographic findings and few cases showed normal ultrasonographic studies.

Conclusion: This study confirmed that joint pain in HD patients has diverse causes not DRA by necessity but other causes must be considered as well as multifactorial etiologies.

A SIMPLE CLINICAL SCORING TOOL CAN BE USED TO IMPROVE PATIENT SELECTION FOR ULTRASOUND IN DIAGNOSING EARLY INFLAMMATORY ARTHRITIS

Ziad Farah1, Oseme Etoni, Nikita Anumalla, Stephen Kelly, Barts Health NHS Trust, Rheumatology, London, United Kingdom

Background: Ultrasonography has been shown to be more sensitive than clinical examination in detecting clinical/subclinical synovitis and improving diagnostic certainty in early inflammatory arthritis (EIA). Local audit suggests increasing demand on ultrasound clinics to aid diagnosis in patients with suspected EIA therefore increasing waiting times. There is limited research to identify the patients most likely to benefit from an early ultrasound.

Objectives: (i) To evaluate the proportion of patients in whom an ultrasound resulted in a change in the pre– to post-scan diagnosis.

(ii) To devise a simple scoring tool to predict patients where an ultrasound may alter the diagnosis/outcome

(iii) To assess if such a scoring tool can be used prospectively in the clinical setting

Methods: We conducted a retrospective analysis of the electronic records of patients attending the rheumatology-led musculoskeletal ultrasound clinic for a diagnostic scan between January and September 2017. Data on pre-test diagnosis, ultrasound findings and post-scan diagnosis was obtained. Clinical data was used to devise a scoring tool to predict variation in pre and post-scan diagnosis. Prospective data was then collected to confirm the validity of this scoring tool.

Results: 200 patient records were reviewed. In 102 patients (51%), the post ultrasound scan diagnosis differed from the pre-scan diagnosis. Patients referred with polyarthralgia of uncertain cause (n=92) were the largest group in whom the post-scan diagnosis differed (64, 69.6%) as the scan was able to identify a diagnosis. Patients with a pre-scan diagnosis of osteoarthritis or fibromyalgia (n=48) were more likely to have no difference in post-scan diagnosis (40, 83.3%).

We generated a score for each patient with one point given to: duration (>6 weeks), (any) tender joints, (any) swollen joints, rheumatoid factor positive, anti-citrullinated protein antibody positive, C-reactive protein (>5mg/L), erythrocyte sedimentation (>age adjusted value), early morning stiffness (>30 minutes), or radiographic erosions. 39 patients scored 0–1, and 4 patients scored 7–9. In none of these categories did the ultrasound alter the diagnosis. Among patients with a score 2–6, the ultrasound altered overall diagnosis in 28% (n=157). Scores 5 and 6 demonstrated most variation between pre and post-scan diagnoses (45%).

We applied the score set prospectively and preliminary data indicates a similar distribution of results (data collection in progress).

Conclusion: (i) Ultrasound contributed to the overall diagnosis in over 50% of patients under investigation for EIA

(ii) A simple clinical scoring tool can predict which patients the scan will make no difference to overall diagnosis.

(iii) Patients with scores in the middle range should be prioritised over those with very low or high scores.

(iv) This can be applied to improve patient selection and maximise the utility of ultrasound in EIA clinics.

PROGNOSTIC VALUE OF 18F-FLUORODEOXYGLUCOSE PET-CT SCORE AT BASELINE ON THE THERAPEUTIC RESPONSE TO PREDNISONE IN PATIENTS WITH POLYMYALGIA RHEUMATICA

Nicolas Giraud1, Maxime Sonntag1, Aline Charpentier1, Hatem Boulaouhou1, Céline Prat1, Daniel Wendling1, Frank Verhoeven1, 1CHRU Besançon, Rheumatology, BESANÇON, France, 2CHRU Besançon, Nuclear imaging, Besançon, France

Background: Polymyalgia rheumatica (PMR) is one of the most common inflammatory rheumatic diseases. To date, there is no imaging procedure that can be used as a prognostic factor for good or poor response to corticosteroid therapy.

Objectives: To evaluate the prognostic value of 18F-fluorodeoxyglucose PET-CT (FDG-PET/CT) score at baseline, on the therapeutic response to prednisone, in patients with polymyalgia rheumatica (PMR).

Methods: This is a monocentric retrospective study realized at the university hospital of Besancon. We included patients with a diagnosis of PMR meeting the 2012 ACR/EULAR criteria, who had performed a FDG-PET/CT at baseline, between december 2012 and december 2017. Patients were treated with an initial prednisone dose of 0.3mg/kg a day, progressively decreased following a standardized tapering dose protocol (10% / month). We excluded patients who received corticosteroids before the FDG-PET/CT, or without baseline FDG-PET/CT. Seventeen specifics previously described hotspots were visually analyzed (1). We realized a semi-quantitative analysis of FDG uptake (4-point score from 0 to 3), following Goerres scoring system (2). Hotspot with 0 indicating no uptake (same as bone); 1, slight uptake; 2, moderate uptake (same as liver); and 3, uptake higher than the liver, with a global range score of 0 to 51. Then we defined two groups of patients according to their resistance to prednisone at 12 months, defined as the reoccurrence of symptoms and/or an increase of systemic inflammation twice during the prednisone tapering.

Results: 93 patients where included: 14 (42%) in the group “resistant” and 19 (58%) in the group “sensitive”. There were 57.6% of women, with a mean age of 67.57 ± 11.63 years. The mean CRP at baseline was 45.02 ± 39.59 mg/L. The mean FDG-PET/CT score at baseline was 18/51. The FDG-PET/CT score at baseline was significantly lower in the resistant group (13.1 vs 22/85, p = 0.019). Resistant patients were younger (61.1 vs 72.4 years, p <0.01), and mostly men (66.5% vs 22%, p<0.02). ROC curve showed a threshold of 9.5/51 with a sensitivity of 61.54% and a specificity of 84.21% [AUC 0.76 (+/- 0.089), p= 0.014]. There was no statistically significant difference concerning CRP and PET/CT score (r =0.25, p=0.15). The prevalence of synovitis (21% vs 57%, p=0.46), and neoplasia (0% vs 15.79%, p=0.78) were similar between the two groups.

Conclusion: Our results suggest that in patients with PMR, a baseline FDG-PET/CT score over 9.5/51 score is predictive of a good response to prednisone.

AB1144 ULTRA HIGH FIELD MRI MICROARCHITECTURE ANALYSIS IMPROVES THE PREDICTION OF PROXIMAL FEMUR FRACTURE: A COMBINED STUDY WITH EX VIVO BIOMECHANICAL TESTS

Daphne Guenoun1, Martine Pilihoux1, Jean-Christophe Soupil1, Sandrine Quis1, Thomas Le Corroller1, Alexandre Fournié1, Vanessa Pauly1, Jean-Pierre Matte1, Monique Bernard3, Maxime Guye3, Patrick Chabrand2, Pierre Chapur2, David Bendahan1, 1Aix-Marseille Univ, CNRS, AP-HM, ISM, Inst Movement Sci, Radiology, Marseille, France, 2Aix-Marseille Univ, CNRS, ISM, Inst Movement Sci, Marseille, France, 3Aix-Marseille Univ, AP-HM, Unité de recherche le EAS279, Santé Publique et Maladies Chroniques: Qualité de vie concepts, usages et limites, déterminants, Santé Publique, Marseille, France

Background: The purpose of this study was to assess cadaveric proximal femurs from the points of view of bone microarchitecture using ultra-high field (UHF) 7 Tesla magnetic resonance imaging (MRI), bone strength using biomechanical tests and bone mineral density (BMD) using Dual-energy X-ray absorptiometry (DXA).

Objectives: We aimed at determining whether bone microarchitecture parameters were related to bone strength and BMD and whether UHF MRI can provide additional information regarding bone strength.

Methods: BMD of ten proximal femurs from five cadavers were investigated using DXA and the bone volume fraction (BVVF), trabecular thickness (Th.B), and trabecular spacing (Th.Sp), fractal dimension (FD), Euler beam stereometrics (Euler Ch.), Connectivity density (Conn.D) and Degree of anisotropy (DA) of each femur was quantified using UHF MRI. The whole set of specimens underwent mechanical compression tests to failure.

Results: BMD and all the microarchitecture parameters except ConnD were significantly correlated with failure load (p < 0.05). The
microarchitecture parameters were correlated to each other but not corre-
lated with BMD. Multiple regression analysis demonstrated that the combi-
nation of the microstructure parameters and BMD improved the prediction of the failure load with for example an improved fracture risk prediction from R² = 0.418 to 0.688 when combining BMD and Euler Ch. Overall, femur bone microarchitecture assessed with UHF MRI was signifi-
cantly correlated with biomechanical parameters. The multimodal assess-
ment of BMD and trabecular bone microarchitecture using UHF MRI improved the fracture risk prediction of femoral bone and might be of interest for the future investigation of selected osteoporotic patients.

Conclusion: We demonstrated that femur bone microarchitecture assessed with UHF MRI was significantly correlated with biomechanical parameters. The multimodal assessment of bone mineral density and trabecular bone microarchitecture using UHF MRI improved the fracture risk prediction of femoral bone and might be of interest for the future investigation of selected osteoporotic patients.

AB1145
FULLY CONVOLUTIONAL NEURAL NETWORK-BASED
SEGMENTATION OF INDIVIDUAL MUSCLES IN MR
IMAGES USING MUSCLES AND BORDERS
PARCELLATIONS

Joris Fournel1, Amaud Le Trot1, Sandrine Gues1, David Bendahan1, Badzh Ghattas1, 2Aix-Marseille Univ, CNRS, CRBBM UMR 7339, Marseille, France, 2Aix-Marseille Univ, CNRS, AP-HM, CRBBM UMR 7339, Rheumatology, Marseille, France, 3Aix-Marseille Univ, CNRS, Institut de Mathématiques de Marseille, UMR 7373, Marseille, France

Background: Segmentation of individual muscles in MR images is chal-
 lenging considering the poor contrast between muscles and the large var-
 iability between and within subjects.

Objectives: The segmentation performance of the Bayesian SegNet net-
work was assessed for the four individual muscles of the quadriceps group. In addition to the classes corresponding to each muscle, we ana-
lyzed the effect of adding four additional classes corresponding to muscle borders. We also investigated the network performance taking into account each muscle individually or the whole set of muscles. The corre-
sponding results were compared with those obtained using a conventional multi-atlas method.

Methods: For the training phase, a dataset of 500 images was used while the testing phase was performed for two other datasets with 140 images each. Four different variants of the same network were assayed considering simultaneous segmentation of individual muscles (On5), separate segmentation of individual muscles (Fr2) and the use of additional classes related to muscle borders in both cases (On5+Fr3). The higher DSI values i.e. 0.96 ± 0.01 for the rectus femoris muscle, 0.93 ± 0.01 for the vastus intermedius muscle, 0.94 ± 0.03 for the vastus lateralis muscle and 0.96 ± 0.01 for the vastus medialis muscle were obtained with the On5 and Fr3 networks i.e. taking into account the muscle border labels in addition to the muscle labels.

Conclusion: Deep-learning based methods are optimal for the segmenta-
tion of thigh muscles and the corresponding efficiency can be improved when considering labels for muscles together with borders.

AB1146
PREVALENCE OF STRUCTURAL CHANGES AT THE POSTERIOR PART OF THE SPINE IN AXIAL Spondyloarthritis EVAULATED WITH MR

Andreas Haidmayer1, Gabriel Adelsmayer2, Rusmir Husic1, Franz Quehenberger1, Angelika Lackner1, Joesf Herrmann1, 1Medical University of Graz, Internal Medicine, Division for Rheumatology and Immunology, Graz, Austria, 2Medical University of Graz, Radiology, Division for general Radiology, Graz, Austria, 3Medical University of Graz, Institute for Medical Information, Statistics and Documentation, Graz, Austria

Background: In clinical trials radiographic damage is frequently quantified by conventional x-ray but neither the thoracic spine nor the posterior parts of the vertebral column including the intervertebral joints, the verte-
bral arch and the spinous process can be evaluated reliably with this instrument. Bone inflammation and areas of enthesitis can easily be detected by magnetic tomography imaging (MRI) and the introduction of high-resolution 3-tesla MRI allows analysis of bone structures more pre-
 cisely than with x-ray without radiation exposure [1].

Patients with axial SpA present with reduced mobility and functional impairment, but radiographic signs of ankylosis are missing on plain radiographs. These particular clinical findings are reinforced by data in the literature showing, that the relation between radiographic dam-
gage, spinal mobility and function is low. Radiographic damage to the pos-
terior parts of the vertebral column may be responsible for the discrepancy found between clinical and radiographic results as suggested by a Dutch group [2].

Objectives: To evaluate the localisation and incidence of new bone for-
mation in the posterior part of the vertebral bodies with MRI.

Methods: In a cohort of 56 patients with diagnosed axial SpA (mean age 50.29y, mean disease duration 14.4y, 76.4% men, 85.7% HLA-B27 positive) we performed a 3-tesla scan with a Siemens Healtcare, Erlangen, Germany). The whole spine was scanned with T1
weighted and Turbo-Inversion Recovery Magnitude (TIRM) sequences in sagittal planes and each segment of the vertebral column was divided into four areas (ventral and posterior part of the vertebral bodies, inter-
vertebral joints and spinous processes) to assess osseous changes like sclerosis, erosion, syndesmophytes, ankylosis, (partial) fusion of interverte-
bral joints and fibroositis of spinous processes.

Results: Syndesmophytes and ankylosis of the ventral segments were present from C7/Th1 down to L5/S1 with a maximum in Th5/6 (82.5%). In the posterior segments of the vertebral bodies we detected a contrary accumulation inside the cervical and lumbar spine with a max. in C5/6 (55.4%) respectively L2/3 (66.1%). Erosions were mainly found at the ventral edges with an accumulation in middle cervical, lower thoracic and the whole lumbar spine (max. Th8/10 24.5%).

Ankylosis of the intervertebral joints was present over the whole spine with a preference of the cervical (max. C5/6 27.7%) and lumbar column (max. L2/3 47.3%). Fibroositis of the spinous processes were rarely found in the middle and lower thoracic spine (Th8-11, each 2.7%), with up to 57.10% of the cervical spine (54.78% for lumbar, 32.18% for thoracic spine) with detectable new bone formation of the posterior seg-
m ents we found no changes of the ventral part.

Conclusion: With high resolution MRI we were able to detect structural in the dorsal part of the spine, which can hardly be assessed by con-
 ventional radiographs. These findings may explain functional disability in patients with non-corresponding findings in x-ray.

AB1147
VERTEBRAL FRACTURE ASSESSMENT: A SIMPLE TOOL TO DETECT VERTEBRAL FRACTURE IN THE OSTEOPOROSIS ASSESSMENT OF PATIENTS WITH TYPE2 DIABETES MELLITUS

Nassima Hanouche1, Salah Ouhadi1, Chafia Dahou-Makhlouf1, 1chu tizi ouzou, TIZI OULZOU, Algeria; 2EPH DELLYS, BOUMERDES, Algeria; 3CHU BAB ELOUED, ALGIERS, Algeria

Background: Vertebral fracture assessment ( VFA) has several bene
fits, including substantially lower radiation dose, lower cost, higher patient con-
venience, and less operator-dependent variance,VFA can be directly assessed during bone mineral density ( BMD) measurement.

Objectives: evaluate the accuracy of VFA performed in the supine posi-
tion by using radiographic views of the spine as the reference standard in patients with type 2 diabetes mellitus

Methods: A total of 207 patients with type 2 diabetes mellitus (mean age, 46.59 ±7.53years; range, 21–60 years) consisting of 102 women
and 105 men, who were suspected of having osteoporosis and who underwent VFA in the supine position and radiography of the spine were evaluated. VFA was analyzed by using a six-marker point method to describe the shape and deformity of each vertebra. Visual radiography of the lateral spine was performed by an experienced radiologist. The agreement between VFA and visual radiography, was assessed by using weighted statistics.

Results: Visual radiography helped identify 51 (24.6%) patients with at least one vertebral fracture versus 49(23.67%) with VFA. Most fractures were present in T7, T12, and L1. Excellent agreement was found between VFA and visual radiography, with 97.3% concordance and 0.89. Sensitivity, specificity, and positive and negative predictive values calculated by level of score for VFA compared with visual assessment were 90.2%, 98.08%, 93.88%, and 96.84%, respectively.

Conclusion: VFA performed with patients with type 2 diabetes, in the supine position, is an accurate method to help detect vertebral fractures when compared with conventional spine radiography. VFA permits combination of fracture assessment with bone mineral density measurement in a single session.

THE RELATION ANALYSIS OF BONE MICROARCHITECTURE EVALUATED BY HR-pQCT, AND SYNOVITIS, BONE DESTRUCTION, SYSTEMIC OSTEOPOROSIS IN RHEUMATOID ARTHRITIS

Naoki Iwamoto1, Konosuke Watanabe2, Tomohiro Koga1, Shin-ya Kawashiri1, Kunihiro Ichinose1, Mami Tama1, Hideki Nakamura1, Nozomi Okh1, Ko Chiba1, Tomoki Origuchi1, Makoto Osaki1, Atsushi Kawakami1.1 Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 2Nagasaki University Graduate School of Biomedical Sciences, Department of Orthopedic Surgery, Nagasaki, Japan; 3Nagasaki University Graduate School of Biomedical Sciences, Department of Diagnostic Sciences, Nagasaki, Japan; 4Nagasaki University Graduate School of Biomedical Sciences, Department of Physical Therapy, Nagasaki, Japan

Background: Periarticular osteoporosis is one of hallmark of rheumatoid arthritis (RA), However, until now the periarticular bone structure including bone mineral density have not been fully elucidated. High-resolution peripheral quantitative computed tomography (HR-pQCT) is a new technique with high spatial resolution that enables us to assess microarchitecture of cancellous and cortical bones that cannot be assessed by conventional X-ray examinations. Recently, few studies using HR-pQCT revealed that bone microarchitecture such as trabecular volumetric densities (Tb.vBMD) were different between RA and non-RA1, but these study had not confirmed findings of HR-pQCT with synovitis assessed by ultrasonography(US) or systemic osteoporosis.

Objectives: To investigate bone microarchitecture evaluated by HR-pQCT in RA.

Methods: This study included 21 RA patient. HR-pQCT imaging analyses quantified bone microarchitecture in 2.3 Metacarpal Head. We measured the bone mineral density (BMD) of lumen spine and femoral neck using Dual-Energy X-ray Absorptiometry (DXA). Synovitis and bone destruction were assessed by US and X-ray, respectively.

Results: Disease duration, age and disease activity were not correlated with bone microarchitecture. BMD of femoral neck was correlated with Tb.vBMD (r=0.84,p<0.01). The joints with US-proven active synovitis [power doppler score (PD) ≥2] showed less Tb.vBMD, trabecular number (Tb.N) and trabecular thickness (Tb.Th) as compared with the patients with US-PD≤2 synovitis (Tb.vBMD:121.5 mg/cm² vs 145.3 mg/cm², Figure 1). These tendencies were also shown in defferent Metacarpal Heads in the same patient (the mean difference of Tb.vBMD, PD≥2 – PD≤2: -11.9 mg/cm²). Moreover, the joints with progressive joint destruction as classified by more than steinbrocker stage 3 showed less Tb.vBMD (122.1 mg/cm² vs 150.0 mg/cm²). The longitudinal analysis of 10 patients revealed that Tb.vBMD and Tb.N were improved along with improvement of disease activity (DAS -2.80: from baseline to 12 months after new treatment initiated , but Tb.Th was not improved.

Conclusion: This study revealed that bone destruction and synovitis were associated with bone microarchitecture, this difference of treatment response may be parameter of bone microarchitecture. However, this study was mainly transverse analysis and small samples, we need longitudinal analysis using larger samples.

CHARACTERIZATION OF SALIVARY PROTEINS IDENTIFIED AS POTENTIAL BIOMARKERS FOR SYSTEMIC LUPUS ERYTHEMATOSUS THROUGH PROTEOMIC ANALYSIS

Ju-Yang Jung, Jiwon Kim, Hyoun-Ah Kim, Chang-Hee Suh. Ajou University School of Medicine, Suwon, Korea, Rep. of (South Korea)

Background: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease characterized by pathogenic autoantibodies and uncontrolled inflammatory response. There are few reliable biomarkers available for diagnosis and monitoring the disease.

Objectives: We tried to find and characterize specific protein components in saliva of patients with SLE for their use as biomarkers in future.

Methods: Salivary proteins were prepared from 11 samples from patients with SLE and healthy controls (HC), and were subjected to 2-dimensional gel electrophoresis (2-DE). The spots with greater than 2 fold change in intensity were identified by matrix-assisted laser desorption/ionization time-of-flight mass spectrometer (MS) analysis. The relative and absolute amounts of the several candidate proteins in saliva of patients with SLE and rheumatoid arthritis (RA), and HC were analyzed using western blotting, and enzyme-linked immunosorbent assay.

Results: Proteomic analysis using 2-DE and MS identified 20 differentially expressed protein spots in the saliva of SLE patients compared in that of HC. Among them, proteins with more than two-fold differences in expression were found as immunoglobulin gamma-3 chain C (IGHG3), immunoglobulin alpha-1 chain C region, protein S100, lactotransferrin, leukaemia-associated protein 7, and 8-oxoguanine DNA glycosylase (OGG1), salivary IGHG3 levels were increased in SLE (3.9 ± 2.2 pg/mL) compared to those in RA (3.1 ± 1.6 pg/mL, p < 0.001) or HC (2.3 ± 1.7 pg/mL, p < 0.001), and salivary lactotransferrin levels were increased in SLE (5.0 ± 1.7 pg/mL) compared to those in RA (3.1 ± 1.6 pg/mL, p < 0.001) or HC (2.3 ± 1.7 pg/mL, p < 0.001). The patients with nephritis had higher salivary IGHG3 (4.7 ± 1.9 pg/mL) than those not (3.6 ± 2.2 pg/mL).

Disclosure of Interests: Naoki Iwamoto: None declared, Ko Chiba: None declared, Atsushi Kawakami Grant/research support from: Astellas Pharma, Consultant for: Astellas Pharma, Speakers bureau: Astellas Pharma

Scientific Abstracts
The vulnerable MP and the more stable CP burden and its progression in RA patients who underwent coronary calcium score (CACS) as well as the influence of change in the burden of the respective lesions on CACS progression.

**Conclusion:** Salivary IGHG3 and lactotransferrin levels were significantly increased in patients with SLE compared to those not, and salivary lactotransferrin levels negatively correlated with variations of ESR (-2.0 ± 4.6 vs 8.4 ± 9.56, p = 0.02) compared to those not. In addition, the patient with increased salivary lactotransferrin had significantly different in changes of hemoglobin (-0.85 ± 0.97 vs -0.42 ± 0.99 g/L, p = 0.02), and changes of complement 3 (-7.6 ± 14.15 vs +7.0 ± 9.34, p = 0.02) compared to those not. In addition, the patient with increased salivary lactotransferrin had significantly different in changes of ESR (-2.0 ± 4.6 vs 8.4 ± 9.56, p = 0.02) compared to those not, and salivary lactotransferrin levels negatively correlated with complement 3 levels (r = -0.5, p = 0.02).

**IMPLICATIONS OF CORONARY ARTERY CALCIUM AND ITS PROGRESSION AS MARKERS OF PLAQUE VULNERABILITY AND PATIENT RISK IN RHEUMATOID ARTHRITIS**

George Karpouzas1, Sarah Ormseth1, Elizabeth Hernandez2, Matthew Budoff2,  
1Harbor UCLA Medical Center, West Carson, United States of America; 2Harbor UCLA Medical Center Cardiology, Torrance, United States of America

**Background:** Atherosclerotic plaque calcification represents a stabilizing physiologic process; calcified coronary plaques (CP) are less prone to rupture and yield lower risk of cardiovascular events (CVE) compared to non-calcified (NCP) or mixed-calciﬁed plaques (MP). Interestingly, however, coronary artery calcium score (CACS) and its progression associate with higher event risk in general patients. We, likewise, reported that CACS predicted cardiac events in rheumatoid arthritis (RA) patients independently of risk factors or cardiac risk scores.

**Objectives:** To address this paradox, we evaluated the contribution of vulnerable MP burden to CACS as well the influence of change in MP burden on CACS progression in RA patients who underwent coronary anatomy evaluation with computed tomography angiography (CCTA).

**Methods:** One hundred-one patients underwent a repeat CCTA within 83 ± 36.6 months from baseline. Total number of segments with plaque (segment involvement score-SIS) and cumulative stenosis severity rendered by plaque over all evaluable segments (segment stenosis score-SSS) were computed for all participants. Coronary lesions were deﬁned as non-calciﬁed (NCP), mixed (MP) or calcified (CP). Generalized Linear Models predicted the contribution of MP and CP plaque burden to the baseline and follow-up CACS as well as the influence of change in the burden of the respective lesions on CACS progression.

**Results:** Mixed and CP burden (SSS-MP and SSS-CP respectively) strongly correlated with CACS at both baseline (r_{mp}=0.75 and r_{cp}=0.77, p<0.001) and follow-up (r_{mp}=0.57 and r_{cp}=0.68, p<0.0001), whereas non-calcified plaque did not (r_{nmp}=-0.03, p=0.85 and r_{ncp}=-0.16, p=0.30 respectively). Both MP and CP burden comparably and signiﬁcantly contributed to CACS magnitude at both times (table 1); MP accounted for 36.5% and 38.5% of explainable variance in CACS while CP accounted for 63.5% and 61.5% of it at baseline and follow-up respectively (all p<0.001). Likewise, change in MP and CP burden from baseline to follow-up signiﬁcantly contributed to and justiﬁed 27% and 73% of explainable CACS change variance.

**Conclusion:** The vulnerable MP and the more stable CP burden and their change signiﬁcantly and collectively contributed to CACS at any time as well as its progression respectively in RA. Therefore, the MP burden and its change embody the vulnerability components within the higher baseline and progressing CACS scores explaining the higher CVE risk observed.

**APPLICATION OF ULTRASOUND TO DISTINGUISHING PMR FROM POLYARTHRITIS**

"1*Tomohiro Kawaguchi, Michihiro Ogasawara, Ken Yamaji, Naoto Tamura. Juntendo University, Department of Internal Medicine and Rheumatology, Tokyo, Japan

**Background:** Japan is the world’s most aged country. The number of patients with polymyalgia rheumatica (PMR) is expected to increase more. Classification criteria including ultrasound ﬁndings were published in 2012, but the ability to differentiate PMR from rheumatoid arthritis (RA) was not signiﬁcant. We will clarify whether recently reported ultrasound ﬁndings (1, 2) which could be characteristic in PMR are helpful for distinguishing from other diseases and treatment outcome in suspected PMR patients.

**Objectives:** Patients who were clinically suspected of PMR and underwent ultrasound examination from March 2015 to July 2018.

**Methods:** Recorded ultrasound images were retrospectively interpreted by the ultrasound expert, who was blind for clinical information. They were classiﬁed into three groups of PMR, RA, others/no inﬂammation. Initial dose of glucocorticoid (GC), therapeutic response, presence or absence of relapse, and concomitant medications were collected and compared among the 3 groups. Cases in which steroids had already been used before ultrasound examination were excluded from the analysis.

**Results:** The number of subjects was 81, and the number of ultrasound examination was 88. The ultrasound expert classiﬁed 29 PMR, 20 RA, 3 others/no inﬂammation. 18.5% (15/81) of the subjects were improved with no GC and relapse. The average prednisolone dose was 15.3 mg in the PMR group, and 9.7 mg in the RA group. Concomitant medications were introduced in 31% (9/29) of PMR group, in 65% (13/20) of RA group.

**Conclusion:** Ultrasound is useful for distinguishing PMR from seronegative RA and other arthralgia. These ﬁndings showed that ultrasound is useful for the proper use of GC and concomitant medications.

AB1152  CORRELATING SERUM RESISTIN LEVEL TO ULTRASONOGRAPHIC FINDINGS OF OSTEOARTHRITIC KNEES AFTER INTRA-ARTICULAR GLUCOCORTICOID INJECTION

Sameh Al-Zayyat, Hany Elta, abdelrahman labib. Al-Azhar University, Cairo, Egypt

Background: Osteoarthritis (OA) is one of the ten disabling diseases affecting 9.6% of men and 18% of women aged over 60 worldwide (1). OA characterized by articular cartilage loss, subchondral bone remodeling, soft tissue damage and low grade synovitis. It is the most common form of arthritis and major cause of disability in the adult population (2). The main source of resistin in humans is mononuclear cells (3). Evidence has shown that higher serum levels of resistin in patients with severe OA compared to controls with no OA and resistin are detected in both serum and synovial fluid, proving its systematical and local involvement in inflammatory changes of OA (4).

Objectives: The aim of this work is to study the effect of local GC intra articular injection on the level of serum resistin in OA knees and to study the relation between different serum levels of resistin and US findings of the knee.

Methods: Thirty patients with primary knee OA Grade 2-3 Kellgren Lawrence score (5) in acute flare according to ACR criteria with or without effusion were recruited for the study from the Physical medicine, Rheumatology and Rehabilitation Outpatient Clinic of Al-Azhar University Hospitals starting from November 2017 till May 2018. Patients with secondary OA. All systemic autoimmune diseases. Previous local GC injection within 3 months preoperative evaluation were excluded. Twenty healthy individuals matched for age, sex and BMI with patients were also enrolled in this study as a control group.

Serum Resistin level was measured and Musculoskeletal ultrasound examination of the knee before and three months after steroid injection was done by TOSHIBA APILO 400. Linear probe frequency 12L5. Effusion was measured by Doppler Ultrasound. Biomed Res Int 2017;2017: 4272960.

Results: Serum resistin showed significant difference (p-value < 0.05) before and after injection. It was 7.6 ng/ml in patients before injection and 5.1 ng/ml in patients after injection.

Conclusion: Resistin could be considered as an important severity marker of knee OA. Serum resistin level is markedly decreased after intra articular steroid injection into OA knee joint. The longer the duration of illness the higher the resistin level. The older the age the higher the resistin level. The longer the duration of illness, the higher the radiological grade..

AB1153  EVALUATION OF DIAGNOSTIC DISCREPANCY USING THE ASAS CRITERIA AND F-18 NaF PET/CT IN PATIENTS WITH SUSPECTED AS

Seung Min Son1, Jung Sub Lee2, Tae Sik Goh2. 1Pusan National University Yangsan Hospital, Yangsan, Korea, Rep. of (South Korea); 2Pusan National University Hospital, Busan, Korea, Rep. of (South Korea)

Background: The latest ASAS diagnostic criteria allow early diagnosis of ankylosing spondylitis by using MRI. Nuclear imaging techniques may detect increased bone turnover not only during inflammation, but probably also paralleling postinflammatory reparative changes at starting point of new bone formation.

Objectives: We focus on diagnostic discrepancy to evaluate AS between fluorine-18 sodium fluoride (F-18 NaF) PET/CT and assessment of spondyloarthritis international society (ASAS) criteria in patients with chronic low back pain suspected ankylosing spondylitis.

Methods: Sixty-eight patients with chronic lower back pain over 3 months and limited lumbar movement were included. Among them, 49 patients who fulfilled ASAS diagnostic criteria were included as AS groups and 19 others were controlled. For clinical assessment, ESR, CRP, BASDAI, and BASFI scores were measured. For imaging assessment, conventional radiography for sacroiliitis and F-18 NaF PET/CT were performed. We defined AS-positive lesions on PET/CT as uptake of sacroiliac joint, syndesmophyte, enthesitis lesions and facet joint.

Results: No significant differences were observed in the baseline demographic evaluation between two groups in terms of age, sex, follow-up period and clinical parameters including BASDAI, BASFI, ESR level. However, there were significant differences in terms of HLA-B27 positive value, 339P level and standard uptake value ratio (SUVR) of sacroiliac joint in patients fulfilled ASAS criteria.

Conclusion: In diagnosing AS, F-18 NaF PET/CT showed 79.59% sensitivity, 84.21% specificity and 80.88% accuracy. This shows the diagnostic value of the F-18 NaF PET/CT, which can be a good alternative to the diagnosis of early ankylosing spondylitis, and can evaluate whole body lesions in a single session.

AB1154  CLINICAL SIGNIFICANCE OF MONOSPECIFIC ANTI-DFS70 IN ANTINUCLEOLAR ANTIBODY (ANA)-POSITIVE PATIENTS

Olalla Lima, Ana Argibay, Melanie Estevez, Brenda Maure, Milarqos Suárez, Lorena Maria Rodríguez Ferreira, Carinta Vázquez Triñanes, Beatriz Gimena, Rut Lorenzo Castro, Iria Villaverde Alvarez, Alberto Rivera. Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: The most commonly used method for ANA detection is the indirect immunofluorescence test (IFT) on HEp-2 cells. Among ANA, anti-dense fine speckled (DFS) 70 antibodies produce a pattern (nuclear dense fine speckled) that can be confused with homogeneous or fine speckled pattern (typical of ANA-associated rheumatic disease, AARD). The presence of anti-DFS70 have been reported in a variety of clinical
systemic sclerosis is a multisystem connective tissue disease characterized by a microvascular damage, which leads to systemic fibrosis, immune dysregulation and progressive involvement of internal organs [1]. According to the classification of the morphological aspects, into the scleroderma pattern proposed by Cutolo et al. are described the early, active and late patterns.

Objectives: The aim of our study is thus to report a correlation between specific nailfold videocapillaroscopy pattern and internal organ involvement.

Methods: All enrolled patients were diagnosed for SSc, according to the American College of Rheumatology criteria and underwent an echocardiographic examination and a nailfold videocapillaroscopy. Myocardial function parameters considered were: global contractility (computed with the Simpson method), linear contractility (computed through the MAPSE) [2], diastolic dysfunction (through the analysis of the transmural flow) [3]; whilst those of lung damage were: PAPs and the evaluation of the right ventricle contractility through the TAPSE [4].

Correlation between nailfold videocapillaroscopy patterns, left ventricle dysfunction and pulmonary disease in systemic sclerosis

AB1155 CORRELATION BETWEEN NAILFOLD VIDEOCAPILLAROSCOPY PATTERNS, LEFT VENTRICLE DYSFUNCTION AND PULMONARY DISEASE IN SYSTEMIC SCLEROSIS

Monaco Luca1, Francesco Masini1, Klodian Gjekoshi2, Emanuele Pinotti1, Roberta Ferrara1, Teresa Salvatore1, Giovanni Guerri2. 1University of Campania Luigi Vanvitelli, Department of Medical and Surgical Sciences, Caserta, Italy; 2University of Campania Luigi Vanvitelli, Medicina di precisione, Caserta, Italy

Background: Systemic Sclerosis (SSc) is a multisystem connective tissue disease characterized by a microvascular damage, which leads to systemic fibrosis, immune dysregulation and progressive involvement of internal organs [1]. According to the classification of the morphological aspects, into the scleroderma pattern proposed by Cutolo et al. are described the early, active and late patterns.

Objectives: The aim of our study is thus to report a correlation between specific nailfold videocapillaroscopy pattern and internal organ involvement.

Methods: All enrolled patients were diagnosed for SSc, according to the American College of Rheumatology criteria and underwent an echocardiographic examination and a nailfold videocapillaroscopy. Myocardial function parameters considered were: global contractility (computed with the Simpson method), linear contractility (computed through the MAPSE) [2], diastolic dysfunction (through the analysis of the transmural flow) [3]; whilst those of lung damage were: PAPs and the evaluation of the right ventricle contractility through the TAPSE [4].

Statistics were performed with SPSS 20 software, by using the Mann Whitney U Test and the Fisher Test.

Results: We enrolled 27 patients, of which 16 showing “active pattern” and 11 “early pattern”, compared to a group of 21 healthy controls.

Of the 11 patients belonging to the “early” group, 1 resulted affected by diastolic dysfunction, whilst 3 had pulmonary hypertension, defined by PAPs ≥40 mmHg [4] (early vs controls; p=0.03). In the 16 patients of the “active” group, instead, 5 were found to have a diastolic dysfunction (active vs controls; p=0.01) and 6 pulmonary hypertension (active vs controls; p=0.003). In the group with “active” pattern we also observed a reduction in TAPSE compared to the control group (2.0 ± 0.2 vs 2.2 ± 0.2; p=0.025) and compared to the group with early pattern (2.0 ± 0.2 vs 2.2 ± 0.3; p=0.07).

None presence of modifications in the global contractility emerged; however, we observed a progressive reduction of the MAPSE (controls 1.76 ± 0.08; early 1.57 ± 0.04; active 1.49 ± 0.12), which resulted statistically significant among the different comparisons (controls vs early p=0.001; controls vs active p=0.0001; early vs active p=0.04).

Conclusion: The analyses showed a strict correlation between the severity of the microvascular alterations, reported by nailfold videocapillaroscopy, and the severity of the cardiopulmonary damage, expressed by an increase in the percentage of pulmonary hypertension, diastolic dysfunction and a progressive reduction of MAPSE and TAPSE.

REFERENCE

[1] Michael Mahler, Luis E. Andrade, Carlos A. Casiano, Kishore Malyavan-
Results: Ninty CTDs patients were enrolled, namely 27.8% systemic sclerosis (SSc), 31.1% primary Sjögren’s syndrome (pSS), systemic lupus erythematosus 11.1%, 7.8% polymyositis, 6.6% dermatomyositis, and 15.5% undifferentiated CTD (UCTD). Male/female ratio was 1:3.1 and a mean age of 63.9±12.7 years; among them 45 (50%) showed ILD at HRCT. The algorithm correctly classified 73/90 patients, with a sensitivity and specificity of 93.3% and 68.9%, respectively, and a diagnostic accuracy of 81.1% (figure 1).

Conclusion: These data confirm the diagnostic accuracy of VECTOR in detection of ILD in CTD patients, as previously described also for RA-ILD. In some CTDs such as SSc, a careful evaluation of lung involvement is quite diffused, while for other CTDs, for example pSS or UCTD, ILD remains often underestimated, with a delay in diagnosis and treatment. Since lung complications represent one of the most serious and frequent cause of poor prognosis for all CTDs patients, the search for a simple, repeatable and radiation-free tool for the screening of these patients is mandatory. The routinely employment of an ES and VECTOR, combined to clinical findings (cough, dyspnea) and respiratory lung function tests, could increase our ability to early identify ILD in CTD patients.

INTER-READER RELIABILITY AND COMPARISON OF FLUORESCENCE OPTICAL IMAGING ENHANCEMENT IN PATIENTS WITH EROSIIVE HAND OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS

Oystein Maugenstret1, Sarah Ohndorf2, Daniel Glintats2, Mads Ammitzbøll-Danielsen3, Yogan Kisten4, Mikkel Østergaard1, Lene Terslev1, Till Ulhig1, Tore K. Kvien1, Ida Kristin Haugen1, Karolinska University Hospital, Department of Medicine, Rheumatology Division, Stockholm, Sweden.

Background: Fluorescence Optical Imaging (FOI) is an imaging technique combining indocyanine green (ICG)-enhanced microcirculation in wrist and finger joints, as a sign of inflammation. A reliable scoring method is essential in the assessment of these images.

Objectives: To assess inter-reader reliability of three FOI scoring methods from Berlin, Stockholm, and Copenhagen, and to compare the amount of enhancement in joint groups of both hands in patients with erosive hand osteoarthritis (OA) and rheumatoid arthritis (RA).

Methods: Patients with erosive hand OA (n=13) and with RA (n=13) underwent FOI of both hands. Five readers blinded for clinical diagnoses scored all finger and wrist joints bilaterally on semi-quantitative 0-3 scales using three different FOI scoring methods. In the Berlin method, FOI enhancement was evaluated on three different images, defined as different phases on the enhancement in the fingertips. A composite image (Prima Vista Mode, PVM) of the 240 first images was also assessed. The Copenhagen method assumed that inflamed tissues will demonstrate a more rapid FOI enhancement than the surrounding tissues, defining inflammation as sharply marginated enhancement over a joint area with clear delineation from surrounding tissues lasting ≥3 sec. The Stockholm method was evaluated in the format of 240 images in ‘temperature palette setting, with additional scrolling through the image sequence to detect ambiguous signals. To evaluate inter-reader reliability, we calculated the intraclass correlation coefficients (ICC) of the sum scores on patient level and weighted kappa values and prevalence and bias adjusted kappa values for ordinal scales (Pabak-OS) on joint level. Finally, we compared the averaged sum scores in the different joint groups in patients with erosive hand OA vs. RA using the Mann-Whitney test.

Results: The ICC of the sum scores was very good for the Stockholm method (0.83), and for Berlin PVM (0.93) and Phase 2 (0.83), while the Copenhagen method (0.65) and Berlin phase 3 (0.73) showed good reliability. Berlin phase 1 showed fair reliability (0.30). On joint level we found moderate to good agreement with pabak-OS for all methods (table). Patients with erosive hand OA had significantly more enhancement in DIP joints across all methods, while PIP enhancement was more common in erosive hand OA for the Berlin PVM and Stockholm methods only. Enhancement in the 1st CMC was not detected in any of the methods, and no consistent differences were observed for the wrist (data not shown).

Conclusion: We found moderate to very good inter-reader reliability on patient level for all methods except for Berlin phase 1 and moderate to good agreement on joint level for all methods. FOI showed different enhancement patterns between erosive hand OA and RA, with more enhancement in the DIP joints in the OA patients across all methods, supporting its validity.

ULTRASOUND IMAGING IN EVALUATION OF ENTHESITIES: STATUS AND PERSPECTIVES

José Alexandre Mendonça,1 Lana Bezerra Fernandes,2 Waldemar Naves Do Amaral,3 Pontifical Catholic University of Campinas, Rheumatology, Sumaré, Brazil;2 Hospital das Clínicas/UFMG, Postgraduate – Dermatology, Goiania, Brazil;3 Hospital das Clínicas/UFMG, Postgraduate – Ultrasoundography, Goiania, Brazil

Background: The high-frequency ultrasound is a reliable method to identify enthesities, including subclinical and early diagnosis, in patients with psoriasis (PsO) and psoriatic arthritis (PsA)1.

Objectives: To establish an epidemiological profile of patients with PsO and/or PsA and to establish the ultrasound (US) profile with gray scale and Doppler in entheses in these groups.

Methods: A case control study conducted in the period from December 2015 to December 2016, at Hospital das Clínicas/UFMG. It was performed in 144 patients with PsO and/or PsA and 24 healthy controls. Patients with and without arthrits/enthesis were submitted to the US. The US findings were according to the MASEI (the Madrid sonography enthesis index). The entheses were studied bilaterally: plantar fascia, distal and proximal ligament of the patella, distal quadriceps tendon, calcaneus tendon, and tendons of the brachial triceps. In addition to the US in the 2nd and 3rd distal interphalanges, the interobserver reliability was calculated in 24 patients - kappa index (k).

Results: In the case group the mean age was 50.13 years, BMI of 24 patients - kappa index (k).

ARE SONOGRAPHIC FINDINGS CORRELATED WITH DISEASE ACTIVITY SCORE IN RHEUMATOID ARTHRITIS REMITTED PATIENTS?

Saoussen Milad, Myriam Moalla, Ala Fazaaz, Kmar Ouenniche, Leila Souabni, Selma Kassab, Selma Chekili, Zakraoui Leith, K Hawthor Ben Abdelghani, Ahmed Laatar. Mongi Slim Hospital, Rheumatology department, Tunis, Tunisia

Background: Obtaining remission is the ultimate and now attainable goal of treatment in rheumatoid arthritis (RA). However, the definition of remission kept changing over the last decade. Several composite scores and indices are now validated to assess remitting RA such as the Disease Activity Index 28 joints (DAS28), and more recently, the Simplified Disease Index (SDAI) and the Clinical Disease Index (CDAI). Despite more stringent definition criteria, progressive radiographic damages still occur in RA patients who reached remission. Defining other criteria for remission including ultrasound (US) might help preventing such evolution.

Objectives: The aim of this study was to compare US findings and composite score results in RA patients that achieved a status of remission according to DAS28.

Methods: Thirty Tunisian patients followed up for RA with DAS28 ≤2.6 for at least three months were enrolled. Among them, we identified patients in remission according to the SDAI (≤3.3) and the CDAI (≤2.8). US (Esaote MyLab 60 machine and a 13-18 MHz linear array transducer) was performed by an experienced rheumatologist blinded to clinical and laboratory data. For each patient, 22 joints were scanned (wrists, metacarpophalangeal, and proximal interphalangeal joints) using a semi-quantitative score.

Results: Over the 26 patients in CDAI remission, ultrasonographic synovitis in B-mode were noted in 81% of patients. The average ultrasound score per patient was 4.58. In PD mode, US abnormalities were noted in 58% of patients. The average PD score per patient was 2.6. Neither correlation between CDAI and B-mode US score (r = 0.104; p = 0.319) nor between CDAI and PD US score (r = 0.251; p = 0.217) was noted.

Finally regarding ankle/foot pain, treatment changes happened in 71.4% of patients owing mainly to changes in diagnosis & detecting subclinical activity. In polyarticular complaints, 8% of patients had changes in treatment decisions respectively of which 75% and 90.8% were patients with hand/wrist & polyarticular complaints, 44.8% and 68.8% of treatment decisions were changed for knee pain, 50% of treatment decisions were changed for elbow pain, and 40% of treatment decisions were changed for shoulder pain. In this observational study on 101 patients with musculoskeletal complaints who have been referredby rheumatologists for a MSUS scan at Zagazig University MSUS Unit in the same department. The patients’ mean age was 41.5 ± 15.67, including 70 females (69.3%) and 31 males (30.7%). Patients included 29 patients with hand/wrist complaints (28.7%), 2 patients with elbow pain (2%), 36 patients with shoulder pain (35.6%), 7 patients with ankle/foot pain (6.9%), 10 patients with knee pain (9.9%), and 17 patients with polyarticular pain (16.8%). The rheumatologists were asked to set a provisional diagnosis and treatment plan before the MSUS scan and to reconsider their own plan for any adjustments afterwards. Results: Regarding all 101 patients, the diagnosis & treatment decisions were changed in 37% and 65% respectively after the MSUS scan as shown in figure (1). Fifty percent of the changes in treatment were classified as major, defined as adding/ changing the dose of steroids, adding the dose of DMARDs and adding/ modifying physiotherapy while the other 50% were major in the form of initiating/ adding DMARDs, interventional treatment referral to surgery. Ten patients out of 29 with hand/wrist complaints encountered change in diagnosis (34.5%), 1 patient out of 2 with elbow pain (50%) and 11 patients out of 36 with shoulder pain (30.6%). In patients with knee pain and ankle/foot pain, changes occurred with 4 patients for each representing 40% and 42.9% respectively. Regarding patients with polyarticular complaints 8 patients representing 47.1% were categorized to different disease entities. Treatment decisions were much more frequently changed in patients with polyarticular complaints owing to a more detailed look into the diseased joint and surrounding structures. Background: The era of musculoskeletal ultrasound (MSUS) is becoming enormous, but the extent to which MSUS has influenced management plans for patients with different musculoskeletal symptoms remains questionable. Objectives: To assess the changes in the provisional diagnosis and treatment decisions made by rheumatologistsafter receiving MSUS reports for their patients. Methods: This study was carried out at Rheumatology & Rehabilitation outpatient clinics in Zagazig University Hospitals in Egypt. This is an observational study on 101 patients with musculoskeletal complaints who have been referred by rheumatologists for a MSUS scan at Zagazig University MSUS Unit in the same department. The patients’ mean age was 41.5 ± 15.67, including 70 females (69.3%) and 31 males (30.7%). Patients included 29 patients with hand/wrist complaints (28.7%), 2 patients with elbow pain (2%), 36 patients with shoulder pain (35.6%), 7 patients with ankle/foot pain (6.9%), 10 patients with knee pain (9.9%), and 17 patients with polyarticular pain (16.8%). The rheumatologists were asked to set a provisional diagnosis and treatment plan before the MSUS scan and to reconsider their own plan for any adjustments afterwards.

Results: Regarding all 101 patients, the diagnosis & treatment decisions were changed in 37% and 65% respectively after the MSUS scan as shown in figure (1). Fifty percent of the changes in treatment were classified as major, defined as adding/ changing the dose of steroids, adding the dose of DMARDs and adding/ modifying physiotherapy while the other 50% were major in the form of initiating/ adding DMARDs, interventional treatment referral to surgery. Ten patients out of 29 with hand/wrist complaints encountered change in diagnosis (34.5%), 1 patient out of 2 with elbow pain (50%) and 11 patients out of 36 with shoulder pain (30.6%). In patients with knee pain and ankle/foot pain, changes occurred with 4 patients for each representing 40% and 42.9% respectively. Regarding patients with polyarticular complaints 8 patients representing 47.1% were categorized to different disease entities. Treatment decisions were much more frequently changed in patients with polyarticular complaints owing to a more detailed look into the diseased joint and surrounding structures.

AB1163 CAN A MUSCULOSKELETAL ULTRASOUND REPORT CHANGE A RHEUMATOLOGIST’S OPINION?

Mohammed A. Mortada, Marwa Hammad, Shima M. Abdelwhab, Samah M. Allan, Amany Ebad, Ghada Dawa, Lobna Kotb, Youmna A. Amer. Faculty of Medicine. Zagazig University, Rheumatology and Rehabilitation, Zagazig, Egypt

AB1164 EDUCATION ON PEDIATRIC MUSCULOSKELETAL ULTRASOUND: A SYSTEMATIC LITERATURE AND EVENTS REVIEW

Valentina Muratore1, Maria-Antonietta Diagostino2, Esperanza Naredo3,4, Jelena Vojinovic5, Silvia Magni-Murzon2,6, Fondazione Policlinico San Matteo, Pavia, Italy; 2APHP Hôpital Ambroise Paré, Boulogne-Billancourt, France; 3Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; 4 Autonomous University of Madrid, Madrid, Spain; 5University of Nish, Faculty of Medicine, Nish, Serbia; 6Ospedale pediatrico Bambino Gesù, Roma, Italy

Background: Recently some Pediatric musculoskeletal ultrasound (PedMSUS) courses have been held on national and international ground. Nonetheless, content, conduct and format of PedMSUS courses have never been investigated and shared.

Objectives: To perform a systematic literature and events review on PedMSUS educational initiatives.

Methods: Educational material/events on PedMSUS were extensively searched on websites/networks (PubMed, Cochrane, Embase, ERIC, Medline, CINAHL, complete, Google, Yahoo, Ask, Baidu, Bing, Lycos, Duckduckgo). The keywords were: “musculoskeletal”, “ultrasound”, “sonography”, “course”, “education”, “training”, “children”, “paediatrics”, “pediatrics”. Only courses/events, articles and books in English were considered. Descriptive analysis was performed on the documentation retrieved.

Results: No articles neither books on educational recommendations for PedMSUS courses were found. A total of 13 PedMSUS courses were identified. Two online courses and three residential ones were not consistent with the purpose and were excluded. Eight courses were finally included for the analysis (Figure 1). Seven were endorsed by EULAR and followed the recommendations for the content and conduct of EULAR MSUS courses. No requirements/skills should be fulfilled for registration; only one level of competency was proposed. The courses were residential of 2-3 days and included theoretical and practical lessons. Lectures were on MSUS examination techniques, physiological musculoskeletal (MSK) anatomy and basic pathology in pediatric rheumatology. Hands-on scanning of healthy models/patients with pediatric rheumatic diseases was generally organized in groups supervised by tutors, and included optimization of the machine settings, identification of pediatric MSK sonoanatomy, correct acquisition of images, and identification of basic pathological findings in children. A competency assessment was performed at the end of only three courses.

Figure 1

Conclusion: MSUS scans have a great impact on rheumatologists’ decisions in clinical practice. Remarkable changes in diagnosis with subsequent significant major changes in treatment plans were due to the ability of MSUS to differentiate between different disease entities. Changes in treatment decisions were very frequent even without changing the diagnosis owing to a more detailed look into the diseased joint and surrounding structures.

AB1165 ULTRASOUND: A SYSTEMATIC LITERATURE AND EVENTS REVIEW

REFERENCES

Figure 1
**FLUORESCENCE OPTICAL IMAGING XIRALITE® IS HELPFUL IN THE DECISION FOR RITUXIMAB RE-THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Sarah Ohrndorf1, Lisa Ridha1, Anne-Marie Gilmm1, Gerd Rüdiger Burmester1, Gabriela Schmittat1, Marina Backhaus1, Jens Klotsche2, Sarah Ohrndorf1, Lisa Ridha1, Anne-Marie Glimm1, Gerd Rüdiger Burmester1, Silvia Magni-Manzoni Consultant for: Abbvie, Speakers bureau: Lilly, Novartis, Janssen, and Celgene GmbH, Jelena Vojinovic: None declared, Agostino: None declared, Esperanza Naredo Consultant for: Abbvie.

**Background:** Rituximab (RTX) is an effective and well-tolerated therapeutic option in rheumatoid arthritis (RA) patients with insufficient response to TNFα inhibitors. However, the exact time point of RTX re-therapy often varies and objective parameters (e.g., imaging, such as MRI and/or musculoskeletal ultrasound [US]) are not yet included in the RA treatment strategy [1].

**Objectives:** The aim of this study was to evaluate the ability of the fluorescence optical imaging Xiralite® (FOI) to predict RTX re-therapy in RA patients - in comparison to clinical, laboratory and US.

**Methods:** In this study, n=31 patients with established RA were included and prospectively followed over one year by DAS28, patient’s VAS and CRP had similar predictive power with AUC of 0.66 each (each p=ns).

**Results:** Of the included 31 patients (female 77.4%, mean age 60.1±11.4, mean disease duration 14.9±7.1 years), n=14 (45.2%) received RTX re-therapy within 12 months: n=3 after 6 months (mths), n=4 after 7 mths, n=5 after 9 mths, and n=2 after 10 mths. In the group with RTX re-therapy, FOI in PVM mode was the only parameter that presented significant increase (beta 0.40, CI 0.08-0.71; p=0.013) – compared to the group without re-therapy. In the prediction model via receiver operating characteristic (ROC) analysis, FOI in PVM reached the highest values of all imaging parameters (phases 1-3, US) at baseline for the prediction of re-therapy over one year with an area under the curve (AUC) of 0.64 (OR 0.9, CI 0.79-1.03), however, without significance (p=0.117). Patient’s VAS and CRP had similar predictive power with AUC of 0.66 each (each p=ns).

**Conclusion:** The FOI Xiralite® in PVM is able to discriminate between groups with and without need for RTX re-therapy better than other included imaging parameters. It is able to predict the need for RTX re-therapy with comparable predictive power to patient’s VAS and CRP. At the same time, FOI is a more objective tool, while patient’s VAS and CRP can also depend on other influence (i.e. psychological, infectious) factors.
SUBCLINICAL ENTHESEAL INVOLVEMENT IN LOWER LIMBS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS: AN ULTRASOUND STUDY

Mohamed Omar1, Mohamed Abdelkareem2, Mohammed Moneer2, Mohamed Elwan1, Alazher, Rheumatology, Assuit, Egypt; 2Alazher, Rheumatology, Assuit, Egypt

Background: Diabetes mellitus (DM) is a group of metabolic diseases characterized by hyperglycemia, which results from defects in insulin secretion, insulin action, or both (1). DM impacts the connective tissue and causes various changes in peri- articular and articular structures. An increase in enthesopathic complications in diabetic patients such as patellar tendinitis bursitis, achilles tendinopathy and plantar fasciitis, was observed in many studies.

Objective: This study aims to detect subclinical lower limb enthesitis in type 2 DM by musculoskeletal ultrasonography & its relation to poor glycemic control & disease duration.

Methods: This study was carried out on 80 persons. Diabetic group forty patients diagnosed as diabetes according to ADA diagnostic criteria. Control group Forty apparent healthy volunteers both groups were matched at age and sex. Sonographic evaluations and scoring were performed according to Glasgow Ultrasound Enthesitis Scoring System (GUESS) on the entheses of both lower limbs.

Results: At the diabetic group the Musculoskeletal Ultrasound findings were as follows. The Quadriceps tendon enthesitis in 30 patients (75%), proximal patellar enthesis was in 28 patients (70%), Distal patellar enthesis in 22 patients (55%), Achilles enthesis in 27 patients (67.5%) & plantar aponeurosis enthesis in 25 patients (55%). There is a statistically significant difference between age and Ultrasound findings p. value <0.05. There is a statistically significant correlation between disease duration and (proximal patellar ligament, Achilles tendon, quadriceps tendon and plantar fascia) thickness p. value<0.05.

Conclusion: Enthesal abnormalities can be documented by ultrasonography in clinically asymptomatic patients with Diabetes. These findings could be related to a subclinical enthesal inflammation.

Disclosure of Interests: None declared
**Results:** Demographics were 60.2±8.3 years of age, 65% female, BMI of 28.6±4.5 of kg/m²; 60% with Kellgren and Lawrence (KL) grade 2 and 40% with a KL grade 3. Semi-quantitative OMERACT ultrasound scores revealed a good to excellent IRR (Kw=0.73 -0.88) for osteophyte and moderate to good IRR (Kw=0.42-0.66) for synovitis. Conversely, quantitative measures of ultrasound pathologies had excellent IRR (ICC=0.84-0.95) except for synovial hypertrophy (ICC=0.67-0.72).

A significant association was found between semi-quantitative ultrasound measurements and MRI outcomes, the absolute feature-specific agreement is called into question. These is moderate to good IRR between operators with varying experience using the OMERACT knee scoring image atlas for osteophyte and synovitis. While quantitative ultrasound measurements showed excellent IRR and significant association with MRI quantitative outcomes, the absolute feature-specific agreement is called into question.

**AB1168**

**SIGLEC1/C1D169 IS A SENSITIVE MARKER FOR MONOMERIC INTERFERONPATHIES**

**Banu Orak** 1,2, **Marc Nikolaus** 1,2, **Ellen Knierim** 1,2, **Angela Kaindl** 1,2, **Manuela Theophil** 1,2, **Axel Panzer** 4, **Barbara Zieba** 5, **Frédéric Ebstein** 5, **Elke Krüger** 5, **Nadine Unterwalder** 6, **Christian Meisel** 6, **Tilmann Kallinic** 1,2.

**Background:** Monomeric Interferonopathies are a rare group of inflammatory diseases that are difficult to diagnose in the onset phase given the lack of well-defined disease-markers. A correlation with interferon-stimulated genes (ISG) has been reported for SIGLEC1 (syn. CD169), in systemic lupus erythematosus (SLE). Furthermore, expression of SIGLEC1 on monocytes is the second highest ISG in SLE.

**Objectives:** To study the relevance of SIGLEC1 as a putative marker for early detection of interferonopathies.

**Methods:** Clinical data, classical inflammatory markers, blood count values and genetic information were obtained from the medical files of eight patients with genetically confirmed monomeric interferonopathies. SIGLEC1 expression was measured by flow cytometry with a highly standardized quantitative assay with a reference range in healthy controls less than 2500 SIGLEC1 molecules/monocyte. Additionally, transcriptional level of SIGLEC1, IFI44L, IFI27, ISG15 and RSAD2 as type I Interferon stimulated genes were assessed by real-time PCR.

**Results:** Eight patients with interferonopathies carried mutations in the genes TREX1 (n=3), IFIH1 (n=2), SAMHD1 (n=2) and RNASE2HB (n=1). Mean age of patients was 12 years (range 6 months to 49 years). Six of eight patients showed neurological symptoms consistent with Aicardi-Goutieres-Syndrome presenting developmental delay and microcephaly. Five patients showed abnormalities on cranial MRI including periventricular calcifications and corpus callosum thinning. Two patients were diagnosed with Singleton-Mertens Syndrome presenting abnormal ossification of extremities and dental anomalies. One patient with homozgyous TREDX1 mutation presented with postnatal glaucoma, microcephaly, sensorimotor polyneuropathy and recurrent fever with persistent chilblain lesions. All patients had elevated SIGLEC1 levels (mean molecules/monocyte +/- SD: 10272 +/- 3746) without high levels of standard inflammatory markers. In six patients, elevated SIGLEC1 expression showed dysregulation of the type 1 interferon pathway prior to genetic testing. The relative expression (ΔCt) of all ISG’s was significantly elevated in comparison to healthy controls (SIGLEC1 p= 0.0167, ISG15 p=0.0015, RSAD2 p=0.0067, IFI44L p=0.0001, IF27 p=0.0056).

**Conclusion:** We report high expression of SIGLEC1 in monomeric interferonopathies like Aicardi-Goutieres-Syndrome. Therefore, SIGLEC1 qualifies as an accessible and cheap diagnostic marker to screen patients with suspected interferonopathy.

**ASSOCIATION OF ANXIETY, DEPRESSION WITH ULTRASONOGRAPHIC EVALUATION OF THE JOINTS, DISEASE ACTIVITY, FUNCTIONAL DISABILITY AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATIC DISEASES:**

**Rita Osipyants** 1, **Victoria Nadtocheeva** 2, **Madina Bogdanova** 3, **Marina Kanevskaya** 4, **Temuri Mirlashvili** 5, **Department of Internal Diseases, RUDN University; Ermanshantsev City Clinical Hospital, Moscow, Russian Federation; 6Department of Internal Diseases, RUDN University, Moscow, Russian Federation; 7FSBI “Polyclinic N6” of the Administrative Department of the President of the Russian Federation, Moscow, Russian Federation; 8Sechenov Moscow Medical University, Moscow, Russian Federation; 9Ermanshantsev City Clinical Hospital, Moscow, Russian Federation

**Objectives:** The aim of this study is to evaluate anxiety and depression disorders and to study their correlation with disease activity, ultrasonographic (US) finding indicative of synovitis, functional status and quality of life in patients (pts) with rheumatic diseases.

**Methods:** 39 pts (F/M–29/10) with rheumatoid arthritis (RA, n=17),ankylosing spondylitis (AS, n=10), psoriatic arthritis (PsA, n=12) were included. All RA pts fulfilled the ACR/EULAR 2010, AS pts - the ASAS, PsA pts - the CASPAR criteria. 20 pts (8 RA, 6 AS, 6 PsA) were performed US examinations (Minrad DC-N6 (China), C5-2, L10-13 MHz probes) included bilateral of the hip and knee joints. Each joint was scored according to the OMERACT definitions of pathology. Functional status (BASFI), disease activity indices (DAS28-CRP, ASDAS-CRP, DAPSA), anxiety and depression levels (Hads-A, Hads-D) and quality of life (RAPID3, EQ-SD) were assessed. The Mann-Whitney U-test was applied for intergroup comparison and correlation was evaluated using a Spearman’s Rank two-tailed test (R value is shown).

**Results:** Median age of 39 pts – 52 (44;61) years and the body mass index (BMI) 28.6±4.5 of kg/m2; 60% with Kellgren and Lawrence (KL) grade 2 and 40% with a KL grade 3. Semi-quantitative OMERACT ultrasound scores revealed a good to excellent IRR (Kw=0.73 -0.88) for osteophyte and moderate to good IRR (Kw=0.42-0.66) for synovitis. Conversely, quantitative measures of ultrasound pathologies had excellent IRR (ICC=0.84-0.95) except for synovial hypertrophy (ICC=0.67-0.72).

A PHASE IV, MULTICENTER, SINGLE-ARM, OPEN-LABEL STUDY TO EVALUATE THE IMPACT OF APRIMO CARNO METAL AND WHOLE-BODY MRI OUTCOMES IN PATIENTS WITH PSORIATIC ARTHRITIS (MOSAIC): RATIONALE, DESIGN AND METHODS

Mikkeli Östergaard1, Walter P. Maksymowczyk2, Mikaël Boesken3, Olga Kubassova4, Priscila Nakasato5, Benoît Guerette6, Lichen Teng7, Philip J. Mease8, 1University of Copenhagen, Copenhagen, Denmark; 2University of Alberta, Edmonton, Canada; 2BiSpiegel and Friedrichberg Hospital, Copenhagen, Denmark; 3Image Analysis Group, London, United Kingdom; 4Celgene Corporation, Summit, United States of America; 5Swedish Medical Center and University of Washington School of Medicine, Seattle, United States of America

Background: Phase III clinical trials have shown apremilast (APR) reduced PsA signs/symptoms and improved physical function, but no study has addressed its impact on structural disease progression. MRI is a highly sensitive, validated tool to assess inflammatory and structural changes, as it can detect soft tissue inflammation, bone marrow edema (BME) lesions, bone erosion and proliferation in peripheral joints and axial skeleton. Whole-body (WB)-MRI, a relatively novel technique in musculoskeletal studies, allows assessment of all peripheral/axial joints and entheseal changes in 1 examination. Recent, consensus-based and semi-quantitative scoring methods were developed and validated. This study is the first to systematically use new state-of-the-art MRI scoring methodologies to assess PsA inflammatory and structural changes in a global clinical trial.

Objectives: To assess APR efficacy on inflammatory indices and imaging outcome measures associated with PsA structural progression by conventional static MRI and dynamic contrast-enhanced (DCE)-MRI of the most affected hand and WB-MRI.

Methods: The study aims to enroll 120 biologic-naive adults with PsA for ≥3 mos to ≤5 yrs and prior treatment with ≥2 conventional DMARDs. Subjects must have ≥3 swollen and ≥3 tender joints, involvement (>1 swollen joint or >1 dactylitis) and ≥1 active enthesis site. After 4-wk screening, all eligible patients will receive APR 30 mg twice daily (titrated during the first 5 days) as monotherapy or in combination with methotrexate for 48 wks, with a 4-wk observational follow-up. Conventional MRI and optional DCE-MRI of the most affected hand and WB-MRI of the entire body will be performed at Wks 0, 24 and 48. The primary endpoint is change from BL to Wk 24 in OMERACT PsA MRI (PsAMRIS) composite score of BME + synovitis + tenosynovitis. Other imaging endpoints include change from BL to Wk 48 in PsAMRIS composite score (BME + synovitis + tenosynovitis) and change from BL to Wks 24 and 48 in PsAMRIS composite score (BME + synovitis), PsAMRIS composite inflammation score (BME + synovitis + tenosynovitis + periarthritis inflammation). PsAMRIS total damage score (erosion + bone proliferation), WB-MRI indices (including peripheral joint inflammation index and peripheral enthesis inflammation index), hip and knee inflammation MRI scores (HIKRISS, KIKRISS), OMERACT heel enthesis MRI indices, axial inflammation indices (SPARCC, CanDen), DEMRIO-Volume and DEMRIO-Inflammation and other DCE-MRI-derived parameters. Clinical parameters will include HLA-C21, cDAPSA, SPARCC Enthesitis Index, Leeds Dactylitis Index, Leeds Dactylitis Index, PASDAS, PGHS, PGHA, Patient's Assessment of Pain, HAQ-DI, and BASDAI and impact of disease (PsAID12). Safety and tolerability also will be assessed.

Results: The study protocol was approved by an independent ethics committee and is now enrolling in the USA. Selected countries in Europe and Russia will also participate. MRI, clinical and patient-reported outcomes will be analyzed.

Conclusion: This study will provide important evidence of APR’s impact on inflammatory/structural changes by assessing PsA structural progression by conventional static MRI and dynamic contrast-enhanced (DCE)-MRI of the most affected hand and WB-MRI. This study will provide important evidence of APR’s impact on structural disease progression. MRI is a highly sensitive, validated tool to assess inflammatory and structural changes, as it can detect soft tissue inflammation, bone marrow edema (BME) lesions, bone erosion and proliferation in peripheral joints and axial skeleton. Whole-body (WB)-MRI, a relatively novel technique in musculoskeletal studies, allows assessment of all peripheral/axial joints and entheseal changes in 1 examination. Recent, consensus-based and semi-quantitative scoring methods were developed and validated. This study is the first to systematically use new state-of-the-art MRI scoring methodologies to assess PsA inflammatory and structural changes in a global clinical trial.

ARE CIRCULATING BLOOD BIOMARKERS FOR INFLAMMATORY RHEUMATIC DISEASES GENDER-DEPENDENT? – SYSTEMATIC REVIEW BASED ON OMICS DATA

Ana Filipa Fernandes1, Atlas Sardoo2, Fernando Pimentel dos Santos2, Ana Varella Coelho1, Vila Real, Portugal; 1NOVA University of Lisbon, CEDOC, NOVA Medical School; 2Faculdade Ciências Médicas, Lisboa, Portugal; 3NOVA University of Lisbon, Instituto Tecnologia Química e Biológica, Oeiras, Portugal

Background: Inflammatory rheumatic diseases (IRDs) are thought to be multifactorial diseases. Female-male ratio in IRDs differs according to the disease. In Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) female prevalence is higher opposing to Ankylosing Spondylitis (AS). Until recently, differences on gender bias observed in predisposition to IRDs, and to their pathophysiology have been understudied and neglected. Recent research using omics approaches shows that gender-bias is widespread in a diversity of pathologies. The integration of omics results, despite the extremely complex crosstalk among the several biomolecules involved, places these methods at the lead of medical research, overcoming limitations and increasing the forecasts of targeted methodologies.

Objectives: The purpose of this systematic review is to aggregate existing omics results on biomarkers for RA, SLE and AS to raise awareness about whether gender can actually play a role on their profiles.

Methods: Two searches were conducted on PUBMED database (22nd November 2018) with a final output of 81268 articles. Both searches were sorted by best matches and for the second thousandth articles ranked no relevance was found for the aim of this review. The first 1000 articles were further analyzed based on the title, abstract and content. Three articles having relevant results were selected from the first thousand publications. Ten more were identified from the cross-references of both searches. The PICO (P, population; I, intervention; C, comparison; O, outcome) concept was used to perform the analysis according to: Patients: adults (>18 years old) with RA, SLE or AS (SpA); Intervention: any –omic study; Comparison: gender information regarding results; Outcomes: identified genes, proteins or metabolites.

Results: Dectin-2, MCP-1 and DC-SIGN polymorphisms where proposed as possible accounts for gender-associated differences in susceptibility to RA. Sex-differentiated and sex-interaction analyses of a GWA study revealed strong evidence of association in both sexes, highlighting links with RA only in one of the genders. Several transcriptomic studies pointed to gender differences on biomarkers profiles for the three diseases. For instance, different expression levels of TNFα, IL-6, IL-17, IL-18, IFNγ as well as X or Y chromosome-linked genes were found in SLE and/or AS. In AS, male patients with syndesmophytes showed higher levels of TNFα and men without syndesmophytes presented higher levels of VEGF, IL-6, TNFα and IL-18 both compared to females-matched. In RA patients, microRNAs 222, 532, 98, and 92a were found significantly down regulated in PBMC of female versus male. Six genes displayed a gender-based expression among male and female SLE patients.

Conclusion: Blood biomarkers signatures for the IRDs analyzed in this study have been shown gender-biased. These will contribute for a better understanding of these diseases pathophysiology and probably to different gender approaches regarding diagnosis, monitoring and therapeutic approach.

ENDOCARDIAL LESIONS IN PATIENTS WITH RHEUMATIC DISEASES: CASE REVIEW

Sergio Rodríguez Montero, Consuelo Ramos Giráldez; PLAZA NAHIA, Jose Luis Marenco. Valme Hospital, Rheumatology, Sevilla, Spain

Background: The infection of a native or prosthetic heart valve usually occurs in patients with structural valvular anomalies that predispose to turbulent flows. Manifestations such as arthralgia, arthritis or back pain appear in up to 40% of patients, which acts as a confounding factor when this infection occurs in patients with rheumatic diseases. On the other hand, in the latter patients, noninfectious endocarditis has been described, which adds even more complexity to the diagnosis.

Objectives: To describe the characteristics of endocardial lesions in patients with rheumatic diseases.

Methods: Patients attending clinics at the Department of Rheumatology were analyzed to determine how many of them required hospitalization for causes directly related to endocardial lesion, from January 2015 until December 2018. The following information was recorded: age, sex, type of rheumatic disease, duration of the disease, immunosuppressive treatment, characteristics of endocardial lesions, complications of endocardial lesions, and cardiovascular risk factors.

Results: All patients were identified from an electronic database. Results regarding to demographic and clinical data are as follows:

Conclusion: The spectrum of endocardial involvement in patients with rheumatic diseases is variable. In this case review, we found lesions of different origin: infectious, thrombotic and tumoral. The appearance of fever of unknown origin in patients with rheumatic diseases, requires ruling out an endocarditis, needing transesophageal echocardiography in case the transthoracic study, which is less sensitive, is negative. It is striking the case of patient 3, a systemic sclerosis with calcinosis in limbs, whose endocardial wart, was studied histologically, revealing in its composition mainly calcium and fibrin. We have not found a bibliographic reference of calcium endocarditis in systemic sclerosis.

In conclusion, patients with rheumatic diseases can develop infectious endocarditis, but also thrombotic valvular vegetations, as well as myxomas. Whose consequences, from their clinical debut, may pose life-threatening situations for the patient. The presence of fever, stroke or embolic events in these patients should put us on the track of an underlying endocardial involvement.

Table 1: Correlation coefficients between twelve spine score. Fusion scores and stability with the highest score in all joint combinations.

Bayesian logistic mixed models were fitted with age, sex, and disease duration included as fixed effects. The model selection was based on the Bayesian information criterion. The χ²-test was used to compare the performance of the different models. The null hypothesis was rejected if the p-value was less than 0.05.

Conclusion: The present study of patients with RA shows that the US examination of both hands only for assessing disease activity is highly correlated for with the 46-joint evaluation at all time points, both regarding GS and Doppler sum scores. Using hands as a reduced joint set US assessment of inflammation could be an option to increase the feasibility of US in routine clinical practice.

Table 1: Prevalence of FJ degenerative changes in patients with RA and age and sex-matched peers.

Results: Prevalence of facet joints changes in patients with RA and group of age and sex-matched controls were not significantly different at any spinal level or in total L5-S1 score. Marginal erosions, that are characteristic feature of joint change in RA, were not found in any subject with RA in our sample. In subjects with RA, individuals with affected FJs and without affected FJs have no difference in any disease parameters and markers (Tables 1 and 2).

Conclusion: In our samples of CT scans we did not find a difference in facet joints changes between the subject with RA and control group. The occurrence of FJs changes among subjects with RA had no correlation with disease duration and activity. According to the findings, we may assume, that facet joints of the lumbar spine are not involved in the inflammatory process of RA, and patients' low back pain is not due to inflammation in this region of the spine.

FACET JOINTS INVOLVEMENT IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

Tatiana Reitblat1, Lina Linov2, Fadi Badeer3, Azara Simonovich3, Leaard Kalichman2, Barzilai MC, Rheumatology Unit, Ashkelon, Israel, 2Barzilai MC, Radiology, Ashkelon, Israel, 3Recanati School for Community Health Professions, Faculty of Health Sciences at Ben-Gurion University of the Negev, Department of Physical Therapy, Beer-Sheva, Israel

Background: Even it is accepted among rheumatologists that rheumatoid arthritis (RA) does not involve the facet joints (FJs) of the spine, the issue is still under debate. Studies that described a prevalence of the FJs in rheumatoid arthritis patients are scarce.

Objectives: To compare the prevalence of FJs changes between patients with RA and age and sex-matched peers.

Methods: We compared computed tomography (CT) scans of 34 patients with RA, who suffered from low back pain, and 70 age and sex-matched controls-people without RA, with low back pain. The changes in FJs were evaluated according to the score proposed by Kalichman et al: joint space narrowing, marginal osteophytes, articular process hypertrophy, subchondral sclerosis, inter-joint vacuum phenomenon, and subchondral cysts. The characteristic joint changes of RA were also evaluated.

Disease activity characteristics, duration of RA, age, and gender were taken from patients' clinical charts.

Results: Prevalence of facet joints changes in patients with RA and group of age and sex-matched controls were not significantly different at any spinal level or in total L5-S1 score. Marginal erosions, that are characteristic feature of joint change in RA, were not found in any subject with RA in our sample. In subjects with RA, individuals with affected FJs and without affected FJs have no difference in any disease parameters and markers (Tables 1 and 2).

Conclusion: In our samples of CT scans we did not find a difference in facet joints changes between the subject with RA and control group. The occurrence of FJs changes among subjects with RA had no correlation with disease duration and activity. According to the findings, we may assume, that facet joints of the lumbar spine are not involved in the inflammatory process of RA, and patients' low back pain is not due to inflammation in this region of the spine.

CORRELATION OF THE FINDINGS OF ULTRASOUND EXAMINATION OF THE LUNGS AND INTERSTITIAL LUNG FIBROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Nikola Raganovic, Institute of Rheumatology, Belgrade, Serbia

Background: Interstitial lung disease is one of the most severe complications in patients with systemic sclerosis (SSc), especially in those with diffuse form of this disease. Carbon monoxide diffusion capacity (DLCO) measurement is an important diagnostic method for assessing lung fibrosis. In recent years, ultrasound (US) lung examination has been used to evaluate the presence of interstitial changes (B lines) in the lungs.

Objectives: Determine whether there is a statistically significant difference in positive US findings on the lungs between the groups of subjects with a diffuse SSc and limited SSc, and whether there is a statistically significant difference in the presence of pulmonary fibrosis between these two groups of subjects. Then determine whether there is a correlation between the presence of B lines on the US examination of the lungs and the finding of lung fibrosis in patients with diffuse and limited SSc.

Methods: The study included 55 patients of both sexes with SSc from the Institute of Rheumatology (28 with diffuse and 27 with limited SSc), aged between 43 and 79 years. Data on the presence of pulmonary fibrosis were based on clinical findings and reduced lung diffusion parameters (DLCO less than 75%). An US examination of the lungs was performed for all patients and the number of B lines in all lung segments was determined. Positive US finding was the finding of 3 or more B lines in at least two adjacent fields of US scanning or more than 5 B lines in any single field of ultrasonics scanning.

Results: There was a statistically significant difference in positive US findings on the lungs between the groups of subjects with diffuse SSc and limited SSc (85.7% versus 44.4%, p <0.001). A statistically significant difference was observed in the presence of pulmonary fibrosis between the groups of subjects with diffuse SSc and limited SSc (85.7% versus 55.6%, p <0.05). It has also been shown that there is a highly statistically significant correlation between the presence of B lines on US examination of the lungs and findings of lung fibrosis in patients with diffuse and limited SSc (r = 0.700, p <0.001).

Conclusion: The conducted study confirmed that there is a highly statistically significant correlation between the presence of B lines in the US examination of the lungs and the findings of lung fibrosis in patients with diffuse and limited form of SSc. The study also found that patients with diffuse SSc had significantly more frequent positive US findings on the lungs, as well as a more frequent presence of pulmonary fibrosis compared to the patients with limited SSc. Introducing US into a routine protocol for monitoring patients with SSc diagnosis would provide a simple, inexpensive, fast and accurate orientation to the development of fibrotic changes in the lungs.

HOW TO DEFINE RHUPUS SYNDROME: SYSTEMATIC REVIEW OF THE CURRENT LITERATURE

Elena Rubini, Silvia Grazietta Foddai, Massimo Radin, Irene Cecchi, Daniela Rossi, Savino Sciascia, Dario Roccattelo, University of Turin, Turin, Italy

Background: Systemic lupus erythematous (SLE) is a chronic autoimmune disease characterized by the presence of multi-systemic manifestations in patients with immunologic anomalies. While joint involvement is present in up to 90% of patients with SLE [1], only a small subset of patients develops erosive arthritis. The term rhupus refers to the coexistence of erosive symmetrical polyarthritis, typical manifestation of rheumatoid arthritis (RA), and clinical signs of SLE in the presence of anti-double-stranded DNA (anti-dsDNA) and/or anti-Smith antibodies (anti-Sm) [2]. However, to date, no consensus exists on how to define the rhupus syndrome.

Objectives: In this study we aim to investigate the definition of rhupus by systematically reviewing the current literature.

Methods: A detailed literature research has been developed a priori to identify articles that reported findings from rhupus patients. The search strategy was applied to Ovid MEDLINE In-Process and Other Non-Indexed Citation 2000 to present. Studies that included rhupus patients were systematically analyzed by two independent reviewers (ER and SGF). Disagreements were resolved by consensus; if consensus could not be achieved, a third party (MR) would provide an assessment of eligibility.

Results: We analyzed clinical and serological data of 176 patients with diagnosis of rhupus derived from a total of 16 studies. All works considered the presence of autoantibodies specific for SLE by including anti-nuclear antibodies (ANA), anti-dsDNA, and anti-Sm antibodies. Only 67% of patients had ANA positivity (113/176), 64% showed anti-dsDNA in serum (113/176) and 17% were positive for anti-Sm antibodies. No heterogeneous data were available on pattern or title of these autoantibodies. Only two studies did not assay ANA or anti-dsDNA. Twelve out of 16 studies tested the occurrence of anti-citrullinated peptide antibodies (ACPAs) that have been reported in 73 patients (41%), rheumatoid factor (RF) was detected in 149 patients (84%) resulting from 13 out of 16 studies. Among clinical criteria of rhupus, an erosive arthritis has been observed in 155 patients (88%), only one study did not take into account the joint erosion. Hematological and cutaneous disorders (64% and 86%,
PLANTOGRAPHIC ASSESSMENT OF FOOT DEFORMITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Russka Shumnaliev, Simeon Monov. Clinic of Rheumatology, Department of Internal Medicine, Medical University-Sofia, Sofia, Bulgaria

Background: In almost one third of the patients with rheumatoid arthritis (RA) the disease begins with involvement of the small joints of the feet with high risk for developing significant foot deformities with disease progression. Irreversible structural changes occur as a result of synovitis combined with mechanical stress. The pain and the impaired static cause functional disability in these patients and the orthotic correction is often limited and with no evidence for effectiveness.

Objectives: To assess the foot structure and determine the incidence of foot deformities in patients with RA with different disease duration ranging from 3 months to more than 10 years.

Methods: Forty two RA patients (32 women and 10 men) underwent assessment of the foot structure under an axial load and while walking on a pressure measuring plate as well as a 3D scan of the feet.

Results: The most common foot deformities found in the study group included hallux valgus deformity in 73.81%, flattening of the medial longitudinal arch in 64.29% and valgus deformity of the calcaneus in 35.71% of the patients.

Conclusion: The introduction of the plantography in the clinical practice offers the opportunity for early diagnosis of foot deformities in patients with RA and indicates the necessity of correction through orthotics or surgery.

TYPES OF JOINT LESIONS IN REACTIVE ARTHROPATHY

Volha Sirotka1, Uladzimir Sirotka2, Alexander Litvyakov1. 1Vitebsk State Order of Peoples’ Friendship Medical University, Department of internal diseases №1, Vitebsk, Belarus; 2Vitebsk State Order of Peoples’ Friendship Medical University, Department of traumatology, orthopedics and military field surgery, Vitebsk, Belarus

Background: Differential diagnosis of ReA has certain difficulties, especially at an early stage in the absence of confirmation of trigger infection. Radiographic signs of joint damage when the response are not specific and appear not earlier than 3-6 months from the onset of the disease; enthesitis this method is not visualized, making it difficult to timely diagnosis of ReA [1]. To determine the tactics of patient management and selection of adequate therapy is no less important to determine the duration and characteristics of the course of ReA.

Objectives: To study the ultrasonic features of joint lesions in reactive arthropathy depending on the course of the disease.

Methods: We examined 66 patients with ReA who met the preliminary international criteria were examined (4th International Workshop on Reactive Arthritis, Berlin 1999). Women were 26 (39%), men - 40 (61%), median age - 34 years (31-42), median duration of ReA- 1 year (0.3-3.25). Among the patients there were 40 (61%) people with acute ReA and 26 (39%) people with chronic ReA. All patients had confirmed chlamydial infection (PCR and IFA). Patients underwent a comprehensive clinical and laboratory examination, MRI and ultrasound of the knee joints. Statistical processing of the information package.

Results: The MRI of the affected joints clearly visualized inflamed entheses and the presence of local osteitis with an erosive defect of the closing plate of the bone (Fig.1).

In patients with acute ReA were visualized: thickening of entheses more than 3 mm (98%), hypo-, anechogenic areas in the projection of the tendon-ligamentous apparatus and places of its fixation (74%), the formation of a bone defect under them with a contour of reduced echogenicity (erosion of acute inflammation - 66.8%) and uneven edges, pronounced effusion (75%), lack of strengthening of local blood flow in the projection of synovia and joint structures (Fig.2).

In patients with chronic ReA, the following were visualized: thickening of entheses to 3 mm (65%), hyperechogenic inclusions in the projection of the tendon-ligamentous apparatus and its fixation sites (53%), the formation of a bone defect under them with a contour of increased echogenicity (erosion of chronic inflammation - 46.9%) and uneven edges, slight effusion (28%), the absence of strengthening of local blood flow in the projection of synovia and joint structures (Fig.3).

AB1180 ULTRASOUND SEMIOTICS OF DEFEATS OF THE JOINTS IN REACTIVE ARTHRITIS AND OSTEARTHROSIS

Volha Sirotska1, Uladzimir Sirotska2, Alexandr Libyakov1. 1Vitebsk State Order of Peoples’ Friendship Medical University, Department of internal diseases, Vitebsk, Belarus 2Vitebsk State Order of Peoples’ Friendship Medical University, Department of traumatology, orthopedics and military field surgery, Vitebsk, Belarus

Background: The most common cause of knee joint damage in people of working age is osteoarthritis. However, in recent years, cases of reactive arthropathy, which often takes a chronic course, have become more frequent [1]. Given the current possible ultrasonic equipment, relevant is the study to study the ultrasonic features of defeat of joints with ReA and OA.

Objectives: To study the ultrasonic features of joint lesions at osteoarthritus and reactive arthritis.

Methods: We studied 55 patients with ReA and 22 patients with OA. Among patients with ReA were 25 women and 20 men, median age was 31 years (18 to 47), the median duration of the current Illipe - of 2.86 (0.07-29.0) months. Among patients with OA were examined in 15 women and 7 men, median age was 56.5 years (43-61), the median duration of flow OA - 139 months (12-360 months). All patients with ReA at the time of the study or in history had confirmed genital chlamydial infection. All patients were multiplescule dynamic study of the knee by the ultrasonic device expert class using a sensor with a frequency of 12 MHz.

Results: As a result of the ultrasound examination of the 110 joints with ReA, we have identified: pronounced synovitis in 69 (62.7%) joints, but the absence of pathological vascularization in the projection of the synovia; narrowing of the joint space 73 (66,4%) joints; heterogeneous structure of the ligament in 82 (75%) joints, tenosynovitis in 20 (18%) joints, thickening entheses in 89 (80.9%) joints; hypoechoic inclusions in projection entheses in 39 thickening entheses in 89 (80.9%) joints, hypoechoic entheses in 72 ture of the ligament in 82 (75%) joints, tenosynovitis in 20 (18%) joints, via; narrowing of the joint space 73 (66,4%) joint; heterogeneous struc-

AB1181 ULTRASOUND PATHOLOGICAL PATTERNS AT CARPAL TUNNEL LEVEL IN RHEUMATOID ARTHRITIS AND IDIOPATHIC CARPAL TUNNEL SYNDROME

Gianluca Smerilli, Emilio Filippucci, Andrea Di Matteo, Antonella Draghesi, Stefania Gasparini, Antonella Inconova, Marco Di Carlo, Walter Grassi. Università Politecnica delle Marche, Rheumatology Unit, Jesi, Italy

Background: High-frequency ultrasound (US) has proven to be a useful imaging tool for the evaluation of carpal tunnel pathology. US impact in the assessment of idiopathic carpal tunnel syndrome (CTS) has been widely investigated, but only few studies have been carried out with the aim of revealing the pathologic conditions responsible for CTS in rheuma-

Fig.1 (a,b,c) Ultrasound examination of knee joints in a patient with ReA

As a result of the ultrasound examination of the 44 joints with osteoarthritis, we have identified: a decrease in the thickness of the cartilage and narrowing of the joint space of degree 1 in 14 (31.8%) joints, reduc-

Results: CTS was diagnosed in 21 out of 112 wrists (18.75%) and in 14 out of 56 RA patients (25%). Enlarged median nerve was found in 4 out of 21 wrists with RA and CTS (19%), in 6 out of 84 wrists of patients without CTS (7.1%) and in 22 out of 24 wrists of patients with idiopathic CTS (91.7%). Flexor tenosynovitis was found in 6 out of 21 wrists with RA and CTS (28.6%), in 8 out of 84 wrists of patients without CTS (9.2%) and in 4 out of 24 wrists with idiopathic CTS (16.7%). Palmar radio-carpal synovitis was found in 4 out of 21 wrists with CTS (19%), in 10 out of 84 wrists of patients without CTS (11.9%) and in 1 out of 24 wrists with idiopathic CTS (4.2%). Marked bone profile irregularities were detected in 3 out of 21 wrists with CTS (14.3%), in 22 out of 84 wrists without CTS (26.2%) and in none of the patients without RA. In RA patients, positive intra-neural PD signal was found in 9 out of 21 wrists with CTS (42.8%) and
in 12 out of 84 wrists without CTS (14.3%). In idiopathic CTS, PD signal was found in 15 out of 24 wrists (62.5%).

**Conclusion:** US allowed a detailed identification of the pathological findings at carpal tunnel in both RA and idiopathic CTS patients. When CTS was diagnosed, different US patterns were distinguished being median nerve less frequently enlarged and synovitis more frequently detected in RA patients. Finally, a positive association was found between the presence of intra-neural PD signal and clinical diagnosis of CTS independently of the diagnosis of RA.

**AB1182**

THE CORRELATION BETWEEN THE ULTRASOUND-DETECTED SYNOVITIS OF SMALL JOINTS AND THE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Xiaoying Sun, Xuerong Deng, Wenhui Xie, Yu Wang, Zhuoli Zhang. Peking University First Hospital, Beijing, China

**Background:** In patients with rheumatoid arthritis (RA), small joints, especially metacarpophalangeal (MCP), and interphalangeal (PIP) joints are frequently affected. Ultrasound (US) is a sensitive method for detecting joint inflammation in patients with RA. So far, what degree does the synovitis of every small joint contribute to the disease activity in RA was not clear.

**Objectives:** The purpose of the present study was to compare the correlation between the ultrasound-detected synovitis of small joints and the disease activity in RA.

**Methods:** 211 RA patients with DAS28-ESR >2.6 were included in this study. Thirty joints, including bilateral metacarpophalangeal (MCP) 1-5, proximal interphalangeal (PIP) 1-5 and metatarsophalangeal (MTP) 1-5 joints, were evaluated by ultrasound scan in all patients. Disease activity was assessed by DAS28-ESR, DAS28-CRP, CDAI, SDAI. Synovitis was detected by using semi-quantitative scoring systems (0-3) for grey scale (GS) and power Doppler (PD). All correlations among US variables and clinical variables were assessed using Spearman’s rank correlation test.

**Results:** Their median age was 51.82 years, median disease duration was 60 months, with 84.3% females. The mean (SD) DAS28-ESR and DAS28-CRP were 4.59±1.51 and 4.18±1.39, respectively. The whole GS scores of MCPs (MCP1-5 joints) showed highest correlation with the disease activity (r=0.404-0.452, p<0.01), including DAS28-ESR, DAS28-CRP, CDAI, SDAI, followed by PD (r=0.318-0.331, p<0.01) and MTPs (r=0.277-0.301, p<0.01). Similarly, the whole PD scores of MCPs also showed highest correlation with the disease activity (r=0.332-0.396, p<0.01), followed by PIPs (r=0.211-0.242, p<0.01), and then the least MTPs (r=0.198-0.222, p<0.01). In individual joint, GS score showed better correlation with disease activity than PD score. In 30 joints, MCP3 joint exhibited the highest correlation between GS score and DAS28-ESR (r=0.411, p<0.01), DAS28-CRP (r=0.459, p<0.01), SDAI (r=0.444, p<0.01). MCP2 joint exhibited the highest correlation between GS score and CDAI (r=0.421, p<0.01). While MCP5 joint exhibited the highest correlation between PD score and DAS28-ESR (r=0.353, p<0.01), DAS28-CRP (r=0.399, p<0.01), CDAI (r=0.368, p<0.01), SDAI (r=0.377, p<0.01). In 30 joints, PIP1 joint showed lowest correlation between GS (r=0.166-0.199, p<0.01) and PD (r=0.134-0.143, p<0.01) score and disease activity.

**Conclusion:** In small joints of RA patients, the ultrasound-detected synovitis of MCPs had best correlation with disease activity, compared with PIPs and MTPs. In individual joint, MCP2, MCP3, and MCP5 joint had the best correlation between ultrasound-detected synovitis and disease activity, while PIP1 joint showed lowest correlation.

ULTRASOUND POWER DOPPLER AND GREY-SCALE JOINT INFLAMMATION: WHAT DO THEY REVEAL ABOUT RHEUMATOID ARTHRITIS?

York Kiat Tan1,2,3, Li Huihua4, John Carson Allen Jr, 1,2 Julian Thumboo5.
1Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore; 3National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore; 4Singapore General Hospital, Health Services Research, Singapore, Singapore; 5Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore

**Background:** Grey-scale (GS) and Power Doppler (PD) imaging are routinely performed when assessing rheumatoid arthritis (RA) joint inflammation using ultrasound (US). While PD vascularity is often regarded as an US feature of more active joint inflammation, the true clinical significance of GS joint inflammation in RA is less understood.

**Objectives:** To gain further insight into US PD and GS joint inflammation through studying their relationship with two distinct, yet important outcome measures: (i) DAS28 – a disease activity measure and (ii) US-detected erosion - a structural joint damage measure.

**Methods:** In this cross sectional study, US PD and GS joint inflammation were graded semi-quantitatively (0-3), while bone erosion(s) was scored dichotomously (1=yes/0=no) at each joint recess. At the patient level, PD and GS scores were correlated with DAS28 and US erosion scores respectively using Pearson’s correlation coefficient, while linear regression was used to characterize the relationship between variables.

**Results:** 1080 joints and 1800 joint recesses from bilateral elbows, wrists, MCPJs, thumbs’ IPJs, PIPJs, ankles and MTPJs were scanned in 30 adult RA patients (baseline characteristics: 76.7% Chinese; 93.3% female; mean (SD) DAS28, 3.58 (1.20); mean (SD) disease duration, 70.3 (61.2) months). PD scores were correlated (r=0.46, P<0.0104) with DAS28 but not with US erosion scores. GS scores were correlated (r= 0.64, P<0.0001) with US erosion scores but not with DAS28 (table 1). Scatter plots for these variables are presented in Figure 1. Results of simple linear regressions showing PD as a predictor of DAS28 (coefficient (95% CI), 0.167 (0.048, 0.286); P<0.0104) and GS as a predictor of US erosion (coefficient (95% CI), 0.223 (0.125, 0.322); P<0.0001) are summarized in table 2.

**Acknowledgement:** The authors thank all the colleagues in our department for kind cooperation in this project and the patients for participating in this study.

Figure 1

Results: Demographic, densitometric, TBS and 3D-DXA parameters are shown in table 1. Of the 73 subjects included, 38 (52%) had pathogenic mutations in ALPL. Between premenopausal women and men above 50 years, 9 subjects (29%) with ALPL mutations had osteopenia and 4 (13%), osteoporosis whereas 4 (13%) and 2 (6.5%) were detected in the HPP-GT group, respectively (p<0.05). Between premenopausal women and men under age 50, only 2 (5%) showed low BMD (Z-score < -2). BMD at femoral neck was significantly lower in the HPP + GT group compared to the HPP- GT group (0.864 ± 0.18 vs 0.948 ± 0.16 (p=0.014), similar findings were found for Wards area (0.695 ± 0.14 and 0.781 ± 0.16, p=0.021) and a trend was observed at the femoral diaphysis (p=0.076), BMD at the LS and TBS assessment did not show differences. Major, hip FRAX and T-FRAX were superior in the HPP + GT group. In terms of the parameters of bone metabolism, ALP levels were lower in the HPP + GT (p= 0.0004), serum phosphate levels were higher in this group (p=0.01) and the rest did not show differences. The 3D-SHAPER software was applied in a subgroup of 52 subjects: volumetric BMD at the PF was lower in the HPP + GT (873.6 ± 84.4 g/cm² vs 819.4 ± 95.3 g/cm²; p = 0.035) with no differences in trabecular vBMD (p=0.117).

Conclusion: HPP + GT group showed lower BMD at femoral neck and wards area and this trend was also observed at the diaphysis. At the femur, vBMD was also lower in this group. No differences in BMD at the lumbar spine and in TBS were found. These findings and its value for predicting the risk of fractures, specially in atypical femoral fractures, must be elucidated.

AB1184 BONE MINERAL DENSITY, TRABECULAR BONE SCORE AND 3D-DXA ASSESSMENT IN ADULT PATIENTS WITH A POSITIVE AND NEGATIVE GENETICAL TESTING FOR HYPOPHOSPHATASIA

Carolina Tomero1, Monica Coronado2, Ludovic Humbert3, Sara García-Carazo1, Carmen Lancha2, Domenico Monachello2, Luis Dominguez-Gadea3, Alejandro Balsa1, Pilar Aguado1, 1 La Paz University Hospital, Rheumatology, Madrid, Spain; 2 La Paz University Hospital, Nuclear medicine, Madrid, Spain; 3 Galgo Medical, Madrid, Spain

Background: Scarcie evidence exists on the assessment of bone mineral density (BMD) in adult Hypophosphatasia (HPP). Recent studies suggest that dual-energy X-ray absorptiometry (DXA) could not appropriately predict their fracture risk and note the importance on further explore bone microstructure.

Objectives: To evaluate BMD at the lumbar spine (LS) and proximal femur (PF) assessed by DXA, the trabecular bone score (TBS) at the LS and the fracture risk assessment (FRAX and adjusted by TBS, T-FRAX) in patients with persistent low alkaline phosphatase levels (ALP) and HPP genetically confirmed (HPP TG +) compared to a group of subjects with the same biochemical abnormality and a negative HPP genetic test (HPP TG -). As a secondary objective, to assess the cortical and trabecular bone at the PF using DXA-based 3D modeling.

Methods: Seventy-three subjects with persistent low ALP levels - at least two values < 35 IU/L and none > 45 IU/L - and a genetic test for HPP performed were included. Individuals were distributed into 2 groups according to their genetic status. BMD was measured using GE-LUNAR iDXA and TBS. The 3D-SHAPER software was employed in a subgroup of 52 subjects matched by age, gender and body mass index. A clinical questionnaire and a battery of lab measures to assess risk factors for Osteoporosis were also performed.

Results: Demographic, densitometric, TBS and 3D-DXA parameters are shown in table 1. Of the 73 subjects matched by age, gender and body mass index. A clinical questionnaire and a battery of lab measures to assess risk factors for Osteoporosis were also performed.
or with nodules of Schmorl, in isolation or in a maximum of two vertebral bodies, to distinguish it from Scheuermann’s disease (2). Image 1.

**Objectives:** Current vertebral indexes, don’t measure a relation between a person height and his vertebra, and if the harmony of the individual is accepted, an index that combines these variables must be created in order to guaranteeing the objectivity of the resultant value.

![Image 1](https://via.placeholder.com/150)

**Methods:** Patients attending physician since 1994, both sexes, 20-55 years old, in whom Type II collagen disease or vertebral dysplasia was suspected, were selected for the study. A control group was created in 2054 formed within 3 days after the onset of symptoms, but our short series did not show any significant difference compared to the previous imaging, on average 6 days after the beginning of their symptoms. 4 early signs in favour of the diagnosis of infectious sacro ilios could be identified: fat infiltration in front of the sacroiliac joint in 86% of cases, bulging and elevation of the anterior part of the joint capsule in 43%, swelling of the piriform (71%) and iliac (71%) muscles on the sacroiliac side. All patients had at least 1 positive sign out of 4, 86% had at least 2. In 1 case, signs of osteitis were present. In 4 out of 7 cases, the injection of iodized contrast medium did not provide any additional element compared to the non-injected sequences. 5 patients underwent an MRI after the scan, which confirmed the signs in favour of the infectious nature of sacroiliitis. MRI detected in one case an aspect of osteomyelitis of the sacrum and iliac bone, but also a hypersignal of the joint space on the T2 sequences (80%) and a better visualization of abscesses.

In the literature, there is data on the interest of the CT scan for the diagnosis of infectious sacro ilitis (1) but there is no precise description of the early signs suggestive apart from the signs of osteitis, which appear later. Hermel et al (2) advised to be careful if the scan is performed within 3 days after the onset of symptoms, but our short series shows that some signs are positive even if the pelvic scan is performed very early. The interest of the scanner, in addition to its rapid access and acquisition, allows on the injected sequences to rule out differential infectious diagnoses of abdominal-pelvic or gynaecological origin, the clinical being sometimes put in defect.

**Conclusion:** Despite its radiant nature, the scanner can be a preferred accessible alternative to MRI for the diagnosis of infectious sacro ilitis with the detection of 4 signs of early onset.

**AB1187**

**IMPACT OF IN-CLINIC ULTRASOUND ON AGE AND GENDER OF PATIENTS SCANNED AND DETECTION OF SYNOVITIS – RESULTS FROM A QUALITY IMPROVEMENT PROJECT**

Yacer Asran, Surabhi Wij, Sreekanth Vasireddy, Bolton NHS Foundation Trust, Bolton, United Kingdom

**Background:** Inflammatory arthritis is more common in women, and the majority of patients have onset before the 6th decade. Synovitis can be difficult to diagnose clinically in the early stages, and can be especially easy to miss where the index of suspicion is low, such as men and the elderly. Ultrasound (US) can confirm synovitis and other conditions in Rheumatology, particularly where examination features are not very obvious. US has traditionally been offered via Radiology services in our hospital as a separate appointment following referral from the
Rheumatology clinic, with variable waiting times causing potential delay in starting treatment such as DMARDs. There is also a cost implication with regard to rebooking of the Radiology scan appointments. In Bolton, an US system was installed in Rheumatology from 2016 to perform in-clinic US, for improving access and reducing referrals to Radiology.

**Objectives:** We aimed to assess the US usage pattern before and after the new Rheumatology US was installed, with respect to access based on age and gender, the pattern of scanning in-clinic, and rate of synovitis diagnosis, using a quality improvement framework.

**Methods:** US referral data from the Radiology department from October 2015 to March 2016 were collated as baseline on a MS Access database. Two Consultant Rheumatologists performed US in-clinic. From May to October 2016 Rheumatology in-clinic data, and also Radiology referral data were collated on the database for comparison. Patient demographics and diagnoses were recorded from clinical letters. Descriptive statistics were processed in MS Excel 2010.

**Results:** Between October 2015 and March 2016, 68 patients (median age 52 yrs; 28% male) had scans in Radiology. Between May and October 2016, 59 patients (median age 60 yrs; 21% male) had scans in Radiology, and 78 patients (median age 59 yrs; 35% male) had scans in Rheumatology clinic. There was no significant difference in scanned areas amongst the three cohorts with the most common overall being hand/wrist area (n=57, 54 and 61 respectively; total 84%), followed by foot/ankle (n=6, 4 and 4 respectively; total 7%). Between the two time periods, there was an increased trend in final working diagnoses of inflammatory arthritis (28 [41%] vs 36 [61%] and 39 [50%] in the 3 cohorts respectively) and a decreasing trend in the final working diagnoses of non-inflammatory conditions (OA, FM, other non-inflammatory pain: 36 [53%] vs 22 [37.3%] and 28 [35.9%] in the 3 cohorts respectively).

**Conclusion:** The availability of Rheumatology US was associated with increased propensity for scanning older patients and a greater proportion of men compared to previously, a qualitative improvement as synovitis diagnosis could be delayed in these groups. The introduction of Rheumatology US was also associated with a trend towards higher proportion of inflammatory diagnoses, suggesting potentially increased appropriate clinical use due to availability in-clinic. This is supported by the majority being hand/wrist scans, suggesting Rheumatology use is mainly aimed at diagnosing synovitis. Although there was a modest reduction of 13% in Radiology referrals between the two time periods, there was an overall increase of scans performed by 101% following introduction of the Rheumatology US service. We therefore recommend Rheumatology in-clinic US provision, as in addition to obvious improvement in time to diagnosis, it is likely to increase the range of patients able to access US eg older patients and men, and also likely to increase the pick-up rate of synovitis by improving patient selection.

**AB1188 AUDIT: IMPACT OF MUSCULOSKELETAL ULTRASOUND USE IN RHEUMATOLOGY CLINICS**

Andrew Wilkinson, Mike Reed, Sara Elise, Forth Valley Royal Hospital, Larbert, United Kingdom

**Background:** Musculoskeletal ultrasound (US) has assumed a prominent role in rheumatological practice as both a diagnostic and monitoring tool. It has utility in excluding and quantifying active synovitis and can play a dominant role in rheumatological practice as both a diagnostic and monitoring tool.1 It has utility in excluding and quantifying active synovitis and can help to identify the underlying disease in these patients.2,3

**Objectives:** We aimed to observe impacts on clinical practice of utilising ultrasound (US) scanners in outpatient clinics in a district general rheumatology service. We were particularly interested to see if this affected treatment choices, follow-up plans and referrals for radiological investigations.

**Methods:** US scanners were obtained and used by 2 rheumatology consultants with previous ultrasound training. Scanning was performed during standard 15 minute appointments within general rheumatology outpatient clinics. No extra time was allocated. Over 8 weeks, we completed questionnaires for each scan and assessed the impact on management decisions.

**Results:** Over 8 weeks, data was collected for 36 consecutive patients scanned. Commonly imaged joints were hands (81%, n=29), wrists (75%, n=27), elbows (41%, n=7), and ankles (14%, n=6). Most common patient diagnoses were osteoarthritis (n=13, 36%), rheumatoid arthritis (n=10, 28%) and psoriatic arthropathy (n=6, 17%). The remaining patients had diagnostic labels including undifferentiated inflammatory arthritis or no formal diagnosis. Abnormalities suggesting active inflammation were seen in 42%. In 33% osteoarthritic changes were observed, erosions were seen in 5%, 20% scans were normal. US altered the management in 58% (n=21/36) of cases. These alterations to management included drug change (n=5), drug stopped (n=3), dose increase (n=1), joint injection (n=3), intramuscular injection (n=2). Of the medications added, 3 were DMARDs, 1 was a biologic therapy and one case was not specified. The medications stopped were all DMARDS. US use in clinic prevented radiological investigation in 72% (26/36) of cases. These were radiology ultrasound (n=23) and MRI (n=3). Hands and wrists scans accounted for 86% of these, drug stopped (n=3). US altered the follow up in 56% (20/36) of cases. Of these, 40% (8/20) were reviewed earlier, and 40% (8/20) of patients were discharged based on ultrasound information. In 16/36 patients, US did not alter management. The average time taken to scan in clinic was 7 minutes per patient. The median time was 5 minutes, with the average skewed due to a few prolonged scans of multiple anatomical areas.

**Conclusion:** This audit has demonstrated that US use has impacted on our clinical practice. We identified patients to be seen earlier and altered management based on US findings.

US-use also prevented radiological investigations in 72% of cases. This has positive impacts on staffing, finances, radiology department capacity and patient convenience. Furthermore, we were able to discharge 40% of patients who otherwise would have been recalled.

Overall, we believe this audit shows positive impacts of MSUS on patient care. Challenges include time pressures of scanning in clinic, time and cost implications of ultrasound training and the need to standardise and record ultrasound methods and findings consistently. Costs are offset by savings to radiology resources and increased discharges. We plan to expand ultrasound usage and train our colleagues to employ ultrasound for our patients.

**AB1189 THE IMPORTANCE OF POSITRON EMISSION TOMOGRAPHY-COMPUTED TOMOGRAPHY (PET-CT) IN FEVER OF UNKNOWN ORIGIN (FUO) AND INFLAMMATION OF UNKNOWN ORIGIN (IUO)**

Tahir Saygin Öğüt, Veli Varsız, Funda Erbasan, Mustafa Ender Terziolu, Akdeniz University, Department of Internal Medicine, Antalya, Turkey

**Background:** Fever of unknown origin (FUO) and inflammation of unknown origin (IUO) are clinical problems but diagnostically challenging for clinicians. Patients are exposed to extensive and expensive medical examinations for the identification of the FUO/IUO. FDG PET-CT can help to identify the underlying disease in these patients.

**Objectives:** The aim of this study was to evaluate the role of PET-CT in patients with FUO/IUO and to identify FDG uptake sites and patterns

**Methods:** Total of 296 patients who were performed 18F FDG-PET-CT between Jan 2014 and Dec 2017 were evaluated, retrospectively. There were a total 62 patients scanned by PET-CT for FUO/IUO. Definitive diagnosis, PET-CT patterns, organ involvement and SUVmax values in these patients were reevaluated.

**Results:** Rheumatic disease in 27 patients (43.5%), 20 malignancy (32.3%) and 6 infectious diseases (9.7%) were diagnosed in the FUO/IUO patients performed PET-CT scan. Systemic vasculitis were the most frequently diagnosed rheumatic disease. 11 patients of the 62 patients (17.7%) were diagnosed large vessel vasculitis (9 Takayasu arteritis, 2
Temporal arteritis. Significant vascular FDG involvement was detected (77.7%) in these patients. 4 of 7 patients diagnosed Takayasu arteritis were not seen an increased FDG finding in the other imaging modalities. Vascular FDG uptake (p < 0.001) was statistically significantly higher in the patients diagnosed with rheumatic disease whereas lymph node (p = 0.013) and bone (p = 0.005) FDG uptake were significantly higher in patients with malignancy. Patients with malignancy had the highest SUV-max mean value (p < 0.001).

Conclusion: Our findings reveal that PET-CT is a useful imaging modality in the FUO/IJO patients. Inflammatory diseases, especially large vessel vasculitis, should be considered in addition to malignancies in these patients, and subclinical inflammation in the blood vessel can be visualized by PET-CT.

AB1190
EXTENDED POLY-DIMENSIONAL IMMUNOME CHARACTERIZATION (EPIC): A WEB-BASED IMMUNE REFERENCE ATLAS OF THE HEALTHY HUMAN IMMUNOME AND A TOOL FOR TRANSLATIONAL MEDICINE

Joo Guan Yeo1,2, Lu Pan1, Martin Wasser1, Pavanish Kumar1, Thaschawee Arkachaisri2, Su Li Poh1, Fauzialia Ally1, Jing Yao Leong1, Kee Thai Yeo1,2, Liyun Lai1, Angela Yun June Tan1, Salvatore Albani1,2, Thaschawee Arkachaisri2,3, Sulipoh1, Fuazia Ally1, Fauzialia Ally1, Jing Yao Leong1, Kee Thai Yeo1,2, Liyun Lai1, Angela Yun June Tan1, Salvatore Albani1,2, Translational Immunology Institute, SingHealth-Duke-NUS Academic Medical Centre, Singapore, Singapore; 2KBC Women’s and Children’s Hospital, Singapore, Singapore; 3Duke-NUS Medical School, Singapore, Singapore

Background: An atlas of the developing immune system will not only improve our understanding of normal immune ontogeny but more importantly, aid in our identification of disease-associated cell subsets. However, such a resource is still unavailable despite accessibility to technologies like mass cytometry due to the general focus on specific cell subsets or ages. There is a critical unmet need for standardized datasets depicting at single cell level and with high dimensionality the entire developmental gradient of the healthy immune system from the neonatal to adult age.

Objectives: We aim to provide a detailed depiction of the architecture of the human healthy Immunome across an entire age gradient.

Methods: We have created a high dimensional atlas of the healthy human immunome (EPIC: Extended Poly-dimensional Immunome Characterization) by interrogating the peripheral blood mononuclear cells (PBMC) of over 200 healthy subjects, ranging from cord blood to adult age, with 63 unique mechanistic and phenotypic markers per cell by mass cytometry (CyTOF). The EPIC analytical and visualization pipeline is based on an open source web-based R Shiny bioinformatics toolkit that allows it to be easily accessible to the research community.

Results: EPIC can be mined in various ways, for instance to follow developmental changes of any given cell subset or to depict the architecture of the Immunome at any given age range. For example, transition developmental milestones were observed in the TNFα+ CD4+ T cells where the size of its memory subset was even smaller than the naive subset at 8 year old. There was a significant reduction and increase in the frequency of the naive and memory TNFα+ CD4+ T cells with a Spearman’s correlation coefficient, rho, of ~0.4662 and 0.4164 respectively. More importantly, we have built and will keep developing datasets from various immune mediated diseases using the same approach. Consequently, by providing the healthy standard, EPIC enables the depiction and dissection of disease-dependent perturbations of the Immunome architecture.

Conclusion: EPIC provides a transformational conceptual advance in Translational Immunology from individual subset focused to immune architecture based approach for the understanding of physiology and pathogenesis of immune mediated mechanisms. We intend to make EPIC available to the entire community in its full capacity.

AB1191
DIFFERENTIAL DIAGNOSIS OF SERONEGATIVE ARTHRITIS: DIAGNOSIS ONE YEAR FOLLOW UP AFTER FIRST DIAGNOSIS

Ichiro Yoshii1, Tatsumi Chijiwa2, Naoya Sawada3, 1Yoshi Hospital, Rheumatology and Musculoskeletal Medicine, Shinnanto City, Japan; 2Kochi Memorial Hospital, Rheumatology, Kochi, Japan; 3Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan

Background: The ACR/EULAR classification criteria (AECG) for rheumatoid arthritis (RA) is well known criteria for early diagnosis of RA with high sensitivity. However, the criteria weigh three points for seropositive, thus automatically subtracted 3 points for seronegative arthritis. Recently, elderly onset RA is increasing, that has relatively higher ratio of seronegative than young onset RA.

Objectives: To compare diagnosis of seronegative arthritis between initial and one year follow up diagnosis after one year follow up.

Methods: Arthritis patient who are sustained for more than one year since first refer despite his/her ACRA or Rheumatoid Factor were negative, were collected. From these patients, difference from initial diagnosis to second after one year follow up was evaluated statistically with chi square test. Mean EACG score and mean involved joint count for large and small joint (LJC and SJC) at initial diagnosis were compared with each of second diagnosis statistically with Mann Whitney U test (MWU). Clinical course evaluated with 28-joints disease activity score (DAS28) and Health Assessment Questionnaire Disability Index (HAQ-DI) for each diagnosis was compared at every other 3 months with MWU. Comparison between 475 seropositive RA patients treated in the same institute and seronegative RA in the study was also evaluated in a same manner.

These patients’ sensitivity and specificity (Sens & Specs) in according with 1987 ACR diagnosis criteria (1987ACR) was also evaluated and compared with Sens & Specs of AECG.

Results: Ninety-six patients were enrolled. In these, RA was diagnosed to 18 patients and 78 were unclassified arthritis as first diagnosis. Second diagnosis of these patients were RA for 41, spondyloarthritis (SpA) for 22, other collagen disease (CD) for 5, osteoarthritis (OA) for 9, hypothyroidism (HTH) for 2, non-tuberculous mycobacterium (NTM) for 1, and unclassified arthritis (UA) for 16. Mean EACG score and range for each second diagnosis was 5.2 and 2 to 7, 4.4 and 3 to 7, 4.4 and 3 to 5, 5.0 and 4 to 6, 4.0 and 4.0, and 4.25 and 3 to 5, for RA, SpA, CD, OA, HTH, NTM, and UA, respectively. There is no significant difference between any pair of second diagnoses. LJC and SJC of each second diagnosis was 3.2 and 9.8, 5.7 and 4.8, 2.4 and 4.8, 2.4 and 8.1, 2.0 and 6, 2 and 2, and 1.8 and 5.9, for RA, SpA, CD, OA, HTH, NTM, and UA, respectively. There is also no significant difference between any pair of second diagnoses (Table).

In clinical course, there is no significant difference between the second diagnoses, and also no significant difference between seropositive and seronegative RA.

In these seronegative arthritis patients, Sens & Specs of RA in accordance with 1987ACR were 75.0% and 43.4%, while 83.3% and 66.7% in accordance with AECG.

Conclusion: Diagnosis of seronegative RA is not uncomplicated, whereas rheumatologist’s diagnostic skill is questioned.

CLINICAL APPLICATION OF 18F-FDG PET/CT IN RHEUMATIC DISEASES

Huazhong, PEKING UNIVERSITY PEOPLE'S HOSPITAL, DEPARTMENT OF RHEUMATOLOGY, BEIJING, China

Background: 18F-Flurodeoxyglucose Positron Emission Tomography/Computed Tomography (18F-FDG PET/CT) is widely used in diagnosing malignant tumors. It is also useful applying to autoimmune diseases.

Objectives: To investigate the clinical application and significance of 18F-Flurodeoxyglucose Positron Emission Tomography/Computed Tomography (18F-FDG PET/CT) in rheumatic diseases.

Methods: Patients who underwent 18F-FDG PET/CT in the Department of Rheumatology and Immunology, Peking University People’s Hospital from January 2012 to July 2018 were retrospectively analyzed for clinical application and imaging characteristics of 18F-FDG PET/CT in rheumatic diseases.

Results: 1. From 2012 to 2018, 459 patients underwent 18F-FDG PET/CT examination in the Department of Rheumatology and Immunology, accounting for 5.79% of the total number of PET/CT examinations in the hospital. Further analysis of 415 patients with complete data, including 158 males (38.07%) and 257 females (61.93%), male to female ratio of 1:1.6, average age of patients are (57 ± 16.2) years old. The highest proportion group of patients is from 45 to 65 years old (201/415, 48.43%). The total number of PET-CT examinations in the whole hospital increased year by year. Compared with 2012, the number has increased nearly 10 times in 2017 among patients in the Department of Rheumatology and Immunology. 2. In patients with rheumatic diseases, major purpose of PET/CT examination included exclusion of tumors, diagnosis, and assessment of the disease activity. 3. Of all the 459 patients, 315 cases may indicate the differential diagnosis of the disease, of which 269 (85.4%) were highly suggestive of rheumatic clinical diagnosis, including 55 cases of vasculitis (17.46%), 54 cases of myositis (17.14%), 34 cases of rheumatoid arthritis (10.79%), 25 cases of systemic lupus erythematosus (7.94%), 25 cases of IgG4-related diseases (7.94%), 10 cases of rheumatic polymyalgia (3.17%) and 6 cases of systemic sclerosis (1.9%); the remaining 46 cases (14.6%) only suggested the possibility of autoimmune diseases.

Conclusion: Rheumatic diseases are complex and diverse, and it is difficult to diagnose. The application of 18F-FDG PET/CT in the diagnosis of diseases is increasingly widespread. The results of this study suggest that 18F-FDG PET/CT to some extent has significance in the classification and diagnosis of rheumatic diseases, especially for the exclusion of malignant tumors.

DIFFUSE WEIGHT IMAGE IS A POTENTIAL MAGNETIC RESONANCE SEQUENCE IN THE PREDICTION OF SPINAL SYNDENSMOPHYTE IN YOUNG PATIENT WITH ANKYLOSING SPONDYLITIS

Sang Yeob Lee, Won Tae Chung, Sung Won Lee, Jin Woo Jeong, Dong-A University, Rheumatology, Busan, Korea, Rep. of (South Korea)

Background: Diffusion-weighted imaging (DWI) is an MRI sequence and has been shown to have advantages over standard MRI sequences in some clinical settings, such as early diagnosis of ischemic stroke and in staging some type of cancers. Different measures of diffusion have been proposed, with the apparent diffusion coefficient (ADC) measure the most widely used. Severe inflammation leads to higher ADC values through increased water in extracellular, less constrained, spaces. Several studies have investigated the clinical utility of DWI in AS, with suggestive evidence that this sequence has valuable discriminatory capacity between AS and non-inflammatory back pain by inflammation degree on sacroiliac joint (SIJ).

Objectives: This study was tested the potential capacity of ADC value estimated by DWI on SIJ as the predictor of new spinal syndesmophyte in young patients with ankylosing spondylitis (AS).

Methods: The 58 patients who fulfilled the ASAS axSpA criteria were enrolled and their age was 18-23 years old. All subjects underwent MRI on SIJ with oblique coronal images parallel to the long axis of the sacrum (fast spin-echo T1WI and STIR) at diagnosis and lumbar spine radiograph at diagnosis, 2 and 4 years sequentially. The ADC value on SIJ measured by DW-MRI at diagnosis and spinal radiographs were scored using the stoke AS Spinal Score (SASSS) at diagnosis, 2 and 4 years sequentially. The ADC value on SIJ showed a positive association with ADC value on SIJ as the predictor of new spinal syndesmophyte. However, multivariate logistic regression analysis was performed to identify that ADC value on SIJ had an important influence on spinal syndesmophyte growth.

Results: The ADC value on SIJ showed a positive association with inflammatory marker such as, ESR and CRP, but no association with BASDAI, BASMI and BASFI. The univariate and multivariate logistic regression analysis showed that ADC value on SIJ had the highest risk of developing new syndesmophytes in spine.

Conclusion: This study showed that the inflammation of AS patient was a positive association with ADC value on SIJ by DW-MRI and the measured the ADC value on SIJ by DW-MRI was the modest discriminating capacity method for predicting development of new spinal syndesmophyte in young AS patients.

OBSERVATIONAL PROSPECTIVE COHORT STUDY TO EVALUATE EFFICACY AND SAFETY OF TAPENTADOL IN PATIENTS WITH RESPIRATORY DISEASE

Maria Del Pilar Ajiardo Guzman1, Raul Maria Veiga Cabello2, Miguel Cantalejo Moreira1, Justo Ruiz Ruiz3, Antonio Zapatero Gaviria3, Maria Del Pilar Ahijado Guzman1, Raul Maria Veiga Cabello2, Miguel de Fuenlabrada, Rheumatology Service, Madrid, Spain.3Htal Universitari,
Central de la Defensa, Rheumatology Service, Madrid, Spain.3Htal Universitario de Fuenlabrada, Service of Internal Medicine, Fuenlabrada, Spain.

Background: Chronic pain analgesia is a concern in clinical practice in rheumatic patients, especially when the intensity is severe. In this case opioids are indicated but also contraindicated in cases of important respiratory depression and, therefore, must be administered with caution to patients with respiratory disease (1). Many of our patients are not in the condition of severe respiratory depression although they present pulmonary pathologies, which could be triggered at the use of certain doses (2). For this reason, it is important the existence of a study that shows that tapentadol is safe in pluripathological patients when used at regular doses in clinical daily practice in Reumathology (3).

Objectives: Single site, non-postmarketing observational study. The main objective is to evaluate the safety of tapentadol prolonged release (TPR) 50 mg/12h, measured as tolerance ("good", "bad" or "not too bad") and by the comparative analysis of gradients between both groups of the study (control group and pathological group), the basal oxygen saturation, and after the dose of TPR (basal pulse oximetry minus the mean of the oxygen saturation after 30 days of study).

Methods: Inclusions criteria arepatients with severe chronic pain (Visual Analogical Scale, VAS≥4) diagnosed from mild to severe chronic obstructive pulmonary disease (COPD) (spirometry after bronchodilation with forced expiratory volume (FEV)/forced vital capacity (FVC)< 70% and FEV1≤50%), and/or obesity, and/or controlled asthma and/or other conditions likely to produce respiratory depression with opioids (pathological group). Exclusion criteria consists in basal oxygen saturation measured by the pulse oximeter inferior to 92%. A descriptive analysis of variables and a comparison of the means were performed.

Results: 29 patients; 12 in control group and 17 pathological group (obesity: 9, controlled asthma: 3; mild to moderate COPD: 7; other pathologies: 7). Overall, the type of pain was nociceptive 59%, neuropathic 21% and mixed 20%; mainly women (67%), caucasian race (92%), median age 60 years old, and with 93% good tolerability and 97% good treatment adherence. Concerning results per groups, at control group, VAS mean, arterial pressure (AP), oxygen saturation (SO2) and heart rate (HR) before and after treatment, 8.3 vs 5.8; 127/74 vs 124/73 (mmHg); 95.6 vs 95.7 (%); 76 vs 73 (bpm). In the pathological group: 7.5 vs 6.5; 131/ 82 vs 127/78 (mmHg); 96 vs 95.5 (%); 75 vs 76 (bpm). Regarding the results as per gradients between groups, no statistically significant differences were found, except for VAS, (p=0.00008). There were no cases of decrease of the oxygen saturation below 92% along the study.

Conclusion: The results support the safety of tapentadol from the respiratory point of view, measured by oxygen saturation, since no statistically significant differences were found between both groups, and, due to the excellent tolerability, as no clinical data showed signs of hypercapnia. No statistically significant differences were found in the oxygen saturation between both groups with the intake of TPR, with excellent tolerability and treatment adherence. There were no cases of decrease of the oxygen saturation below 92% along the study.

KNOWLEDGE AND PERCEPTIONS OF PORTUGUESE FAMILY PHYSICIANS TOWARDS ANKYLOSING SPONDYLITIS: RESULTS FROM THE ASSESSMENT OF RESULTS IN ANKYLOSING SPONDYLITIS(AREA) STUDY

Filipe Araújo1, Cláudia Duarte2, Jorge Brandão3, Rui Cernadas4, Elsa Matutes5, Luís Cunha Miranda6, José Canas Da Silva7, José Gomes Da Silva7, Pedro Simões Coelho8.1Hospital de Sant'Aña, Parede, Portugal, 2NOVA IMS Information Management School, Lisboa, Portugal, 3Apmg – Associação Portuguesa De Medicina Geral E Familiar, Lisboa, Portugal, 4Serviços Médicos Continental, Gaia, Portugal, 5Liga Portuguesa Contra as Doenças Reumatológicas, Lisboa, Portugal, 6IPR – Portuguese Institute of Rheumatology, Lisboa, Portugal, 7Hospital Garcia de Orta, Almada, Portugal, 8National Association of Ankylosing Spondylitis, São Domingos de Rana, Portugal

Background: Ankylosing spondylitis (AS) patients have a significant delay between symptom onset and disease diagnosis, reaching on average 7 to 10 years in developed countries. Understanding the reasons behind this delay is essential to reduce the individual and socio-economic burden of the disease.

Objectives: To assess knowledge and perceptions of Portuguese family physicians (FP) towards AS and determine whether these contribute to the diagnostic delay at the primary care level.

Methods: The Assessment of Results in Ankylosing spondylitis (arEA) study was developed by the NOVA-Information Management School (Lisbon) in collaboration with the Portuguese Society of Rheumatology, the Portuguese Association of Family Physicians (APMGF) and the National Association of Primary Care Units (USF-AN), the National Association of AS Patients and the Portuguese League Against Rheumatic Diseases. The arEA aimed at assessing reasons for delayed diagnosis of AS, as well as disease impact in patients’ lives, global health and work. A comprehensive online survey was developed and sent to FP associated with APMGF and USF-AN, collecting data on demographics, global knowledge and diagnostic and treatment attitudes towards AS.

Results: 91 FP responded the survey, 51.6% female, more frequently from the 25-44 year-old age group, half of which had <5 years of clinical experience. Most FP (70%) did not consider AS to be a relevant disease in everyday clinical practice but recognized (90%) there was a delay in diagnosis (5 years on average). Nevertheless, knowledge over AS was adequate. On average, prevalence was considered to be 56 cases per 1000 persons (close to the actual prevalence of 47 cases per 1000 persons reported in the epidemiological study EpiReumPt). When assessing a patient with suspicious AS, the most valued symptoms/signs were inflammatory back/buttock pain, extra-articular manifestations (uveitis, enthesitis, dactylitis, psoriasis) and sacroiliitis on imaging (4.1, 3.9 and 3.9 on a 1-6 scale, respectively); 92.5% of FP refer the patient to a hospital consultation, rheumatology in 88.5% of cases; 37.5% of FP initiate treatment, with NSAIDs in 81% of cases. A mean delay of 9 months between patient referral and first hospital consultation was also reported (>1 year in 22%). In 73.4% of cases, no specific referral protocol exists for AS or other rheumatic inflammatory conditions; 33.8% of FP felt that the development of such protocol would improve access, while 36.8% considered that a rheumatologist acting as consultant in primary care units would facilitate identification and referral of inflammatory conditions.

Conclusion: Portuguese FP reported significant delay in hospital consultation after referral of suspicious AS cases. They apparently had good knowledge of AS, though responses may have been influenced by a younger, more updated and willing-to-participate physician population (selection and response bias).

PREGNANCIES IN AUTOIMMUNE DISEASES: EXPERIENCE OF TWO CENTERS IN CALI, COLOMBIA: 2011- 2018

Álvaro Arbeláez-Cortés1,2,3,4, Maria Andrea Moreno Salamanca1, Diana Carolina Quintero González1,2, Centro Médico Imbanaco de Cali S.A., Cali, Colombia; 2Centro Médico Imbanaco de Cali S.A., Cali, Colombia; 3Universidad Libre de Cali, Internal Medicine, Cali, Colombia; 4Universidad Libre de Cali, Cali, Colombia

Background: The outcome in pregnancy varies according to the rheumatic disease. The outcome in pregnancy varies according to the rheumatic disease. The outcome in pregnancy varies according to the rheumatic disease. The outcome in pregnancy varies according to the rheumatic disease.

Objectives: To describe the pregnancies outcomes of women with rheumatic diseases at two reference centers in Cali, Colombia.

Methods: Descriptive study. Records of pregnant patients attended from August 2011 to December 2018 were reviewed. Thirty-nine patients were found, 11 without a defined rheumatic entity (10 with positive ANA only, 2 with anti-dsDNA antibodies, 1 with anti-CCP and 1 with anti-PPA).

RESULTS IN ANKYLOSING SPONDYLITIS (arEA) STUDY

AB1193

AB1194

AB1195
and 1 with incomplete criteria for antiphospholipid syndrome), and 28 with an autoimmune rheumatic disease. A total of 41 pregnancies occurred (2 women with 2 pregnancies) and were chosen for the final analysis (Table).

**Results:** The mean gestational age at the first rheumatology visit was 16.8 ± 8.9. The mean age at the end of pregnancy was 29.5 ± 5.7 years. Only nine pregnancies were planned (34.6%). Among the patients with a defined autoimmune disease the diagnoses were: systemic lupus erythematosus (SLE) (12), rheumatoid arthritis (RA) (5), antiphospholipid syndrome (APS) (2), autoimmune hemolytic anemia (AHA) (2), juvenile idiopathic arthritis (JIA) (2), overlap syndrome (OS) (3: 2 SLE/SSc; 1 SLE/Sjögren’s)’ mixed connective tissue disease (MCTD) (1) and undifferentiated connective tissue disease (UCTD) (1). There were 8 pregnancies exposed to teratogenic drugs (MTX 5, LEF 1, MMF 1, CYC 1); 2 ended in fetal loss and 1 had a congenital pneumonia. There were 27 full-term births, 37-40 weeks (wk); 8 preterm births, 23-36 wk (4 twins); 1 stillbirth, 26 wk; and 3 abortions (2 in the same mother). Seven patients had an active disease before pregnancy, 13 during pregnancy (7 SLE, 3 RA, 2 AHA, 1 MCTD) and 13 during the puerperium (7 SLE, 4 RA, 1 EMTC). No maternal deaths, neonatal lupus or congenital heart block were documented in this series. Four patients did not require any medication. One woman received treatment for pulmonary tuberculosis, and other was on anti-retroviral treatment for HIV infection. At the last follow-up, 2 patients were still pregnant.

**Conclusion:** The outcome of rheumatic disease during pregnancy remains variable. It seems that SLE patients tend to be more active and flare more commonly than other patients. The documented complications were similar to those reported in the literature.

**AB1196** A REVIEW OF ELECTRONIC RHEUMATOLOGY REFERRALS AT THE QUEEN ELIZABETH UNIVERSITY HOSPITAL (GLASGOW, UK) AND HOW THIS HAS LED TO SERVICE IMPROVEMENTS

Aniriane Law1, Saira Bato1, Kay Graham1, Sajjad Noor1, James Mitchell1, Laura Harrington1, Gareth Ingram1, Sandeep Bawa2, David Croisbie2. NHS Greater Glasgow and Clyde, Garthavell General Hospital Rheumatology, Glasgow, United Kingdom; 1NHS Greater Glasgow and Clyde, Queen Elizabeth University Hospital Rheumatology, Glasgow, United Kingdom

**Background:** Our department provides a service for inpatient Rheumatology reviews Monday to Friday, 9am to 4pm, with a guaranteed review timeframe of 48-72 hours. We work predominantly on the QEIH site, which comprises 1677 acute inpatient beds. We launched an electronic referral system for inpatient Rheumatology reviews in February 2018. Inter-specialty referrals are an essential part of most inpatient stays. In a time of increasing service demand within the NHS it is important that we have an effective system to manage our time and resources.2 Electronic referrals allow us to audit our workload, our efficiency at reviewing patients and allow for accountability of both the referrer and reviewer, therefore improving patient safety.3 Using a set proforma allows us to improve communication, the quality of the referral and triage effectively.4

**Objectives:** We performed a baseline review of the new system.

**Methods:** We reviewed all electronic referrals between 8.2.18 and 13.8.18. We collected data on demographics, timing, reasons for referral and outcomes.

**Results:** There were 346 referrals (58.4% female, mean age 64 years). Most (78%) were made from medical wards; the mean number of referrals per month was 49.4. Referrals were most frequently made on Fridays (23%). Most were in-hours (81%). The most common reason for referral was: a request for review (212; 61.3%); phone advice (70; 20.2%); procedural requests (50; 14.5%). 207 referrals (59.8%) were made for new patients, 91 (26.3%) for patients known to Rheumatology prior to admission, and 48 (13.9%) for patients already seen during the current admission. 50% of procedures were performed on knees and 50% on other joints. 82% of patients were seen within 72 hours.

**Conclusion:** The use of the electronic referrals system has made it simple to review the workload of our Rheumatology on-call service. We have used the data on reason for referral to guide the topics for our educational meetings to improve patient management. We actively contribute to the procedural teaching on knee joint aspiration both in junior doctor’s formal training sessions, and opportunistically on wards following referral. This is a core procedure required for training completion for medical trainees in the UK and should help reduce referrals and manage patients in a more time efficient and cost-effective manner. We have also improved documentation by recording the time, date and name of the reviewer in our electronic entry.

We intend to collect data in the same period this year, to assess changes in referral pattern in the 12 months since the system was initiated and the impact of our interventions.

**AB1197** EFFECTS AND SAFETY OF THE YELLOW FEVER VACCINE 17DD IN PATIENTS WITH IMMUNOMEDIATED RHEUMATIC DISEASES

Blanca Ricky1, Lucas Peixoto Da Silva2, Geclima Salviato Pileggi1.

1UNIVERSIDADE FEDERAL DO RIO DE JANEIRO, INTERNO MEDICINA, RIO DE JANEIRO, Brazil; 2UNIVERSIDADE DE SÃO PAULO, UNIDADE DE PESQUISA CLÍNICA, RIBEIRÃO PRETO, Brazil

**Background:** The yellow fever is an acute infectious disease caused by the amarillic virus. It is present in tropical areas of South America and...
Africa and is transmitted to humans through the bites of the infected female mosquitoes, found in the endemic forest zones. The vaccine is produced with attenuated viruses and represents an essential prevention method. It confers prolonged immune protection and is considered to be safe in the general population. For the immunosuppressed condition under which many patients with immunemediated rheumatic diseases (IMRD) are submitted, little is known about its efficacy and safety in this group.

**Objectives:** The aim of this study is to analyse the effects of the vaccine in patients with IMRD.

**Methods:** The methodology of this research consisted of the application of a form-based interview, the analyses of the vaccine card and medical records, if existent. The requirement to take part as a volunteer was to be an IMRD patient that was vaccinated against yellow fever.

**Results:** 60 ambulatorial patients, unadvisedly vaccinated or not, were evaluated. Of those, 40 (66.7%) were female and 20 (33.3%) were male with an age range varying from 8 to 48 years. It was observed that 52 (86.7%) presented no adverse effects from the vaccine, while 7 (11.7%) presented at least one side effect and 1 (1.7%) exhibited a severe reaction of the underlying rheumatic disease. In the group of 7 patients that registered any side effects, it was described 1 case of bilateral optic neuritis with temporary vision loss, initiated three weeks after the vaccination. The other side effects registered were mild and included: 3 occurrences of headache and 1 record of each of the following: fever, local pain, arthralgia, myalgia, nausea, coryza and diarrhea.

**Conclusion:** Our data suggested that the vaccine exhibits a relative degree of safety in these patients. The benefits of the immunization should be evaluated by the rheumatologist, taking in account the risk of infection and lethality of yellow fever in patients who live or are visiting the endemic areas. The recommendations are that the vaccination in this group must always be planned, done under medical orientation and order. It should preferably be applied in patients under disease remission, without immunosuppression treatment or in those who, under immunosuppression, it is possible to temporarily suspend this treatment in order to the vaccine be administered.

AB1198 EVALUATION OF THE WAITING TIME AND QUALITY OF RHEUMATOLOGY REFERRAL AT A TERTIARY CARE CENTER OF PORTO ALEGRE - RS, BRAZIL

Vanessa Busato, Deise Provesan, Romulo Silveira, Sheila Hickmann, Guilherme Bongiorno, Camila Cruz, Sheron Zamboni, Julio Simon, Markus Bredemeier. Hospital Nossa Senhora da Conceição, Rheumatology, Porto Alegre, Brazil

**Background:** To improve waiting time for a first consultation with a rheumatologist has become an important challenge in many countries [1, 2]. In 2008, a previous survey [3] evaluating the referrals to our Service, we observed long waiting times (median 3 days to 8 years) and that only 31% of consultations were related to hypothesis of systemic inflammatory rheumatic diseases (SIRD), which should be properly managed at a resourceful tertiary care center. In 2015, a new process of triage for referrals (based on a protocol recording relevant information and judgment by a rheumatologist) was introduced in our state health system aiming to improve quality of referrals and reduce waiting lists [4]. However, this system is applied only for patients from cities other than the capital (Porto Alegre, RS).

**Objectives:** To evaluate the waiting time and quality of referral for first Rheumatology consultations at a tertiary care center of South Brazil, comparing the present results with those obtained 10 years ago in a similar survey [3].

**Methods:** In a cross-sectional study, information regarding all first consultations at the Rheumatology Service of Hospital Nossa Senhora da Conceição were prospectively collected from Oct 2017 to Mar 2018. Referred patients were characterized in terms of demographic features, diagnostic hypothesis formulated by the rheumatologist and time from initial referral. For analytical purposes, patients with adequate referrals were considered to be those that presented high probability of SIRD, needing assistance at secondary or tertiary level of care. The results were compared with data collected in the same way in 2008 [3]. Chi-square test was used for statistical analysis.

**Results:** Of 444 appointments for scheduled for new patients, 87 (19%) did not attend. The features of the remaining 357 patients were: female-85%, mean (SD) age= 50 (15) years. The waiting time for consultation ranged from 7 days to 63,8 months (median 12.7, IQR= 4.4-14.1). Diagnostic suspicion of SIRD occurred in 186 (52%). Among SIRD, rheumatoid arthritis (23,5%) was the most frequent, while among non-SIRD, osteoarthritis (21,0%) and fibromyalgia (20,7%) were the most common diagnostic hypotheses. A SIRD was the main hypothesis in 75/193 (38%) patients from the capital, comparing with 111/174 (67,7%) among those from other cities (P=0,001), indicating better selection of the latter group of patients. A reanalysis of data collected in 2008 revealed that, at that time, the prevalence of suspected SIRD was not significantly different between patients from capital (76/262, 29.0%) and those from other cities (74/225, 32,9%; P=0,354).

**Conclusion:** We observed improvement in the quality of referrals from other cities comparing to those from the capital of our state, suggesting a better selection process in the former [4]. Despite the efforts to reduce the waiting time for Rheumatology consultations, we observed an increase when compared to 2008. We believe that the delay is secondary to an increase of the demand without a proportional increase in the number of rheumatologist in the public health system. The elaboration of guidelines with standardized information required for referral and triage process seems to be promising to improve access to consultations in Rheumatology.

AB1199 BARRIERS AND FACILITATORS TO THE IMPLEMENTATION OF A STRATIFIED MODEL OF CARE FOR LOW BACK PAIN PATIENTS IN PRIMARY CARE IN PORTUGAL

Carmen Caeiro1, Sofia Paiva1, Luis Gomes1, Rita Fernandes1, Helena Canhão2, Ana Maria Rodrigues2, Rute Sousa1, Ana Cristina Fryxell1, Lília Vicente1, Jaime Branco2, Eduardo B. Cruz2. Escola Superior de Saúde - Instituto Politécnico de Setúbal, Setúbal, Portugal; 1EPideCo Unit, CEDOC, NOVA Medical School, Lisbon, Portugal; 2ACES Arribida, Setúbal, Portugal

**Background:** The results of a recent study have suggested that the current clinical practice is not in line with clinical guideline recommendations and may not be delivering the best outcomes to Low Back Pain (LBP) Portuguese patients. Since the stratified primary care approach has demonstrated clinical and cost-effectiveness in the UK and other countries, the SPLIT project aimed to introduce a similar approach that involves general practitioners (GPs) and physiotherapists (PTs) in the triage and targeted treatment of low back pain patients, in Portugal. In order to facilitate the implementation of this project a training program for GPs and PTs was delivered by rheumatologists and PTs. Considering the specific organization of the Portuguese primary care, it was important to explore the perceptions of the GPs and PTs, who attended to the training, regarding the implementation of the SPLIT stratified model of care in the Portuguese context.

**Objectives:** Identify and understand the potential barriers and facilitators to the implementation of the SPLIT stratified model of care.

**Methods:** After obtaining ethical approval, two focus groups (one for each professional group) were carried out. The focus groups were based on a semi-structured interview schedule, audio-recorded and transcribed verbatim, thematic analysis was conducted. Firstly, two researchers independently coded the transcripts. Secondly, these researchers discussed the codes and examined their scope and relevance. Thirdly, the researchers developed a coding scheme that included the main themes and sub-themes, as well as the connections among them.
Results: The potential barriers were identified and explored by both professional groups. The introduction of change into the routine delivery care was identified as one of the most important barriers. According to the GPs’ perspective, the possibility of inadequate referral was considered as an issue. The PTs highlighted the challenges inherent to the psychosocial informed physiotherapy treatment of patients classified with high risk of developing persistent and disabling pain. More specifically, they emphasized the need to receive mentoring sessions in clinical practice, in order to develop competences for the management of psychosocial issues. In what concerns to the potential facilitators to the implementation of the model, the participants’ personal motivation was considered as one of the most important factors. The alignment of the SPLIT model with the mission and goals of the health care units where the project was going to be piloted was also identified as an important facilitator. Finally, both professionals considered that the SPLIT model may facilitate the interdisciplinary approach to the management of this condition, as it clarifies the specific contribution of GPs and PTs in the approach to LBP patients.

Conclusion: The knowledge about the potential barriers and facilitators to the implementation of the SPLIT stratified model of care may contribute to the successful implementation of stratified care for LBP patients in Portugal.

AB1200 IMPROVEMENT IN THE QUANTITY AND QUALITY OF OBSERVATIONAL DATA COLLECTED FOR US VETERANS ENROLLED IN THE VETERANS AFFAIRS RHEUMATOID ARTHRITIS REGISTRY USING AN ELECTRONIC AUDIT, FEEDBACK, AND DATA CORRECTION SYSTEM

Grant Cannon1, Jorge Rojas2, Neil Bell2, Namrata Singh4, Ted Mikul5, Liron Caplan6, Gail Kerr7, Joshua Baker8, Angelo Gatto9, Jennifer Barton10, Angelo Gaffo9, Jennifer Barton10, Deana Lazaro11, J Steuart Richards12, Brian Sauer1.

Background: The Veterans Affairs (VA) Rheumatoid Arthritis (RA) registry is an observational cohort study of US Veterans with RA at 11 VA Medical Centers. VARA investigators capture clinical and laboratory disease activity measures (DAMs) during clinic visits via standardized templates in the electronic health record (EHR). Six clinical (tender/swollen joints, patient/provider global, MD-HAQ, pain) and 2 laboratory (ESR, CRP) DAMs are extracted post-visit using natural language processing (NLP).

Objectives: This analysis determined the impact of an audit, feedback and data correction system on the quantity and quality of DAMs collected in the VARA registry.

Methods: After September 2017, VARA site investigators were provided monthly feedback reports of incomplete/missing DAMs for the prior month to allow sites to correct data entry errors. Updated and/or corrected data were entered into the EHR via note addendums and then automatically re-extracted by NLP to complete the capture of DAM data. DAMs from October 1, 2016 to September 30, 2017 (pre-feedback implementation – Pre-IMP) was compared to October 1, 2017 to September 30, 2018 (post-feedback implementation – Post-IMP).

Results: During the pre-IMP period, there were 2,411 notes with DAMs collected on 1,116 unique patients compared to 2,873 notes on 1,208 unique patients in the post-IMP period - an increase of 92 (8.2%) unique patients and 460 (19.1%) notes. Enrollment in the VARA registry only increased by 121 (6.5%) during post-IMP period. During post-IMP period, there were 541 notes identified with deficiencies in clinical DAMs and monthly audit and feedback reports were provided to VARA sites to allow corrections. Individual site review resulted in 376 additional DAMs in 225 notes, with complete resolution of all errors in 137 (25.3%) notes. The quantity of DAMs collected increased from 15,709 to 21,064, a 34.1% increase with the average number of DAMs collected per note rising from 4.9 to 5.6. The quality of data improved as demonstrated by the proportion of notes with all 6 clinical DAMs increasing from 52.5% to 81.1% and other improvements in quality/completeness as noted in table.

Conclusion: An audit, feedback, and efficient data collection system improved both the quantity and quality of DAMs collected. The improvement in the collection of DAMs in RA patients will further enhance epidermoligic and outcomes studies of RA and provide higher quality longitudinal data to enhance the care of RA patients.

MANAGEMENT OF COMORBIDITY IN INFLAMMATORY ARTHRITIS: GEOCOI PROJECT

Santos Castañeda1, M Carlos, González2, María del Carmen Castro Villegas3, Silvia García-Díaz4, Juan Carlos Hermosa5, Cristina Lajías6, Leticia León7, Juan Carlos Obaya8, María Rodero9, Carmen Suarez10, Virginia Villaverde10, Juan Carlos Torre-Alonso9,10.

Background: The impact of comorbidity on the diagnosis, prognosis, and treatment of rheumatic diseases could be very high. However, several studies have depicted a sub-optimal assessment of comorbidity in these diseases.

Objectives: To generate common, simple and practical support materials (checklists, questionnaires and other complementary materials) for rheumatologists, health professionals and patients, in order to: 1) Assess comorbidity; 2) Identify and implement preventive procedures; 3) Define referral criteria to other health professionals, in patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), and psoriatic arthritis (PsA).

Methods: This project was promoted by CONARTHITIS (Association of patients with arthritis), OPENREUMA (Multidisciplinary association of professionals dealing with patients with rheumatic diseases) and SORCOM (Rheumatology Society of the Madrid Region). A multidisciplinary team specialized in comorbidity in inflammatory arthritis was established (6 rheumatologists, 2 primary care physicians, 2 nurses, 1 internist, 1 psychologist). A qualitative study was performed following these phases: 1) Review of the GECOAR1, GECOAX2 and GECOAP3 projects, that were focus on the evaluation of comorbidity in RA, axSpA and PsA, as well as an exhaustive bibliographic search in Medline; 2) Generation of preliminary checklists (different versions and formats) to be used by health professionals and patients for the identification, management and prevention of comorbidity; 3) Patient focus group in which the preliminary patients checklist was evaluated and discussed; 4) Nominal group meeting in which the selected health professionals analyzed all the checklists and modified them taking into account the opinion of the patients; 5) External evaluation of the modified checklists by patients, health professionals and rheumatologists, all of them outside the project; 6) Generation of the final checklists based on everything collected in the previous phases.

Results: Three checklists for clinical practice were designed, two for health professionals (one to identify comorbidity, another on prevention/health promotion), one for patients. The comorbidity checklist includes, for example, the evaluation of cardiovascular risk factors, depression and anxiety, allergies or infections. The prevention checklist includes life style issues (smoking, diet, exercise), social life, sexuality, sleep, or oral hygiene. The checklists also specify the evaluation method (questions, specific questionnaire, etc.).

Conclusion: The use of specific checklists for the identification, management and prevention of comorbidity inpatients with RA, axSpA and PsA might contribute positively in their prognosis.

AB1202

SWITCHING OF ETANERCEPT IN A MONOGRAPHIC CONSULTATION OF BIOSIMILAR CLINICAL PRACTICE AND ECONOMIC COST

Background: The recent appearance of biosimilars by the European Medicines Agency in January 2015 allows a quality treatment in rheumatic diseases with a lower cost. We present our initial experience in a specific biosimilar consultation with the introduction of biosimilar Etanercept (BE).

Objectives: To describe the switching experience from original etanercept (OE) to BE and to evaluate the economic impact of this strategy.

Methods: Retrospective study carried out in a tertiary level hospital. We included patients treated with OE which were evaluated in the Specific Biosimilar Consultation where a rheumatologist and a nurse proposed them switching to BE. Demographic, clinical and pharmacistheapeutic variables of all patients were collected. The outcome evaluated was the drug switch as well the reasons why the change was not made. To analyze the economic impact, the estimated savings in the use of BE vs OE was calculated, [costs according to the net prices of our center (PVL - discount)+VAT].

Results: The registry included of 133 patients treated with OE from the Rheumatology Department of our center, only 56 patients were evaluated in a period of 3 months in the specific biosimilar consultation: 73% were women over 53 years (17-75 years). Regarding the diagnosis: 45% rheumatoid arthritis, 46% psoriatic arthropathy and 9% ankylosing spondylitis. All patients chosen to switch from OE to BE should have stable base disease (defined as low activity according to the specific scale for each pathology), approval of the change by a evaluating physician and patient, signing the informed consent.

Finally, the switch from OE to BE was performed in 31/56 patients (55%). In the 25 patients who did not change: 3 patients (12%) had moderate or high disease activity, in 8 patients (32%) the change was not accepted by the patient or by the evaluating physician and 14 patients (56%) were in remission of the disease. The patients chosen were in a dosage regimen of 50 mg/week, so the annual costs per patient are 9143.16€ with OE and 6095.44€ with BE. The switching to BE represent annual savings of 3047.72€ per patient and 94479.32€ total.

Conclusion: The experience with the implementation of a specific biosimilar consultation in our center has been positive. In the first 3 months of its operation, the switching from OE to BE have been made in 55% of patients allowing savings allowing savings of 3047.72€ per patient/year.

AB1203 BURDEN DISEASE OF RHEUMATOID ARTHRITIS IN COLOMBIA, 2015

Francy Cuervo1, Ana María Santos1, Ignacio Angarita1, Juan Camilo Rueda1, Rodrigo Girardo1, Jesús G. Ballesteros2, Ingris Peláez-Ballestas1, Diana Díaz-Jiménez2, Pedro Santos-Moreno2, Diana Padilla-Ortiz2, Viviana Reyes3, Carlos Castañeda-Orjuela1, John Londono1. 1Universidad de La Sabana, Chía, Colombia; 2Central Military Hospital, Bogotá, Colombia; 3National Institute of Health, Colombian National Health Observatory, Bogotá, Colombia; 5Biomab, Bogotá, Colombia

Background: The prevalence of rheumatoid arthritis (RA) in Colombia according to the COPCORD study was 1.49%. The disease burden data available in our country are based on the results of the Global Burden Disease study (GBD) of 2016. However, the GBD study takes reference data from non-Colombian residents that was extrapolated to our population, given the absence of demographic data at that moment.

Objectives: To estimate the disease burden of RA for 2015.

Methods: A descriptive study was developed. The reference data of the population was taken by DANE (Departamento Administrativo Nacional de Estadística) and the WHO (World Health Organization). The GBD disability definitions were adapted from individual questions of functionality and quality of life questionnaires of the COPCORD study in Colombia (1). A Markov model was developed to calculate the years of life lost due to premature mortality (YLL), years lived with disability (YLD) and Disability-Adjusted Life Year (DALY).

Results: The distribution of cases by age and severity levels of RA are shown in figure 1 and 2 respectively.

Abstract AB1203 Figure 1. Distribution of cases by age and sex

Since direct death due to RA were not registered according to the search of the ICD-10 codes in DANE, the YLL was 0. The YLDs in total were 118,358. The DALYs were 118,358 for a rate of 361.54 per 100,000, which is higher than the GBD 2016 results (60 per 100,000).

Conclusion: The burden disease of rheumatoid arthritis is higher than that referred by GBD. Holistic approaches are required to reduce these parameters of impact on the public health of Colombians. Our data on DALYs usefulness lies in the urgent need for an early diagnosis, to reduce disability and thereby improve the quality of life of patients. Even though, RA was not the registered primary cause of death, it is necessary to explore mortality-associated conditions due to this rheumatic disease.

1Universidad de La Sabana, Rheumatology, Chía, Colombia; 2Universidad Nacional Autonoma de Mexico, Faculty of Medicine, Ciudad de Mexico, Mexico; 3National Institute of Health, Colombian National Health Observatory, Bogotá, Colombia; 5Biomab, Bogotá, Colombia

Background: Low back pain (LBP) is the second most frequent rheumatic disease in Colombia. According to the COPCORD study, LBP prevalence was 7.24% (CI 95% 6.28-8.34%) (1).

Objectives: To estimate the disease burden of LBP for 2015.

Methods: A descriptive study was conducted. A Markov model was developed based on cases with LBP, distribution of disability and mortality according to DANE (Departamento Administrativo Nacional de Estadística) and the WHO (World Health Organization) reference data. The results are shown in terms of the years of life lost due to premature mortality (YLL), years lived with disability (YLD) and finally as Disability-Adjusted Life Year (DALY).

Results: The distribution of cases by age of LBP are shown in figure 1.

Abstract AB1204 Figure 1. Distribution of cases by age and sex

An algorithm was designed to determine the distribution in percentages of severity levels, according to the GBD definitions (figure 2).

Abstract AB1204 Figure 2. Distribution of severity levels of rheumatoid arthritis
According to ICD-10 codes, 9 deaths were reported, so the YLL were 124. The YLDs were 264,658. Finally, the DALYs were 264,782 for a rate of 808.82 per 100,000, which is higher than the GBD 2016 results (647 per 100,000).

**Conclusion:** The main cause of burden of disease of rheumatic disease in Colombia is due to LBP. The burden is because of the YLD, related to the frequency of cases in people younger than 50 years of age. It is necessary for an early detection and development of intervention strategies.

### AB1205

**ABSTRACT**

**BURDEN DISEASE OF OSTEOARTHRITIS IN COLOMBIA, 2015**

**Francy Cuervo,** 1 Ignacio Angarita, 1 Ana María Santos, 1 Eugenia-Lucía Saldarriaga, 1 Juan Camilo Rueda, 1 Jesús G. Ballesteros, 2 Rodrigo Giraldo, 2 Ingris Peláez-Ballestas, 3 Diana Díaz-Jiménez, 2 Pedro Santos-Moreno, 2 Diana Padilla-Ortiz, 2 Viviana Reyes, 2 Carlos Castañeda-Orjuela, 2 John Londono 2

**Background:** Osteoarthritis (OA) is the most prevalent rheumatic disease in Colombia, as reported by the COPCORD 2015 study. The prevalence is 10.81% (IC 95, 9.68-12.06) (1).

**Objectives:** To estimate the disease burden of OA for 2015

**Methods:** A descriptive study was developed. The reference data of the population was taken by DANE (Departamento Administrativo Nacional de Estadística) and the WHO (World Health Organization). It was necessary to develop an algorithm to determine the distribution in percentages of severity levels, according to the GBD definitions. A Markov model was elaborated to calculate the years of life lost due to premature mortality (YLL), years lived with disability (YLD) and Disability-Adjusted Life Year (DALY).

**Results:** Figure 1 shows the distribution of cases by age of OA, with the highest frequency of cases over 50 years in both sexes.

**Abstract AB1205 Figure 1. Distribution of cases by age and sex**

Figure 2 describes the distribution of the severity levels of the disease, with most cases being moderately severe.

**Abstract AB1205 Figure 2. Distribution of severity levels of rheumatoid arthritis**

The YLLs were 781 and the YLDs were 245,626. Finally, the DALYs calculated were 246,408 for a rate of 752.69 per 100,000.

When compared with that reported data by the GBD 2016, the burden of disease for OA was 204 (IC95% 143-278). The results of the present study show that the burden of the disease is higher, and the conditional factor is the YLDs.

**Conclusion:** Osteoarthritis is a frequent and disabling rheumatic disease that confers a large burden of rheumatic disease affecting people over 50 years of age. The treatment of OA should be focused on reducing disability and holistic intervention strategies to promote good quality of life.

### AB1206

**ABSTRACT**

**SELF-REPORT OF FRACTURE HISTORY COMPARED TO FRACTURE CODES FROM AN ELECTRONIC HEALTH RECORD DATASET**

**Maria Daniel,** 1 Amy Mudano, 2 Elizabeth Rahn, 2 Andrea Lacroix, 3, 4 Jeffrey Curtis, 4 Kenneth Saag, 3 University of Alabama at Birmingham, Birmingham, United States of America; 2 Group Health Cooperative, Seattle, United States of America; 3 University of California San Diego, La Jolla, United States of America

**Background:** Self-reported fracture history data is frequently used in epidemiological studies of osteoporosis. Self-reported fracture data may differ from fracture history coded in electronic health records (EHR) due to imperfect patient recall, incomplete communication with clinicians, or lack of a universal EHR. Because both self-reported fracture history and EHR data can define phenotypes for clinical research studies, it is important to understand how these 2 data sources compare.

**Objectives:** To compare self-reported fracture history using survey data with fracture codes from an available EHR dataset.

**Methods:** Self-reported fracture data was derived from the Activating Patients at Risk for OsteoPoroSis (APROPOS) trial, which recruited participants from the Global Longitudinal study of Osteoporosis in Women (GLOW) cohort. Prior fracture data was collected using a survey deployed June - August 2015. Women were asked if they ever had a fracture and for each fracture type the date of the most recent one. Data on fractures recorded in the EHR September 2011 - June 2015 was obtained from Kaiser Permanente Washington Health Research Institute. We excluded skull, toes and fingers fractures. We defined concordance between the EHR and self-reported data if the location of a fracture was reported to be the same and if the reported dates were within 1 year of each other. Kappa (κ) statistic described the concordance between the 2 sources of fracture history. Descriptive statistics

ASSESSMENT OF RHEUMATIC DISEASES PATIENTS EXPERIENCE WITH THEIR HEALTHCARE USING IEXPAC. FACTORS ASSOCIATED AND AREAS OF IMPROVEMENT:

Javier de Toro-Santos1, L María. García Vivía2, Lucia Pantoja3, Cristina Lerín Lozano5, Silvia García-Díaz2, Yvonne Mestre6, Sabela Fernández6, Luís Cea-Calvo6, Hospital Universitario A Coruña, A Coruña, Spain; 2Hospital Universitario de Basurto, Bilbao, Spain; 3Hospital del Bierzo, Ponferrada, Spain; 4Hospital de Manacor, Manacor, Spain; 5Hospital de Sant Joan Despí Moises Broggi, Barcelona, Spain; 6Merck Sharp and Dohme, Madrid, Spain

Background: The experience of patients with healthcare has been associated to important outcomes. The experience of patients with healthcare has been associated to important outcomes. The experience of patients with healthcare has been associated to important outcomes.

Objectives: We describe the experience with healthcare of patients with rheumatic diseases from Spain self-reported through IEXPAC, a validated questionnaire, and the influence of demographic and health care-related factors.

Methods: The IEXPAC scale ("Instrument to Evaluate the Experience of Patients with Chronic Diseases", http://www.iemac.es/iexpac/) was developed and validated in Spain by health care professional and social organizations, experts in quality of healthcare and chronic patients (1). It consists of 12 items with Likert responses from "always" to "never" and yields an overall score from 0 (worst) to 10 (best experience). Three factors with sub-scores derive from the scale: Factor 1 (productive interactions, average of items 1, 2, 5 and 9, on patient-health care professionals relationship), Factor 2 (new relational model, average of items 3, 7 and 11, on the use of new technologies and contact with other patients) and Factor 3 (self-management, patients` ability to self-care, average of items 4, 6, 8 and 10). Data were obtained through an anonymous survey to patients from 25 Spanish hospitals. Bivariate comparisons and a multivariate analysis were made to explore the association between scores and demographic and health care-related characteristics.

Results: 625 patients received the survey, 359 (57.4%) returned it (mean age 55 years, 67% women). The percentage of patients who responded "always" or "nearly always" to the different statements is displayed in table 1. Mean overall IEXPAC score was 5.5 (SD 2.0), sub-scores were: productive interactions: 7.5 (2.5); new relational model: 1.7 (2.1); self-care: 6.5 (2.5). Overall score was higher (better experience) in men (p= 0.022), in those needing follow-up in a different region (p= 0.004), seen by a lower number of physicians (p= 0.025), seen by the same physician each time (p= 0.001), treated with lower number of medicines (p= 0.039) or with subcutaneous or intravenous (SC/IV) drugs (p= 0.083). Multiple linear regression models (table 2) showed that being followed up by the same physician, being seen by lower number of specialists, and being treated with SC/IV drugs were associated to better overall experience scores. Associations were similar for the productive interactions and self-management factors.

Conclusion: Through IEXPAC, patients with rheumatic diseases identified areas of improvement in healthcare, especially those related with access to reliable information and services, interaction with other patients and continuity of health care after hospital discharge. Better experience was associated to being seen by lower number of specialists or being followed-up by the same physician each time, and also with treatment with SC/IV drugs, maybe in relation to the more personalized care these patients receive.

Table 1. Word-for-word IEXPAC items. Percentage of patients who responded "mostly" or "always" to each item.

AB1208 POINT PREVALENCE OF UVEITIS AND ARTHRITIS AMONG SCHOOL CHILDREN IN A DEVELOPING COUNTRY

Fiman Dessouki. Faculty of medicine, Alexandria university, Alexandria, Egypt

Background: Sight-threatening uveitis associated with pediatric rheumatologic diseases, especially juvenile idiopathic arthritis, often remains asymptomatic till late. On the other hand, children with indolent asymptomatic uveitis may later on develop the characteristic arthritis of juvenile idiopathic arthritis, especially the oligoarticular rheumatoid factor negative type. A multidisciplinary screening of children at the peak age of developing these potentially handicapping manifestations, allows active case finding and facilitates a comprehensive ophthalmic-rheumatologic management plan.

Objectives: A point prevalence study aiming at active case finding and describing the prevalence of uveitis and arthritis among school children between the ages of 4 and 9 years in 10 screened schools in Egypt.

Methods: All children between the ages of 4 and 9 years in 10 screened schools in Egypt. A point prevalence study aiming at active case finding and the not diagnosed groups, split by CRP results.

Results: A total of 6372 children were screened, 3418 of them were females (53.6%) and 2954 were males (46.4%). Thirty four children were found to have uveitis (0.5%). Of these, 26 children were females (76.5%) and 8 children were males (23.5%). Two female children were known uveitis patients and were on treatment. A hundred and eleven children had arthralgia. Of these, 56 children had clinically evident arthritis at the time of screening. Twenty eight children with arthritis were females (50%) and the other twenty eight children were males (50%). Three girls were previously known to be arthritis patients (2 with juvenile idiopathic arthritis and one with psoriasis). Eleven children had both uveitis and arthritis. All cases detected to have uveitis, arthralgia, or arthritis, in the study were referred to tertiary clinics for further management.

Conclusion: Screening of school children for uveitis and joint manifestations in developing countries with a modest socioeconomic status, is a method of active case finding that helps an, as early as possible, implementation of the proper plan of management.

SociaL Media use in Rheumatology Patients

Mustafa Ergöçen1, Okan Aydin2, Emire Seyahi1, 1Istanbul University -Cerrahpasa Medical Faculty, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Istanbul University -Cerrahpasa Medical Faculty, Internal Medicine, Istanbul, Turkey

Background: The impact of social media on individual or institutional communication and knowledge acquisition is non-negligible. Whether patients (patients) with rheumatic diseases share information about their health on social media is unknown.

Objectives: We aimed to investigate how often and to what extent patients with a rheumatic condition use social media. We also wanted to know whether they communicate with their doctors through social media and what their expectations are.

Methods: Consecutive patients with diverse diagnoses attending a rheumatology outpatient clinic were studied. Patients completed a self-administered questionnaire (1) which was modified. Information on demographic features, educational status and diagnosis was also recorded.

Results: 397 patients completed the questionnaire (Table). 329 patients with devices, 40 (12%) of these patients were not using social media. 68 patients without devices, thus social media users reached 73% (289/397). While, Facebook users and non-users were similar according to age, gender or educational status, Twitter users were more likely to be male and more educated (Figure). 96% were willing to communicate with their doctors through social media and what their expectations are.

Conclusion: This survey showed that younger and more educated patients had significantly more communication devices. Facebook was the most preferred social media website. More educated patients prefer using Twitter, Instagram and Pinterest and younger patients Instagram and Pinterest. The majority thought that social media was a useful information source about health. While only 23% had an actual connection with their rheumatologist through social media, 75% desired to be friends on the Facebook.

AB1211  A RETROSPECTIVE ANALYSIS OF LABORATORY ABNORMALITIES FOUND DURING METHOTREXATE MONITORING AND THE COST IMPLICATIONS
Sadrive Eriksson, Arslan Sidhu, Tom Walton. Colchester Hospital, East Suffolk and North Essex NHS Foundation Trust, Rheumatology, Colchester, United Kingdom

Background: Methotrexate (MTX) remains the first line treatment in major- ity of cases of inflammatory arthritis. The current British Society of Rheumatology (BSR) Guidelines suggest checking Full blood count (FBC), ALT/AST, Creatinine at 0.2, 4, 10, 14, 18 weeks and then 12 weekly. Despite this close monitoring recommendation, MTX is generally considered a safe drug by Rheumatologists and its use has grown signifi- cantly over last two decades.

Objectives: To evaluate the incidence of liver, renal and haematological toxicities during Methotrexate treatment and calculate the cost implications.

Methods: 101 patients (30 males 71 females) (Age 40-89 year Mean 66.5 year) prescribed MTX were randomly selected and retrospective analysis was performed. 91 Rheumatoid arthritis, 8 Psoriatic arthritis and 2 patients had Undifferentiated Inflammatory Arthritis. 20 patients had Early Inflammatory Arthritis (<1 year) and 81 had established disease. 24 patients were on MTX for <1 year. Average dose of MTX in our cohort was 15mg once weekly (Min 7.5mg Max 25mg). All patients were on folate supplementation. Blood investigations over last 1 year were reviewed individually for all patients. Severe Liver toxicity (LS) was defined as ALT/AST >100 U/l; unexplained reduction in albumin <30 g/l. Severe renal toxicity (RS) was defined as Creatinine increase >105 fL and HS. Severe haematological toxicity (HS) was defined as WCC <3.5 × 10 9/l, MCV <80 fL and HS. Severe haematological toxicity (HS) was defined as WCC <3.5 × 10 9/l, MCV <80 fL and MS was <75 fL. Mild liver toxicity (LM) was between normal and LS values. Severe haematological toxicity (HS) was defined as WCC <3.5 × 10 9/l, MCV >105 fL, Neut <1.6 × 10 9/l, PLT <140 × 10 9/l unexplained eosinophilia >0.5 × 10 9/l and mild haematological toxicity (HM) was between normal and HS. Severe renal toxicity (RS) was defined as Creatinine increase >30% over 12 months and/or calculated GFR <60 ml/min. Mild renal tox- icity (RM) was between normal and RS.

Results: Over 1 year, 101 patients had total of 609 blood tests for MTX monitoring (Min 1 Max 17). FBC, Liver Function Test, Urea & Electrolytes, CRP and ESR each cost £8.54. LS was found in 4 patients, LM in 15, HM in 3 and RM in 2 patients. MTX was stopped in all 4 patients with LS. Mild toxicities (LM, HM and RM) recovered after close monitoring or reduction in dose. 5 patients with mild toxicities were on MTX for <1 year. Rest of the patients were on stable dose of MTX for >1 year. All patients with severe and mild toxicities did not have any significant comorbidities compared to rest of the patients. It was calculated that detecting one LS cost (£09x8.54)/4 = £1300.2. Similarly one HM cost £346.7, one RM £1733.6 and one RS £2600.43. These costs does not include travel expenses, parking charges and time off work for appointments in phlebotomy.

Conclusion: Our cohort shows that mild liver toxicity is the most com- monly found abnormality during MTX monitoring and patients on stable doses still need monitoring for liver toxicity. Haematological and renal toxic- ities are much less common and a more relaxed monitoring schedule may be acceptable for these parameters. Regular monitoring for inflam- matory markers (CRP, ESR) causes an extra cost burden. The direct cost for identifying each abnormality is considerable.

AB1212 POLYPHARMACY AND OUTPATIENT HEALTHCARE USE IN RHEUMATOID ARTHRITIS: PATTERNS AND ASSOCIATIONS
George E. Fragiou1, Savvas Psarrelis2, Christina Flourou3, Andreas Tofandaris3, Panayiotis Ayerdi4, University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2Nicola General Hospital, Rheumatology, Nicosia, Cyprus; 3Nicosia General Hospital, Internal Medicine Department, Nicosia, Cyprus; 4King’s College, Department of Inflammation Biology, London, United Kingdom

Background: Polypharmacy is a considerable problem in people with rheumatic diseases, including rheumatoid arthritis (RA), related amongst others to worse disease outcomes and increased cost for the health-sys- tem. (1).

Objectives: To assess polypharmacy in RA and usage of the health-care system (outpatient clinics) in a real-world setting.

Methods: Medical records of 170 consecutive RA patients from a large outpatient service of a central hospital were retrospectively reviewed. Demographic char- acteristics, treatment for RA and comorbidities as well as frequency and type of visits to any outpatient services were recorded. The latter included rheumatologists, “medical specialists” (general physicians, cardiologists, respiratory physi- cians, oncolologists, dermatologists, gastroenterologists, hematologists, nephrolo- gists and neurologists) and “surgical specialists” (general surgery, orthopedics, neurosurgery, urology, ophthalmology, ENT, maxillofacial and vascular surgery). Disease duration was defined as the time between RA diagnosis and the end of the study (May 2018). Univariable and multivariable analyses were performed (Table).

Results: Data from 170 RA patients (77.1% female) with a mean±SD age of: 62.1 ± 13.7 years and disease duration: 87.8 ± 22.0 months, were recorded. The median number of non-rheumatic drugs received throughout disease duration was 3. Only 7% of the patients were not receiving any additional drugs, while 15.3%, 40.6% and 56.4% had received 1, 2 and 3 non-rheumatic drugs, respectively. The most com- monly used non-rheumatic drugs were, anti-hypertensive, anti-osteoporotic and lipid-lowering drugs. Higher total number of drugs correlated with age of the patient and longer disease duration. Methotrexate (MTX) experi- enced or biologic-naive patinets, had received a larger number of non- rheumatic drugs compared to those who had not received methotrexate or were biologic-experienced. Multivariable analysis confirmed age and exposure to methotrexate/biologics to be positively and negatively associa- tion respectively, with the number of non-rheumatic drugs received (Table).

Number of visits to rheumatologists/year were: median (range) 2.9 (0.5 – 13.6). The number of visits was correlated with age of the patients, dis- ease duration and number of non-rheumatic drugs received. Multivariable analysis, identified, disease duration, number of non-rheumatic drugs received and being MTX-naive as predictors of number of rheumatology visits (Table).

PATIENTS’ PERSPECTIVES OF OUTCOMES AFTER TOTAL KNEE AND TOTAL HIP ARTHROPLASTY: A NOMINAL GROUP STUDY

Susan Goodman1, Bella Mehta1, Serene Mirza1, Mark Figgie1, Peter Sculco1, Michael Parks1, Jassvinder Singh1, Hospital for Special Surgery, Main Campus, New York, United States of America; 2UB School of Medicine, Birmingham, United States of America

Background: Utilization rates of total joint replacements (TJR) are high and rising to treat advanced symptomatic arthritis, but there is little qualitative research to define the most important outcomes from the patient perspective.

Objectives: To assess the most important outcomes of TJR from the patients’ perspective using nominal group technique (NGT).

Methods: Recruited patients were ≥18 and had received total hip (THR) or total knee replacements (TKR). Participants completed a questionnaire including demographics and pain and function measures, and answered “What result/results matter the most to a patient undergoing/having a knee or hip replacement?”. Outcomes were independently selected, listed in a round robin, and ranked by the group using NGT.

Results: 36 patients participated in 6 nominal groups in January 2019. 42% were men (Table 1). For THR, 94% reported no/mild pain. For TKR, 81% reported no/mild pain/pivoting or on stairs, 1 patient reported severe pain. Satisfaction was high, 97% reported very/somewhat satisfied with pain relief. Of 216 total votes, A) pain received 98 votes, B) function 92 votes, C) quality of life 40; D) adverse events 16 votes and E) revision 2 votes, the remainder 8 votes were distributed to post-op concerns including access to rehabilitation or education (Table 2).

Conclusion: Pain, function, quality of life, and adverse events are the outcomes ranked highest by patients, supporting their inclusion in TJR clinical trials.

PRELIMINARY STUDY OF THERAPY ADHERENCE CONTROLLED BY PRESCRIPTION OF MEDICATION AND SELF-PERCEPTION ADHERENCE OF INFACRURAL CHRONIC DISEASE PATIENTS

Elena Grau García1, Jose Iviron Cortés1,2, Emilio Monte Boqueit3, Cristina Alcañiz Escandell1, Inmaculada Chalmea Verdejo1, Marta De la Ribera Navarro1, Jorge Juan Fragol-Gal1, Roxana Gonzalez Mazzaro1, Luis Gonzalez Puig1, Isabel Martinez Cordelí1, Rosa Negueruelos Abuissé1, Jose Eloy Oller Rodriguez2, Francisco Miguel Ortiz Sanjuan1, Cristobal Pávez Perales1, Elvira Vicens Bernabeu1, Carmen Nájera Herranz1, Inés Cánovas Olmos1, Antonio Luis Garcia Cebrián1, Jose Luis Poueda Andrez1, Jose Andrez Román Ivorra2,3,1, Rheumatology Department, HUP La Fe, Valencia, Spain; 2Medical School, UCV, Valencia, Spain; 3Pharmacy Department, HUP La Fe, Valencia, Spain

Background: The absence of therapy adherence is a public health problem and leads to negative consequences in inflammatory chronic disease. The measurement of therapy adherence has demonstrated effectiveness on the improvement of compliance, but it is difficult to estimate because it is based on indirect measurements. With high probability there will be discrepancies between different measurements.

Objectives: To estimate the discrepancies between therapy adherence controlled by prescription of medication, Morisky-Green test and self-perception adherence patients under biological subcutaneous treatment or under Jakinhibs oral treatment.

Methods: Observational study including inflammatory chronic disease patients under biological subcutaneous treatment or under Jakinhibs oral treatment, selected consecutively. We performed a preliminary stage where patients were contacted by telephone and after that the questionnaire was sent to the email address they provided. The questionnaire included Morisky-Green test and a self-perception adherence scale (0-10). Data about dispensation of medication was collected from the pharmacy service. We defined as “adherent patient” a dispensation rate over 80%.

Results: 54 patients were contacted, and 37 of them full-filled the questionnaire. 28 full-filled the online questionnaire but the other 9 preferred the paper format. The patients from the online format questionnaire had a mean age of 50.86 years (range 22-74), and patients of paper format questionnaire had a mean age of 61.38 years (38-71). We observed a high proportion of patients with university studies among those who preferred the online format.

Conclusions: Among the 37 surveyed patients a discrepancy between therapy adherence controlled by dispensation of medication and adherence by Morisky-Green was observed (94.6% vs 72.97%, P<0.005). Moreover, 72.97% of patients considered easy or very easy to follow the prescribed therapy, and in the self-perception adherence scale the 54.05% of them scored 10, the 21.62% scored 9, the 21.62% scored 8 and the 2.7% scored 6. Among the analyzed factors which may affect the therapy adherence, the oral route of administration showed more adherence rate controlled by dispensation of medication (P<0.019) and with Morisky-Green adherence rate (P<0.016). No other association with other factors as age, gender or time of disease evolution was observed.

Conclusion: Younger patients and those with university studies preferred to full-fill the online questionnaire. A discrepancy between therapy adherence controlled by prescription of medication and adherence by Morisky-Green was observed. Moreover oral route of treatment showed more therapy adherence than subcutaneous route of treatment. Even if the patients are no self-considered as 100% adherents (Morisky-Green), a tendency of collect the medication on a regular basis was observed. This seems to indicate that instead of the controlled dispensation of medication by Pharmacy, patients with lower therapy adherence will collect all the medication.

CURRENT PRACTICE OF HYDROXYCHLOROQUINE PRESCRIPTION AND MONITORING IN INDIA - A NATIONAL SURVEY

Shilpa Jagadeesh1, Arumugam Moorthy2, B G. Dharmamand3, University Hospitals Leicester, Rheumatology Registrar, Leicester, United Kingdom; 2University Hospitals Leicester, Consultant Rheumatologist, Leicester, United Kingdom; 3Vikram Hospital, Consultant Rheumatologist, Bengaluru, India

Background: Hydroxychloroquine was introduced as an anti-malarial during World War 2 and since then has found numerous indications for usage as an immunomodulator. Research is ongoing for new uses of the drug. Hydroxychloroquine is generally considered to be safe and monitored less rigorously than other DMARDs that have strict blood monitoring regimes. Emerging evidence of increased risk of retinal toxicity possibly due to widespread usage in a population with diverse co-morbidities has prompted updates to prescription and monitoring guidelines worldwide.

Objectives:
2. Understand awareness of cross specialty guidelines.
3. Explore barriers to evidence based monitoring.

Methods: Questionnaire based survey shared to practicing clinicians (consultant rheumatologists, immunologists, postgraduate trainees, other clinicians with interest in rheumatology) who prescribe Hydroxychloroquine. Results analyzed through excel spreadsheet and charts.

Results: We received 61 responses from clinicians nationally. 88.5% were consultant rheumatologists, 6.6% consultant immunologists and others included clinicians with interest in rheumatology. Special interest was CTD for 47.5% and 36% inflammatory arthritis. All respondents worked in urban areas and average experience in specialty was 9 years. Majority saw in excess of 500 patients month. 61 clinicians saw in excess of 24,700 patients per month and on average started more than 2481 patients on Hydroxychloroquine. Approximate prescription rate was 41 patients per clinician per month. Indications included connective tissue disease and inflammatory arthritis mainly. Other indications include antiphospholipid syndrome, osteoarthritis, post viral, arthropathy, dermatomyositis and diabetotic arthropathy.

Pretreatment tests as per international guidelines were recommended by 35% clinicians only which includes baseline Optical coherence tomography 25%, or eye evaluation by ophthalmologist 10%. 54% clinicians advised OCT after 5 years (47.5%) or formal ophthalmology monitoring (6.5%) in line with published international guidance. Barriers to following required pretreatment tests and monitoring we noted from this survey include lack of awareness or disagreement with guidelines (lack of conclusive data), doubtful cost effectiveness and nonadherence by patients due to cost implications.

Conclusion: There is need to improve awareness of existing evidence based guidelines on prescription and monitoring of Hydroxychloroquine by international ophthalmology and rheumatology organizations. There is more data needed to prove effectiveness of current guidelines beyond doubt. We also need to better counsel and educate patients on the drug so adherence can be improved.

CHECKING IN WITH IMMUNE CHECKPOINT INHIBITORS: RESULTS FROM A NEEDS ASSESSMENT SURVEY OF CANADIAN RHEUMATOLOGISTS

Ahmad Abdullah1, Nancy Maltez2, Marie Hudson3, Aurore Fifi-Mah4, Shahin Jamal5, The Canadian Research Group of Rheumatology in Immunology and Rheumatology (CanRIO). University Hospitals of Leicester, Consultant Rheumatologist, Leicester, United Kingdom; 2University Hospitals of Leicester, Consultant Rheumatologist, Leicester, United Kingdom; 3Vikram Hospital, Consultant Rheumatologist, Bengaluru, India

Background: Immune checkpoint inhibitors (ICI) have revolutionized the treatment of cancer. However, enhanced immune activation from ICI has been associated with immune-related adverse events (irAE), including autoimmune rheumatologic diseases such as inflammatory arthritis, spondyloarthritis, polymyalgia rheumatica-like syndrome and inflammatory myositis, among many others. This emerging field represents a challenge given that experience with these conditions is limited and evidence-based recommendations do not yet exist.

Objectives: The Canadian Research Group of Rheumatology in Immunology and Rheumatology (CanRIO) is an emerging network of rheumatologists interested in rheumatologic irAE (rh-irAE). CanRIO undertook a needs assessment survey to understand the need for education and recommendations for the management of rh-irAE in the rheumatology community in Canada. The primary objective was to recognize the knowledge gaps, if any, and understand current patterns of practice in this newly emerging area.

Methods: A 25-item electronic survey was developed by the CanRIO investigator group. The survey, which was available in both French and English, was distributed via electronic mail to 574 members of the Canadian Rheumatology Association (CRA). Responses were collected over a period of 14 days. Results were summarized using descriptive statistics.

Results: Of the 574 CRA members who were invited to participate, 83 responded (response rate of 14.5%). Half of the respondents were adult rheumatologists from academic centres and 26% from the community. Over 25% of the respondents were not familiar with ICI and irAE. Half of the respondents had not seen or managed patients with irAE, and among the remaining, the majority had seen less than 5 patients with irAE. Inflammatory arthritis was the most common rh-irAE encountered. Other rh-irAE included sicca, myositis, sarcoid and vasculitis. Prednisone and methotrexate were the most common treatment strategies. Almost half of the respondents (43.6%) had been asked for advice from oncologists regarding discontinuation of ICI for irAE, and of these, almost half (48.7%) reported that they were either ‘slightly confident’ or ‘not confident at all’ in providing advice. Over half of the respondents had not yet been asked to provide advice concerning ICI for patients with pre-existing auto-immune diseases. The vast majority (87.2%) agreed that there was a need for clinical practice guidelines for the management of rh-irAE.

Conclusion: The survey highlighted the important knowledge gaps in the emerging field of rh-irAE. Given the increasing use of ICI in a growing number of cancer types and stages, referrals for rh-irAE are likely to increase. There is strong rationale to develop educational programs and clinical practice guidelines to support Canadian rheumatologists who will be increasingly responsible for managing rh-irAE.

WHY DO PATIENTS CLAIM? ANALYSIS OF THE CLAIMS MADE BY PATIENTS THROUGH CUSTOMER SERVICE

Enrique Judez Navarro1, Carlos Sánchez-Piedra1, Gines Sanchez Nieves1, Isabel Labiano2, Manuela Sianes3, Gloria Garcia Consuegra1, Sandra Soro1, M Angeles Garcia Morales3,1 Complejo Hospitalario Universidad de Albacete, Rheumatology, Albacete, Spain, 2Spanish Society of Rheumatology (SER), Madrid, Spain

Background: Analysis of the claims made by patients could be an indicator of quality and show strengths and aspects of improvement in the organization of a rheumatology department.

Objectives: The aims of the present study are to evaluate these claims, describe the sociodemographic and clinical characteristics of claiming patients and to determine the association between medical history and types of complaints.

Methods: Cross-sectional study. Claims made by patients treated by a rheumatology department between 04/2016 and 12/2017 were analyzed. A descriptive analysis of these claims was carried out followed by a multivariate logistic regression model to determine the effect of the diagnosis of Fibromyalgia (FM)/Chronic Widespread Pain (CWP) on the type of claim and its association with clinical variables. A p <0.05 was considered significant.
Results: One hundred and nine patients (mean age 54.7 ± 18.5 years, 76% women and 50.5% residents in rural areas) made 113 claims. The main reasons for claiming were: "advance medical evaluation and/or tests" (45.1%), "request for evaluation by a specific physician" (24.8%) and "rejection of evaluation by specific physician" (13%, 3%). 67% of the claims were satisfied. The least satisfied claims were "request for evaluation by specific doctor" (39.3%) while claims for "cancellation of evaluation" were satisfied in 88% of the cases.

Median time between claim and previous medical visit was 44 [28-82] days. Patients whose claims were due to "unpleasant attendance" were the first to complaint (median 28 [2-72] days) but waited for the longest time to be attended (median 103 [46-147] days). "Cancellation of evaluation" was attended after a median of 31.5 [28-33] days.

The main reasons for medical evaluation were: inflammatory/systemic disease in 25 patients (22.15%), neck and low back pain in 23 patients (20.35%) and FM/CWP also in 20.35% of patients. As personal medical history, Psychiatric Disorders were present in 20.5% of patients and multiple comorbidities in 19.6% of patients. Twenty patients had no medical history of interest.

Regarding the type of claims, differences were observed related to the diagnosis and the patient’s medical history. The logistic regression model (FM as dependent variable) adjusted for sex, age, rural area, time to/after the claim and medical history showed that patients with FM/CWP requested more frequently to "be evaluated by other physician" (OR of 23.92 [95% CI, 1.4-409.06] and "reject to be evaluated by a specific physician" (OR of 8.48 [95% CI, 1.2-60.09]) than the rest of the patients and also presented more frequently with psychiatric history (OR of 22.39 [95% CI, 1.15-437.23])

Conclusion: the present study reflects main reasons for claiming of patients treated in a rheumatology department. Reasons of claiming and comorbidities of patients with FM/CWP differ from those of the rest of patients. These findings may be of interest for the organization of resources in rheumatology departments.

EFFECTS OF A WORKPLACE-CENTERED COUNSELING OF INDIVIDUALS WITH MUSCULOSKELETAL COMPLAINTS: A PROSPECTIVE COHORT STUDY

Harald Leis1, Miriam Huckle2, Veronika Machold-Fabrizi3, Josef S. Smolen1, Klaus Machold1.
1Medical University of Vienna, Department of Rheumatology, Vienna, Austria; 2Klinikum Klagenfurt, Department of Internal Medicine and Gastroenterology, Hepatology, Endocrinology and Nephrology, Klagenfurt, Austria; 3Wilheminespital, 6th Medical Department with Nephrology and Dialysis, Vienna, Austria

Background: Employed people with musculoskeletal complaints often seek medical advice when symptoms are chronic and lead to loss of workability.

Objectives: A brief examination was offered in the workplace setting to detect and to counsel individuals with symptoms of Rheumatic and musculoskeletal diseases(RMDs).

Methods: Employees received a questionnaire regarding musculoskeletal problems. In case of a positive screening, consultation by RMD specialists was offered. If necessary, participants were referred to a clinic specialized in RMDs. Employees’ work was categorized into physically-highly-demanding(HD) and less-demanding(LD).

Results: 6170 employees were invited. 413 participated in the counselling program, 344 were enrolled in the study. 56.6% of the participants had previously diagnosed RMD. Among the specialists’ assessment, this percentage decreased to 35.7%. Men with LD-workload had significantly higher wellbeing (EQ-5d scale) compared to women with both LD (p=0.034) and HD (p=0.001). LD and HD differed significantly regarding percentage with painful upper (p=0.006) and lower (p=0.016) limbs. Back pain was distributed equally among all groups. HD women reported significantly higher use of NSAIDs (p=0.001).

The mean interval from Referral to patient review was 11.5 weeks in Feb 2006, 7.15 weeks in August 2012 and 6.6 weeks in Feb 2016. In parallel with the diagnosis of inflammatory arthritis we also looked at mean timeframe from 1st review to initiation of DMARDs which is demonstrated in the chart below.

Figure 1

Conclusion: • Mean interval between primary care referral to first outpatient review has improved significantly over the period of 10 years
• Mean interval for DMARD initiation in inflammatory arthritis patients has also improved in the 10 years’ time

AB1218

ANALYSIS OF REFERRAL TRENDS TO A SECONDARY CARE RHEUMATOLOGY SERVICE FROM GENERAL PRACTICE: OVER A TEN-YEAR PERIOD

Ganesh Kasavkar, Kaushik Chaudhuri, Roxanne McVittie. University Hospital Coventry and Warwickshire, Rheumatology, Coventry, United Kingdom

Background: The practice of Rheumatology in the UK has undergone significant change in the past decade. These have been driven by developments in our understanding of the diseases; early arthritis clinics; changing population demographics; changes in the health services (NHS) all of which have influenced referral patterns to rheumatology.

Objectives: To analyse referral data from primary care over three time points of a month at a time, over a decade – from 2006 to 2016 to assess changing trends, if any, of patients attending Rheumatology.

Methods: We analysed referrals from the primary care in the months of Feb ’06 (n=89), Aug ’12 (n=50) and Feb ’16 (n=100). We looked at the following: reason for referral and our response, referral to out-patient review interval; outcome and final diagnosis.

We also analysed between first appointment and DMARD initiation in inflammatory arthritis.

Results: Referrals were grouped as demonstrated in the table below.

DISTRIBUTION OF RHEUMATOLOGISTS AND YOUNG RHEUMATOLOGISTS’ ORGANIZATIONS ACROSS THE WORLD: STILL ROOM FOR IMPROVEMENT

Aurelie Najm1, Julia Spierings2, Savino Sciascia3, Elena Nikiphorou4, Alexandre Sepriano5, Alessia Alunno6, EMEUNET Working Group.

King’s College London, London, United Kingdom; 2Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; 3Center of Research of Immunopathology and Rare Diseases, Department of Clinical and Biological Sciences, University of Turin, Turin, Italy; 4Department of Inflammation Biology, King’s College London, London, United Kingdom; 5Leiden University Medical Center, London, Netherlands; 6University of Perugia, Perugia, Italy

Background: Rheumatology is a rapidly advancing specialty. The increasing understanding of autoimmune mechanisms and advanced therapies have improved care for patients with chronic inflammatory conditions immensely. National and international collaborations are growing and are key to scientific developments. Still, the number and geographical distribution of rheumatology organizations globally, is not known.

Objectives: To gain further insights into the distribution of established and young rheumatologists’ organizations beyond Europe. Furthermore, we intended to explore correlations between presence of rheumatology organizations and demographic and socio-economic parameters.

Methods: A systematic online search was performed independently by three investigators (AN, SS, JS). Keywords used in the search related to three main themes (i) Rheumatology (rheumatology or rheumatologist(s) or rheumatism), (ii) Organizations (associations or young organization or society or group or association or league or federation) and (iii) country’s name. All identified rheumatology organizations worldwide were reported. Countries were grouped in eight regions according to their geographic location. General demographic information (including population, area, pop. density, net migration, infant mortality, GDP, literacy, phones, arable, crops, climate, birth-rate, death rate) was retrieved from World Bank Open Data by one extractor (SS). Descriptive statistics and quartile distribution for each analysed variable were performed using Excel® (Microsoft Office) and SPSS® software. Using the total number of countries per region as the denominator.

Figure 1. Overview of the percentage of national rheumatology societies

Results: Four international societies and three junior international organizations (EMEUNET, PANLAR junior, ALPAR Young rheumatologists) were identified. Out of the 227 countries assessed, 89 national rheumatology organizations were identified (n=4, 2%). Rheumatology societies were more frequent in Eastern Europe (n=18/27, 67%), Middle east (n=10/15, 67%) and Western Europe (n=19/29, 66%) (Figure 1). Rheumatology societies were more frequently found in countries in the upper quartiles (Q1) of population density, gross domestic product and literacy when compared to Q2-4 (as assessed for Liase Frisenklev, r=0.05). Conversely, it was significantly less frequent in countries with high migration and infant mortality (Q1 Vs Q2-3, p=0.043 and p=0.039, respectively).

Conclusion: National rheumatology societies were identified in less than half the countries across the globe and were unequally distributed. We only found 7 national young organizations. Such organizations are needed, as trainees can highly benefit from educational and networking offers. Further steps will include the exploration of the impact and the reasons for lack of such establishments in some countries.

AB1221 VIEWS OF PRIMARY CARE PHYSICIANS AND RHEUMATOLOGISTS REGARDING SCREENING FOR HYPERLIPIDEMIA AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

Iris Navarro-Milian1,2, Anna Cornelius-Schecter1, Ronan O’Beirne3, Melanie Moms4, Geyanne Liu5, Susan Goodman6, Andrea Cherrington7,ไ Hspital for Special Surgery, New York, United States of America; 2University of Alabama at Birmingham, Birmingham, United States of America; 3University, New Haven, United States of America

Background: Screening of hyperlipidemia in rheumatoid arthritis (RA) is suboptimal, despite RA patients’ high risk for cardiovascular disease (CVD) mortality.

Objectives: To identify barriers to screening for hyperlipidemia among patients with RA from the viewpoint of primary care physicians (PCPs) and rheumatologists.

Methods: We recruited rheumatologists and PCPs nationally to participate in separate moderated structured group teleconference discussions using the nominal group technique. Participants in each group generated lists of barriers to screening for hyperlipidemia in patients with RA, then each selected the three most important barriers from this list.

Results: Twenty-six rheumatologists participated in 3 groups and 20 PCPs participated in groups. The resulting barriers were organized into physician-, patient- and system-level barriers. Rheumatologists prioritized physician level barriers (e.g. ‘ownership’ of hyperlipidemia screening), whereas PCPs prioritized patient-level barriers (e.g. complexity of RA itself). See Table 1 for details.

Conclusion: These rheumatologists were conflicted about whether screening of CVD risk among patients with RA should fall within the role of the rheumatologist or PCPs. On the other hand, participating PCPs were concerned about the overall effect of RA and RA treatments in the context of screening hyperlipidemia.

AB1222
PATIENT PREFERENCES FOR THE USE OF DIGITAL TOOLS AND SOCIAL MEDIA IN DIET AND EXERCISE INTERVENTIONS
W. Benjamin Nowell1, Kelly Gavigan1, Jeffrey Curtis2, Shilpa Venkatachalam1, Francois Ban1, Amin Yakubu2, Alexis Ogdie2, 1Global Healthy Living Foundation, Upper Nyack, United States of America; 2University of Alabama at Birmingham, Birmingham, United States of America; 3Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States of America

Background: Healthy behavior changes such as improving diet/exercise are important to improve outcomes in rheumatic and musculoskeletal disease (RMD) patients. These changes require incentives, whether internal or external motivation or social support.

Objectives: To assess feasibility of using digital symptom tracking and social media peer support to conduct diet/exercise health behavior change interventions among adults with inflammatory arthritis (IA) and osteoarthri- tis (OA).

Methods: A 37-item cross-sectional survey was developed and adminis- tered online and via mobile app in the ArthritisPower research registry. Participants (pts) were eligible if they were ≥ 18 years of age, resided in the US, and reported physician diagnosis of IA or OA. Pts reported on use of technology and social media, experience with exercise and weight loss programs, and interest in various program features. We descriptively reported differences between respondents with IA (RA, PaA, AS) and OA. Results: 418 pts completed the survey. A majority were female (59.5%) and white (89.5%); mean age was 56 (10.5). The proportion of pts who were obese (BMI >30) was higher among OA than IA pts (67.7% and 50.0%, respectively; p<0.001). Most pts were willing to provide blood samples remotely and use WiFi-enabled digital scale and blood pressure monitor for a trial (Table). Interest in social media for peer support and apps differed between IA vs OA pts; more IA pts used an app to help them exercise (35.1% vs. 19.2% of OA pts, p<0.001) and were interested in using an app to track diet and exercise in the context of peer support on Facebook (72.2% vs. 62.3% of OA pts, p=0.04). The most commonly used social media platform overall was Facebook (93.3% of pts) followed by Twitter (51.9%) and Instagram (41.9%). Pts cited pain/discomfort moving (57.4%) and sedentary behavior, such as watching TV, (47.6%), as their biggest weight loss challenges. OA pts reported depression (46.9%, p=0.01) and disliking exercise (34.6%, p=0.003) as bigger challenges to weight loss than did pts with IA (34.0% and 20.8% respectively). Motiva- tions to exercise also differed between groups: more IA than OA pts said building muscle was a top motivation (54.5% and 43.1%, respectively; p=0.03).

AB1223
A SYSTEMATIC REVIEW OF STUDIES INVESTIGATING THE EFFECTIVENESS OF ADALIMUMAB PATIENT SUPPORT PROGRAMMES
Peta Doštenović Bonča, Aleša Lotrič Dolinar, Mitja Oblak, Faculty of Economics – University of Ljubljana, Ljubljana, Slovenia

Background: Adalimumab patient support programmes (A-PSPs) are offered to patients with chronic inflammatory indications creating the need to study how such A-PSPs assist patients and other stakeholders in improving health outcomes. A deeper understanding of the effects of A-PSPs can improve treatment outcomes and experience of patients being treated with adalimumab.

Objectives: To review current studies evaluating A-PSPs, summarize their general characteristics and methodology, and recommend future research work in the area of A-PSPs.

Methods: Studies were identified through Web of Science and were cross-checked by searching through PubMed and MEDLINE databases, following PRISMA guidelines. Full-text papers and conference proceedings identified by the database search were reviewed for relevance.

Results: 17 studies evaluating the impacts of A-PSPs on patient out- comes were identified – 6 full-text articles and 11 meeting abstracts. Most research was done at the international level or in North America [1-3]. In only 5 reviewed studies a prospective study design was applied. Indications most commonly investigated were rheumatoid arthritis and inflammatory bowel disease. 12 studies evaluated the impact of all interventions of A-PSPs while others assessed the impact of Coach Care Calls or phone calls. Patient outcomes most commonly measured were persistence, adherence and low disease activity or remission. Overall, patients using any of the interventions of A-PSPs experienced significantly better improvements in all studied patient outcomes at different follow-up assessments compared to those not enrolled into any of the programme’s interventions. Study population sizes and ratios between assigned users and non-users of interventions differed between studies. The most frequent follow-up assessments were after 12 and 24 months of treatment with adalimumab. Data for analysis was mostly obtained by linking a patient support database and claims administrative database, and in 5 cases by applying patient and physician reported surveys. Methodology for assessing the differences between users and non-users of interventions of A-PSPs consisted of univariate and multivariate methods, where the causal relationships between the impact of patient support program and patient outcomes were estimated by regression modelling adjusted for multiple confounders.

Conclusion: Interventions of A-PSPs have been shown to have a positive impact on all investigated patient outcomes. Main recommendations for
future studies are to design a prospective study, include persistence and adherence measures in the study design, and to assess patient outcomes with additional measures such as patient outcomes based on a patient-centric approach and adverse effects.

Disclosure of interest: This literature review was funded by AbbVie Inc.

IS THERE A NEED TO OPTIMIZE REFERRAL DIAGNOSIS TO A RHEUMATOLOGY DEPARTMENT?:

Tobias Hoffmann, Peter Oelzner, Gunter Wolf, Alexander Pfeil, Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine III, Jena, Germany

Background: The initial visitation of patient suffering from rheumatic disease related symptoms often occurs in absence of a rheumatologist.

Objectives: This study evaluated the following questions: I. Which medical specialists referred patients to a rheumatology department? II. To quantify the accordance of the presumptive diagnosis and the final diagnosis of a rheumatologist.

Methods: 1151 patients (355 men and 796 women) were admitted to a hospital for rheumatological diagnostic. The referral medical specialists were identified. Kappa-Analysis was performed to evaluate the presumptive diagnosis and the final diagnosis by the rheumatologists.

Results: 73.0% of the referrals were performed by general practitioner. The other referrals were: 7.7% rheumatologist, 4.8% specialist in internal medicine (excluding rheumatology), 4.3% orthopaedic surgeon, 1.0% orther surgeon and 9.2% other specialists.

The highest accordance of the presumptive diagnosis and the final diagnosis was k=0.534 for rheumatologists and k=0.400 for specialist in internal medicine (excluding rheumatology). Lower kappa values were evaluated for general practitioner (k=0.345), orthopaedic surgeon (k=0.310) and other specialists (k=0.252).

Conclusion: The referrals were frequently realized by general practitioners. In this context the presumptive diagnosis of a general practitioner presents a low accordance with the final diagnosis. In this context, general practitioners should achieve a detailed education in the assessment of rheumatic-related symptoms to optimize the dedicated referral to rheumatological departments.

Disclosure of Interests: Tobias Hoffmann: None declared, Peter Oelzner: None declared, Gunter Wolf: None declared, Alexander Pfeil: Grant/research support from: This study is a part of the Investigator Initiated Study “The quantification of inflammatory related periarticular bone loss in certolizumab pegol treated patients with rheumatoid arthritis” which is funded and supported by UCB Pharma GmbH, Monheim, Germany (number: IIS-2014-101458).

AB1225
POSSIBLE EARLY DETECTION OF ADVERSE EVENTS USING REMOTE SYSTEMATIC WEEKLY ELECTRONIC MDHAQ

Theodore Pinca, Rush University Medical Center, Chicago, United States of America

Background: Adverse events of medications are reported to account for 5% of hospital admissions in the USA, including 10% in the elderly. Warnings from doctors and pharmacies concerning adverse events are given at initiation of new medications, but adverse events occur between visits and reporting depends primarily on communication between a patient and a health professional, which may be variable. Therefore, recognition and reporting of adverse events remain relatively haphazard. Several reports present strategies for systematic monitoring for adverse events, primarily involving telephone contacts from nurses to patients. A far less expensive systematic approach based on patient self-report using a remote electronic multidimensional health assessment questionnaire
ONE YEAR’S RESULTS OF A PROTOCOLIZED HIGH RESOLUTION RHEUMATOLOGY CLINIC

Orlando Pompei Fernández1, Susana Gil Barato2, Belén Álvarez Rodríguez2, Juan Ramón De Dios2, Margarida Vasques Rocha2, Claudia Stoye2, Jaime Calvo2.
1Araba University Hospital, Rheumatology, Vitoria-Gasteiz, Spain; 2Araba University Hospital, Rheumatology, Vitoria-Gasteiz, Spain

Background: Mechanical musculoskeletal pathologies put high demands on the Public Health Service, as they affect a significant percentage of the population, and cause both temporary and permanent disabilities.

The specialised High Resolution Rheumatology Clinic (CAR in Spanish) at our centre started up in October 2017, and focuses on the diagnosis and treatment of pathologies which are fundamentally of a mechanical ethology. The centre covers a population of approximately 328,868 inhabitants (Alava 2018 census).

The aim of our study, carried out at the unit over one year, is to determine the patients’ epidemiological features.

Objectives: • To provide the Primary Care Centres with a “fast-track” and immediate care system in order to guide, diagnose, and treat patients who have worsening acute or chronic mechanical affictions to the musculoskeletal system.

• Diagnosis confirmation, request for non-accessible tests, adaptation of treatments mainly for the primary care doctor.

• To speed up and reduce waiting lists, for both inflammatory rheumatic pathologies and mechanical rheumatic pathologies, by establishing new referral guidelines.

• To draw up protocols in agreement with primary care doctors and related specialists.

• To act as a support for other medical services.

Methods: The main services available are those offered mainly to primary care level. There are 3 clinics a week, attending to approximately 30 new patients per week. 1330 patients are included in the study, seen at the High Resolution Rheumatology Clinic (CAR) over 12 consecutive months (November 2017 – 2018), with non-complex regional pathologies and/or soft tissue rheumatism, which are able to be resolved with one or two visits.

Results: 1330 patients were seen, with an average age of 58 ±15.6 years, 64.84% female and 35.16% male, mainly for musculoskeletal ailments. In order of frequency, the visits were for shoulder (25.79%), hip (16.10%), axial skeleton (15.13%), ankle/foot (13.06%), wrist/hand (12.08%), knee (11.21%), and elbow (6.63%).

61.95% of the patients were discharged after the first visit, and one year later, this figure rose to 90.15% of all the patients discharged; only 2.78% made a return visit after being discharged. 22.26% were referred to other services, mainly Traumatology and Orthopaedics (10.53%), Rehabilitation and Physiotherapy (9.72%); and the Pain Management Unit (1.65%). The 3.68% were referred to the usual Rheumatology department.

For 52.33% of the patients seen, there was no need to request more than one diagnostic tests, even though 12.41% visited for reasons other than the main one. Moreover, 63.08% received some kind of infiltration injection. The negative point was that 7.89% of the referrals had been made from Primary Care to several specialists at the same time; and 7.98% were consultations regarding traumatic injuris.

Conclusion: Systematising a clinic for mechanical musculoskeletal pathologies which have a high chance of being resolved in the short term, means that the quality of the care given, the waiting times, and the demand on the health service can be improved. Developing these can have important repercussions on waiting lists for other related services, and even for the Rheumatology service itself, allowing more serious cases to be seen earlier. Creating multi-disciplinary units should be encouraged, in order to improve care quality and prevent the various medical services involved from all carrying out fragmented courses of action. New guidelines should be drafted to optimise the care and management of new resources and/or links to other services, as the most prevalent pathologies can be identified.

Most of the patients seen represent the economically active part of the population; there therefore, repercussions as far as sick leave, disability leave, etc. is concerned.

PREFERRED REFERRAL PROTOCOL FOR RECENT ONSET ARTHRITIS IN ADULTS FROM PRIMARY CARE TO RHEUMATOLOGY

Consuelo Ramos Giráldez1, María Espinosa2, Carolina Merino Arguméñz3, Patricia Fernández Crespo4, Olga Rusinovich5, Fernando León Vázquez6, José Luis Andreu Sánchez7, Carmen Barboddio Mateos8, Valme Hospital, Rheumatology Unit, Seville, Spain; 2Infanta Sofia Hospital, Rheumatology Unit, Madrid, Spain; 3Puerta de Hierro Majadahonda Hospital, Rheumatology Unit, Madrid, Spain; 4San Juan De la Cruz Primary Care Centre, Pozuelo de Alarcón (Madrid), Spain

Background: The time of rheumatoid arthritis (RA) evolution until treatment begins is key to controlling the disease. Many studies have shown that a prolonged duration of symptoms at the onset of treatment is associated with a more severe course of RA. The time from symptoms onset to first DMARD prescription is >12 weeks in Spain, because of diagnostic delay due to either patient-related factors (delay in consultation), Primary Care Physician (PCP) (delay in consultation/referral) or rheumatologist (delay in consultation/referral).

Objectives: To evaluate the usefulness of teleconsulting as a preferred referral tool from PCP to Rheumatology for early detection, diagnosis and treatment of inflammatory joint disease in adults, in the health area of a tertiary hospital.

Methods: A preferential referral circuit was established between the PCP and the Rheumatology Service of a tertiary hospital, defining the referral criteria as “patient suspected of recent onset arthritis (ROA)”: arthritis or inflammatory arthralgia in >1 peripheral joint for >2 weeks with neither traumatic cause nor previous diagnosis of rheumatic disease. PCP performed first assessment, the request for initial tests (blood test including acute phase reactants, rheumatoid factor ± ANA, elemental urine and hands radiography) as well as the referral to Rheumatology with “ROA suspicion” motive. These consultation requests were cited from the Rheumatology Service within <15 days of receipt.

Before the protocol was established, its functioning was communicated as a face-to-face clinical session: by 2 rheumatologists in a Health Centre (HC) and by 1 PCP in the rest of the HC in the area. A poster was

Disclosure of Interests: None declared

edited and published, exposing criteria and referral method for PCP’s offices.

Results: During the first 6 months 33 patients were correctly referred. 78.8% were women and the average age was 49 years old. 48.8% (16 patients) were diagnosed with some inflammatory arthropathy: 31.5% were RA (5 cases); other diagnoses were arthropathy due to microcrystals deposit (2), overlap SLE/RA (1), MCTD(1), psoriatic arthritis (1), spondyloarthropathies associated with IBD (1) or inflammatory arthralgia associated with retropertitoneal fibrosis (1). 12% (4 patients) were diagnosed with hands incipient osteoarthropathy and 33.8% (12 patients) with arthralgias without data on inflammatory pathology. One patient missed her follow-up. The median time from symptom onset to Rheumatology assessment was 90 days in all patients; in the inflammatory pathologies subgroup, 68.8% was assessed in <12 weeks, with a median of 60 days and a mean of 96 days, starting treatment in this subgroup in the first assessment by Rheumatology.

Conclusion: In our experience, the establishment of a specific protocol in collaboration with Primary Care for the preferential referral of patients with suspected recent onset arthritis, obtained diagnoses not only for patients with rheumatoid arthritis, but also for other systemic autoimmune diseases in early stages, as well as early treatment initiation (<12 weeks) in most of these patients. In addition, it turned out to be an effective and comfortable referral route for PCP with suspected connective and/or inflammatory arthritis.

Disclosure of Interests: Consuelo Ramos Giráldez Speakers bureau: Sanofi, María Espinosa: None declared, Carolina Menino Argumánez: None declared, Patricia Fernández Crespo: None declared, Olga Rusinovich: None declared, Fernando León Vázquez: None declared, José Luis Andreu Sánchez: None declared, Carmen Barbadillo Mateos: None declared

ACCESS TO RHEUMATOLOGIC TREATMENTS AND AUTOIMMUNE CONDITIONS IN LATIN AMERICA

Genessi Maldonado1, Daniella Cobeña1, Enrique Soriaño2, Letty Moreno3, Carolina Rico3, Espritu Santo University, Rheumatology, Guayaquil, Ecuador; Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; Centro de Reumatología y Rehabilitación, Guayaquil, Ecuador

Background: To know the availability of treatment for rheumatologic and autoimmune diseases in early stages, as well as early treatment initiation (<12 weeks) in most of these patients. In addition, it turned out to be an effective and comfortable referral route for PCP with suspected connective and/or inflammatory arthritis.

Disclosure of Interests: None declared.

Methods: A digital survey was created using Google Forms, it was approved and endorsed by the scientific committee of PANLAR, and later sent to the different Rheumatology associations of the region. The data was compiled in the statistical program SPSS for analysis.

Results: 456 surveys were filled by rheumatologists from 23 countries. The majority were females (54%). The mean age was 47.18 ± 11.79 [25-78] years. 91% reported access to DMARDs, methotrexate 95%, azathioprine 94%, cyclophosphamide 92%, hydroxychloroquine 92%, leflunomide 90%, mycophenolate mofetil 90%, sulfasalazine 88%, cyclosporine a 80%, tacrolimus 64%, chloroquine 60%. 85% have access to biological drugs: rituximab (27%), infliximab (24%), etanercept (18%) and adalimumab (12%), anakinra (10%) and rilonacept (3%). 58% have access to biosimilars: belimumab (97%), tocilizumab (73%), abatacept (67%), golimumab (63%), certolizumab (59%), secukinumab (55%), ustekinumab (44%), certolizumab (59%), belimumab (47%), canakinumab (22%), sanilumab (63%), certolizumab (59%), secukinumab (55%), ustekinumab (44%), certolizumab (59%), belimumab (47%), canakinumab (22%), sanilumab (63%), certolizumab (59%), secukinumab (55%), ustekinumab (44%), certolizumab (59%), belimumab (47%), canakinumab (22%), sanilumab (63%), certolizumab (59%), secukinumab (55%), ustekinumab (44%), certolizumab (59%), belimumab (47%), canakinumab (22%), sanilumab (63%), certolizumab (59%).

Conclusion: It is evident that most Latin American countries have access to drugs focused on rheumatic diseases, however, there are substantial differences in countries that do not have access to all therapies. In addition, newer treatment as small molecules are less accessible to the region.

AB1229 RHEUMATIC DISEASES REMISSION DURING PREGNANCY: MYTH OR REALITY? FACT OR HOPE?

Euthalia Roussou1,2 3, Josie O’henney3, Victoria Sampson3, Asma Aziz3, London, Rheumatology, Romford London, United Kingdom; Barking Havering and Redbridge University Hospitals NHS Trust, Rheumatology, Romford London, United Kingdom; Barking Havering and Redbridge University Hospitals NHS Trust, Obstetrics and Gynaecology, Romford, United Kingdom

Background: A Rheumatology Obstetric Combined Clinic (ROCC) has been running in our trust since 2013 for patients with any musculoskeletal (MsK) rheumatological disease. Observing pregnant ladies in this clinic it became noticeable that patients with msk diseases do not always go into remission during pregnancy.

Objectives: To register their perception of disease activity during pregnancy and from their memory of that disease activity before pregnancy. A secondary aim was to assess whether the remission (or flares) during pregnancy was disease specific or trimester specific.

Methods: Patients with MsK disorders attending ROCC were given 2 different 10 cm visual analogue scales (VAS) asking them to grade the current (at the time of the assessment in ROCC) disease activity and their perceived disease activity prior to pregnancy. The recorded diseases were: (1) Lupus and other Connective Tissue Diseases= 18 [(33.3%) of whom 13 were having Lupus and 5 Sjogren’s syndrome, (2)SPAs =16 [(28.6%)] of whom 4 had Ankylosing Spondylitis (AS) and 12 Psoriatic arthritis (PsA)], (3) Rheumatoid Arthritis (RA) =9 (16.7%), Antiphospholipid Syndrome (APS) =7 (13%) and other =4 (7.4%). In the “other” group there was 1 patient with sarcoidosis, 1 with Adult Onset Still’s disease, 1 JIA which progressed to CREST, 1 knee pain. The last group was excluded from the analysis. SPSS was used for statistical analysis and chi square to assess the difference between the 2 groups.

Results: We analyzed data from 50 patients who attended the ROCC. At the time of presentation mean age (± sd) was 33.4 years (± 4.29) range 22-43y while age of disease presentation was 25.5 (±8.06) range 22-43y. The weeks (w) of pregnancy during the time of assessment were (mean) 22.2 (±8.6) w ESR (mean in mmHg) was 27 (± 21.7), CRP 13.6 (±14.18). Disease activity at presentation on a VAS was 4.24 (± 2.8) while reported disease activity prior to pregnancy was exactly the same of 4.24 (± 3.07).

Looking at groups of diseases of RA and SpA patients showed reduction in the reported disease activity during pregnancy while CTDs and APS showed an increase, both of which however was not statistically significant (ss (table1)

Disease activity at trimester 1, 2 and 3

Abstract AB1229 Figure 1. shows DA according to trimester before and during pregnancy

Conclusion: In our group of pregnant patients with MsK diseases the overall disease activity is the same during pregnancy and before as measured by a VAS. Looking at the diseases patients with RA and SpA showed some reduction and patients with CTDs and APS showed an increase both not statistically significant. Looking at reported VAS according to trimester of pregnancy, it is in the 1st trimester that pregnant patients report reduced activity.

DISEASE ACTIVITY OF RHEUMATIC DISEASES DURING PREGNANCY COMPARED TO REPORTED DISEASE ACTIVITY PRIOR TO PREGNANCY AS OBTAINED FROM AN ANTENATAL RHEUMATOLOGY OBSTETRIC COMBINED CLINIC AND MODE OF DELIVERY

Euthalia Rousou1, Josie O’Cheney2, Victoria Sampson3, Asma Azi4, Barking Havering and Redbridge University Hospitals NHS Trust, Rheumatology, Romford, United Kingdom; 2Barking Havering and Redbridge University Hospitals NHS Trust, Obstetrics and Gynaecology, Romford, United Kingdom; 3Barking Havering and Redbridge University Hospitals NHS Trust, Obstetrics and Gynaecology, Romford, United Kingdom; 4Barking Havering and Redbridge University Hospitals NHS Trust, Obstetrics and Gynaecology, Romford, United Kingdom

Background: A Rheumatology Obstetrics Care Clinic (ROCC) was established at our antenatal unit to ensure specialist care for women with complex rheumatological conditions (RC). Although patients are often counselled about a likely improvement in their RC in pregnancy, this was not the experience of our patients’ group from the ROCC.

Objectives: To obtain pregnant women with RC disease activity (DA) scores during and prior to pregnancy. To assess modes of delivery (MoD) and compare them to our general non-arthritic population MoD.

Methods: Patients suffering from any RC attending a dedicated highly specialized antenatal ROCC were given 2 separate 10cm visual analogue scales (VAS) asking them to grade on each one of them the current (at ROCC) DA and their perceived DA prior to conception. Electronic delivery records were used to collect obstetric and foetal outcomes. SPSS was used for statistical analysis and chi square to assess the difference between the 2 groups.

Results: Data from 54 patients who attended the ROCC included of whom 50 were analyzed. At the time of presentation mean age (±sd) was 33.4 years (± 4.29) range 22-43y while age of disease presentation was 25.5 (± 8.06). The weeks (w) of pregnancy during ROCC were (mean) 22.2 (±8.6) range 9-37 w. ESR (mean) was 27 mm/h (± 21.7), CRP 13.6 mg/L (±14.18). DA at presentation on VAS was 4.24cm (±2.8) and prior to pregnancy was 4.24cm (± 3.07).

The recorded diseases were: Connective Tissue Diseases (CTD)=n=18 (33.3%) Spondyloarthropathies (SpA)=n=16 (29.6%). Rheumatoid Arthritis (RA) =n=9 (16.7%), Antiphospholipid Syndrome (APS)=n=7 (13%) and other n=4 (7%). The group of other (Still’s disease 1, Juvenile idiopathic arthritis 1, fibromyalgia 1 and knee pain 1) were excluded from analysis. Looking at the disease groups RA and SpA patients’ showed a reduction in the reported DA during pregnancy while CTDs and APS showed an increase; neither was statistically significant (ss).

Conclusion: In our group of pregnant patients with RC the overall DA is the same during pregnancy and prior to conception. DA according to diseases showed that women with RA and SpA had a reduction in DA and those with CTDs and APS had an increase.

The MoD showed similar percentages in vaginal and CS delivery rates as per normal population suggesting that MoD is not impacted by RC.

Acknowledgement: Patients for filling the ROCC questionnaire

INCIDENCE OF TUBERCULOSIS IN PATIENTS WITH RHEUMATIC DISEASES USING TNF INHIBITORS: A SYSTEMATIC REVIEW

Natalia Santos, Nicole Andrade, Rafael Chaikr. Hospital de Clínicas de Porto Alegre, Department of Rheumatology, Porto Alegre, Brazil

Background: The TNF inhibitors (anti-TNF) are indicated for the treatment of several rheumatic diseases, but their use is associated with an increased risk of tuberculosis. Many measures of preventive care have been adopted, but some groups of patients appear to be at greater risk of developing infection.

Objectives: The primary objective is to estimate the incidence of tuberculosis in patients with rheumatologic diseases exposed to anti-TNF. The secondary objectives are to evaluate the incidence of tuberculosis by region and subgroups of diseases, to assess the presentation of tuberculosis in these patients and the time elapsed between onset of anti-TNF and the development of active granulomatous disease.

Methods: A systematic review of the literature was conducted in Medline (Pubmed, Embase), Cochrane Library and Lilacs with inclusion of observational studies. The selection of articles was performed by two independent reviewers and the disagreements were resolved by consensus.

The primary endpoint was described in measure of incidence and secondary outcomes through subgroup analyzes and means comparisons.

Results: We included 54 observational studies with a total of 98,483 patients exposed to anti-TNF. Among the exposed patients, 947 cases of tuberculosis were documented (pulmonary form in 62.2% of cases), with a cumulative incidence of 9.62 cases per 1,000 patients exposed [CI: 9.01 - 10.23]. Regarding TB incidence considering the different continents, we found the following distribution: South America with 11.75 per 1,000 patients exposed [CI: 7.17 - 16.33], North America with 4.34 per 1,000 patients exposed [CI: 3.31-5.38], Europe with 6.28 per 1,000 patients exposed [CI: 5.34 - 7.14] and Asia with 13.47 patients per 1,000 patients exposed [CI: 12.44 - 14.49]. There were no significant differences in TB incidence among the described diseases (rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis and juvenile idiopathic arthritis). The mean time of the medication until the endpoint was 14.49 months.

Conclusion: The overall incidence of TB in individuals with rheumatic diseases anti-TNF was 9.62 cases/103 patient-years, being higher in South America and Asia compared to North America and Europe. Most cases occurred in the first XX months of use and the predominant form was pulmonary. There were no differences in incidence between diseases.

AB1233  PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES CONNECT AND LEARN ABOUT HEALTH-RELATED ISSUES USING SOCIAL MEDIA

Paul Studenic1, Simon Stones2, Alessia Alunno3, Valentin Ritschl4, Elena Nikiforou5. 1 Medical University of Vienna, Division of Rheumatology, Vienna, Austria; 2 University of Leeds, School of Healthcare, Leeds, United Kingdom; 3 University of Perugia, Rheumatology Unit, Department of Medicine, Perugia, Italy; 4 Medical University of Vienna, Section for Outcomes Research, Vienna, Austria; 5 King’s College London, Academic Rheumatology Department, London, United Kingdom

Background: Smartphone applications and social media (SM) are increasingly used, transforming the way in which people communicate. Peer interaction, remote information access and community building are just some of the uses of SM, presenting novel opportunities and challenges, especially for people with chronic conditions such as rheumatic and musculoskeletal diseases (RMDs).

Objectives: To explore the perspectives of people with RMDs on using SM for health-related purposes.

Methods: A questionnaire-based survey, co-designed in English by rheumatologists and patient research partners and translated into German, Italian, Spanish, Russian, French and Portuguese, was issued between May and December 2018, distributed via patient organizations and SM platforms. We report on the main quantitative exploratory analyses.

Results: A total of 992 participants started the survey; 853 (86%) participants reached at least 25 of 31 questions and were subsequently included in analyses. Participants were from 56 countries, with 50% from the UK, Germany, Portugal and Spain; 11% were outside of Europe. 60% of participants reported a good or very good experience in the use of SM. More than half (56%) were between 35 and 54 years, 90% were female, 37% had >1 RMD and 62% were multimorbid.

The use of smartphones, SM, SM for health-related purposes was affirmed by 93%, 95% and 76%, respectively. They started this in particular to connect with other people living with the same condition (58%). In general, 50% use SM to seek medical information, treatment options and to exchange experiences. Facebook (56%), Google+ (17%) and YouTube (17%) were the top three used platforms for health-related purposes; while Facebook (88%), YouTube (50%) and Instagram (47%) were most popular for general use. Platforms, that are usually used are not always the preferred one for health-related purposes, since only 16% of Instagram, 28% of YouTube and 67% of Facebook users prefer the same for health-related purposes. The greatest advantage of SM is to connect different experiences and exchange knowledge with peers. More than half voiced concerns regarding confidentiality and 21% were hesitant of disclosing their condition. Virtual appointments are still novel, since only 4% reported experience.

SM use and education were comparable between groups with different levels of multimorbidity, although health was poorer (p=0.001) and they were older (p=0.001). Participants more frequently considered that information provided by primary care physicians was inadequate (p=0.014) and wanted to make their voice heard (p=0.006), but at the same time were more skeptical about reliability of information on SM (p=0.036).

Conclusion: The use of SM for health-related purposes is widespread among people with RMDs, mainly as a means to connect and exchange knowledge, experiences and empower individuals to better manage their health. The strong concerns about confidentiality and better guidance of patients may improve health literacy and the relationship between the patient and the health care team, addressing new avenues and challenges in healthcare.

Acknowledgement: We would like to thank PARE in their support distributing this survey study.

OUTCOME OF EDUCATION WITH REGARD TO INFLUENZA AND PNEUMOCOCCAL VACCINATIONS IN INFLAMMATORY ARTHRITIS PATIENTS ON DMARDS

Michela Frendo, Noriana Tziatzou, Daniel Debattista, Thomas Degiorgio. Mater Dei Hospital; Rheumatology, Tal-Qroqq, Malta

Background: Inflammatory arthritis (IA) patients on immunosuppressant disease modifying drugs (DMARDS) are at an increased risk of infections. Influenza and pneumococcal vaccines are recommended as part of the BSR and EULAR guidelines for the clinical management of these patients. Prior to commencing DMARDS, the patients are reviewed by the nurse specialist, who discusses the benefits versus risks of DMARDS, necessary monitoring and recommends the pneumococcal and influenza vaccines.

Objectives: The aim of this audit is to assess the uptake of the pneumococcal and the influenza vaccine in IA patients prior to starting biologic or synthetic DMARDS as advised by the nurse specialist during the education visit with the patient.

Methods: The study sample included 139 patients with various types of IA, including rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis, who attended the rheumatology nurse education sessions prior to starting DMARDS in a secondary care hospital in 2017. Verbal advice supported by a vaccination leaflet developed in 2016 was given by the rheumatology nurse. Data was compiled by means of a telephone questionnaire.

Results: One hundred and twenty six (90.6%) participants recalled being given advice on vaccinations. Seventy eight (62%) of these patients recalled receiving the influenza vaccine. The rest (28%) did not receive the vaccine for various reasons including fear of side effects, fear of developing a worse infection, belief of inefficacy and fear of injections. A significant improvement (p=0.0084) in the influenza vaccination rates was noted since a previous audit in 2016, where following verbal education by a rheumatologist, only 41.4% received the influenza vaccine. A significant improvement in uptake was also noted in the pneumococcal vaccination rates since only 17.2% of the patients received the pneumococcal vaccine in 2016 compared to 62.7% in 2017 (p<0.0001). Various reasons including fear of side effects, belief of inefficacy, fear of injections and financial implications were given by patients who did not receive the pneumococcal vaccine.

Overall, 62% of the patients received both vaccines after education given by the rheumatology specialist nurse and receiving the vaccination leaflet.

Conclusion: This audit showed a significant progress in the uptake of the influenza and pneumococcal vaccinations in patients with inflammatory arthritis following verbal advice by the specialist rheumatology nurse and the introduction of a vaccinations’ educational leaflet.

Disclosure of Interests: None declared

COST-SAVING FOR HEALTH SERVICES DETECTING THE MISDIAGNOSIS OF RHEUMATOID ARTHRITIS USING IMAGING IN THE PROCESS OF DIAGNOSIS: EVIDENCE FROM REAL-WORLD

Omaira Valencia1, Pedro Santos-Moreno2, Edwin Castillo3, Nelson Alvis4. 1Biomab Center for Rheumatoid Arthritis, Research, Bogota, Colombia; 2Biomab Center for Rheumatoid Arthritis, Scientific direction, Bogotá, Colombia; 3Biomab Center for Rheumatoid Arthritis, Rheumatology, Bogotá D.C., Colombia; 4Alzack Foundation, Health Economics, Bogota, Colombia

Background: The diagnosis of rheumatoid arthritis (RA) using EULAR criteria through conventional assessments remains controversial, especially for those with seronegative results, many of patients without other diagnostic aids as imaging, could be wrong diagnosis followed by expensive treatments (1-3).

Objectives: To evidence through real-world data how the use of imaging within a screening process of diagnosis of RA can save future costs for unnecessary treatments in patients with misdiagnosis of RA.

Methods: A retrospective real-world data (RWD) analysis was developed from medical records of patients with presumptive RA diagnosis reportedly seronegative for both rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (ACPA), and who met ACR/EULAR 2010 classification criteria, in the period between July 2016 and June of 2017; patients were assessed by imagenology (X-ray, ultrasound (US) or magnetic resonance imaging (MRI)) according to the screening diagnosis protocol in a center of internal attention for rheumatoid arthritis (CIA-RA) in order to confirm diagnosis of RA, or classify patients in an alternative proper diagnosis. Direct costs of diagnosis was estimated in two scenarios: the conventional diagnosis and the screening process of diagnosis in the CIA-RA.

To quantify the cost-savings for this process we also estimated the cost of treatment for the first year after diagnosis for patients with RA and patients with the most common diagnosis found after screening.

Results: 440 patients were referred to our center with presumptive diagnosis of RA in the period, who were assessed for ACPA and RF obtaining a seronegative result for both. After screening process just 115 patients were classified as RA, 98 as SRA and 16 as Nonspecific RA; 12.2% were identified by X-Ray, 67.7% were identified by US and 20% by MRI. The most frequent misdiagnosis found was Osteoarthritis in the 72.5% of patients assessed by the screening process. In that way, the conventional diagnosis cost $54.4, while the CIA-RA screening diagnosis cost was $247.1 per patient, however there was found a potential cost-saving from using the CIA-RA screening process of diagnosis of $1,440,494 per year due to the pharmacological cost saving of 325 patients who requires treatment for RA and not for OA.

Conclusion: According with our findings the use of imaging within a diagnostic screening process combining conventional criteria is a useful tool to discard false positive diagnosis of RA. Despite the fact that at first sight, the cost of screening process of diagnosis is more expensive than conventional diagnosis, after one year of treatment it can be assumed potential cost-savings using the proposed approach.

IMPROVING CLINICAL OUTCOME AND REDUCING COST FOR PATIENTS WITH RHEUMATIC DISEASES VIA ONLINE INTERACTION WITH RHEUMATOLOGISTS BASED ON SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILE TOOL

Yong Wang1, Li Luo2, Qin Li3, Wen Wang4, Anbin Huang4, Hong Zhang5, Peng Ji6, Yangping Zhao7, Lingxun Shen7, Zhengang Wang8, Feng Wei8, Hui Xiao9, Yuhua Jia5, Fei Xiao9, Fengchun Zhang9,10, SSDM Collaboration Group, China;
1The first Hospital Affiliated to AMU (Southeastern Hospital), Chongqing, China; 2The affiliated hospital of xinjiang medical university, Urumchi, China; 3The First People’s Hospital of Yunnan Province, Kunming, China; 4First Affiliated Hospital of Medical University Of Harbin, Harbin, China; 5Union Hospital Affiliated Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China; 6First Affiliated Hospital of Harbin Medical University, Harbin, China; 7Tongren hospital of Harbin Medical University, Harbin, China; 8First Affiliated Hospital of Harbin Medical University, Harbin, China; 9First Affiliated Hospital Of Anhui, Hefei, China; 10Union Hospital Affiliated Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China

Background: Without efficient primary medical care and follow-up system in China, patients can choose any hospitals or doctors they like in seeking care. As a result, most patients rush to large hospitals. Once patients left those clinics, no follow up data is available. Surveys show that over 40% of the rheumatic patients don’t need to go to a hospital, only need advice from rheumatologists. SSDM is a series of applications for chronic diseases management, which strengthens the interaction between doctors and patients based on valuable clinical data. Our previous study showed that patients can master the SSDM and perform self-management after training, including evaluations on disease activity and health assessment questionnaire (HAQ), as well as medication and lab test data entries.

Disclosure of Interests: None declared

BASED ON SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILE TOOL

Yong Wang1, Li Luo2, Qin Li3, Wen Wang4, Anbin Huang4, Hong Zhang5, Peng Ji6, Yangping Zhao7, Lingxun Shen7, Zhengang Wang8, Feng Wei8, Hui Xiao9, Yuhua Jia5, Fei Xiao9, Fengchun Zhang9,10, SSDM Collaboration Group, China;

Background: Without efficient primary medical care and follow-up system in China, patients can choose any hospitals or doctors they like in seeking care. As a result, most patients rush to large hospitals. Once patients left those clinics, no follow up data is available. Surveys show that over 40% of the rheumatic patients don’t need to go to a hospital, only need advice from rheumatologists. SSDM is a series of applications for chronic diseases management, which strengthens the interaction between doctors and patients based on valuable clinical data. Our previous study showed that patients can master the SSDM and perform self-management after training, including evaluations on disease activity and health assessment questionnaire (HAQ), as well as medication and lab test data entries.
Objectives: To evaluate the feasibility and benefit of improving medical economics and disease activity outcomes in rheumatoid patients through online consultation using the SSDM. The SSDM includes doctors’ and patients’ interfaces. The patients’ terminals include self-assessments (DAS28, SLEDAI, HAQ), medication management, adverse events management and lab data entry, data synchronization to the mobile of the authorized doctor. On the basis of these data, the rheumatologists can accept the request from their follow-up patients and practice consultation through SSDM in the form of text or voice.

Results: From Feb 2015 to Jan 2019, 679 rheumatologists supplied 7,405 patients (RA 35%, SLE 23%, AS 9.5%, gout 8.8%, Sjogren syndrome 3.8%, OA 3.4% and other 16.5%) with 10,527 consultations. The consulting fee ranged from RMB 0 to 500 yuan (USD: RMB ~1-6.81) each in average of 78.10 ± 45.12 yuan, which matched the registration fee in hospital. The total fee for consultations was 822,169 yuan RMB. 37% patients receiving online consultation lived in different cities from the rheumatologists. If the patients seek medical care in hospital, in addition to the registration fees and medical expenses, the mean cost of transportation, accommodation, and lost wages was 577.48 ± 505.21 (200 - 2,800) yuan. The total cost of all patients would have been 6,079,135.00 yuan RMB, which is 7.39 times more compared with the cost of online. Among 2,611 RA and 1,671 SLE patients with repeat consultations, respectively. Survey shows that satisfaction rate with the consultations is 100%.

Conclusion: Through online disease management and consultations using SSDM, Chinese patients with rheumatic diseases enjoy good quality of care at lower cost with high satisfaction. Armed with data science, SSDM may supply the rest world with an option for reshaping the healthcare system.

AB1237
COST OF ILLNESS AND QUALITY OF LIFE IN ANKYLosing SPONDylitis PATIENTS TREATED WITH ADALUMmAB IN CHINA
Ya Xia, Liudan Tu, LV Qing, Yutong Jiang, Zetao Liao, Shuangyan Cao, Quang Wei, Jieruo Gu.

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease which may lead to limited physical function, impaired quality of life and increased economic burden for society. There were many studies about the superior effects of biologic agents on symptom release, disease activity and functional remission in AS patients. However, studies on the economic burden and health-related quality of life of AS patients in China were lack.

Objectives: To access the cost of illness, work limitation and quality of life in active ankylosing spondylitis (AS) patients using adalimumab in China.

Methods: A prospective study was performed in 91 patients with active AS in China. Adult patients (aged ≥ 18 years) fulfilled the 1984 New York modified criteria of AS with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) ≥ 4 and C reactive protein (CRP) ≥ 6 were enrolled from rheumatology center from Jan 2017 to Aug 2017. All participants received adalimumab (40mg per 2 weeks) therapy and completed questionnaires about disease characteristics, quality of life, direct and indirect costs. Only patients with pay-work completed the Work Limitation Questionnaire (WLQ) to accesses the impact of chronic health conditions on job performance and productivity. Quality of life was measured using the Ankylosing Spondylitis Quality of Life (ASQoL) and EuroQoL-5 Dimensions (EQ-5D).

Results: A total of 91 patients with mean age of 30 years old (87.8% males) and mean disease duration of 10 years received adalimumab treatment for 24 weeks. 78.02% of patients have a paid job with average work productivity loss of 28% measured by WLQ. The annual estimated cost of each patient was $35238.8 while the direct cost accounted for 90.2% and the cost of medication accounted for 76.6%. There were significant differences in change of ASQoL (change, 3.89 [95%CI, 3.06 to 4.71]; P<0.0001) and EQ-5D (change, -0.19 [95%CI, -0.24 to -0.31]; P<0.0001) scores from baseline and 24 weeks, with more improvements after therapy compared with baseline. Cost of illness was estimated as $21927.38 per quality-adjusted life year and $15728.16 per BASDAI unit, respectively.

Conclusion: The cost of AS patients treated with adalimumab therapy was high in China and symptoms and QoL improved significantly after therapy.

AB1238
PATIENTS’ PERCEPTIONS OF SUPPORT PROGRAMS FOR THE TREATMENT OF CHRONIC INFLAMMATORY DISEASES

Background: Adherence to therapy in chronic diseases such as inflammatory rheumatic diseases (CIRD), inflammatory bowel diseases (IBD) and psoriasis (PsO) is a major condition to achieve positive outcomes. Patient support programs (PSPs) were developed to improve the quality of care and enhance adherence to therapy.

Objectives: To evaluate the perception of patients treated for inflammatory chronic diseases towards PSPs.

Methods: All available PSPs were identified at the national level, and their services were classified into categories: financial, logistic, educational, and emotional support. Consecutive adult patients with CIRD, IBD, and PsO, enrolled in a PSP for more than 3 months, were interviewed by a trained medical student. Demographic data, disease and treatment characteristics were collected at the physician’s clinic. Global satisfaction was estimated using a 5-points Likert scale, adherence to treatment was measured by the Compliance Questionnaire for Rheumatology (CQR). PSPs services were classified according to their importance to the patient using a 5-points Likert scale. An open questionnaire identified the patients’ perceptions qualitatively. Predictive factors of satisfaction were identified.

Results: Forty-seven patients were included in the study, 53% were males, with a mean age of 49.8 years (SD 15.2) (Patients’ characteristics in Table 1). The majority declared that the PSP was very useful (95.7%) and were highly satisfied with the programs (97.9%). Higher attributes were assigned, by decreasing order, to: financial (copy program, providing of free samples), logistic (hotline, refrigerating box), educational (educational material) and emotional support. Nursing services and telephone reminders were rated as least important (Figure 1). Most open comments gave higher appreciation to financial support (54%), followed by education (38%) and logistics (8%). High appreciation of education was associated with lower age, type of treatment and PSP. Shorter treatment duration was associated with appreciation of educational material, emotional support and telephone reminders.

Conclusion: Patients were highly satisfied with PSP programs, and ranked the financial support as the most important followed by logistics, whereas education, nursing services and telephone reminders were found less important. Lower age and shorter treatment duration were associated with higher appreciation of education and support.

CQR score, mean (SD) 86.9 (6.8)

Results: We found that male patients had differences in diagnosis duration, level of creatinine, uric acid, RAP. We did not reveal differences in age, a functional class, a risk scale, and the majority clinical, tool and hemodynamic indicators. However, there were significant differences in survival. So, in male group survival was 21 [12; 51] months, in comparison in female group 74 [48; 119] months, p<0.02. Thus, the male sex was an independent predictor of poor prognosis (HR 2.92 [95%CI 1.21; 7.03], p = 0.018) of PAH-CTD. 

Conclusion: These results indicate that female PAH-CTD patients have better long-term prognosis than male, despite lack of many distinctions. It needs to be considered at outcome assessment.

Epidemiology, risk factors for disease or disease progression

GENDER DIFFERENCE IN PULMONARY ARTERIAL HYPERTENSION, ASSOCIATED WITH CONNECTIVE TISSUE DISEASES

Alexander Volkov, Natalia Yudkina, Ekaterina Nikolaeva, Evgeny Nasonov. VA Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: Pulmonary arterial hypertension (PAH) is a progressive fatal disease with a known gender dimorphism. However, data on gender differences at patients with pulmonary arterial hypertension, associated with connective tissue diseases (PAH-CTD), currently not enough.

Objectives: Therefore, this study aimed to investigate the role of gender in clinical future, hemodynamic data and survival PAH-CTD.

Methods: We examined the long-term prognosis of 97 consecutive PAH-CTD patients, mean age 49 years (7 males and 90 females) diagnosed in our Institute from January 2009 to December 2018. The primary outcome was death. We used nonparametric analysis, Cox regression and the Kaplan-Meier method to assess variables obtained at baseline. All patients received PAH-specific therapy according to the current recommendations.

Results: We found that male patients had differences in diagnosis duration, level of creatinine, uric acid, RAP. We did not reveal differences in age, a functional class, a risk scale, and the majority clinical, tool and hemodynamic indicators. However, there were significant differences in survival. So, in male group survival was 21 [12; 51] months, in comparison in female group 74 [48; 119] months, p<0.02. Thus, the male sex was an independent predictor of poor prognosis (HR 2.92 [95%CI 1.21; 7.03], p = 0.018) of PAH-CTD.

Conclusion: These results indicate that female PAH-CTD patients have better long-term prognosis than male, despite lack of many distinctions. It needs to be considered at outcome assessment.

MOST PREVALENT COMORBIDITIES IN PRIMARY SJÖGREN’S SYNDROME IN A HISPANIC POPULATION

Nicolas Alfaro1, Janett Carmen Riegatorres2, Gabriela Hernandez-Molina3, Rosa-Elda Barbosa-Cobos4, Ana Cecilia Arana Guajardo2, Mario Alberto Garza Elizondo5, Dinaociangel Galarza-Delgado6, Cassandra Michele Skinner Taylor7, Amaya Llorente-Chavez2, Cesar Vidal Solis2, 1Hospital Universitario ‘Dr. José Eleuterio González’, Servicio de Reumatología e Inmunología Clínica, Monterrey, Nuevo León, Mexico; 2Hospital Universitario ‘Dr. José Eleuterio González’, Servicio de Reumatología e Inmunología Clínica, Monterrey, Nuevo León, Mexico; 3Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Department of Immunology and Rheumatology, Ciudad de México, Mexico; 4Hospital Juarez de Mexico, Department of Rheumatology, Ciudad de México, Mexico

Background: Comorbidities are an important issue to consider in patients with rheumatic diseases (RD), as well as the clinical assessment of the autoimmune disease. Looking for concomitant diseases is a necessary step for a global approach of the rheumatic patient, knowing that some diseases are more frequent in patients with RD than in the general population and could influence the course of RD and achievement of treatment goals. Despite this, there is a need of new evidence about primary Sjögren’s Syndrome (pSS) comorbidities and their association with clinical outcomes.

Objectives: To determine the prevalence of comorbidities in patients with pSS in Mexican population.

Methods: This was a national, multicenter, cross-sectional, and observational study. We included 393 patients with pSS, diagnosed according to the American-European Consensus Group (AECG) criteria 2002 or ACR/EULAR 2012 criteria. Comorbidities, serological profile of autoantibodies, Schirmer’s test, sialometry and histopathological assessment from minor salivary gland biopsies reported in the medical records were evaluated by a rheumatologist. The comparisons between the study groups were carried out using the two-tailed Student’s t test, x2 test, and unidirectional. A value of p<0.05 was considered statistically significant.

Results: At least one comorbidity were reported in 310 (78.9%) patients. 2 to 4 comorbidities were reported in 183 (46.6%), and only 18 (4.6%) had at least 5 comorbidities. Thyroid disease was the most frequent comorbidity, observed in 91 (23.2%) subjects, being hypothyroidism the main cause. Smoking (21.9%) and hypertension (19.6%) were in second and third place. Psychiatric disease was present in 62 (15.8%) patients being depression and anxiety disorders the most frequent, appearing in 49 (79%) and 12 (19.3%) patients respectively. Regarding malignancy, we documented 10 (2.5%) patients with lymphoma, and 4 (1%) patients with breast cancer. The rest of comorbidities are shown at Figure 1 and Table 1. There was no significant difference for each variable measured between the groups except for the mean age (p=0.001).

<td>59 (71.1)</td>
</tr>
</tbody>
</table>

GSM; Minor salivary gland. P; asymptotic significance, ** statistical significance

Conclusion: The systematic evaluation of comorbidities in patients with pSS is essential for an integral management. Physicians should be aware that these conditions might directly impact quality of life, prognosis, treatment response and healthcare costs. We encourage further research for the identification of new approaches in benefit of the patients.

COLCHICINE USE DURING PREGNANCY: CASE REPORTS

Nesrin Caglayan Duman1, Murat Karabacak2, Medine Gulcebi Idriz Oglu1, Nevusn Inanc2, Zehra Nur Turgan Ask1, Pamir Atagündüz3, Songül Ozkula1, Rezzan Gulhant1, Zafer Goren1, Filiz Onal1, Haner Direskeneli1, Atilla Karaş1, 1Marmara University, School of Medicine, Department of Pharmacology, Istanbul, Turkey; 2Marmara University, School of Medicine, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey

Background: If used during pregnancy it is known that colchicine passes through the placenta to the fetus. Although it has been shown to increase the risk of congenital malformations in animal studies, there is no increase in undesirable results in humans. The guidelines indicate that the use of colchicine in pregnancy and lactation is appropriate. However, data from clinical studies and case reports for the use of colchicine during pregnancy are not sufficient.

Objectives: The aim of this study was to evaluate pregnant and/or nursing patients who were consulted to our teratology information center for colchicine use.

Methods: Colchicine treated patients during pregnancy was included in this study. Patients consulted to our information service between 2012-2018 were evaluated for risk assessment of colchicine. Information regarding pregnancy outcomes was recorded by telephone interviews with patients.

Results: Indications for colchicine use in 34 cases (33 patients; one of them had pregnancy twice) were familial Mediterranean fever (n=21), Behçet’s disease (n=9), systemic lupus erythematosus (n=1), ankylosing spondylitis (n=1) and vasculitis (n=1). Of the cases, 22 used the drug in pregnancy and lactation, 12 used only in pregnancy period. Of the 34 pregnancies, three had elective termination of pregnancy (the reason in one case was cytomegalovirus infection, the other is unplanned-unwanted and the other was unknown) and three had spontaneous abortion. Twenty eight had given birth, 19 of them were term and 9 of them were preterm. Delivery mode of 18 were caesarean and 10 of them were vaginal birth. A total of 30 live birth infant (two twins) exposed to colchicine due to their mother’s treatment. Twenty three infant was healthy and the remaining 7 had different problems. Four of them cardiac [minor cardiac septal defect which not needs operation (n=2), pink tetralogy of fallot (n=1), heart valve stenosis (n=1)], nephrolithiasis, inguinal hernia and death (respiratory distress after birth) (table 1).

Conclusion: Currently, systematic review and meta-analysis driven data suggests that colchicine does not significantly increase the incidence of foetal malformations or miscarriage and colchicine for FMD should not be withheld on this basis during pregnancy. Although the causality between colchicine use and the abortion reported mostly cardiac and rare problems such as tetralogy of fallot is not proven, the contribution of colchicine cannot be ruled out totally and should be bearded in mind in cases of colchicine use for indications other than FMD or Behçet’s disease.
OBSERVATION: Obese patients are at an increased risk for metabolic syndrome and related comorbidities, which contribute to a higher incidence of cardiovascular diseases.

BACKGROUND: Obesity and metabolic syndrome (MS) are associated with an increased risk of premature death due to cardiovascular causes. Patients with obese or metabolic syndrome are at a higher risk for inflammation, which contributes to a higher risk for cardiovascular disease. BMI and AC are related to metabolic syndrome and inflammatory parameters.

OBJECTIVES: To assess the influence of BMI, AC and MS on disease activity and quality of life in RA and OA, using parameters of inflammatory activity (sedimentation rate (SR) and C-reactive protein (CRP), Activity Score (DAS28), Visual Analogue Pain Scale (VAS) and Health Assessment Questionnaire (HAQ) and to compare patients with BMI and AC.

METHODS: A cross-sectional study, including 150 patients with RA, diagnosed according to ACR/EULAR criteria and 75 patients with PsA (CASPAR criteria). Assessment of weight, height, AC, SR and CRP of all patients, followed by the dorsal spine (41.9%) and cervical spine (9.6%).

RESULTS: Age, duration of illness, schooling and professional class were assessed according to WHO definition. Participants completed HAQ and quality of life in rheumatoid arthritis (RA) and PsA.

CONCLUSION: These results suggest that increased BMI and AC are associated with increased disease activity and quality of life in RA and PsA.

AB1244 TUBERCULOUS SPONDYLODYSITIS: A CASE SERIES ANALYSIS

Lobra Ben Ammar1,2, Aicha Ben Tekaya1,3, Ines Mahmoud1,2, Olfa Saidane2, Mohammed Ben Hammama1,2, Leila Abdellama1,2, Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; Charles Nicolle Hospital, Cardiovascular Surgery, Tunis, Tunisia

BACKGROUND: Spinal tuberculosis or Pott’s disease is one of the many manifestations of active tuberculosis and is still common in Mediterranean countries such as Tunisia with high endemicity. Definitive diagnosis of tuberculosis spondylodiscitis requires the identification of Mycobacterium tuberculosis.

OBJECTIVES: We aimed to describe clinical, laboratory, diagnostic and therapeutic features of spinal tuberculosis.

METHODS: Retrospective study including 64 patients followed up in our department between 1999 and 2019. Clinical, biological and radiological data were collected. Therapeutic approach was studied.

RESULTS: We studied 64 patients included 35 women and 17 men with a mean age of 56 years old [16 - 86]. Seven patients had a contact with Mycobacterium Tuberculosis Bacilli and 5 patients had a history of pulmonary tuberculosis. The median delay of consultation was 6 months. Inflammatory back pain was found in 79%. Other clinical symptoms: 37.5% fever, 40.3% night sweats, 74.1% impaired general condition. Neuroradiologic imaging was performed in 16.1% of cases. 7 patients had another localization of tuberculosis. The inflammatory biological syndrome was found in 92% of cases. The lumbar spine was involved in 58% of patients, followed by the dorsal spine (41.9%) and cervical spine (9.6%).

Disclosure of Interests: None declared
radiographs revealed narrowing of disc spaces in 67.7% of cases and vertebral erosion, vertebral fracture and a paravertebral spindle in 52.5%.

Computed tomography and Spinal magnetic resonance imaging was performed respectively in 62.9% and 70.9% of cases. They showed paravertebral abscess in 66.1%, epiduritis in 56.4%, intra-discal abscess in 3.22%, spinal cord compression in 8.06%, and vertebral osteolysis in 9.67% of cases. Tuberculin Skin Test was performed in 57 (92%) patients and it revealed a positive result in 29 (47%) patients. Discos vertebrae biopsy was performed in 45 patients and was contributive in 32.2% of cases revealing caseating granulomas. A four-drug therapy including isoniazid (INH), rifampin (RMP), pyrazinamide (PZA) and ethambutol (EMB) were administered to 59 (95.16%) patients for the initial two months. Three patients received initial three-drug combination therapy. Following the initial 4-drug regimen, most patients continued to receive a two-drug regimen with RMP and INH for a mean duration of nine months. Over 80% of patients had an immobilisation.

Adverse effects of anti-TB therapy were noted in 17.7% of the patients; (nausea-vomiting: 1.6%, hematotoxicity: 9.6%, rash: 3.2%, hyperuricemia: 3.2%). A surgery was needed for 6.4% of patients. Neurological complication occurred in 4 cases, sepsis occurred in 2 other cases and 2 patients were dead.

Conclusion: Spinal tuberculosis results in a significant rate of morbidity due to its insidious course and delayed diagnosis. Early establishment of definitive etiologic diagnosis and appropriate treatment is of paramount importance to prevent development of sequelae.

COMPARATIVE ANALYSIS OF SPONTANEOUS INFECTIOUS SPONDYLITIS: PYOGENIC VERSUS BRUCELLA

Lobna Ben Ammar1, Aicha Ben Tekaya1, Rawdha Tekaya1, Olfa Saidane1, Mohammed Ben Hammama2, Ines Mahmoud1, Leila Abdelmoula1.
1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; 2Charles Nicolle Hospital, Cardiovascular Surgery, Tunis, Tunisia

Background: Infectious spondylitis is an infectious disease of the spine or paraspinal structures that can be caused by various microorganisms. Without adequate chemotherapy, the outcome can be fatal or result in severe neurologic damage. Therefore, differentiating the etiology of spondylitis is very important.

Objectives: To compare the clinical features, laboratory and radiological aspects, treatment and outcome data of patients diagnosed as brucellar spondylitis (BS) and pyogenic spondylitis (PSP).

Methods: Retrospective study including 45 (22 BS and 23 PSP) spondylodiscitis hospitalized in our department between 1999 and 2019. The diagnosis was based on clinical, biological, radiological and bacteriological data.

Results: The patients' mean age was 54 years. There were 31 men (68.8%) and 14 women (31.2%). There was no difference in mean age and sex between the two groups (p=0.8 and p=0.4; respectively).

The pyogenic group had a relatively higher proportion of Predisposing factors especially diabetics (p=0.04). PSD patients suffered an impaired general condition more frequently than BSD patient (p=0.01) while BSD patients complained of night sweats more frequently compared to PSD cases (p=0.025).

The peak CRP value was higher in the pyogenic group than in the brucella group (87 mg/L and 37 mg/L, respectively, p=0.027), whereas the ESR was not significantly different between the groups (71 mm/h and 67 mm/h, respectively, p=0.7). We found no statistically significant difference regarding the seat of the spondylitis. Whereas, multifocal involvement was higher in PSD (p=0.049). Radiologically, the frequency of prevertebral, paravertebral, epidural, and psoas abscess formations and spinal cord compression was similar in both groups (p=0.8).

Surgical interventions and percutaneous sampling and/or abscess drainage were applied more frequently in PSD but with no significant difference (p=0.23). Favorable clinical outcome rate was 60% in PSD and it was 72% in BSD group (p=0.39).

Conclusion: The clinical and radiological manifestations of spontaneous spondylitis differ based on the causative organism. Pyogenic spondylitis patients tend to have a more severe clinical course and a higher CRP level. However, there was no significant difference regarding the presence of abscess and epiduritis or the occurrence of complications between brucella and pyogenic spondilitis.

PREDICTORS OF IMPAIRED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC DISEASES

Amr Ben Hadji Ali1, Nouha Ghiriss, Wissal Ben Yahia1, Amira Atig1, Ahmed Bouker1, Ahmed Guiga1, Neiroz Ghannouchi1. Farhat Hached Hospital, Internal Medicine, Sousse, Tunisia

Background: Systemic diseases are heterogeneous diseases that represent one of the leading causes of disability in the industrialized world and can even reduce life. They are associated with high rates of disability, premature mortality, and significant social costs.

Objectives: The objectives of our study were to evaluate the quality of life (QoL) of patients with systemic disease and a comparison between these patients, to search for factors predicting the impairment of quality of life during systemic diseases, and to evaluate work disability of those patients.

Methods: We conducted a cross-sectional study at the Internal Medicine Department of the Farhat Hached Hospital in Sousse between July 2017 and September 2017. We investigated patients with systemic rheumatic, thrum or remission who were present as outpatients or were admitted to the ward during this period. The outcomes were baseline Short Form Health Survey physical (PCS) and mental (MCS) component summary scores (QoL). Work disability was evaluated by the work productivity assessment instrument (WPAI) questionnaire. Correlations were calculated by the test t student or Anova factor test and comparison with chi2 test.

Results: Two hundred thirty five patients were included, 183 females and 52 males. The average age was 48.3 years with extremes between 15 and 90 years old. Forty seven per cent of the population had work during the study. The most frequent diseases were: Systemic lupus erythematosus (SLE) in 66 patients, Behçet syndrome in 33 patients and Sjogren primary syndrome (SLE) in 27 patients. Mean PCS were 52.55 ± 17.3 and MCS scores were 47.74 ±14.8. For the predictors related to patients: the age (PCS: r=-0.250, p<0.000), (MCS: r=-0.160, p=0.014), the presence of comorbidities (PCS: p<0.000) and the low level of education (p=0.001) were significantly correlated with impaired QoL, the presence of profession was not significantly correlated with QoL. For the predictors related to the disease: inflammatory myositis influences most the QoL. Pulmonary manifestations (PCS: p<0.021, MCS: p=0.006) were the most correlated with impaired QoL. Disease index of activity was calculated in 3 diseases and it was significantly correlated with impaired QoL; SLE (PCS: r=-0.581, p<0.000); (MCS: r=-0.494,p=0.000),SSP (PCS: r=-0.500,p=0.007), (MCS: r=-0.522, p=0.005), Systemic sclerosis (PCS: r=-0.698, p=0.012), (MCS: r=-0.710,p=0.01)). Work disability was evaluated in working patients: absenteeism as 31.16±24, productivity impairment at 48.77 and systemic sclerosis was the most disease predictive of absenteeism and work disability (p=0.011).

Conclusion: QoL may be severely impaired in patients suffering from systemic diseases. We studied for the first time the predictors of impaired QoL for all patients followed in our department. Our study concord with literature (1), beside the objective criteria resulting from clinical examination and biological investigations, it seems essential to take into account the individuality of each patient. This measure aims to further humanize medical practice and maintain the quality of life of patients.

AB1247

RISK FACTORS FOR ADVERSE CLINICAL OUTCOME IN SEPTIC SPONDYLODICTIS

Aicha Ben Tekaya1, Lobna Ben Ammar2, Olfa Saidane1, Rawdha Tekaya1, Mohammed Ben Hammama2, Ines Mahmoud1, Leila Abdelmoula1, Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; Charles Nicolle Hospital, Cardiovascular Surgery, Tunis, Tunisia

Background: Spondyloarthritis is defined as a serious infection of the intervertebral disc and/or adjacent vertebrae. It can lead to neurological sequelae and put life-threatening ones into play.

Disclosure of Interests: None declared

Objectives: To describe the clinical features and outcomes of septic spondylodiscitis and to identify factors associated with an unfavourable clinical outcome.

Methods: Retrospective study including 107 patients followed up in our department between 1999 and 2019. Clinical, radiological and microbiological data were collected.

We divided patients into two groups: patients with unfavourable clinical outcome (defined as death, drug toxicity, neurological complication, sepsis or persistent pain) (Group 1) and patients with a favourable one (Group 2).

Results: We included 107 patients (49 women and 58 men), with a mean age of 55 years old [16 - 86]. The median delay of consultation was 3 months. Predisposing factors were found in 59 patients (55.1%). Inflammatory back pain was seen in 78.5% of cases. Neurologic deficits were noticed in 16.8% of cases: motor deficit in 1.8% of cases, spinal cord compression in 1.8% of cases and Cauda equina syndrome in 2.6% of cases. An inflammatory biological syndrome was found in 90.6% of cases. The lumbar spine was involved in 55%. The spondylitis was multifocal in 19.6% and multi-stage in 15.8% of cases. CT and Spinal MRI was performed respectively in 60% and 78.8% of cases and showed paravertebral abscess in 63.5%, epiduritis in 54.2%, intra-discal abscess in 46.7%, spinal cord compression 9.3%, and vertebral osteolysis in 8.4% of cases. The causative microorganism was mycobacterium tuberculosis in 59.8%, brucella in 20.56%, and pyogenic germs in 16.8% of cases. 34.5% of patients had an unfavourable clinical outcome: persistent pain was noticed in 18.7%, drug toxicity occurred in 13% of cases, neurological complication occurred in 10.2% of cases, sepsis occurred 3.7% of cases and 3.7% of patients were dead.

In the group1 the frequency of diabetes, impairment of the general state and clinical evidence of neurological impairment at presentation was higher, but with no statistically significant difference. Similarly, the presence of paravertebral abscess, epiduritis or spinal cord compression was slightly more frequent, with no significant difference.

There was no statistically significant difference in the age (p=0.15), the localisation and the causative microorganism (p=0.68).

Conclusion: Spondylodiscitis is a rare but serious condition that leads to significant long-term morbidity. In our study, unfavourable clinical outcomes was found in the presence of diabetes, neurological impairment at presentation and the presence of paravertebral abscess, epiduritis, or spinal cord compression in MRI but with no statistically significant difference.

Disclosure of Interests: None declared
ADL was suspended. These results suggest a direct relationship between the time of exposure to ADL and concomitant use with DMARDs and corticosteroids at dose >2.5 mg, similar findings are also described in other studies.

AB1250
SLE AND SEXUAL FUNCTION: ARE WE FORGETTING MEN?
Jonathan Campos-Guzmán1, Ana Barrera-Vargas1, Samuel Govea-Peláez1, Diana Gómez-Martín1, Jorge Alcocer-Varela1, Diana Padilla-Ortiz2, Javier Merayo-Chalico1. 1Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Immunology and Rheumatology, Ciudad de México, Mexico; 2Universidad de La Sabana, Rheumatology, Cundinamarca, Colombia

Background: Whereas SLE is uncommon in men, the disease is usually more severe and requires more aggressive immunosuppressive therapy in male patients. There are multiple studies regarding sexual aspects in women with SLE, but information about sexual function in male patients is quite scant.

Objectives: To determine the relationship between SLE and sexual function alterations in men, through the application of validated questionnaires.

Methods: We performed a longitudinal study in a third-level referral center in Mexico City. We included men aged ≥16 years who fulfilled ACR criteria for SLE and who were sexually active. All subjects answered the International Index of Erectile Function-15 (IIEF-15), the SF-36 and the International Index of Erectile Function-15, the SF-36 and the International Index of Erectile Function-15 (IIEF-15), the SF-36 and the SF-36 Health Survey.

RESULTS: We included 108 male SLE patients. Mean age was 37.2±11 years and most patients (87%) were taking immunosuppressive therapy. Comorbidities were present in 58% of subjects, with dyslipidemia and hypertension being the most prevalent (34% and 28%, respectively). The prevalence of sexual dysfunction (SD) was 53%. In the basal visit, the only significant differences between the patients with SD and those without SD were a lower education degree (p=0.007) and persistent lymphopenia (p=0.01). There was a positive correlation between global IIEF-15 score and SF-36 score (r=0.46, p=0.001). The physical function domain had the highest correlation (r=0.50, p=0.001). Likewise, there was a weak negative correlation between IIEF-15 and HAQ score (r=0.25, p=0.012). Also, the IIEF-15 had a weak correlation with the absolute lymphocyte count (r=0.27, p=0.005) and oxidized LDL (r=0.31, p=0.04). In the follow-up visit the only significant differences between the patients with SD when compared with subjects without SD was a low absolute lymphocyte count (1031±89 vs 1458±119, p=0.005); the correlations mentioned in the baseline visit remained significant. Regarding erectile function, 44% of the subjects had some degree of dysfunction. The rest of the variables are shown in Table 1.

Abstract AB1250 Table 1. Demographic, clinical and laboratory features

<table>

<tr>
<td>Time since SLE diagnosis (years)</td>
<td>9.1 ± 0.6</td>
</tr>
</tbody>
</table>

Clinical Features
- Total score IIEF-15: 58.7 ± 1.3
- Erectile function: 23.9 ± 0.6
- Intercourse satisfaction: 10.9 ± 0.3
- Organic function: 8.1 ± 0.2
- Sexual desire: 7.5 ± 0.1
- Overall satisfaction: 8.1 ± 0.1
- Total score SF-36: 69.2 ± 0.3
- Secondary antiphospholipid syndrome (n, %): 16/108 (14.8)
- SLEDAI score (points): 4.2 ± 0.4
- Others comorbidities (n, %): 63/108 (58.3)
- Laboratory features: Hemoglobin (mg/dl): 15.3 ± 0.2
- Leukocytes (x10⁶/mm³): 5.9 ± 0.2
- Absolute lymphocyte count (mm³): 1362±676
- Serum creatinine (mg/dl): 1.4 ± 0.1
- C3 levels: 104.1 ± 3.2
- C4 levels: 19.7 ± 1.2
- Anti-dsDNA antibodies: 208±2.704
- Use of immunosuppressive treatment (n,%): 95/108 (87.9)
- Renal function (n, %): 58/108 (53.7)
- Azaithioprine (n, %): 31/108 (28.7)
- Antimalarial (n, %): 73/108 (67.5)
- Cyclophosphamide (n, %): 42/108 (38.8)
- Cyclophosphamide exposure previous 6 months (n, %): 7/108 (6.4)
- Anticoagulation (n, %): 18/108 (16.6)
- Non-immunosuppressive treatment (n, %): 85/108 (78.7)

Conclusion: Sexual function is affected in men with lupus, regardless of comorbidities and treatment. Interestingly, lymphopenia is persistently associated with an impaired sexual function, which could be related to the role it plays in endothelial dysfunction and atherosclerosis. The patients’ disease perception, which is influenced by their academic level and physical role in their daily activities, seems to affect their sexual performance and quality of life.

AB1251
ASSOCIATION BETWEEN VITAMIN D DEFICIENCY AND A HIGHER RATE OF DISEASE ACTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS
David Castro-Corredor, Marco Aurelio Ramirez Huaranga, Javier José Mateos Rodriguez, Mª Dolores Mínguez Sánchez, Marcos Paulino Huertas, José Luis Cuadra Diaz. Rheumatology Department. Hospital General Universitario Ciudad Real, Ciudad Real, Spain

Background: Spondyloarthritis is a group of chronic inflammatory diseases with involvement of the axial skeleton (mainly), and also of peripheral joints. Patients with spondyloarthritis have a significant prevalence of vitamin D levels below normal and that would correlate with the degree of activity of the disease.

Objectives: To determine the association between vitamin D deficiency and the degree of activity of the disease (inflammatory activity) in a cohort of patients with spondyloarthritis.

Methods: Observational, extensive and transversal study. We propose a retrospective review of the database of patients with spondyloarthritis who were treated in the outpatient clinics of the Rheumatology Service of the General University Hospital of Ciudad Real during September 2016 to September 2018. Patients with the data will be selected. necessary for the analysis of the variables under study. The variables evaluated will be described using measures of frequency and measures of central tendency/dispersion as appropriate. To assess the association between vitamin D deficit and activity index, the odds ratio (OR) will be calculated. All analyzes were performed with a confidence level of 95% using SPSS 21.0.

RESULTS: The first advances of the results of the study are presented. 101 patients were analyzed, of which 58 were men and 43 women, with a mean age of 46.3 years (+/- 13.05 DE), 15 (14.8%) were non-radiographic axial spondyloarthritis, 48 (47.52%) anklylosing spondylitis, 24 (23.76%) psoriatic arthropathy, 3 (2.97%) spondyloarthropathy associated with inflammatory bowel disease, and 11 (10, 89%) were other types of spondyloarthritis. The average of the activity was a BASDAI of 4.355 (+/- 2.376 SD), 64 patients were in activity (BASDAI> or = 4) and 31 patients (30.69%) with an elevation of acute phase reactants. Vitamin D levels were 24.52 (+/- 9.21 SD). 77 patients (76.24%) presented figures
of vitamin D deficiency or insufficiency. When performing the association analysis, the vitamin D deficit/insufficiency presented an OR 12.46 (95% CI: 4.01-39.08), which is the degree of activity measured with BASDAI. Regarding the comparative analysis of means between vitamin D deficiency/insufficiency and BASDAI it is +2.253 (95% CI: 1.241 to 3.266, p < 0.0001).

Conclusion: In our study, patients with spondyloarthritides who have a vitamin D deficit correlate with presenting disease activity (BASDAI+ or − 4). Therapy with vitamin D along with increasing bone turnover and low levels of vitamin D could be related to the pathophysiology of osteoporosis related to spondyloarthritides, and may adversely affect the patient’s functional status and quality of life.

Disclosure of Interests: None declared

FUNCTIONAL STATUS CHANGES ASSOCIATED WITH INFLAMMATORY ARTHRITIS IN REPUBLIC OF MOLDOVA

Víctor Cazañas, Liliana Groppa, Eugen Rusu, Larisa Rotaru, Lia Chisliari. State University of Medicine and Pharmacy "Nicolae Testemitanu"; Rheumatology and Nephrology, Chisinau, Moldova, Republic of

Background: Inflammatory joint disease is a burden to the patient and society, due to medical costs and the impact it has on the health-related quality of life. Functional status plays a significant role in quality of life impairment.

Objectives: To study and compare functional status changes between different inflammatory joint diseases and degenerative joint disease.

Methods: The study included 1500 patients with inflammatory joint disease and 400 patients with degenerative joint disease were included in this study. In the first group, 645 (43.0%) were diagnosed with rheumatoid arthritis, 330 (22.0%) - psoriatic arthritis, 100 (6.7%) - anklyosing spondylitis, 200 (13.3%) - axial spondyloarthritis, 135 (9.0%) - gout, 20 (1.3%) - other crystal arthrop-ritis, 45 (3.0%) - early arthritis and 25 (1.7%) with other arthritis. Physical examination and functional status was assessed and performed. Descriptive statistics and Mann-Whitney U tests were used to compare the study groups, as well as the subgroups within the inflammatory disease group.

Results: Both groups were comparable according to sex, with a predominance of female sex (♂ = 86.4% and 30.74% respectively, p < 0.001), and no difference in sex distribution (mean ranks of U test = 950.98 and 967.44, p = 0.524). Mean age was significantly lower in the inflammatory joint disease group (44.76 vs 60.19, p < 0.001). The Mann-Whitney U test showed a significantly greater mean rank in the inflammatory disease group (999.07 vs 790.66, p < 0.001), suggesting an overall higher functional class, and thus worse functional status in the inflammatory joint disease group. Further analysis using the same method, between subgroups in the inflammatory joint disease group, showed a higher mean rank (worse functional status) in patients with rheumatoid arthritis, when compared with psoriatic arthritis (501.95 vs 460.73, p < 0.05) and early arthritis (352.24 and 248.83, p < 0.001). Psoriatic arthritis showed a higher mean rank, compared to axial spondyloarthritis (282.88 vs 254.97, p < 0.05) and early arthritis (193.34 vs 148.83, p < 0.01). Gout patients showed a higher mean rank (worse functional status), when compared to rheumatoid arthritis (453.65 vs 377.28, p < 0.001), psoriatic arthritis (281.33 vs 213.23, p < 0.001), ankyllosing spondylitis (127.07 vs 105.75, p < 0.05), axial spondyloarthritis (184.67 vs 156.75, p < 0.01) and early arthritis (101.70 vs 56.89, p < 0.001), thus making it the subgroup associated with the poorest functional status. Ankylosing spondylitis showed a higher mean rank, when compared to psoriatic arthritis (238.13 vs 208.64, p = 0.05), axial spondyloarthritis (151.75 vs 129.88, p = 0.05) and early arthritis (81.63 vs 53.83, p < 0.001). Axial spondyloarthritis and other crystalline arthropathies both showed higher mean ranks compared to early arthritis (130.0 vs 91.89 and 43.2 vs 28.56 respectively, p < 0.01), making early arthritis the subgroup associated with the best functional status. No significant differences were found when comparing rheumatoid arthritis with anklyosing spondylitis, axial spondyloarthritis and other crystalline arthropathies.

Conclusion: This is the first study conducted on a national scale to assess the impact of inflammatory joint disease on functional status. Inflammatory joint disease involved a younger age group, when compared to degenerative joint disease, with a higher impact on the functional status. Interestingly, gout was associated with one of the poorest functional status, suggesting the need for a more aggressive approach toward this disease. After gout, a significantly impaired functional status was associated with rheumatoid arthritis, anklyosing spondylitis and axial spondyloarthritises, whereas early arthritis was generally associated with a better functional status, when compared to other inflammatory diseases.

Disclosure of Interests: None declared

DETERMINATION OF RISK FACTORS OF DEVELOPMENT OF HYPERURICEMIA IN PROFESSIONAL ATHLETES IN SOME SPORTS

Maria Chikina, Maxim Eliseev, Olga Shelabina, Svetlana Glukhova, Irina Kruglova, Evgeny Nasonov, Alexander Lila. V.A. Nasonov Research Institute of Rheumatology, Moscow, Russia, Mocca, Russian Federation; Federal scientific and clinical center for sports medicine and rehabilitation of the Federal medical and biological Agency, Mocca, Russian Federation

Background: Prevalence of hyperuricemia worldwide has been steadily increasing over the past decades and becomes higher with age. The number of studies on the prevalence of hyperuricemia and its role in development of diseases in some social groups is low, yet there is data on its high frequency in professional athletes.

Objectives: to assess impact of certain factors upon the risk of development of hyperuricemia in professional athletes in some sports.

Methods: the study was performed as retrospective. Out of 753 athletes in six sports, 267 athletes who met the study criteria were selected. The inclusion criteria: professional athletes aged 18-40, serum uric acid level <360 µmol/l, according to screening tests. The exclusion criterion was refusal to undergo a thorough medical examination.

Out of 753 athletes, 228 (30.3%) showed high uric acid level in their screening test, 258 (34.3%) athletes refused to undergo a medical examination. 267 people were included in the study, 130 men (48.7%) and 137 women (51.3%), with the mean age of 24.4±5.2 years and the average observation period of 3.0±0.3 years.

Parametres in inflammaton: anthropometric measurements, laboratory tests (serum levels of lactate, creatinine, crude protein, triglycerides, thyroid-stimulating hormone (TSH), AST, ALT, myoglobin, testosterone, uric acid (UA)), glomerular filtration rate (GFR) (using the MDRD formula) with subsequent statistical analysis.

Hyperuricemia was defined as SUA level >360 µmol/L. Hypercholesterinemia - as serum cholesterol level >5.0 mmol/L, hypertriglyceridemia - as serum TG level >1.7 mmol/L. High serum creatinine level as >100 µmol/L. Statistical analysis was conducted using the applied programs package of descriptive statistics STATISTICA 12.0 (StatSoft., Inc., USA).

Results: Hyperuricemia developed in 60 athletes (22.5%), including 51 (39.2%) men and 9 (6.6%) women. The frequency of risk factor detection was the following: hypercholesteri- nemia was detected in 91 (34%) professional athletes, hypertriglyceridemia - in 10 (3.7%), reduction in GFR <100mL/min - in 46 (17.2%), BMI >25 kg/m2 (OR 2.470, 95% CI (1.243;4.909) p=0.01), hypertriglyceridemia (OR 4.857, 95% CI (1.056;22.339) p=0.042), BMI >25 kg/m2 (OR 2.470, 95% CI (1.230;4.105) p<0.008).

Conclusion: hyperuricemia developed in professional athletes in 22.5% cases in 3-year observation period along with low frequency of many traditional risk factors (obesity, hypercholesterinemia, hypertriglyceridemia, chronic kidney disease), which can be linked to the peculiarities of diet. This fact calls for a detailed investigation of the dietary intake of athletes with the purpose of its optimization.

AB1254
LOW-BACK PAIN CHRONICITY IN A PRIMARY CARE SETTING IS ASSOCIATED WITH MALADAPTIVE PSYCHOSOCIAL FACTORS, OTHER CHRONIC PAIN CONDITION AND HIGH LEVELS OF PAIN AT BASELINE
Eduardo B. Cruz1, Luis Gomes2, Jaime Branco2, Ana Maria Rodrigues3, Rita Fernandes3, Carmen Caioiro3, Sofia Paiva3, Isabel Pinto3, Rubina Moniz3, Helena Canhão3, 1Instituto Politécnico de Setubal, Physiotherapy, Setubal, Portugal, 2EpicDoc Unit, CEDOC – NOVA Medical School/Faculdade de Ciências Médicas – Universidade Nova de Lisboa, Portugal, Lisboa, Portugal, 3ACES Arábida, Setubal, Portugal

Background: Low back pain (LBP) is the leading cause of disability in Portugal and worldwide. The majority of the patients use primary health care services but the treatment outcomes are unknown. Findings of prognostic studies indicate that a marked reduction in mean pain and disability is expected in the first 6-8 weeks, for acute or persistent LBP. Beyond that time frame period, improvement slows and thereafter the probability to develop a persistent disabling back pain condition improves. Therefore, it seems important to measure the patients’ outcomes at this time point to better assess the effectiveness of the care provided.

Objectives: This study aims to describe the short-term outcomes for LBP patients treated in a primary health care centre in Portugal and to identify the prognostic factors for non-recovery and poor health related quality of life (HRQoL).

Methods: 116 patients with LBP were consecutively recruited from 7 different primary care units in Portugal. Baseline assessment includes sociodemographic and clinical data, psychosocial factors, pain, disability, and HRQoL. Pain, disability and HRQoL were then assessed at 8-weeks follow-up. A Global Rating of Change Scale to assess patient perception of improvement with treatment was added in the follow-up reassessment. Recovery criteria were determined according to the Minimal Clinically Important Difference established for pain and disability (reduction of ≥30% from baseline). The EQ-5D-3L index was dichotomised into ‘poor’ HRQoL (<0.6) and ‘good’ HRQoL (≥0.6), based on a proposed cut-off for having sufficient capacity to be able to work for a population with LBP. The relationship between variables on baseline and non-recovery/poor HRQoL was modulated through logistic regression.

Results: Of the 116 participants enrolled, 110 completed the 8-weeks follow-up. (mean age of 48.06±11.41). Approximately half of the participants (53.4%) were acute presentations of LBP. The main treatment strategy was medication (83.5%), with only 8.3% of patients having been referred for physiotherapy. At 8 weeks follow-up, there were statistically significant improvements in pain, disability and HRQoL (p<0.05). However, 38% of the patients reported they felt the same or worse, 76.4% had a poor HRQoL, and only half of the patients reached the established recovery criteria (49% in disability and 50% in pain). In the adjusted model, the probability of non-recovery (p<0.05) was associated with the presence of maladaptive psychosocial factors (OR: 1.65, 95% CI 1.13-2.40, for pain; OR: 1.61, 95% CI 1.15-2.24, for disability), a chronic pain condition (OR: 1.71, 95% CI 1.53-1.88, for pain; OR: 1.76, 95% CI 1.42-1.89, for disability), and high levels of pain at baseline for pain (OR: 1.26, 95% CI 1.09-1.39). Poor HRQoL was associated to the female gender (OR: 1.88, 95% CI 1.61-1.96), chronic pain condition (OR: 1.68, 95% CI 1.03-1.98) and high levels of pain intensity at baseline (OR: 1.36, 95% CI 1.11-1.67).

Conclusion: These results suggest there is a room for improvement in the healthcare delivered to LBP patients in the Portuguese primary healthcare setting.

SELF-PERCEPTION OF CARDIOVASCULAR RISK IN RHEUMATOLOGIC DISEASES: CASE-CONTROL STUDY
Dionicio Angel Galarza-Delgado1, José Ramón Azpiroz-López2, Iris Jazmín Colunga-Pedraza1, Karla Paola Cuellar-Calderón3, Ileana Cecilia Reynosa-Silva4, Marielva Castro-González5, Carolina Marlene Martínez-Flores6, Raymundo Pineda7, 1Hospital Universitario Dr José Eleuterio Gonzalez, Cardiology, Monterrey, Mexico; 2Hospital Universitario Dr José Eleuterio Gonzalez, Cardiology, Monterrey, Mexico; 3NOVA Medical School/Faculdade de Ciências Médicas – Universidade Nova de Lisboa, Portugal, Lisboa, Portugal; 4ACES Arábida, Setubal, Portugal, 5ACES Arábida, Setubal, Portugal

Background: Several immune-inflammatory diseases are associated with an increased prevalence of cardiovascular diseases. Risk reduction through improved control of traditional cardiovascular risk (CVR) factors and the adoption of healthy lifestyle behaviors are critically important to reduce the CVR, although the general population must be aware of their CVR to make healthy sound decisions. Individuals who perceive an increased risk are more likely to adopt behaviors to reduce it, such as smoking cessation, exercise, weight loss, and medication compliance.

Objectives: The aim of this study is to assess the awareness of the CVR in patients with/without rheumatic diseases (RD).

Methods: Observational, cross-sectional study was design. Subjects with RD attending an outpatient clinic were consecutively recruited (RA, SLE, PsA OA, Sjögren syndrome, fibromyalgia, scleroderma, osteoporosis and osteopenia). A complete clinical history was made and a self-applied questionnaire (Precaution Adoption Process Model) was used to assess the awareness of the CVR in patients with RD. Comparisons were made to controls without RD. Frequencies (%), media and median values (q25-q75) were used for descriptive analysis and Chi Square test for comparisons.

Results: 250 patients were included with 76 controls and 174 cases. Demographic characteristics shown in table 1. The majority of the patients located themselves in stage 1 of their CVR perception 31.6% in cases vs. 30.3% in controls (p>0.05), other results are shown in figure 1. In the case group, 69.5% have not made any changes to reduce their CVR and the same was seen in controls. Most of the individuals are unaware of their higher CVR even though they have traditional CVR factors. Only 30.5% of the group of RD have received information from a health care provider about their CVR.

Conclusion: Even though patients with RD have and increased CVR, most of the individuals perceived it the same as the control group. The majority of the individuals (69.5%) haven’t made any changes to reduce their CVR and many of them didn’t have any source of information about their CVR, and according to EULAR recommendations the rheumatologist is the one responsible. Therefore, they should commit to give a better education to their patients.

HIGH PREVALENCE OF DEPRESSION IN RHEUMATIC DISEASES: CASE-CONTROL STUDY

Dionicio Ángel Galazar-Delgado1, José Ramón Azpiri-López2, Iris Jazmin Colunga-Martinez2, Marielva Castro-González1, Carolina Marlene Martinez-Flores2, Raymundo Pineda1. 1Hospital Universitario Dr José Eleuterio Gonzalez, Rheumatology, Monterrey, Mexico; 2Hospital Universitario Dr José Eleuterio Gonzalez, Cardiology, Monterrey, Mexico

Background: Prevalence of depression is higher in subjects with rheumatic diseases (RD) when compared to other general medical conditions. It’s associated with chronic pain and long-term medical treatment. The Patient Health Questionnaire 9 (PHQ-9) is an extensively validated screening tool, with a negative predictive value of 99%; it has several advantages, like being self-applied and able to be used by any clinician. Currently there are no trials using this screening tool in Mexican rheumatic patients.

Objectives: To determine the prevalence of depression in a group of rheumatic subjects and compare it to non-rheumatic controls.

Methods: An observational, cross-sectional study was designed. Subjects with RD attending an outpatient clinic were consecutively recruited. A complete clinical history with information about exercise history, and the PHQ-9 screening tool were performed to every subject. Subjects without RD were recruited as controls. Descriptive analysis was done using frequencies (%) and median (p25-p75). Comparisons were done using Chi-square and Mann-U Whitney’s test, considering p<0.05 as significant.

Results: A total of 269 subjects were included. Demographic characteristics are shown in Table 1. In the RD group, a higher percentage were female (p<0.001) and had a higher median age (p<0.001). A higher prevalence of depression was found in the RD group (p<0.002). Regarding exercise history, subjects with an inactive lifestyle had a higher prevalence of depression (p<0.001). This remained significant after evaluating only subjects with RD (p<0.007) and controls (p<0.003).

Conclusion: Patients with RD have a higher prevalence of depression than non-rheumatic controls (p<0.001). An inactive lifestyle was associated with a higher prevalence of depression in our cohort, both in RD subjects and in controls (p<0.001). This is the first study that evaluates the PHQ-9 screening tool in Mexican patients with RD. The physicians should be aware of it and use screening tools to detect depression disorders and provide an adequate treatment.

CARDIOVASCULAR RISK FACTORS IN GOUT COMPARED TO AS, PSA AND RA – RESULTS FROM A QUESTIONNAIRE STUDY

Mats Dehlin1, Ulrika Bergsten2, Eva Klingsberg1, Anton Landgren1, Lennart T. H. Jacobsson1, 1Sahlgrenska Academy, Institution of Medicine, Dept of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2RandD Department at Region Halland, Halmstad, Sweden

Background: Increased risk for cardiovascular disease (CVD) is a hallmark for many rheumatic diseases including gout, anklyosing spondylitis (AS), psoriatic arthritis (PsA) and rheumatoid arthritis (RA). This is likely explained by a combination of increased occurrence of CVD risk factors (CVDRF) and chronic inflammation and in gout possibly by increased serum urate levels.

Objectives: To compare the prevalence of CVDRFs and CVD in gout, AS, PsA and RA.

Methods: All individuals aged ≥18 years with at least one ICD-10 diagnosis of gout (M10), AS (M450), PsA (M073) and RA (M056/M060) recorded by a physician during a two year period (Jan 2015 through Feb 2017) were identified at 12 primary care centers and three rheumatology units in the Western Sweden Health Care Region. A total of 1589 gout, 1095 AS, 1200 PsA and 1246 RA subjects were sent a questionnaire which included questions on demographics, CVDRFs (smoking, alcohol consumption, physical activity (PA) and comorbidities (diabetes (DM), hypertension (HT), dyslipidemia (DL), acute coronary syndrome (ACS) and stroke). High alcohol intake was defined as >4 std drinks/week. Low PA was defined as <3 hours of moderate PA/week. Primary non-responders received a second mailing of the questionnaire. All prevalences were indirectly age standardized (IAS) to the population of Sweden 2017, due to the differences in age distribution between the diseases. Chi square test with significance level .05 was performed. IAS prevalences for BMI, PA, DM and HT for the general population (GP) was retrieved from the National public health survey from 2015 which was sent to more than 100 000 randomly selected citizens in Sweden aged 16-84.

Results: Response rates ranged from 53.6% (AS) to 59.6% (RA) and after excluding subjects who had not provided complete information on the evaluated variables we included 2437 individuals. The gout and RA

Disclosure of Interests: None declared

patients were older (mean age 71 (SD 12) and 66 (SD 13) years respectively) compared to AS and PsA (mean age 50 (SD 14) and 55 (SD 13) years respectively). When adjusting for these differences by IAS by sex, both prevalent CVD (stroke, ACS) and all traditional risk factors were more common in gout compared to RA, AS or PsA (Table 1+2), except for alcohol intake in women, where highest exposure was seen in PsA (Table 2). The male AS patients displayed the highest PA level and the lowest prevalence of stroke (table 1). Smoking was least common in male PsA and female AS and RA patients (table 1+2).

Navarro-Hernández4, Valeria-Nicole Mera-Riofrío3, Natalia Prado-Bachegaa3, Monica Vazquez-Del-Mercado5, Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Departamento de Biología Molecular y Genómica, Guadalajara, Mexico; 2Hospital Civil Dr. Juan I. Menchaca, Servicio de Reumatología-PNPC 04096 CONACYT, Guadalajara, Mexico; 3Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Departamento de Biología Molecular y Genómica, Guadalajara, Mexico; 4Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Instituto de Terapéutica Experimental y Clínica, Departamento de Fisiología, Guadalajara, Jalisco, México, Guadalajara, Mexico; 5Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Departamento de Biología Molecular y Genómica, Guadalajara, Mexico

Background: This is the first study where suboptimal doses of enalapril proved to be successful for the reduction of arterial stiffness in a clinical trial of rheumatoid arthritis (RA) patients.

Objectives: The aim of this study was to analyze the effect of enalapril on arterial stiffness through the evaluation of subclinical parameters in RA patients without traditional cardiovascular risk factors or previous comorbidities.

Methods: Fifty-three patients were enrolled in a clinical, randomized, closed-label trial. The subjects were randomly assigned into two groups: One receiving 5 mg of enalapril (27) and 5 mg of placebo (26), both twice a day. Clinical assessment and evaluation of arterial stiffness were performed. The entire set of evaluations were analyzed at the baseline and at the end of 12 weeks of intervention.

Results: A significant reduction in delta CAVI of 0.21 in the enalapril intervention group was found. In contrast, an increase of 0.39 was observed in the placebo group. The delta CAVI reduction was not influenced by age or peripheral systolic blood pressure (pSBP).

Conclusion: Enalapril seems to be effective in CAVI reduction in RA patients. The effect of enalapril intervention on arterial stiffness translated to the clinical context, might be interpreted as a reduction of 6.4 years of arterial aging.

AB1261 CADMIUM TOXICITY AS A PROBABLE CAUSE OF OSTEOPENIA IN ADOLESCENTS AND ITS RELATION TO BAD DIETARY HABITS

Adel Elbeija1, Hesham Elsedouky2, 1Al-Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt; 2Al-Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt

Background: Cadmium is a naturally occurring minor element; it has been recognized as an occupational health hazard for many decades. Water and food are the main source of environmental cadmium exposure in non-smokers in most parts of the world. Cadmium accumulates gradually in the human body, where it gives rise to a number of adverse health effects and especially to kidney and bone. Several studies have addressed a possible association between long-term low-level environmental cadmium exposure and osteoporosis. Osteoporosis is a large and escalating public health problem.

Objectives: This study was conducted to assess the bone mineral status in secondary school students in Egypt and to measure cadmium level in their blood and urine and possible relationship between cadmium retention and bone mineral abnormalities as well as its consumption from some food and drinks commonly utilized by those students.

Methods: Two hundred secondary school students from different secondary schools in Egypt were included in this study(100 males, and 100 females). Bone mineral content was assessed in the 200 students by Quantitative Ultrasoundography (QUS) of the calcaneus using the ultrasound bone densitometer unit PEGASUS PRESTIGE, OSTEOMED, FRANCE. Students with abnormal bone mineral status (T score < -1) were considered osteopenic, data obtained from this osteopenic group were compared

AB1259 CHARACTERISTICS OF METABOLIC SYNDROME IN AN ASIAN COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

Claire Tee Min Li1, Elampiani Elangovan2, Chia Mun Woo3, Chien Joo Lim3, Khai Pang Leong1, Ee Tzu Koh1, Tan Tock Seng Hospital, Rheumatology, Allergy and Immunology, Singapore, Singapore; 2THO Holdings Pte Ltd, Singapore, Singapore; 3Tan Tock Seng Hospital, CMR – Clinical Research and Innovation Office, Singapore, Singapore

Background: Metabolic syndrome (MS), the concurrence of hypertension, abdominal obesity, dyslipidemia and glucose intolerance, is an important risk factor for type II diabetes mellitus (T2DM) and cardiovascular disease (CVD). CVD is a leading cause of morbidity and mortality in patients with rheumatoid arthritis (RA). Studies in RA suggest that inflammation and glucocorticoid use predispose to MS, and that MS is associated with active disease.

Objectives: To investigate the prevalence and characteristics of MS in our cohort of RA patients.

Methods: A total of 409 patients who fulfilled the 1987 ACR criteria for RA and with complete data for classification of MS were included. MS was defined according to the Adult Treatment Panel III report of the National Cholesterol Education Programme (NCEP/ATP III). Information related to demographics, disease onset, serologies, disease activity and treatment was collected. Independent t-test or Mann-Whitney U test was used to compare continuous quantitative data, while Pearson Chi-square or Fisher Exact test for categorical data. Logistic regression was used to identify factors associated with MS. All the statistical tests were two-tailed, and p value <0.05 was considered as statistically significant.

Results: Fifty-two patients (12.7%) fulfilled the criteria for MS. Most of the patients in the cohort were female (85.3%) and non-smokers (84.6%). The mean age was 60.5±11.09 years and mean BMI 23.67±5.06. The patients with MS were significantly older (age 64.21±6.63 vs 59.96±11.32, p=0.010). The mean disease duration was 14.09±9.74 years. Rheumatoid factor and anti-cyclic citrullinated peptide antibody were present in 80.0% and 95.1% respectively. 4.4% of them had a history of CVD or stroke/transient ischaemic attack but the prevalence was the same in patients with and without MS. Comparing the two groups, there was no significant difference in the history of ever-smoking (15.4% vs 15.4%, p=0.699), disease duration (16.44±10.11 vs 13.72±9.66 years, p=0.458), cumulative glucocorticoid use (p=0.649), DAS28 score (2.12±1.09 vs 2.11±1.24, p=0.767) and HAQ score (0.13 vs 0.13, p=0.002). There was also no significant difference in the use of metotrexate, leflunomide or biologics. The commonest MS criteria fulfilled were hypertension (88.5%) and dyslipidaemia (84.6%). 46.2% of the patients with MS had T2DM. Males were less likely to have MS than females [adj. OR (95%CI): 0.039 (0.005, 0.292), p=0.002].

Conclusion: MS is found in 12.7% of our RA patients and they were significantly older than those without MS. In our study, MS does not have a significant association with RA disease activity, disease duration, glucocorticoid use or disease modifying anti-rheumatic treatment.

Disclosure of Interests: None declared

to those from a group of apparently healthy students with normal T score (T score > -1).

Results: Osteopenic group were 52 students (26%); 16 males and 36 females, their mean age was 15.46 ± 0.40 years. Cadmium level in blood and urine was significantly higher in osteopenic group, Interpreted of dietary habits in the osteopenic and control groups revealed that carbonated beverages, potatoes chips, corn snacks intake were significantly increased in osteopenic group, whereas no significant difference was detected in milk, tea, and coffee intake. T score was negatively correlated with blood cadmium, urine cadmium, as well as carbonated beverages, potatoes chips, corn snacks. Cadmium concentrations in tap water as well as in commercial mineral water were negligible, but its concentration in carbonated beverages, potatoes chips, corn snacks was relatively high.

Conclusion: Osteopenia and osteoporosis are not uncommon problem among secondary school students in Egypt. Cadmium exposure, evident by high blood and urinary levels, is a risk factor for development of low BMD. Fault dietary habits, including increased carbonated beverages, potatoes chips, and corn snacks intake, contributes to the occurrence of osteopenia.

THE RELATIONSHIP BETWEEN HYPERURICEMIA AND HEART RATE IRREGULARITY, USING DATA FROM THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2016

Yeonghee Eun1, Eun-Jung Park2, Ji-Young Chai3, Hoon-Suk Cha3, Eun-Mi Koh1, Hyungjin Kim1, Jaejoon Lee1,3, Samsung Medical Center, Department of Medicine, Seoul, Korea, Rep. of (South Korea), National Medical Center, Department of Medicine, Seoul, Korea, Rep. of (South Korea), Bundang Jaseung General Hospital, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)

Background: Hyperuricemia is one of the well-known cardiovascular risk factors. In recent studies, hyperuricemia has been shown to be an independent risk factor for atrial fibrillation, which may be associated with oxidative stress or inflammation. There is still a lack of data on the association of hyperuricemia and arrhythmia other than atrial fibrillation.

Objectives: In this study, we investigated the relationship between hyperuricemia and heart rate (HR) irregularity using representative sample data of adult Korean population.

Methods: The study included 5870 subjects aged 19 years or older who completed the uric acid measurement in the Korean National Health and Nutrition Examination Survey conducted in 2016. Logistic regression was used to analyze the association between hyperuricemia and HR irregularity identified by the examiner at the time of the survey.

Results: Subjects with HR irregularity were older, had more smoking and drinking, had a higher prevalence of HTN, and had lower glomerular filtration rate than those with regular heartbeat. In the presence of hyperuricemia, the HR irregularity was three times higher than in the absence (HR 3.65, 95% CI 1.77-7.53, P = 0.0005). The association of HR irregularity and hyperuricemia was significant in most subjects, especially in those older than 65 years, with diabetes and hypertension.

Conclusion: Hyperuricemia was highly correlated with HR irregularity in adult Korean representative sample data, especially in subjects with conventional cardiovascular risk factors such as old age, hypertension, diabetes, and smoking and drinking. Further researches are warranted to clarify the relationship between hyperuricemia and arrhythmia and its mechanism.

AB1264

THE RELATIONSHIP BETWEEN SERUM URIC ACID AND PULMONARY FUNCTION IN KOREAN ADULT POPULATION: DATA FROM THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2016

Yeonghee Eun1, Eun-Jung Park2, Ji-Young Chai3, Hoon-Suk Cha3, Eun-Mi Koh1, Hyungjin Kim1, Jaejoon Lee1,3, Samsung Medical Center, Department of Medicine, Seoul, Korea, Rep. of (South Korea), National Medical Center, Department of Medicine, Seoul, Korea, Rep. of (South Korea), Bundang Jaseung General Hospital, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)

Background: Hyperuricemia is associated with several comorbidities. The association between uric acid and pulmonary function is still controversial.

Objectives: The aim of this study was to evaluate the relationship between serum uric acid and pulmonary function in Korean adult population.

Methods: A total of 3,177 (weighted n = 19,770,902) participants aged 40 years or older from the 2016 Korean National Health and Nutrition Examination Survey were included and performed cross-sectional study.

Results: Participant with hyperuricemia was older than participants with normouricemia in females. Body mass index, Mean arterial pressure, and hemoglobin A1c, and estimated glomerular filtration rate (eGFR) were significantly associated with uric acid levels in both sex. Hyperuricemia was significantly associated with decreased FEV1 and FVC in females after adjustment for age, income, region, education, marital status, alcohol consumption, smoking, body mass index, mean arterial pressure, hemoglobin A1c, and eGFR (β = -0.143, P-value = 0.002 and β = -0.159, P-value = 0.001, respectively). There was no significant association between uric acid levels and lung function in males. After additional adjustment for respiratory disease including pulmonary tuberculosis, asthma, and lung cancer, hyperuricemia was associated with decreased FEV1 and FVC in females (β = -0.142, P-value = 0.001 and β = -0.161, P-value < 0.001, respectively)

Conclusion: Hyperuricemia was associated with decreased FEV1 and FVC in female general population.

EVALUATION OF ADHERENCE TO TREATMENT IN PATIENTS OF RHEUMATIC DISEASES

Svetlana Yakupova; Etra Fatykhova; Veneta Mukhamadieva; Igor Serdyuk; Rifkat Abdrazikov; KSMU, Department of Hospital therapy; Kazan, Russian Federation; KGMU, Hospital therapy, Kazan, Russian Federation; KSMU, Kazan, Russian Federation; Republican Clinical Hospital, Center of rheumatology, Kazan, Russian Federation; Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation.

Background: Patient adherence to treatment is one of the most important factors influencing the effectiveness of therapy, the course of the disease and the prognosis of the patient’s life. In addition to understanding the degree of adherence, it is important to study the factors that reduce patient adherence. In 2008, the Russian questionnaire for evaluation of adherence to treatment was developed, assessing adherence to drug therapy, to medical care, to lifestyle modification and general adherence to treatment. The questionnaire showed good sensitivity (93%) and specificity (78%).

Objectives: Using the questionnaire, assess the level of adherence to treatment, to drug therapy, medical care and to to lifestyle modification of patients with rheumatic diseases.

Methods: The study included 130 patients (30 men and 100 women) with rheumatic diseases observed in the hospital (63.1%) or outpatient (36.9%). The average age of patients was 53.1 ± 11.72 years (from 27 to 81). 69 patients (53%) suffered with rheumatoid arthritis, with ankylosing spondylarthritis 21 (16.2%), with osteoarthritis 13 (10%), with psoriatic arthritis and systemic vasculitis in 7 patients (5.4%), the remaining 10% were other rheumatic diseases. The average disease duration is 12.3 years. Patients received NSAIDs (83.8%), glucocorticoids (62.3%), methotrexate (39.2%), immunosuppressive specialty drugs (23%), cyclophosphamide (3.8%), hydroxychloroquine (3%), sulfasalazine (2, 3%), leflunomide (1.5%), azathioprine (0.8%). Based on the data obtained in points and comparing them with theoretically possible, the level of adherence was assessed as high (76% or more), medium (51-75%) and low (50% or less).

Results: The high level of adherence was observed only in 12 people (9.2%), in 66 patients (50.5%) - medium and in 52 people (40%) - low. Men had a higher level of adherence (57.6%) than women (55.4%). Among those using non-traditional methods of treatment (33.1%), adherence to treatment was 54.5%, for non-applicants (66.9%) the level of adherence was higher - 56%. The average level of adherence to drug therapy was 61%, to medical care - 48.8%, to lifestyle modification and general adherence to treatment was 50.8% - an average level, which indicates a lack of adherence. The lowest level of adherence is noted for modifying the lifestyle - 48.8%, which depended on the sex and duration of the disease.

Conclusion: Patient adherence to treatment is one of the most important factors influencing the course of the disease and the prognosis of the patient’s life. In addition to understanding the degree of adherence, it is important to study the factors that reduce patient adherence. Patient adherence to treatment is one of the most important factors influencing the effectiveness of therapy, the course of the disease and the prognosis of the patient’s life. In addition to understanding the degree of adherence, it is important to study the factors that reduce patient adherence. Patient adherence to treatment is one of the most important factors influencing the effectiveness of therapy, the course of the disease and the prognosis of the patient’s life. In addition to understanding the degree of adherence, it is important to study the factors that reduce patient adherence.

REFERENCES

All these factors must be considered when discussing the strategy and tactics of treatment with each patient in real clinical practice.

THE CORRELATION BETWEEN SMOKING AND DISEASE ACTIVITY AND MRI INFLAMMATION IN EARLY AXIAL SPONDYLARTHRITIS IN AN EGYPTIAN COHORT

Fatma Fayed, Abeer Abdelati. Alexandria, rheumatology and immunology unit, Alexandria, Egypt

Background: Literature suggests that smoking is one of the crucial triggering factors of rheumatological diseases. (1) In axial Spondyloarthritis (axSpA), classified into radiographic SpA (AS) and non-radiographic SpA (nrSpA), smoking associated with disease activity and extra-articular manifestation. (2) The relationship between smoking and HLAB-27 as well as MRI inflammation in axSpA patients and the difference between nrSpA and AS regarding smoking have not been studied to date in details. Objectives: to investigate the influence of smoking on disease activity and MRI inflammation in axSpA patients (AS and nrSpA).

Methods: sixty Egyptian patients (42 males and 18 females) with the mean age (31.33 ± 7.02), with early active axial spondylarthritits (49 AS and 11 non-radiographic SpA) within two years disease duration, diagnosis based on ASAS classification criteria. All clinical indices (BASDI, BASFI, BASMI, ASDAS-CRP) were applied to all patients. HLA-B27 and the inflammatory markers (ESR, CRP) was done. MRI of sacroiliac joints was performed in a standard protocol using short tau inversion recovery and T1 sequences (slice thickness 3-4mm, both semi-coronal and semi-axial orientations), and scored by the Berlin method. Smoking use assessed by smoking pack-year index.

Results: of all 60 patients, 38 smokers and 22 non-smokers. No significant difference regarding smoking packs index between nrSpA and AS. (p=0.822) There was a robust correlation between smoking packing index and the Berlin score of MRI in all axSpA patients (rs=0.631) (p=<0.001). Moreover, there was a significant correlation between smoking and C-reactive protein (rs=0.952) as well as HLA-B27. (rs=0.340) (p=0.001) Furthermore, a significant relationship between smoking and activity indices (BASDI (rs=0.961) and ASDAS-CRP (rs=0.938)). Otherwise, no significant correlation among smoking, BASMI, and BASFI as well as ESR.

Table (1): Correlation between smoking pack index and different parameters

THE PREVALENCE OF RHUPUS SYNDROME IN A MONOCENTRIC TERTIARY REFERRAL COHORT

Silvia Grazietta Foddai, Elena Rubini, Massimo Radin, Irene Cecchi, Daniela Rossi, Savino Sciascia, Dario Roccatello. University of Turin, Turin, Italy

Background: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are two systemic chronic autoimmune diseases characterised by a wide spectrum of clinical and immune-pathological features. In clinical practice, the concept of Overlap Syndrome is defined when the two diseases coexist in the same patient. Rhupus syndrome is a rare clinical condition, characterized by overlap of SLE and RA. However, it is still subject to debate whether the syndrome should be considered a distinctive entity or an aggressive form of SLE. To date, the estimated prevalence of rhupus is unknown.

Objectives: To evaluate the prevalence of patients with rhupus syndrome in our tertiary care center.

Methods: We chart-reviewed all patients with a diagnosis of SLE[1] or RA[2], based on the current ACR classification criteria, who presented to our outpatient clinic rheumatology unit. Clinical and laboratory data were retrospectively collected from patient notes. Diagnosis were systematically analyzed by two independent reviewers (SGF and ER). Disagreements were resolved by consensus; if consensus could not be achieved, a third party (SS) would provide an assessment of eligibility.

Results: One-hundred eighty-two patients with a diagnosis of SLE and 253 patients of RA, were identified. Out of 182 SLE and 253 RA cases analysed, only 2 patients fulfilled rhupus criteria. The estimated prevalence in our cohort was 0.46% (2/437).

In Figure 1 are illustrated the clinical manifestations of SLE (Panel A; Malar rash) and RA (radiograph-documented erosive polyarthritis) of the two patients.

Additionally, we identified 7 patients (1.61% of the total cohort) that only partially fulfilled both criteria for SLE and RA. In detail, 1 patient (0.23%) manifested with an overlap of clinical manifestations of SLE and RA, while 1 patient had an overlap of both laboratory criteria. Two patients (0.46%) presented with clinical criteria of RA and laboratory criteria for SLE and RA and 3 patients (0.69%) with clinical criteria of SLE and laboratory criteria for SLE and RA. Patient’s selection is resumed in Figure 2.

Figure 1

Conclusion: The prevalence of rhupus observed in our study was relatively low (0.46%). However, we identified up to 1.6% of patients partially fulfilling a diagnosis of rhupus. Rhupus syndrome is a rare and aggressive clinical condition and further prospective studies and an harmonization of classification criteria are highly needed.

VASCULAR INVOLVEMENT IN BEHÇET’S DISEASE : ABOUT 67 CASES

Aya Fraj, Raja Elami, Wafa Garbouj, Zainab Alaya, Rim Khalfallah, Heyfa Tounsi, Innen Chabane. Mohamed Taher Maamouri Hospital, internal medicine department, Nabeul, Tunisia

Background: Behçet’s disease (BD) is a systemic vasculitis which ethiopathogenesis still poorly understood.

Vascular involvement is one of the major causes of mortality and morbidity in this disease. It occupies a special place in the cardiovascular pathologies because of its venous and arterial tropism all confounded caliber but also because of its pejorative prognosis as well on the functional level as vital.

Objectives: Our goal was to present the various venous and arterial manifestations of BD, their epidemiological, clinical, evolutionary and therapeutic characteristics.

Methods: This is a retrospective study over a period of 9 years [2009-2018] that enrolled 87 patients who met the international criteria for Behçet’s disease. The characteristics of vascular involvement were studied.

Results: Twenty-two patients had vascular involvement (25%). There are 17 men and 5 women (sex ratio H/F=3,4), mean age at diagnosis of angina Behçet 39 years [22 years-63 years]. The vascular lesions were indicative of the disease in 17 cases (77%), and for the other 5 patients, the mean time to onset of vascular disease compared with the diagnosis of BD was 2 years.

Patients’ fulfilling the diagnosis of rhupus syndrome is resumed in Table 1.

Venous thrombosis involved 20 patients (90%). They were deep in 16 patients, superficial in one patient and superficial and deep in 3 patients. It was recurrent in 14 patients.

The most common site of deep vein thrombosis was the lower limbs (n=17). The others had unusual sites: inferior vena cava thrombosis (n = 3), superior vena cava thrombosis (n = 2), sus- hepatic vein (n=1) and upper limb thrombosis (n = 1). Pulmonary embolism was noted in one case.

Arterial damage involved 4 patients (20%) divided into arterial aneurysms (3 cases) and arterial thromboses (2 cases). The locations were divided as follows: lower extremity arteries in 2 cases, upper limb arteries in one case, pulmonary artery in 2 cases and abdominal aorta in one case. Lower limb ischemia had occurred in one patient.

Two patients (10%) had mixed vascular, arterial and venous involvement, confirming the multiple and ubiquitous nature of angio-Behçet.

The treatment was based on colchicine, anticoagulants and corticosteroids in venous thromboses. Immunosuppressive therapy was started in 4 patients in front of the unusual site.

In arterial cases, corticosteroids in combination with immunosuppressant were prescribed. Flattening of the aneurysm was indicated in 2 cases with simple operative follow-up.

Conclusion: Behçet disease (BD) is very common in the Mediterranean basin, mainly affects the 30-year-old man. This systemic disease is characterized by oral aphthosis, genital ulcers and systemic involvement including ocular, gastrointestinal, neurological, and vessels that make the severity of the disease.

All types of vessels, regardless of size and seat, may be affected, with venous tropism. In our study we have just supported current literature data regarding the extensive and recurrent venous thrombosis during MB. The seriousness of this venous involvement lies in the involvement of the cavernous veins and in pulmonary embolism.

Arterial damage, such as thrombosis and/or aneurysm, is rare but maybe life-threatening.

Early diagnosis, intensive and appropriate treatment, regular follow-up and the involvement of a multidisciplinary team including internists, vascular surgeons and radiologists are key to better management of patients with angio-Behçet.

Our study illustrates the frequency and significance of vascular involvement in BD.

**EVALUATIONS OF ANTIRHEUMATIC DRUGS AT PRECONCEPTIONAL, PREGNANCY AND POSTPARTUM PERIODS OF RA PATIENTS’ IN A UNIVERSITY HOSPITAL: PRELIMINARY RESULTS**

Nesrin Caglayan Duman1, Atilla Karna1, Nevruzn Inanc2, 3, Marmara University, School of Medicine, Department of Pharmacology, Istanbul, Turkey; Marmara University, School of Medicine, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey

Background: Rheumatoid arthritis (RA) spontaneously improves during pregnancy and disease activity decreases in approximately two-thirds of pregnant but this decrease does not last long and postpartum exacerbation can be seen. Conversely discontinuation of antirheumatic drug (ARD) during pregnancy may be a risk factor for exacerbation of RA. In case of preconceptional, pregnancy and postpartum (P&P&P) situations during RA treatment, current options are discontinuation of inappropriate medications and switching to appropriate ones. With the latest BSR and EULAR guidelines on prescribing drugs in P&P&P, treatment options expanded with some of the biologic drugs.

Objectives: The aim of this study is to analyse alterations of ARD use (discontinuation, increasing or switching) at P&P&P periods of RA patients’ retrospectively between 2002-2018.

Methods: In our records there are 25 cases of 19 female RA patients who having at least one pregnancy experienced out of 140 RA patients. The data were collected by telephone calls and patient file. Female patients that had no pregnancies after the RA diagnosis were not included. Preconception period was defined as 1 year before estimated last menstrual date. Postpartum period was defined as 1 year after infants’ birth.

Results: RA patients participating in our study of 140 female (age median 55 (26-87)), 121 of them (86%) did not give birth after the RA diagnosis. 19 of them (age median 39 (26-61)) had been pregnant after the RA diagnosis (%14) and 14 of them gave birth 1, 4 of them gave birth to 2, one of them gave birth to 3. Twelve out of 140 (9%) patients had postnatal diagnosis. Each of the pregnancies counted as one case so some female patients represented in our data more than ones. While 22 of cases used the ARD before pregnancy (88%), it decreased 18 of
cases (72%) after giving birth. Drug use rate (n=12, 48%) was most lowest particularly 3. trimester and first 3 months after birth (Figure 1). While there was a change such as discontinuation, increasing or switching in the treatment of 15 patients (60%) compared to before and after pregnancy and 6 of them (24%) continued to increase treatment (added drug to preconception treatment). More than half of the patients used steroids and nonsteroidal antiinflammatory drug in all periods (Figure 2).

**Conclusion:** In conclusion the present study suggests that RA patients and doctors avoid the use of ARDs other than steroids and NSAIDs in P&P&P periods. The fact that 60% of the patients undergoing postpartum drug change were showed that pregnancy affected the RA treatment regimen. The need for steroid and NSAID in a high proportion of patients during P&P&P periods indicates the continuation of RA disease activity and the necessity of strong RA treatments during all these periods.

TREATMENT OF RHEUMATOID ARTHRITIS WITH ESTABLISHMENT OF A PROSPECTIVE COHORT FOR INTERSTITIAL LUNG DISEASE: COMPARISON OF BASELINE CHARACTERISTICS BETWEEN RHEUMATOID ARTHRITIS PATIENT WITH OR WITHOUT INTERSTITIAL LUNG DISEASE

Juyeon Kang1, Hyoungyoun Kim1, Ga Young Ahn1, Seung-Ah Jeong1, Hye Won Kim1, Chan-Bum Choi1, Tae-Hwan Kim1, Jae-Bum Jun2, Sang-Cheol Bae2, Daehyun Yoo1, Dong Won Park1, Jang Won Sohn1, Ho Joo Yoon3, Su Jin Hong4, Yo Won Choi5, Youkyung Lee6, Sang-Heon Kim7, Soo-Kyung Cho8, Yoon-Kyung Sung1, 1Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Hanyang University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3Hanyang University College of Medicine, Hanyang University Guri Hospital, Radiology, Guri, Korea, Rep. of (South Korea); 4Hanyang University College of Medicine, Radiology, Seoul, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) has a clinical significance of high mortality rate in patients with RA. Hence, we established a multidisciplinary prospective single center cohort for RA-ILD patients with multidisciplinary collaboration called the HUMANISM. Patients with RA who have checked a chest computed tomography (CT) scan within previous 2 years were eligible for the enrollment, and they were classified according to the presence of ILD by expert radiologists. All RA patients were assessed with various outcomes of RA, and reviewed for treatment pattern of medications annually.

Objectives: To introduce a prospective, non-interventional cohort of RA-ILD patients, HUMANISM cohort and to compare baseline characteristics and treatment patterns between RA patients according to the presence of ILD using the enrollment data of this prospective cohort.

Methods: We compared the baseline characteristics between RA patients with and without ILD using the Chi-square test and Student’s t-test. For RA-ILD patients, we described the ILD patterns that could be identified in high-resolution CT (HRCT) to determine their dominant radiological characteristics.

Figure 1. Patient selection flow of HUMANISM cohort

RESULTS:
A total of 74 RA-ILD patients and 239 RA patients without ILD were consecutively enrolled between May 2017 and October 2018. At the baseline, RA-ILD patients showed higher proportion of male patients and older age compared to RA patients without ILD. They also showed higher RF positivity than those without ILD. RA-ILD patients also have higher disease activity measured with DAS28. In the treatment, oral glucocorticoids (OC) are used in higher rate and higher doses in RA-ILD patients than those without ILD. Methotrexate (MTX) use rate was higher in RA without ILD patients compared to RA-ILD patients, but there was no difference in the prevalence of biological DMARDs. In HRCT findings of RA-ILD patients, usual interstitial pneumonia (UIP) and non-specific interstitial pneumonia (NSIP) dominant patterns were common, followed by organizing pneumonia (OP), and overlapping patterns combined with NSIP or UIP.

Conclusion: We found that RA-ILD patients showed higher disease activity, male predominance and older age than those without ILD. Treatment patterns were different in the use of MTX or OCs. In our HUMANISM cohort, common HRCT findings of RA-ILD patients were UIP and NSIP.
OF 60 PUBLICATIONS REFERRING TO BIG DATA IN RHEUMATOID AND MUSCULOSKELETAL DISEASES, 33 APPLIED ARTIFICIAL INTELLIGENCE STATISTICAL TECHNIQUES: A SYSTEMATIC LITERATURE REVIEW INFORMING A EULAR TASKFORCE

KEDRA Joanna1, Timothy R. Radstake2, Laure Gossec3,4, Suranne Huguet1,2, Sorbonne Université, Pitié Salpêtrière hospital, Paris, France; 3University Medical Center Utrecht, Utrecht, Netherlands

Background: Big data are defined as data sets that are too large or complex for traditional data-processing application software to adequately deal with. Artificial Intelligence (AI) includes various statistical techniques which can deal with big data. The current use of these concepts in publications related to RMDs is unknown.

Objectives: To assess the current use of big data and AI in the field of RMDs.

Methods: A systematic literature review (SLR) was performed in PubMed MEDLINE in November 2018, with key words referring to "big data" (All Fields) OR "Artificial Intelligence"[Majr]) and RMDs. All original reports published in English and referring to big data in RMDs were analyzed. We collected general information on the paper (including year of publication and impact factor of the journal, and country of the first author), and information on the rheumatoid disease, the number of data analyzed and the statistical methods used. The analysis was descriptive.

Results: Of 648 articles, 60 met the inclusion criteria. Among them, 34 (57%) were observational studies including 22 (37%) cohort studies, 3 (5%) were experimental studies, 7 (12%) were literature reviews or literature data mining and 16 (27%) were general reviews which provided no original data. Among the 44 original papers, the mean year of publication was 2015 (SD=5.0, range 1991-2018), with 38 articles (86%) published during the last 5 years. The mean impact factor was 5.1 (SD=8.5, range 1.6-41.9). The mean number of data was 1.4 million (SD=4.6 million, range 212 MRIs – 25 million units of observation). Many articles were written by European (N=16, 36%) or US (N=15, 34%) authors. Most papers were on inflammatory joint diseases (N=17, 37%) (Figure 1); 7 (16%) were applied to -omics and 9 (20%) to imaging. Statistical methods were based on AI in 33 papers (75%) of 44, specifically Machine Learning (N=28 articles, 64%) (Figure 2), with varied methods applied (mostly different kinds of Artificial Neural Networks, N=17).

Conclusion: Big data is an emergent area in the field of RMDs, and we found 60 papers on various diseases and with diverse applications of “big data”. Most of these papers were published very recently, and some in high impact factor journals, indicating the interest of researchers for this field. Overall, 33 publications mentioned AI techniques to deal with big data, whereas 11 used usual statistical methods. The heterogeneity of methods used indicates the need for further research in this area, and for collaboration with data scientist specialized in big data, particularly to determine which statistical methods (traditional or AI) should be used. These findings will inform a EULAR taskforce on big data in RMDs.

AB1275

COMPARATIVE ANALYSIS OF LOCAL COMPLICATIONS OF HIP AND KNEE ARTHROPLASTY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

Alexander Khranov, Maxim Makarov, Sergey Makarov, Alexey Rybinikov, Sergey Maglevanyi, Vera Amirdzhanova, Gayane Vardkova, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications. It can be caused by: an inflammatory process, the osteoporosis, the reduced physical activity and variability of functional movement, long term glucocorticoid therapy, biologic and disease-modifying antirheumatic drugs. All of the above reasons provide elongated wound healing period, the development of infectious complications, increased risk of periprosthetic fractures.

Objectives: to provide a comparative analysis of local complications of hip and knee arthroplasty in RA and osteoarthritis (OA) patients.

Methods: We analyzed 2142 operations: hip (n = 1177) and knee (n = 965) replacement, which were performed to patients with RA and OA between 1998 and 2018.

Disclosue of Interests: None declared.

**Results:** There were 2142 hip and knee arthroplasty performed, including 1118 operations on patients with RA and 1024 operations on patients with OA. The number of local complications after total hip replacement was 155 (7.22%): 96 (5.76%) of them were patients with RA and 59 (5.76%) patients with OA. There were 1177 hip arthroplasty performed, including 467 operations on patients with RA and 710 operations on patients with OA. The number of local complications after total hip replacement was 85 (7.22%): 48 (10.28%) of them were patients with RA and 37 (5.21%) patients with OA. There were 965 knee arthroplasty performed, including 651 operations with RA patients and 314 operations in patients with OA were performed. The number of local complications after total knee replacement was 70 (7.25%): 48 (7.37%) of them were patients with RA and 22 (7.00%) patients with OA. We revealed a significantly greater number of complications in patients with RA (p<0.005).

**Conclusion:** Local complications after hip and knee arthroplasty with RA patients (8.59%) more than in OA patients (5.76%) in 1.5 times. It shows that the operative treatment of patients with RA requires a special approach and more gentle management of patients with RA in co-operation with rheumatologist and careful treatment of the bone with surrounding tissues during the surgery.

**Abstract AB1277**

**THE RISK OF DIABETES MELLITUS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: A COHORT STUDY**

Hemin Lee1, Yinzhu Jin1, Jun Liu1, Ezra Cohen2, Seoyoung Kim1,3

1B Brigham and Women’s Hospital, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Boston, United States of America; 2Boston Children’s Hospital, Department of Rheumatology, Boston, United States of America; 3Brigham and Women’s Hospital, Division of Rheumatology, Immunology and Allergy, Department of Medicine, Boston, United States of America

**Background:** Few studies have suggested higher prevalence of type 1 diabetes mellitus (DM) in juvenile idiopathic arthritis (JIA). To date, the risk of type 1 or 2 DM among patients with JIA has not been fully understood.

**Objectives:** To examine the incidence rate (IR) of DM in JIA patients compared to patients with asthma and healthy children.

**Methods:** We conducted a cohort study using a U.S. claims data from Truven MarketScan (2005-2016). We identified individuals between age 6 and 18 with ≥2 diagnoses of JIA with International Classification of Diseases (ICD)-9 and 10 diagnostic codes followed by one dispensing of JIA-treatment medication. For comparison, we selected 1) children with asthma and 2) healthy individuals. Each JIA patient was matched by age, sex and index date to 5 asthma patients and 5 healthy children. The primary outcome was DM, identified with 1 ICD diagnostic code followed by one dispensing of an antidiabetic drug. We assessed type 1 DM and type 2 DM separately, and composite endpoint of type 1 or 2 DM, IR and hazard ratio (HR) of DM in JIA patients versus patients with asthma and healthy subjects was calculated along with stratification by age (6 to 12 versus 13 to 18).

**Results:** After 1.5 matching, there were 74,385 healthy children, 74,385 asthma patients, and 14,877 JIA patients. The mean age in all cohorts was 13.9 years and 66.9% were female. During a mean follow up of 3.72 years, the composite IR of DM in the JIA group was 0.85 per 1,000 person-years (95% Confidence Interval [CI]: 0.61-1.19) compared to 0.63 (0.54-0.74) per 1,000 person-years in the asthma population and 0.53 (0.45-0.62) per 1,000 person-years in the healthy population (Table 1). The multivariable adjusted HR (95% CI) associated with DM in JIA was 1.27 (0.77-2.07) compared to the asthma group and 1.47 (0.90-2.42) compared to the healthy population (Table 2). Age-stratified analyses also showed numerically increased risk of DM in JIA patients.

**Conclusion:** In our cohort of 163,647 children with 14,877 JIA patients, JIA was associated with a numerically higher, albeit not statistically significant, risk of type 1 or 2 DM compared to asthma patients or healthy children.

**Abstract AB1277**

**PREVALENCE OF THE DIFFERENT ANTI-CARBAMYLATED PROTEIN ANTIBODIES ISOFORMS IN FIRST-DEGREE RELATIVES OF PATIENTS WITH RHEUMATOID ARTHRITIS IN A LATIN POPULATION**

Ana Sofia Leal Pramascio, Cesar Vidal Solis, Luis Eduardo Ramirez Monterrubio, Lorena Pérez Barbosa, David Vega Morales, Jorge Antonio Esquivel Valerio, Mario Alberto Garza Elizondo, Dionicio Ángel Galarza Delgado, Karina Itzel González Márquez. Hospital Universitario Dr José Eleuterio Gonzalez, Reumatología e Immunología Clínica, Monterrey, Mexico

**Background:** Rheumatoid arthritis (RA) affects approximately 1.5% of the population worldwide and 0.5-3.3% of the Mexican population. Anti-carbamylated proteins (anti-CarP) antibodies are identified in RA patients with a prevalence up to 44%2, early arthritis, first-degree relatives (FDR) of patients with RA with a prevalence of 16%, and healthy controls with a prevalence of 4.7%. There is no evidence regarding the prevalence of the three different isoforms of anti-CarP antibodies worldwide.

**Objectives:** Establish the prevalence of the different isoforms of anti-CarP antibodies (IgA, IgM, IgG) in FDRs of patients with RA.

**Methods:** It is an observational descriptive cohort. Subjects underwent a complete physical examination, made by a certificated rheumatologist, which included clinical and serological measurements. The serological measurements included anti-citrullinated peptides antibodies (ACPAs), RF, and anti-CarP detected by ELISA using carbamylated fetal calf serum, according to Shin J et al with some modifications.

anti-CarP IgA isoform was >125 U/mL, for the IgG isoform was >90 U/mL, and for the IgM isoform was >300 U/mL. The FDRs were classified as: suspicious arthralgia for progression according to Van Steenvergen criteria; undifferentiated arthritis (UA) and RA according to ACR/EULAR 2010; and soft tissue rheumatic diseases.

Results: A total of 144 FDRs from 99 RA patients were enrolled. The demographic characteristics are shown in Table 1. The prevalence (Table 2) for anti-CarP was 2.8% for IgA, 4.2% for IgG, whereas IgM was not detected. The serologic association was for RF/ACPA 4.8%, RF/anti-CarP 2.7%, FR 64.5%, ACPA 1.3%, ACPA/anti-CarP 0.69%, anti-CarP 3.4%, and no RF/ACP/anti-Carp was observed.

The group of suspicious arthralgia for progression had 2 subjects positive for IgG anti-CarP, the group of UA had 1 subject positive for IgA anti-CarP, albeit no anti-CarP for the RA group was present. Soft tissue rheumatic diseases group had 5 subjects positive for IgG anti-CarP, while the asymptomatic group had 2 subjects positive for IgA anti-CarP.

AB1278 ANNNOUNCEMENT OF CHRONIC RHEUMATIC INFLAMMATORY DISEASE: THE RHEUMATOLOGIST’S POINT OF VIEW

Background: The onset of a chronic rheumatic inflammatory disease (CRD) is a turmoil in a patient’s life. The announcement, first step of information (a legal and ethical necessity), will leave a lasting impression on the patient’s history.

Methods: 39 private practice rheumatologists from the CREER group, 52% women, mean age 59 years. 222 CRD including 56% rheumatoid arthritis (RA), 27% spondyloarthropathy (SPA), 17% others. Survey including 31 questions. Direct eye contact 89%, gesture 56%, modulated tone 43%, silence 36%, compassionate approach 26%. Gaining confidence by: listening to, explanations, empathy, frankness.

The rheumatologist thinks that he is reassuring and comforting 100%, empathic 98%, transparent 72%. He calms 42%, supports, is optimistic because he is sensitive to the patient’s reactions 61%, but sometimes destabilized by a treatment refusal. He mentions life quality 51%, invites him to question it 58%, encourages him on a mutual management of the CRD 92% and insists on treatment compliance. He gives few documents, rarely mentions patient organizations, speaks about chronic disorder status, informs the treating physician and is always available.

Results: The announcement is different depending on: the type of CRD (59%), its presentation, the prognosis (29%), the induced emotion, the patient’s profile, 82% (intellect 41%, personality 22%, age 16%), the information to provide (course of treatment).

Duration of consultation: long 51%, doubled 64%. Time given to assimilate the information 93%, to discuss 90%. Explanations given 100%, rephrased 32%, repeated 27%, verified 9%.

Announcement unchanged if patient alone or accompanied; handling adapted to its degree of worry. If patient is anxious, depressive, rebellious or denying: see him again 29%, re-explain 22%, listen to, adapt.

When comparing the rheumatologist’s and the patient’s assessment about the announcement, there is globally an agreement, but it’s less affirmative for all the items. However, the patient thinks his rheumatologist more frank than he really is. Indeed, he announces with feeling and spends time on it, but not enough for the patient. He is less comforting, reassuring and explaining what he believes. He mentions the treatment inconveniences and life quality, which is well perceived. But he should guide more to annex treatments. For all the suggested items, the SPA patients are less optimistic than the RA patients.

Conclusion: the announcement takes into account above all the patient’s profile, the type and the seriousness of the CRD. The rheumatologist dedicates a lot of time on the announcement, which is made step by step, but still too fast for the patient. He explains, listens to, reassures, comforts by using human methods to gain the patient’s confidence. He supports him and helps him to manage his disease. He involves the patient and stays available. The patient feels well informed and taken care of in his entirety with empathy.

AB1279 PHYSICAL ACTIVITY LEVELS AND ATTITUDES IN PATIENTS WITH AXIAL AND PERIPHERAL SPONDYLOARTHRITIS

Shao-Hsien Liu, Divya Shridharmurthy, Kate Lapane, Stephen Morais, Catherine Dubé, Jonathan Kay. University of Massachusetts Medical School, Worcester, United States of America

Background: Spondyloarthritides is one of the common inflammatory rheumatic diseases in adults, with an overall prevalence of 0.5 to 1%. Based on clinical manifestations and the Assessment in Spondyloarthritides International Society (ASAS) criteria, spondyloarthritides can be distinguished as predominately axial or peripheral. Despite the health-related benefits of regular physical activity, patients with spondyloarthritides, are generally less active than those without disease. Studies evaluating the differences in physical activity levels and attitudes towards exercise of patients with axial and peripheral spondyloarthritides are limited.

Objectives: To characterize and compare self-reported physical activity and attitudes towards exercise among patients with axial and peripheral spondyloarthritides.

Methods: We used baseline information from an on-going, longitudinal, single-site, prospective cohort study consisting of 244 patients with spondyloarthritides including psoriatic arthritis, anklyosing spondylitis, and other spondyloarthropathies. Attitudes and beliefs towards exercise were assessed from 5 domains including: 1) general attitude towards exercise; 2) support from other people; 3) benefits in exercise/physically active; 4) concerns about being active; and 5) exercise/physical activity behavior. A continuous, 100-point scale (range: 0-100) was used to evaluate each attitude and beliefs towards exercise. High scores indicated that the individual found exercise more beneficial and/or liked engaging in physical activity. Physical activity levels were assessed using

Disclosure of Interests: None declared
the total metabolic equivalent (MET) to incorporate the frequency, duration and intensity by different type of activities. Minutes spent in each level of activity (e.g., sedentary, moderate, and vigorous) were then summed for each week. Adjusted multivariable linear models estimated the relationship between physical activity levels and disease status.

Results: Overall, nearly 80% of the study sample had predominantly peripheral spondyloarthritis. The average age for participants with peripheral disease was 53.2 (standard deviation (SD):12.9) and for those with axial disease was 50.2 (SD: 12.4). Most of the study participants were men, white, non-Hispanic, married, and had attended at least some college, regardless of predominant joint distribution (peripheral versus axial).

While the median for general attitude towards regular exercise in participants with peripheral disease was 88.5, the median score was 81.0 in participants with axial disease. The median score regarding benefits of exercise/physical activity to improve general function was 97.0 among participants with peripheral disease and 96.5 among those with axial disease; the median score for pain relief was 67.0 in participants with peripheral disease and 66.5 for those with axial disease. Regardless of predominant joint distribution, walking, bicycling, and swimming were the most common types of exercise. Compared to participants with predominately peripheral disease, participants with axial disease spent more time per week engaging in light physical activities (adjusted β: 13.0 hrs/week; 95% confidence interval: 0.4 to 25.6 hrs/week) after adjusting for sociodemographic and clinical factors.

Conclusion: Patients with spondyloarthritis have positive attitudes towards physical activity/exercise, regardless of their predominant joint distribution, and believe that these activities improve general function and, to a lesser extent, relieve pain. However, patients with axial disease spend more time per week engaging in light physical activities than do those with peripheral disease.

EPIDEMOLOGICAL PROFILE OF PATIENTS WITH FIBROMYALGIA IN A SPECIALIZED INSTITUTE IN MEDELLÍN, COLOMBIA 2010-2016

Marcela Huenao Pérez1, Diana Carolina colombia Medrano1, Alejandra Arboleda Ramirez2, Julian Zea Osorio1, Sara Bedoya Monsalve1, Inetare.
1Universidad Cooperativa de Colombia, Medellín, Colombia; 2Instituto Neurológico de Medellín, Colombia

Background: Fibromyalgia is a common cause of chronic musculoskeletal pain in the world, with diverse clinical manifestations and with a ruinous effect on the quality of life of patients. The estimations of prevalence in the general population are very variable (0.2% - 6.4%) as well as the clinical presentation.

Objectives: This study aims to describe the sociodemographic and clinical characteristics of patients with fibromyalgia treated in a specialized institution between 2010 and 2016, in Medellín, Colombia.

Methods: We performed a retrospective, descriptive, secondary source study of patients diagnosed with fibromyalgia from a specialized institution between 2010 and 2016. Descriptive statistics and period prevalence tools were applied for the variables studied, among which was evaluated the use of the diagnostic criteria (1990 or 2010) of the American College of Rheumatology.

Results: We evaluated 1106 records of patients diagnosed with fibromyalgia. The median age was 54 years (IQR 16), the age of greatest presentation is between 40 and 65 years for both sexes, 95.1% were women and a 51.1% were married or living with their partner. 23.6% of the patients had a basic and middle level education (secondary and technological level), 50% of the population came from the department of Antioquia (for a prevalence for this period in the year 2010 to 2016 of 0.017%), and 54% resided in the city Medellin. The proportion of people with low and medium low socioeconomic status was 26.3%, while 41.4% reported being active in a job. The symptoms most frequently presented among the patients were myalgia (70.2%), sleep disturbances (59.9%), chronic fatigue (49.5%), headache (47.3%) and muscular weakness (40.5%). When analyzing by sex, headaches were more frequent in women (48.8%) than in men (24.1%). The most commonly reported comorbidities were psychiatric disorders (31.1%, where depression was most recorded with 24.1%), migraine (30.9%) and hypertension (27.9%). The most used criteria to make the diagnosis of fibromyalgia were those of 1990 with 62.2%. Regarding treatment, the most used were serotonin reuptake inhibitors and dual inhibitors (52.6%), along with acetaminophen (41.2%) and pregabalin (39%); only 8.2% of patients received non-pharmacological interventions (physical and psychological therapy).

Conclusion: Fibromyalgia is an important pathology in specialized medical consultation, accompanied by myalgia, sleep disturbances, chronic fatigue, headaches and muscle weakness. Psychiatric pathologies are the most frequently associated comorbidities and the 2010 criteria of the American College of Rheumatology are not yet widely applied. The treatment of fibromyalgia is complex and probably more effective with a transdisciplinary approach involving both pharmacological and non-pharmacological interventions.

USAGE OF PROOF-BP TO PREDICT HYPERTENSION IN MEXICAN-MESTIZO RHEUMATIC PATIENTS

Doria Rodríguez Ángel Galarrza-Delgado1, José Ramón Apzín-López2, Iriz Jazmin Colunga-Pedraza1, Carolina Maríne Martinez-Pérez3, Karla Paola Cuéllar-Calderón1, Ileana Cecilia Reynosa-Silva1, Marielva Castro-González2, Raymundo Pineda2.
1Hospital Universitario, “Dr. José Eleuterio González”, UANL, Rheumatology, Monterrey, Mexico; 2Hospital Universidad, “Dr. José Eleuterio González”, UANL, Cardiology, Monterrey, Mexico.

Background: Subjects with rheumatic diseases have an increased risk of cardiovascular morbimortality. Hypertension (HTN) is a key modifiable risk factor for cardiovascular events (1). A recently published and validated prediction model (Predicting Out-of-Office Blood Pressure, PROOF-BP) has been proposed as a tool to improve diagnosis of HTN, and detection of out-of-office HTN in subjects with a previous diagnosis, with a c-statistic (AUC) of 0.86 in non-rheumatic subjects (2). This model has not been explored in rheumatic patients.

Objectives: To evaluate the diagnostic performance of the PROOF-BP algorithm for the prediction of HTN in subjects with/without rheumatic diseases.

Methods: A cross-sectional, observational trial was designed. Subjects were recruited at a rheumatology outpatient clinic in northeastern Mexico. Subjects with/without rheumatologic conditions were recruited. Complete clinical history with somatometry of each subject was registered. BP was measured by an experienced healthcare provider using current recommendations, with an OMRON HEM-7121 BP monitor. Calculations using the PROOF-BP online site were done, and risk categories were assigned to each subject using their predicted out-of-office BP: low (<130/80 mmHg), medium (130/80-145/90 mmHg) and high risk (>145/90 mmHg). Subjects in the medium and high risk strata were then asked to return for further evaluation and additional BP measurement, to define each diagnosis of HTN. We used frequencies (%) and median (IQR) for descriptive analysis. Diagnostic accuracy of each category was determined using 2 x 2 tables.

Results: A total of 217 subjects were included. Baseline characteristics are shown in Table 1. The most frequent rheumatic disease was RA (n=78, 35.9%). Using PROOF-BP, 84 (38.7%) subjects were stratified as medium or high risk. Of these, only 36 (42.8%) returned for evaluation. A final diagnosis of HTN was attained in 14 (38.8%) of those who returned. Diagnostic performances of the low and high risk categories are shown in Table 2. In 21 (67.7%) cases of the medium risk category the
A Big-data Approach to Electronic Health Record Data – Using Dimensionality Reduction and Clustering Techniques to Study Longitudinal Relationships Between Diseases

Marc Maurits1, Thomas Huizinga1, Soumya Raychaudhuri2,3, Marcel Reinders4,5, Elizabeth Karlson6, Erik van den Akker6,7, Rachel Knevel3,1
LUMC, Leiden, Netherlands; 2Brigham and Women’s Hospital, Centre for Data Sciences, Boston, United States of America; 3Brigham and Women’s Hospital, Rheumatology, Boston, United States of America; 4LUMC, Leiden Computational Biology Centre, Leiden, Netherlands; 5LUMC, Molecular Epidemiology, Leiden, Netherlands

Background: Hypothesis-free, longitudinal collection of patient health data in the form of Electronic Health Records (EHR) offers a wealth of valuable information on complex, slow-developing diseases in regard to aetiology and comorbidities. Conventional analytical methods are ill suited for the highly dimensional, sparse data contained within EHR, highlighting a need for more sophisticated, high-throughput tools. As t-Distributed Stochastic Neighbour Embedding (t-SNE) and Density-Based Spatial Clustering of Applications with Noise (DBScan) are designed to identify patterns in high-dimensional data with possible non-linear relationships, we hypothesized that these methods can aid identification of associations in diseases with multiple aetiologies.

Objectives: Proof of principle showcasing the value of t-SNE and DBScan in detecting longitudinal relationships between diseases in EHR data.

Methods: The Partners HealthCare Biobank from Boston, Massachusetts, includes 64,819 patients with longitudinal visit data from hospitals and general practitioners between June 1987 and June 2017. Each visit and procedure (N = 24,377,442) is coupled to an ICD code (International Classification of Disease) describing a disease or examination. We randomly split the data into two datasets of 32,424 and 32,395 individuals: set 1 to optimise t-SNE and DBScan and set 2 for replication. To trim the overly detailed hierarchy of ICDs, we translated them to Phenotype Codes (PheCodes).[3] t-SNE further reduced dimensionality and indicated groups of patients based on their PheCodes and separated patients based on PheCode patterns rather than singular codes. Subsequently DBScan identified clusters of patients in t-SNE space, by grouping patients based on relative Euclidean distance. Finally transition-probability matrices were constructed for all codes in each cluster, from which probabilities, clusters could be constructed. We defined replication as an overlap in ≥25% of the PheCodes between a cluster of set 1 and 2. Similarity was further assessed by calculating the absolute dissimilarity in transition probabilities for codes shared by matched clusters.

AB1282

A BIG-DATA APPROACH TO ELECTRONIC HEALTH RECORD DATA – USING DIMENSIONALITY REDUCTION AND CLUSTERING TECHNIQUES TO STUDY LONGITUDINAL RELATIONSHIPS BETWEEN DISEASES

Marc Maurits1, Thomas Huizinga1, Soumya Raychaudhuri2,3, Marcel Reinders4,5, Elizabeth Karlson6, Erik van den Akker6,7, Rachel Knevel3,1

We defined replication as an overlap in ≥25% of the PheCodes between a cluster of set 1 and 2. Similarity was further assessed by calculating the absolute dissimilarity in transition probabilities for codes shared by matched clusters.

REFERENCES

Disclosure of Interests: None declared

RESULTS
The average (range) number of codes per individual was 376.3 (1–8,419) and 375.9 (1–10,315) spread over 4106 (1–10,781) and 4153 (1–10,746) days for set 1 and 2 respectively. Even though our input data was a sparse, high-dimensional (1,865) matrix of PheCodes, t-SNE and DBScan could clearly separate various unique patient groups with 284 and 295 clusters in set 1 and 2. Clusters consisted of patients with PheCodes of well-defined disease entities such as cardiovascular diseases and neurological disorders with objectively meaningful disease sequences. 34.5% of the clusters identified in set 1 were replicated in set 2 based on our replication criteria. Figure 1 shows the results of each step.

Conclusion: Our proof of principle supports the use of unsupervised techniques such as dimensionality reduction and data clustering to identify longitudinal associations between medical events. These methods could prove useful in our quest to identify medical risk factors for incompletely understood diseases.

WHEN SHOULD WE EVALUATE CYTOMEGALOVIRUS INFECTION IN IMMUNOSUPPRESSED PATIENTS WITH CONNECTIVE TISSUE DISEASES?

Yoichi Nakayama1, Ryuichi Sada1, Hirofumi Miyake2, Hiroyuki Akebo1, Yukio Taughashi1, Tieni Hospital, Department of General Internal Medicine, Tieni, Japan; 2Tieni Healthcare University, Center for Healthcare Education and Research, Tieni, Japan

Background: Cytomegalovirus (CMV) infection is an opportunistic and often problematic infection in patients with connective tissue diseases (CTD patients) who undergoes immunosuppressive therapy. However, in immunosuppressed CTD patients, CMV infection tends to be overdiagnosed, because it manifests with various symptoms and shows organ involvement. Little is known about when to suspect CMV infection and when to conduct CMV pp65 antigenemia assay in immunosuppressed CTD patients.

Objectives: To investigate the characteristics of patients who underwent CMV antigenemia assay and indirectly contributing factors of CMV infection in immunosuppressed CTD patients in a single center of Japan.

Methods: Medical records of hospitalized CTD patients who underwent CMV antigenemia assays between April 2015 and July 2018 were retrospectively reviewed. Patients were divided into groups with/without CMV antigenemia. Clinical features, basal immunosuppressive therapies, and laboratory data were analyzed.

Results: Overall, 108 patients were enrolled into the study; of these, the positive (group A) and negative (group B) CMV antigenemia groups had 49 and 59 patients, respectively. The underlying CTDs included systemic lupus erythematosus (n=27), anti-neutrophil cytoplasmic antibody-associated vasculitis (n=26), rheumatoid arthritis (n=22), polymyositis/dermatomyositis (n=13), and others (n=20). Glucocorticoid was used in 101 (93.5%) patients, and mean prednisolone dose was 27.1±18.3 mg/day. Pulse glucocorticoid therapy and intravenous cyclophosphamide (IVCY) therapy was administered in 14 (13.0%) and 22 (20.4%) patients, respectively. Group A patients had a significantly higher rate of Charlson Comorbidity Index (CCI) ≥3 (69.4% vs. 30.5%, p<0.001). Mean prednisolone dose was significantly higher in Group A (32.9±15.5 mg/day vs. 22.3±19.0 mg/day, p<0.001). Pulse glucocorticoid therapy (26.5% vs. 1.7%, p<0.001) and IVCY (36.7% vs. 6.8%, p<0.001) were administrated significantly more often to Group A patients than Group B. Multivariate logistic regression analysis revealed CCI ≥3 (odds ratio (OR) =3.21, 95% CI 1.13-9.16) and IVCY therapy (OR=8.89, 95% CI 1.99-39.7) as independent risk factors of CMV antigenemia. The result suggested that pulse glucocorticoid therapy could relate to CMV antigenemia (OR = 9.07, 95% CI 0.96-85.7).

Based on the prediction criteria for CMV antigenemia defined as the presence of one or more contributing factors including CCI ≥3, pulse glucocorticoid therapy, IVCY, and myelosuppression; sensitivity and specificity were 89.8% (95% CI 81.3-98.4) and 44.1% (95% CI 31.4-56.8), respectively. With contributing factors limited to CCI ≥3 and IVCY, sensitivity and specificity became 75.5% (95% CI 63.5-87.5) and 64.4% (95% CI 52.2-76.6), respectively.

Conclusion: Having multiple comorbidities and being on intensive immunosuppressive therapy, such as pulse glucocorticoid therapy and IVCY, were related to CMV antigenemia in CTD patients. The prediction criteria, including CCI ≥3, pulse glucocorticoid therapy, IVCY, and myelosuppression are helpful to clinically rule out CMV infection.

THE PATIENT EXPERIENCE: A PROCESS EVALUATION OF A PILOT PRAGMATIC USING REMOTE MONITORING OF SYMPTOMS

Alexis Ogdie1, Michael George1, Kathleen Bush1, Mitesh Patel1, W. Benjamin Novell1, Joshua Baker1, 1University of Pennsylvania, Philadelphia, PA, United States of America; 2Global Healthy Living Foundation, Upper Nyack, NY, United States of America

Background: Traditional randomized controlled trials (RCTs) are important for testing drug efficacy but this study design is burdensome for patients (pts) and clinicians. Pragmatic trials addressing real world comparative effectiveness are equally important but challenging to conduct. We piloted a trial platform aspiring to optimize the patient experience and minimize patient and physician burden. The trial (NCT02912221) tests an incentive strategy informed by behavioral economics to increase physical activity in pts with rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

Objectives: To understand patient experiences using mobile applications (apps) and wearable activity devices (WAD) in a pilot pragmatic trial

Methods: Pts had RA or PsA with active disease defined by a Routine Assessment of Patient Index Data (RAPID3) score ≥3 (range 0-30). After screening and informed consent, pts received a WAD (Fitbit™) and were asked to set up the device and an Arthritis Tower account, a research registry where pts track patient-reported outcomes (PRO). A web-based platform, WayToHealth, was used to collect WAD data and deliver incentives. After a two-week baseline period, pts selected a daily step goal and were randomized to a financial loss-aversion incentive arm or control. In both arms received weekly text messages reporting the number of days the step goal was met. In-person assessments were conducted at baseline and 14 weeks; pts completed weekly PROs (RAPID3, PROMIS Fatigue, PROMIS Sleep Disturbance and adverse event assessment) via mobile app or a web link. At 14 weeks, pts underwent a semi-structured interview to assess the patient experience in the trial. Content analysis was used to evaluate the responses.

Results: To date, 27 pts completed the 14-week follow-up interview. Mean age was 48 (SD 14), 85% were women, 17 (63%) had PsA and 10 (37%) had RA. Mean disease duration was 9 years, mean swollen joint count (0-66) was 6.2 (SD 5.6) and tender joint count (0-68) was 8.1 (SD 9.1). The mean RAPID3 was 10.3 (SD 4.6). Overall pts enjoyed participation in the study and provided useful feedback for improvement (Table). Weekly PRO capture was acceptable to most but PROs need to be streamlined to remove repetitive questions. Pts frequently set goals they were not able to achieve and suggested the ability to change their goal in future studies.

Conclusion: In this pilot pragmatic trial, only two in-office visits were conducted and all other data captured remotely. Pts enjoyed the experience and found the digital platform easy to use. Such trial designs will become increasingly important in conducting real-world comparative effectiveness and adjunct therapy trials.

Table: Lessons learned from patient perspective in pragmatic trial

<table>
<thead>
<tr>
<th>Trial Format</th>
<th>Pts enjoyed tracking progress</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weekly check ins kept pts accountable</td>
<td></td>
</tr>
<tr>
<td>Most pts completed surveys via a text link (over App or web portal)</td>
<td></td>
</tr>
<tr>
<td>Time to complete surveys was 5 min</td>
<td></td>
</tr>
<tr>
<td>Pts requested a text box to record reasons for not feeling well (e.g., injury, illness)</td>
<td></td>
</tr>
</tbody>
</table>

PROs
| Repetitive questions in the PROMIS measures annoyed pts |
| MDHQ questions were not always relevant |
| Tracking sleep helped understand level of fatigue |
| Emotional wellbeing questions were appreciated |
| Desire to track individual PRO goals |

Wearable Activity Device
| Served as a reminder to move |
| Annoyed by need to charge |
| Creating teams and self-competition was motivating and fun |

Some exercise not captured (e.g., swimming, biking)

Physical activity
| Goals frequently set too high; allow for a goal change |
| Weekly goals may be better than daily goals |
| Weather influenced physical activity; being accountable encouraged exercise indoors |
| Overexertion sometimes lead to pain and stiffness |
| Some reported knee/foot pain with increasing steps |

IGA RF IS ASSOCIATED WITH HIGH AGE OF RHEUMATOID ARTHRITIS ONSET

Eleftheria Pertsinidou1, Lars Klareskog2, Lars Alfredsson3,4, Linda Mathsson1,5, Monika Hansson6, Helga Westerlund7, Johan Askling8, Saedis Saevarsdottir9, Johan Rönnelid1. 

1Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; 2Rheumatology Unit, Karolinska Institute, Department of Medicine Solna, Stockholm, Sweden; 3Karolinska Institute, Institute of Environmental Medicine, Stockholm, Sweden; 4Stockholm County Council, Center for Occupational and Environmental Medicine, Stockholm, Sweden; 5Thermo Fisher Scientific, Uppsala, Sweden; 6Karolinska Institute, Department of Medicine, Solna, Stockholm, Sweden

Background: IgM RF and anti-CCP2 have been shown to associate with young age at RA diagnosis [1, 2]. By contrast, little is known about the association between other RF isotypes and age at onset, or sex.

Objectives: To examine the association between individual RA autoantibodies, sex and age at RA onset.

Methods: Anti-CCP2, IgA-, IgG- and IgM-RF were analysed centrally in baseline sera from 1600 Epidemiological Investigations in RA (EIRA) patients aged 18-70 years and classified according to the 1987 ACR criteria within one year of first symptoms. Cut-offs for RF isotypes were determined at the 98th percentile based on the EIRA RA-free controls, close to the 98.4% anti-CCP2 specificity.

Results: Anti-CCP2, IgA-, IgG- and IgM RF were found in 1020 (64%), 692 (43%), 529 (33%), and 916 (57%), of the patients, respectively. Mean (median) age at diagnosis among men was 54 (57) year, higher than 51 (54) years among women (p<0.0001). The figure shows the autoantibody distribution in relation to sex and age tertiles. In univariate analysis, anti-CCP2 and IgM RF were both associated with lower age at RA diagnosis (table). When occurrence of all four autoantibodies were compared simultaneously as independent variables and with age at diagnosis as dependent variable in multiple regression, a strong association between IgA RF and higher age at RA diagnosis appeared, and the association between IgM RF and low age at RA diagnosis weakened (table). IgA RF and IgG RF associated with male sex, but IgM RF with female sex. No sex-difference was seen for anti-CCP2 (table). When the multiple regression was adjusted for sex, the association between IgM RF and age disappeared, whereas the strong associations between IgA RF and high age and between anti-CCP2 and low age at diagnosis persisted (table).

Conclusion: On average, IgA RF positive (vs. negative) RA patients are almost four years older at the time of diagnosis; the opposite was found for anti-CCP2 and IgM RF. Whereas sex-differences explain the age-association for IgM RF, this is not the case for anti-CCP2 and for IgA RF.

AB1286  EVALUATION OF CARDIOVASCULAR RISK FACTORS AND PREVALENCE OF METABOLIC SYNDROME IN PATIENTS WITH DIAGNOSIS OF ANKYLOSING SPONDYLITIS:

Severino Correia Do Prado Neto1, Érika Carvalho de Aquino2, Jozeilia Rêgo2, Nílizo Da Silva1, Fabiana Pin11, Hospital das Clínicas de Goiânia – Universidade Federal de Goiás, Goiânia, Brazil; 2Universidade Federal de Goiás, Goiânia, Brazil

Background: Cardiovascular events are the main causes of mortality in patients with Ankylosing Spondylitis. In addition, a higher prevalence of Metabolic Syndrome is reported in this group. With immunobiological therapy, much progress has been made in controlling the inflammatory process, but the cardiovascular risk remains high.

Objectives: To evaluate the prevalence of cardiovascular risk factors and Metabolic Syndrome in patients with Ankylosing Spondylitis at the Rheumatology Outpatient Clinic of HC-UFG and to correlate them with epidemiological, clinical, laboratory and radiographic characteristics of the disease.

Methods: Data from 59 patients were collected in medical records between July and August 2018. Clinical characteristics, cardiovascular risk factors and metabolic components were analyzed. Descriptive analyzes of the data were made, prevalences and their reasons were calculated. The associations between variables were assessed by chi-square test and Fisher’s exact test.

Results: 81.4% were male, 67.8% self-denominated non-whites, average age 46.7 years. Isolated axial joint involvement was the most frequently observed (54.2%). Enthesopathic lesions were identified in 30.51% of the cases. Uveitis had a higher prevalence (22.02%), 4.2 times higher in the subgroup with HLA-B27 positive (p=0.0002). HLA-B27 was present in 67.8%. Advanced sacroiliitis (grades 3 and 4) and syndesmophytosis were identified in 61.1% and 49.2%, respectively, but didn’t present significant correlation with the presence of HLA-B27. 64.4% were using anti-TNF alone or in combination. The majority of the patients (72.9%) were sedentary. Clinical comorbidities were reported in 66.1% of the cases, with dyslipidemia (45.8%), systemic arterial hypertension (37.6%) and diabetes mellitus (13.6%) being the most common. Metabolic Syndrome was diagnosed in 23.7% of the samples. Normal levels of triglycerides and fasting glycemia and lower prevalence of Metabolic Syndrome had a statistically significant association with the presence of HLA-B27 (p=0.006; 0.026 and 0.014, respectively). Patients with HLA-B27 present had 61% lower frequency of Metabolic Syndrome. There was no association between the syndrome and its components with anti-TNF therapy; BASDAI; BASFI; metric evaluation; uveitis; degree of sacroiliitis and syndesmophytosis.

Conclusions: The prevalence of Metabolic Syndrome was below that is described in other populations. The presence of HLA-B27 was considered a protective factor for Metabolic Syndrome, triglyceride levels and fasting glycemia. This finding may be related to the presence of several HLA-B27 alleles, usually non-subtyped, and to the great ethnic miscegenation of the Brazilian population. Our observation suggests that spondylitics should be routinely evaluated for cardiovascular risk factors.

AB1287  DISEASE EVOLUTION OF PRIMARY SJOGREN’S SYNDROME – A LONGITUDINAL STUDY

Inês Reis de Figueiredo1, Jessica Tam2, Dennis Lendrem2, Josephine Vila3, Elizabeth Kidd4, Julie Norris5, Ben Hargreaves6, Wan Fai Ng7,8,11, Universidade de Doencas Auto-Imunes/Medicina 7.2, Hospital de Curit Cabral, Centro Hospitalar Universitário Lisboa Central (CHULC), Lisboa, Portugal; 7Macclesfield Research Group, Institute of Cellular Medicine, Newcastle University, Newcastle-Upon-Tyne, United Kingdom; 8Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Newcastle-Upon-Tyne, United Kingdom

Background: The natural history of primary Sjögren’s syndrome (pSS) remains poorly understood. It has been suggested that the initial presentations may predict the course of disease (1), with gradual reduction of biological activity as measured by serum Immunoglobulins levels (2), while symptoms such as fatigue remaining stable over time(3).

Objectives: To evaluate how pSS progresses over time using ESSDAI (Eular Sjögren’s Syndrome Disease Activity Index) and the ESSPRI (Eular Sjögren’s Syndrome Patient Index), ECO2-Time trade off (TTO) and Visual Analogue Scale (VAS) of health states.

Methods: Routine clinical data from a large single centre cohort in the UK were analysed on patients with ≥3 clinical visits, including up to the 10th visit. Outcomes (ESSDAI/ESSPRI and their component scores, ECO2-3L and VAS) were analyzed by a random effects linear regression using STATA 14.

Results: 346 patients out of 856 included, with a female preponderance of 89%, and median age of 63 years. The median follow up time was 4.9 years, and median disease duration of 12 years. Anti-Ro was positive in 61%, and anti-La in 42% of the patients. ESSDAI score decreased 0.1 point per visit (p=0.006). Anti-Ro and anti-La positive patients exhibiting a lower score (p=0.012 and 0.031), and patients with MALT at presentation had a score up to 6 points higher (p= 0.002). Regarding the ESSDAI domains, the constitutional and haematological domains showed increased activity (p-values<0.0001 and 0.018), with Anti-Ro and/or Anti-La patients having higher scores (p<0.0001 and 0.001). In contrast, the glandular, articular and peripheral nervous system domains showed decreases over time (p-values 0.003, 0.006 and <0.0001). ESSPRI score increased 0.05 point/visit (p<0.0001). While Dryness scores remained relatively constant, Pain and Fatigue components of the ESSPRI increased over time (both p<0.0001). Dryness scores were higher in female patients (p=0.04). ECO2-TTO worsened by 0.03 point/visit (p<0.0001), but the VAS health states remained stable.

Conclusion: Our data suggest that symptoms of fatigue and pain as well as health utility worsen over time, whereas different ESSDAI domains showed different trends over time. Longer term follow-up to further understand the natural history of pSS is warranted.

AB1288  PREVENTION OF VENOUS THROMBOEMBOLISM AND THE RISK OF POSTOPERATIVE COMPLICATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER TOTAL HIP ARTHROPLASTY:

Alexey Rubnikov1, Evgenii Bialik2, Tatiana Reshetnya2, Sergey Makarov2, Alexander Khramov2, Sergey Maglevaniy2, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 3Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: According to the administrative data, confirmed by several meta-analyses, patients with rheumatoid arthritis (RA) in comparison with the General population shows an increased risk of venous thromboembolic complications more than twice. Drug prevention can reduce the risk of venous thromboembolism (VTE) in patients with rheumatic diseases.

Objectives: The aim of this study was to analyze frequency of VTE, risk of bleeding and complications of the postoperative wound in patients with RA and osteoarthritis (OA) who underwent primary THA. Each group of patients was divided into 3 subgroups by type of drug therapy (1-nadroparin calcium; 2-dabigatran etexilate; 3-nadroparin calcium with transfer to dabigatran etexilate).

Methods: Study included 486 patients (212 - with RA and 274 - with OA) who underwent primary THA. Each group of patients was divided into 3 subgroups by type of drug therapy (1-nadroparin calcium; 2-dabigatran etexilate; 3-nadroparin calcium with transfer to dabigatran etexilate). Intra-and postoperative blood loss and the wound healing process were assessed during the first 7 days after surgery.

Results: Postoperative VTE were reported in 36 (7.4%) of 486 patients. VTE in patients with RA were detected significantly less frequently than in OA (1.2% and 6.1%, p = 0.0013). Bleeding that required transfusion
of blood in RA were found significantly more often than in OA (respectively 14.4% and 5.7% of cases; P<0.001). The number of cases requiring cancellation of anti-coagulant therapy in patients with RA was significantly higher compared with the OA group (6.4% and 1.4%, respectively). Slow wound healing in RA was more common (n = 56; 26.4%) than in OA (n = 14; 5.1%). In patients who underwent monotherapy with calcium nadroparin VTE occurred more often than when using combination therapy (p<0.0001) and more often than in the group of dabigatran etexilate (p = 0.054).

Conclusion: The frequency of VTE, the risk of bleeding and complications of postoperative wound in patients with RA and OA after THA were analyzed. So, our study determined the dependence of VTE complications and bleeding risk according to the patient's underlying nosology. Also the advantage of combined postoperative therapy over others was evaluated.

Disclosure of Interests: None declared

Results: Among 64 patients included a musculoskeletal syndrome was detected in 46 patients (71.8%), whereas diffuse muscle pain was observed in 42 (65.6%) patients, and 83% of them had associated arthritis. Serological, imaging and clinical findings suggested more frequently a seronegative arthritis, whereas few patients developed rheumatoid arthritis and arthritis secondary to a connective tissue disease. A direct correlation between pre-existing autoimmune disease and pain symptoms before cancer diagnosis and risk of developing arthritis under AI therapy was observed. Mean vitamin D levels were significantly lower in patients with diffuse myalgia compared to patients with no diffuse myalgia (11.2±5.8 versus 29.5±10.8 ng/ml; t-test p < 0.0001), suggesting a potential involvement of vitamin D deficiency in diffuse muscle pain.

Conclusion: The etiology of AI-associated pain syndrome remain unknown, but clinical, serological, imaging data may be useful to identify the true origin of the musculoskeletal syndrome, as well as a detailed anamnestic history may be useful to identify autoimmune predisposing factors. Myalgias and generalized weakness are likely associated with hypovitaminosis D and might be misdiagnosed as fibromyalgia. The management of these patients should become a multispecialistic task.

AB1291 ASSOCIATION OF CCL2 GENE POLYMORPHISMS AND THEIR SERUM LEVELS WITH SUSCEPTIBILITY TO KNEE OSTEOARTHRITIS

Amar Chandra Sharma, Rajeswar Nath Srivastava, Sudeep Srilvastava, Saloni Raj, Indian Institute Of Toxicology Research, Ghertu Campus, Develomental Toxicology Division, Lucknow, India

Background: Osteoarthritis (OA) is one of the most depleting chronic disorders and its pathogenesis is yet to be unfold. It is characterized by pain, swelling, stiffness, decreased ability to move and, sometimes, the formation of bone spurs. Knee Osteoarthritis (KOA) is multifactorial and remains largely understudied at molecular level. The available literature suggested that the development, onset and progression of OA is significantly affected by genetic factors. Chemokines are small, secreted proteins that released from chondrocytes and synovial fibroblasts of KOA patients. In this case control study, we investigated the possible association between promoter polymorphisms rs1024611 and the polymorphism rs4586 in exon 2 of the chemokine (C–C motif) ligand 2 (CCL2) gene and knee OA.

Objectives: To investigate the possible association between promoter polymorphisms rs1024611 and the polymorphism rs4586 in exon 2 of the CCL2 gene and KOA.

Methods: DNA was obtained from 300 primary knee OA patients and 300 healthy controls. CCL2 genomic variants (rs1024611 and rs4586 polymorphisms) were detected by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP). In addition, the effect of serum levels of rs1024611 and rs4586 on lesions and controls were examined by enzyme-linked immunosorbent assay (ELISA).

Results: The rs1024611 A/G promoter polymorphism was associated with KOA [genotype frequency, p= 0.007; allele frequency, p= 0.01]. Significant association was observed between the G carrier of the rs1024611 A/G promoter polymorphism and primary knee OA patients (p=0.01). However, no significant difference was found in the rs4586 polymorphism. Haplotype type frequency analysis revealed a significant difference (x²= 8.01, p=0.02). The CCL2 serum levels of subject with the G carrier (285.0 ± 86.5 pg/mL) of the rs1024611 A/G promoter polymorphism was statistically higher than that of subjects with the non-G carrier (160.5±47.8 pg/mL). Further in relation with clinical severity of KOA, we observed significant association of the G carrier of the rs1024611 A/G promoter polymorphism with both Visual analogue scale (VAS) (p<0.01) and Western Ontario and McMaster Universities (WOMAC) score (p<0.05).

Conclusion: The G carrier of the rs1024611 A/G promoter polymorphism was found to be associated with primary knee OA, and could be a susceptibility factor in the development of primary knee OA in the North Indian population.

AB1292 PREVALENCE OF VITAMIN D DEFICIENCY AND ITS ASSOCIATED FACTORS AMONG RHEUMATOID ARTHRITIS PATIENTS MANAGED IN A RHEUMATOLOGY UNIT OF A TERTIARY CARE HOSPITAL IN SRI LANKA

sethuyi silva1, Gunendrika Kasthuriartha2, Buddhika Mahesh3, Janalini Sashikaran1,2, College of Specialists in Rheumatology and Rehabilitation – Sri Lanka, colombo, Sri Lanka; 3College of Specialists in Rheumatology and Rehabilitation – Sri Lanka, colombo, Sri Lanka; 1University of Melbourne, Melbourne, Australia

Background: Prevalence of unrecognized vitamin D deficiency can be high among Rheumatoid Arthritis (RA) patients. Lack of mobility among these patients prevent them receiving adequate sun exposure. Low levels of vitamin D could potentially cause a higher disease burden and disease activity.

Objectives: To determine the prevalence of vitamin D deficiency and its associated factors among RA patients managed in a rheumatology unit of National Hospital of Sri Lanka (NHSL).

Methods: A descriptive cross-sectional study was done among patients with RA with a calculated sample size of 137. Being diagnosed according to ACR – EULAR criteria and availability of serum vitamin D level were among the inclusion criteria. Patients with disability due to causes other than RA were excluded. All patients satisfying the eligibility criteria were invited to be recruited. A data extraction sheet was utilized. Data was collected by investigators. The associations were evaluated with Chi square test and Spearman correlation coefficient at a significance level of 5%. Ethics approval was obtained from ethics committee of NHSL.

Results: The response rate was 92%. The median (IQR) age of participants’ were 56.5 (49.0 to 64.25). Among participants, majority (n=117, 92.9%) was females. Only 11.1% (n=14) had normal vitamin D levels. The insufficient and deficient categories comprised of 38.1% (n=48) and 50.8% (n=64). The commonest symptoms included; joint pain (n=101,80.2%), fatigue (n=84,66.7%) and muscle pain (n=78,61.9%). Deficiency or insufficiency was lowest in the occupation category of “agricultural and labourer” (37.5%) while 100% in many indoor-occupied categories and among Muslims. “Deficiency or insufficiency” was significantly associated with muscle pain (p<0.001) but not with CDAI (p=0.896), fatigue (p=0.549), joint pain (p=0.735).

Conclusion: Vitamin D “deficiency or insufficiency” is common among patients with RA and commoner in the sub-categories with muscle pain and with restricted sun-exposure. More research must be promoted in this regard.

AB1293

SMAD3 GENE POLYMORPHISMS AND EXPRESSION IN SERUM AND CARTILAGE INFLUENCE THE RISK OF KNEE OSTEOARTHRITIS

Rajeswar Nath Srivastava, Amar Chandra Sharma, Sudeepit Srivastava, Saloni Raj, King George’s Medical University, orthopaedic sugery, Lucknow, India

Background: Knee Osteoarthritis (KO A) is the most common degenerative arthritis, a type of arthritis that is caused by breakdown of articular cartilage with eventual loss of the cartilage of the joints. Smad3 is a key intracellular messenger in the transforming growth factor β signaling pathway. Previous study suggested Smad3 gene mutation is a possible predisposing factor for human OA and found gene mutation in OA, providing insight into the function of SMAD3 mediated TGF-β signals in the development of OA and also suggested that Smad3 gene mutation may be a risk factor for genetic susceptibilities to OA. In this case control study, we investigated the possible correlation between the SNPs Smad3 (rs6494629, FokI; A/C; rs2289263) in Smad3 gene and susceptibility to OA and validated in serum and cartilage.

Objectives: To investigate the possible association between SNPs (rs6494629 and rs2289263) of the Smad3 gene and KOA.

Methods: In this study cases consisted of men and women >40 years that fulfilled American College of Rheumatology (ACR) clinical and radiographic criteria for knee OA. Venous blood samples were obtained from all cases as well as controls for genetic analysis. Polymerase chain reactions were performed for SNP analysis using specific primer. Total protein was measured in serum by an enzyme linked immunosorbsent assay according to the manufacturer’s Protocol (ELISA) and in cartilage tissue done by western blot.

Results: A total of 200 cases that confirmed radiographic knee OA and equal number of age and sex matched healthy controls were enrolled. There was no significant difference in demographic characteristics between the cases and controls. A SNP (rs6494629 and rs2289263) mapping to intron 1 of SMAD3 was associated with knee OA (P < 0.013 and P < 0.044, respectively). Within the SNPs (rs6494629) of Smad3 gene, genotype CC and CT was found to be significantly (p<0.013) associated with knee OA as compared with the CC genotype and SNP rs2289263 genotype CC and CA was found to be significantly (p<0.044) associated with knee OA as compared with the AA genotype. In addition when alleles were compared, C allele of both the studied SNP was observed to be significantly associated with knee OA. Serum levels of Smad3 in KOA patients with rs6494629 TT, CT and CC genotypes were significantly higher than healthy subjects with the same rs6494629C/CT genotypes (all P < 0.001, P < 0.0006, P < 0.017 respectively). Increased serum levels of Smad3 were also observed in KOA patients with rs2289263 AA, CA and CC genotypes compared to controls (all P < 0.006, P < 0.0006, P<0.004). We performed Immunoblot analysis on cartilage tissue from 15 cases and 10 controls. The Smad3 level in cases was significantly higher than controls (P < 0.006).

Conclusion: Our data indicate that genetic variation in the SMAD3 gene is involved in the risk of knee OA in North Indian populations, confirming the results from previous studies on the potential importance of this gene in the pathogenesis of OA. Further we also validated these genetic variations at protein level in both blood and tissue and found significant association.

IMPACT OF INFERTILITY, PREGNANCY LOSS AND CHILDBEARING DECISION ON FAMILY SIZE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

Dayang Masyiniarde Suahal1, Nurulrozaiqin Mohd Jamid1, Noraini Mat Husin2, Hailui Hadi Aditi1, Rashidah Bahari3, Nor Shuhailah Shahin1, 1Hospital Putrajaya, Medicine, Putrajaya, Malaysia; 2Hospital Raja Permaisuri Bainun, Ipoh, Medicine, Ipoh, Malaysia; 3Hospital Putrajaya, Clinical Research Centre, Putrajaya, Malaysia

Background: Systemic lupus erythematous (SLE) and Rheumatoid Arthritis (RA) often affects women in their reproductive years. These women are faced with a life-long illness that may have considerable impact not only on their physical health, but also on their reproductive potential. Fertility of these women may also be affected by the disease, treatment and/or organ damage.

Objectives: To determine the role of infertility, pregnancy loss and childbearing decision and patients concerns on family size in women with SLE and RA.

Methods: A cross sectional study using a self-administered reproductive history questionnaire completed by women with SLE/RA attending Rheumatology clinic follow up in Hospital Putrajaya, Hospital Tengku Ampuan Rahimah, and Hospital Raja Permaisuri Bainun, Malaysia from 1 January 2017 to 30 June 2017.

Within each disease cohort, women were identified into 3 groups, those with fewer children than planned (group A), those with same number of planned children (group B) and those with completed family or not interested in having any children (group C). Data on number of child, pregnancies, miscarriages and self reported infertility were recorded.

For group A, data on patient concerns and the factors that could impact family building were also obtained.

Results: Total of 110 women with SLE and 91 women with RA were surveyed. The mean age of women with SLE and RA were 37.6 years (+/- SD 7.4) and 45.37 years (+/- SD 11.7) respectively. Majority of women (48.8%) with SLE and RA were in group A with 59% (n=65) of women with SLE and 33% (n=33) of women with RA had fewer children than originally planned. The average numbers of pregnancies were similar in both cohorts, but women with SLE had less child and were more likely to report infertility and had higher rate of miscarriages (Table 1). SLE group A had a similar number of pregnancies, but 1 less child compared to SLE group B and C (Table 2). Similarly, among women with RA, group A had 1 less child with similar number pregnancies and miscarriage rate (Table 2). In both groups of women, concerns about inability to care for a child, damage from medications, and genetic transmission of their disease were associated with a lower pregnancy rate.

Table 1. Numbers of pregnancy, live births, miscarriages and rate of infertility among women with SLE and RA

</tr>
</tbody>
</table>

*values are the mean +/- SD unless otherwise indicated

Conclusion: In this population, more than half of women with RA or SLE had fewer children than desired. Other than patient choice, infertility and miscarriage also play an important role on family size.
DISCREPANCIES BETWEEN THE RHEUMATOID ARTHRITIS PATIENT POPULATION IN RANDOMIZED CONTROLLED TRIALS OF BILOGICS AND THAT IN REAL-WORLD SETTINGS: A STUDY USING THE IORRA COHORT

Eri Sugano1, Eiichi Tanaka2, Eisuke Inoue1, Mai Abe1, Mika Kawano3, Rei Yamaguchi1, Naoki Sugimoto1, Katsunori Ikari4, Ayako Nakajima1, Atsuo Taniguchi5, Hitomi Yamanaka6, Sanae Okumura1, Hiroshi Taniguchi1,2, Letizia Rumiantsjeva1,2, Masaaki Kawano1, Ayako Sugano1, Eiichi Tanaka1, Eisuke Inoue1, Mai Abe1, Mika Kawano1, Reymundo Solone1, Chugai Pharmaceutical, Daiichi Sankyo Co., Eisai Pharmaceutical, Janssen Pharmaceutical K.K., Nilsson Pharmaceutical, Pfizer, Teikyo University Hospital, Center for Rheumatic Diseases, Mie, Japan

Background: Randomized controlled trials (RCTs), which are currently considered to provide the highest level of evidence, include patients with high disease activity and exclude those with comorbidities often seen in real-world settings. With the increasing recognition of the importance of real-world evidence, attention is being given to discrepancies between RCT-based evidence and the patient population in routine clinical practice; however, few reports addressing these gaps in the context of rheumatoid arthritis (RA) are available.

Objectives: To evaluate the proportion of patients meeting the inclusion criteria in RCTs of biologics for the treatment of RA conducted in Japan using the real-world IORRA cohort.

Methods: The inclusion criteria used in Phase 2 or Phase 3 RCTs of the following biological DMARDs (bDMARDs) were extracted: infliximab (IFX), etanercept (ETN), adalimumab (ADA), golimumab (GLM), certolizumab (CZP), abatacept (ABT), tocilizumab (TCZ), and infliximab (IFX-BS). Patients participating in the IORRA study during the period when each RCT was conducted (Cohort A) and those who initiated treatment with each bDMARD at our institute in 2016 (Cohort B) were included in the analysis. The proportion of RA patients in Cohorts A and B who met the RCT inclusion criteria was assessed.

Results: A total of 19 RCTs were conducted in Japan (IFX: 2; ETN: 1; ADA: 2; GLM: 2; CZP: 3; ABT: 2; TCZ: 6; IFX-BS: 1). Key trial inclusion criteria were age, RA duration, tender joint count (TJC), swollen joint count (SJC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), methotrexate (MTX) use, corticosteroid use, and prior bDMARD therapy. The number of patients participating in the IORRA analysis during the period when each RCT was conducted ranged from 1,777 to 6,843 (mean = 5,470) (Cohort A). The median/average [range] proportion of RA patients meeting all RCT inclusion criteria was 0% [0.0–23%] [range: 0.0–16.2%]. The proportion by criterion was 93.9%/92.4% [59.7–99.9%] for age, 68.9%/57.1% [9.0–96.6%] for RA duration, 11.6%/16.0% [4.5–33.0%] for SJC, 14.6%/17.2% [3.7–33.9%] for TJC, 27.8%/32.1% [20.1–49.8%] for CRP, 60.2%/58.7% [43.7–66.8%] for ESR, 14.8%/40.6% [13.1–73.9%] for MTX use, 95.9%/99.3% [98.5–99.8%] for prednisolone (PSL) use, and 91.9%/92.0% [85.6–98.0%] for prior bDMARD use. In Cohort A, the proportion of RA patients meeting the RCT inclusion criteria was low, particularly with respect to SJC, TJC, and MTX use. Among 337 patients who initiated bDMARD therapy at our institute in 2016, a total of 139 biologic-naïve patients (IFX, 3; ETN, 33; ADA, 11; GLM, 21; CZP, 17; ABT, 25; TCZ, 28; IFX-BS, 1) were included in the analysis (Cohort B). In Cohort B, the median/average [range] proportion of RA patients meeting all RCT inclusion criteria was 0.0%/2.3% [range: 0.0–16.2%]. The proportion by criterion was 99.8%/99.1% [94.1–100%] for age, 20.8%/26.5% [0.0–57.1%] for SJC, 11.8%/17.0% [0.0–50.0%] for TJC, 33.3%/34.9% [0.0–66.7%] for CRP, 58.3%/57.3% [0.0–75.0%] for ESR, 23.5%/35.5% [0.0–100%] for MTX use, and 100%/100 [100% for PSL use. As in Cohort A, the proportion of RA patients meeting the inclusion criteria was low in Cohort B, particularly with respect to SJC, TJC, and MTX.

Conclusion: It is important to note that evidence from RCTs of bDMARDs is based on a limited RA population in real-world settings.

PREGNANCY IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: MATERNAL AND FETAL COMPLICATIONS

Tatiana Kiseleva1, Olga Tsatsulina2, Elizaveta Rumyantseva2, Maria Vinogradova1, Tatiana Fedorova3, Nina Rozina3, Elizaveta Rumyantseva2,2, Federal State Budget Institution “Research Center for Obstetrics, Gynecology and Perinatology”, Moscow, Russian Federation;3Moscow State University, Fundamental Medicine, Moscow, Russian Federation

Background: Systemic lupus erythematosus is a chronic autoimmune disease often affecting women in fertile age. The physiological changes in T-regulators (Th1/Th2) activity during pregnancy can cause SLE flare. Women with SLE are at high risk for maternal and fetal complications. The high SLE activity is associated with higher risk of PE and lower birth weight, compared with population controls. Nevertheless, no detailed analysis of the relationship between clinical features/laboratory parameters and unfavorable pregnancy outcome in patients with SLE has been carried out in the recent studies.

Objectives: This study aimed to analyze influence of SLE activity, laboratory parameters and medications on risk of maternal and fetal complications.

Methods: A retrospective single-center cohort study 11/2014-12/2018: 43 pregnancies in 42 patients with proved SLE and > 20 weeks of gestation, mean age was 31.5 years. Renal function at conception and after delivery, pregnancy outcomes, clinical and laboratory parameters were collected. PE was diagnosed by the WHO 2008 criteria. The sPT/PF/F ratio was used as the main differential marker to exclude lupus nephritis exacerbation in cases of increased proteinuria. All patients and their newborns were analyzed for hemoglobin and platelet levels, glomerular filtration rate, serum creatinine, AST, ALT, fibrinogen, D-dimer, aPTT antinuclear factor and antiphospholipid antibodies concentrations, the using/non-use of glucocorticoids, hydroxyclochloquine, low molecular weight heparins and aspirin were analyzed as potential risk factors of unfavorable pregnancy outcomes: PE, premature delivery, low birth weight, low Apgar score at 1 and 5 minutes after birth.

Results: In 12 cases (27.9%) there was no activity of SLE, in 16 cases (37.2%) there was low activity, in five (11.6%) – moderate, in three (7%) – high, in seven cases (16.3%) SLE activity was not assessed. SLE activity showed significant negative correlation with week at which labor occurred (p = 0.003, R = –0.477) and birth weight (p = 0.005, R = –0.461) and we found a significant fivefold increase in preeclampsia in patients with high activity of SLE (p = 0.011, OR = 4.95, 95% CI 1.449 to 16.931). Hemoglobin levels in third trimester correlated positively with birth weight (p = 0.04, R = 0.322). The dosage of glucocorticoids showed a significant correlation with week of delivery (p = 0.011, R = –0.382). Interestingly, the increase of aPTT in the third trimester had an almost significant effect on the risk of developing PE (p = 0.059, OR = 1.237, 95% CI 0.958–1.596). Unfortunately, lupus anticoagulant (LA) at that moment was not measured. Other studied parameters were not associated with risk of PE.

Conclusion: High SLE activity significantly increases the risk of gestational complications and unfavorable pregnancy outcomes. We suggest that regular monitoring of antiphospholipid antibodies, especially LA is needed. In this study, laboratory parameters did not significantly affect the risk of PE.

**AB1297 CARDIOVASCULAR EVENT AND RISK FACTORS IN PRIMARY SJÖGREN’S SYNDROME FROM LATIN-AMERICAN COHORT**

Valeria Valim1, Gabriela Hernandez-Molina2, Virginia Fernandes Moça Trevisani1, Maria Lúcia Lemos Lopes3, Ayesa Cesar Pinheiro4, Anastasia Secco5, Sabrina Zanardi Machado1, Samira Tatyma Miyamoto1, Patricia Sasaki6, Antonio Catalán-Pelleff1. Study Group on Sjögren’s Syndrome of PANLAR.

1University Federal do Espírito Santo, Vitória, Brazil; 2University Federal de Pernambuco, Recife, Brazil; 3University Federal de São Paulo and University de Santo Amaro, São Paulo, Brazil; 4Hospital Imandade da Santa Casa de Misericórdia do Porto Alegre and Universidade Federal do Porto Alegre, Porto Alegre, Brazil; 5University Federal de Pernambuco, Pernambuco, Brazil; and 6Hospital B. Rivotavida, Caba, Argentina

**Background:** Inflammation has been associated with higher cardiovascular risk in rheumatic autoimmune diseases. Primary Sjögren’s syndrome (pSS) is associated with increased cardiovascular morbidity1. However, few and controversial data on the prevalence of cardiovascular events in pSS have been reported2-3 with no data regarding on Latin-American pSS patients.

**Objectives:** To assess the cardiovascular event and to evaluate its association with traditional and disease associated risk factors in pSS.

**Methods:** We included 455 patients with pSS according to AECG 2002 or AOR-EULAR 2016 classification criteria, attending tertiary referral centers from Brazil (n=183), Mexico (n=236) and Argentina (n=36). We retrospectively registered demographics, disease duration, cardiovascular event (CE) (coronary heart disease, cerebrovascular accident, peripheral arterial disease), smoking, and use of prednisone (PDN), immunosuppressors and antimalarials. We evaluated traditional risk factors and scored the ESSDAI, ESSPRI and SSDDI at last follow-up.

Pottot5, Thalies B. Clemente5, Eman S. Magalhães1, Marcela M. Thebae5, Olindo Assis Martins Filho5,1, UFES, Vitória, Brazil; 2Fiocruz, Rio de Janeiro, Brazil; 3FioCruz, Belo Horizonte, Brazil; 4EMESCAM, Vitória, Brazil; and 5FioCruz, Vitória, Brazil

**Disclosure of Interests:** SORES, Vitória, Brazil

**Background:** Vaccines should be used with caution in autoimmune diseases (AID).1

**Objectives:** To evaluate prospectively adverse events and efficacy of the Yellow Fever vaccine in patients with AID.

**Methods:** Prospective study, including 190 individuals, 47 with Rheumatoid Arthritis (RA), 36 primary Sjögren’s Syndrome (SS), 48 Ankylosing Spondylitis (AS), 8 Systemic Sclerosis (SSc), and 24 Systemic Lupus Erythematosus (SLE), and 29 Healthy Controls (HC). All individuals received 17DD YF vaccine, for the first time during the 2017 Brazilian Campaign, aged ≥ 18 years, had no or low disease activity, low immunosuppression. Exclusion Criteria: previous vaccination for yellow fever or PRNT > 1:50 at baseline, primary or secondary immunodeficiency, under treatment with cyclophosphamide, chlorambucil, mycophenolate mofetil, calcineurin inhibitors, azathioprine> 2mg/kg/day, prednisone> 20mg/day, methotrexate> 20mg/week or any immunobiological drug. Viremia (CRP) and plaque reduction neutralization test (PRNT; GeoMean title) were measured before (D0) and D3, D4, D5, D6, D7, D14, D28 after vaccine. Adverse events (AE) were registered through patient report diary and medical interview at D7, D14 and D28.

**Results:** Mean age was 52 years old for AID and 56 for HC. No serious adverse event was reported. However, mild local AE was more reported in AID as compared to HC (34.2% vs. 3.4%, p=0.000). The frequency of AE was higher in AID compared to HC (34.1% vs. 3.4%). The Risk (Odds Ratio; 95%CI) for AE was 14.53 (1.9-109.7, p=0.000) and AID subgroups: AS=14.5 (1.9-116.2, p=0.0016), SLE= 15.5 (5.7-43.6, p<0.001). Viremia was slightly late and low in AID (D6=5.6 x 10 3) compared to HC (D5= 8.3 x 10 3). Seropositivity rates were lower in AID after 28 days (78% vs. 96%, p=0.04) as well as in HC (72% (p=0.02) and SLE (73%, p=0.03) compared to HC (Figure 1). Viremia was slightly late and low in AID (D6=5.6 x 10 3) compared to HC (D5= 8.3 x 10 3). Seropositivity was statistically lower at D14 in AID as compared to HC (21% vs. 75%, p=0.04) and remained lower at D28 in AS and SLE subgroups.

**Conclusion:** Efficacy was lower in AID, especially in SLE and AS, in spite of viremia peak at D5-D6 similar to HC. Taking together, results suggest that YF vaccine is safe in AID with low disease activity and under low immunosuppression, but probably a booster dose should be necessary.

AN ONGOING ANTICENTROMERE ANTIBODY RESPONSE ASSOCIATES WITH PROGRESSION TOWARDS SYSTEMIC SCLEROSIS

Nina van Leeuwen1, Maaike Boonstra1, Jaap Bakker1, Corrie Wortel1, Hans Ulrich Scherer1, Rene Toes1, Thomas Huizinga1, Jeska de Vries-Bouwstra1, Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Leiden, Clinical chemistry, Leiden, Netherlands

Background: Although some dated studies suggest a possible association between clinical characteristics and isotypes of antcentromere antibodies (ACA) in patients with systemic sclerosis (SSc), characteristics of ACA have not been described thoroughly in SSc.

Objectives: 1. Describe characteristics of antcentromere antibody (ACA) response in a large cohort of SSc patients. 2. Evaluate differences between ACA response between SSc patients fulfilling ACR 2013 criteria and those with very early diagnosis of SSc (VEDOSS).

Methods: ACA IgG, IgM and IgA levels were assessed in serum samples of patients visiting the Leiden SSc care pathway and who were IgG ACA+ at baseline. Patients had to fulfill either the ACR criteria or the VEDOSS criteria. Differences in isotype expression and levels between the two groups were evaluated, also with stratification for disease duration. Furthermore, in the SSc group we determined correlations between isotypes and disease duration and evaluated if isotype positivity was associated with clinical manifestations.

Results: ACA characteristics were measured in 167 ACA IgG+ patients. Thirty-five patients (21%) fulfilled the VEDOSS criteria and 132 (79%) the ACR criteria. ACA IgG+ patients displayed a broad isotype usage with 75% being ACA IgA+ and 66% being ACA IgM+ in serum. Patients within the SSc group showed higher ACA IgG levels and a higher percentage of ACA IgM positivity compared to the VEDOSS patients. Notably, these findings remained valid after stratification for disease duration, demonstrating that VEDOSS patients that did not progress to SSc within at least 5 years had lower ACA IgG levels and were less frequently positive for ACA IgM. In the SSc group, moderate correlations between isotypes were found; ACA IgM positivity was associated with occurrence of digital ulcers (p=0.02).

Figure 1

Conclusion: We observe a clear difference in the quality of the centro-mere-specific immune response between VEDOSS patients and SSc patients, also when stratifying for disease duration. The higher ACA IgG levels and presence of ACA IgM in SSc patients indicates that the ACA response in SSc is more pronounced showing signs of ongoing activity. These data indicate that the ACA B cell response is potentially relevant in disease development. In addition, ACA isotype expression and ACA IgG levels might contribute to better identify VEDOSS patients at risk for SSc development.

AUTOIMMUNE/INFLAMMATORY SYNDROME INDUCED BY ADJUVANTS DUE TO SILICONE BREAST IMPLANT AND RHEUMATIC DISEASES:

Olya Lidia Vera Lastra1, Maria del Pilar Cruz Dominguez1, Luis Javier Jarac, Gabriel Medrano Ramirez1, 1Unidad Medica de Alta Especialidad Hospital de Especialidades Dr Antonio Fraga Mouret Centro Medico Nacional La Raza, Internal Medicine, Mexico City, Mexico; 2Unidad Medica de Alta Especialidad Hospital de Especialidades Dr Antonio Fraga Mouret Centro Medico Nacional La Raza, Direccion de investigacion y educacion, Mexico City, Mexico; 3Hospital General de Mexico, Rheumatology, Mexico City, Mexico

Background: Silicone is considered biologically inert; thus it has been employed in many medical devices and nowadays is commonly used in plastic surgery for mammary prosthesis. The most common adverse reaction after silicone breast implant (SBI) is capsular contracture due to a foreign body reaction. Autoimmune Rheumatic Diseases (ARD) have been associated with SBI or siliconosis as part of the spectrum of Autoimmune/Inflammatory Syndrome Induced by Adjuvants (ASIA). Silicone is an adjuvant that may ‘bleed’ and subsequently may be a chronic stimulus to the immune system.

Objectives: To determine the frequency of rheumatic diseases (ARD) and associated factors in patients with ASIA induced by SBI (ASIA-SBI).

Methods: This study was performed between 2012 to 2018 in a tertiary hospital from a cohort of 200 patients with ASIA (associated of oily substance, vaccines and siliconosis according to Shoenfeld criteria). We selected those patients with ASIA induced by SBI and clinical manifestations of any autoimmune disease. The clinical manifestations of ARD were evaluated and classified according to The American College of Rheumatology or EULAR criteria for some rheumatic diseases. We also investigated family history of autoimmune diseases, tobacco smoking coexisting allergies and comorbidities such as hypothyroidism, depression, anxiety and others. Main autoantibodies, histological findings were also evaluated. We used descriptive statistics for analysis.

Results: There were 30 women patients with mean age 48.5±16.3 46 years old, mean disease duration of disease 6±5.5 years. The mean time of appearance of clinical manifestations after SBI was 8 ±4.9 years. The rheumatic diseases (RD) or ARD were Systemic sclerosis (SSc) 7, Fibromyalgia (FM) 6, Systemic lupus erythematous (SLE) 3, rheumatoid arthritis (RA) 6, overlap syndrome 2 (SSc plus SS and SLE plus SSc), Sjogren syndrome (SS) 1, Takayasu arteritis 1, Still disease 1, tunnel carpal syndrome 1, antiphospholipid syndrome 1 and angiopedia and uticaria 1. We found family history of rheumatic disease in 40%, allergic history (food, drugs) in 40% and smoking in 50%. Hypothyroidism was observed in 30% and anxiety 30%. Patients were treated according to the rheumatic disease. Ten cases had their prostheses removed because extracapsular ruptured implants, with re-implantation of new prosthesis in 8 patients. Two patients experienced improvement of complaints after explantation of the implant.

Conclusion: We found a prevalence of ASIA associated to SBI of 15%. The main RD were SSc, FM and RA. We observed an association with family history, allergies and smoking in these patients. Further studies are necessary to determine if SBI has a cause –effect relationship in the rheumatic disease manifestations.

IMMUNE REGULATION THERAPY PROMOTED THE RECANALIZATION OF CORONARY ARTERY IN A PATIENT WITH ANTI-PHOSPHOLIPID SYNDROME: A CASE REPORT AND LITERATURE REVIEW

Bin Wang, Li Fang, Chong Gao, Li Xiao-Feng. Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Thrombosis is considered as a major feature of antiphospholipid syndrome (APS). Once formed, thrombosis will threaten life and long-term oral anticoagulant therapy is required. In addition, some patients underwent percutaneous coronary intervention (PCI), but in-stent restenosis (ISR) is the most common complication of PCI. There is currently insufficient treatment for such patients. Because APS is an autoimmune disease, we developed a new therapy (Sirolimus based immunomodulatory) to treat a APS patients with ISR after PCI.

Objectives: Assess the degree of stenosis of the various branches of the coronary arteries, and to observe the changes in the number of regulatory T cells (Tregs) in the peripheral blood of patients.

Methods: An APS patient with coronary artery involvement was found in-stent restenosis after implantation of the stent. After sirolimus and other immunomodulatory treatments, coronary angiography and coronary CTA were performed to assess the degree of stenosis of the various branches of the coronary arteries, and to observe the changes in the number of regulatory T cells (Tregs) in the peripheral blood of patients.

Results: After 6 months of immunomodulation therapy, the patient did not have clinical symptoms such as chest tightness and tightness. Four consecutive coronary angiography and coronary CTA (dual source) showed disappearance of left main plaque. Stenosis, the degree of stenosis in the anterior descending stent was reduced from 90% to 66%; the degree of right coronary stenosis was reduced from 50% to 30%; new stenosis and new thrombosis did not occur in other branches. The absolute number of Treg cells in peripheral blood gradually increased from 34.41 to 50.83 cells/μl.

Conclusion: Sirolimus is an inhibitor of mTOR that is a serine/threonine kinase in two different complexes (mTORC1 and mTORC2) to promote cell proliferation and neovascularization. Antiphospholipid antibodies activate the mTOR pathway in endothelial cells in culture. When pretreated with mTOR inhibitors prevents this process from occurring. Sirolimus specifically inhibits the mTOR pathway and prevents neointimal hyperplasia and neovascularization in the coronary arteries. In ASP patients with coronary artery involvement, the reduction of Treg cells may also be an important cause of immune tolerance deficiency. Sirolimus also increased the number of Treg cells. If early use of immunomodulators such as sirolimus for prophylaxis, it may prevent re-stenosis after stenting. The successful treatment of this patient also provided us with new diagnostic and therapeutic ideas.

SOCIAL MEDIA USE IN SYSTEMIC LUPUS ERYTHEMATOSUS IMPACT ON PREVALENCE OF ANXIETY AND DEPRESSION

Peiwen Yi1, Zhaohui Zheng1. The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: The psychological problems of patients with Systemic lupus erythematosus (SLE) have been widely concerned. Studies found that the SLE patients showed a prevalence of depression in SLE cohorts ranging from 17% to 75%, and anxiety being 6%-52%. Factors contributing to mood disorders are various. As a nontraditional form of media, social media has become increasingly popular worldwide. Previous study has demonstrated that social media use (SMU) plays a significant role in adolescents’ psychological functioning[1-2], whether SMU could impact the mental health of SLE patients, no previous finding of SMU on SLE patients is reported.

Objectives: We aimed to explore the potential association of the patterns of social media use (SMU) with anxiety and depression in patients with systemic lupus erythematosus (SLE).

Methods: The relevant data were collected from 402 SLE patients aged 18-60 years in the First Affiliated Hospital of Zhengzhou University between July 2018 and October 2018 for subsequent analysis. Demographic and clinical characteristics, the patterns of SMU, the reasons and barriers to SMU were recorded. Anxiety and depression were assessed using hospital anxiety and depression scale (HADS). Adjusted estimates of association were derived using logistic regression.

Results: The incidence of anxiety and depression were 41.1% and 28.4% respectively among SLE patients with a mean score of 6.71±3.65 and 5.45±3.86 in each subscale. Patients without social media were more likely than those with social media to develop anxiety or depression (P=0.05, P=0.001), besides, the presence of depression also had a association with the duration for SMU (P=0.05).

Conclusion: Depression and anxiety are prevalent in patients with SLE and high frequency of SMU may decline the risks of anxiety and depression, to educate patients use social media properly may result in alleviation of anxious and depressive symptoms in patients with SLE.

CHRONIC KIDNEY DISEASE IN RHEUMATOID ARTHRITIS: PREVALENCE AND RISK FACTORS

Natasha Chebotareva, Tatyana Androsova, Ekaterina Kuznezzova, Sechenov First Moscow Medical University, Moscow, Russian Federation

Background: The problem of chronic kidney diseases (CKD) in rheumatoid arthritis (RA) patients have not been fully studied. The role of biological therapy (BT) is poorly understood.

Objectives: Aim of the study was to examine the prevalence, risk factors and histological variants of CKD in RA, and impact of pharmacotherapy.

Methods: 135 patients with RA from 2013 to 2018 were enrolled in this study. Age, gender, duration of RA, drug therapy, ESR, CRP, DAS28, renal function, proteinuria (PU), histological variants were analyzed. Arterial hypertension, weight, sex, lipids and glucose levels were also assessed.

Results: The incidence of CKD in RA was 30.4% (41 from 135). CKD 3-4 stages with eGFR < 60ml/min/1.73m2 was detected in 14.8%
patients. The duration of the disease, high ESR and DAS28 score, NSAIDs treatment and hyperlipidemia were risk factors for CKD in RA (Fig 1). We also found negative correlation between the DAS28 and eGFR (Fig 2).

Amyloidosis was the most common histologic pattern (51.52%), followed by chronic glomerulonephritis (CGN) (24.24%) and tubulo-interstitial nephritis (24.24%). Among CGN mesangial glomerulonephritis was the most frequent (Table 1). Renal amyloidosis was associated with a duration of RA, presence of systemic symptoms and CRP level. The levels of PU were lower, and eGFR levels were higher in patients treated with BT than in patients treated with synthetic disease-modifying anti-rheumatic drugs (DMARDs) (Fig 3).

Conclusion: CKD is often developed in patients with high RA activity. Treatment with biological agents is associated with a lower PU and higher GFR levels.

nephelometric assay. The cut-off value of serum IgG4 was 201 mg/dl. We compared the levels of serum IgG4 among patients with different types of malignancy.

Results: (1) Among the 90 patients, 18 patients were gallbladder carcinoma, 6 patients were lung carcinoma, 34 patients were liver carcinoma, 6 patients were gastrointestinal carcinoma, and 19 patients were pancreatic carcinoma. In gastrointestinal carcinoma, the highest (237.85±50.92 mg/dl), but the sample is too small. Serum IgG4 level in liver carcinoma was higher than other types of malignancy (180.5 ± 32.04 mg/dl vs gallbladder carcinoma 114.4 ± 15.01 mg/dl, p<0.01). vs pancreatic carcinoma 91.63 ± 19.89 mg/dl, p<0.01 vs lung carcinoma 67.47 ± 11.75 mg/dl, P<0.01).

Conclusion: Elevated serum IgG4 level is common in patients with malignancies, while patients with liver carcinoma have significant higher serum IgG4 level than those with gallbladder carcinoma, pancreatic carcinoma and lung carcinoma. This suggests that IgG4 may have different role in different types of tumor.

Validation of outcome measures and biomarkers.

Soumaya Bousaid, Takoua Aissaoui, Sonia Rekik, Samia Jemmali, Houda Ajlani, Hela Sahli, Elhem Cheour, Mohamed El Euch. Hospital Rabta, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatism in adults. It affects the synovial membrane, evolves by outbreaks and can lead to joint destruction. It generates a physical disability that causes an impairment of quality of life and professional activity.

Objectives: To study the socio-demographic, clinical and professional characteristics of patients and to assess the impact of RA on quality of life and professional activity.

Methods: We conducted a retrospective, descriptive study on patients’ files, followed at the rheumatology department of LA RABTA university hospital, for RA aver a period of ten years. The target population was patients having a professional activity at the time of the discovery of the disease. We assessed disease activity by the Disease Activity Score 28 (DAS28-CRP), work impact by the “Work Productivity and Activity Impairment” questionnaire (WPAI:RA) and quality of life by the Health Assessment Questionnaire (HAQ). The data was entered into an excel table and analyzed using SPSS software version 19.0. In all statistical tests, the significance level was set at 0.05.

Results: We collected 25 cases of RA. Mean age was 50.36 ± 8.28 years with a sex ratio of 1.08. The mean age of RA was 9.8 years and the mean age of onset was 40.56 ± 9.84 years. The study population occupied a manual job in 84% of cases. The average professional seniority was 21.76 ± 12.83 years. Patients reported having stopped work because of their illness in 44% of cases. The mean of DAS28-CRP was 4.32 ± 1.57, 72% of the study population had moderate to severe RA activity. The mean HAQ was 1.38 ± 0.69 with 76% of cases suffering from “moderate to severe” or “severe to very severe disability”. The evaluation of the work productivity and activity impairment by the WPAI:RA questionnaire objectified an absenteeism of 30.7 ± 9.4%, a presenteeism of 46.7 ± 26.4%, a work productivity loss of 60.4 ± 33.8% and an activity impairment of 57.2 ± 25.4%. A positive and statistically significant correlation was noted between the results of WPAI and HAQ, between the results of WPAI (except absenteeism) and DAS28CRP and between HAQ and DAS28-CRP.

Conclusion: RA causes a significant functional disability that affects the professional activity and quality of life of patients. Early diagnosis and treatment of this disease can slow the progression of the disease. Occupational medicine plays an important role in the early detection and maintenance of employees with RA at work.

THE RHEUMATOID ARTHRITIS FLARE QUESTIONNAIRE (RA-FQ) IS AN EASY TO ADMINISTER PATIENT-REPORTED OUTCOME MEASURE THAT TRACKS WELL WITH THE CLINICAL DISEASE ACTIVITY INDEX (CDAI) OVER TIME IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS (ERA) IN 2 DIFFERENT HEALTH SETTINGS

Vivian Bykiewicz1,2, Orit Scher1, Marie-France Valois4, Glen Hazlewood5, Gilles Boire6, Carol Hitchon7, Louis Bessette8, Carter Thorne9, Edward Keystone9, Diane Tin9, Caroline Benson10, Janet Pope10, Clifton Bingham11, Susan J. Bartlett11,12, CATCH Investigators, CATCH-US Investigators, OMERACT Flare Group, Hospital for Special Surgery, New York, United States of America; 1Weill Cornell Medical College, New York, United States of America; 2University of Toronto, Toronto, Canada; 3McGill University, Montreal, Canada, 4University of Calgary, Calgary, Canada, 5Université de Sherbrooke, Sherbrooke, Canada, 6University of Manitoba, Winnipeg, Canada; 7Laval University, Quebec, Canada; 8Newmarket Medical Center, Newmarket, Canada; 9Western University, London, Canada; 10Johns Hopkins University, Baltimore, United States of America

Background: RA patients may cancel scheduled visits with their rheumatologist. In clinical practice, a validated patient-reported disease activity measure that tracks well with traditional clinical indices could address an important gap by providing real-time information on RA disease activity when a visit to the rheumatologist is not possible.

Objectives: To assess concordance between the 5-item patient-reported Rheumatoid Arthritis Flare Questionnaire (RA-FQ) (1,2) and the Clinical Disease Activity Index (CDAI) in patients with early RA (ERA) treated in rheumatology clinics in 2 countries with different health systems.

Methods: Data were analyzed from patients enrolled in the Canadian early Arthritis CoHort (CATCH) between Nov 2011 and March 2017 and in the Consortium of early Arthritis Cohorts- USA (CATCH-US) from Dec 2014 to Dec 2018. Both observational studies had a similar design; enrolled patients diagnosed with ERA (< 1 year of persistent symptoms) by a rheumatologist who completed similar regular protocolized clinical assessments, laboratory investigations and PROMs. The RA-FQ, designed to assess worsening of RA inflammation, is a short composite PROM (total score 0-50) that sums 5 single items (NRS 0-10) querying pain, fatigue, stiffness, function and participation. The present analysis includes patients meeting ACR 1987 or 2010 ACR/EULAR criteria, with RA-FQ and CDAI at baseline and at least 1 other follow up (FU) over 12-months. We compared mean scores of the RA-FQ and CDAI over time and calculated intraclass correlation coefficients (ICC) to assess concordance between measures in the 2 cohorts.

Results: The study included 818 Canadian and 75 American early RA patients. Age, male sex, and disease activity was higher in the Canadian cohort, while post-secondary education was higher in the US cohort (Table1). RA-FQ and CDAI scores tracked closely with one another over time in both cohorts (Canada ICC: 0.76; US ICC: 0.80).

Conclusion: There was high concordance between the RA-FQ and CDAI measures over the 1st year of follow up in 2 early RA samples recruited in 2 countries. The RA-FQ may help patients and clinicians track patient disease activity between clinic visits.
EVALUATION OF SERUM LEVELS OF ASC FOR THE DIAGNOSIS AND MONITORING OF CRYOPYRIN ASSOCIATED PERIODIC SYNDROMES (CAPS)

Background: Dominantly gain-of-function mutations in the NLRP3 gene lead to Cryopyrin associated periodic syndromes (CAPS) characterized by constitutive activation of the inflammasome, increased secretion of interleukin (IL)-1beta and IL-18, and systemic inflammation. IL-1beta and active caspase-1 subunits are released in the serum together with the oligomeric particles of the adaptor ASC (apoposis-associated Speck-like protein with a caspase-recruitment domain) after activation of the inflammasome complex and, as a consequence, patients with CAPS show an increased serum concentration of ASC particles.

Objective: Patients suffering from CAPS are characterized by clinical manifestation similar to other autoinflammatory diseases. This phenomenon together with the lack of specific laboratory tests makes difficult the diagnosis of CAPS. In this context the development of a test for the evaluation of serum ASC levels could provide novel biomarkers facilitating early disease diagnosis and able to monitor treatment responses.

Methods: We analysed, with a novel ELISA assay, the levels of ASC particles in serum and plasma of normal subjects, CAPS patients and patients with autoimmune disorders (Multiple Sclerosis (MS), Type 1 Diabetes (T1D) and juvenile idiopathic arthritis), to confirm that ASC presence in the serum is not due to other chronic inflammatory processes and, as a consequence, patients with CAPS show an increased serum concentration of ASC particles.

Results: ASC particles were higher in untreated CAPS patients with respect to healthy controls and patients suffering from MS and T1D. These data suggest that ELISA quantitation of ASC protein could represent a novel and additional strategy for the diagnosis and monitoring of CAPS patients suffering from CAPS.

AB1305
AB1306 PILOT STUDY OF ADHERENCE IN PATIENTS WITH RHEUMATOLOGICAL DISEASES AUTOIMMUNE

E.C. Cervantes Pérez1, Jose Ramón Maneiro Fernández1, Begoña Moreira1, José Antonio Mosquera Martínez2, Natalia Bea1, Susana Romero-Yuste1, 1Complexo Hospitalario Universitario de Pontevedra, Rheumatology Service, Pontevedra, Spain, 2Complexo Hospitalario Universitario de Pontevedra, Rheumatology Service, Pontevedra, Spain

Background: Data on adherence in patients with autoimmune rheumatological diseases are limited.

Objectives: To analyze the adherence to treatment in patients with autoimmune rheumatological diseases.

Methods: A cross-sectional study was performed in patients from the Complexo Hospitalario Universitario de Pontevedra with diagnosis of systemic lupus erythematosus (SLE), Sjögren’s Syndrome (SS) and Systemic Sclerosis (SE).

The patients filled an anonymous survey that included data about demographic, diagnosis and treatment. Adherence to treatment was assessed using the Spanish Compliance Questionnaire in Rheumatology (sCQR) [1]. Likewise, a linear regression analysis was carried out in order to identify factors related to adherence to treatment. A significant value was considered as p < 0.05. Stata version 11.1 (Stata/IC 11.1 for Windows, StataCorp LP, College Station, TX) was used to perform all analyzes.

Results: A total of 44 patients participated in the study, although 90.9% of the surveys carried out could be used for the analysis. A total of 25 (62.5%) SLE, 9 (22.5%) SS and 6 (15.0%) SE participants participated. The average age was 48.9 ± 12.8 years (See Table 1). According to the sCQR 82.5% were compliant patients. None of the studied variables was associated with the adherence rate: sex (p = 1.000), age (0.134), time of evolution (p = 1.000), level of education (p = 0.677), marital status (0.392), illness (p = 1.000), number of drugs ingested per day (p = 0.873), treatment with steroids (p = 0.679) or antimalarials (p = 1.000).

Conclusion: The adherence rate in our cohort was 82.5% higher than previously reported in other studies. [2,3] The sCQR could be a useful and easy-to-apply tool for the study of adherence in these patients.

AB1307 STUDY OF CONCORDANCE AND EQUIVALENCE AMONG BARTHEL, LAWTON, HAQ AND BASFI QUESTIONNAIRES IN RHEUMATOID AND SPONDYLOARTHRITIS PATIENTS

Miguel Angel Belmonte Serrano, Antonio Lozano Saez, Arantxa Conesa, Maria Copovi Moya. Hospital General Universitari de Castelló, Rheumatology, Castelló de la Plana, Spain

Background: Assessment of functional capacity of patients is usually performed using disease-specific questionnaires for rheumatoid arthritis (HAQ) and for axial spondyloarthropathies (BASFI). However, recent studies have shown that disease-specific, general indexes such as Barthel and Lawton-Brody (LB) are used to establish disability in legal environments and in emergency rooms. Few studies have compared specific vs. generic questionnaires in rheumatic patients [1].

Objectives: To assess the equivalence between disability questionnaires of generic type, applicable to general population and various diseases (Barthel and LB), with specific questionnaires for rheumatic diseases (HAQ and BASFI).

Methods: A cross-sectional study was conducted in consecutive outpatients with inflammatory rheumatic diseases (rheumatoid arthritis, psoriatic arthritis, spondyloarthropathies) in usual daily clinical practice in a rheumatology clinic of a tertiary hospital.

The patients self-completed the questionnaires (Barthel, LB, HAQ, and BASFI) in a single session. HAQ was only filled by peripheral arthritis patients, while BASFI was only given to spondyloarthropathy subjects. Scores were also computed for SDAI, DAS28 and BASDAI in most patients. Intraclass correlation was used to measure concordance between questionnaires.

Results: A total of 214 patients where studied. There was good correlation between the scores of the indexes studied, especially between the two generic questionnaires (R = 0.45 p < 0.01). We observed a high ceiling effect in the scores of both Barthel, (70% of patients obtained values 95 over a maximum of 100) and Lawton-Brody (60% had values > 23 over a maximum of 24) tests. The disease-specific questionnaires showed a less skewed distribution. The agreement between Barthel’s and Lawton’s tests was significant when measured by the intraclass correlation (R = 0.48 p < 0.01). However, we could not find any significant correlation between the generic questionnaires and the HAQ questionnaire or the BASFI (R < 0.3).

Conclusion: The Barthel and Lawton-Brody indices show an important ceiling effect in rheumatic patients, and seem to evaluate dimensions of health other than rheumatic questionnaires such as HAQ and BASFI, and thus they are not interchangeable. This point must be taken into account when performing medicolegal or emergency room assessments. Our result is in line with other previous studies[1]

AB1308 FAILURE TO BIOLOGICAL THERAPY: WHEN TO EXPECT IT?

rim dhari1, Salma Atthimi1, Marwa Slouma1, Leila Metou1, Imen Gharsallah1, Bassem Louzir1, Maroua Meddeb2, Mahdi Dridi2. 1Military Hospital, rheumatology, Teboulib, Tunisia; 2Military Hospital, pharmacology, Teboulib, Tunisia

Background: Using Biologic agents, has considerably improved the treatment of inflammatory diseases. But it is associated to the capacity of inducing an immune response in patients that could result in unwanted adverse events or treatment failure.
Objectives: The aim of this work was to compare the clinical and biological response to biotherapy with the presence of ADA and the residual dose rate.

Methods: We analysed the medical records of 69 patients treated with biotherapy between September 2017 and October 2018. The 3 pathologies were considered: rheumatoid Arthritis (RA) diagnosed by ACR/EULAR 2009 criteria, Spondyloarthritis (SPA) according to Assessment of Spondyloarthritis International Society (ASAS) And crom'hs disease (CD) classified upon the 2006 Montreal classification. We did search the presence of anti-body anti-drugs (ADA) and the residual dose for the following therapies: Etanercept (ETN), Infliximab (IFX), Adalimumab (Ad) or Rituximab (RTX).

Results: The mean age was 43.33 ± 11.4 years. The sex ratio M/F was 1.57.

Regarding the RA: they were 13 patients. 10 had positive (ACPA) and seven positive (RF). All the patients had an initial treatment by conventional synthetic disease modifying antirheumatic drugs (csDMARDs) before moving to bDMARDs. 14 were in concomitant disease modifying therapy. The DAS28-ESR average was at 4.12 [2.67 à 5.79]. We found positive ADA in only one patient analysis. There were 8 responding versus five non-responding patients, according to the clinical and biological evaluation of disease activity.

28 patients were in the SPA group: 13 with an axillary spondyloarthritis. 14% had the HLAB 27. It was an active disease in 15 cases. ASDAS-CRP average was 4.87 ± 0.17 [4.7; 5]. The received biotherapy was IFX 50%, ETN 28.6% and Ada 21.4%. 10 patients had a positive ADA and 8 of them had a rate superior to 100 UI. 19 patients were considered as non-Responding.

In the CD group, 28 patients were enrolled. All of them had a previous immunosuppressor treatment. Same patients in association with biotherapy. It was positive ADA in 7 cases. And 7 patients were non-responding to the treatment.

The residual dose of drugs was calculated for each drug and it is explained in the following table:

<table>
<thead>
<tr>
<th>Therapy</th>
<th>Positive ADA</th>
<th>Positive ADA</th>

<tr>
<td>RTX</td>
<td>Responding</td>
<td>Non-responding</td>
<td>Responding</td>
<td>Non-responding</td>
</tr>
</tbody>
</table>

Positive ADA was associated with therapy failure in all type of biotherapy (p<0.001). A low residual dose was associated to therapy failure only in the case of IFX (p<0.005).

In multivariate analyses, the predictive factors associated with therapeutic failure were: positive ADA (p<0.008) and advanced age at diagnosis, below 30 years old age (p=0.020). Hosmer index=0.452.

Conclusion: Immune response induced in patients treated with biotherapy can be quantified now thanks to ADA dosage and the residual dose assessment.

AB1309 QUANTIFICATION OF MINIMAL RESIDUAL DOSE ASSOCIATED WITH BIOLOGICAL THERAPEUTIC RESPONSE ANTI DRUG ANTI BODIES: ARE THEY ALL NEUTRALIZING?

Salma Athimni1,2, Maroua Slouma1, Leila Metou1, Imen Gharsallah1, Basssem Louzi1,2, Maroua Meddeh1,2, Mahdi Drid1,2, Medical Hospital, rheumatology, Tbeoubou, Tunisia; 2Military Hospital, pharmacology, Tbeoubou, Tunisia

Background: The use of biologicals was associated to the capacity of inducing an immune response in patients that could neutralize the drug.

The anti-body anti-drug (ADA) assay was a revolutionary tool to prevent treatment failure.

Objectives: The aim of this work was to asses if the presence of ADA in patients system is sufficient to preclude failure and indicates the switch of treatment.

Methods: We enrolled 69 patients treated with biotherapy between September 2017 and October 2018. 3 pathologies were considered: rheumatoid Arthritis (RA) diagnosed by ACR/EULAR 2009 criteria, Spondyloarthritis according to Assessment of Spondyloarthritis International Society (ASAS) And crom'hs disease (CD) classified upon the 2006 Montreal classification. We did search the presence of anti-body anti-drugs (ADA) and the residual dose for the following therapies: Etanercept (ETN), Infliximab (IFX), Adalimumab (Ad) or Rituximab (RTX).

Results: The mean age was 43.33 ± 11.4 years. The sex ratio M/F was 1.57.

Regarding the RA: they were 13 patients. 10 had positive (ACPA) and seven positive (RF). All the patients had an initial treatment by conventional synthetic disease modifying antirheumatic drugs (csDMARDs) before moving to bDMARDs. 14 were in concomitant disease modifying therapy. Positive ADA was associated with therapy failure in all type of biotherapy (p<0.001). A low residual dose was associated to therapy failure only in the case of IFX (p<0.005).

Positive ADA was associated to a low rate of residual dose in the case of IFX and Ada. This association couldn’t be evaluated for RTX (none) and ETN (just one positive rate).

Conclusion: The ADA assay was a revolutionary tool allowing the evaluation of treatment response but it cannot be considered without the clinical assessment of patient. The evaluation residual dose should be concomitant to value and guide the therapeutic decision.

AB1310 PROSPECTIVE USE OF THE GLUCOCORTICOID TOXICITY INDEX (GTI) IN A COHORT OF VASCULITIS PATIENTS

Lisa Ehlers1, Edgar Wibe1, Desiree Freier1, Sandra Hermann1, Eli Mioslawsky2, Yuqiong Zhang2, Frank Buttgereit1, John H. Stone2.

1Division of Rheumatology, Allergy, and Immunology, Medicine, Boston, United States of America

Background: The Charité Rh-GIOP is a prospective study of disease- and bone-related data from patients with chronic inflammatory diseases treated with glucocorticoids (GCs). The Glucocorticoid Toxicity Index app (GTI 2.0) measures changes in GC-associated morbidity. The GTI captures...
Thirty-four (92%) patients had changes in GC toxicity between V1-V2. The mean CWS & AIS were 34.8 and 11.1, respectively. Twenty-eight patients (76%) had CWS >0, indicating worsening toxicity. Twenty-one (57%) had AIS >0, also consistent with overall GC toxicity worsening. The GTI captured changes in GC toxicity over time well, with a strong positive correlation between CWS and AIS.

Methods: Vasculitis patients were included if starting GC or having a flare requiring increased GC doses. Doses were calculated in prednisone (PRED) equivalents. Nearly all patients had received GC (often for years) before baseline (V1). Data for the 9 GTI domains were collected at V1 and follow-up (V2). These included: medications for hypertension, hyperglycemia, and hyperlipidemia; body mass index; bone mineral density; and data pertaining to muscle strength; skin toxicity, neurophysiologic effects, and infections. Data for the blood pressure, glucose control, and lipid domains were inferred from treatment changes. We used multivariate logistic regression models to examine the relationship of PRED dose to the likelihood of CWS worsening and AIS improvement.

Results: 37 patients (25F; 12M) of mean age 66.6 years (range: 40.5-81.7) were included. Diagnoses: GCA (n=7), PMR (14), AAV (10), EGPA (4), and PAN (2).

Table 1. Prednisone Dosing

Conclusion: The GTI captured changes in GC toxicity over time well, both improvement and worsening. Cumulative PRED dose correlated strongly with increase in the Cumulative Worsening Score.

TIME-COURSE CHANGE OF NEUTROPHIL-LYMPHOCYTE RATIO, MONOCYTE-LYMPHOCYTE RATIO AND PLATELET-LYMPHOCYTE RATIO IN PSORIATIC ARTHRITIS PATIENTS AND RESPONSE TO BIOLOGIC THERAPY

Raquel Ferreira, Sara Ganhão, Salomé Garcia, Bruno Miguel Fernandes, Sofia Pimenta, Miguel Bernardes, Lúcia Costa. São João Hospital Centre, Porto, Portugal

Background: Recently, systemic inflammation has been shown to be a key determinant of prognosis. Neutrophil-lymphocyte ratio (NLR), monocyte-lymphocyte ratio (MLR), and platelet-lymphocyte ratio (PLR) has been related to inflammation status and suggested as additional markers of response to bDMARDs in patients with rheumatoid arthritis. However, few studies were yet developed about this subject in psoriatic arthritis (PsA).

Objective: The aim of this study was to investigate the time-course of change of NLR, MLR and PLR levels in PsA patients after 6 and 12 months of bDMARD therapy and to evaluate their clinical significance and utility in monitoring response to biologic agents.

Methods: An observational retrospective study was performed in patients with PsA under bDMARD, followed at our Rheumatology department until December 2018. Demographic and clinical data were collected from the national database. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and total blood count were consulted before and after 6 and 12 months of biologic treatment and NLR, MLR and PLR were calculated by dividing neutrophil, monocyte and platelet count by lymphocyte count, respectively. Disease activity was evaluated with DAS28 and ASDAS.

Results: A total of 83 patients were included. Forty-three were females (51.8%). The mean age at diagnosis was 41 years (±11.3) and the median disease duration at start of biological therapy was 6.9 years (min:1.4; max:32.4). In total, 67.5% of the patients had a high CRP level (n=56), 91.6% had a positive ESR (n=76) and 43.4% had a positive ANA (n=35). Almost all patients fulfilled the CASPAR criteria for PsA (n=78; 94%). At the baseline, 25 patients (30.1%) had high disease activity and 45 patients (54.2%) had high disease activity according to ASDAS criteria. The most used bDMARD was etanercept (n=29; 35%), followed by golimumab to others 2 patients. Fifty-nine patients were concomitantly treated with csDMARD. The median value of CRP was 1.5mg/dL [0.03-30]. The median value of ESR was 33mm/hr [4-98], 11 [2-75] and 10 [1-68] at baseline, 6 and 12 months, respectively. The significant correlation was found between ΔNLR, ΔMLR and ΔPLR with ΔCRP and ΔESR levels, ΔDAS28 and ΔASDAS was calculated using the Spearman’s test.

Conclusion: Our data showed that NLR, MLR and PLR decreased promptly in parallel with decrease of CRP and PLR with ESR for up 6 months of therapy with biologics. This results, in agreement with the literature, suggests that NLR, MLR and PLR may be seen as a useful marker for monitoring systemic inflammation in PsA patients. Further studies are needed to better emphasize the importance of these parameters and to evaluate their utility to monitor the effectiveness of biologic therapy.

Disclosure of Interests: None declared

NMR SPECTROSCOPY REVEALS ALTERATIONS OF URINARY ACETATE AND CITRATE LEVELS FOLLOWING CYCLOPHOSPHAMIDE THERAPY IN PATIENTS WITH LUPUS NEPHRITIS

Suhas Ganguly1,1, Umesh Kumar2, Nikhil Gupta2, Anupam Guleria3, Sanjukta Majumdar1, Sanat Phatak1, Smiti Chaurasia1, Amita Aggarwal1, Dinesh Kumar2, Ramnath Misra1,3. 1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Rheumatology and Clinical Immunology, Lucknow, India. 2Centre of Biomedical Research, Lucknow, India

Background: Metabolomics, the study of global alterations in small metabolites is a useful tool to look for novel biomarkers. Recently, we reported a reprogramming of the serum metabolomic profile on nuclear magnetic resonance (NMR) spectroscopy following treatment in Lupus Nephritis (LN).

Objective: We explored urinary parameters using NMR Spectroscopy in patients with biopsy proven proliferative lupus nephritis. Change in parameters after 6 months Cyclophosphamide induction treatment and its correlation with disease activity was assessed.

Methods: Urine obtained from Lupus Nephritis (n=18, F=16, M=2) at diagnosis and following induction therapy with cyclophosphamide, and healthy controls (n=18, median age 35,all females) were stored at -80 °C. Metabolomic profiling was done using high resolution 800 MHz 1D 1H NMR spectroscopy. Urinary ratio of metabolites was calculated- (Metabolite1000)/Creatinine. Disease activity was measured using SLEDAI.

Results: Urinary metabolite fingerprint of LN patients differed from healthy controls by having significantly raised urinary acetate/creatinine (LN=41.84±100.6, HC=12.36±9.40, p<0.002) and reduced urinary citrate/creatinine (LN=34.22±54.8, HC=114.52±70.9, p<0.0001). Urinary citrate (88.68±98.33) increased after 6 months of Cyclophosphamide, while urinary acetate showed a trend towards decrease(14.77±9.98). AUC for urinary citrate/creatinine and acetate/creatinine were 0.9136 and 0.8086. The urinary acetate levels correlated with SLEDAI (r=0.337, p=0.048). Urinary citrate levels correlated with C3 (r=0.362, p=0.03) and negatively correlated with uPCR (r=0.346, p=0.039).

Conclusion: The decreased urinary citrate mirrors the finding seen in serum of the patients done earlier which reflects dampened alcoholic glycocolysis and oxidative phosphorylation.(1) Raised urinary acetate levels possibly reflects proximal renal tubular injury leading to increased urinary excretion(2). Change in levels with treatment show that urinary metabolomics parameters are potential noninvasive biomarkers for diagnosis and monitoring treatment response in LN

Figure: The bar graph represents the correlation of urinary metabolites and clinical parameters between groups: C3 (in blue), C4 (in red), and NC (in green). The significantly higher values for C3 and NC compared to C4 and NC groups demonstrated the diagnostic potential of these urinary markers. The values on the right side shows the correlation analysis parameters between urinary metabolic profiles and clinical parameters.

ROLE OF NEUTROPHIL TO LYMPHOCYTE RATIO, EOSINOPHIL TO LYMPHOCYTE RATIO, PLATELET TO LYMPHOCYTE RATIO, EOSINOPHIL TO LYMPHOCYTE AND BASOPHIL TO LYMPHOCYTE RATIO IN ASSESSING DISEASE ACTIVITY IN SPONDYLOARTHRITIS

Salomé García, Bruno Miguel Fernandes, Sara Ganhalo, Raquel Ferreira, Miguel Bernardes, Georgina Terroso, Lúcia Costa. Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal

Background: Neutrophil to lymphocyte ratio (NLR), monocyte to lymphocyte ratio (MLR), eosinophil to lymphocyte ratio (ELR) and basophil to lymphocyte ratio (BLR) have been demonstrated to be promising systemic inflammation markers. NLR, MLR and PLR have been associated with disease activity in Spondyloarthritis (SpA) but the results remain conflicting.

Objectives: We aim to determine the role of NLR, MLR, PLR, ELR and BLR in assessing disease activity in SpA.

Methods: Observational retrospective study was performed including consecutive patients with the diagnosis of SpA (according to ASAS classification criteria) followed at our Rheumatology Department. Demographic, clinical (including BASDAI, BASFI, ASDAS ESR and ASDAS CRP indices) and laboratorial data were collected from our national database at baseline and 6 months after initiation of a tumour necrosis factor inhibitor (TNFi). Correlations between variables were studied using Spearman correlation analysis and comparison between groups was performed using Wilcoxon test.

Results: The mean age of patients (n=297) was 41 years old (± 12), 160 (53.9%) were males with mean disease duration of 12.4 (IQR 14.8) years. Two hundred and seven patients (69.7%) had Ankylosing Spondylitis, 26 (8.8%) Inflammatory Bowel Disease related SPA and 36 (12.1%) Undifferentiated SpA. Seventy-three (24.7%) patients were taking glucocorticoids and regarding conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) use before starting the TNFi: 188 (63.3%) were not under any csDMARD and the remaining ones were under Sulphasalazine (70, 23.6%), Methotrexate (MTX) (21, 7.1%), Azathioprine (AZA) (5, 1.7%), Leflunomide (1, 0.3%) or associations between Sulphasalazine and AZA or MTX. Regarding the TNF inhibitor, the majority of patients initiated Adalimumab (n=168, 28.6%), Golimumab (n= 61, 25.6%) or Infliximab (n= 57, 23.9%).

At the evaluation 6 months after introducing a TNFi, we found less and lower than mean baseline values, as they were also for NLR, MLR and PLR (p<0.01).

At the baseline evaluation, in anti-TNF naïve patients, NLR and MLR were positively correlated with the majority of parameters evaluated: ESR level (r=0.322; r=0.203, p<0.01 respectively), CRP level (r= 0.475; r=0.221, p<0.01 respectively), ASDAS-ESR (r=0.25; r=0.192, p<0.01 respectively), ASDAS-ESR (r=0.257; r=0.206, p<0.01 respectively) and BASMI (r=0.288; r=0.150, p<0.01 respectively). No correlations were found with BASDAI. PLR was positively correlated with ESR level (r=0.379; p<0.01), CRP level (r= 0.331; p<0.01), ASDAS-CRP (0.215; p<0.01) and ASDAS-ESR (r=0.208, p<0.01). No correlations were found between those parameters and ELR or BLR.

At the evaluation 6 months after introducing a TNFi, we found less and weaker correlations than in naïve patients: NLR and PLR correlate positively with CRP (r=0.302; 0.315, p<0.01 respectively) and, reaching lower statistical significance, PLR correlate also with ASDAS-ESR (0.156, p>0.05); NLR with BASMI (0.184, p>0.05) and ELR (0.179, p>0.05); MLR with CRP (0.179, p>0.05), ASDAS-ESR (0.183, p>0.05) and BASMI (0.177, p>0.05) respectively.

Conclusion: NLR, MLR and PLR may reflect disease activity and could represent future inexpensive potential parameters to evaluate disease activity or severity in SpA.

MIOSESIS AUTOANTIBODIES PROFILE: DIAGNOSTIC RELEVANCE

Alexia Garcia Dorta1, Yvelise Barrios2, Sonia Peña Montelongo1, Hernández Díaz Marta1, Andrea Molino Calero1, Beatriz Rodríguez Lozano1, Andréis Franco2, Sagrario Bustabad1. 1Hospital Universitario de Canarias, Rheumatology, La Laguna, Spain; 2Hospital Universitario de Canarias, Immunology, La Laguna, Spain

Background: The idiopathic inflammatory myopathies (IIM) are autoimmune systemic diseases that can affect several organs, but with special impact in the muscular-skeletal system. Autoimmunity is believed to have a role in its pathogenesis, with the presence of Autoantibodies (Abs) in more than 50% of the patients. Those Abs have been classified into Myositis-Specific Autoantibodies (MSA), with the Anti-Jo being the most frequent; and Miositis-Associated autoantibodies (MAA), also found in other connective tissue diseases. The availability of a multiplex analysis (Myositis Profile) has opened up new possibilities for the specific investigations of these Abs in the day-to-day clinical practice 1-2.

Objectives To describe the clinical spectrum and the Ab results obtained from the myositis profile in patients (hospital admissions and ambulatory) of a tertiary university hospital.

Methods Retrospective descriptive study (January to June 2018) of the results obtained on the myositis profile. The clinical characteristics of the sample is described in the context of the Abs results. We considered that applications of this Myositis Ab Profile were justified if they had EPIID and/or if they had 2 or more clinical and/or analytical characteristics associated with MII. Myositis Profiles consisted in a solid phase ELISA from EuroLINE MII 16 Antigens (MII-alfa, MII-beta, TIF gamma, MDAS, NXP2, SAE1, Ku, Pm-Scl100, Pm-Scl75; Jo-1, SRP, PL7, PL12, EJ, OJ, RO-52). Statistical analysis SPSS 17.0.

Results A total of 165 applications were studied, 47% requested by Reumatology, 30% by Neurology and 9% by Internal Medicine. Justifications were: ILD (n=49); osteoarticular (n=30), connective diseases (n=27), oculomyastitis (n=17), CK-NAC elevation (n=11), fibromyalgia (n=7) and others (n=22). 41% men and 59% women, Average Age 58 (+/- 15 years). We observe an increase of CKNAC, GPT, GPT y LDH in 21%, 12% and 24% respectively. They refer muscle weakness in 18%, Raynaud’s phenomenon in 10%, arthritis in 15%, heliotrope eruption in 4%, Gottron’s papules in 1% and mechanics hand in 1%. Using the criteria specified in the method section, 52% of the applications were justified, being the 57% of them as ILD study. 32 (20%) of the 165 profiles were positive. 10 of the 49 patients with ILD had positive Abs (figure 1), 90% me. 8 of the 17 patients with myositis had positive Abs (figure 1), 63% women. 75% of them (6/8) were positive for MSA, the 65% were Anti-Jo (4/6). 1 patient with myositis associated with neuropia (anti-CJ). 2 of 3 muscle biopsy were consistent with MII. 2 of 7 EMG were compatible. The 14 remaining patients had some positive Abs (figure 2): 7 connective tissue diseases studies, 4 osteomuscular pathology, 1 auto-inflammatory disease, 1 CK-NAC elevation and 1 with inflammatory bowel disease (IBD).

Conclusion The use of this Ab profile as a protocol for patients with ILD without myositis clinical features, allowed us to classify a group of patients with autoimmune diseases. In this group, the distribution by sex, 9 males and 1 woman is highlighted. We achieved the diagnosis on the 47% of patient with myositis clinical suspicion. The usefulness of myositis profile allowed us to detect antibodies which are not in other immunologic assays. Distribution by sex, 3 men and 5 women.

AGREEMENT BETWEEN SUBJECTIVE AND OBJECTIVE DEFINITIONS OF INACTIVE DISEASE IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Gabriella Giancane1,2, Maria Francesca Gicchino1, Alessandra Alongi1, Chiara Campone1, Alessandro Consolaro1,2, Angelo Ravelli1,2, 1I.R.C.C.S. Giannina Gaslini, Genova, Italy; 2Università degli Studi di Genova, Genoa, Italy

Background: The choice of an appropriate definition of inactive disease (ID) is important because ID has been identified as the ideal therapeutic goal in the treat-to-target strategy in juvenile idiopathic arthritis (JIA).1 Several criteria for ID in JIA have been proposed, including Wallace 2004 and 2011 criteria and JADAS10 and clinical JADAS10 (cJADAS10) criteria. However, a recent study2 has shown that these criteria do not always identify the same group of patients. In addition, it is unknown whether and to what extent the formal definitions of ID agree with the subjective perception of disease remission by the physician and the parent.3

Objectives: To investigate the concordance between current criteria for ID and subjective judgment of disease remission by physicians and parents in children with JIA.

Methods: We evaluated the clinical data of the last visits made in 669 children with JIA from March 2007 to December 2010 to identify all visits in which the caring physician and a parent judged subjectively and independently the child’s disease state as remission or non-remission and the parent declared whether he/she was satisfied or non-satisfied with current illness state (i.e. Parent Acceptable Symptom State, PASS).4 All visits judged subjectively by the physician and the parent as remission or judged in PASS by the parent were examined to identify those who met the Wallace 2004 and 2011 criteria and the JADAS10 and cJADAS10 criteria for ID. Visits which met both subjective and objective definitions were defined as concordant.

Results: Of the 246 visits in which the physician judged subjectively the disease state as remission, 34.6% and 27.6% met the 2004 and 2011 Wallace criteria, respectively, and 38.6% and 54.5% met the JADAS10 and cJADAS10 criteria for ID, respectively. (Figure 1) Of the 338 visits in which the parent judged subjectively the disease state as remission, 19.8% and 18% met the 2004 and 2011 Wallace criteria, respectively, and 34.9% and 48.8% met the JADAS10 and cJADAS10 criteria for ID, respectively. (Figure 2) In 76.4% of visits judged as remission by the physician, the parent provided the same evaluation. In 55.6% of visits judged as remission by the parent, the physician provided the same evaluation. (Figure 1-2) Of 467 visits judged in PASS by the parent, 17.6% and 14.8% met the 2004 and 2011 Wallace criteria, respectively, and 26.6% and 37.5% met the JADAS10 and cJADAS10 criteria for ID, respectively.

Conclusion: The JADAS10 and cJADAS10 criteria for ID were more concordant with physician’s and parent’s subjective judgment of remission and with parent’s satisfaction with current illness state than Wallace criteria. The cJADAS10, which lacks the acute phase reactant, revealed the best concordance with both physician’s and parent’s subjective assessment. Physician-parent agreement was greater for remission judged by the physician than for remission judged by the parent.

What is a total knee or total hip arthroplasty failure? A Patient perspective using nominal groups

Jasvinder Singh1, Bella Mehta2, Serene Mirza2, Mark Figgie3, Peter Sculco7, Michael Parks5, Susan Goodman1. 1UAB School of Medicine, Birmingham, United States of America; 2Hospital for Special Surgery, Main Campus, New York, United States of America

Background: Total joint replacements (TJR) are commonly performed elective surgeries for people with end-stage arthritis. However, there is relative lack of qualitative research to define the patient perspective of what constitutes a failure of TJR.

Objectives: To discover when a TJR is considered a failure from the perspective using nominal group technique (NGT). Total joint replacements (TJR) are commonly performed elective surgeries for people with end-stage arthritis. However, there is relative lack of qualitative research to define the patient perspective of what constitutes a failure of TJR.

Methods: Patients who had undergone elective total hip (THR) and/or knee replacements (TKR) met in nominal groups to answer the question “When would you consider a knee or hip replacement to be a failure?” Patients competed questionnaires including demographics, pain, function, and satisfaction, independently listed their ideas and then ranked them with the group after clarification.
Results: Six groups with 35 patients were held, all of whom had undergone THR or/and TKR between 2016 and 2018. Of these, 42% were male, 58% female (Table 1). Overall pain and function scores were high, Hip Disability and Osteoarthritis Outcome Score (HOOS) JR 95.3 (SD±/11) and Knee Injury and Osteoarthritis Outcome Score (KOOS) JR 83.7 (SD±/12.8) (range 0-100, higher score=less pain/functionality limitation), and 86.1% were very/somewhat satisfied with their quality of life. The concerns ranked highest by the patients equating a TJR failure were A) refractory index joint pain (67 votes); B) unable to resume normal activities or go back to work (38 votes); C) minimal or no improvement in quality of life (24 votes); D) post-operative adverse events (40 votes); E) early revision surgery (32 votes); F) death (7 votes); G) expectation-outcome mismatch (1 vote); continuing secondary depression (1 vote) (Table 2).

Conclusion: Poor results for pain, function, quality of life, or adverse events are the outcomes ranked highest by patients, defining TJR failure from the patients’ perspective.

Abstract AB1317 Table 2. Theme: When would you consider a hip or knee Score replacement a failure?

NG 1-6, 35 people, 14 Male, 21 Female; 8 African-American, 25 White, 2 Asian, 210 votes

A. Pain: Still in pain/remains unchanged/persists 67
   - "Primary factor for getting surgery. Pain impacts every facet of life"

B. Activities: Cannot regain normal function or activities/physical disability persisted 38
   - "Can't reach a goal – goal is to reach the top of the stairs or room"

C. Quality of life
   - "Can't go back to work and can't walk. Purpose of surgery to get back life. Going to theater, cooking. Social, mental, physical, emotional."

D. Adverse Events: Infection, implant rejection, bone damage, complications 40
   - "Infection sets you back, psychological event, when does it get cured, do I have to go back for surgery. Start questioning everything."

E. Revision: Having another surgery for the same problem 32
   - "Did not want to go through it again"

F. Death: Infection leading to death, implant causing death, death during surgery 7
   - "Friend died of infection, that's why I came here"

G. Other
   - "When outcomes don't meet expectations"
   - "combined votes; NG= nominal group"

AB1318 VALUE OF NEW BIOMARKERS IN THE DIFFERENTIAL DIAGNOSIS OF SARCOIDSIS AND TUBERCULOSIS

B Harkrishnan1, C B Mithun1, Jyothi V. Srankth1, Renjitha Bhaskaran1, 2Amrita Institute of Medical sciences, Department of Clinical Immunology and Rheumatology, Ernakulam, India; 2Amrita Institute of Medical Sciences, Department of Biostatistics, Ernakulam, India

Background: Due to multisystem involvement with almost similar presentation, tuberculosis (TB) and sarcoidosis poses a diagnostic challenge. As both of them show granulomatous inflammation in tissue, even histopathological examination is not helpful to differentiate the two. As a result of this difficulty, new biomarkers for differentiating the two are being investigated. Previous studies (1,2) done in other regional population attempted to show the efficacy and role of Neutrophil by lymphocyte ratio (NLR) and platelet/lymphocyte ratio (PLR) to differentiate sarcoidosis from TB, with inconsistent results. We attempt to see if these biomarkers can be used in our population to differentiate the two.

Objectives: The aim of our study was to investigate the value of neutrophil/lymphocyte ratio (NLR), and platelet/lymphocyte ratio (PLR) to differentiate TB from sarcoidosis. In addition, we also studied Neutrophil/lymphocyte/albumin/globulin ratio (NLR by A:G ratio) as a novel marker for differentiating the two.

Methods: Patients recruited for the study were selected retrospectively from hospital records during the period of September 2017 to December 2018:

1. 50 consecutive pulmonary TB patients diagnosed based on sputum acid-fast bacilli (AFB) positivity and/or culture–positivity
2. 39 consecutive patients diagnosed with sarcoidosis by an experienced Rheumatologist on clinical and histological grounds.
3. 50 consecutive healthy subjects who presented to general comprehensive check up on Monday of every week. Subjects who were having any autoimmune disease or infections were excluded.

We collected the information including clinical and biochemical parameters at the time of presentation, from the hospital records. NLR, NLR by A:G ratio and PLR were calculated. To test the statistical significance of continuous variables between sarcoid and tb student’s t test/Mann Whitney U test was used. To find the cut off value of study variables, ROC curve was used. Diagnostic measures like sensitivity, specificity, predictive values and accuracy was computed.

Results: Though age was comparable, sex ratio varied between groups with more females in sarcoidosis group. Leukocyte count and neutrophil percentage, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), NLR, NLR by A:G and PLR were significantly higher in the TB group compared with sarcoidosis (for all parameters P < 0.001). Table showing ROC analysis results and accuracy rates of NLR, NLR by A:G ratio and PLR in detection of tuberculosis among sarcoidosis and tuberculosis groups

Conclusion: TB vs sarcoidosis is a challenging diagnostic dilemma. Our retrospective study shows the role of NLR, NLR by A:G ratio and PLR in differentiating TB from sarcoidosis. These biomarkers can help to guide our clinical judgement in differentiating these two causes of granulomatous inflammation.

EFFICACY AND SAFETY OF THE TREATMENT WITH JAK INHIBITORS IN PATIENTS WITH RA. RESULTS OF A CASE SERIES OF USUAL CLINICAL PRACTICE  

Blanca Hernández-Cruz, Dolores Ruiz-Montesinos, José Javier Pérez Venegas. Hospital universitario virgen macarena, Rheumatology, Seville, Spain  

Background: The JAK inhibitors, a new group of targeted synthetic DMARDs were marketed in Spain in 2018. These oral drugs are a good therapeutic alternative for patients with MTX failure. These are not biologic DMARDs and its place in clinical practice is not clear.  

Objectives: To identify the clinical characteristics of the patients treated with JAK inhibitors in a Rheumatology service in the South of Spain. To know the efficacy and safety of these drugs used in usual clinical practice.  

Methods: Setting: Rheumatology department in a 3rd level University Hospital. Design: an observational and analytical case series. From September 2018 to January 15, 2019 clinical data were collected of all patients with RA (ACR/EULAR 2010) treated with JAK inhibitors. The variables collected were demographics, clinical, related to RA, comorbidities, activity (DAS28ESR) and EULAR response. Safety variables included adverse events, and adverse events that caused the interruption of the treatment. The protocol was approved and conducted according to the local ethic committee regulations. The statistical analysis was done with descriptive and inferential non parametric tests. Data are shown as median (percentile 25 – percentile 75).  

Results: In the study period, 33 patients were treated with JAK inhibitors. Two patients were excluded of this review due to lack of an evaluation of follow-up. Data of 31 RA patients are presented. They were female (74%) with RF+, ACPA+ and erosive disease in more of 90% of cases; 61% had at least one comorbidity. The Charison comorbidity index was 3 (2-6). The median age at the time of the start of the JAK inhibitor was 63.3 (56.8 – 70.7) years. The disease duration at the time of the start of the JAK inhibitor was 14.7 (8.6 – 27.5) years. All the patients had received synthetic conventional DMARDs, the number of previous scDMARDs was 2 (2 – 6); 26% had been treated with biologic DMARDs. The number of previous bDMARDs was 2 (1 – 5); 26% (84%) patients were treated with baricitinib and 5 with tofacitinib, oh these 25 (77%) were treated with corticosteroids, the median daily dose of prednisone was 7.5 (5 – 15) mg/day, and 16 (52%) were treated with MTX; the mean weekly dose was 15 (10 – 25) mg/week. The baseline DAS28ESR was 4.9 (4.1 – 5.7) and the end DAS28ESR was of 2.6 (2.07 – 3.5), p<0.0001; the EULAR response was good in 15 (52%), Moderate in 11 (35%) and Poor in 5 (13%). At the last visit 15 (38%) were in remission (DAS28ESR ≤2.6), and the follow-up was of 11.1 (6.8 – 16.7) months. In 8 patients the treatment was stopped, one due to primary inefficacy, three due to secondary inefficacy and in five patients due to adverse events The most relevant adverse events were one case with septic arthritis of the knee after a intra articular injection; one case with a community acquired pneumonia; one case with pyometra, one breast cancer recurrence, one severe neuropenia and one with severe psoriasis flare. There were no thrombotic events. The only variable related with remission was the low baseline DAS.  

Conclusion: The JAK inhibitors are tsDMARD with good profile of efficacy and safety in clinical practice. The patients treated with these drugs had a long and severe disease with failure to several drugs and poor prognostic variables, and a high comorbidity index, however these drugs show good response rates.

NEUTROPHEL-TO-LYMPHOCYTE RATIO AND PLATELET-TO-LYMPHOCYTE RATIO ARE ASSOCIATED WITH DISEASE ACTIVITY IN POLYMALGIA RHEUMATICA  

Ju-Yang Jung, Jiwon Kim, Chang-Hee Suh, Hyoun-Ah Kim. Ajou University School of Medicine, Rheumatology, Suwon, Korea, Rep. of (South Korea)  

Background: Polymyalgia rheumatica (PMR) is a systemic inflammatory disorder, which develops inflammatory pain and stiffness of large joints. There is no specific serological marker or test to differentiate PMR. There is no specific serological marker or test to differentiate PMR.  

Objectives: To identify the clinical characteristics of patients with PMR compared with patients with RA (all p < 0.001). NLR, PLR, and MLR were correlated with specific serological values, including CRP and amin, in patients with PMR. After disease activity resolved, NLR (2.95 ± 2.32, p < 0.001), PLR (137.5 ± 82.3, p < 0.001), and MLR (0.26 ± 0.16, p < 0.001) decreased significantly. By comparing patients according to the disease course, swollen joint counts were higher in the chronic course group compared with the remission group (p = 0.03), while NLR, PLR, and MLR levels were similar.  

Conclusion: This study found that NLR, PLR, and MLR in patients with PMR were higher than in those with RA. Furthermore, NLR, PLR, and MLR levels were associated with disease activity and specific clinical features, although they could not predict prognosis in patients with PMR.

PSYCHOMETRIC PROPERTIES OF THE ASAS HEALTH INDEX IN PATIENTS WITH ACTIVE AS/RADIOPHAGIC AXIAL SPA WHO HAVE PRIOR INADEQUATE RESPONSE/INTOLERANCE TO TNF INHIBITORS IN A PHASE 3 TRIAL  

Uta Klitz1,2, Désirée van der Heijde3, Annelies Boonen4, Lianne S, Genders2, Theresa Hunter4, Kathleen Wyrwich5, Yan Dong6, Gaia Gallo4, Juergen Braun1,2, RheumaZentrum Ruhrgebiet, Herne, Germany; 5Ruhr-Universität Bochum, Bochum, Germany; 6Leiden University Medical Centre, Leiden, Germany; 7Maasstricht University Medical Center, Maasstricht, Netherlands; 8UCSF School of Medicine, San Francisco, United States of America; 9Eli Lilly and Company, Indianapolis, United States of America  

Background: The Assessment of SpondyloArthritis international Society Health Index (ASAS HI) assesses function, disability, and health in patients with ankylosing spondylitis/radiographic axial spondyloarthritis (ASI-/axSpA).  

Objectives: To evaluate the psychometric properties of the ASAS HI in patients with active ASI-/axSpA in a placebo-controlled study of ixekizumab, a humanized IL-17A monoclonal antibody (COAST-W, NCT02696798).  

Methods: The ASAS HI questionnaire consists of 17 dichotomous items that yield a total score ranging from 0 (good health) to 17 (poor health). The psychometric properties of the questionnaire, including test-retest reliability, convergent and discriminant validity, and responsiveness, were evaluated using pooled data from three exposure groups (placebo and ixekizumab 80 mg every 2 or 4 weeks). Adults enrolled fulfilled ASAS criteria (sacroiliitis defined centrally by modified New York Criteria and ≥1 SpA feature), had active disease (BASDAI > 4, back pain > 4), and either prior inadequate response or intolerance to 1 or 2 TNF inhibitors.  

Results: Mean baseline ASAS HI score was 9.7 (SD=3.62, n=316). Intraclass correlation (0.78) indicated test-retest reliability of ASAS HI between screening and baseline. ASAS HI score was moderately correlated at baseline (r=0.30, Figure [circles]) and strongly correlated at Week (Wk) 16 (r=0.50; Figure [crosses]) with BASDAI, BASFI, SF-36 PCS, and spinal pain, and strongly correlated at both baseline and Wk 16 with EQ-5D-5L UK Population-based Index and SF-36 MCS. Greater improvements in disease activity were associated with greater improvements in ASAS HI scores at Wk 16 (Table).  

Conclusion: The ASAS HI demonstrated reliability, validity, and responsiveness in adults with ASI-/axSpA, supporting its use in clinical trials.
Figure. Correlation between ASAS-HI and other health measures

Table. Association between ASAS-HI and other health measures

**Note:** An ANCOVA model with change in ASAS-HI score as dependent variable and clinical and outcome response and baseline ASAS-HI as independent variables was applied. Post hoc comparison was conducted using Scheffé's correction.

OSTEOPHYTOSIS PROCESS SUGGEST INVOLVEMENT OF MAST CELLS, REVEALED BY WHOLE TRANSCRIPTOME ANALYSIS OF OSTEOARTHRITIS PATIENTS

Priya Kulkarni1, Sulev Koks2, Abhay Haralkar3, Aare Martson3. 1University of Tartu, Department of Pathophysiology, Tartu, Estonia; 2Bharati Vidyapeeth University, Department of Pharmaceutical Biotechnology, Pune, India; 3University of Tartu, Department of Traumatology and Orthopedics, Tartu, Estonia

Background: Cartilage-loss is a central pathophysiology of osteoarthritis while synovitis, sub-chondral bone sclerosis and osteophytes (OFs) formation are counted as integral phenomenon. Osteophytosis is a process of OFs formation, in which mesenchymal stem cells from peristeum and synovium, along with a number of cytokines, growth factors and biochemical factors gives out bony out-growth at margin of the affected joint. Although frequently associated, OFs are one of the less focused areas in OA research, particularly from the molecular mechanism point of view, involved in their formation. Also, it is a good ambiguity if OFs is a pathological condition with altered biochemical milieu or a functional adaptation for joint health.

Objectives: Accounting its importance in clinical OA and the obscure biochemical background, this study strives for a deeper comprehension of molecular mechanism and active pathways, involved in OF formation

Methods: We performed whole transcriptome analysis of OFs, collected from six knee OA patients during knee replacement surgery. Non-OF tissue from tibial plateau of the same patient was used as a control. After RNA isolation, RNA-seq was performed using SOLiD 5500W platform and fragment sequencing chemistry. For differential gene expression analysis, non-normalized raw counts were used for the EdgeR package. To find differential transcriptome between OF and control, we used group-wise comparisons where negative binomial fitting was followed by exact test. Finally, RT-PCR of significantly expressed genes was run for transcriptome validation.

Results: After cluster analysis, total 597 genes were significantly expressed between OFs and controls out of which, 323 genes were seen up-regulated (LogFC > 2) while 274 were down-regulated (LogFC < 2). Further, 88 genes showed marked increase (P<0.01); here CP3A, Selectin E, MS4A2, PLA2G2A and CD44 were prominent. Similarly, 23 genes were with a noteworthy down-regulation (P<0.01) and APOB, CADM2, TNEFF2, GNAZ and GABRA2 remained as first five. GO analysis of the best extracted genes indicated significant involvement of ECM proteoglycan, GABA receptor pathway (Reactome 2016 - homo sapiens WP2031 and homo sapiens WP231 respectively). Finally, trascriptome results were validated using RT-PCR of significantly expressed genes (CP3A, MMP-1, 3 and 13).

Conclusion: Significant expression of CXCL9, 10, 11 and PGRF indicate chemotaxis and immune cells deployment; outstanding CP3A and MS4A2 indicate active involvement of mast cells. Accounting a previous knowledge that ‘mast cell products’ are linked with increased osteoblastic and osteoclastic activity and impose pathological changes in articular and peri-articular tissue, marked expressions of MC products or mediators here, enable us to propose an association between MCs and OF. Presence of E-selectin on endothelial cell surface is known to promote adhesion of neutrophils and further release of TNFα and IL1. Expression of PLA2G2A suggests increased prostaglandin synthesis and indicates activation of inflammatory cascade. In conclusion, this transcriptome analysis suggests a significant association of mast cells with osteoarthiysis. The genes involving chemotaxis, degranulation, cytokinin synthesis mark the initiation of OF. On the other hand, proteases metrinmodelling enzymes may indicate their growth. A host of different signalling molecules denotes involvement of canonical and non-canonical pathways that warrants further investigations.

AB1324
MEASUREMENT PROPERTIES OF THE 10-ITEM CONNOR-DAVIDSON RESILIENCE SCALE AMONG PATIENTS WITH TOTAL KNEE REPLACEMENT BASED ON ITEM RESPONSE THEORY

Ka Keat Lim1, Yu Heng Kwan2, Seng Jin Yeo2, William Yeoh2, Julian Thumboo2,3, David Matchar1,6, Ying Ying Leung1,2
1Duke-NUS Medical School, Programme in Health Services and Systems Research, National University of Singapore, Singapore; 2Singapore General Hospital, Department of Orthopaedic Surgery, Singapore, Singapore; 3Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 4Duke-NUS Medical School, Singapore, Singapore; 5Duke University Medical Center, Department of Medicine (General Internal Medicine), Durham, United States of America

Background: The number of older adults undergoing total knee arthroplasty (TKR) for knee osteoarthritis (OA) has been increasing. While psychological resilience may have a role in outcomes after TKR[1], no psychological resilience scale has been validated among patients with knee OA.

Objectives: To examine the measurement properties of the 10-item Conner-Davidson Resilience Scale (CD-RISC10) among older adults with knee OA.

Methods: Using data from 700 consecutive consented patients with knee OA enlisted for TKR, we examined four measurement properties of CD-RISC10. For structural validity, we fitted graded response model (grm) and examined standardized root-mean square residual (SRMR) for unidimensionality, Chi-square p-value for item fit, residual correlation for local independence and item characteristic curves for overall structure. For measurement invariance, we examined Cronbach’s alpha. For construct validity, we hypothesized that CD-RISC10 as a measure of psychological resilience would be moderately correlated (Pearson’s R 0.30–0.50) with self-efficacy and mental well-being but weakly correlated (Pearson’s R<0.30) with physical and social well-being (Table 1). For measurement invariance, we examined uniform and non-uniform differential item functioning (DIF) between gender, age group (< median 66 vs >66 years), and language (English vs Chinese) and reported the McFadden’s R2. We used mixed and ldfit packages on Rx64 v3.5.1 to examine grm and DIF respectively. We reported the findings based on COSMIN user manual for the selection of health Measurement Instruments (COSMIN[n]).

Results: Of the 700 patients (age 65.5±6.9 years old), 70.6% were females, 83.9% Chinese, 55% responded questionnaire in Chinese. Mean CD-RISC10 score was 27.5±5.2, with minimal floor (0.1%) and ceiling effects (3.9%). CD-RISC10 demonstrated unidimensionality (SRMR<0.05), local independence (residual correlation<0.025), monotonicity (adequate looking item characteristic curves) and internal consistency (Cronbach’s alpha=0.91). Items 1 and 4 had potential misfit (Chi-square p<0.01). All a-priori hypotheses were met (Table 1). No item had significant DIF with age, gender and language, except item 4 had borderline non-uniform DIF across language (McFadden’s R2=0.03).

Conclusion: We demonstrated structure validity, internal consistency, construct validity and measurement invariance of CD-RISC10 in the measurement of psychological resilience among older adults with knee OA.

Objectives:

- To quantify and compare grip strength and hand function in patients with RA, PsA and Pso to relate these outcomes to disease activity.

Methods:

- Patient diagnosed with RA (ACR/EULAR 2010), PsA (Caspar) and Pso and 54 healthy individuals were included in the study after written informed consent. Maximal isometric grip strength (kPA) was measured with a hand dynamometer (Lafayette Instrument, Lafayette, IN, USA) as the highest value out of three measurements. Hand function was determined by way of the Moberg Picking-Up Test (MPUT) and the fastest (s) of two measurements was used. Disease activity was calculated as DAS28_ESR and TJC/SJC 76/76 was recorded. One-way Analysis of Variance (ANOVA), factorial ANOVA and Games-Howell post-hoc testing was performed (p<0.05).

Results:

- 101 RA (63 f; 38 m; age: 59.1±13.2 yrs), 92 PsA (48 f; 44 m; age: 54.8±11.5 yrs) and 51 Pso patients (19 f; 32 m; age: 47.3±14.1 yrs), as well as 54 healthy control subjects (30 f; 24 m; age: 54.6±16.5 yrs) participated in the study. Disease duration (yrs) was not different between groups (RA: 11.0±10.1; PsA: 9.1±9.75; Pso: 12.5±11.7; p=0.156) but Pso patients in our cohort were younger compared to RA and PsA patients. Mean DAS28_ESR was < 3.2 for all patient groups with control subjects (DAS28 1.6 ± 0.7) having lower scores compared to all patient groups and Pso patients presenting with lower DAS28 (2.3 ± 1.3) compared to RA (3.0±1.3) and PsA (2.9±1.3). While TJC was higher for all patients compared to controls (RA: 5.2±6.8; PsA: 5.9±8.1; Pso: 3.2±6.4; CON: 0.5±1.4; p<0.00), SJC was higher for RA and PsA compared to Pso and CON (RA: 0.7±1.0; PsA: 0.9±2.2; Pso: 0.1±0.3; CON: 0.5±1.4; p=0.00). Grip strength of the dominant and/or affected hand of RA patients was lower compared to PsA, Pso and CON (Figure 1A). In contrast to this, hand function of the same hand in all tested patient groups was reduced compared to CON (Figure 1B). The results for grip strength and hand function were not different for the dominant and the affected hand and are independent of age differences between groups.

Conclusion:

- Overall, RA patients showed significantly lower grip strength compared to PsA and Pso patients as well as to the control group, whereas all three patient groups performed worse in the MPUT compared to the control cohort. This suggests that grip strength may be preserved longer than hand function in patients with inflammatory rheumatic disease. Further, it was surprising that hand function was reduced in Pso patients without arthritic correlate compared to healthy subjects. This suggests that hand function may provide a potential parameter for discriminating Pso patients at risk for subclinical joint involvement.

This study was funded by research support from Novartis Pharma GmbH.

INCREASED FIBRINOGEN TO ALBUMIN RATIO IN ANKYLOSING SPONDYLITIS: CORRELATION WITH DISEASE ACTIVITY

Meng Liu, Yukiha Huang, Zhengqiang Huang, Qidang Huang, Xin Guo, Yuling Wang, Wengming Deng, Zhi-Xiang Huang, Xin Guo, Meng Liu, Yukai Huang, Zhengping Huang, Qidang Huang, Xin Guo, Meng Liu, Yukai Huang, Zhengping Huang, Qidang Huang, Xin Guo, Meng Liu, Yukai Huang, Zhengping Huang, Qidang Huang, Xin Guo, Meng Liu, Yukai Huang, Zhengping Huang, Qidang Huang, Xin Guo, Meng Liu, Yukai Huang, Zhengping Huang, Qidang Huang, Xin Guo

Background:

- Fibrinogen to albumin ratio (FAR) has emerged as a new effective biomarker which can reflect the severity of chronic inflammation. However, none of study has focused on the role of FAR in ankylosing spondylitis (AS).

Objectives:

- The study aimed to investigate the association between FAR and the disease activity of AS.

Methods:

- The retrospective study included 117 AS patients and 165 age- and gender-matched healthy controls. AS patients were divided into remission group (Bath Ankylosing Spondylitis Disease Activity Index
(BASDAI < 4) and active group (BASDAI ≥ 4). Remission group included 60 patients and active group included 57 patients. Fibrinogen, albumin, FAR, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were collected. Relationships between FAR and BASDAI as well as other biochemical indexes were assessed by the Spearman's correlations analysis. Receiver operator characteristic (ROC) curves were performed to discriminate AS patients from healthy subjects and active group from remission group. Furthermore, binary logistic regression analysis was conducted to evaluate the risk factors of AS disease activity.

Results: FAR, fibrinogen, CRP and ESR were higher in AS patients compared with healthy controls (P < 0.05), while albumin was lower (P < 0.05). ROC results showed that area under curve (AUC) of FAR (0.818, 95%CI: 0.760 - 0.876) and albumin (0.841, 95%CI: 0.788 - 0.894) were higher than fibrinogen (0.772, 95%CI: 0.707-0.836), CRP (0.677, 95%CI: 0.598 - 0.756) and ESR (0.784, 95%CI: 0.721 - 0.847). Positive correlations were found between FAR and BASDAI (r = 0.488, P < 0.001), CRP (r = 0.858, P < 0.001) and ESR (r = 0.817, P < 0.001). Besides, FAR, fibrinogen, CRP and ESR in active group were higher than remission group (P < 0.05), while albumin was lower (P < 0.05). ROC results showed that AUC of FAR (0.691, 95%CI: 0.598-0.768) was higher than fibrinogen (0.676, 95%CI: 0.577-0.776), albumin (0.665, 95%CI: 0.567 - 0.783), CRP (0.646, 95%CI: 0.545 - 0.746) and ESR (0.667, 95%CI: 0.569 - 0.766). FAR was a risk factor of the disease activity in AS patients (OR: 1.354, 95%CI: 1.067 - 1.718, P = 0.013).

Conclusion: FAR was increased in AS patients compared with healthy controls and significantly correlated with the disease activity of AS. FAR might be a potential useful inflammatory biomarker to monitor disease activity of AS patients.

Joy MacDermid1, Samuel Jumbo2, Michael Kaliu3, Tara Packham3, George Athwal2, Ken Faber2. 1Western University, Physical Therapy, London, Canada; 2Western University, Surgery, London, Canada; 3McMaster University, Rehabilitation Science, Hamilton, Canada

Background: The Brief Pain Inventory (BPI-SF) and McGill Pain Questionnaire (SF-MPQ-2) are general-use, self-report, multidimensional pain assessment outcomes frequently used for pain assessment in musculoskeletal (MSK) conditions. Synthesizing knowledge on their measurement properties, as assessed in MSK conditions, should provide a deeper understanding of their strengths and limitations.

Objectives: To systematically locate, critically appraise, compare and summarize clinical measurement research about the BPI-SF and SF-MPQ-2 in pain-related musculoskeletal conditions.

Methods: Four databases (Medline, CINAHL, EMBASE & SCOPUS) were systematically searched for relevant citations, each for the BPI-SF and SF-MPQ-2. We included articles that reported the psychometric properties (e.g. validity, reliability, responsiveness) and interpretability indices (e.g. minimal clinical important difference) of both tools, as assessed in mixed and specific MSK studies. Independently, two reviewers extracted data and assessed the quality of evidence with a structured quality assessment tool for measurement studies and according to the updated Consensus-based Standards for the selection of health Measurement Instruments (COSMIN) guidelines.

Results: Twenty-five articles were included (BPI-SF, n=17; SF-MPQ-2, n=8). Both tools lack reporting on their cross-cultural validities and measurement error indices. High quality studies suggest that they are internally consistent (α = 0.83-0.96), and they associate modestly with similar outcome measures (r = 0.3-0.69). There is evidence that the BPI-SF conforms to its two-dimensional structure in MSK studies; the SF-MPQ-2 four-factor structure was not clearly established. In seven reports, high to moderate quality evidence was seen in supports of the BPI-SF known group validity (n=2) and responsiveness (n=5) but none was available for the SF-MPQ-2. Furthermore, the SF-MPQ-2 was more frequently associated with floor effects in MSK studies than the BPI-SF (SF-MPQ-2, 42% vs BPI-SF, 6%).

Conclusion: The SF-MPQ-2 has emerging evidence whereas the BPI-SF evidence is more mature. Both tools displayed high-quality evidence in support of their internal consistency and criterion-convergent validities. High to moderate quality evidence suggests the BPI-SF subscales have a better responsiveness, restest reliability, known group validity and structural validity than the SF-MPQ-2.

THE PRELIMINARY VALIDATION OF LASER DOPPLER FLOWMETRY IN SYSTEMIC SCLEROSIS ACCORDING TO THE OMERACT FILTER: A SYSTEMATIC REVIEW

Karin Melsen1, Sarah Van Impe2, Carmen Pizzoni3,4, Maurizio Cutolo5,6, Vanessa Smith1,2, Ghent University; Ghent University Hospital, Department of Internal Medicine; Department of Rheumatology, Ghent, Belgium; 2Ghent University, Ghent, Belgium; 3University of Genoa, Research Laboratory and Academic Division of Clinical Rheumatology, Genoa, Italy; 4San Martino Polyclinic Hospital, Genoa, Italy, Internal Medicine, Genoa, Italy; 5VIB Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium

Background: Systemic sclerosis (SSc) is characterised by a widespread vasculopathy. The vasculopathy comprises the skin microcirculation and results in features such as Raynaud’s phenomenon (RP) and digital trophic lesions. The quantification of the skin blood perfusion at the level of the finger (FBP) is a major need in the assessment of SSc in clinical and research setting. Up to now, laser doppler flowmetry (LDF) has been the most thoroughly investigated instrument to assess the FBP in SSc.

Objectives: To investigate the validation status of LDF in SSc according to the Outcome Measures in Rheumatologic Clinical Trials (OMERACT) filter.

Methods: Literature was systematically reviewed to detect all reports in which the assessment of the FBP in SSc patients was described. The OMERACT filter, including the domains of truth, discrimination and feasibility was applied and the quality assessment was done by the Good Methods Checklist. Comparison between studies was eased by grouping the results per dynamic test situation (basal circumstances, cold/hot challenge and occlusion).

Results: The systematic search resulted in 4340 hits. After title and abstract screening 228 hits remained and of these, 79 full texts described the assessment by LDF. Fifty studies were included for quality assessment of which 17 studies were retained for conclusion making (fig 1).

An overview of the validation status of LDF is given in table 1. Expert consensus is lacking on the face and content validity of LDF in SSc. The construct validity of LDF is partially validated (e.g. the correlation with laser speckle contrast imaging was attested in one study). Conflict results exist on the discriminant capacity of LDF to distinguish healthy from diseased, primary from secondary RP and to differentiate between disease subtypes. The addition of a heat challenge, as well as the evaluation of the post-occlusive hyperemic response to the LDF-measurement has the potential to elicit a difference between healthy and diseased. Lastly, there are no data on the feasibility of LDF in SSc.
Table 1. Validation of LDF according to the OMERACT filter

<table>
<thead>
<tr>
<th>TRUTH DISCRIMINATION FEASIBILITY</th>
<th>SMEAR VASCULAR ADHESION MOLECULE-1 AS AN INDEPENDENT MARKER FOR ENDOTHELIAL ACTIVATION IS ELEVATED IN ACTIVE RHEUMATIC DISEASES: A MULTIVARIATE ANALYSIS</th>

<td></td>
<td>SMOLE VASCULAR CELL ADHESION MOLECULE-1 AS AN INDEPENDENT MARKER FOR ENDOTHELIAL ACTIVATION IS ELEVATED IN ACTIVE RHEUMATIC DISEASES: A MULTIVARIATE ANALYSIS</td>
</tr>
</tbody>
</table>

Conclusion: This systematic review emphasizes the very preliminary validation status of LDF in the assessment of the FBP in SSc. No single application method has emerged as fully validated according to the OMERACT filter.

Cross-sectional study with 230 patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and RA patients, according to ACR/EULAR 2010 classification criteria, aged between 40 and 70 years, were recruited and followed for 12 months. Disease activity, body composition, fatigue and urine metabolome were measured. Body composition was assessed by total body dual-energy x-ray absorptiometry (DXA) for measurement of appendicular lean mass index (ALMI). Disease activity was assessed by Disease Activity Score-28 with erythrocyte sediementation rate (DAS28-ESR). Fatigue as assessed by the Functional Assessment of Chronic Illness Therapy (FACIT). Nuclear Magnetic Resonance spectroscopy (NMR) measurements were performed to evaluate the profile of metabolic changes during the 12mo follow-up, resulting in the identification of 48 metabolites in urine collected at the baseline and after one year. Frequency analysis, Pearson Correlation and Multivariate data analysis with orthogonal projections to latent structures (OPLS) method were performed and a statistical significance was considered as p<0.05. Results: The study population was characterized by the majority of women (86.7%), mean age 56 years old, mean disease duration of 8 years, around 80% with positive anti-CPP and RF. There was a significant increase of citric acid, creatinine, L-serine and urea during the follow-up, metabolites that are involved in the muscular-related metabolism. There was no substantial variation in the DAS28-ESR (baseline: 3.8, after

**AB1330**

**AB1331**
12 months: 4.0) and there was no significant correlation between changes in the metabolome pattern and DAS28-ESR score (p=0.05). Fatigue was negatively correlated with L-serine/creatinine (r: -0.4, p<0.001). Appendicular lean mass index (ALMI) also showed a positive difference which correlated with the increase of urea and creatinine (r: 0.3, p=0.019).

Conclusion: This prospective metabolic analysis indicated that the RA might be associated with amino acid metabolism alterations probably related to inflammation injury and muscle fatigue. These findings suggest that urine metabolome analysis may be an interesting approach to study and monitor the systemic impact of RA.

COST EFFECTIVE BIOMARKER IN PREDICTING SLE IN DEVELOPING COUNTRIES – NEUTROPHIL LYMPHOCYTE RATIO (NLR), PLATELET LYMPHOCYTE RATIO (PLR), MPV

V S Srikanta1, M Gopala Krishna Pillai2, Niluyi Shrestha Rajkumar3, AIM Hospital, Internal Medicine, Kochi, India; 2AIM Hospital, Rheumatology, Kochi, India

Background: SLE is a disease which is easily missed in regular clinical practice. In developing countries due to lack of investigation modalities and rheumatologist, early identification of the diseases process is delayed. By the time the patient reaches a higher medical care centre there is a significant time loss and advancement of the disease. NLR, PLR, RDW and MPV can be calculated from a complete blood count which will be available at any grass route heath centre.

Objectives: To identify Cost effective biomarkers in predicting SLE in developing countries. Focussing on markers - Neutrophil Lymphocyte Ratio (NLR), Platelet Lymphocyte Ratio (PLR), MPV.

Methods: This is a retrospective hospital based observational study conducted screening patients admitted from January 2016- November 2018 in with a diagnosis of SLE. We identified 150 patients with SLE and their NLR, PLR, and MPV data were collected and were correlated with equal control group without SLE

Results: We found that NLR, PLR, and MPV were highly significant with a-p value of 0.001 to be used as bio marker and also when further analysis was done using ROC curve with an area under curve of 76%, a p-value of 0.001 to be used as bio marker and also when further analysis was done using ROC curve with an area under curve of 76%, 81% and 78% respectively when compared with the control group.

Conclusion: We conclude that NLR, PLR and MPV is cost-effective bio marker which costs (< 1 Euro) in predicting SLE and also play a great role in monitoring following up referring patient to higher centre for biopsy at a golden period which will aid in early management which will limit the mortality and morbidity associated with the disease

CELL-FREE DNA AND BIOLOGICAL TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Vanda Mlynarikova1, Frantisek Malis1, 2,*, Peter Celen2, Barbora Vikova1, Emoke Stenova3.

1National Institute of Rheumatic Diseases, Rheumatology Department, Piestany, Slovakia (Slovak Republic); 2Comenius University Faculty of Medicine, Institute of Molecular Biomedicine, Bratislava, Slovakia (Slovak Republic); 3Comenius University Faculty of Medicine, Institute of Pathophysiology, Bratislava, Slovakia (Slovak Republic); 4Comenius University Faculty of Natural Sciences, Department of Molecular Biology, Bratislava, Slovakia (Slovak Republic); 5University Hospital, Comenius University Faculty of Medicine, 1st Department of Internal Medicine, Bratislava, Slovakia (Slovak Republic)

Background: Cell free DNA (cfDNA) are DNA fragments released from the cell nucleus into extracellular compartment and is therefore detectible in plasma or serum. The most common reason for this release is tissue damage, cell death and inflammation of diverse origin. In regard to autoimmune diseases, increased levels of cfDNA has been found in plasma/serum in patients with systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and Sjögren’s syndrome. The results of some published works, appointing the correlation between levels of cfDNA and RA activity, are controversial, that’s why the position of cfDNA as a potential new biomarker remains unclear.

Objectives: The aim of our study was to describe the effect of biological therapy on the concentration of cfDNA and explore the correlation between therapeutic response DAS28 score and cfDNA levels. This potential correlation could define cfDNA as a new marker of treatment response and also potentially also clarify the role of cfDNA in the pathogenesis of RA.

Methods: Plasma samples of 40 patients with RA were collected before, as well as 3 and 12 months after starting treatment with tumor necrosis factor α-inhibitor (TNFα-inhibitor). Total cfDNA was quantified fluorometrically. Treatment response was evaluated by using DAS 28 scoring system and C-reactive protein.

Results: The treatment with TNFα-inhibitors showed statistically significant changes of DAS28 and cfDNA. According the EULAR treatment response defined by DAS28 changes, patients with good response showed statistically significant decrease of cfDNA in month 3 (p<0.005), but the improvement in month 12 was just on the border of statistical significance (p<0.059). There was also a slight decrease in a group without improve-DAS 28 response in month 12 (p=0.054). In the entire group there was found slight positive (r=0.44), statistically significant (p<0.0073) correlation between the levels of cfDNA and DAS 28 score after 12 month of treatment.

Conclusion: Even if treatment with TNFα-inhibitors decreases plasma cfDNA, there are other markers with better correlation with disease activity. We consider, that the changes in cfDNA levels after biological treatment could determine the role cfDNA more as a consequence of the inflammation, rather than the cause of inflammation in this autoimmune disease, but further research is needed.

AN OPEN-SOURCE WEB-BASED ANALYTICS PLATFORM FOR THE HUMAN IMMUNE ATLAS

Martin Wasser1, Joo Guan Yeo1, Pavanish Kumar1, Thaschawee Arkachaisri2, Su Li Poh1, Fauziah Aly1, Jing Yao Leong1, Kee Tai Yeo1, Salvatore Albani1, 1Translational Immunology Institute/SingleHealth Duke-NUS Academic Medical Centre, Singapore; 2KK Women’s and Children’s Hospital, Rheumatology and Immunology, Singapore, Singapore

Background: Mass cytometry (CyTOF) measures the expression of many proteins (currently up to 40) in single cells. It applies CyTOF to characterise cellular diversity of the immune system in peripheral blood and other tissues. Using a growing collection of CyTOF data acquired from blood of clinically and demographically diverse human subjects, we have built our version of the immune atlas, called EPIC (Extended Poly-dimensional Immunome characterisation).

Objectives: We will discuss two main objectives of this project. To integrate CyTOF data, metadata, cell annotations or other inferred data into the immune atlas, we developed a novel data analytics pipeline. To provide a user-friendly gateway that helps researchers explore the immune atlas and gain new insights about their own CyTOF data, we implemented a web-based data analytics application using the R Shiny programming environment.

Methods: The core components of the atlas are ‘immune maps’, which comprise CyTOF data of samples labeled with identical antibody panels and grouped according to a common biological theme. Besides protein expression patterns, immune maps contain clinical and demographic metadata, as well as phenotypic information inferred from clustering and cell type annotation. To intuitively analyse these complex multi-dimensional data, we developed a Shiny/R web application that has two main objectives. First, clients can explore the immune atlas at different levels of detail using a wide range of interactive visualisation methods, such as bar charts comparing the abundance of all or subsets of immune cell types in different age groups, or tSNE/UMAP scatter plots providing global perspectives of expression domains. Second, users can upload their own CyTOF data and, through pattern matching, obtain instant estimates about the abundance of selected immune cell populations in their own samples.

Results: We tested our system using immune maps constructed from healthy paediatric samples. Manually gated ground truth data along with interactive visualisation techniques were used to measure the accuracy of our pipeline in detecting and annotating homogenous cell populations. In addition, we will demonstrate how immune maps can be applied to classify uploaded CyTOF data.

Conclusion: Our interactive immune atlas platform promises to improve our understanding of the changing immunome landscape in response to disease, treatment and ageing.

AGE-RELATED MUSCULOSKELETAL STIFFNESS AMONGST HEALTHY SUBJECTS

Hugh Watson1, Amalie Lynggard2, Lars-Erik Bartels2, 1Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 2Randers Regions Hospital, Department of Internal Medicine, Rheumatology, Randers, Denmark

Background: A patient questionnaire for evaluating musculoskeletal stiffness (MSQ) has been developed for rheumatoid arthritis (RA) (Halls 2015) and also tested in chikungunya disease. Joint stiffness is associated with older age in adults.

Objectives: The aim of this study was to evaluate the variation in MSQ scores with age in a cohort of healthy adults.

Methods: Subjects aged 18 years old were enrolled at two sites. Subjects were engaged in, or had completed, tertiary education. Subjects with a diagnosis of joint disease, Parkinson’s disease or multiple sclerosis were excluded. Each subject completed a 21-item questionnaire designed to evaluate the severity of musculoskeletal stiffness, its physical impact and psychosocial impact, and to provide an overall stiffness score. Results are expressed as a percentage of the maximum possible score.
coincidence rate was 92.72%-94.79%. The sensitivity and specificity values of ELISA proposed by the manufacturer for clinical diagnosis RA were 82% and 95%. The two methods had the same detection effect.

**Conclusion:** The current commercially available methods for detecting anti-CCP antibodies were roughly the same, and the consistency between LETIA and ELISA were high. In general, the LETIA was more accurate and sensitive than the ELISA in the detection of anti-CCP antibodies in serum. Overall diagnostic performance of ELTIA can be compared. LETIA provided reliable information about antibody levels that made it useful in monitoring disease activity. Comparable to the classic ELISA, ELISA may even be replaced in the future.

**PERFORMANCE EVALUATION OF PARTICLE-ENHANCED TURBIDIMETRIC IMMUNOASSAY FOR ANTINUCLEAR ANTIBODIES DETECTION IN COMPARISON WITH LINE IMMUNOASSAY**

Van Qin, Jing Luo, Xiang-Cong Zhao. The Second Hospital of Shanxi Medical University, Taiyuan, China

**Background:** Detection of antinuclear antibodies (ANAs) supports the clinical diagnosis of ANA-associated rheumatic diseases, such as systemic sclerosis (SSc), systemic lupus erythematosus (SLE), primary sjogren’s syndrome (SjS) and mixed connective tissue disease (MCTD) [1-3]. Throughout history, a number of autoantibody detection methods have emerged, for instance, indirect immunofluorescence (IIF), radioimmunonassay (RIA), enzyme-linked immunosorbent assay (ELISA) and line immunoassay (LIA) [4]. With the development of detection technology, new methods to detect ANAs were continuously developed by numerous manufacturers, for example, particle-enhanced turbidimetric immunoassay (PETIA). Therefore, in the current study, we evaluated for the first time the performance of PETIA in the detection of anti-nuclear antibody and compared it with commercial LIA.

**Objectives:** To evaluate the clinical performance of PETIA for the detection of ANAs in comparison to the currently commonly used LIA.

**Methods:** Total 606 serum samples from diseased and healthy controls were assayed to simultaneously determine SSA, Sm/RNP, SSB, Sm and U1-SnRNP antibodies by the PETIA and LIA. The sensitivity, specificity, consistency and area under curve (AUC) were analyzed for each antibody between PETIA and LIA.

**Results:** The positive rate and specificity of PETIA and LIA for ANA specific target antibodies were comparable. Compared with LIA, the sensitivity of SSA, SSB and Sm were 100.00%, 88.89% and 90.00%, while Sm/RNP and U1-SnRNP were 75.00%, 70.59%, respectively; Sm/RNP, SSB, Sm and U1-SnRNP have high specificity, respectively 97.87%, 98.90%, 97.06% and 94.68%, while SSA specificity is general, 81.52%. Under manufacturer’s cut-off values, the consistent rates of SSA, Sm/RNP, SSB, Sm, and U1-SnRNP between PETIA and LIA were 87.22%, (116/133), 92.06% (116/126), 96.61% (114/118), 97.03% (98/101) and 88.28 (113/128), respectively. Excellent consistencies were found between PETIA and LIA for the detection of Sm/RNP, SSB and Sm antibodies (kappa=0.75), and kappa coefficients were 0.776 (p<0.001), 0.901 (p<0.001) and 0.841 (p<0.001), while the coincidence for anti-SSA and U1-SnRNP detection were moderate (0.40<kappa<0.75), and Kappa coefficient was 0.731 (p<0.001) and 0.685 (p<0.001), respectively.

**Conclusion:** The performance of PETIA for the detection of antibodies to nuclear specific antigen was satisfying to correlate with that of LIA. With the additional benefits of short detection time, quantitative output and high universality, PETIA can better meet the requirements of quantitative detection of specific target antibodies.

Results: A statistically significant difference was found between three groups in terms of normalized suprahyoid muscle activity (p<0.001) (Table 1). The difference between three groups was caused by the difference between Group 1 and Group 2 (p<0.001) and between Group 1 and Group 3 (p=0.040) in favor of Group 1. No difference was found between Group 2 and Group 3 (p=0.104) (Table 2-4).

1 recurrent infection, 3 did not do their screening test, 1 did not do the recommended vaccination.

**Conclusion**

- We assume that in our clinic pre VC and, indeed, in the majority of UK Rheumatology Departments about 90% of patients recommended for a biologic by a specialist eventually ends up taking that medication and give that assumption potential costs savings with this model are estimated as equivalent to 35 patients (approx. £1400/yr. - drug costs savings calculated vs current cheapest option, SB4 ($400/yr.)).

**PATIENT EDUCATION IN PSORIATIC ARTHRITIS:** ADDRESSING AN UNMET NEED

Keziah Austin1, Nia Jones2, Roopa Prasad1, 1University Hospitals Bristol NHS Foundation Trust, Department of Rheumatology, Bristol, United Kingdom; 2University Hospitals Bristol NHS Foundation Trust, Department of Medicine, Bristol, United Kingdom

**Background:** Patient education should be integral to the care of people with inflammatory arthritis [1]. Research suggests that the majority of patients with Psoriatic Arthritis (PsA) would like to receive education about their condition [2]. There are limited studies in PsA but randomised controlled trials in rheumatoid arthritis have demonstrated that patient education improves compliance to medication [3], disease specific knowledge [4] and coping mechanisms [5]. In our department, patient education in PsA was recognised as an unmet need.

**Objectives:** To pilot an educational session for PsA patients, to assess whether this improved patients’ understanding of their condition, and to determine whether an education programme would be a useful adjunct to patient care.

**Methods:** Adult PsA patients attending their rheumatology clinic appointments were asked to complete a short survey on whether they would be interested in attending an education session and the aspects they would like to have covered. Those who expressed interest were invited to attend a 2.5 hour multidisciplinary team (MDT) session which covered 1) a general overview of PsA; 2) medications used in PsA; 3) the role of physiotherapy and occupational therapy; 4) flares and self management. Patients were asked to evaluate their knowledge or understanding before and after each topic covered, on the same day, using a series of 1-10 Likert scales. They were specifically asked whether they found the education session helpful, whether they would recommend it to other PsA patients, whether they would be interested in developing a PsA patient support group.

**Results:** 25 patients were invited to the session and 9 patients attended.

- There were 5 males and 4 females, across a wide range of age categories.
- There were statistically significant improvements in all topics covered, including a mean improvement of 120% in how well informed patients felt about PsA in general (p<0.0001); a mean improvement of 79% in confidence in accessing help from the MDT (p<0.01); a mean improvement of 211% in how well informed patients were about medications available (p<0.0001); a mean improvement of 86% in confidence in self-managing a flare (p<0.0001). All patients found the session helpful overall and all patients stated they would recommend it to others. Several patients expressed interest in developing a PsA patient support group.

**Conclusion:** All PsA patients demonstrated a greater awareness and understanding of their condition following a 2.5 hour education session. This study indicates that an education programme is a useful and important adjunct to patient care and supports extending this to the wider PsA patient population.

**ONLINE CME IMPROVES ADOPTION OF JAK INHIBITORS IN CLINICAL PRACTICE BY RHEUMATOLOGISTS**

Elaine Bell, Robert McCarthy, Medscape LLC, New york, United States of America

**Background:** The treatment landscape for RA is evolving rapidly. The JAK inhibitors are oral small molecules that have recently been approved for use in RA.

**Objectives:** This online CME-accredited educational activity was designed to address the challenges of integrating JAK inhibitors into clinical practice in RA and measure changes in practice

**Methods:** Non-US rheumatologists, dermatologists and primary care physicians (PCPs) participated in an online activity consisting of a 30-minute video roundtable discussion between 4 experts, with synchronized slides, posted online on August 25 2017. A Planned Change Assessment (PCA) survey (data collected through April 3 2018) with qualitative follow-up interviews was used to measure intent to change and actual change in clinical practice following participation in the activity. A 2-question PCA survey in multiple choice format, which was administered immediately following the activity, asked:

What do you perceive as barriers to making the above selected changes in your practice?

What will you do differently in your practice as a result of participating in this activity?

**Results:**

- 267 non-US physicians completed the initial PCA survey and 44 completed a follow-up assessment approximately 8 weeks later, resulting in a matched subset of 37 learners. Qualitative interviews were conducted with 13 learners
274 learners (96%) indicated that they intended to make a change as a result of participating in the activity with most learners selecting multiple changes.

- The most common intended changes for rheumatologists were using a JAK inhibitor for the first time (65%) and selecting a JAK inhibitor when oral dosing is preferred (54%)

- Other than systems barriers such as reimbursement and lack of availability of JAK inhibitors, the most common anticipated barriers to change for rheumatologists related to lack of knowledge about MOA and safety, and lack of confidence in their use

- 44 learners completed the follow-up assessment: 42 (96%) reported making changes in their clinical practice

- For rheumatologists, the most common actual changes were using a JAK inhibitor first-line (55%) and considering a JAK inhibitor when oral dosing is preferred (54%)

At follow-up the key barriers reported by rheumatologists related to systems barriers/availability and lack of confidence in using JAK inhibitors.

**Conclusion:** Learners in this activity reported increased knowledge about new treatment options for RA and the MOA of JAK inhibitors. The PCA assessment showed that the activity was most effective at prompting rheumatologists to more frequently consider using a JAK inhibitor as a first-line treatment in appropriate patients. Use of new therapies, however, may be challenging due to lack of availability of JAK inhibitors in many countries and financial burdens in others. Further education would help rheumatologists to gain confidence in using JAK inhibitors, overcome knowledge gaps, and meet challenges related to lack of access to JAK inhibitors.

**IMPACT OF THERAPEUTIC PATIENT EDUCATION ON THE SAFETY OF PATIENTS ON BIOThERAPY FOR CHRONIC INFLAMMATORY RHEUMATISM**

**BENCHEIR IMEN, Daila Bendjenna. University Public Hospital of Constantine, Rheumatology, Constantine, Algeria**

**Background:** Patients treated with biotherapy should be aware of the specific complications. The acquisition of safety skills is one of the objectives of therapeutic patient education programs in chronic inflammatory rheumatism.(1,2,4)

**Objectives:** Evaluation of the impact of the “EST-RIC” therapeutic patient education program on the safety skills of patients on biotherapy for chronic inflammatory rheumatism.

**Methods:** Descriptive cross-sectional study evaluating the impact of integration into a therapeutic patient education program on the skills of patients treated in a day hospital at the Constantine rheumatology department for chronic inflammatory rheumatism, using the validated “BioSecure” questionnaire (3).

**Results:** Of sixty patients, fifty-two patients (86.6%) completed the questionnaire. Forty-three patients have spondyloarthritis (83%) (Tab1). The median Biosecure score was 62.90/100 (SD 10.83). Fifty-two percent of the patients had integrated the therapeutic education program. Their Biosecure score was significantly higher than that of naive patients with therapeutic education (median score 69/100 in the ETP group versus 58/100, p <0.001) (Fig 1). The Biosecure score varied significantly with the lower level of education (p <0.0001), in the subgroup of patients with a professional activity (P = 0.008) and in patients whose treatment was introduced for less than one year (p <0.0001) and who had a pathology whose diagnosis was less than 5 years (p <0.008)

**Conclusion:** The integration of patients undergoing biotherapy into a specialized program of therapeutic patient education is correlated with a better mastery of theoretical safety skills.

**PUBLIC AWARENESS OF RHEUMATOID ARTHRITIS IN MONGOLIA**

**Lkhamb-Edrene Byambadorj1, Nandin-Endere Danzan1, Tsoleden Darisuren2, Devshit Zorig1, Enkhjin Bat-Erdene2, Davsaadulam Enkholbd2, Zulgerel Dandii1. 1Mongolian Rheumatology Association, Ulaanbaatar, Mongolia, 2Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia**

**Background:** Rheumatoid arthritis (RA) is multifactorial, chronic, inflammatory disease which in the absence of early diagnosis can lead to joint destruction and disability. In the last decade, rheumatology has been developed as independent branch in Internal medicine in Mongolia, published rheumatological textbooks. The Mongolian Rheumatology Association has also introduced a RA guideline and conducted training that has led to the use of DMARDs in treatment and improves patient’s quality of life is improving in Mongolia. Nevertheless, we have many patients with a late RA diagnosis in Mongolia. In some studies, poor public awareness of RA correlates with high level of disability.

**Objectives:** To develop understanding about current levels of public awareness of rheumatoid arthritis in patients coming to the outpatient department of the First central hospital in Ulaanbaatar, Mongolia.

**Methods:** This was a cross-sectional descriptive study conducted in the outpatient department of the First central hospital of Ulaanbaatar in Mongolia for 3 days. The study population consisted of adults. Data collection was performed by using questionnaire of developed by the NRAS, addressed to assess awareness on RA.

**Results:** Total 376 persons stood for 3 days in outpatient clinic in First central hospital. 26 of them refused and 350 of them participated our study. The average age of the participants was 37.79. Participants responded, 22% of them know RA, 78% of whom do not know RA for rheumatologists, the most common actual changes were using a JAK inhibitor first-line (55%) and considering a JAK inhibitor when oral dosing is preferred (54%).

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.5159
rheumatoid arthritis. Understanding about the disease symptoms: 50.5% responder answered they to do not know RA symptoms; 29% correctly identified joint swelling; 17.4% correctly identified morning stiffness; 12.6% correctly recognized extreme fatigue as a symptom; and only 6.5% correctly stated that smoking can increase the risk factor for RA. Understanding about disease impacts: 21.1% correctly recognized genetics as a factor; 17% knew that women are more vulnerable than men; only 3% correctly stated that undertaking exercise and obesity is also a risk factor and 23% identified sore throat can increase RA. Understanding about disease factors: 49.4% of participants correctly recognized extreme fatigue as a symptom; and only 6.5% correctly stated that smoking can increase the risk factor for RA. Only 7% correctly stated that genetics is a factor; 17% knew that women are more vulnerable than men; only 3% correctly stated that undertaking exercise and obesity is also a risk factor and 23% identified sore throat can increase RA. Understanding about disease symptoms: 50.5% of participants who have not responded to do not know that most of them misidentified disease symptoms, risk factors and impacts. The only good thing was most of the participants thought awareness of RA improvement certainly. A good awareness of RA can be one of the basic solutions for the early diagnosis of RA in Mongolia.

Conclusion: In Mongolia, public awareness of rheumatoid arthritis was poor. Most of the participants responded to do not know. Other participants who have not responded to do not know that most of them misidentified disease symptoms, risk factors and impacts. The only good thing was most of the participants thought awareness of RA improvement certainly. A good awareness of RA can be one of the basic solutions for the early diagnosis of RA in Mongolia.

EFFECTIVENESS OF A RHEUMATOLOGY EDUCATIONAL PROGRAM TO IMPROVE METHOTREXATE PRESCRIBING PRACTICES FOR RHEUMATOID ARTHRITIS IN THE SOLE PUBLIC ADULT RHEUMATOLOGY CLINIC IN ETHIOPIA

CApril Hitchon1, Becky Abdissa Adugna2, Birhanu Demelash2, Rosie Scuccimarra3, Ines Colmegna3, Frehiwot Kifle4, Paul Calderon5, Addisu Ababa University, Addis Ababa, Ethiopia; McGill University, Montreal, Canada; Emory University, Atlanta, United States of America; Arizona Arthritis and Rheumatology Associates, Phoenix, United States of America; Jefferson University, Philadelphia, United States of America

Background: Treatment of recent onset Rheumatoid Arthritis (RA) is key to preventing deformities. Initial treatment with methotrexate (MTX) is standard of care. RA treatment in resource-limited countries is complicated by competing health priorities and a lack of rheumatologists. The sole public adult rheumatology clinic in Ethiopia, is at Tikur Anbessa Specialty hospital (TASH) (Addis Ababa). Due to the lack of rheumatologists, care is provided by internists with limited rheumatology training.

Objectives: To evaluate changes in RA management practice patterns following a series of educational activities provided by visiting rheumatologists.

Methods: With local faculty support, visiting rheumatologists conducted educational activities at TASH between July 2016 and December 2018 (2 continuing medical education workshops; 4 clinical preceptorships lasting 2-4 weeks each). Clinical charts of a convenience sample of RA patients seen in the TASH rheumatology clinic were reviewed in September 2016 (n=48) by a team of rheumatologists and a second set in December 2018 (n=78) by an internist. Socio-demographics, arthritis features, treatment patterns and drug safety monitoring were recorded when documented. Practice patterns were compared between 2016 and 2018 using univariate statistics.

Results: The patients were mainly female (90%) with a mean (standard deviation) age of 36(13) years, resided in Addis Ababa (61%) and scored by competing health priorities and a lack of rheumatologists. The sole public adult rheumatology clinic in Ethiopia, is at Tikur Anbessa Specialty hospital (TASH) (Addis Ababa). Due to the lack of rheumatologists, care is provided by internists with limited rheumatology training.

Objectives: To evaluate changes in RA management practice patterns following a series of educational activities provided by visiting rheumatologists.

Methods: With local faculty support, visiting rheumatologists conducted educational activities at TASH between July 2016 and December 2018 (2 continuing medical education workshops; 4 clinical preceptorships lasting 2-4 weeks each). Clinical charts of a convenience sample of RA patients seen in the TASH rheumatology clinic were reviewed in September 2016 (n=48) by a team of rheumatologists and a second set in December 2018 (n=78) by an internist. Socio-demographics, arthritis features, treatment patterns and drug safety monitoring were recorded when documented. Practice patterns were compared between 2016 and 2018 using univariate statistics.

Results: The patients were mainly female (90%) with a mean (standard deviation) age of 36(13) years, resided in Addis Ababa (61%) and received government funded health care (57%). When documented, (95% in 2016 vs 99% in 2018, p<0.0001) was prescribed more commonly in 2016 than 2018 (p=0.001). More patients were seropositive in 2016 compared to 2018 (32/43 vs 14/75, p<0.001) and more had radiographic damage (erosions, joint space narrowing, periarthritis osteopenia) (21/27 vs 39/71, p<0.05). Between 2016 and 2018, prednisolone use remained common (92% in 2016 vs 89% in 2018, p=0.05) often in high doses (last visit daily dose 7.5mg (0-100) vs 5mg (0-100) p=NS; maximum daily dose 7.5 (0-100) vs 20 (0-100) p=NS) with continued documentation of steroid toxicity (45% vs 20%). The only available DMARDs prescribed were MTX (112/127; 97%) and chloroquine (50/125,40%). Median prescribed weekly MTX dose increased between 2016 and 2018 (starting dose 5 vs 7.5 mg/week p<0.01; maximum dose 7.5 vs 12.5 mg/week p<0.0001) and was co-prescribed with folate by 84% in 2016 vs 93% in 2018 (p=NS). Documentation of drug safety for those prescribed MTX improved with...
adequate pre-MTX labs (hematology, renal and liver panel and or hepatitis serology) requested by 46% in 2016 to 90% in 2018 (p<0.0001). When documented, MTX use was often interrupted (2016 17/24, 2018 14/43 p=0.003) and mainly due to limited drug availability.

**Conclusion:** An educational program conducted with support from the local medical community has potential to improve management of rheumatic disease in resource limited regions without adequate rheumatology capacity. However, interventions must be maintained over time and changes in practice measured to ensure that appropriate diagnosis and safe prescribing practices continue until local rheumatology expertise and capacity is available.

**AB1344 CLINICAL ASSESSMENT OF THE MUSCULOSKELETAL SYSTEM HANDBOOK AND ACCOMPANYING VIDEOS: 15 YEARS OF USE**

Cheuk Yin Li, Sophia Wakefield, Donna Andrew, David Coady, Versus Arthritis. 1Newcastle University, Newcastle upon Tyne, United Kingdom; 2Cardiff University, Cardiff, United Kingdom; 3Versus Arthritis, Chesterfield, United Kingdom; 4City Hospitals Sunderland, Sunderland, United Kingdom

**Background:** 15 years ago, Arthritis Research UK (ARUK) produced the ‘Clinical Assessment of the Musculoskeletal (MSK) System’ handbook and a set of accompanying videos; ‘Regional Examination of the Musculoskeletal System’. (1) There has been an evaluation of the use of this resource showing that they are widely used among medical students and healthcare professionals. Recently, ARUK has merged with Arthritis Care to form Versus Arthritis, and previous publications are due to be rebranded.

**Objectives:** This project aims to review how the handbook and videos are being used 15 years on. The secondary aim is to gain insight into any changes that may need to be made going forward as Versus Arthritis seeks to revise and update the original materials.

**Methods:** In September 2019, a clinical group was formed to review the current handbook’s content and format. The project team was invited to take part in the surveys and disseminate them within their professional networks and across every UK medical school.

**Results:** 78 people took part in the survey; this included 61 users (students, trainees and medical school teachers).

**User Survey:** ‘How to access the handbook?’ respondents said online (36%), via an app (31%) or printed version (10%). 83% of respondents said they found the handbook very useful, 100% said it was easy to understand, 95% said it was well illustrated, and 75% said the video clips were very useful. 100% of respondents said the handbook did not contradict any existing teaching received.

When asked what would improve the handbook, the most popular response was case studies. When asked what the most useful thing was, most respondents commented on the structure and how clear and concise it was. When asked what the least useful thing was, respondents felt it lacked detail regarding the rationale behind the purpose of the examinations.

**Teacher Survey:** 17 medical school representatives completed the survey. 94% of respondents use the resource. Most provide their students with the online version of the handbook (64%). 88% thought the resource was very useful for their students. 94% said the resource maps well to the current MSK curriculum. When asked what would improve the handbook the most popular response was abnormal examination findings. The least popular response was patient exercise videos and sheets.

**Content Review:** Several comments were made suggesting the use of more appropriate language. Recommendations were made to introduce sections on physical activity, self-management and the multidisciplinary team involvement. A suggestion was made to include the patient’s ‘ideas, concerns and expectations’ concept.

**Conclusion:** The consensus is that the resource is already very good and maps well to the MSK curriculum taught by the medical schools. It would benefit from adding new contents, e.g. examination clips of patients with pathology. We would need to be wary of overcomplicating the purpose of the new resource.

It was also highlighted that the resource would benefit from a refresh of the layout, including clear headings and more up to date images and diagrams. Several comments were made around the format to include an online resource that students could use to incorporate examination videos with experts explaining the findings.

**AB1345 CONTEXTUAL FACTORS IMPACTING OSTEOARTHRITIS MANAGEMENT IN URBAN AND RURAL COMMUNITY-DWELLING SENIORS: AN ANALYSIS BASED ON THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING DISABILITY AND HEALTH**

Joy MacDermid1,2, Karen Lee1, Amanda All3. 1Western University, Faculty of Health Science, London, Canada; 2St Joseph’s Health Centre, Hand and Upper Limb Centre, London, Canada

**Background:** Living with arthritis requires lifelong management that can be influenced by person, place and context.

**Objectives:** The objectives of this study were to: (1) identify contextual factors that influence OA management in rural and urban-dwelling seniors, and (2) examine how contextual factors identified by rural and urban-dwelling seniors are explained in terms of the ICF framework.

**Methods:** Semi-structured interviews were conducted with 20 community-dwelling seniors in Ontario, Canada; purposively including 11 seniors from an urban setting and 9 seniors from a rural setting, all over the age of 65, and previously diagnosed with OA. Broad questions on self-management and information seeking were explored. Interview concepts related to the environmental and contextual factors component were extracted from interview transcripts and organized into subthemes. Meaningful concepts were linked by 2 raters to ICF categories according to established linking rules. Descriptive analyses were performed.

**Results:** A total of 891 meaningful concepts were identified; 481 from interviews with 11 urban-dwelling seniors, and were linked to 54 ICF categories: 24 Environmental Factors, 21 Activities and Participation, and 9 Body Functions and 410 meaningful concepts from interviews with 9 rural-dwelling seniors; 57 ICF categories: 27 Environmental Factors, 24 Activities and Participation, and 6 Body Functions. Within Activities and Participation component, “d839 Education” was the most code for both groups. From the Body Functions component, “b1800 Experiences of Self” followed by “b1301 Motivation” were most mentioned. Environmental factors represented 203 of 481 (42.2%) urban concepts and 253 of 410 (61.7%) rural concepts. The concepts linked to the Activities and Participation category were similar across urban and rural groups (17.3% and 17.1%). Personal Factors (e.g. “adapting to life with OA”, “self-sufficiency”, “pain tolerance”, “age”) or “no/ not covered” (e.g. “feeling old”, “embarrassed by OA”, “being a burden”) were not coded. In 12.8% urban and 20.6% rural content was labeled as Personal Factors. Chapter e5 services, systems and policies was the chapter with the highest coverage overall. Within the environmental factors “e355 Health Professionals” was the most common code for both urban and rural groups, and mentioned in almost all interviews. Participants frequently discussed physician’s attitudes and misconceptions towards patients with OA.

**Conclusion:** The complex interaction of personal and environmental factors impacting OA management in both urban and rural communities was illustrated. Rurality influences some aspects of the complexity, but many common themes occur.

PATIENTS’ BELIEFS ABOUT MEDICINES PRESCRIBED FOR THEIR RHEUMATOID ARTHRITIS OR SPONDYLOARTHITIS

Nathalie Madeira, Candida Silva, Claudia Miguel, Dina Medeiros, Filipe Barcelos, Helena Santos, Ricardo Trinca, Alexandra Cardoso, Luís Cunha Miranda. Instituto Português de Reumatologia, Rheumatology, Lisbon, Portugal

Background: Adherence to therapies is determined by multiple factors, some of which are patient’s related and include economic resources, knowledge, attitudes, beliefs, perceptions and expectations about medication.

Objectives: To assess patients’ beliefs about prescribed medication for their rheumatic disease (rheumatoid arthritis (RA) or spondyloarthritis (SpA), including psoriatic arthritis) and to determine the existence of any association between these beliefs and clinical and socio-demographic variables.

Methods: Observational cross-sectional study which included RA patients according to 1987 ACR and/or 2010 ACR/EULAR criteria and SpA patients according to 2009 ASAS classification criteria (CC) for axial SpA or to 2011 ASAS CC for peripheral SpA, on subcutaneous biological therapy, followed at our Center, able to complete questionnaires autonomously and who agreed to participate. Socio-demographic and clinical data, anxiety and depression through the Hospital Anxiety and Depression Scale (HADS) and fatigue using the Functional Assessment of Chronic Illness Therapy - Fatigue questionnaire (FACIT-F) were collected. To assess beliefs about medication, the cross-culturally adapted Portuguese version of the Beliefs about Medicines Questionnaire (BMQ)-Specific was used, asking patients to apply it considering only the prescribed medicines for AR or SpA. The BMQ-Specific comprises two subscales: a five-item Necessity scale (Specific-Necessity, SN) and a six-item Concerns scale (Specific-Concerns, SC). Each item is scored on a five-point Likert scale (from 1 = strongly disagree to 5 = strongly agree). Statistics: descriptive, Mann-Whitney and Kruskal-Wallis tests and Spearman correlation, p <0.05.

Abstract AB1346 Table 1: Descriptive statistics of the continuous variables of the RA and SpA patients

Results: We obtained data from 84 patients, 45 SpA (53.6%) and 39 (46.4%) RA patients. Table 1 presents the descriptive statistics of the continuous variables. In RA group, 92.3% were female, 84.6% under anti-TNF, 66.7% under their 1st biologic and we found an association between BMO-SC score and HADS-anxiety (p=0.013) and positive correlations between BMO-SC score and Patient Global Assessment (PGA) (p=0.031), VAS pain (p=0.004), Physician’s Global Assessment (PhGA) (p=0.004), DAS28 (p=0.007), and HAQ (p<0.001). In SpA group, 62.2% were female, 86.7% under anti-TNF, 77.8% under their 1st biologic and BMO-SN score was positively correlated with VAS nocturnal back pain (p=0.047), PhGA (p=0.045) and BAFSI (p=0.003).

Conclusion: In RA patients, those with higher disability and a clinically more active disease presented higher levels of concern regarding the medication. In SpA, patients with a more aggressive disease, with nocturnal pain and worse function have a stronger conviction of the necessity and efficacy of the medication.

ASSESSMENT OF PATIENTS’ KNOWLEDGE ABOUT BIOLOGIC THERAPY AS A SELF-COMPLETION QUESTIONNAIRE. IS IT A GOOD WAY TO DO IT?

Nathalie Madeira, Candida Silva, Claudia Miguel, Dina Medeiros, Filipe Barcelos, Helena Santos, Ricardo Trinca, Alexandra Cardoso, Luís Cunha Miranda. Instituto Português de Reumatologia, Rheumatology, Lisbon, Portugal

Background: Lack of knowledge from a patient in his therapy may lead to a misuse process, increasing the probability of failure to achieve the therapeutic goal.

Objectives: To evaluate if the assessment of the RA and SpA patients knowledge in their biologic therapy could be done as a self-completion questionnaire.

Methods: Observational cross-sectional study which included patients with RA according to 1987 ACR and/or 2010 ACR/EULAR criteria or SpA according to 2009 ASAS classification criteria (CC) for axial SpA or to 2011 ASAS CC for peripheral SpA (including patients with psoriatic arthritis), on subcutaneous biological therapy who agreed to participate. Patients’ knowledge about their biologic therapy was assessed using the “Conhecimentos do doente sobre os seus medicamentos” (CPM-PT-P) meaning “Patient’s knowledge about his medicines”, intercultural adaptation for the Portuguese version of the original Spanish questionnaire, CPM-ES-ES. This questionnaire was created to be used as an interview, but we decided to give it to patients and ask them to complete it autonomously, reading the questions and writing their answers, considering only their biologic therapy. It consists of 11 questions, each with a score based on patient’s answer: incorrect = -1, the patient doesn’t know = 0, incomplete = 1 and correct = 2. The final score is calculated using the mathematical formula described by the authors, ranging from 0 (doesn’t know the medicine) to 2 points (optimal knowledge). Statistics: descriptive, Mann-Whitney and Kruskal-Wallis tests and Spearman correlation, p <0.05.

Results: We included 84 patients, 45 of which with SpA (53.6%) and 39 (46.4%) RA. In the RA group, 92.3% were female, 84.6% were under anti-TNF, 66.7% were under their 1st biologic, the median age was 60.0 (51.0-66.0) years and the median time in treatment with current biologic was 31.0 (20.0-62.0) months. In the SpA group, 62.2% were female, 86.7% were under anti-TNF, 77.8% were under their 1st biologic, median age was 47.0 (39.5-57.0) years and median time in treatment with current biologic was 37.0 (12.0-83.0) months. Fifteen incomplete questionnaires were excluded. Sixty patients (87.0% of the 69 valid questionnaires) didn’t meet the minimum criteria necessary to ensure correct use of medication (correct answer to the first 5 questions), thus obtaining a CPM score of 0. The mean CPM score was 0.2 (±0.5), the median 0 (0), the minimum 0 and the maximum 1.7. There were no differences in CPM according to age, time in treatment with the current biologic, disease duration, n of previous biologics, gender, educational level, diagnosis, current biologic and n of other concomitant drugs. Table 1
describes the scores obtained in each domain of the questionnaire. We noticed that if we ask the same questions orally, the patients knew more than what the questionnaire revealed.

AB1348 PERSPECTIVES OF PATIENTS WITH INFLAMMATORY ARTHRITIS REGARDING CARDIOVASCULAR RISK: A QUALITATIVE STUDY

Iris Navarro-Milian1,2, Sarah Young3, Sally Shurbaji4, Chastity McDavid5, Anna Cornelius-Schecter4, Bernadette Johnson5, Andrea Cherrington5, Liana Fraenkel5, Jeffrey Curtis4, Monica Safford1.

Background: Cardiovascular disease (CVD) is the most common cause of death among patients with inflammatory arthritis (IA) such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS). Objectives: To elicit perspectives of patients with IA to inform the design of a patient-centered intervention for a CVD risk reduction intervention.

Methods: This was a qualitative study guided by Bandura’s Social Cognitive Theory, placing special emphasis on knowledge about the relationship between arthritis and CVD as well as barriers and facilitators to receiving healthcare related to CVD risk such as screening and management for hyperlipidemia. We recruited patients from a single academic center with either RA, PsA, or AS to participate in focus groups. Data were analyzed thematically.

Results: We conducted three focus groups with a total of 17 participants (5 participants in two and 7 participants in one of the focus groups) of mean age 56 (SD=7.7) years; 15 were women; 3 were on a statin; and 1 previously had a stroke. Barrier Themes 1-2: 1) Need for information about arthritis, prognosis, and IA medications; 2) Lack of knowledge about how IA increases cardiovascular disease (CVD) risk; Facilitator Themes 3-5: 3) Lifestyle changes to reduce overall CVD risk; 4) Potential roles for peer coaches; and 5) Improving doctor-patient communication about IA, medications, and CVD risk. Patients expressed that improving Themes 2 and 5 could facilitate CVD screening.

Conclusion: Education about increased CVD risk could help activate patients with IA engage in CVD risk reduction strategies. Peer coaches appears to be a reasonable tool towards that goal.

AB1349 PATIENT INVOLVEMENT IN BASIC RHEUMATOLOGY RESEARCH IS CHALLENGING BUT FEASIBLE. A 3 YEAR’S RESPONSIVE EVALUATION OF ADDED VALUE, PITFALLS AND CONDITIONS FOR SUCCESS

Maarten de Wit1, Yvette Neijland2, Frank van den Hoogen2, Peter van der Kraan3, Anna Cornelius-Schecter1, Bernadette Johnson4, Andrea Cherrington4, Liana Fraenkel5, Jeffrey Curtis4, Monika Safford1.

Background: Empirical evidence for effective patient-researcher collaboration in basic research is lacking.

Methods: Empirical evidence for effective patient-researcher collaboration in basic research is lacking. A qualitative study to explore the feasibility and impact of patient involvement in basic rheumatology research and to identify facilitators and barriers.

Results: In total 13 patient representatives (PRs) and 15 basic researchers participated. PRs experienced basic research as complex due to lack of understanding bio-molecular processes and the use of technical jargon. Their initial role was mostly listening, sometimes asking questions and why progress takes so much time. PRs obtained insight in the biological processes of their own disease. It inspired PRs to stay involved and why progress takes so much time. PRs obtained insight in the biological processes of their own disease. It inspired PRs to stay involved and why progress takes so much time. PRs obtained insight in the biological processes of their own disease. It inspired PRs to stay involved and why progress takes so much time. PRs obtained insight in the biological processes of their own disease. It inspired PRs to stay involved and why progress takes so much time.

Conclusion: The CPM-PT-PT underestimated the level of knowledge about biologic therapy in our population, suggesting the need to assess it during the clinical interview.

Table 1. Themes and Key Points That Emerged From Focus Groups of Patients with Inflammatory Arthritis

<table>
<thead>
<tr>
<th>Theme</th>
<th>Quotes from patients</th>
</tr>
</thead>
<tbody>
<tr>
<td>Need for information about IA and medications</td>
<td>“When I was first diagnosed, as far as the medications and the side effects and what I could expect. Like I said, everything I read was bad, and it didn’t—I’m probably going to take it the rest of my life, and you have to get your blood tested every three months to make sure everything’s looking good.”</td>
</tr>
<tr>
<td>Lack of understanding regarding the association between CVD risk and IA</td>
<td>“I never even thought about it. Had no idea that it would even affect my heart like that. I’m still in shock [laughter] that has to do with the arthritis.”</td>
</tr>
<tr>
<td>CVD risk reduction as an integrated lifestyle modification</td>
<td>“They (doctors) know about the medicines and everything, so I’ll ask them, ‘Is there something I could do or take that would help it?’ We’ve got to do our part, too. We’ve got to exercise. We got to watch what we eat. Stress. I know stress will cause a lot of stuff to come on.”</td>
</tr>
<tr>
<td>Possible uses for peer coaches around relevant CVD risk factor mitigation approaches</td>
<td>“It would’ve been nice if I would talk to somebody who, maybe, was on the medication and could tell me, ‘Well, I haven’t had any problems with it,’ or, ‘Yeah, it does this.’ I’m sure it affects different people differently.”</td>
</tr>
<tr>
<td>Improving doctor-patient communication about IA</td>
<td>“If I’m at home, and all of a sudden, I’m like, ‘Why didn’t I ask her that?’ Let’s write it down. Then when I go to my peer coach, maybe, with those questions, they can also help me to understand that.”</td>
</tr>
</tbody>
</table>

Facilitators of patient involvement related to a) education of principles of participatory research; b) training of patient-researcher collaboration; c) development of a common language level; d) open mind and respectful communication; e) professional support; and f) leadership commitment. Main barriers were the complexity of pathogenetic processes for patients and time commitment for researchers. All participants found the collaboration worthwhile.

Reported impact was divers. Having to look at their work from a helicopter view encouraged researchers to attain a holistic view of people with a rheumatic condition and skills to explain their research for a lay audience. Patients experienced personal satisfaction after sharing experiences and receiving recognition from others. For the research process, a few examples were reported where patients input led to new topics on the research agenda. One example was the grant application to explore determinants of fatigue in the laboratory, directly prompted by patients. More substantial benefits were experienced for the development of patient-friendly educational materials and lay summaries of research protocols, dissemination of research findings through interviews and presentations, and even promotion of patient participation in national scientific societies of which the researchers are a member. Little impact was reported on the actual results of basic research.

Conclusion: Long term patient involvement in basic research is feasible and worthwhile. Despite the time investment, both patients and researchers experience valuable benefits that outweigh the lack of tangible impact on research findings.

HOW TO REDUCE THE NOCEBO EFFECT IN RHEUMATOLOGY? A SYSTEMATIC REVIEW OF RISK FACTORS AND INTERVENTION STRATEGIES

Juliette Petit, Karine Loutai, Francis Berenbaum, Catherine Beaumais.
Rheumatology department APHP Saint-Antoine Hospital, Sorbonne Université, INSERM, PARIS, France

Background: Nocebo effect (NE) defines any declared negative side effect of a drug that is non-specific, non-explained by its pharmacokinetic, and non-dose dependent. Recently, it has been pointed out as the main factor that reduces the rate of switches from a biologic originator to biosimilars in rheumatology.

Objectives: To identify the risk factors (RFs) and interventions strategies to reduce the NE in rheumatism and musculoskeletal diseases (RMDs), and more specifically in BS switches.

Methods: MEDLINE, Embase and Cochrane databases were systematically searched (inception to 15th November 2018) using relevant keywords: search1: “musculoskeletal diseases” and “nocebo” or “non-specific side effect” (NSSE); search2: “biologics” and “nocebo” or “non-specific side effect”. Inclusion criteria were: studies on pharmacological treatments, studies investigating RFs for NE or NSSEs, studies specifically describing an intervention aimed to reduce NE. Studies on non-RMDs and fibromyalgia were excluded.

Results: Of 212 and 639 references screened respectively in search1 and search2, 151 duplications were deleted, 32 mentioning NE or equivalent were read in full text by 2 independent investigators and consensually selected.

No study met inclusion criteria for NE risk factors: 6 studies investigated the RFs of discontinuation after switch to BS, 3 with etanercept (ETN), 3 with infliximab (IFX), one investigated risk factors of back switch (meaning return from BS to BS ETN), one study analyzed a genetic factor of intolerance to methotrexate (MTX) in juvenile idiopathic arthritis (JIA) and one study assessed the RFs for overall discontinuation of biologics. Although contextual factors were mentioned, no study tested RFs on NE responders only. RFs for a negative outcome were low self-efficacy, small-size rheumatology department, early start of IFX BS after its introduction on the market.

Only 5 studies met the inclusion criteria for specific interventions to reduce NE. One was about countermeasures used to reduce MTX tolerance in children with JIA: including covert dosing and taste masking, with no significant results. The other four studies aimed to reduce NE related to a switch: by a shared decision-making method (ETN, one study), assessed by a structured communication strategy (ETN, one study and two by a standardized information (ETN, one study; IFX, one study). Rate of NS-SE was mentioned in 3 studies, and the outcome (NS-SE rate compared to NE-SE rate of control group) was mentioned in only 2 studies. However, the assessment of intervention efficacy was not possible, since comparison was performed with historical cohorts.

Conclusion: Although nocebo effect is an important issue in rheumatology, especially as an explicative factor for limiting the retention rate when switching from biologic originators to biosimilars, its risk factors and intervention strategies to prevent it are poorly known. Our results encourage studies to better understand the risk factors associated with nocebo effect and the means to reduce it, particularly in the context of switches from bio-originators to biosimilars.

DO WE NEED A PATIENT PEER MENTOR PROGRAM IN DAILY PRACTICE FOR PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AND IF SO, HOW SHOULD THIS BE ORGANIZED?

Kristien Van der Elst1,2, Lore Bangels, Lianne Peerlings, Lies De Caluwé, Ilse Langens, Veerle Stouten, Diederik De Cock, Rene Westhovens1,2, Patrick Verschueren1,2,3, University Hospitals Leuven, Rheumatology, Leuven, Belgium, 1KU Leuven – University of Leuven, Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium, 3KU Leuven – University of Leuven, Department of Public Health and Primary Care, Academic Center for Nursing and Midwifery, Leuven, Belgium, 4Patient research partners, Leuven, Belgium

Background: Management and support by an interdisciplinary rheumatology team are essential for achieving optimal disease outcomes in rheumatoid arthritis (RA). Nevertheless, health professionals generally do not experience the disease themselves, and patients may have specific educational needs that can only be provided by other patients having gone through the same experience. Furthermore, patients with RA may benefit most from such additional care interventions in the early disease stage when they are particularly faced with threats to their normal life. Peer mentoring has been studied and successfully implemented in other chronic conditions, however, this is rather a new care concept in the field of rheumatology.

Objectives: Among four key stakeholders in the management of early RA, we aimed (1) to uncover the current experience with, need for and attitude towards implementing peer mentoring in the care for patients with early RA in Flanders; (2) to gather ideas for the content and format of a peer mentor program.

Methods: We conducted an explorative qualitative focus group study. In total, five focus groups were organized to capture the perspective of each of the following stakeholders: patients with early RA (n=10), representatives of patient organizations (n=5), rheumatologists (n=10) and rheumatology nurses (n=5). Data were analyzed using the constant comparison method as presented in the Qualitative Analysis Guide of Leuven. Two patient research partners helped to analyze and interpret the data.

Results: Most stakeholders perceived a potential need for peer mentoring in early RA. However, they underscored that this would be largely person and disease phase dependent suggesting that peer mentoring should be presented as an option to patients, rather than a standard of care. The addition of peer mentoring would be foremost situated in providing disease perspective and a sense of recognition to newly diagnosed patients. For some stakeholders, it was difficult to get a clear picture of such a program, which made it difficult for them to formulate an opinion on a specific format. The health professionals particularly mentioned the current lack of a formal framework for collaborating with patient experts, and the need for carefully selected and well-trained peer mentors. Stakeholders shared the view that the development of a peer mentor program and its integration within the current care context should ideally take place in cooperation with and under supervision of health professionals.

Conclusion: Our results underline that peer mentoring in early RA holds potential for certain patients under certain circumstances, yet a clear framework for an expert in the daily care of patients with early rheumatoid arthritis.

HPR Epidemiology and public health (including prevention)

AB1352-HPR  INVESTIGATION OF EFFECT OF DISEASE AND RELATED FACTORS IN INDIVIDUALS WITH FIBROMYALGIA

Bilge Basak Calik1, Aylin Keskin1, Eilif Kurubali2, Berma Cagla Caglayan1, Ugur Karasu3, 1Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey; 2Pamukkale University, Department of Rheumatology, Denizli, Turkey

Background: Fibromyalgia (FM), one of the most common rheumatologic disorders, is characterized by widespread pain in the body, sensitivity in the certain anatomical regions, fatigue, sleep disorders and reduced pain threshold, uncommon and extra-articular rheumatism disease (1). It has been reported that impairments in functional capacity and quality of life cause significant limitations in individuals with FM (2).

Objectives: The aim of this study was to examine the effect of disease and to investigate the factors associated with the disease in individuals with FM.

Methods: In our study, 334 voluntary individuals with FM (324 female, 10 male) who applied to Pamukkale University Department of Internal Medicine, Department of Rheumatology were diagnosed according to 2010 American College of Rheumatology criteria whom participated in the study with the mean age of 47.55±10.46 (years). Fibromyalgia Impact Questionnaire (FIQ) was used to determine the effect of disease, Beck Depressive Inventory (BDI) and Beck Anxiety Inventory (BAI) for emotional status and Pittsburgh Sleep Quality Index (PSQI) for sleep quality, right after demographic information and disease related data were recorded. Multiple regression analysis were used to examine the factors related to disease activity.

Results: High body mass index (B=1.21, p=0.023), high tender point score (B=427, p=0.000), high depression score (B=350, p=0.000), high anxiety score (B=258, p=0.000) and poor sleep quality (B=157, p=0.002) corresponded to the higher FIQ score. However, age (B=-0.19, p=0.716), level of education (B=0.09, p=0.858) and disease duration (B=0.054, p=0.331) did not significantly affect FIQ.

Conclusion: As a result of our study the progress of body mass index in individuals with FM, increase in number of tender points, poor sleep quality, depression and anxiety were among the factors affecting the disease. Therefore, these factors must be considered in order to reduce the severity of the disease in individuals with FM.

REFERENCES
[2] Arnold LM, Crofford LJ, Mease PJ, et al. Patient perspectives on the severity of the disease in individuals with FM. Therefore, these factors must be considered in order to reduce the prevalence of pain medications followed by a combination of paracetamol. See table 1. The prevalence of pain medications usage was not with associated disease activity.

Pain medication   n     %
Paracetamol       2407    34
Paracetamol + opioids                                     744    11
NSAID             633     9

Conclusion: As other studies have shown the prevalence of pain medication in patients with RA is high. The most prescribed medication was paracetamol or opioids, coinciding with other studies (1). This descriptive study is useful for further studies to develop in Colombia and Latin America. Additionally, it is important to consider other alternative therapies in order to approach in painful condition like RA.

AB1354-HPR DESCRIPTION OF INDIVIDUALS WITH FIBROMYALGIA SYNDROME

Berma Cagla Caglayan1, Eilif Kurubali2, Aylin Keskin1, Bilge Basak Calik1, Ugur Karasu3, 1Pamukkale University, Physical Therapy and Rehabilitation, DENIZLI, Turkey; 2Pamukkale University, Department of Rheumatology, DENIZLI, Turkey

Background: Fibromyalgia (FM) affects negatively physical and mental health and reduces quality of life. The most common symptom is chronic widespread musculoskeletal pain in FMS. As other studies have shown the prevalence of pain medications used in patients with RA is high. The most prescribed medication was paracetamol or opioids, coinciding with other studies (1).

Objectives: This study was planned to investigate comorbidities, number of medication and to determine the most painful body region in individuals with FM.

Methods: The study included 166 individuals (161 women, 5 men) who were diagnosed with FM, with a mean age of 47.56±10.91 years. Comorbidities, number of medication which were used for FMS or other diseases of participants were recorded also painful body regions were assessed for 28 regions. The categorical variables were expressed in number and percentage.

Results: The results showed that a total of 42.2% (n=71) of individuals in this study had no comorbidities, 11.4% (n=19) of individuals had hypertension and 7.8% (n=13) of individuals had asthma. When the number of medication were examined, a total of 66.3% (n=110) of individuals did not use any medication, 25.8% (n=43) of individuals did use one type of medication with FM-related and 4.2% (n=7) of individuals did use two type of medications with FMS related. Painful body regions were reported by 74.1% (n=123) for neck, 66.3% (n=110) right shoulder, 68.7% (n=114) left shoulder, 68.1% (n=113) right knee and 68.1% (n=113) left knee.

Conclusion: In general, there was no comorbidity with FMS. The study found that individuals with FMS usually did not use medication. Also neck were found the most painful body region in individuals with FMS.

A SYSTEMATIC LITERATURE REVIEW (SLR) ON NURSING SENSITIVE OUTCOMES IN SYSTEMIC SCLEROSIS (SSC)

Khatija El Aoufy, Laura Rasero, Guya Piemonte, Gianni Vigili, Serena Guiducci, Cosimo Bruni, Silvia Bellando Randone, Marco Matucci-Cerinic. University of Florence, Florence, Italy

Background: SSC affects significantly patients functionality and Quality of Life (QoL). Specific Nursing Sensitive Outcomes (NSOs) still need to be established in SSC.

Objectives: This SLR was aimed at identifying NSOs in SSC patients and the related screening tools.

Methods: Medline, CINHAL, EMBASE and PsycINFO were searched to identify relevant studies. Experimental and observational studies that reported nursing interventions and NSOs were included. All potentially eligible studies were read in full text and examined against the selection criteria previously listed. Quality assessment was carried out through Critical Appraisal Skills Programme tools; and, the OMERACT (Outcome Measures in Rheumatology) comprehensive conceptual framework for health was used to contextualise and summarize findings.

Results: 7015 records were screened for title and abstract, 39 full-text were identified and assessed. Eleven studies were included in this SLR. For the core area “pathophysiological manifestations” 4 domains (health status, digital ulcers, clinical efficacy and fatigue), and, for the core area “impact on life” 5 domains were found (functionality, patient knowledge, patient satisfaction, psychological status and quality of life). Thus, NSCs identified were physical function and parameters, health events, upper limb functionality, patients knowledge of disease complications, degree of self-management, need for nursing interventions, self-efficacy, health efficacy, psychological state, depressive mood and QoL.

Disclosure of Interests: Khadija El Aoufy: None declared, Laura Rasero: None declared, Guya Piemonte: None declared, Gianni Vigili: None declared, Serena Guiducci: None declared, Cosimo Bruni: None declared, Silvia Bellando Randone: None declared, Marco Matucci-Cerinic: Grant/Research support from: Actelion, MSD, Pfizer, BMS, Chemomab, Sanpeidia, Speakers bureau: Actelion, BMS, MSD, Janssen DOI: 10.1136/annrheumdis-2019-eular.7685

Figure 1

Conclusion: The results identify outcomes that may allow the structuring of a preliminary behavioural flow chart for nursing SSC case management. Further researches are warranted to examine the multidimensional and complex role of nursing in SSC management.

Flow chart of the SLR:

REFERENCES
Methods: Observational cross-sectional study in patients with intravenous BT from Day Hospital of a tertiary hospital in Madrid. Sociodemographic, disease features (weight, height, work disability (WD), diagnosis, treatment) and PRO (FIRS, FACIT-F, HAD, and GHQ-28) were collected. We defined the Si according to the answer at the 6th and 7th questions of section D of the GHQ-28. The Sa was registered according to the patient’s clinical history. The categorical variables were analyzed with the Chi square test. A logistic regression analysis was performed to evaluate the possible factors associated with suicidal behavior (SB). To evaluate the variance of discrete quantitative variables between groups the Kruskal-Wallis test was used, with a post-hoc analysis with U-Mann Whitney, to determine the difference between pairs.

Results: We included 321 patients, 65% women, with a mean age (range, SD) of 56 years (89-15, 14.1), and a mean disease duration (SD) of 16 years (DS-31-9.7). The sociodemographic and clinical characteristics are described in Table 1 and 2. Of all patients, 4% had had 1 or more Sa and 11% had Si. 23% of patients had associated fibromyalgia (FIRST), 47% fatigue (FACIT-F), 27.4% anxiety (A-HAD), 16.2% depression (D-HAD) and a 48.6% a probable psychic disorder (GHQ-28). The final logistic regression model includes FACIT-F, IL, D-HAD, and first biological with Cox R2 and Snell 20.1% and Nagelkerke 35.5%. The area under the curve was 0.849 with significance p<0.001 [95% CI (0.786 - 0.912)]. Regarding the GHQ-28 score, a significant difference was observed among the diagnostic groups (p<0.001); in post-hoc, a lower score was observed among patients with ankylosing spondylitis p<0.001. We also observed a significant difference among the treatment groups (p<0.001) for the GHQ-28 score. In the post-hoc analysis, the Abatacept group had a significantly higher mean p=0.042 of GHQ-28 score, however, in the multivariate analysis no significant difference was observed p=0.418.

Conclusion: There is a high prevalence of Si and Sa in patients with BT. Depression, fatigue, sleep disorders, fibromyalgia and work disability were associated with a higher prevalence of SB.

MENTAL FUNCTIONS IN PATIENTS WITH
SPONDYLOARTHROPATHIES

Elizabeth Mogstad 1, 2, Ann Bremrander 1, 2, 3, 4, Emma Haglund 4, 5, Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 2 RED Spenshult, Halmstäd, Sweden; 3 Department of Regional Health Research, University of Southern Denmark, Odense, Denmark; 4 Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark; 5 Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden.

Background: Earlier studies have found strong correlations between worse health and an unhealthy lifestyle, such as not meeting recommendations of moderate-to-vigorous physical activity, being overweight or obese and the use of tobacco in patients with spondyloarthritides (SpA). The impact of more than one unhealthy lifestyle habit (LSh) is however, scarcely described.

Objectives: To study the combined effects of unhealthy LShs on health-related quality of life (HRQoL) and physical and mental functions in patients with SpA. Differences between SpA subgroups and gender were also studied.

Methods: Postal questionnaires were in 2009 and 2011 sent to all patients diagnosed with SpA and registered in the Skane Healthcare Register. This study included patients who at both time points responded to the survey, were ≥20 years, and had ankylosing spondylitis (AS), psoriatic arthritis (PsA) or undifferentiated spondyloarthritides (USpA). Cross-sectional data from the 2011 questionnaire were available for 1601 patients (AS n=455, PsA n=883, USpA n=263), with a mean age of 58 (13) years (52% women). Self-reported levels of weekly physical activity at moderate or vigorous intensity, (MVPA), use of tobacco (cigarettes and/or snuff) and BMI (overweight or obese) were dichotomized as “healthy” or “unhealthy”. The number of unhealthy LSh were then summarized and straitified into four groups (scoring 0-3, 0=no unhealthy LSh). HRQoL was assessed with EQ-5D (0-1, worst-best), and physical function with BASFI. Disease activity (BASDAI), pain, fatigue (0-10, best-worst), anxiety, and depression (HADa/d) (0-21, no disorder) were available for 1601 patients (AS n=455, PsA n=883, USpA n=263), with a mean age of 58 (13) years (52% women). Self-reported levels of weekly physical activity at moderate or vigorous intensity, (MVPA), use of tobacco (cigarettes and/or snuff) and BMI (overweight or obese) were dichotomized as “healthy” or “unhealthy”.

Results: Fourteen percent (n=226) reported none of the studied unhealthy LSh, while 35% (n=555) reported one, 38% (n=611) two, and 15% (n=209) three unhealthy LSh. Reports of one and more unhealthy LSh had increasing negative impact on HRQoL. (from mean 0.74 (SD 0.19) to 0.57 (0.30)), disease activity (from 3.2 (2.1) to 4.5 (2.3)), physical function (3.2 (2.1) to 4.4 (2.0)), VAS-fatigue (4.2 (2.7) to 5.5 (2.7)), anxiety (4.8 (4.2) to 5.6 (4.4)) and depression (3.3 (3.3) to 4.8 (3.8)) in patients with SpA (p=0.019–5). Our findings support that the combined effect of unhealthy lifestyle habits have negative impact on many aspects of health. There is a need for interventions aiming at screening for not only one but several unhealthy lifestyle habits combined, and to offer coaching to increase behavioral change and promote better health.

BENEFITS OF HYDROGINASTICA IN ELDERLY WITH
OSTEOPOROSIS

Mataus Arantes 1, Sonia Bertolini 2, Amelia Pasqual Marques 1, 3, 4, 5, University of Sao Paulo, Department of Physical Therapy, Speech Therapy and Occupational Therapy, Sao Paulo, Brazil; 2 University Center of Maringa, UNESCUMAR, Department of Health Promotion, Maringa – PR, Brazil.

Background: The aging of the population has repercussions in several social sectors, among them health, with a view to increasing the frequency of Chronic Non-Communicable Diseases. It is worth highlighting Osteoporosis, since it is associated with increased mortality and dependencies, becoming a growing public health problem. As a form of maintenance and prevention of osteoporosis it is indicated the performance of physical exercises, among them water gymnastics stands out.

Objectives: The study aimed to present and discuss studies on the benefits of water aerobics for the elderly with osteoporosis.

Methods: For the development of the present study a bibliographic research was carried out in the years 2010 to 2017 through searches in national and international journals indexed in PubMed, Scielo, Lilacs and Medline databases. The descriptors used were: Elderly, Aging Process, Hydrogeology, Aquatic Activity, Osteoporosis and Health Promotion in Portuguese, Spanish and English. The search period was between the months of February and March of 2017 and after selecting the articles, to extract the definitions about the theme, they were read.

Results: We can identify that water aerobics is a practice that addresses these benefits in the elderly with osteoporosis. Another aspect found in the studies is that water gymnastics provides the elderly with improved socio-affective relationships.

Considering the current natural losses due to aging on some physical characteristics, water aerobics is an important exercise practice option. The activities in the aquatic environment are indicated for a considerable gain of muscular mass and reduction of the loss of the same one, aiding in the tonification of the musculature, the loss of fat and the increase of the resistance. For the elderly with osteoporosis this modality is a preventive aid that contributes to improve their quality of life.

Among the studies found, one performed in Japan in the elderly with osteoporosis, found an increase in VO2max, flexibility and increased strength of hydrogymnastics participants; in Israel, the elderly women reduced the Muscle Mass Index and body fat. In Brazil, a study verified the improvement of functional capacity in elderly women practicing water aerobics.

PREVALENCE OF TOBACCO AND ALCOHOL CONSUMPTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Laura Villarreal 1, Michael Cabrera 2, Pedro Santos-Moreno 3, Diana Bultraga-Garcia 4, 5, 6, 7, Biomab – Center for rheumatoid arthritis, Psychology, Bogot, Colombia; 2 Biomab – Center for rheumatoid arthritis, EHR administration, Bogot, Colombia; 3 Biomab – Center for rheumatoid arthritis, Rheumatology, Bogot, Colombia; 4 Biomab – Center for rheumatoid arthritis, Nursing research, Bogot, Colombia

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory arthritis leading to progressive joint and organ system damage and disability. It has been demonstrated that smoking and alcohol consumption is a risk factor for poor response to RA treatment.

Objectives: To describe the prevalence of smoking and alcohol consumption in patients with rheumatoid arthritis.

Methods: We conducted a retrospective study, patients were followed during 12 months. Smoking and alcohol consumption were assessed through yearly questionnaires. The disease activity and functional status were measured annually by the DAS28. We calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We estimated the prevalence smoking and alcohol consumption and explored if there was an association between DAS28 and smoking or alcohol consumption.

Results: We included 6491 patients. patients, 82% were female and 18% male; median age was 60 years (IQ=50-67), regarding disease activity, mean DAS28 was 2.59 ± 1.08. The prevalence of alcohol consumptions was 2.26% while smoking 7.83%. We did not find an statistical association between smoking alcohol consumption and DAS28.

Conclusion: Our study showed a small prevalence of patients with rheumatoid arthritis who smoke or consume alcohol without any associations between smoking or alcohol consumption with disease activity. This could be attributed to a low prevalence in our study. Further research is needed in order to propose other methodological approaches to explore this association.

Laura Villarreal: None declared, Michael Cabrera: None declared, Pedro Santos-Moreno: Grant/research support from: Dr Santos has received research grants from Janssen, Abbvie and UCB, Speakers bureau: Dr Santos has received speaker fees from Sanofi, Lilly, Bristol, Pfizer, Abbvie, Janssen and UCB, Diana Bultraga-Garcia: None declared.

Water aerobics for the elderly has been gaining momentum and growing numbers of fans, so much so that in the last 10 years the popularity of exercise in the aquatic environment has increased significantly. **Conclusion:** With the present study it can be verified that the hydrogymnastics presents numerous benefits for maintenance and prevention of osteoporosis in the elderly. Regular practice of water aerobics contributes to good body health, as well as providing physical and mental well-being and social interaction among its practitioners. This study may provide important health professionals with knowledge about the importance of encouraging and intensifying regular physical exercise, including hydrogymnastics, as one of the determinants of elderly health promotion.

**THE EFFECTS OF 4 WEEK REHABILITATION PROGRAM ON PATIENT OUTCOMES IN PATIENTS WITH KNEE OSTEOARTHRITIS**

Orur Aydogdu, Setir Kilikap, Beyzanur Dagpn, Zbeyir San, Marmara University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey

**Background:** Osteoarthritis (OA) is the most common form of arthritis and a major cause of pain and disability in older adults (1). Older adults with knee OA report lower physical functioning and increased difficulty in performing activities of daily living compared with older adults without knee OA (2). Knee OA treatment aims to improve physical functions, quality of life, prevent disability, and decrease pain. Therapeutic exercises and physiotherapy treatment applications are recommended for the patients with knee OA (3).

**Objectives:** The purpose of this study was to examine the effects of 4 week physiotherapy and rehabilitation program on range of motion, balance, knee swelling, and activities of daily life, quality of life, and functional status in patients with knee osteoarthritis. It was hypothesized that 4 week rehabilitation program might provide improvements in measures of the patient outcomes in patients with knee osteoarthritis.

**Methods:** Twenty-seven healthy subjects were participated in the study. Subjects had no surgery history of lower extremity. Range of motion, balance, knee swelling, activities of daily life, quality of life, and functional status were assessed by Goniometer, Berg Balance Test, Tape measure, Barthel Index, WHQOL Scale, WOMAC Scale, respectively. The physiotherapy and rehabilitation program started after the first assessment and was applied as 20 sessions for a total of four weeks, five sessions per week. All of the assessments procedures were performed again after the treatment.

**Results:** There were statistically significant improvements in measures of range of motion, balance, knee swelling, and functional status between pre- and post treatment (p<0.05). However, no significant difference was found in activities of daily life and quality of life after the 4-week rehabilitation program (p>0.05).

**Conclusion:** Based on our findings, short-term effects of physiotherapy and rehabilitation program may be beneficial on range of motion, balance, knee swelling, and functional status in patients with knee osteoarthritis. However, 4-week rehabilitation program has no effect on activities of daily life and quality of life in patients with knee osteoarthritis.

**THE INVESTIGATION OF THE QUALITY OF LIFE AND FUNCTIONAL ABILITIES IN PATIENTS WITH JUVENILE SCLERODERMA**

Arzu Dag1, Ela Tanakı2, Amra Adrović3, Özgür Kasapçopur4, 1Istanbul Yeni Yüzyl University, Faculty of Health Science, Department of Physiotherapy and Rehabilitation, Istanbul Turkey, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Faculty of Health Science, Department of Physiotherapy and Rehabilitation, Department of Neurologic Physiotherapy and Rehabilitation, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey; 4Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey

**Background:** Juvenile scleroderma (JS) is a rarely seen chronic connective tissue disorder. There are two main disease forms: juvenile localized scleroderma (JLS) and juvenile systemic sclerosis (JSS). These conditions share some common pathophysiologic features which are mainly characterized by inflammation and fibrosis of the skin. In JLS, fibrosis involves restricted areas of the skin, whereas in JSS it also affects the internal organs.

**Objectives:** There have been few studies of quality of life in pediatric scleroderma and these focused predominantly on self-perception and the influence of skin involvement. Our cross-sectional study aimed to describe the influence of juvenile scleroderma on functional ability and quality of life in relation to clinical and demographic measures.

**Methods:** 30 patients (26 girls, 4 boys) with JS between the ages of 6-18 years and 30 healthy controls (20 girls, 10 boys) with similar age and gender were included in our study. Patients with either localized scleroderma or systemic sclerosis (SSc) attending pediatric rheumatology clinics, together with their parents were asked to complete a set of 3 validated measures. Children completed their functional ability status with Childhood Health Assessment Questionnaire (CHAQ) and Jelson Taylor Hand Function Test (JHTFT). The quality of life were evaluated with Scleroderma Health Assessment Questionnaire (SHAQ). Clinical and demographic data were provided by consultant pediatric rheumatologists and physiotherapists.

**Results:** The mean age of the JS group was 14.06 3.24 years (86% female, 14% male, while their 53 localized scleroderma, 47 SSc) and of the control group was 12.43 3.24 years. There were significantly differences between the two groups in functional ability scores (JHTFT), (CHAQ) and quality of life scores (SHAQ) (p<0,05). In JS group, the total-CHAQ score was 0.470.63 (range 03, 0 indicating no impairment), the JHTFT-Total left hand and right hand scores were 44.059.83 and 41.497.42 second respectively, and the median SHAQ-Total score was 0.34 (range 06, 0 indicating no impairment).

**Conclusion:** Functional ability disabilities in JS patients cause limitations in daily living activity. Scleroderma had only a moderate effect on quality of life and functional abilities as measured by the 3 validated instruments. Although a small number of children reported greater impairment, this is an encouraging finding, given its potential disfiguring and debilitating effects.

## AB1364-HPR PRELIMINARY CASE REPORT ON SHARING PATIENT HISTORY IN CLINICAL TREATMENT OF RHEUMATOID ARTHRITIS

Mie Fusaama1, Susan Oliver2, Hideko Nakahara3, Yvonne van Eijk-Hustings4, Yuriko Kuroe5, NVT West Osaka Hospital, Osaka, Japan; 2Susan Oliver Associates, London, United Kingdom; 3Department of Patient & Care/ Clinical Epidemiology and Medical Technology Assessment (KEMTA), Amsterdam, Netherlands; 4Gifu College of Nursing, Gifu, Japan

**Background:** Rheumatoid arthritis (RA) is a chronic disease with periods of flare-ups and remissions, affecting daily life. Therefore, this disease requires lifelong management and support by the patients, social circle, and health professionals (HP).  

**Objectives:** The aim of this study was to follow up the history of patients with RA, and demonstrate an improved understanding at each point in their disease trajectory, whilst encouraging them to cope, and enabling HP to optimize support provided.

**Methods:** We conducted two 30-minute interviews with patients with RA. Interview questions included the patients’ perspective of their disease and disease information, effects on daily life, as well as psychological considerations using the Corbin and Strauss Chronic Illness Trajectory Framework approach [1].  

This study was approved by the ethics committee of our hospital and informed consent was obtained.

**Results:** The first case: An unmarried 68 year old female living alone. The patients mother also suffered from RA. The patient was vaguely aware of the hereditary nature of RA (pretrajectory phase) and did not result in a big shock to her and she accepted her the diagnosis relatively smoothly (trajectory onset phase). She was prescribed initially pre-scribed methotrexate but this proved ineffective and infliximab was commenced. Remission was achieved and at that time she was satisfied with her relationship with her primary physician (stable phase).

Two years after beginning infliximab, she developed chest pain. However, her primary physician did not explore the problem and advised her that she had depression. She began to distrust him (unstable). She asked for infliximab to be stopped and requested her care be transferred to B university hospital where her mother was being treated. However, she was refused treatment due to the non-severity of her condition. She was unable to come to terms with refusal, and her physical and mental state deteriorated (downward phase).

Her mother advised the patient to go to D hospital, where she was put on Etanercept achieving remission with no complications (comeback phase). At D Hospital; (1) her condition and the need for treatment were clearly explained to her, and she was able to actively participate in shared decision making; and (2) she was given access to support from Health Professionals (HP) such as nurses, who offered a patient centered approach listening to her concerns and advising her appropriately whilst offering general psychological support.

A further 4 patients were interviewed. We will show the key phases of trajectories of their illnesses, the patients opinions about sharing their information with HP through interviewing, and the possibility of behavior change in the patients journeys.

**Conclusion:** This study shows that a patient centered approach taking into account the stages of the illness trajectory benefits patients perceptions of their disease and ability to cope with their condition. It also highlights the importance of having the support of others social circle, particularly at challenging times.

Making a thorough record of the patients disease and QOL trajectory allows the patient to understand their disease process and associated life changes, and assist health professionals to provide the optimal support and resolve problems when they arise.  

This preliminary study focuses on understanding the value of different phases of the trajectory of illness and sheds more light on the relationship between patients and HP and how the disease process and patients perspectives of their disease can facilitate mutual trust and smooth future treatment.

## AB1365-HPR INVESTIGATION OF THE ACUTE EFFECTS OF TAPPING ON TISSUE TEMPERATURE, MUSCLE STRENGTH, FUNCTION AND BALANCE IN PATIENTS WITH KNEE OSTEOARTHRITIS

Sevap Gurcan Unumot,1 Derya Ozer Kayas,2 Efil Umay Aalan,2 Izmir Katip Celebi University, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 2Izmir Katip Celebi University, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 2Izmir Katip Celebi University, Department of Physical Medicine and Rehabilitation, Izmir, Turkey

**Background:** Osteoarthritis (OA) mostly affects knee joint. It causes tissue temperature changes, muscle weakness, functional and balance impairments. Taping can be used to support knee joint. However, contradictory results presented in the literature (1-3).

**Objectives:** The aim of this study was to investigate the acute effects of taping on tissue temperature, muscle strength, function and balance in patients with knee OA.

**Methods:** Thirty-four patients with unilateral OA (34 females, age=60.118.29 years, height =159.765.27m; weight=80.1112.29 kg) were included. The patients were treated with a flexible kinesiology tape (Thera-Band Kinesiology tape, Cramer, USA). Supporting techniques for quadriceps muscle, patellar position and patellar tendon were applied. Before taping and after 30 min of application, tissue temperature with a thermal camera (Testo882, Germany), knee flexor and extensor muscle strength with a dynamometer (Lafayette, USA), function with timed up and go test and balance with computerized balance system (Prokin PK-254P, Tecnobody, Bergamo, Italy) were assessed. The paired samples t-test and Wilcoxon test used for analyses.

**Results:** The tissue temperature of the effected (34.661.16) and non-effected sides (34.871.08) of the cases were different (p=0.033). However, no significant difference was observed for tissue temperature before and after the taping (p=0.145). In the comparison of the effected side and non-effected side muscle strength, a significant difference was found for extensors (p=0.035). After taping the effected side, differences were found for extensor and flexor muscle strength (p=0.00; p=0.001) in comparison to before taping. While there was a significant difference in the time walking test before and after taping (p = 0.026), there was no difference for the balance scores (p> 0.05). The values of the cases before and after taping showed at Table 1.

**Conclusion:** It was observed that taping might not affect tissue temperature and balance. However, muscle strength and function could be affected positively with the acute supporting effect of taping.

THE EFFECTS OF LAND AND WATER BASED MULTIDIMENSIONAL FUNCTIONAL MOBILITY EXERCISES ON PULMONARY FUNCTIONS IN ANKYLOSING Spondylitis Patients

Barih Gurpınar1, Nursen Iltin2, Sema Savcı1, Nurullah Akkoç2. 1Dokuz Eylül University, İzmir, Turkey; 2xxxxxx, İzmir, Turkey

Background: Pulmonary manifestations are common in ankylosing spondylitis (AS) yet there is not enough evidence about the results of different interventions on pulmonary functions.

Objectives: The aim of this study was to evaluate the pulmonary effects of land and water based multidimensional functional mobility exercises on pulmonary functions in AS patients.

Methods: This is a single-blinded, randomized and experimental study conducted in outpatient clinic and thermal center. A total of 38 patients with definite ankylosing spondylitis according to the modified New York criteria were recruited for the study. Patients were randomly allocated to aquatic (AG) and land (LG) exercise group twice in a week for 8 weeks. Pulmonary Function Tests (PFT), maximal inspiratory mouth pressure (MIP), and maximal expiratory mouth pressure (MEP) were measured before and after the intervention.

Results: 3 patients from AG and 6 from LG missed 4 sessions consecutively. In AG, PEF (p<0.004), VC (p=0.025), MVV (p=0.006) and MIP (p=0.001) improved significantly on the other hand in LG FEV1/FVC (0.049), PEF (p<0.007) and MVV (p<0.004) significantly increased.

Conclusion: Performing multidimensional functional mobility exercises in water and on land could have different results. Exercising in water could have additional benefits such as increasing inspiratory muscle strength.

EFFECTIVENESS OF THE BARBERIC TREATMENT ON THE PERCEIVED PAIN, FATIGUE AND FUNCTIONALITY OF WOMEN WITH FIBROMYALGIA

Ruth Izquierdo Alventosa1, Izquietsing2, Sara Corts Amador2, Luca Gimeno-Baris Gurpinar1, Nursen Ilcin1, Sema Savci1, Nurullah Akkoç2.

1Fundacion FIVAN, Valencia, Spain; 2University of Valencia, Physiotherapy, Valencia, Spain; 3Utrecht U, Utrecht, Netherlands

Background: Fibromyalgia (FM) is a chronic pain syndrome accompanied by other symptoms such as fatigue or altered functionality. 1 One of the most common non-pharmacologic treatment is physical exercise because of its known positive influence on pain as a consequence of the physical condition improvement. 2 However, they use to present a lack of adherence to this type of therapeutic programs may be attributable to post-exercise pain. 3 For this reason, alternative approaches that do not involve physical efforts, such as hyperbaric therapy, may be effective to reduce pain, fatigue or functionality in women with FM. 4

Objectives: To compare the effectiveness of hyperbaric therapy and physical exercise on pain, fatigue and functionality in women with FM.

Methods: A randomized control trial was conducted. 28 women with FM were divided in two intervention groups: One group, composed of 14 women, received a low-intensity physical exercise program twice a week for 8 weeks (PEG). The other group received 40 sessions of hyperbaric treatment, 5 times per week (HBTG). To determine the effect of these therapeutic programs, the perceived pain was assessed with an analogue visual scale. Further, the fatigue was measured with the Borg scale and the covered walked distance with The Six minutes walk test. The measurements were conducted two times, before and one week after finishing the treatment. The effect of the treatments was statistically analyzed with a mixed factorial ANOVA with the between-subject factor called group (categories: PEG and HBTG) and with the within-subject factor called intervention (categories: pre and post-intervention).

Results: Our study shows that hyperbaric treatment significantly improved functionality and reduced the levels of pain and fatigue (Table 1). The physical exercise intervention improved functionality, but this program could not reduce the experienced intensity of pain nor the perceived fatigue (p<0.05).

Abstract AB1367HPR Table 1. Effect of the physical exercise program and hyperbaric therapy on pain, fatigue and functionality.

<table>
<thead>
<tr>
<th></th>
<th>Pre-intervention</th>
<th>Post-intervention</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pain PEG</td>
<td>6.21 (2.29)</td>
<td>5.57 (2.24)</td>
</tr>
<tr>
<td>Fatigue PEG</td>
<td>6.86 (2.82)</td>
<td>7.21 (2.52)</td>
</tr>
<tr>
<td>Distance PEG</td>
<td>489.21 (76.39)</td>
<td>516.64 (71.58)</td>
</tr>
<tr>
<td>PEG</td>
<td>7.43 (1.70)</td>
<td>5.07 (2.50)</td>

Background: Long-term morbidity and mortality in patients with rheumatoid arthritis (RA) are increased11 due to the increased risk of comorbidities
including cardiovascular disease (40-70% incidence\(^2\), 5-12.9% prevalence\(^3\)), diabetes (IR of 8.6 per 1000 person-years\(^4\); 20%\(^5\)), interstitial and within countries\(^10\).

in the roles and responsibilities of healthcare professionals (HCPs) across health care delivery systems throughout Europe, there is also variability in the roles and responsibilities of healthcare professionals (HCPs) across and within countries\(^10\).

Objectives: This study aimed to identify good practices within the roles of HCPs in the care of RA and associated comorbidities and to understand how these practices may be implemented in other centres. Methods: This study interviewed multidisciplinary teams at 12 selected specialist centres across Europe (1 centre per country) and examples of HCPs who had expanded roles and responsibilities were identified. Further, the questions whether these practices improved quality of care and could be implemented in other centres were addressed. Results: This Europe-wide study identified good practice examples of enhanced roles and responsibilities for HCPs such as nurses, physiotherapists, occupational therapists and podiatrists that varied with different categories of patients and their corresponding needs. The scope and depth of extended roles also varied between different countries and health systems. Examples included.

AB1369-HPR

THE EFFECTS OF CLINICAL PILATES TRAINING IN INDIVIDUALS WITH PRIMARY SJOEGREN’S SYNDROME

KESKIN Aylin1, Bilge Basakci Calik1, Elif Gur Kabul1, Murat Tasci2, Veli Cobanakara3, Pamukkale University, School of Physiotherapy and Rehabilitation, DENIZLI, Turkey; Pamukkale University, Department of Rheumatology, DENIZLI, Turkey

Background: Primary Sjogren’s syndrome (PSS), occurs in people with no other rheumatic disease, is a chronic, systemic, autoimmune disease characterized by lymphocytic infiltration of all exocrine glands, especially tears and salivary glands (1,2). Exercise training is commonly recommended in the approach of individuals with rheumatic disease and clinical pilates training have positive effects on endurance, functional mobility and quality of life. Nonetheless there is limited study related exercise training and no study which examined the efficacy of clinical pilates training in individuals with PSS in literature. Therefore, our study is very important. Objectives: The aim of the study was to examine the effects of clinical pilates training on trunk and lower extremity endurance, functional mobility, emosyonel status, sleep quality, functional level and quality of life in individuals with PSS.

Methods: The study included 23 voluntary individuals (22 female,1 male; mean age: 50.529.38 years), with PSS who were diagnosed with primary Sjogren’s syndrome according to 2016 American College of Rheumatology/European League Against Rheumatism Classification Criteria and according to Chisholm-Mason classification between grade 3 and 4 who applied to Pamukkale University Department of Internal Medicine, Department of Rheumatology. Anterior and lateral bridge was used to determine trunk endurance, 30-Second Chair Stand Test (30s-CST) and The Timed Up and Go (TUG) Test for lower extremity endurance, Lower Extremity Functional Scale (LEFS) for functional mobility, Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI) for emotional status, Pittsburgh Sleep Quality Index (PSQI) for sleep quality, Health Assessment Questionnaire (HAQ) for functional level and Short Form 36 (SF-36) for quality of life. Light after demographic information and disease related data were recorded. The all assessments were made before and after clinical pilates training. All participants attended 60-min exercises training (5-min warm up, 45-min clinical pilates exercises, 10-min cool down) three times a week for 8 weeks which was progressively challenged and applied by a Physiotherapist with 2 years of experience in this field. Wilcoxon test were used to examine the factors related to functional level.

Results: After training in all evaluations a statistically advanced level of significant improvement compared to pre-training values in individuals with PSS (p<0.001).

Conclusion: Muscular endurance and functional level and the associated with emosyonel status, sleep and quality of life are important for individuals with PSS. Exercise approaches for these parameters are recommended. This study showed that clinical pilates exercises program have positive effects on trunk and lower extremity endurance, functional mobility, emosyonel status, sleep quality, functional level and quality of life in individuals with PSS.

AB1370-HPR | COMPARISON OF SLEEP, FATIGUE AND SEXUAL PARAMETERS OF RHEUMATIC DISEASES

Fatma Bing Kumburoğlu, Gamze Ann, Nur Baru Karaca, Sule Aşrap Bilgen, Edibe nallı, Hacettepe University Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; Hacettepe University Faculty of Medicine, Department of Rheumatology, Ankara, Turkey.

Background: Chronic pain, sleep, and fatigue are common complaints in rheumatic disease (1). However, each rheumatic disease has different characteristics. So that it can be thought that individuals can be affected by different diseases in different ways (2).

Objectives: The aim of this study is to compare sleep, fatigue and sexual parameters in different rheumatic diseases.

Methods: Individuals diagnosed with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS) and Fibromyalgia (FM) who applied to the Rheumatology Department of the Medical Faculty of Hacettepe University were included in the study. After the demographic characteristics of the individuals were recorded; sexual function, sexual willingness, fatigue, and sleep features were assessed with 11th, 27th, 29th and 30th items of BETY-Biopsychosocial Questionnaire (BETY-BQ) which is developed in rheumatic patients (3).

Results: 160 RA, 108 AS, and 131 FM patients were included in the study. The scores of individuals on scales are shown in Table 1. There was no statistically significant difference among the three groups in terms of BMI (p>0.05), while the mean age of RA patients was statistically different from the other two groups (p<0.05). The sleep, fatigue and sexual parameters (sexual function, sexual willingness) were examined with Kruskal Wallis analysis. When analyzed in terms of differences according to RA, AS and FM, the responses to sleep (p=0.015) and sexual functioning (p=0.003) were found different according to the diseases. However, there was no significant difference in the sexual willingness (p=0.248) and fatigue (p=0.708) related to the disease. Mann-Whitney U test was performed to test the significance of a pairwise difference using Bonferroni correction to adjust for multiple comparisons revealed that the difference between the groups was due to RA patients (Table 2).

Conclusion: As a result, all the patients who participated in this study have sleep, fatigue, and sexual problems. Although the mean age of RA patients is higher than other patients, it is quite interesting that they have less sleep and sexual function problems. On the other hand, it was expected that symptoms of RA and AS diseases due to their inflammatory nature would be worse than FM. Moreover, it can be estimated that AS patients have spinal involvement and this situation may affect their sexual function, but FM patients results in terms of these parameters were unclear. It was concluded that the psychosocial characteristics were taken into consideration especially in FM patients sexual parameters, fatigue, and sleep features during the disease management.

AB1371-HPR | EFFECTS OF MORNING STIFFNESS ON THE PSYCHOSOCIAL AND FUNCTIONAL STATUS OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Fatma Bing Kumburoğlu, Aykut zadro, Selcan Demir, Yelda Bilgen. Edibe nallı, Seza zen, Hacettepe University Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey.

Background: Juvenile Idiopathic Arthritis (JIA) is a chronic childhood autoimmune disease that has significant implications on a childs physical health and psychosocial integration (1). Common symptoms of JIA include pain, joint stiffness, joint swelling, fatigue, and decreased physical function (2).

Objectives: The aim of this study is to investigate the effects of morning stiffness on the psychosocial and functional status of patients with JIA.

Methods: 387 JIA patients were included in this study. To determine the functional status of the patients functional subscale of The Juvenile Arthritis Biopsychosocial-Questionnaire (JAB-Q) and Childhood Health Assessment Questionnaire (CHAQ) were used. Psychosocial subscale of JAB-Q was used to assess psychosocial status. Finally, morning stiffness was measured as “less than 30 minutes”, “between 30 minutes and 1 hour” and “more than 1 hour”.

Results: A total of 162 boys and 225 girls participated in the study (Table 1). The effect of morning stiffness on functional and psychosocial status was measured as less than 30 minutes”, “between 30 minutes and 1 hour” and “more than 1 hour”. There was statistically significant difference between the functional status (CHAQ Total, p=0.001; CHAQ General VAS, p=0.012; CHAQ Pain VAS, 0.001; Function JAB-Q, p=0.001) of the patients and the duration of morning stiffness. However, there was no significant difference between the duration of morning stiffness and psychosocial status. Mann-Whitney U test was performed to test the significance of a pairwise difference using Bonferroni correction to adjust for multiple comparisons revealed that the difference between the groups was due to the morning stiffness duration “less than 30 minutes” group (Table 2).

| 1= <30 min morning stiffness, 2= 30 min-1 hour morning stiffness, 3= >1 hour morning stiffness.

Conclusion: In our study, as a result psychosocial status was not affected by duration of morning stiffness. On the other hand, functionality of patients were getting worse as the duration of morning stiffness increases. It was concluded that psychosocial status should be dealt with independently of functional status, and children should be supported to participate in psychosocial environment such as school attendance, social activities.

THE INVESTIGATION OF THE RELATIONSHIP BETWEEN PSYCHOSOCIAL STATUS OF CHILDREN WITH JIA AND PARENTS

Aybüke Şerif Yavuz, Aybüke Sevier, Gamze Arnı, Yasin Zel Arslayı, Fatma Birgül Kumburuğlu, Nur Banu Karaca, Şekan Dersin, Yelda Bilgiler, Edibe naı, Seza zenı. 1Hacettepe University Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of diseases characterized by unknown origin arthritis that begins before the age of 16 years (1). Therefore, families are often affected by the disease of children. Parents and children often disagree with assessing different aspects of disease activity in JIA (2).

Objectives: The aim of this study is to investigate the relationship between children with JIA and their parents’ psychosocial status.

Methods: A total of 345 children with JIA and their parents were included in the study (n = 690). Juvenile Arthritis Biopsychosocial Questionnaire (JAB-Q) was administered to the subjects (3). The psychosocial status of the individuals was evaluated by this questionnaire.

Results: The mean age of children included in the study (n = 345) was 12.32 ± 3.76 years. While the median value of the Child Psychosocial score was 10 (min: 0 max: 38), the median value of the Parent Psychosocial score was 6 (min: 0 max: 20). Correlation coefficients and statistical significance were calculated by using the Pearson test. A positive low correlation was found between the psychosocial status of the child and parents (r = 0.273, p <0.001) (Table 1).

Table 1. Correlations:

</tr>
</tbody>
</table>

Conclusion: It was observed that there was a low relationship between the psychosocial status of children and parents. It was concluded that child and parents psychosocial status may be affected by other variables such as high disease activity, school attendance. Further studies are needed in this area including different variables and interaction psychosocial status.

THE EFFECTIVENESS OF BIOPSYCHOSOCIAL EXERCISE PROGRAM ON PAIN COPING IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND FIBROMYALGIA

Aybüke Sevier, Aybüke Şerif Yavuz, Gamze Arnı, Yunus Zel Arslayı, Fatma Birgül Kumburuğlu, Nur Banu Karaca, Ali Akdogan, Edibe naı. 1Hacettepe University Faculty of Physical Therapy, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Rheumatology, Ankara, Turkey

Background: Ankylosing spondylitis (AS) and fibromyalgia (FM) are rheumatic diseases with a high incidence in the community. Although many studies have been done on pain in these patient groups, the studies on coping with pain are very limited (1, 2). The aim of this study was to examine the relationship between patients’ biopsychosocial characteristics and coping with pain in AS patients.

Objectives: The aim of this study was to investigate the biopsychosocial characteristics of patients with rheumatic diseases who were inpatients, outpatients and participated in an exercise intervention regularly.

Methods: A total of 105 patients were included in the study (inpatient, outpatient, exercise intervention) (Table 1). For exercise intervention group, BETY as a biopsychosocial exercise model was applied 3 days a week for 3 months [2]. Biopsychosocial characteristics of the patients included in the study were evaluated by BETY-Biopsychosocial Questionnaire (BETY-BQ) (3). In addition to the total score of BETY-BQ, the same time pain, functionality and fatigue, sexuality, emotional status and socialization subcategory of this questionnaire were evaluated on item basis among each patients.

Results: The demographics variables and BETY-BQ scores of the patients were shown in Table 1. There were a statistically significant differences among three groups. After post-hoc analysis, it was determined that there is no difference between the BETY-BQ scores of the inpatients and outpatients (p> 0.05), whereas the BETY-BQ scores of the patients who participated in the group exercise were lower (p<0.05). When the items were analyzed, it was found that patients (items 2, 3, 5, and 12), functional- ity and fatigue (items 6, 7, 11, 26, and 28), emotional status (items 16 and 17), and sleep (item 30) subcategory scores were also lower in patients who participated in BETY programme (p<0.05).

<td>38.8121.73</td>
</tr>
</tbody>
</table>

Conclusion: It is surprising that the biopsychosocial characteristics of the inpatients and outpatients were similar. According to this result, inpatients shouldn’t be thought as worse than outpatients. On the other hand, the patients who participated in exercise intervention were improved in terms of biopsychosocial aspects. The positive effects of the BETY program on the biopsychosocial status of individuals have been demonstrated formerly [4]. It was concluded that inpatients should be supported to exercise in terms of their biopsychosocial needs during hospitalization period as well as rheumatic outpatients need.

EFFECT OF SCHROTH METHOD AND SCIENTIFIC EXERCISE APPROACH TO SCOLIOSIS (SEAS) ON THE COBB ANGLE AMONG THE ADOLESCENT WITH IDIOPATHIC SCOLIOSIS: A COMPARATIVE STUDY

Jalpa Shah, T Padma Priya, Paliniyan Arunagam, R Kousalya, Sri Venkateshwara Medical College Hospital and Research Centre, physiotherapy, Puducherry, India

Background: Scoliosis is a three-dimensional deformity of the spine and trunk leading to physical and functional disability. Among adolescent, idiopathic scoliosis is the most common (80% - 89%) form of scoliosis with prevalence ranging between 0.47% and 5.2% in general population. As the evidence on the comparative efficacy of various physical therapy in scoliosis is sparse, we conducted a comparative study assessing efficacy of Schroth method of exercise group (SEG) and scientific exercise approach to scoliosis group (SEASG).

Objectives: To compare efficacy of Schroth method and SEAS among adolescent with scoliosis.

Methods: Thirty subjects, both male and female of the age group of 10 to 18 years, with mild-moderate idiopathic scoliosis defined as the spinal radiographic Cobb angle in the range of 20 to 45 and riser sign of 0-2 were randomly allocated to Schroth method of exercise group (SEG, n=15) and scientific exercise approach to scoliosis group (SEASG, n=15). Subjects with diagnosis of spinal injury, previous spinal surgery, gibbus, limb deformity, infection and malignancy were excluded. The SEG and SEASG performed Schroth and scientific exercise respectively, 5 times a week for 7 weeks. To quantify the magnitude of spinal deformity, Cobb angle measurements were obtained by using radiograph to gain pre-post interventional differences. (Figure 1)

Results: SEG showed the significant changes in pre (mean sd 31.2 5.20) and post (mean sd 27.4 5.17) Cobb angle measurements. SEASG also showed the significant changes in pre (mean sd 31.33 5.26) and post (mean sd 29.4 5.9) Cobb angle measurements (Figure 2). Comparing both the groups by unpaired t test suggested SEG to be more efficacious than the SEASG with the t value (4.22) for change in Cobb angle (p < 0.0001) (Figure 3).

Conclusion: The study establishes the role of physical therapy in idiopathic scoliosis of mild to moderate degree among adolescents. Schroth method of exercise performs better compared to the SEAS in patients with mild to moderate scoliosis.

</tbody>
</table>

Conclusion: Although both AS and FM are rheumatic diseases, it is known that FM patients experience more intense psychosocial stress. They are, therefore, resistant to change (4). We found that the positive change in pain coping skill is not seen in FM group. It is concluded that FM patients regarding in pain coping strategies they need to attend exercise programs and need to be educated about pain coping skills for a longer period.

Role of Nurse-led Telephone Follow-up to Patient Activation Measure in Patients with Polymyalgia Rheumatica and Giant Cell Arteritis

Pia Toftegaard, Amir Emamifar, Alexandra Brink Walling, Susanne Hjmark Jakobsen, Peter Thye-Rnn

Background: Poor adherence to the osteoporosis prophylaxis medications has been reported before, which may result in treatment failure.

Methods: This is an ongoing 1-year prospective cohort study, 37 consecutive steroid treated patients with newly diagnosed PMR/GCA were included. Patients were seen by the physicians at baseline, 1st and 4th month, where they were interviewed about their compliance towards osteoporosis prophylaxis medications, i.e. Calcium/Vitamin D supplements and Bisphosphonates if Tscore £ -2.5, using a standardized questionnaire.

Results: 85.3% and 75.8% of the patients were completely adherent to their osteoporosis medications at 1st and 4th month, respectively. (figure 1) The difference between level of adherence to the osteoporosis medications at 1st (=week 4) and 4th month (=week 16) was not statistically significant. (P value:0.369). Decreased adherence in patients was mainly due to forgetfulness.

Conclusion: Compared to the earlier findings we found a higher level of adherence in this group of patients. Nurse-led telephone follow up as well as educating the patients respecting the importance of the osteoporosis medications for preventing steroid related side effects, may enhance and subsequently maintain high level of adherence to the osteoporosis medications. Our findings are in line with our earlier study indicating a high level of adherence to the osteoporosis medications in PMR/GCA patients.

Patient Activation Measure in Patients with Rheumatoid Arthritis

Laura Villarreal, Fernando Rodriguez, Pedro Santos-Moreno, Diana Buitrago-Garcia

Background: The Patient Activation Measure (PAM) is a 13-item measure that assesses patient knowledge, skill, and confidence for self-management. The measure was developed using Rasch analyses and is an interval level, unidimensional, Guttman-like measure. The current analysis is aimed at reducing the number of items in the measure while maintaining adequate precision(1). A Spanish adaptation of the scale was performed in 2017.

Methods: We performed a quantitative, observational, cross-sectional, and questionnaire-based study, convenience sampling was used. Participants were recruited in a specialized RA center, during a patients meeting. We applied the PAM-13 scale validated in Spanish. The scale has a score from 1 to 4 divided in four levels where level 1 represents a disengaged patient and suggests that the doctor is in charge of their health; level 2: the patient becomes aware but struggling; level 3: The patient is taking action and considers himself as a part of the healthcare team, and level 4 represents a patient that maintains behaviors and pushes forward. The maximum score is 52 points.

Results: 322 patients participated, 23 patients generated incomplete PAM scores (response rate 92%) and were excluded. From total 93% of patients were women. Mean age was 60 years 10; mean PAM-13 Was 19.83 6.16. In our study 68% of patients were in level 2 according to PAM-13 scale which means that they are becoming aware of their knowledge, skills and self-management but are still struggling. See table 1. In average 80% of patients answered each question to be in level 1 or 2, 15% in level 3 and only 5% in level 4.

Conclusion: This is the first study in our country where the Patient Activation Measure is applied in patients with rheumatoid arthritis. Thus, it might be useful to implement patient activation monitoring, since the level of activation is low in patients with RA.

EFFECT OF CLINICAL CHARACTERISTICS, HABITS, PHYSICAL ACTIVITY LEVELS AND FUNCTIONAL CAPACITY ON QUALITY OF LIFE IN SYSTEMIC SCLEROSIS PATIENTS

Hazal Yakut1, Sevgi zalevl1, Ahmet Merih Birlik2. 
1Dokuz Eylül niversitesi Fizik Tedavi ve Rehabilitasyon Ynya Kolu, İzmir, Turkey; 2Dokuz Eylül niversity Hastanesi, İmmunoloji-Romatoloji Anabilim dalı, İzmir, Turkey

Background: In patients with Systemic sclerosis (SSc), many factors such as inactivity, smoking, gastrointestinal system involvement are reported to have an adverse effect on overall health related quality of life, and quality of life is in line with the prognosis of the disease (1,2).

Objectives: The aim of this study was to investigate the effect of clinical characteristics, habits, physical activity levels and functional capacity of patients with SSc on quality of life.

Methods: Twenty-three SSc patients were included in the study. The ages of patients, the amount of cigarette consumption, duration of diagnosis and body mass indexes (BMI) were questioned and recorded. Functional capacities of patients were measured by 6 Minute Walking Test (6MWT). Physical activity levels of patients were calculated using the International Physical Activity Questionnaire (IPAQ; using metabolic equivalent-MET). Quality of life was evaluated by the short form SF-36 quality of life questionnaire (SF-36 QoLQ). The SF-36 questionnaire was evaluated as two subscales, physical and mental.

Results: The mean age of the patients was 51.00±11.10 years and the duration of diagnosis was 7.60±4.80 years. BMI was 26±6.07 kg/m² and amount of cigarette consumption was 6.02±3.30 packeyear(s). The mean physical activity levels (IPAQ) were 281.68±60.45 MET, 6MWT distance were 435.39±80.45 m, SF-36 QoLQ-physical were 32.48±13.42 and SF-36 QoLQ-mental were 38.56±11.42 score. It was found that there was a significant correlation between SF-36 QoLQ-physical and BMI (p = 0.043, r = 0.426), 6MWT (p < 0.001, r = 0.737) and IPAQ (p < 0.001, r = 0.647). There was a significant correlation between the SF-36 QoLQ-mental and 6MWT (p < 0.020, r = 0.483) and IPAQ (p = 0.032, r = 0.614).

Conclusion: Reduced levels of physical activity in SSc patients affect functional capacity. Reduced physical activity level and functional capacity decrease the quality of life of patients related to both physical and mental health. Physical health related quality of life of patients is negatively affected by the increase in BMI. Functional capacity, clinical characteristics, habits and physical activity levels should be evaluated and improved in treatment programs aimed at improving the overall health-related quality of life of patients.

EFFECTS OF DIFFERENT EXERCISE MODELS ON PAIN, FUNCTIONALITY, BALANCE, PROPRIOCEPTION AND COGNITION FEATURES OF PATIENTS DIAGNOSED WITH FIBROMYALGIA

Hadi Yavuz1,2, Trker Şahinkaya1, Aysegul Ketenç1, Gikhan Metin1. 1Istanbul University, Physical Medicine and Rehabilitation, Istanbul, Turkey; 2Istanbul University, Sports Medicine, Istanbul, Turkey; 3Istanbul University-Cerrahpusa, Physiology, Istanbul, Turkey

Background: Fibromyalgia syndrome (FMS) is a chronic disease characterized by diffuse pain, fatigue, sleep disturbance, cognitive impairment, and other physical symptoms that adversely affect physical and sensory functions and impair quality of life. Nowadays, in the treatment of FMS, low intensity aerobic exercises and exercise programs combined with other treatment methods are recommended.

Objectives: The aim of this study was to evaluate the effects of aerobic and balance-proprioception exercises on the symptoms of Fibromyalgia (FMS) and the superiority of the two exercise models.

Methods: 51 female patients who adhere to the inclusion criteria were divided into two groups randomly. Aerobic Exercise Group (AEG; n=26) and Balance-Proprioceptive Exercise Group (BPEG; n=25) was applied to the exercise laboratory under the supervision of physiotherapist in Istanbul Medical Faculty, Department of Sports Medicine 3 days a week for 6 weeks. Before and after the program Pain (VAS), functional status (FIO), postural stability (Biodex balance system), knee joint proprioception (Cybex isokinetic dynamometer) were evaluated. Cognitive status was assessed by Standardized Mini Mental State Examination (SMMSE) only before program.

Results: There wasn’t statistically significant difference between demographic (age, weigh, BMI etc.) and clinic (VAS, FIO, Biodex, Cybex, SMMSE) features of the groups at the beginning (p>0.05). Parameters measured in both groups after exercise programs showed progress compared to initial levels (p<0.05). There isn’t the superiority between two exercise groups in terms of VAS, FIO scores (p<0.05). Recovery is found to be better at BPEG in balance parameters (eyes open overall stability index (EOOSSI) and eyes open anteriorposterior stability index (EOAPSSI)) and some parameters that belongs to proprioception (p<0.05).

Conclusion: It is determined that aerobic exercise and balance-proprioception exercise programs at BPEG are effective in positive way methods for functionality, pain, proprioception and balance parameter recovery of the patients. Except EOOSSI and EOAPSSI balance parameter values; according to other parameters it is found that aerobic exercise and balance-proprioception exercises are equal to each other. It is found out that balance-proprioception exercises are superior to aerobic exercises for improving EOOSSI and EOAPSSI. It is revealed that balance proprioception exercises are more effective for curing proprioception. It is observed that patients with FMS had deterioration in cognitive functions.

PATIENT SATISFACTION IS HIGH IN PATIENTS TRAINED TO SELF-INJECT WITH A BUTTON FREE AUTO-INJECTION USING VIDEO TRAINING

Dawn Homer, Modality Partnership Community Rheumatology Service, Erdk Medical Practice, Birmingham, United Kingdom

Background: Once-weekly subcutaneous injection of methotrexate can optimize long-term treatment of rheumatic diseases such as rheumatoid arthritis.1 However, available self-injection devices vary in terms of ease of use and level of operational dexterity required.

Objectives: This pilot study compared patient satisfaction with use of a methotrexate pre-filled, button-free, auto-injector pen (Nordic Pharma, UK) for subcutaneous injection with previous use of a button-activated pen device were invited to change to a button-free auto-injector by letter. They were given the option to self-train using an online video or receive one-to-one instruction from a rheumatology nurse. Initial follow-up took place immediately after the first injection; invitation to participate in a 10-minute telephone questionnaire to evaluate their experience of using their new device took place after 3-4 weeks. Satisfaction with the device was assessed overall and according to 7 specific autoinjector attributes: ease of injection; experience of injection; comfort in hand; use with dexterity issues or during flare-ups; confidence in full dose being given; convenience of storage and disposal; and portability.

Results: Thirty-three patients were invited to change to an auto-injector: 22 patients responded (response rate: 64.7%), 19 of which made the assessment and completed the survey. 78% of patients overall were satisfied or very satisfied with administering methotrexate using the auto-injector; 85% of patients were equally or more satisfied with the use of an auto-injector pen compared to their previous device. Patients were equally or
more satisfied with the new device across all 7 autoinjector attributes: convenience of storage and disposal (100.0%), portability (100.0%); comfort in the hand (94.1%); confidence in full dose being given (88.9%); use with dexterity issues or during flare-ups (85.7%); ease of injection (82.4%); experience of injection (68.4%). Self-training via video did not negatively affect satisfaction: 83.3% of those patients confident in their ability to perform self-injection correctly after viewing the video were satisfied or very satisfied with their new autoinjector device. Three patients discontinued with the new device: one switched to oral therapy for reasons unrelated to the device; two returned to their original device.

Conclusion: This pilot study showed that patients were more satisfied with use of a methotrexate button-free auto-injector device than with their previous auto-injector device across all 7 user attributes and that satisfaction was maintained with use of self-training. Patient views regarding acceptability and use of auto-injection devices should be considered when making device switches based on cost and nurse resource allocation to ensure continued adherence with injected medication.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

AB1380-HPR THE EFFECTS OF CERVICAL RANGE OF MOTION ON POSTURAL STABILITY IN PATIENTS WITH CHRONIC NECK PAIN

Onur Avşarduoğlu1, Gülşah Kılçı1, Tolga Taşböcek1, Zübeyir San1, 1Marmara University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey

Background: Neck pain is a common musculoskeletal problem within chronic pain and it affects up to 71% of adult population during their lifetime (1). Chronic neck pain is related to a series of disabilities: a range of reported pain, postural stability problems, and cognitive dysfunction (2). However, there is no report that investigates the relationship between range of motion and postural stability in patients with chronic neck pain.

Objectives: The purpose of this study was to investigate the relationship between range of motion and postural stability in patients with chronic neck pain.

Methods: Thirty subjects of mean age 28.50 ± 10.95 years who admitted chronic neck pain to a Private Physiotherapy Clinic were participated in this study. While goniometer was used for cervical range of motion, pedalo sensarmove system was used for postural stability. In addition, pain and disability were measured with visual analogue scale, neck disability index, respectively.

Results: It was found that limitation of cervical range of motion was not correlated to postural stability deficits (p>0.05). The neck pain and disability status was not associated with level of postural stability (p>0.05).

Conclusion: The findings of this study showed that postural stability may not be affected by the limitation of cervical range of motion, and also neck pain intensity, neck disability status in patients with chronic neck pain. Further research with larger sample sizes is warranted.

AB1381-HPR ADAPTABILITY, EFFECTIVENESS AND SAFETY OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS

Fernando Rodriguez1, Anggie Aza2, Michael Cabrera3, Pedro Santos-Moreno4, Diana Buitrago-Garcia5.

1Biomab – Center for rheumatoid arthritis, 2Patient coordinator, Bogot, Colombia; 3Biomab – Center for rheumatoid arthritis, Business administration, Bogot, Colombia; 4Biomab – Center for rheumatoid arthritis, EHR administration, Bogot, Colombia; 5Biomab – Center for rheumatoid arthritis, Rheumatology, Bogot, Colombia; 6Biomab – Center for rheumatoid arthritis, Nursing research, Bogot, Colombia

Background: Tofacitinib is a, selective JAK inhibitor that preferentially inhibits Janus kinase (JAK) 1 and JAK2. Oral tofacitinib 5 mg twice daily or 11 mg once daily is indicated for the treatment of moderate to severe active rheumatoid arthritis (RA) in adult patients who have responded inadequately to, or who are intolerant of, one or more DMARDs. Mainly, one of the strengths of Tofacitinib, is that it is a very suitable medicine for those patients who are afraid of applying a general biologics medicine, or who are of advanced age or are at high risk of adverse events, therefore it’s easy to discontinue it.

Objectives: We aim to describe the tolerance and adaptability of patients to Tofacitinib, as well as the effectiveness and safety in patients with RA in a real-life setting in Bogot, Colombia.

Methods: During 2017 and 2018 we followed-up patients from a RA specialized center in Colombia receiving Tofacitinib. Patients were treated with therapeutic goals type T2T and a multidisciplinary approach. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3-5 weeks (DAS28 > 5.1), every 7-9 weeks (DAS28 ≥ 3.1 and < 5.1), and every 11-13 weeks (DAS28 < 3.1). Tender joint count (TJC), swollen joint count (SJC) and HAQ were measured on each visit. Therapy had to be adjusted with DAS28 > 3.2. We divided patients in four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) patients and one aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission. On the other hand, we evaluated the tolerance and adaptability of patients to Tofacitinib. Adverse events were classified according the Common Terminology Criteria for Adverse Events (CTCAE) of the World Health Organization. Descriptive epidemiology for continuous variables, measure of central tendency and dispersion for qualitative and categorical variables through percentages and averages were calculated.

Results: We included 59 patients receiving tofacitinib, 92% were women and 8% men during last two years. Mean age was 60.11. From total, 70% of patients received anti-TNF drugs before tofacitinib and the other 30%. In reference to the adaptability, most of the patients up to 95% expressed to be happy with the oral intake and the suitable dosage of the medication. Regarding effectiveness, mean DAS28 at beginning was 4.6.83 and at the end 2.6.63. At the beginning of follow-up 57.6% of patients were in moderate disease activity according to DAS28 and 33.9% in severe disease activity, while at the end of follow up 64% of patients achieved remission and 16.9% low disease activity during the 12 weeks of follow-up. See table 1. Regarding safety 2 patients presented a dermatological adverse event (herpes zoster) with adverse event rate of 3.3%.

Abstract AB1381HPR Table 1. DAS28 in patients receiving tofacitinib.

Conclusion: Tofacitinib is a very suitable medicine in patients with RA and improved disease activity in impressive way; also proved to be very safe, except the occurrences of herpes zoster, which is an aspect to take into account in its prescription, but none of patients presented another serious adverse events.

AB1382-HPR 1 COMPARISON OF EFFICACY OF DIFFERENT REHABILITATION APPROACHES IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS

Elif Baysal1, Miray Bukarlı2, Esra Atılgan3, Devrim Tanrıkulu1. 1Istanbul Medipol University, Istanbul, Turkey; 2Istanbul Medipol University, Physical Therapy and Rehabilitation, Istanbul, Turkey; 3Istanbul Medipol University, Ergotherapy, Istanbul, Turkey. Background: Osteoarthritis (OA) is the most common rheumatologic disease in the world, resulting primarily in progressive cartilage destruction. OA-induced changes are the main cause of disability and are mostly seen in the knee joint. Objectives: To investigate the effects of different rehabilitation practices on the range of motion, muscle strength, pain, physical function and quality of life in patients with knee OA. Methods: Thirty patients between the ages of 40-65 with knee OA were included in the study and divided into 3 groups. Transcutaneous Electrical Nerve Stimulation (TENS), ultrasound, hotpack/coldpack and home exercise program were given to the 1. group (n=10) for 15 days. 2. group (n=10) received three doses of Platelet-Rich Plasma (PRP) followed by home exercise program for 15 days. The control group (n=10) received only home exercise program for 15 days. All individuals were evaluated using ‘Goniometer’ for Range of Motion (ROM), ‘Manual Muscle Test’ for M. Quadriceps femoris muscle strength, ‘Visual Analogue Scale’ for pain, ‘The Western Ontario and McMaster Universities Arthritis’ (WOMAC) Scale for physical function and ‘Short Form-12 Quality of Life Scale’ Mental (SF-12 - MC) and Physical Component (SF-12 - PC) for quality of life at baseline and end of treatment.

Results: Statistically significant difference was found at pain and WOMAC score at the time of activity in all groups (Table 1). Statistically significant difference was found at ROM and SF-12 PC score in group 1 and 2, at resting pain and SF-12 MC score in control group (p <0.05) (Table 2). Conclusion: In addition to electrotherapy treatment and PRP in knee OA treatment, it is thought that home exercise program can be used to relieve symptoms and improve quality of life in knee OA.

AB1383-HPR THE VALIDITY AND RELIABILITY OF UNSUPPORTED UPPER LIMB EXERCISE TEST IN INDIVIDUALS WITH RHEUMATOID ARTHRITIS

S. Yaprak Cetin1, Bilge Basakci Calik2, Ayse Aydin3, Ugur Cavlak4. 1Akseniz University, University of Physiotherapy and Rehabilitation, Antalya, Turkey; 2Pamukkale University, School of Physiotherapy and Rehabilitation, Denizli, Turkey; Antalya Education and Research Hospital, Rheumatology, Antalya, Turkey; 4European University of Lefke, Physiotherapy and Rehabilitation, Antalya, Turkey. Background: Rheumatoid arthritis (RA) is a systemic, inflammatory disease that causes pain, joint destruction and disability. RA affects the function of the hand and upper extremities; function deteriorates as the disease progresses and affects independence. Unsupported upper-limb exercise (UULEX) test was developed to evaluate upper extremity function and endurance in individuals with Chronic Obstructive Pulmonary Disease. It is suggested that this test can be used in other clinical cases with arm disabilities.

Objectives: The aim of this study was to examine whether the UULEX Test is valid and reliable in individuals with RA.

Methods: 71 individuals with RA (15 male, 56 female) with an average age of 52.15 ± 10.11 were included in the study. The Intraclass Correlation Coefficient (ICC) was used to assess the reliability of the UULEX test. Each individual was assessed by one physiotherapists in two different sessions, a week apart. The correlations of the UULEX test with Disabilities Arm, Shoulder and Hand (DASH), Health Assessment Questionnaire (HAQ), 30 sec Push Up Test and 6 Peg Board Ring Test were assessed for concurrent validity.

Results: Intrarater reliability of final level, final weight, duration of the UULEX Test were determined to be excellent (ICC = 0.922, 0.960, 0.958). A moderate to excellent correlation was found between UULEX Test and DASH, HAQ, 30 sec Push Up Test and 6 Peg Board Ring Test (p<0.05).

Conclusion: The results of this study showed that the UULEX test is a valid and reliable method in the assessment of upper extremity endurance in individuals with RA.

The relationship between quality of life, trunk strength and spinal mobility in SpA patients

Ganze Nalan Inar, Serap zg, Hacettepe University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey

Background: Spondyloarthritis (SpA) can seriously affect spinal mobility and trunk strength. Even though exercise therapy is considered one of the keystones of non-pharmacological treatment, guidelines on exercise programs remain vague due to a lack of objective measurements of physical parameters such as trunk mobility and strength. Data on these parameters are scarce for both axial and peripheral SpA-patients (axSpA and perSpA pts).

Objectives: The aim of this study was to measure trunk strength and spinal mobility in SpA-pts and compare these parameters to healthy subjects matched for gender and age and to determine differences between the pts when grouped based on symptom duration and on presence of radiographic sacroiliitis.

Methods: SpA-pts of the Be-Giant cohort were consecutively asked to participate in the study. After informed consent, BASDAI, BASFI and BASMI were evaluated. To measure trunk and cervical strength, pts performed 2 repetitions of a maximal isometric contraction for flexion, extension, lateral flexion and rotation on the Daehak II device (Emed). The maximum value of the 2 repetitions was kept for further analysis. For assessments of lateral flexion and rotation, measured with the DBD, the mean was calculated for right and left measurements. Spinal mobility and trunk strength were compared with a healthy reference population, matched for gender and age by mean of Wilcoxon singed-rank tests. When comparing the perSpA with the r-axSpA and the nr-axSpA, a Kruskal Wallis test was used. A Mann-Whitney U test was used to check for differences between groups based on symptom duration.

Results: Thirty-one SpA-pts participated of which 18 were male (58%). Twenty-four (77%) were classified as axSpA and 7 (23%) as perSpA. Six (19%) of the axial pts had radiographic sacroiliitis and 18 (58%) were non-radiographic. Median time since diagnosis was 5 years and median symptom duration was 7.8 year. Mean age of the pts was 41 years (range: 21-58 years) and their BMI was on average 24 (range: 17-33).

Conclusion: Based on the results of the present study, quality of life seems to be related with spinal mobility. On the other hand, no relationship was identified between the physical activity level and spinal pain. In order to determine the exact relationship, further studies with larger samples and with more varied levels of physical activity are needed.

2156 Scientific Abstracts
Background: For assessing symptoms of depression in systemic sclerosis (SSc), the Patient Health Questionnaire-8 (PHQ-8) may be useful in clinical care as it is short and easy to administer. The English version of PHQ-8 has been found to be reliable and valid in SSc. Objectives: To assess aspects of validity and reliability of PHQ-8 in Swedish (PHQ-8 Swe) for individuals with SSc.

Methods: Patients meeting the 2013 ACR/EULAR SSc criteria were recruited. The PHQ-8 Swe content validity was assessed via individual interviews (11 patients, 10 healthcare professionals, HPs) which was transcribed and analysed by content analysis. Patients ages, disease durations and symptoms of depression varied. The HPs had different occupational backgrounds and experiences in SSc care. Reliability was tested by internal consistency and test-retest reliability. Sixty-seven patients (median age 62 [minmax: 28-87]) completed the PHQ-8 Swe on two different occasions.

Results: Content validity: The instruction, items, and response options were generally considered easy to understand; however, some clarifications were suggested. Among HPs, it was expressed that some items could be perceived as emotionally demanding for patients especially in recent onset disease. Further they experienced that PHQ-8 was problem-rather than possibility-based. Introducing the PHQ-8 to patients and the need for follow-ups of the answers to the questionnaire were stated as essential. It was further expressed that PHQ-8 covered key aspects of symptoms of depression in SSc nevertheless examples of items suggested to be included were purpose in life, thoughts about death, and loneliness. The items were overall experienced as important without redundancy, and that some items could reflect more general SSc-related symptoms.

Cultural adaption: Possible adjustments to the PHQ-8 translation were made. This version was back translated into English and compared with the original English version. Thereafter, minor changes were made. A final PHQ-8 Swe version was tested for reliability. Reliability: Cronbachs alpha was 0.86 and the corrected item-to-total correlation range was 0.420.78. There were no significant differences between test-retest for seven of the eight items. The median weighted kappa coefficient was 0.63. The median PHQ-8 Swe total score was 4 (0-10, no-severe depressive symptoms). There were no significant differences for total scores between test and retest and the ICC was 0.81.

Conclusion: Content validity of PHQ-8 Swe was satisfactory and a positive quality was indicated for aspects of reliability in individuals with SSc tested in this study. Although some items could be interpreted as covering more general SSc-related symptoms, the PHQ-8 could be valuable for detecting patients with symptoms of depression in need of discussing emotional issues, as reflected in our study. Further studies of the PHQ-8 Swe usefulness are currently being undertaken via evaluation of other psychometric aspects.

AB1386-HPR FORCE SENSE EVALUATION OF THE KNEE JOINT FOLLOWING MENISCOTOMY RELATED WITH DEGENERATIVE MENISCAL TEAR

Cansu Geyrek1, Ozgur Irmak Kinkil1, Ahmet Ozgur Atay1, 2Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey, 3Hacettepe University Faculty of Medicine, Department of Orthopaedics and Traumatology, Ankara, Turkey

Background: Meniscal tears are associated with degenerative knee disease, which can range from mild chondral changes not visible on a radiograph to established knee osteoarthritis. Meniscectomy related with degenerative meniscal tear may affect the force sense of the knee joint which is defined as the ability to accurately reproduce a given force. Objectives: The aim of this study was to compare the force sense of the knee joint of the patients with degenerative meniscal tear following meniscectomy with healthy peers.

Methods: Fifteen patients with meniscectomy and 18 healthy aged matched individuals were included in this study. Evaluation of force sense in the knee joint was measured with the use of a pressure biofeedback device, sphygmomonanometer, (Stabilizer, TM, Chattanooga Group Inc., Chattanooga, TN). The pressure bag of this device was placed under the knee joint. All subjects were instructed to extend the knee via Maximal Voluntary Isometric Contraction (MVIC) for 5 s. Each measurement was repeated three times with 1-min rest intervals and the average constant errors observed on the pressure biofeedback device were recorded as mmHg. Subjects were instructed to obtain at 50% of MVIC. They were asked to maintain the contraction (reproduce the target force) for 5 s. The reproduction force was subtracted from the target force to create a trial error score. Higher error scores indicated lower force sense.

RESULTS: There were no difference in terms of mean age, body mass index between patients (53.67.2 years, 26.21.8 kg/m2) and healthy peers (53.47.09 years, 25.63.2 kg/m2), respectively (p=0.05). Lower accuracy of the knee extensions during the 50% MVIC task was significantly seen in patients with meniscectomy (5.422.07 mmHg) compared to healthy group (1.881.11 mmHg) (p<0.001).

Conclusion: Results of this study demonstrated that higher force sense deficits are present in patients with meniscectomy related to degenerative meniscal tear compared to healthy peers. Thus, knee proprioceptive training focus on force sense might be developed to improve functional capabilities of knee joint especially following meniscectomy. It is also important to establish effective and feasible evaluation interventions for health professionals in clinical practice for assessing proprioception in terms of force sense in degenerative knees.

TREATMENT ADHERENCE AMONG PATIENTS WITH INFLAMMATORY ARTHRITIDES TREATED WITH bDMARDs: AN OBSERVATIONAL STUDY USING I-CQRs QUESTIONNAIRE AND THE ADMINISTRATIVE CLAIMS DATABASE

AB1388-HPR

Letizia Moini1, Desire Bastardo1, Cristina Visentin2, Francesca Ometto2, Ernesto De Minis3, Cecilia Giron2, Costantino Bottos1,2,4, LOCAL HEALTH UNIT 2, Hospital Pharmacy, Castelfranco Veneto -Montebelluna Hospitals, Castelfranco (TV), Italy; 2Local Health Unit 2, Planning and Management Control Department, Treviso, Italy; 3UNIVERSITY OF PADOVA Department of Medicine, DIMED, PADOVA, Italy; 4Local Health Unit 2, Department of Clinical Medicine, Castelfranco Veneto-Montebelluna Hospitals, Montebelluna (TV), Italy; 5University of Padova, Department of Pharmaceutical and Pharmacological Sciences, DSF, Padova, Italy

Background: Effective treatments have been introduced for inflammatory arthritides (IA)s in the last decades. However, adherence remains suboptimal. Objectives: The aim of the study was to assess treatment adherence among patients with IA treated with bDMARDs in a community hospital with the Italian 5-item Compliance Questionnaire for Rheumatology (I-CQRs) [1] and the hospital administrative claims database. Methods: We conducted a monocentric, cross-sectional, observational study in IA patients (disease duration >1 year, undergoing treatment with self-administered bDMARDs, capable to complete the questionnaire unaided) recruited in a community hospital from February to October 2018. Treatment adherence was defined according to I-CQRs and to the Medication Possession Ratio (MPR) obtained from the claims database. To investigate variables associated with adherence, demographic, social, and clinical characteristics were considered. I-CQRs has 5 questions, with Likert-answering scale ranging from 1 to 4, an algorithm allows to classify the patient as poorly or highly adherent (i.e., likely to take >80% of their medications correctly) [1]. MPR was obtained by dividing the number of dosage units withdrawn by patients by the prescribed number of dosage units. Agreement between the I-CQRs and MPR definition of high adherence definitions was tested with McNemars test, while the association with patients characteristics with chi-square or Fishers exact test. Results: A total 174 patients completed the I-CQRs (median age 60 years, range 51-67; 37% males), affected by ankylosing spondylitis (16%), rheumatoid arthritis (RA) (62%), psoriatic arthritis (22%) with a median duration of 15 years (range 10-20). Etanercept (49%), adalimumab (20%), abatacept (8%) and tocilizumab (7.5%) were the most prescribed first-line biologics. Association with a conventional synthetic DMARDs was prescribed to 3.4% of subjects. High adherence rate, assessed with I-CQRs, was 85% overall, and 85% in RA patients. Significant differences were observed between highly and poorly adherent patients according to I-CQRs: lower educational status (lower primary or secondary school, and the use of cDMARDs were associated with poor adherence (both with p<0.001); while the use of bDMARDs was negatively associated with high adherence (p=0.05). High adherence rate measured with MPR was 72%. The agreement between high adherence, measured with I-CQR5 and MPR, was low (p=0.0005). Conclusion: The study showed that IA patients treated with bDMARDs with a higher educational level are more adherent to physician prescription, as assessed by I-CQR5. I-CQR5 might overestimate adherence compared to MPR. In our study, the high adherence rate measured with I-CQR5 was higher compared with a report from a large outpatient clinic in the same area, which was limited to RA patients (80% vs 40.1%) [1]. Our study may suggest that adherence benefits more from a close and stable relationship with the health care practitioner, such as in our centre, which is smaller than large outpatients clinics in which patients are followed by a health care professionals equipe rather than a single physician.

THE ASSOCIATION BETWEEN THE AMOUNT OF DIASTASIS RECTI ABDOMINIS AND THE STRENGTH OF ABDOMINAL MUSCLES IN PREGNANT WOMEN

AB1389-HPR

Olbala Napir1, Trkan Akbayrak1, Gamze Nalan inar1, Esra zelpasaco2, Emine Baran3, Ceren Ohran1, Serap zg1f, Mehmet Sinan Beksa3, 4Hacettepe University, Faculty of Health Sciences, Department of Physical Therapy and Rehabilitation, Ankara, Turkey; 5Hacettepe University, Faculty of Medicine, Department of Obstetrics and Gynecology, Ankara, Turkey

Background: Diastasis recti abdominis (DRA) is a common musculoskeletal problem, which is defined as a separation of the inter-recti distance between the two bellies of the rectus abdominis muscle at the linea alba.1 Due to the hormonal, postural and musculoskeletal changes, and mechanical strain, the anterior abdominal wall becomes stretched and elongated during pregnancy. Studies have shown that DRA may occur between 27% and 100% in the second and third trimesters of pregnancy.2 Although it has been reported that imbalance in the strength of the abdominal wall muscles altered with the facial tension, the role of abdominal muscle strength on DRA has not been clarified yet. Objectives: The present study assessed the relation between the severity/amount of DRA and the degree of abdominal muscle (rectus abdominis (RA), external and internal oblique muscles) strength in pregnant women. Methods: A total of 153 pregnant women between 14 and 35 weeks of a singleton pregnancy were included in the present study. The finger width method was used to measure the amount of DRA. The amount of separation was determined by the palpation of the medial sides of RA at three reference points: on the umbilicus, 4.5 cm above and 4.5 cm below of the umbilicus. After the subject contracts RA in hook lying position when her arms were in extended position, the size of the diastasis was measured by the number of fingers.2 The strength of abdominal muscles was assessed by the manual muscle test in supine hook lying position. The correlation between the amount of DRA and the degree of abdominal muscle strength was analyzed by the Spearman correlation. Results: The mean age was 28.40±3.69 years, mean Body Mass Index was 27.01±1.26 kg/m2, and mean gestational age was 28.12±5.03 weeks. A negative correlation was found between the amount of the diastasis at 4.5 cm below of the umbilicus and the strength of the RA (r=-0.219, p=0.007), right (r=-0.296, p=0.015) and left external oblique muscles (r=-0.293, p=0.017). Conclusion: Based on the findings of the present study, the separation of RA on the lower level of umbilicus may be negatively associated with the strength of RA and oblique abdominal muscles. Therefore, to decrease the severity of DRA, abdominal strengthening programs should be provided to pregnant women.

Emine Baran1, Ceren Orhan1, Serap zg1f, Mehmet Sinan Beksa2, 3UNIVERSITY OF PADOVA, Department of Medicine, DIMED, PADOVA, Italy 3UNIVERSITY OF PADOVA, Department of Medicine, DIMED, PADOVA, Italy 4Local Health Unit 2, Department of Clinical Medicine, Castelfranco Veneto-Montebelluna Hospitals, Montebelluna (TV), Italy

Objectives: To investigate variables associated with adherence, demographic, social, and clinical characteristics were considered. I-CQR5 has 5 questions, with Likert-answering scale ranging from 1 to 4, an algorithm allows to classify the patient as poorly or highly adherent (i.e., likely to take ≥80% of their medications correctly) [1]. MPR was obtained by dividing the number of dosage units withdrawn by patients by the prescribed number of dosage units. Agreement between the I-CQR5 and MPR definition of high adherence definitions was tested with McNemars test, while the association with patients characteristics with chi-square or Fishers exact test. Results: A total 174 patients completed the I-CQR5 (median age 60 years, range 51-67; 37% males), affected by ankylosing spondylitis (16%), rheumatoid arthritis (RA) (62%), psoriatic arthritis (22%) with a median duration of 15 years (range 10-20). Etanercept (49%), adalimumab (20%), abatacept (8%) and tocilizumab (7.5%) were the most prescribed first-line biologics. Association with a conventional synthetic DMARDs was prescribed to 3.4% of subjects. High adherence rate, assessed with I-CQR5, was 85% overall, and 85% in RA patients. Significant differences were observed between highly and poorly adherent patients according to I-CQR5: lower educational status (lower primary or secondary school, and the use of cDMARDs were associated with poor adherence (both with p<0.001); while the use of bDMARDs was negatively associated with high adherence (p=0.05). High adherence rate measured with MPR was 72%. The agreement between high adherence, measured with I-CQR5 and MPR, was low (p=0.0005). Conclusion: The study showed that IA patients treated with bDMARDs with a higher educational level are more adherent to physician prescription, as assessed by I-CQR5. I-CQR5 might overestimate adherence compared to MPR. In our study, the high adherence rate measured with I-CQR5 was higher compared with a report from a large outpatient clinic in the same area, which was limited to RA patients (80% vs 40.1%) [1]. Our study may suggest that adherence benefits more from a close and stable relationship with the health care practitioner, such as in our centre, which is smaller than large outpatients clinics in which patients are followed by a health care professionals equipe rather than a single physician.

PASSIVE COPING STRATEGIES BUT NOT PHYSICAL FUNCTION ARE ASSOCIATED WITH WORSE MENTAL HEALTH, IN WOMEN WITH CHRONIC WIDESPREAD PAIN—A MIXED METHOD STUDY

Katarina Aili1,2,3,1 Stefan Bergman4,1,5 Ann Bremander6, Emma Haglund1,7,8
Ingrid Larsson1,2,3

University of Southern Denmark, Department of Regional Health Research, Odense, Denmark
1Lund University, Department of Clinical Sciences, Lund, Sweden; 2Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden

Background: Chronic widespread pain (CWP) is a common condition (approximately 10% prevalence), that affects women twice as often as men. There is a lack of knowledge in how different coping strategies relates to health status during CWP development in a general population.

Objectives: To explore different ways of coping with CWP and to relate the different coping strategies to health-related factors, before and after developing CWP.

Methods: A sequential explorative mixed methods study including 19 women 45-67 of age, who had reported CWP in a survey 2016, but not in 1995. Individual interviews were analysed with a phenomenographic approach, and resulted in four categories of coping strategies. These categories were further explored with regard to four dimensions of health status (physical function, bodily pain, vitality and mental health) as measured by SF-36 (0-100, a lower score indicates more disability) and sleep problems measured both in 1995, and 2016.

Results: The qualitative analysis revealed four categories representing different coping strategies, where each woman was labelled by the most dominant category; the mastering woman, the persistent woman, the compliant woman and the conquered woman. The first two categories emerged as being active coping strategies, and the latter two as passive. Women with passive strategies reported significantly lower vitality (median 54 vs 93, p=0.021) in 1995, before they had developed CWP compared with those with active coping strategies. No differences were seen between the groups on physical function, bodily pain or sleep.

In 2016, there were still a difference between the passive and active group regarding mental health (median 56 vs 80, p=0.022), but not for vitality (median 35 vs 40, p=0.707). No differences were seen between the groups on physical function or bodily pain. All eight women with passive strategies reported problems with sleep in 2016, as compared to 6 of the 11 women with active strategies (p=0.045).

Conclusion: Women that reported CWP in 2016, but not in 1995, described both active and passive coping strategies. The qualitative findings were associated with differences in vitality and mental health already in 1995, before they had developed CWP. Further, those with passive coping strategies reported worse health with regard to mental health and sleep problems in 2016. Interestingly, the groups did not differ in bodily pain or physical function neither in 1995 nor in 2016, which implicates the importance for the clinician to take the typical coping strategy into consideration, when meeting these patients in clinical settings.

GO-BEYOND: A REAL-WORLD PERSISTENCE STUDY WITH GOLIMUMAB IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND RHEUMATOID ARTHRITIS IN TURKEY

Servet Akalı1, Umut Kalyoncu1, Ediz Dalkılı1, Hakan Emrongil1, İsmiro Katip Celebi University, Rheumatology, İzmir, Turkey; 2Hacettepe University, Rheumatology, Ankara, Turkey; 3Uludag University, Rheumatology, Bursa, Turkey; 4Trakya University, Rheumatology, Edirne, Turkey

Background: Axial spondyloarthritis (axSpA) and rheumatoid arthritis (RA) are chronic inflammatory diseases and associated with substantial health and economic burden since these conditions affect individuals in their productive years. Adherence to treatment is a major problem for inflammatory rheumatic diseases.

Objectives: In the present study, we aimed to evaluate rates of persistence with golimumab (GLM) therapy in axSpA and RA patients using real-world data.

Methods: This multicenter, non-interventional, retrospective study enrolled 329 patients diagnosed with axSpA (n=269) and RA (n=60) who currently receive or have received golimumab therapy for at least 3 months either as first-line treatment (biologic naive group) or as second-line treatment after failure to another anti-TNF or biologic agent (biologic-experienced group). In addition to the patients demographic and clinical characteristics, data on drug continuation and disease activity scores such as ASDAS/BASDAI and DAS-28 scores were retrieved from the patient records. A regression analysis was conducted to determine the factors associated with drug discontinuation including age, gender, smoking status, disease duration, presence of comorbidities, disease activity measures, concomitant csDMARD use.

Results: Only 28 (10.4%) axSpA and 7 (11.6%) RA patients were biologic-experienced. The changes in disease activity scores of RA and axSpA patients on therapy during 2-years of follow-up are presented in figure a and b.

Golimumab therapy provided good and long-term improvement in the disease activity scores in both RA and axSpA patients. At 6, 12 and 24 months treatment persistence rates were 86.4%, 74.5% and 65.5% for RA and 93.5%, 81.9% and 75.5% for axSpA patients, respectively. Persistence with GLM was similar between biologic-nave and experienced patients. GLM persistence was also similar in RA and axSpA groups (figure c). Regression analysis revealed that smoking (HR 0.523; p=0.006), presence of comorbidity (HR 2.731; p<0.001) and disease duration (HR 0.957, p=0.038) were significant predictors of drug persistence in GLM treated patients.

Conclusion: Our results show that GLM therapy is an effective treatment option with high drug retention rates in both RA and axSpA patients independent of previous biologic exposure. Smoking, co-morbidities and disease duration may affect the continuation of golimumab treatment in inflammatory rheumatic diseases.
The aim of this study is to compare the quality of life, function and emotional status of inpatients and outpatients with rheumatic diseases. The study included 78 patients (inpatient, n = 31; outpatient, n = 47) with rheumatic disease. The Health Assessment Questionnaire (HAQ) (2) and SF-36 (3) were used to evaluate the functionality and quality of life, and the Hospital Anxiety and Depression Scale (HADS) (4) was used to determine their emotional status. The variables were investigated using visual and analytical methods to determine whether or not they are normally distributed. Since physical function, mental health and general health perception values of SF-36 and HADS-Anxiety were normally distributed, the Students T-test was used to compare these parameters between two groups. Physical role limitation, pain, social status, emotional difficulty, energy viability of SF-36, HAQ and HADS-Depression were not normally distributed. Thus, Mann-Whitney U test was used to compare these scores between two groups.

**RESULTS**

The mean age of the subjects (n = 78) included in the study was 46.09 ±13.89 years and the mean BMI was 27.59 ± 15.08. There was a significant difference in depression, anxiety and pain and social functioning sub-parameters of SF-36 (p < 0.005) but there was no significant difference in other parameters (p > 0.005).

**Conclusion**

It was thought that during the period of admission to the hospital, inpatients should be supported in terms of pain management, social functioning and anxiety and, depression as well as taking medication. Besides, caregivers in hospitals should encourage inpatients with regard to maintaining physical activity.

**AB1393-HPR CAN SUPPORT FROM SIGNIFICANT OTHERS RELIEVE SICKNESS ABSENCE IN EARLY RHEUMATOID ARTHRITIS?**

**Maria Bengtsson**1,2, ranja Dahlin2,3, Ingrid Thyberg2,4, Mathilda Björk1,4. 1Linping university, Department of social and welfare studies, Division of occupational therapy, Norrköping, Sweden; 2Linkping university, Department of behavioural sciences and learning, Division of psychology, Linkping, Sweden; 3Linkping university, Department of clinical and experimental medicine, Division of neuro and inflammation science, Linkping, Sweden; 4Region stergtland, Department of rheumatology, Heart and medicine center, Linkping, Sweden

**Background:** Persons with rheumatoid arthritis (RA) are at higher risk of sickness absence, and the probability of returning to work is lower compared to the general population. In order for persons with RA to continue working, support from the social environment is claimed to be of importance. However, this relation needs to be further investigated.

**Objectives:** To analyze how support from significant others affects the associations between disease related variables (medication, disease activity and activity limitations) at time for RA diagnosis and sickness absence one year after diagnosis.

**Methods:** Data were collected from 326 (71% women) patients in working age (18-63 years) included in the Swedish early RA cohort TIRA-2. Data were collected between 2006-2015. At the time of inclusion, mean age was 50 years (SD=11), 89% were prescribed disease modifying anti-rheumatic drugs (DMARDs), mean disease activity score 28 joint count (DAS28) was 4.73 (SD=1.34), and mean score for activity limitation reported by Health Assessment Questionnaire (HAQ) was 0.91 (SD=0.60). The number of days with sickness absence during the first year after diagnosis and inclusion was retrieved from the Swedish Social Insurance Agency. Perceived support from significant others, family and friends separately, were self-reported

**Results:** The mean age of the subjects (n = 78) included in the study was 46.09 ±13.89 years and the mean BMI was 27.59 ± 15.08. There was a significant difference in depression, anxiety and pain and social functioning sub-parameters of SF-36 (p < 0.005) but there was no significant difference in other parameters (p > 0.005).

**DOI:** 10.1136/annrheumdis-2019-eular.7315
by VAS scales, zero indicating no support and 100 indicating full support. The associations of disease activity, activity limitation and DMARD use with sickness absence and how these associations were moderated by support from significant others, were analyzed using zero-inflated negative binomial regression.

Results: Higher activity limitation (HAQ) was associated with lower risk of sickness absence (p<.001) but more days with sickness absence (p=.001). Higher disease activity (DAS28) was associated with lower risk of sickness absence (p=.003). However, when including family support, this association was not significant (p=.117) and associated with higher risk of sickness absence, but the association was weaker with family support (p=.029). Disease activity was also associated with more days of sickness absence (p=.013). The use of DMARDs had no significant relation to sickness absence (p=.150) or number of days with sickness absence (p=.852). Although, when including support from friends, DMARD use was associated with higher risk of sickness absence (p=.041). However, this association decreased significantly with support from friends (p=.029).

Conclusion: Support from significant others has an impact on previously known relationships between disease activity, use of DMARDs and sickness absence. Hence, support from significant others has the possibility to help decrease sickness absence among persons with RA one year after diagnosis.

**BURDEN IN CAREGIVERS OF PATIENTS WITH RHEUMATIC CONDITIONS**

Diana Buitrago-Garcia, Laura Villarreal, Michael Cabrera, Pedro Santos, Moreno, Fernando Rodriguez

Background: Rheumatoid arthritis (RA) is a chronic, disease that affects more than 1% of global population, it is a long term condition that causes pain and disability. Evidence had shown that most of the patients are moderately disabled, which brings the necessity of a caregiver to become the patients companion due to its chronic disease. The caregiving role can have an impact in the psychological and physical sphere of the caregivers life.

Objectives: The aim of this study was to explore demographic characteristics and caregiver burden through the Zarit Scale.

Methods: We conducted a cross sectional study in a meeting where caregivers in a rheumatoid arthritis specialized setting. We collected sociodemographic information, and applied the Zarit caregiver burden interview (ZBI) adapted to Spanish. The ZBI includes 22 questions which has 5 responses from 0 (never) to 4 (nearly always), where scores lower than 47 indicated little to no burden, 47 to 55 low burden and >55 intense burden. We calculated means, and standard deviations for continuous variables and categorical variables were presented as rates.

Results: We applied a survey to 132 caregivers. Mean age was 52 years SD 19 and 72% were women, 78% of them were taking care of their pelvic floor symptoms as well. Therefore decrease in the range of motion of the hip joint due to AS complicates pelvic pain and sexual dysfunction.

Objectives: The aim of study was investigation of sexual satisfaction and sexual dysfunction in partner of patients with AS.

Methods: 50 individuals: 21 female partner of patients with AS with an average age of 40.38 5.31, 29 male partner of patients with AS with an average age of 52.37 5.84 were included in this study. The male partners were evaluated with the International Index of Erectile Function (IIEF) and the female partners were evaluated with the Female Sexual Function Index (FSFI).

Results: Total score of FSFI was 52.37 5.84 (Sexual desire:5.472.01, arousal:11.664.97, orgasm: 8.524.74, lubrication:12.005.06, satisfaction: 8.474.49, pain:8.044.17) in female partner. Erectile score of IIEF was 24.35 6.65, orgasm score was 8.85 3.28, sexual desire score was 7.271.70, sexual satisfaction score was 10.373.86 and general sexual score was 6.142.63 in male partner.

Conclusion: According to the results of the study, female partner had moderate sexual dysfunction, male partner had mild erectile function. This study showed that the sexual functions of female and male partners of patients with AS were affected negatively. Further studies need to assess their pelvic floor symptoms as well.

[AB1397-HPR] CLINICAL FEATURES IN COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN KAZAKHSTAN

Bakytsholpan Issayeva1, Maira Saparbayeva1, Shabaran Kaygaly1, Moldir Kulshymanova1, Kanat Nurgaliev1, Samal Issayeva1, Gulshat Dalibayeva1, Maira Bizhanova1, Balzhan Kulymbetova2, Karlygash Rysbekova2, Moldir Kulshymanova1, Kanat Nurgaliev1, Samal Issayeva1, Gulshat Dalibayeva1, Maira Bizhanova1, Balzhan Kulymbetova2, Karlygash Rysbekova2, Aralym Atasheva2, Elena Aseeva2, Sergey Solovey2.

1: Astana Medical University, Astana, Kazakhstan; 2: V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Systemic lupus erythematosus (SLE) refers to socially significant diseases and the improvement of diagnosis, treatment of the disease belongs to the target indicators of the State Program in Kazakhstan.

Objectives: The aim of this study was to assess the demographic, clinical features, the degree of activity, damage to internal organs and therapy in patients with SLE.

Methods: The study involved 89 patients with a documented diagnosis of SLE (ACR, 1997) hospitalized for inpatient treatment in rheumatology centers. The register included an assessment of gender, age, Disease Activity Index (SLEDAI 2K), organ Damage Index (DI, SLICC, 2012), and therapy. For qualitative signs, absolute and relative values (n, %) are presented.

Results: In the studied cohort of patients with SLE prevailed women (98.8%), the mean age of patients was 33.61±4.7 years, 47% of them under 30 years old. The debut of the disease in the overwhelming majority (52%) patients is associated with stress, pregnancy and childbirth. By ethnicity, Kazakhs - 67 (75.2%), Russian - 7 (7.8%), Uighurs - 6 (6.7%), Korean - 5 (5.6%), others 5 (5.6%). 56% of patients had higher and secondary-special education. Only in a third of patients SLE was diagnosed in the first months of the disease, the rest had erroneous diagnoses, such as rheumatoid arthritis, reactive arthritis, and other systemic diseases. The disease activity (SLEDAI 2K) was very high in 9 (10.1%), high in 24 (26.9%), medium in 39 (43.9%), low in 15 (16.8%) patients and without activity were 2 (2.2%) patients.

Among SLE patients, 92% with mucocutaneous manifestations, 64% had photosensitivity, 56.2% had enanthema, 77.5% had arthritis and arthralgia, 28.1% with serositis, 55% had renal involvement, 25.8% had neurological and 58.4% had hematological disorders. Irreversible organ damages (SLICC) were detected in 67.4% of patients: low DI (1 point) - 26 (29.3%), moderate (2-4 points) - 33 (37.1%) and high (> 4 points) - in 3 (3.4%) patients. Medium and high DI were observed in patients with renal and neurological involvement.

Patients were predominantly in therapy: methylprednisolone (98%), cyto- statics and mycophenolate mofetil (42.3%), hydroxychloroquine (39%). Biological therapy (rituximab, belimumab) was performed in patients with a high degree of activity, nephritis, and neutropenia and in 6 (6.7%) patients with good effect and the possibility of reducing glucocorticoids to minimal doses.

Conclusion: Creating a register and forming a cohort allows for a more complete assessment of activity, organ damage and therapy in patients with SLE.

[AB1398-HPR] RHEUMATOID ARTHRITIS– BIOLOGICAL DMARDS EXPERIENCE IN TAWAM HOSPITAL, UAE, A 2-YEAR RETROSPECTIVE STUDY

Basma Beirain1, Imad Jassim2, 1: Tawam Hospital, Pharmacy Department, Al-Ain, United Arab Emirates; 2: Tawam Hospital, Rheumatology Department, Al-Ain, United Arab Emirates

Background: Arthritis is the leading cause of disability in America, affecting 50 million adults. Although there is currently no cure for rheumatoid arthritis (RA), improved understanding of RA disease pathogenesis in recent years has led to the development of new treatments. Disease Modifying Anti-Rheumatic drugs (DMARDs) are added at early stages in the treatment of RA to suppress inflammation; they may be used as monotherapy or more commonly in combination. The aim of this study was to present more comprehensive profile of RA, psoriatic arthritis (PSA) and ankylosing spondylitis (AS) is aimed at achieving the lowest disease activity and remission. Patient compliance is considered necessary for the success of treatment in chronic diseases.

Objectives: The objective of this study was to assess the patient adherence to their medications and clinic visits in addition to assessing the prescribing, screening and monitoring parameters of biological disease modifying agents (DMARDs) according to the care pathway at Tawam Hospital and EULAR recommendations.

Methods: A retrospective observational review using data from the computer based system at Tawam hospital. All adult patients with RA, PSA and AS starting a biological DMARD during our study period; December 2016 to December 2018 were eligible.

Results: A total of 54 patients were included. Eighty percent were females. Sixty three percent RA patients, 24% PSA patients and 13% AS patients. Indication, dosing and blood monitoring criteria were met for 100% of the patients. Vaccination criteria was met in only 20%. Screening criteria was met by 57%. Ninety two percent of the RA and PSA patients were started on methotrexate for 3 months before biologics initiation as per guidelines. Forty three percent of AS patients used 2 non-steroidal anti-inflammatory drugs before starting biological therapy.

Medication adherence was measure by: the duration of therapy, consistent clinic visits and regular medication refills. Eighty four percent of the number of patients had adherence to therapy for 6 months or more. Twenty six percent were consistent with their monthly clinic visits. Sixty one percent were compliant with their monthly medication refills.

RA patients were further analysed as they made the majority of our patients. Ninety seven percent of the RA patients had a baseline DAS documented. Eighteen percent had a baseline of DAS28<2.6. Fifty percent had a baseline DAS28>3.2. Twenty nine percent had a baseline DAS28>5.2. Three percent of the patients started on a biologic with no documented baseline DAS. One hundred percent of the patients had a documented DAS. One hundred percent of the patients had a documented DAS including the 18% that had DAS28>2.6; however the reasons were clearly stated (example of reasons, contemplating pregnancy, adverse reaction to previous treatment).

The DAS 28 was documented again at the end of the study period. Fifty nine percent of the patients had DAS28<2.6. Twenty six percent had DAS between 2.6-3.2, twelve percent had DAS28>3.2 and three percent of the patients had a DAS28>5.1. All the patients with DAS28>3.2 (15%) changed their treatment regimen.

Conclusion: This audit concluded 100% compliance with the care pathway at Tawam Hospital and EULAR recommendations in the treatment of RA, PSA and AS with regards to starting a biologic treatment, switching treatment, dosing and monitoring. Overall the patients adherence to their clinic visits and medication refills was satisfactory; however improving adherence to therapy could therefore dramatically improve the efficacy of drug therapy. However there was a gap in the vaccination and screening parameter which indicates a need to add a tool in computer system to aid the physicians in fulfilling this gap.

**FOOT AND ANKLE ASSESSMENT IN PATIENTS WITH DIFFERENT GRADES OF KNEE OSTEOARTHRITIS**

**KARAPINAR MERVE1, Ferdi Baskurt1, Zelilha Baskurt1, Meric Unal2.**  
1Faculty of Health Science, Physiotherapy and Rehabilitation, ISPARTA, Turkey; 2Faculty of Medicine, Sports Medicine, ISPARTA, Turkey

**Background:** Foot and ankle profile has long been considered to contribute to the development of knee osteoarthritis (OA). It may alter the mechanical alignment and dynamic function of the lower limb especially knee functions. It is important to determine compensatory changes in the foot and ankle posture in patients with different grades of knee osteoarthritis. Because it may help in understanding the role of foot orthoses, footwear modifications or treatment strategies on alignment and function of knee.

**Objectives:** This present study was designed to assess the changes in foot and ankle profile among different grades of knee OA.

**Methods:** Patients were assessed with physical examination including foot and knee specifically and anteroposterior and lateral direct radiographies. All patients were divided into four groups for medial compartment OA severity by using the Kellgren-Lawrence grading system of knee OA on weight bearing knee radiographies. The Western Ontario and Mc Master University Osteoarthritis Index (WOMAC) questionnaire was performed to assess pain and the functional status of the patients. Structural foot profile was assessed by the Foot Posture Index (FPI) system and American Orthopaedic Foot and Ankle Society (AOFAS)anklehindfoot and midfoot scales.

**Results:** The study included forty-four patients with mean age 57.12±12.2 years. In terms of severity of knee OA groups; percentages for grade 0-1, 2,3 and 4 were 25%, 22.7%, 25%, 27.2% respectively. In the grade 4 and knee specifically and anteroposterior and lateral direct radiographies. All patients were divided into four groups for medial compartment OA severity by using the Kellgren-Lawrence grading system of knee OA on weight bearing knee radiographies. The Western Ontario and Mc Master University Osteoarthritis Index (WOMAC) questionnaire was performed to assess pain and the functional status of the patients. Structural foot profile was assessed by the Foot Posture Index (FPI) system and American Orthopaedic Foot and Ankle Society (AOFAS)anklehindfoot and midfoot scales. The study indicated that differences of the severity of OA were higher (p < 0.001). Besides, foot pronation was also increased as the severity of osteoarthritis increased. In the grade 0-1 and grade 2; AOFAS-hindfoot and midfoot scores were higher (p<0.001) compared to severe OA (grade 3 and grade 4).

**Conclusion:** The study indicates that differences of the severity of OA have influence on the foot and ankle profile to different degrees. Therefore, it is clinically important to give appropriate orthotics advice or treatment to patients with different degrees of OA to correct the pronation of foot to different degrees.

SELF-REPORTED PHYSICAL FUNCTION AND ASSOCIATED FACTORS IN INDIVIDUALS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Gizem Irem Kinikli1, Susanne Pettersson2, Sevval Karahan3, Elisabet Svennungsson1, Casrina Bostm2,3, Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; 2Karolinska Institute, Inflammation and Infection Theme, Karolinska University Hospital and Department of Neurobiology, care sciences and society, Stockholm, Sweden; 3Hacettepe University, Faculty of Medicine, Department of Biostatistics, Ankara, Turkey; 4Karolinska University Hospital; Unit of Rheumatology, Department of Medicine, Stockholm, Sweden; 5Karolinska Institute, Department of Neurobiology, care sciences and society, Stockholm, Sweden

Background: Physical activity and exercise have many positive effects in patients with Systemic Lupus Erythematosus (SLE) (1) and poor self-reported physical function has been reported to predict mortality (2). To facilitate and improve physical activity/function, it is thus important to investigate what factors are associated with good physical function. Few previous studies have addressed these issues (3).

Objectives: The aim of this study was to identify factors associated with good self-reported physical function, such as walking and running in individuals with SLE.

Methods: A total of 198 patients (mean age: 51.5±16.1 years; BMI: 24.7±7.4 kg/m²) with SLE participated. The outcome, self-reported physical function was assessed with the question: How much do you think you can manage concerning walk, jog, and run? (From Physical Activity Questionnaire, PAQ). Disease activity was assessed using the SLAM-R and organ damage with SLICC/ACR-DI. The VAS part of EQ-5D, was used to assess self-reported health related quality of life (HRQL). Hospital Anxiety and Depression Scale (HADS) was used to assess anxiety/depression levels. Self-reported exercise during the last year was assessed by questions from PAQ and sitting hours as well as physical activity level was determined from International Physical Activity Questionnaire Short Form (IPAQ-SF). Logistic regression analyses estimated the associations of the following independent variables: age, sex, BMI, disease activity, organ damage, HRQL and anxiety/depression levels, exercise last year, sitting hours and physical activity level, on the dependent variable self-reported physical function (PAQ-question). Statistical significance was defined as a p value <0.05.

Results: Median SLAM-R was 6 (IQR:6), SLICC-DI was 1 (IQR:3), EQ-5D VAS was 72.2 (IQR:22.1) and depression level 4 (IQR:5). Median Self-reported exercise during the last year (PAQ) was exercise irregularly. Median sitting hours a day (IPAQ-SF) was <5 hours. Median physical activity level was moderate (IPAQ-SF). Age (p<0.001; Odds ratio:6.40), SLICC-DI (p=0.002; Odds ratio:4.02) and EQ-5D VAS (p<0.001; Odds ratio:4.20) were significantly associated with better self-reported physical function (Nagelkerke R Square=0.437).

Conclusion: The results demonstrated that SLE-patients who report low physical function are older patients with more organ damage. However, patients who reported low HRQL also reported low physical function. Our results imply that patients with low self-reported HRQL are at risk for not being enough physically active. To break this vicious circle is a challenge for physicians and physical therapists that care for patients with SLE.

INVESTIGATION OF SPINE POSTURE, MOBILITY AND REDUCED HAND FUNCTION AFFECTS ACTIVITY OF JIA PATIENTS

Deniz Ozar Kayalar1, Seyda Toprak Celentano2, Izmir Katip Celebi University, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 3Ankara Yildirim Beyazit University, Department of Physiotherapy and Rehabilitation, Ankara, Turkey

Background: Low back pain (LBP) is the most common musculoskeletal complaint especially in women that causing disability and growing as a global burden (1,2). Changes in spine structures and alignment have been important in the occurrence of LBP (3,4).

Objectives: This study aimed to investigate spine posture, mobility and postural competency in women with and without LBP.

Methods: Thirty-four women with LBP having moderate to severe disability (age: 50.509.26 years; body mass index (BMI): 34.765.42 kg/m²) and age-paired matched 37 asymptomatic healthy women (age: 48.948.99 years; BMI: 31.976.88 kg/m²) were included. Oswetry Disability Index (ODI) was used for disability assessment (higher scores indicated more severe disability (0-50)). Overall spine posture, mobility, postural competency and spine check scores were evaluated using the Spinal Mouse (Idig, Fehraltorf, Switzerland) device in standing position. The scores were evaluated between as poor “0” and “100” as perfect. T test was used for analysis.

Results: The mean score of ODI was 32.258.27 (moderate to severe disability). The scores of spine posture, mobility, postural competency and total spine check of women with LBP were found 24.7615.65; 25.1114.60; 36.0421.58; 30.2612.06, respectively; while, the scores of asymptomatic women were found 34.6716.27; 34.4521.47; 38.2115.18; 38.7215.06, respectively. Lower postural (p=0.011), mobility (p=0.037) and total spine check scores (p=0.011) were found in women with LBP compared to the controls; however, the postural competency was similar (p=0.722).

Conclusion: Women with LBP had poor spine posture, mobility and total spine check scores, but similar postural competency in comparison to controls. In the clinics, considering these parameters might be important while planning the optimal treatment for LBP.

JIA TEAMWORK FOR IMPROVING PATIENTS’ ACCEPTANCE OF INTRAARTICULAR GLUCOCORTICOID INJECTIONS IN LOCAL ANESTHESIA IN OUTPATIENT DEDICATED SERVICE

Aurora Pucacco1, Hanan Jadoun1, Angela Aquilani2, Fabio Basta3, Andrea Uva2, Rebecca Nicolai1, Fabrizio De Benedetti1, Silvia Magni-Manzoni1, Gianfranco Rotton1, Fabrizio De Benedetti1, Silvia Magni-Manzoni Consultant for: Abbvie, Speakers bureau: Abbvie

Background: The discomfort and anxiety related to the medical care of patients with juvenile idiopathic arthritis (JIA), ampered by frequent and ongoing visits, diagnostic tests, medications and hospital stays, can negatively impact on the compliance during examinations and procedures, particularly intraarticular glucocorticoid injections (IAGI) in local anesthesia. A dedicated personnel for supporting patients and their caregivers may provide them relief, thus contributing also to a more serene environment for operators.

Objectives: To identify an appropriate approach for the relief of JIA patients most critical issues related to IAGI in local anesthesia. To provide preliminary validation of the approach identified.

Methods: In the first part of the study the nurse of the IAGI outpatient service at the study center had conversation with all consecutive JIA patients and caregivers seen at the service, while preparing them to IAGI in local anesthesia and while on discharge. In agreement with the patient, the nurse synthesized in keywords and registered each patients most relevant feelings with regard to the IAGI procedure. Patients and caregivers were also asked to suggest feasible tools for a better acceptance of the procedure. The results were discussed within the JIA team, who selected in a questionnaire the most frequently reported keywords and identified the most feasible among the proposed supportive tools. Secondly, all consecutive JIA patients seen at the service were asked to complete the feeling-status questionnaire after the IAGI. As the tools were available, the questionnaire was completed after IAGI procedures tool-supported. Statistics included descriptive analysis and Students t-test for comparison between feelings rating by patients with and without supportive tools (significance: p-value<0.05).

Results: From the list of keywords obtained by the first 10 patients with the nurse, the most reported stress, anxiety, fear, and anger were included in a feeling questionnaire composed of a VAS 0-10 (0=none, 10=worst) for each keyword. Among the suggested supportive tools the JIA team identified as feasible: colored drawings/pictures in the procedure room and the availability of favourite songs/videos/cartoons on tablet just prior and during IAGI. Forty-one patients completed the questionnaire in a mean time of 22 seconds. Among them, 24 (59%) were supported by the selected tools, been meantime available, during IAGI procedure.

Abstract AB1404HPR Table 1. Mean of response to the feeling-questionnaire by JIA patients seen at the IAGI outpatient service without (A) and with (B) supportive tools

<table>

</table>

*VAS 0-10, 0=none, 10=worst

Conclusion: Our preliminary results highlight that a setting for IAGI more comfortable for patients provide an improvement in the JIA patients feelings rating undergoing injection procedures in local anesthesia. The nurses attitude to patients and the teamwork were fundamental in collecting the patients perspective and in adapting their suggestions to the IAGI outpatient service environment.

REDUCED HAND FUNCTION AFFECTS ACTIVITY PERFORMANCE AND QUALITY OF LIFE IN PERSONS WITH SIBM

Malin Regardt1, Karolinska Institute, LIME, Stockholm, Sweden; 2Karolinska University Hospital, Function area Occupational Therapy and Physiotherapy, Stockholm, Sweden

Background: Reduced hand function is common in persons with (IBM) (1). Information regarding how hand function deficits affect activities of daily living and quality of life is limited (2,3). There is a need to improve treatment and increase knowledge on how to assess different aspects of SIBM.
AB1406-HPR | DIET AND LUPUS: WHAT DO THE PATIENTS THINK?

George Robinson1, 2, Thomas Moddernell3, Chris Wincup2, Lucia Martin-Gutierrez3, James Wilton3, Anastasia Kalea4, Coiziana Curtin5, Ines Pineda Tarkowski6, John Nepomuceno Staff7. 1Medical School, University of Liverpool, Liverpool, United Kingdom; 2University College London, Neuroscience, London, United Kingdom; 3University College London, Institute for Liver and Digestive Health, London, United Kingdom; 4University College London, Metabolism and Experimental Therapeutics, London, United Kingdom

Background: Cardiovascular disease (CVD) is the leading cause of mortality in patients with systemic lupus erythematosus (lupus). Therefore, using diet to control blood lipid levels and modify CVD risk could be a promising therapeutic strategy to control disease symptoms.

Objectives: The primary objective of this study was to learn about lupus patient experiences with diet including their opinion on considering diet as a therapeutic option. The secondary objective was to obtain this information in a cost and time effective manner.

Methods: A lay summary and a 15 question diet-based online survey was publicly available for 3 weeks. Social media was used to promote the survey through relevant charities, hospitals and research groups.

Results: 300 responses were received, 284 of whom had lupus. Patients reported that there was a lack of clinical counselling regarding diet with only 24% of patients stating that their doctor had spoken to them about diet. Despite this, 100% of patients stated that they would change their diet if they knew it would help their symptoms and 83% would take part in a future diet-based clinical trial. Text analysis of patient research suggestions identified a particular interest in using diet to treat fatigue and manage disease flares.

Conclusion: This project successfully gathered patient information regarding diet and lupus over a short timeframe using an anonymous social media platform. The survey provided evidence that patients support further research and potential diet intervention studies investigating the effect of diet on the symptoms of lupus.

AB1407-HPR | NEUROLOGICAL MANIFESTATIONS DURING THE BEHÇET DISEASE

Souki Wafa1, Sameh Sayhi2, Najah Boussella3, Rim Dhaibi4, Faiza Ajili4.

1Military Hospital, Tunis, Tunisia; 2Military Hospital, Tunis, Tunisia; 3Autoimmune Disease Unit, University of Tunis El Manar, Tunis, Tunisia; 4University of Tunis El Manar, Tunis, Tunisia

Background: Behçet disease MB is a systemic inflammatory disease whose common histopathological substratum is a vasculitis that can reach all vessels. Neurological impairment is one of the diagnostic criteria for MB. A serious condition affects the functional and vital prognosis.

Objectives: The aim of our work was to study the epidemiological, clinical, therapeutic and evolutionary characteristics of patients with BD with neurological involvement.

Methods: This was a retrospective, monocentric, descriptive study of NB from the adult population collected from a population of 150 patients monitored for MB. The study was conducted in the Neurology and Internal Medicine departments over a period of 19 years, from January 1997 to December 2015. Patients meeting the criteria of the international Study Group of the MB of 1990, those of the International Criteria for Behcet Disease (ICBD) and the diagnostic criteria of Neuro-behçet defined proposed by the international consensus of experts of 2014.

Results: We collect 35 patients. The gender ratio was at 6 with 30 men for 5 women. The mean age of our population was 34+ 1.92 years. The neurological manifestations had inaugurated the MB in 55% of the cases. Ninety-four percent of patients had central nervous system involvement, while two patients had peripheral polyradiculoneuritis. Central involvement was parenchymal in 85% of cases, nonparenchymatous in 3% of cases and fixed in 6% of cases. Cerebral imaging showed predominant demyelinating lesions in periventricular and brain stem in 15 patients, a pseudo-tumor appearance in 3 patients, and vascular lesions with arterial aneurysm and cerebral thrombophlebitis in 2 patients. Therapeutically, all patients received corticosteroid therapy with immunosuppressive therapy for 15 patients. Three patients had received an immunomodulatory treatment of anti-TNF a Type. The evolution was by push in 60% of cases, primary progressive in 20% of cases and secondarily progressive in the rest of the cases. Three-quarters of patients with parenchymal brain injury had a favorable outcome. The Outcome was unfavorable in all patients with diffuse disease, brain stem damage, spinal cord injury, angio-behavior, polyradiculo-neuropathy and mixed impairment. The change in visual impairment (NORB) was favorable in one case in two.

Conclusion: Neurological manifestations of MB are serious complications, and are typically poor prognosis both on a vital and functional level. Mortality remains high and neurological sequelae (motor and neuropsychological) are heavy. The prognosis in all the worse because the treatment is instituted late, hence the interest of an early and well conducted treatment.

Disclosure of Interests: None declared

BACKGROUND: The lack of efficacy of biological therapies in rheumatic patients causes a change of treatment, usually to another biological therapy. A significant number of studies have been published in relation to the reasons that cause this inefficacy, however, no studies have evaluated the influence of the weight and lipid profile of patients in this process.

OBJECTIVES: To analyze the influence of weight and lipid profile in the relapse and change of biological therapy.

METHODS: Retrospective-descriptive study. Rheumatic patients in treatment with biological therapies were recruited from January 2016 to December 2018. Sociodemographic data were collected (age and sex), along with anthropometric variables (weight, height, waist circumference and hip perimeter), toxic habits, comorbidities and variables related to the treatment. Associations between variables were analyzed using a Chi-square and T student. P-values < 0.05 were considered statistically significant.

RESULTS: Two hundred and nine patients were enrolled, of which 80 (38.3%) were male and 129 (61.7%) were female. The mean age (SD) was 48.9 ± 12.8 years. One hundred and twenty and twenty patients (57.4%) suffered rheumatoid arthritis, 35 (16.7%) spondyloarthritis, 29 (13.9%) psoriatic arthritis and 10 (4.8%) spondyloarthropathies. One hundred and fifty-three (73.2%) had not switched of biological therapy, 51 (24.4%) switched of biological therapy once and 5 (2.4%) three or more times. Statistically significant differences were found in the obese males who switched of biological therapy in relation to obese males who not switched (35.6% vs. 11.1%). Accordingly, the percentage of patients with hyperlipemia that switched of biological therapy was significantly higher than those who did not (29.4% vs. 13.1%).

The number of evolution and diagnosis we also involved, so that patients with more years of evolution and more years from the diagnosis had a higher percentage of switched (p = 0.006 IC 95% -17.22, - 0.96 and p = 0.042 -18.32; -0.37 respectively).

CONCLUSION: Being obese male and with hyperlipidemia could be a risk factor that would condition the lack of response to a biological therapy and thus the need of switching to another.

REFERENCES
[3] Ganzetti G, Campanati A, Bettacchi A, Brandozzi G, Brisigotti V, Bugatti L, Escudero A, Escudero A. Effectiveness of dog-assisted therapies for people with Alzheimer’s or people with brain injuries, but all of them analyzed a reduced sample number (1) or did not show a good methodological structure (2). Regarding the reduction of pain and quality of life, different studies showed positive results in the use of assisted therapies with dog (6). However, this subject has not been evaluated yet in patients suffering Rheumatologic diseases.

OBJECTIVES: The main objective of this study is to evaluate the influence of companion animals on the perception of outbreaks in rheumatic diseases. Secondary objective: to analyze if having companion animals affected the general state of health or the degree of physical activity.

METHODS: Prospective descriptive study. Consecutive patients attending rheumatology consultation were recruited during the month of October 2018. Sociodemographic data were collected (age, sex, cohabitation with companion animals, type of exercise performed) along with Beck questionnaires to assess depression, SF-12 to assess quality of life, and VREM (Spanish Short Version of the Minnesota Leisure Time Physical Activity Questionnaire) to assess the degree of physical activity. Associations between variables were analyzed using a Chi-square and T student. P-values < 0.05 were considered statistically significant. The main variables: dog, cat and other animals, were analyzed separately and then unified in a new variable called companion animals. The spss v19 program was used for data analysis.

RESULTS: Seventy one patients were enrolled, of which 30 (42.3%) were male and 41 (57.7%) were female. The mean age (SD) was 58.7± 15.31 years. Thirty two patients (45.1%) suffered rheumatoid arthritis, 8 (11.3%) spondyloarthritis, 8 (11.3%) osteoarthritis, and patients with fibromyalgia, becet, gout and scleroderma were present in a lower percentage. Regarding the coexistence with companion animals, 19 (26.6%) lived with dogs and 7 (9.9%) with cats.

The results of this study did not demonstrate any significant relationship between the duration of the outbreaks, the depressive state or the degree of physical activity and the coexistence with companion animals. However, statistically significant differences were found in the quality of live perceived by patients living with dogs in relation to patients without companion animals, so that we found higher scores in the mental SF-12 (56.5 vs 44), (p = 0.036, 95% CI - 24.41, - 0.80), the physical SF-12 (51.7 vs 39), (p = 0.042, 95% CI -25, -0.5) and total SF-12 (56.11 vs 43.85), (p = 0.016, 95% CI 22.4, -2.2).

CONCLUSION: Coexistence with dogs improves the perception of the quality of life of patients, both physically and mentally.

THE SELF- AND SHARED-MANAGEMENT OF PAEDIATRIC-ONSET RHEUMATIC AND MUSCULOSKELETAL DISEASES BY CHILDREN, YOUNG PEOPLE AND THEIR FAMILIES: INITIAL FINDINGS FROM A THEORY-GLEANING PROCESS WITH PATIENT ORGANISATION REPRESENTATIVES

Simon Stones, iSMART Research Group, University of Leeds, School of Healthcare, Leeds, United Kingdom

Background: Encouraging children and young people (CYP) with rheumatic and musculoskeletal diseases (RMDs) and their families to adopt self-management behaviours from the point of diagnosis is likely to positively influence the long-term health and wellbeing of CYP. However, there is limited evidence of such interventions targeted at CYP and families.

Objectives: Therefore, the aim of this study was to identify What works, for whom, in what circumstances, and why.

Methods: The study was based on the logic of realist evaluation and the Individual and Family Self-Management Theory. Realist evaluation is a recognised model of theory-driven evaluation which enables an in-depth appreciation of how complex health interventions may or may not work in real-world settings. In this study, a realist evaluation was undertaken using qualitative research methods to explore and refine theories regarding self- and shared-management interventions. The realist evaluation began with a set of initial programme theories, which were initially tested through interviews with one group of stakeholders involved in providing self- and shared-management support. Interviews were transcribed individually and data were analysed in NVivo using a realist logic of analysis to identify contextual influencers, interventions mechanisms and outcomes.

Results: In order to refine and consolidate theories about the self- and shared-management of RMDs by CYP and their families, theory was gleaned from patient organisation representatives with experience of supporting CYP and families. Contextual influencers discussed included the characteristics of: i) individual CYP living with RMDs; ii) the family dynamic; iii) peer and social interaction among both CYP and families; iv) the educational environment; and v) Organisational processes and structures. Patient organisation representatives highlighted the family dynamic and navigating organisation processes and structures as key influencers on CYPs willingness and ability to begin their self-management journey in an age- and developmentally-appropriate manner.

Conclusion: Concepts gleaned during the first phase of the study, particularly around the influence of family dynamic, will be further tested, refined, and consolidated with other groups of stakeholders, including CYP with RMDs; families; healthcare professionals from the paediatric rheumatology multi-disciplinary team; school staff; and patient organisation representatives. In time, it is anticipated that the findings will form a programme specification detailing what works, for whom, in what circumstances, and why with regards to the self- and shared-management of paediatric-onset RMDs.

**AB1412-HPR** CHANGES OF GAIT SPEED AND PAIN AFTER APPLYING KINESIOTAPE ON QUADRICEPS FEMORIS MUSCLE IN PATIENTS WITH KNEE OSTEOARTHRITIS

Klejda Tani, Irena Kola, Vjolcica Shpata, Fregen Dhamaj, University of Medicine, Faculty of Medical Technical Sciences, Tirana, Albania

**Background:** Knee osteoarthritis is a chronic degenerative disease, known as the most common cause of difficulty walking in older adults and subsequently is associated with slow walking. Functional decline, increased risk of falls and presence of pain are, in many studies, related to the muscle weakness caused by osteoarthritis especially weakness of the quadriceps muscles. Pain is very noticeable while walking in rugged terrain, during ascent and descent of stairs, when changing from sitting to standing position as well as staying in one position for a long time. Many studies have shown that the strength of the quadriceps femoris muscle can affect gait, by improving or weakening it. Kinesio Tape is a physiotherapeutic technique, which reduces pain and increases muscular strength by irritating the skin receptors.

**Objectives:** The aims of this study was firstly to verify if the application of Kinesio Tape on quadriceps femoris muscle decreases time needed to accomplish the 10 meter walk test in patients with knee osteoarthritis and also in subjects without knee osteoarthritis. Secondly if applying Kinesio Tape on quadriceps femoris muscle reduces pain while walking only in patients with knee osteoarthritis.

**Methods:** In this study we observed the change of gait speed with the help of the 10-meter walk test before, one day and three days after the application of Kinesio Tape in quadriceps femoris muscle. We compared the results of the gait speed in two groups. In the first group, the Patients group, participated 102 out-patients with a clinical diagnosis of primary knee osteoarthritis, while in the second group, the Control group, participated 73 subjects with a main excluding criterion a clinical diagnosis of primary knee osteoarthritis. Secondly, we observed the change of pain, while walking for 10 meters at normal speed for the Patients group, before one day and three days after the application, with the help of Numerical Pain Rating Scale - NRS.

**Results:** Our results indicated that there was a significant increase of gait speed in both groups while walking for 10 meters three days after application of Kinesio Tape on quadriceps femoris muscle. However there was not a significant change one day after the application of Kinesio Tape compared before its application in both groups. Also, there was a significant reduction of pain level 1 and 3 days after application of Kinesio Tape, compared to the level of pain before its application.

**Conclusion:** Our results indicated that there was a significant decrease of time needed to accomplish the 10 meter walk test and also a significant decrease of pain while walking for 10 meters, Kinesio Tape is a technique that can be used especially when changing walking stereotypes is a long term goal of the treatment.

**AB1413-HPR** FACTORS AFFECTING ACTIVITIES OF DAILY LIVING IN WOMEN INDIVIDUALS WITH SCLERODERMA

Serap Acar1, Nazerin Hande Sezgin2, Sema Savci1, Aylin Tannier2, Buse Ozcak Kahraman1, Aydan Kokan Avsar1, Ahmet Merih Birlik2,3, Dokuz Eylul University, School of Physical Therapy and Rehabilitation, Izmir, Turkey; Dokuz Eylul University, Graduate School of Health Science, Izmir, Turkey, Dokuz Eylul University, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Izmir, Turkey

**Background:** Scleroderma is a multisystemic chronic disease with hand involvement in many patients and responsible for marked disability. Patients with scleroderma have reduced ability to perform activities of daily living (ADL) and several factors may be associated with difficulties in ADL and impairment of upper extremity functions.

**Objectives:** Aim of this study was to indicate the relationship among activities of daily living and pain, fatigue, disease severity, upper extremity strength and functional disability in patients with scleroderma and to identify the factors affecting activities of daily living in individuals with scleroderma.

**Methods:** Thirty five women individuals with scleroderma with mean age 56.46 ± 10.45 were included into the present study. The activities of daily living was evaluated with Miliken ADL questionnaire, pain with visual analog scale (VAS), fatigue with fatigue severity scale (FSS), disease severity with modified Rodnan score (MRS), upper extremity strength with handgrip strength and functional disability with Health Assessment Questionnaire (HAQ). The relationships among the variables were analyzed by the Spearman correlation test. Correlation coefficients between Miliken ADL and other variables were determined by linear regression. The statistics were analyzed by SPSS 23.0 version.

**Results:** The Miliken ADL did not significantly correlated with MRS and VAS (p > 0.05), whereas Miliken ADL did significantly correlated with handgrip strength (r = 0.680, p < 0.001), FSS (r = -0.729, p < 0.001), HAQ (r = -0.867, p < 0.001). Additionally, handgrip strength, fatigue severity scale and HAQ were significant and independent determinants for activities of daily living, accounting for 95.0% of the variance in Miliken ADL in patients with scleroderma.

**Conclusion:** The findings of this study show that scleroderma patients daily life is affected by the disease at different levels. Impaired hand function and difficulties in the performance of ADL are common in scleroderma and may influence an individuals functional disability. Therefore, provide therapeutic interventions at the optimal time it is important to follow the development of these factors in the early stages of the disease.

AB1414-HPR  PATIENTS’ EXPERIENCES OF FATIGUE IN AXIAL SPONDYLOARTHRITIS

Cecilia Mercieca1, 1, Sarah Ryan2, Andrew Borg3, 1 Mater Dei Hospital, Rheumatology, Tal-Qroqq, Malta; 2 Keele University, Rheumatology, Stoke-on-Trent, United Kingdom; 3 Mater Dei Hospital, Rheumatology, Tal-Qroqq, Malta

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory arthritis that predominantly affects the spine and the sacroiliac joints. Fatigue is recognised as a central axSpA symptom. AxSpA fatigue is under-explored and often not addressed. Attention in clinical practice seems to be focused on pain and disease activity.

Objectives: The objectives of this study were to explore the meaning, contributing factors and the impact of fatigue on the axSpA patients. Self-management and the role of clinicians were also explored.

Methods: A qualitative phenomenological approach was used. A purposive sample of 10 patients with axSpA, who were experiencing fatigue (≥7cm on a 10cm VAS scale and attending a specialist rheumatology clinic were selected. The participants completed a demographic questionnaire, the Bath ankylosing spondylitis disease activity index (BASDAI) and the Bath ankylosing spondylitis functional index (BASFI) outcome measures. Semi-structured interviews using open-ended questions lasted 30-60 minutes. Interviews were tape-recorded and transcribed verbatim. Data was analysed using Colaizzi’s framework. Two independent reviewers and 5 participants reviewed the data.

Results: Five males and five females were selected to participate in the study. The mean age was 46.6 years (29 - 69). Seven participants were working. The mean BASDAI was 5.4 and mean BASFI was 5. Most of the participants had disease duration of longer than 5 years. The six themes that emerged from the data are:

1. The meaning of fatigue
2. Fatigue patterns
3. Factors that modulate fatigue
4. The impact of fatigue
5. Self-management of fatigue
6. Professional support

Fatigue was defined as an unpredictable, extreme and persistent tiredness. Fatigue had a cognitive and physical component, which was not related to physical activity and did not resolve by rest or sleep. Fatigue was distinguished from tiredness. Tiredness was perceived as a normal feeling which occurred after physical activity and was resolved by rest or sleep.

The severity, duration and frequency of fatigue varied. Fatigue was described as having a multi-factorial aetiology. Fatigue had an overall negative impact upon patients lives affecting their quality of life, leading to psychological and emotional consequences. Participants struggled to self-manage fatigue, receiving no support from health care professionals.

Conclusion: This research has contributed to a better understanding of the patients experiences of axSpA fatigue. Fatigue was described as a huge burden and life-changing. AxSpA fatigue should be acknowledged in clinical practice. AxSpA patients should be asked about fatigue during their clinical consultation. Fatigue should be addressed in its own right and independently from pain and disease activity.

Disclosure of Interests: None declared

AB1415-HPR  PATIENTS PERSPECTIVES ON SELF-MANAGEMENT OF AXIAL SPONDYLOARTHRITIS FATIGUE

Ntoriana Tziatzou1, 1 Andrew Borg2, Cecilia Mercieca1, Sarah Ryan2, 1 Mater Dei Hospital, Rheumatology, Tal-Qroqq, Malta; 2 Keele University, Rheumatology, Stoke-on-Trent, United Kingdom

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory arthritis that mainly affects the axial skeleton and can lead to bony ankyloses. Pain, stiffness and fatigue are the most frequently axSpA-reported symptoms. AxSpA fatigue is multidimensional incorporating physical, psychological and social components, implying that self-management strategies are crucial.

Objectives: This study aimed to explore the self-management of axSpA fatigue. Patients perceptions of whether clinicians give importance to axSpA fatigue were also explored.

Methods: A qualitative phenomenological approach was used. A purposive sample of 10 patients with axSpA, who were experiencing fatigue took part in either a focus group or support day. The focus on the patients’ experiences of axSpA fatigue. Fatigue was not addressed in the clinical setting. Participants felt that they were not guided and supported enough to manage fatigue. More information was needed from health care professionals (HCP) on fatigue management. There was a feeling that HCP focused on the management of pain rather than fatigue.

Conclusion: This research highlighted a clear lack of knowledge about self-management skills to manage axSpA fatigue. Lack of adjustments and coping with fatigue was prominent even in patients who had long disease duration. Furthermore, fatigue was not addressed in clinical practice.

Understanding patients beliefs is an important step towards guiding them to self-manage fatigue. Patients should be guided in implementing self-management plans that would fit their goals, priorities and lifestyle. Self-management is important in improving health outcomes and quality of life.

AB1417-HPR  A REVIEW OF PUBLIC PATIENT INVOLVEMENT AND ENGAGEMENT (PPI/E) AT THE ARTHRITIS RESEARCH UK CENTRE FOR ADOLESCENT RHEUMATOLOGY AT UCL, UCLH AND GOSH

James Wilson1, Caitlin Clifford1, Hema Chaplin1, Despina Eleftheriou1, Anna Radrzewska1, Jozianna Curnin1, George Robinson1, Lucia Martin1, Emma Gutierrez1, Deballi Sen1, 1 University College London, Rheumatology, London, United Kingdom; 2 UCL Institute of Child Health, III, London, United Kingdom; 3 University College London Hospital, Adolescent Rheumatology, London, United Kingdom

Background: The adolescent and young adult (AYA) rheumatology clinical service has a well established culture of involving our users in shaping how services are delivered. Since its inception in 2012 the Arthritis Research UK Centre for Adolescent Rheumatology has worked to offer every patient within the clinical service the opportunity to participate in research.

Objectives: This was achieved by 2015 and from 2014 we renewed our focus on an active involvement programme to promote the role of young people in prioritising and designing our research agenda and workstreams. We are currently developing our strategy for the next five years and reviewing our experience to date.

Methods: PPI/E activity records were searched for the period October 2014 to April 2016. This included number of patients involved, their age and diagnosis, and the type of activity along with the number of times they have been involved.

Results: 19 PPI/E activities were organised. From a total of 1554 adolescent and young adult patients 150 patients having been involved in PPI/E the age range was 11-27 and 118 were female.

The activities consisted of focus groups (79%) and support days (11%) all but two of which were disease specific groups.

The disease specific PPI/E activities have been focused on JIA, JSLE, and JDM. The number of patients involved in these activities were 24.62% (n=99), 24% (n=17) and 66% (n=25) respectively. The mean instances of involvement per disease were 2.09 for JIA, 2.53 for JSLE and 3.96 for JDM.

Conclusion: Our results show that many of our patients have taken part in PPI/E activities (11.19%) with over 65% of our JDM patients having taken part in either a focus group or support day. The focus on
inflammatory rheumatic disease is in keeping with the stated aims of our Centre. The mean instances of involvement ranging from 2.09 to 3.56 suggest that patients feel PPVE is worthwhile. We aim to share our results with the young people who have driven this work and will consider how we might move forward. We aim to consult with the group of patients we serve who have not been part of this process to date.

HPR Professional education, training and competencies

AB1417-HPR  RHEUMATOLOGY NURSE PRACTICE: EDUCATION TO IMPROVE THE UNDERSTANDING OF RHEUMATIC DISEASES

Linda Grinnell-Merrick1, Iris Zink1, Elizabeth Kirchner1, Jacqueline Fritz1, Monica Richey2, Cathy Patty-Resk1, Carrie Beach1, Vickie Sayles1, Eileen McCullagh1, Eileen Lydon1, Sheree Carter1, Scott Kober2.

Rheumatology Nurse Practice. Looking at the Horizon: What Does the Future Hold in the Treatment of Rheumatoid Arthritis?

Methods: Each print issue contained a combination of evidence-based content related to the main theme, along with a series of individual essays written by faculty members. These essays all linked to the main theme of the issue. Live broadcasts were intended to bring a real-life, case-based perspective to the education.

Results: Improvements of >25% in both knowledge and competence were found in any of patient outcome variables between the groups post treatment in both groups (p<0.05). However, no significant differences were found in any of patient outcome variables between the groups (p>0.05).

Conclusion: We could report that mobile-phone-based home exercise training program decreases systemic inflammation in COPD: a pilot study.

AB1418-HPR  MOBILE-PHONE-BASED HOME EXERCISE TRAINING PROGRAM IN PATIENTS WITH KNEE OSTEOARTHRITIS

Onur Aydogdu1, Uluhd Sevin2, Zeybiir San. Marmara University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey

Background: Most rehabilitation programs are hospital-based and rely on regular supervision (1). However, mobile health technologies such as smartphone applications may provide lower-cost ways to monitor and train the patients (2). We have developed a mobile-phone application for monitoring and training the patients at home.

Objectives: The purpose of this study was to compare a mobile-phone-based home exercise training program along with supervised physiotherapy program to a brochure-based home exercise training program along with supervised physiotherapy program in patients with knee osteoarthritis. We hypothesized that the patients who received mobile-phone-based home exercise training program along with supervised physiotherapy program over 3 weeks would have better balance, quality of life and less pain and disability score versus the patients who received brochure-based home exercise training program along with supervised physiotherapy program.

Methods: This was a randomized, prospective, comparative clinical study. The study included 40 patients, aged 45-65 years, who diagnosed with a grade 2-3 knee osteoarthritis. The patients were randomly divided into two groups. While one group (n=20) received a mobile-phone-based home exercise training program along with supervised physiotherapy program, the second group (n=20) received a brochure-based home exercise training program along with supervised physiotherapy program as 15 sessions for a total of three weeks, five sessions per week. Pain intensity, balance, disability, and quality of life were measured with Visual Analogue Scale, Berg Balance Scale, WOMAC, and SF-36, respectively. All of the assessments procedures were performed again after the treatment.

Results: There were statistically significant improvements in measures of pain intensity, balance, disability, and quality of life between pre- and post treatment in both groups (p<0.05). However, no significant differences were found in any of patient outcome variables between the groups (p>0.05).

Conclusion: We could report that mobile-phone-based home exercise training program is not superior to brochure-based home exercise training program in terms of patient outcomes over 3-week program.

EFFICIENCY OF INDIVIDUAL STEEL ORTHESIS IN
THE USE OF SUBCUTANEOUS METHOTREXATE IN
MANAGEMENT OF INFLAMMATORY ARTHRITIS

Methods: During the year, under our supervision there were 156 patients aged from 32 to 67 years. Gender composition - 123 (79%) - women, and 32 (21%) - men. The average time between the onset of clinical symptoms and the first day of treatment was 134 days. The average spur size was 4.3 mm. In 80% of patients, a history of pain lasted for more than 3 months. Patients were divided into 2 groups. The experimental group (G1) used individually manufactured insoles (78 people: 61 - women, 17 - men). The control group (G2) used factory insoles (78 people: 58 - women, 20 - men). 152 patients (98%) completed the protocol: 78 (100%) in G1 and 74 (96%) in G2. The criterion for inclusion in the study was the diagnosis of the heel spur. The diagnosis was made based on anamnesis, ultrasound of the plantar aponeurosis, and radiography of the heel region. The exclusion criteria were patients with heel spurs without heel pain, as well as systemic diseases: rheumatoid arthritis, diabetes mellitus, and severe vascular pathology. The degree of longitudinal flat-footedness, stability of the foot, individual deformities of the feet were clinically evaluated using clinical and functional methods and the method of vacuum trace modeling [2]. Individual insoles were made based on frame materials in the projection of the arches of the foot. Dense materials maintain a constant tension of the plantar aponeurosis. G1 patients were made full contact insoles with a correction of the transverse arch, without adding relief elements under the heel. The control group used factory-made insoles from different manufacturers, with soft elements under the heel. Measurement parameters: average pain intensity on a VAS scale; duration of pain throughout the day; distance traveled; subjective comfort when using insoles. The observation period is 12 calendar months.

Results: The average VAS score in G1 decreased from 5.4 ± 0.3 at the beginning of the study to 1.01 in 62 patients (81%). 15 patients reported pain reduction, the average VAS score was 2.1 ± 0.3. Complete relief of G1 pain has been reported in patients with an osteophyte size of less than 5 mm. G1 patients regained their usual movement distance of 3.9 km per day. Cases of recurrence of heel pain is not recorded. No patients experienced discomfort from the use of insoles throughout the entire period of adaptation. In G2, the VAS score decreased from 5.6 ± 0.3 at the beginning of the study to 2.9 ± 0.3. Patients of the G2 group were able to increase the distance of movement to 1.2 km per day.

Conclusion: When using individual insoles, 93% of patients reported complete relief of pain. 7% of patients noted a significant reduction in pain. The use of individual insoles in the treatment of plantar fasciitis made it possible to reduce pain in a shorter time.

THE USE OF SUBCUTANEOUS METHOTREXATE IN
INFLAMMATORY ARTHRITIS: TRANSLATING
RESEARCH INTO PRACTICE USING QUALITY
IMPROVEMENT METHODOLOGY.

Aicha Bouraoui1, Evgenia Guryanova2, Chuvash State University, Cheboksary, Russian Federation, Chuvash State University, Rheabilitation, Cheboksary, Russian Federation

Background: The most common cause of heel pain is the heel spur, which is 75% of patients with heel pain. The intensity of the pain does not depend on the size of the spur, as determined on the radiographs. Often sharp in shape and large in size, the spurs are a random X-ray finding. At the same time, severe pains in the heel region are possible with a normal radiograph [1].

Objectives: The purpose of this study is to establish the effectiveness of the treatment of patients with pain syndrome in the heel spur, by affecting the main components of the pathogenesis of individually manufactured orthopedic insoles.

Results: The majority of patients with inflammatory arthritis should have trial of s/c methotrexate before starting biologics unless there is contraindication. We reviewed the data of 50 patients to assess management of patients with IA using our biologic register. We used the 5 why strategy to have better understanding of the lack of prescribing of s/c mtx and variations in clinical practice. By applying improvement science we standardized our pathway, included methotrexate s/c trial prior to biologics. We also conducted a number of interventions including multidisciplinary educational events and one to one meetings, we mobilized and organised our resources in better way to meet our patients needs. We monitored our data over time and reviewed our practice accordingly.

Conclusion: In summary, our baseline data showed poor use of s/c Mtx in patients with IA despite the growing evidence of its benefit. In order to translate research findings into practice we used 5 whys methodology to have better understanding of the barriers within our systems, we applied QI methodology and standardized our practice for better use of resources at lower cost.

VIRTUAL CLINICS IN THE PRESENT- A PREDICTOR FOR THE FUTURE?

Tina Parish1, Maathu Ratnaraj1, ‘Tazeen J. Ahmed2. 1St George’s University of London, London, London, United Kingdom; 2Croydon University Hospital, London, United Kingdom

Background: There is great interest in non face to face (F2F), Internet or app based patient interact at the moment. As these become established, we look at the non F2F appointments already happening in telephone and virtual clinics in a busy urban rheumatology department. Here we look at the type of diagnoses dealt with in a non F2F environment and potential outcomes from these non F2F appointments.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2021-eular.8007

AB1419-HPR

AB1420-HPR
Objectives: To assess the efficiency and utilization of virtual and telephone clinics in a general rheumatology department.

Methods: Data was collected from electronic (Cerner) patient records on 240 patients who had a virtual appointment in May 2018. The data was analysed using Excel 2010.

Results: 240 patients had virtual appointments in one month. 121 (50.4%) were via telephone and 119 (49.6%) via patient letter. 34 (14.1%) patients had multiple virtual/telephone appointments. 129 (54%) were carried out by consultants, 78 (32%) by nurses and 33 (14%) by registrars. 37% had rheumatoid arthritis. 32 (13%) appointments lead to a prescription. Virtual appointments produced 44 referrals, including 18 to another specialty, 16 to physiotherapy, and the rest to hand therapy or podiatry. Most patients had a F2F appointment before and after their virtual appointment in May 2018. 1 patient had died before having a second face to face appointment and 13 (5%) were discharged from their virtual appointment.

Conclusion: Consultants undertook the bulk of virtual clinics, and these appointments resulted in the majority of referrals and prescriptions. Virtual appointments reduce the waiting times for contact with a healthcare professional between appointments. Many patients had several virtual appointments between face to face appointments and this cohort may benefit from more scrutiny. Current technology already improves communication and leads to significant changes in patient care without requiring face to face appointments.

Appointments reduce the waiting times for contact with a healthcare professional between appointments. Many patients had several virtual appointments between face to face appointments.

Abstract AB1422-HPR MODERATE AND HIGH ADHERENCE TO A DISEASE MANAGEMENT MODEL IN PATIENTS WITH RHEUMATOID ARTHRITIS IMPROVES CLINICAL RESULTS IN A BIG UNICENTRIC COHORT

Laura Villareal1, Fernando Rodriguez2, Michael Cabrera3, Pedro Santos-Moreno4.

1Biomab – Center for rheumatoid arthritis, Psychology, Bogot, Colombia; 2Biomab – Center for rheumatoid arthritis, Psychology, Bogot, Colombia; 3Biomab – Center for rheumatoid arthritis, EHR administration, Bogot, Colombia; 4Biomab, Rheumatology, Bogot, Colombia

Background: Rheumatoid arthritis (RA) is an inflammatory, chronic disease of unknown etiology. Usually it leads to deformity and destruction of joints through the erosion of cartilage and bone. Over 90% of patients with RA report to suffer symptoms in hands and joints, swelling, loss of motion, muscle weakness among others. These symptoms affect all aspects in a patients life. Therefore, management of a patient with RA should not only include evaluate outcomes related to the rheumatology specialty, on the contrary, aspects such as physical disability, nutrition, mental health, among others should be taken into account. Centers of excellence in rheumatoid arthritis have proposed a multidisciplinary model of care with an initial diagnosis, treatment prescription and follow-up with a rheumatologist, periodic consultations with a physiatrist, psychologist, physiotherapist, occupational therapy nutrition, and, a patient focused program. With a multidisciplinary model of care the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA.

Objectives: The aim of this research was to define adherence/attendance to a multidisciplinary model of care for patients with RA that attend to a RA specialized center in Colombia.

Methods: We implemented the center of excellence model program proposed by REAL-PANLAR group in 2015 (3). In order to define adherence to the multidisciplinary model the authors performed an informal expert consensus to propose a model to measure adherence to the model. The authors proposed three levels of adherence. We proposed three levels of adherence as follows: High adherence: For rheumatology patients had to attend between 6 and 12 consultations in one year. For physical therapy, physiatry, psychology, occupational therapy and nutrition patients had to attend to 3 or more consultations during one year per each specialty. Moderate adherence: For rheumatology patients had to attend between 3 and 5 consultations in one year. For physical therapy, physiatry, psychology, occupational therapy and nutrition patients had to attend to 2 or 4 consultations during one year per each specialty. Low adherence: For rheumatology patients had to attend between 1 and 2 consultations. For physical therapy, physiatry, psychology, occupational therapy and nutrition patients achieved only 1 consultation or less during one year per each specialty. We performed a descriptive analysis and compared the level of adherence and disease activity.

Results: During 2018 we reviewed the medical charts of 6851 patients diagnosed with rheumatoid arthritis; 82% were female and 18% were male. Mean age was 59 years 13 years old. Regarding disease activity mean DAS28 was 2.69 0.84. Most of patients that were considered as Moderate or High adherent achieve remission or LDA. See table 1. Levels of Adherence in Patients with RA

Conclusion: This is an initial approach in order to evaluate patients adherence and attendance to a new implemented multidisciplinary disease management model of attention for patients with RA in Colombia. Our descriptive study demonstrated that patients with moderate or high adherence can achieve better clinical outcomes compared to those who aren’t adherent to the model.

Disclosure of Interests: Laura Villareal: None declared, Fernando Rodriguez: None declared, Michael Cabrera: None declared, Pedro Santos-Mereno Grant/research support from: Dr Santos has received research grants from Janssen, Abbvie and UCB, Speakers bureau: Dr Santos has received speaker fees from Sanofi, Lilly, Bristol, Pfizer, Abbvie, Janssen and UCB

Abstract AB1423-HPR ELICITING THE AGENDA OF PATIENTS WITH MUSCULOSKELETAL DISORDERS; THE PHYSIOTHERAPIST-PATIENT INTERACTION

Sercan Yilli1, Serkan Kalmaz1, Furuk Altay2, Elif Turgut2. 1Hacettepe University, Ankara, Turkey; 2Hacettepe University, Department of Physiotherapy and Rehabilitation, Ankara, Turkey

Background: Eliciting main concerns via interview is important for patient-centered care and for planning individualized rehabilitation program (1, 2). Recently, it has been shown that clinicians often fail to elicit the patients agenda and, when they do, they interrupt the patients discourse (3). However, the prevalence of agenda setting in physiotherapy as a health care provider and the physiotherapist-patient interaction remains relatively unexplored.

Objectives: The aim of this study was to describe agenda elicitation in rehabilitation, to determine the frequency of encounters in which physiotherapists elicited the patients with musculoskeletal disorders agenda, the proportion and timing of interrupted answers.

Methods: An audio-recording analysis of 52 clinical encounters recorded during first physiotherapist-patient interaction were performed. The elicitation of the patient agenda characteristics as the time to interruption or to complete statement were analyzed.

Results: Physiotherapists elicited the patients agenda in all (96.1%) clinical encounters. Interestingly, in those encounters in which physiotherapists elicited patient concerns, the clinician interrupted the patient after a median of 15 seconds (interquartile range 6 to 22 seconds). In the uninterrupted encounters in which physiotherapists elicited patient concerns, the patients with musculoskeletal disorders was state their agenda in 241.45 seconds.

Conclusion: Physiotherapist emphasize to elicit the patients agenda, however, they interrupt expression very sooner. Eventually, the failure to elicit the patients agenda inhibits the physiotherapists-patient communication and this would lead to failure to plan rehabilitation program based on the needs of each patient.

REFERENCES

*EFFECTING A CHANGE AS A PATIENT INSIGHT PARTNER*

Stephanie Skelfington1, Emma Dorris2, 1University College Dublin, Patient Voice in Arthritis Research, Dublin, Ireland; 2University College Dublin, Centre for Arthritis Research, Dublin, Ireland

**Background:** In my patient advocacy work I had experience in every aspect except research, so it was an opportunity to talk to another or former PIP to build my PPI within UCD CAR.

**Objectives:** To prepare patient insight partners (PIPs) with no or limited experience of PPI there should be an opportunity to talk to another or former PIP about their experience or perhaps a leaflet detailing such experience which can be given to new PIPs. This is something not currently done within UCD, but, in response to my suggestion, Im working with UCD CAR to produce.

**Methods:** A personal perspective

**Results:** My formal involvement in this project started with my being invited to be a member of the interview panel choosing the postdoctoral researcher for the project. My remit was to ask the candidates about the impact of the project beyond just the science aspect, to try to figure out who just wanted a job, and who was interested and passionate about this project. I was not only choosing someone for the position but someone I was committing to work with for three years.

One of my first tasks was to act as a mentor in plain English to help the chosen researcher prepare a lay summary of the project. This helped both of us get to grips with the project and its objectives, as well as working out our working dynamic. I work most closely with the project researcher, who has worked in rare disease but not in rheumatology. She has been very receptive and not only took an interest in learning more about the disease area but me as well. I was introduced me to her first as a mentor, and second as a patient advocate. This helped us get to know each other and opened discussions including how PPI could aid her work and how invaluable it is from the patient perspective. This has given our relationship a great start and in a relatively short period we have built the great foundations for an excellent working relationship on a project we are both share a passion for.

For the researchers, to improve the process of PPI I would like some honest feedback on my performance as a patient insight partner. It may not be every patients ideal, but PPI is a knowledge exchange and we learn from each other even more along the way. The reciprocal learning nature of this blog is the number one reason for its creation.

**Conclusion:** Anyone thinking about being a PIP should be aware of how important it is to share their expert knowledge in such as setting and shouldn’t let their fear or perceived lack of knowledge hold them back. They should be willing to be an equal and expect to be treated as such and be willing to contribute fully to the knowledge exchange process including giving honest constructive feedback.

Despite this relationship still being quite new we have plans to grow and build my PPI within UCD CAR.

The Global Osteoarthritis Patient Perception Survey (GOAPPS)-The First Global Survey to Directly Compare Patient Perceptions Regarding Their OA Care: A Pilot Study

Angie Botto-van Benden1, Guy Eakin1, Rosa Scortino1, Maritza Quintero1, Jordi Monfort3, Patrick du Souich4, Francisco de Abajo5, Ingrid Müller6, Elke van Delft1,2, Harold van Garderen3, Rob Braamburg1, Raymond Pieters4.

Background: Globally, osteoarthritis (OA) is the third condition associated with disability. Science holds the key to finding better treatments and a cure. Still, it is essential to learn what is important to patients from the patients to implement the most effective global management of OA. The International Osteoarthritis Task Force, an initiative of the Osteoarthritis Foundation International (Barcelona, Spain) and the Arthritis Foundation (Atlanta, United States) with participation from member organizations in additional countries created the Global Osteoarthritis Patient Perception Survey (GOAPPS) - the first global survey to directly compare quality of life (QoL) & patient perceptions of care in the same OA patient survey across languages and cultures.

Objectives: The goal of the survey was to help all stakeholders in OA healthcare develop a better understanding of patients perceptions and how they may differ between cultures by collecting data on adult OA patient perceptions regarding their OA care. The survey will also collect data on patient demographics, OA symptomology, and impact of OA on daily functioning and QoL. Understanding patients needs and perceptions of care is the first step in optimizing global OA management.

Methods: Observational, cross-sectional study by online survey data collection translated into three languages. We collected data on patient demographics, symptomology, OA impact on daily activity and QoL to investigate the relationship between patient perceptions of their OA care, symptoms and impacts, and QoL. The questionnaire comprised of 4 sections: clinical characteristics, relationship with physicians and treatment, perception of attention, treatment and information received and auto-evaluation of QoL. Inclusion criteria included resident age 18 or older with an OA.

Results: A total of 1485 surveys were completed from 7 countries. 1264 surveys were answered in English, 218 in Spanish and 3 in Italian; analysis of cultural differences was unable to be carried out in this pilot. Data show that the majority of the respondents were female (90%) and more than 55 years of age (82%). The majority (73%) of patients had knee OA, followed by hand (57%) and spine (54%). Comorbidities included hypertension (50%) and obesity (43%). Nearly all patients reported limitations related to physical activities (97%), followed by work activities (49%), social interaction (43%) and sex life (23%). 37% of patients experience emotional or mental health issues. The 58% says their doctor adequately explained their diagnosis and 55% understand the treatment options. Importantly, 41% of respondents are not satisfied with their OA treatment and 79% would like access to non-drug/non-surgical treatments. While 52% of respondents rate their QoL as good, 95% would rate it better if their OA was eliminated.

Conclusion: The results emphasize the significant impact of OA disease on patients daily activities and their desire to play an active role in managing their disease. Notably the majority asks for access to additional options for non-drug/non-surgical treatments stressing the need for an OA management improvement. This is a pilot survey and the results do not permit analysis of cultural differences. Continued survey distribution & analysis will determine differences in patient perception of QoL between OA patients living in different countries to further optimize global OA management.

AB1427-PARE PATIENTS AS RESEARCHERS OF TIETZES SYNDROME AND COSTOCHONDRITIS USING PARTICIPATORY NARRATIVE METHODS OF INQUIRY

Elke van Delft1,2, Harold van Garderen3, Rob Braamburg4, Raymond Pieters4.

1 Association of Tietze and costochondritis patients, Heukelum, Netherlands; 2 Maassstad Hospital, Rotterdam, Netherlands; 3 StoryConnect, Wageningen, Netherlands; 4 University of Applied Sciences Utrecht, Utrecht, Netherlands

Background: Tietzes syndrome and costochondritis are rare, inflammatory rheumatic disorders characterised by chest pain. Pain is most commonly localised unilaterally at the costochondral junctions, with more than one junction generally affected (1). Whereas the conditions are considered self-limiting and in two-thirds of the cases resolve within one year (2,3), they can last up to several years or be recurring (4), limiting the patients ability to function in occupational demands and activities of daily living. The exact cause is not known and therefore it remains a challenge to take on an effective treatment approach.

Objectives: This study aims to gain more insight into patients and medical professionals experiences with and handling of Tietzes syndrome and costochondritis.

Methods: It was noticed that hardly any research is done on Tietzes syndrome and costochondritis and hardly any medical professionals are specialised in these conditions. This sparked the idea to involve patients themselves as researchers of the conditions. To that end an online platform called a StoryPoint was designed, based on the Participatory Narrative Inquiry (PNI) approach (5). This StoryPoint allowed patients and medical professionals to anonymously share and do research on their personal experiences with the conditions. This online assessment was followed by a live meeting with patients suffering from Tietzes syndrome or costochondritis. During this meeting the online gathered narratives were evaluated using group narrative evaluation methods (5).

Results: In total 53 experiences were retrieved. Approximately 60% of patients experienced complaints on a daily basis (figure 1). The reported limitations in daily living were inability to perform physical exercise, a lack of energy and incommprehension from the environment.

REFERENCES
Treatments advised by specialists that relieved complaints were physical therapy, breathing techniques and NSAIDs. Relaxation, low impact movement and warmth were solutions that patients initiated themselves and were perceived helpful. Of all treatments advised by a medical professional, 70% improved complaints, 22% had no effect at all, and 8% worsened the complaints (figure 2). Of the treatments that patients initiated themselves, 76% improved complaints and 22% had no effect (figure 2). We are currently involving a wide variety of medical professionals and researchers for further evaluation of the narratives.

**Conclusion:** Tietzes syndrome and costochondritis can be very limiting conditions, especially when complaints become chronic. Treatments advised by medical professionals are hardly any more effective than treatments initiated by patients themselves. Since both conditions are rare and relatively unknown, medical specialists have difficulties recognising, diagnosing and treating these conditions. It is important that medical professionals become more familiar with Tietzes syndrome and costochondritis and become involved in this type of patient-driven research approaches.

CANNABIS-BASED PRODUCTS FOR MEDICINAL USE: EXPLORING THE VIEWS AND EXPERIENCES OF PEOPLE WITH FIBROMYALGIA

Simon Stones 1,2,3, Des Quinn4, Fibromyalgia Action United Kingdom, 1University of Leeds, School of Healthcare, Leeds, United Kingdom; 2Fibromyalgia Action United Kingdom, Paisley, United Kingdom; 3European Network of Fibromyalgia Associations, Hest-op-den-Berg, Belgium

Background: A review by the Chief Medical Officer (CMO) of the United Kingdom (UK) in 2014 recommended moving cannabis-based products (CBP) from Schedule 1 of the Misuse of Drugs Regulations 2001 into Schedule 2, allowing CBP to be prescribed for medicinal purposes under controlled conditions by doctors on the Specialist Register of the General Medical Council. This prompted the National Institute for Health and Care Excellence (NICE) to develop guidance on prescribing CBP for medicinal use, which Fibromyalgia Action UK were invited to comment on. Anecdotally, we know that some people with fibromyalgia use CBP to help with pain relief; however, we wanted to explore these experiences further, while summarising people’s thoughts of the draft scope guidelines.

Objectives: The aim of the survey was to understand experiences of CBP among people with fibromyalgia, including people’s opinions of the NICE draft scope guidelines.

Methods: An online survey, hosted through Microsoft Forms, was disseminated via social media and Fibromyalgia Action UK’s website between November and December 2018.

Results: A total of 69 people initially responded; with 66 eligible to participate. The average time to complete was 14.05 minutes. Over three-quarters (77%) reported using CBP. The types of CBP that people had used are shown in Fig 1. Over half reported using Cannabidiol (CBD)/Hemp oil (55%), currently marketed as a food supplement. Around one quarter (26%) used herbal cannabis, with few reporting use of plant-derived/synthetic delta-9-tetrahydrocannabinol (THC) or THC/CBD sprays (3-5%). Of the 50 who responded, 52% reported using CBP for medicinal purposes on a daily basis; 28% stated they used CBP during a fibromyalgia flare. While some people did not report any benefits, one of the clear benefits reported by people was pain relief. People also reported improved sleep and mood, less fatigue, and reduced anxiety. When asked to score the current NICE draft scope guidelines, 48 people responded, with an average rating of 3.88 (1=very poor; 5 = excellent). Some felt that the scope was quite vague, difficult to digest, unclear as to who should and shouldn’t be prescribed CBP, and lacked specific reference to conditions like fibromyalgia. There were also concerns in the time it takes to develop guidance. When asked about confusion among society distinguishing CBP for medicinal purposes from food supplements marketed as CBD/Hemp oil, of 63 respondents, 86% felt there was confusion which needs addressing. Individuals felt that alternative treatment options like CBP should be available to people with fibromyalgia, with additional research to identify the evidence for its potential benefit and safety.

Conclusion: The survey highlights that people with fibromyalgia are using CBP, but not necessarily those that are prescribed by a medical professional. There is an appetite among patients with fibromyalgia to explore the option of alternative treatment using CBP. There is widespread confusion among society distinguishing CBP from CBD/Hemp oil marketed as food supplements, which could be leaving certain individuals vulnerable. The development of national guidance is welcomed; however, investment in research to prove the efficacy and safety of CBP in people with fibromyalgia is also needed, to ensure that patients have appropriate access to safe treatments.

Best practice campaigning

ME AND MY DILEMMA – A DANISH CAMPAIGN

Connie Ziegler, Gigførgenringen – Danish Rheumatism Association, Gentofte, Denmark

Background: The Danish Rheumatism Association wanted to raise awareness on the challenges people face on a daily basis living with an invisible disease like some RMDs. In addition, the fact that many people are living with a RMD experience that their surroundings have a lack of understanding the daily struggles they have living with a chronic disease.

Objectives: We wanted to increase the general awareness of RMDs and to show our presence in another context than expected. In addition, the campaign should open up for some difficult talks in an entertaining way giving people an occasion to continue the talks at home. Finally the campaign should show that RMDs are not only related to old people and that consist of a wide range of different stories about living with RMDs. Just getting the word out about a disease that rarely receives a lot of focus in the public.

We received about 100 dilemmas, most of them we had to moderate a lot in order to be real dilemmas that could be discussed, have pros and cons and also to make sure that there was a variation in age, gender, diagnose and subject. Between 200-300 people attended each show, which was less than we expected, however Denmark experienced one of the warmest months of May ever and since the shows were planned inside the malls that explained the limited attendance.

The people who did attend the shows were all in the target group, having either a RMD or were related to someone with a RMD.

Conclusion: It was quite a bit of work getting the shows ready, but they fulfilled their purpose in raising awareness to the public and still reach our target group in a new way and in a new context.

By recording all the shows we were able to make 5 great podcasts on different dilemmas, which people with RMD and their relatives can relate to and discuss.

Patient information and education

**ESTABLISHING A PATIENT TRAINING CENTER OF RHEUMATOLOGY**

Souzi Makri, CYPLAR, Limassol, Cyprus

**Background:** Patient education is considered of pivotal importance for the Organization. Patients should be informed, educated and well trained to acquire the necessary skills needed to deal with the challenges of living with a chronic disease. Equally important is the need of patients to acquire certain skills, necessary for advocating for their rights and representing their Organizations, both at the National but also at the European level. Realizing the above issues, the National Organization decided to create this training centre at its own premises, as it was noted that there was a lack of expertise in the above area, and that patients needed to be empowered to be equal partners in health decisions, but also effective Self managers of their condition.

**Objectives:** One main objective is to educate individual patients to Self manage their disease by accepting the new situation in their life, but also by learning how to effectively communicate with HPs, to be adherent to treatment, to cope with family work and social environments, and to regain self-confidence. The other objective is to train expert patients, enhance their knowledge and empower them for representing the Organization on all relevant Health committees and participate on all stages of the decision making process.

**Methods:** First step was to create a Brand name and acquire the relevant certificate of the establishment of the training centre. After the certification process had been finished, two volunteers from the Organization were trained by the National Authority of Human Resources and after successfully passing the 8-hour examination, they became certified trainers. A committee, under the two coordinators is now in the process of revising the modules of the first 5 courses which are offered initially, by restating the aims and objectives of each course as well as the training procedure, teaching techniques, methods and evaluation process. The courses are: The self-management (running), the expert patient (running) Self Diagnosis (running), Training for parents of Children with Rheumatic diseases (Coming before the end of Year), “Rebuilding the story of our life” – Systemic Sculpture method (Running from October 2019- April 2019)

The plans for the next steps include the creation of training course on building patient advocacy skills (Participation in Health committees, HTA, Advisory committees etc) and one on recruiting and training of volunteers.

**Results:** The experience from the implementation at the initial stage of the three training courses (Self-management, expert patient and self-diagnosis) shows that patients are happy to join, to share experiences and feelings and they successfully attempt to use the skills acquired in their everyday life. Some of the Organization’s members have now become members on National Health committees. These include the Committee for Pricing of Medical products, National Health Insurance, ad hoc for updating the rights of patients, rare diseases, for digital Health etc. Success of the existing modules has led the Organization to decide on building an online portal for digital learning.

**Conclusion:** The creation of a rheumatology training centre for patients, although at its initial stage, has shown positive results for patients, by enhancing their ability to deal in an effective way with the chronic disease but also in improving their skills and knowledge to strive for effective advocacy and for being part of all in decisions that affect their rights in health.

---

**EASY TO OPEN/EASY TO USE: ACCESSIBILITY FOR PEOPLE WITH REDUCED HAND FUNCTION**

Nina Utens, Stockholm, Stockholm, Sweden

**Background:** One fifth of Sweden’s population, more than 1.5 million people, has reduced hand function.[1] For the European population, it would equal well over 60 million people.

People with reduced hand function, for example due to illness or age, are often unable to handle products or packaging without additional daily living aids. In addition to the 20 percent of the population with reduced hand function, often due to rheumatic disease, women on average have 40 percent lower hand strength than men. In other words, the market for inclusive design is huge and concerns a large portion of all consumers. The Swedish Rheumatism Association, SRA, has for many years fought for accessibility of products and services for our members. The SRA has a history spanning over 15 years of activism for inclusive design. The highlight being the launch of the universal standard SS-ISO 17480:2015 Packaging - Accessible design - Ease of opening, of which the SRA was a big contributor. However, the aim for this abstract is not to put emphasis on previous successes but to describe current attempts to make the packaging industry adapt a more inclusive design for the many people with reduced hand function.

Every third year thousands of delegates visit Scanpack, Northern Europe’s biggest packaging fair. Last year was the first time the SRA attended as an exhibitor, making the SRA the only non-profit organisation working for people with rheumatic diseases, to participate. 463 exhibitors from around 30 countries attended, with 16,500 delegates in total, of which 12,900 were visitors. The fair took place on October 23-26, 2018 in Gothenburg, Sweden.

**Objectives:** “Products that are functional and easy-to-use for people with reduced hand function, are suitable for everyone”. This tagline defined our work for inclusive design. We focused on three objectives in order to make our stand more visible and to participate. The three initiatives are:

1. Individuals with reduced hand function in Sweden.
2. Women have weaker hand strength, compared to men. How much weaker? 56 percent of the survey responses were correct. Correct answer: about 20 percent.
3. Results: Representatives from leading packaging companies and visitors to Northern Europe’s biggest packaging fair learnt that there is room for improvement in the packaging industry to adapt a more inclusive approach towards design that benefits people with rheumatic diseases.

**Conclusion:** Half of the participants who visited the SRA’s exhibition answered correctly to our questionnaire regarding reduced hand function, suggesting there is room for improvement in the packaging industry to adapt a more inclusive approach towards design that benefits people with rheumatic diseases.

Building patient led organisations.

PARE0005 REFRESHING THE SOCIAL MEDIA STRATEGY OF FIBROMYALGIA ACTION UK: RESULTS OF A NATIONAL PATIENT ORGANISATION SURVEY

Simon Stones1,2,3, Reece Henderson1, Des Quinn1. Fibromyalgia Action United Kingdom, Paisley, United Kingdom; 2European Network of Fibromyalgia Associations, Hassel-op-den-Berg, Belgium; 3University of Leeds, School of Healthcare, Leeds, United Kingdom

Background: Patient organisations have traditionally provided support for patients. However, the method by which people seek support is increasingly desired across social media, particularly among certain populations within the fibromyalgia community who rely on social media as a key form of communication. In addition, the activity of patient organisations on social media is evolving to encompass greater advocacy and awareness activities with a growing target population of different stakeholders. To address this growing demand, Fibromyalgia Action UK conducted an online survey to inform the organisation’s future social media strategy.

Objectives: The aim of the survey was to understand the preferences of people interacting with Fibromyalgia Action UK’s social media platforms, in order to inform the organisation’s evolving social media and wider communications strategy.

Methods: An online survey was disseminated via Facebook, Twitter and a post on Fibromyalgia Action UK’s website over a one-month period, between October and November 2018. Questions focused on general demographics, social media branding, style and content.

Results: A total of 301 people responded to the survey, 89% of whom had been diagnosed with fibromyalgia and 5% of whom were a friend or relative. More than half of respondents (60%) were aged between 45 and 64 years, with only 13% of respondents aged under the age of 35 years. 91% of respondents felt happy with the organisation’s current branding, with 78% rating the organisation’s social media sites as ‘Good’ or ‘Excellent’. While 92% of respondents were happy with the organisation’s current social media content, around half (51%) suggested an increase in the amount of visual posts (such as infographics), and two thirds (66%) suggested an increase in news articles and patient/carer stories.

Conclusion: The survey highlights the need for more visual, engaging content to inform and educate people about fibromyalgia and related activities. Respondent demographics also highlighted a limited interaction on social media with younger people under the age of 35 years. Together, these findings have prompted the organisation to launch a new campaign, titled ‘BecomeFibroAware’, using visual content to inform, educate and empower the community, as well as an increased focus on engaging younger people with fibromyalgia.

PARE0006 LIVING WITH A RHEUMATIC DISEASE: A RESEARCH ABOUT QUALITY OF LIFE AND WORK CONDITIONS

Antonella Celano1, Serena Mingolla1, Matteo Santopietro2. 1APMAR Onlus, Lecce, Italy; 2WeResearch, Milan, Italy

Background: There are 5 million people who suffer from rheumatic diseases in Italy with an annual expenditure of the health system, estimated for the chronic forms, around 4 billion euros. During the World Arthritis Day 2018 the Association of Persons with Rheumatic and Rare Diseases - Apmar Onlus presented the results of the survey “Living with a rheumatic disease” with the aim of raising public awareness by disseminating data useful to understand the quality of lives of people living with one of the 150 rheumatic diseases.

Objectives: The research investigated:
- The quality of life of people with a rheumatic disease
- The work problems and conditions experimented by people suffering from a rheumatic disease.

Methods: The survey was both qualitative and quantitative. The qualitative phase was held in Milan and was preparatory to the development of the questionnaire distributed at national level. In the first phase two groups of five people were interviewed for two hours. The people interviewed in the focus groups were women and men, age 25-55 years (50% 25-40; 50% 41-55) with at least one rheumatic disease, currently workers/ laborers at least part-time.

In the quantitative phase, a questionnaire was administered throughout the national territory to a sample of 1,020 people, women and men, age 18-75 years with at least one rheumatic disease, currently workers/ laborers at least part-time or who worked for a period preceding the diagnosis of rheumatic disease. The used methodology of on-line investigation was the Cawi (Computer Aided Web Interview).

Results:
- 89,1% of separated and/or divorced interviewed reported that the disease caused problems in the sexual relationship with the partner as to cause their divorce/separation;
- 61% of the sample had to reduce working activities significantly, in many cases abandoning the job completely;
- 26.3% of the sample stated that he prefers not to speak about his illness either with his work colleagues or with his boss and/or superiors.

Conclusion: Rheumatic diseases affect relationships and social life negatively. The research shows how the rheumatic disease can have a particularly critical effect in the relationship with the partner. The problems arising in the relationship of the couple are so meaningful, and cause of misunderstandings and psychological suffering to be considered among the main causes of divorce and separations.

Rheumatic diseases heavily affect the working life. From the research emerges that people with rheumatic diseases that have managed to preserve their work despite the disease, are often reluctant to talk about their health conditions at work. The main reason is the fear of worsening and/or compromising their relations with colleagues and superiors with consequent negative effects on work tasks and the risk of losing their workplace.

People suffering from rheumatic diseases in Italy declare that their condition of difficulty due to the pain, is often underestimated, this leads them to take a closing attitude for the fear of not being understood. The respondents also expressed the fear that in the highly competitive society we live in, there is no place for people to express their pain: they are afraid of being considered weak and in a certain way “to be put aside” and so they must therefore “show themselves strong”.

PARE0007 RHEUMATISM CHALLENGE 2018 – “RHEUMATISM IN MOTION” WE ARE GOING IN THAT TOGETHER!

Hana Smunova1, Edit Mullerova2. 1Institute of Rheumatology, Prague, Czech Republic; 2Czech League Against Rheumatism, Prague, Czech Republic

Background: Czech League Against Rheumatism plays an important role in promoting rheumatic patients in the Czech Republic. Its activity is aimed at:
- raising awareness about RA for early diagnosis and RA treatment
- improve an attitude of the Czech patients to the modern treatment, including the biological treatment
- co-operate on the change together with the professional community, regulatory authorities and Health Insurance Companies.
- striving to qualify the people with so called “moderate activity” of the disease for the biological treatment.
• the struggle for full and equal life for people with rheumatic and musculoskeletal diseases
• the establishment of regional clubs and specific patient groups of Czech League Against Rheumatism

Objectives: Creating a campaign Rheumatism Challenge 2018 - “Rheumatism in motion” We are going in that together! The aim of this campaign is improving the health condition of people with RMDs. To motivate patients to move regularly and raising patient awareness about the importance of physical activity.

Methods: Walking as a means to reach a goal is the main content of this campaign. The aim of each participant in this campaign is to reach as much as possible steps and kilometers every months. Exiting challenges prompts patients to higher goals and giving them courage. Through walking Czech League Against Rheumatism wants to improve physical and mental health of people with RMDs. Wants to maintain a joint mobility and reduce a pain. Know and find the right kind of movement for each patient.

Information about this campaign is published on the webpage, Facebook and Instagram of Czech League Against Rheumatism.

Results: This campaign managed to raise awareness about the importance of physical activity. On-line and off-line, more than 500 HCPs and patients with rheumatic and musculoskeletal diseases among the general public. Information about the campaign was in press and television. The campaign continues in 2019. In response to the campaign has increased the number of members in Czech League Against Rheumatism.

Conclusion: This campaign seems to be very useful in promoting how important physical activity is for patients with RMDs. This campaign can support patients be more healthy and more physically active. Active approach to one another life can inspire other patients and their families and friends. Very important is also the support of this campaign from the professional community, medical doctors and health professionals.

PARE0008 UNDERSTANDING THE IMPACT OF ANKYLOSING SPONDYLITIS IN DAILY LIFE OF THE PORTUGUESE PATIENTS: RESULTS FROM THE ASSESSMENT OF RESULTS IN ANKYLOSING SPONDYLITIS (AREA) STUDY

Filipe Araújo1, Claudia Duarte1, Jorge Brandão2, Rui Cemadas1, Elsa Mateus1, Luís Cunha Miranda1, José Canas Da Silva1, José Gomes Da Silva3, Pedro Simões Coelho1, Catarina Marques2, 1Hospital Sant’Ana, Rheumatology and Osteoarticular Unit, Lisbon, Portugal; 2NOVA IMS Information Management School, Lisbon, Portugal; 3APMFG – Associação Portuguesa de Medicina Geral e Familiar, Delegação Distrital de Coimbra, Coimbra, Portugal; 4Serviços Médicos Continental, Lisbon, Portugal; 5Liga Portuguesa Contra as Doenças Reumatológicas, Lisboa, Portugal; 6PRP – Instituto de Reumatologia, Lisboa, Portugal; 7Hospital Garcia de Horta, Lisboa, Portugal; 8National Association of Ankylosing Spondylitis, Oeiras, Portugal, 9Portuguese League Against Rheumatic Diseases, Lisbon, Portugal

Background: AS is known to have a significant burden upon the individual and family life. It is essential to assess the impact of AS in patients’ lives, to raise awareness and improve early referral, diagnosis and treatment, for a better quality of life.

Objectives: To assess the impact of AS in the life of Portuguese patients (work, daily activities, social life).

Methods: The Assessment of Results in Ankylosing Spondylitis (aERA) study was developed by the NOVA-IMS in cooperation with: Portuguese Society of Rheumatology, Portuguese Association of Family Physicians, National Association of Primary Care Units, National Association of AS Patients and the Portuguese League Against Rheumatic Diseases. The aERA aimed at assessing reasons for delayed referral of suspicious cases of AS to the rheumatologist, as well as disease impact in patients’ lives, global health and work. A comprehensive online survey was developed with the collaboration of LPCDR and sent to AS patients. Data on demographics, lifestyle habits, daily life activities, working habits, disease indexes and healthcare utilization, health status/quality of life indicators, EQ-5D and BASDAI scales. A generalized linear model was adjusted in order to identify the factors impacting on quality of life of patients.

Results: 354 patients responded the survey, 42.1% female, most frequently from the 35-44 year-old age group. Mean age at disease onset was 27 years old, while the diagnosis was confirmed 7 years later. In the previous 12 months, the average of working days lost due to AS issues was 37 (including sick leaves). During that period, AS has affected work productivity in average around 73 days. Cumulatively, patients’ relatives or friends had also lost about 13 days of work, to provide them assistance. Regarding limitations in daily life activities, house cleaning (55.5%), physical exercise (46.5%), getting in/out of bed (45.6%), using stairs (37.9%), shopping (37.4%) and tying shoes (35.2%) were reported as being highly limiting by AS. As for the social life, family and friends’ relationships were reported as not being affected by over 60% of AS patients. However, 19.8% of the respondents have reported a worse relationship with their partners after diagnosis, and 29.7% reported having decreased the frequency of sexual intercourse. Leisure activities, were only reported as not being affected by 34.6% and 40.5% of patients, while the practice of sports has much decreased in 40.7% of the respondents. Almost 80% had mobility issues during the last year, and of 65% had their usual activities/routes affected by AS. The average BASDAS score is 5.5 and the EQ visual analogue scale 55. Analyzing the impact of treatment, biologics and biosimilars were reported as having significantly improved patients’ quality of life, except for physical or sexual activity.

Conclusion: AS has a major impact in the daily life of patients, work productivity, social relationships and leisure activities. Early diagnosis and treatment, along with physical rehabilitation/exercise plans, can reduce this impact and improve their quality of life.

Best practice campaigning

PARE0009 THE PHYSIOLOGIC AND EMOTIONAL BURDEN OF RHEUMATOID ARTHRITIS: DATA FROM RA MATTERS, A WEB-BASED SURVEY OF PATIENTS AND PHYSICIANS IN EUROPE AND CANADA

Rinke Alten1, Neil Betteridge2, Francesco de Leonardi3, Nicole Tietz3, Mariana Guerreiro4, Mart van de Laar4, Schlosspark Klinik University Medicine, Berlin, Germany; 2Neil Betteridge Associates, London, United Kingdom; 3Elv Lilly and Company, Indianapolis, United States of America; 4Arthritis Centre Twente, Medisch Spectrum Twente, Enschede, Netherlands

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory disorder that negatively affects the patients’ health-related quality of life (QOL).1 Despite much progress in addressing the burden of RA, a gap exists in terms of understanding ‘what really matters’ to patients with RA, and balancing patients’ QOL aspirations with clinical targets in key treatment decisions.

Objectives: This international survey investigated how RA affects the lives of patients according to the perceptions of both patients and healthcare providers (HCPs), in order to help health professionals attune their care on the domains that really matter to patients.

Methods: Data were collected from patients with RA, and rheumatologists or HCPs who treat RA in Canada, France, Germany, Italy, Netherlands, Spain, Sweden, and UK using a structured, closed-ended questionnaire in their local language. Respondents for the survey were recruited from survey panels of verified unique respondents, as well as through social media. Data were summarized in terms of both frequency and percentages of patients to understand the experience of patients living with RA on daily activities, relationships, work, and aspirations.

Results: Overall, 5400 adult patients (81% female; mean age 52 years), and 808 rheumatologists or HCPs participated in the survey between November 2016 and February 2017. Of these, the highest proportion of patient and HCP respondents were from the UK (n=1250) and France (n=230), respectively. Overall, 52% of patients and 62% of HCPs believed that the emotional impact of RA is not well understood by people without the disease; whereas 46% of patients and 52% of HCPs had a similar belief with regards to the physical impact of the disease. Patients who felt that the impact of RA is less well understood by others expressed more negative feelings about every aspect of their life with RA. Important relationships with spouse or partner, children, family, friends, and colleagues were generally affected negatively. Almost half of the patients (48%) who participated in the survey reported that they were forced to take long-term leave/retirement or experienced slow career progress since being diagnosed with RA; more than 3 in 5 patients found exercising to be difficult; and almost 1 in 4 patients found difficulties in taking care of personal grooming. Aching/stiff joints, pain, and fatigue were the key physical barriers to daily life for patients, and 65% of patients felt frustrated when they were unable to undertake or complete daily activities due to their disease. Two-thirds of patients wished to be able to accept their life with RA and do what they can to cope with it in the future. Over half of
the patients (52%) had a hope that the physical impact of RA will be better understood in the future.

Conclusion: Despite major advancements in the treatment of RA, the chronic disease continues to significantly affect many aspects of patients’ lives, including relationships, career progression, daily activities, and ability to work. Both patients and HCPs felt that the physical and emotional impact of RA is not well understood by people without the disease. In line with a recently published study, pain, fatigue, and physical function remain primary barriers for patients to live a normal life and to participate fully.2 In RA treatment decisions, patients’ personal goals and patient-reported outcomes should be given greater consideration along with clinical targets.

PARE0010 INSIDE OUT – A PHOTO CAMPAIGN TO CREATE AWARENESS FOR YOUNG PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

Meike Voeten1, Elke van Delft2, Anne Haenen1, Wendy Olds1, Youth-R-Well.com, Eindhoven, Netherlands; 1Maassand hospital, Department of rheumatology, Rotterdam, Netherlands

Background: Inside Out is a photo campaign of Youth-R-Well.com, the organisation for young people (16-30 years) with rheumatic and musculoskeletal diseases (RMDs) in the Netherlands. The project was inspired by Unga Reumatiker, the youth organisation in Sweden and their campaign Against the invisible side of RMDs. The campaign of Unga Reumatiker showed that young people can suffer from rheumatic diseases, even though these diseases are invisible. Youth-R-Well.com recognized that the invisibility of an RMD can have a major impact on the lives of young people and wanted to create a similar photo campaign to show the invisible side of RMDs.

Objectives: The main objective of this project was to create more awareness for rheumatic and musculoskeletal diseases affecting young people.

One of the hardest parts of living with an RMD is the invisibility of the disease in daily life. We wanted to show that even though you cannot see it, young people have to deal with the consequences of having an RMD on a daily basis. We also wanted to show other young people who are in a similar situation, that they are not the only one.

Methods: To make the invisible side of an RMD visible for others, Youth-R-Well.com created Inside Out, an eight part photo campaign. Eight young people with different types of RMDs, took part in this project. From each individual, two photos were taken: one photo in daylight and one photo in the dark with their rheumatic-spots highlighted by blacklight paint. Next to the photos, the participants introduced themselves in a few sentences and ended with a life quote with a focus on the positive side of life. They were all telling very different and very personal stories. The general quote of the photo campaign was “Although you cannot see it from the outside, it is still there”. The photo campaign was posted on Facebook and Instagram. The photo campaign was released the week before World Arthritis Day, in which the photos of one person were shared on each day. The final photo, a group photo with all the young people and their black light photos, was shared on World Arthritis Day 12 October 2018.

Results: It was a successful campaign, in which we reached almost 30.000 people on Facebook and 5.000 people on Instagram. The success of the project and all the shares and great comments it received were overwhelming. The power of two photos next to each other had a large impact on people who were not familiar with the fact that RMDs do exist among young people. As a result of the great comments, this photo campaign is going to be exhibited in Reade, the center for Rehabilitation and Rheumatology in Amsterdam, to reach more people and make them more aware of the invisibility of RMDs.

Conclusion: Based on inspiration from a youth organisation in Sweden, Youth-R-Well.com created the successful campaign Inside Out. We managed to create more awareness for young people with RMDs and the invisible side of having an RMD. We will continue to spread this campaign and show that young people with RMDs are not alone.

Acknowledgement: First of all, we want to thank all our brave participants who took part in this campaign. Secondly, we want to thank Unga Reumatiker, who inspired Youth-R-Well.com to launch this amazing photo campaign.

Innovations in arthritis health care

PARE0011 PILOTING THE FIRST PATIENT PARTNERS PROGRAM FOR AXIAL SPONDYLOARTHRITIS: THE JOURNEY OF BELGIAN PATIENTSTOCOME EXPERT TEACHERS IN RHEUMATOLOGY

Jahel Roens1, Philippe Gadeyne1, Luc Ghekiere2, Liliane Ovaere3, Thijs Swinnen4, Philippe Caron2,1Patient Partners Program Belgium vzw asbl, PPR-SPA, Sint-Joris-West, Belgium; 2University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium; 3University Hospital Ghent, Rheumatology, Gent, Belgium

Background: Patients with axial spondyloarthritis (axSpA) were trained to deliver experience-based workshops to medical students, general practicioners, physiotherapists and other healthcare providers concerning axSpA. The most important aims of these workshops are to improve the early diagnosis and to increase awareness of axSpA in the medical sector. Taking an expert role as a patient however requires an extensive training.

Objectives: To describe the training program in detail and to illustrate both the less successful and the optimal implementation steps taken thus far.

Methods: In its first iteration, the training program was developed as a resource book including a curriculum, significant amounts of homework, without enough time for practical exercises. This resulted in a drop-out of a large portion of trainees. Thereafter, the training method has been adapted by copying successful parts of the approach of The Patient Partner® Program for Rheumatoid Arthritis (launched in 1999). Also, more concrete training opportunities via a DVD demonstrating the complete course and training materials, as well as offering hands-on trainings during a three day overnight stay were added. Besides creating opportunities for intensive practicing with each other, there was also more time for informal contacts and it allowed for proper group dynamics. So there is more time for sharing among them with a similar background. A comfortable environment was created for the candidates, enabling them to go through a complete process and giving them sufficient time to train all the components of the program.

Results: On February 22nd 2018, five fresh SpA-patients started the training, all five of them successfully completed the training on June 2nd 2018. On a first evening of familiarization, trainers tried to know more about the motivation of the trainees, while in an individual interview a rheumatologist reassured that the candidates have the correct diagnosis, as their story should be consistent. The selected candidates received part 1 of the training manual by mail and they were invited to profoundly study the terminology and the anatomy, related to their disease. During the first full day of the training, the trainers took time to explain the terminology and anatomy. Later on this constituted the building blocks of the course. The trainers closed this first day demonstrating the history taking and they asked the trainees to study at home their personal medical file.

On day 2, the homework of the previous day was first discussed, followed by related exercises. Day 2 finished with the demonstration of the clinical examination.

The training program was completed with three days with overnight stay. During these days a lot of practical exercises of the clinical examination were organized, followed by a discussion of the impact of the disease and the importance of active participation. The program ended with a general rehearsal and a written as well as an oral test to evaluate how each trainee had assimilated all this.
Conclusion: In the training program PPP SpA, the trainees learn to tell a uniform and academically correct story. This contains an accurate history taking and a correct clinical examination reinforced by the personal history of the Patient Partner. Moreover the whole process helps each Patient Partner to have a better insight in their own illness, a better capacity to cope and to develop more skills in the dialogue with medical practitioners. The experienced positive feedback of the trainees after every course is the best motivation to continue with this approach.

Disclosure of Interests: None declared

INVOLVEMENT OF PATIENTS IN ERN RECONNET: A SUCCESSFUL INITIATIVE RAISING PATIENTS' LEADERSHIP AT EUROPEAN LEVEL

Alain Comet1, Charissa Hermine Frank2, Ilaria Galetti3, Jürgen Grunert4, Versa Guimaraes5, Lisa Matthews6, Sander Otter7, Ana Vieira8, I lupus Europe, Ramfund, Initiative e.V., Koersel, Belgium; 2Federation of European Scleroderma Associations, Roma, Italy; 3Deutsche Eihers-Danklos Initiative e.V., Fürth, Germany; 4LiSBOA, Portugal; 5Relapsing Polychondritis Awareness and Support, London, United Kingdom; 6IVLE, UTRECHT, Netherlands

Background: European Reference Networks (ERNs) are virtual networks involving centres of expertise across EU Member States with the aim of tackling rare and complex diseases. The ERN ReCONNET involves currently 26 healthcare professionals (HCPs) from 8 countries and cover rare and complex connective tissue and musculoskeletal diseases (rCTDs). Patient participation and involvement, also through EURORDIS, is a characteristic of ERNs.

Objectives: To demonstrate that patients’ involvement and collaboration across disease and geographic borders via the ERN ReCONNET effectively brings better care for people living with rCTDs.

Methods: The European Patient Advocacy Groups (ePAGs) provide patients’ opinion and input in all activities of the ERN. They relay the views of their wider communities, evaluate how the ERN acts on patient views, contribute to projects and research, develop and disseminate patients’ information, ensure that patient rights and choices are taken into account in decision-making and identify national groups to work with the ERN’s HCPs. To structure the patients’ involvement, a Patients’ Organizations Working Group led by a Senior and a Junior Coordinator, developed and approved its own Terms of Reference. Patients’ Representative Disease Coordinator (PDR) have been identified for most diseases. They bring patient perspective, liaise with HCPs and their wider patient community. Three ePAGs are voting members of the Steering Committee.

Results: ePAGs have collaborated intensely in ERN activities, organising and participating to regular meetings, providing their input into projects. They co-designed and disseminated surveys on clinical practice guidelines (cPGs) to patients and their families, evaluate how the ERN acts on patient views, contribute to projects and research, develop and disseminate patients’ information, ensure that patient rights and choices are taken into account in decision-making and identify national groups to work with the ERN’s HCPs. To structure the patients’ involvement, a Patients’ Organizations Working Group led by a Senior and a Junior Coordinator, developed and approved its own Terms of Reference. Patients’ Representative Disease Coordinator (PDR) have been identified for most diseases. They bring patient perspective, liaise with HCPs and their wider patient community. Three ePAGs are voting members of the Steering Committee.

Conclusion: The ERN ReCONNET is a great opportunity for patients’ leadership, bridging from EULAR and its PRP program to ERN and other EU initiatives. It will make a tremendous impact on the EU diagnostic and treatment landscape bringing a better quality of life to people with rCTDs.

EDUCATING PEOPLE WITH RMDs TO FOLLOW A CORRECT DIET: AN INNOVATIVE 3 STEPS PROJECT

UGO VIORA, Sara Severoni, Silvia Tonolo, ANMAR Italia, Rome, Italy

Background: Patients associations in Italy as in all the European countries have a strong role not only in empowering people with Rheumatic and Muscle-skeletal Diseases (RMDs), but also in educating them to new healthier lifestyles, comprehending physical activity and diet.

In Italy, the special relationship between people and food make our job more difficult than in other countries and it needs to try new ways driving people with RMDs to a correct diet without feeling different from the healthy population.

Objectives: 1. to make patients, their families & care givers and the society aware of how much important is to follow a correct diet to prevent some of the damages that may be related to rheumatic diseases; 2. to make patients and their families aware of the importance to rely on experts in setting up correct dietary regimes; 3. to educate people with RMDs to a correct diet and healthy lifestyle, showing them it is possible to eat meals appetizing, tasty and also appearing beautiful even if following an appropriate and healthy regimen.

Methods: STEP 1 - ANMAR published “RMDs and diet”. The booklet written by dr. Annalisa Olivotti, biologist and nutritionist, contains all topics concerning diet and RMDs; the Rheumatologist position and some suggestions by patients are present too. The booklet has been sent to all people receiving the ANMAR magazine “Sinergia” and was available for free in all ANMAR events and on its website.

STEP 2 – Since September 2018, through the regional associations, ANMAR organized a series of events to educate all the population and especially patients, their families and care givers, to follow a healthy diet, as a first aid to the pharmacological therapies.

STEP 3 - To complete the educational pathway of each meeting, all participants can experience how fun may be eating in a healthy way, having a dinner cooked by local chefs who have previously received a complete list of the most suitable foods for proper nutrition for people with RMDs.

Results: The project is still ongoing: nowadays we can refer these data:

- 15.000 copies of the booklet “RMDs and Diet” were published and distributed
- 5 meetings were organized, directly approaching a total of 450 people
- All participant highly appreciated the healthy menu cooked in the dinners
- 54 new recipes have been sent to the regional Association of Piemonte, leader of the project
- Using a “free – offer” request to enjoy the dinner, the project may also become a good fundraising way for the regional association organizer.

Conclusion: Data collected seem to confirm this one may be a suitable way to overcome the Italian cultural gap which leads to live diet as a bad and depressing lifestyle, as in Italy eating is not only a way to feed on, but an enjoyable moment. We hope further data will enforce this first impressions and definitely confirm it.

Patient information and education
PATIENT VOICE IN GOUT – A EUROPEAN PATIENT SURVEY TO UNDERSTAND THE NEEDS OF PEOPLE LIVING WITH GOUT

Ana Vieira1, Sebastian Micalef2, Mary Vella3, Brian Lynch4, Neil Betteridge4, Gudula Petersen5, Victoria Romero Pazos6, 1Liga Portuguesa Contra as Doenças Reumáticas, Lisboa, Portugal, 2AGORA, Athens, Greece, 3Arthritis and Rheumatism Organisation Malta, Mgarr, Malta, 4Arthritis Ireland, Dublin, Ireland, 5National Rheumatoid Arthritis Society, Maidenhead, United Kingdom, 6Grünenthal, Aachen, Germany.

Background: Gout is one of the most common forms of inflammatory arthritis in Europe, but awareness of it is relatively low. There is limited information available about the impact of gout on patients, and more generally on society.

Objectives: To give gout patients a voice to better understand the impact that the disease has on their lives.

Methods: From June to September 2018, gout patients from 14 European countries were invited to complete a 15 minutes online survey. Adult (18+) patients diagnosed with gout who met the criteria and finished the survey were included in the analysis. The design and content of the survey has been developed together with several patient and clinical experts to ensure that the most relevant aspects of the disease were covered. The questionnaire was translated into 11 different languages and checked that patient-friendly language was used. Patients were recruited via patient associations, leaflets provided to doctors and consumer online market research panels to reach the targeted number of patients.

Results: 1,100 gout patients completed the survey, 78% of respondents were male and 22% female. The mean age of participating patients was 55 years, 56% were employed or studying. The mean age of patients at diagnosis was 45 years and 38% were diagnosed during their first flare. The patients had on average 2.9 flares per year and the length of their last flare was 5 days on average. 84% of patients experienced moderate to severe pain with their most recent flare, 63% had severe pain with their worst flare ever. Patients reported that gout has a significant impact on their daily activities: on their ability to walk (59%), changes in mood and mental well-being (43%) and difficulties relating to their partner (26%). 27% of patients reported that their self-esteem has dropped.

Inconvenience (53% of patients), agony (37%) and frustration (32%) were the words patients most often associated with gout. 10% of patients (or a family member) have retired or lost a job because of their gout.

Despite reporting these not-insignificant impacts of gout on their lives, 79% of patients said that they are satisfied with their current treatment. However, two-thirds (68%) of younger patients (18-35 years) reported that they are satisfied with their current treatment. Despite reporting these not-insignificant impacts of gout on their lives, 79% of patients said that they are satisfied with their current treatment. However, two-thirds (68%) of younger patients (18-35 years) reported that they are satisfied with their current treatment.

Conclusion: The results of this survey demonstrate that gout has a significant impact not only on patients, but also on their families and society. Gout seems to lead to stigma and many patients may feel guilty about their lifestyle choices. Actions need to be taken to manage dissatisfaction of patients and to encourage them to speak up to request better management of the disease. There seems to be an urgent need to educate both patients and the general public about the seriousness of gout and the burden on patients and their families. The results of this survey will be used for communication with healthcare professionals to better address patients’ unmet needs.

EMOTIONAL HEALTH AND WELL-BEING MATTERS

Matthew Bezant1, Hayley Mcban2, Ailsa Bosworth1, 1National Rheumatoid Arthritis Society, Maidenhead, United Kingdom, 2City, University of London, London, United Kingdom

Background: The most common co-morbidities amongst people with RA are mental health conditions, such as depression and anxiety, as evidenced by previous surveys and reports by the NRAS. NRAS also understands, through interaction with its membership across the UK, that mental health and well-being are important issues for people living with RA and JIA. NRAS therefore partnered with City University to undertake a survey exploring the impact of RA and adult JIA on mental health.

Objectives: To explore the psychological impact of Rheumatoid Arthritis (RA) and Juvenile Idiopathic Arthritis (JIA), along with any psychological support people may have received or would like to have access to, to help manage the anxiety, emotions and stresses that come with being diagnosed with and living with RA or JIA and its treatment.

Methods: Following a focus group held in Central London in early 2018 with a dozen NRAS members, NRAS and City University designed a survey to look at a range of aspects relating to emotional health and well-being, including validated questionnaires to compare data to existing research. The survey was open between May and July 2018, with participants recruited via NRAS newsletters, social media platforms, the NRAS HealthUnlocked forum and via healthcare professionals at rheumatology units. A total of 1,999 people participated in the survey and a final sample of 1,650 was used for analysis.

Results: The survey found that people with RA and adult JIA were less satisfied with their life, believed the things in their life were less worthwhile, and were less happy. The proportion of people who scored poorly on life satisfaction and life worth was over 7 times greater in those with RA and adult JIA than the national average. Despite this, the survey found that 2 in 5 people had never been asked by a health professional about their emotional and psychological well-being, and 1 in 3 people who had requested or been offered support had never received it. Positive experiences that respondents shared of psychological support, such as GP’s and rheumatologists being very supportive, the importance of family, and services offered by NRAS, demonstrate the benefits of good and appropriate support being available. Negative experiences, such as lack of health professional understanding about mental health, lack of understanding of RA by counsellors, and lack of personalised care demonstrate the future work that must be done to help adequately support people with RA and adult JIA.

Conclusion: The survey has demonstrated the need to provide more effective self-management techniques of emotional as well as physical well-being, ultimately leading to overall improved health outcomes. In line with NICE guidelines, other additional support is needed, such as the availability of cognitive behavioural therapy and the implementation of mental health and well-being assessments at annual review. Further research is needed into specific areas, such as health inequalities and why people with severe mental health issues experience poorer disease activity, understanding why adults with JIA have poorer life quality than people with RA, and understanding the impact of psychological interventions for people with adult JIA.

**PARE0017** EXPLORING DIFFERENCES IN THE AGE ON ONSET OF JIA BETWEEN MALES AND FEMALES: A PARENT-LED SURVEY

Richard Beesley1, Simon Stones2, Juvenile Arthritis Research, Tonbridge, United Kingdom; 2University of Leeds, School of Healthcare, Leeds, United Kingdom

**Background:** The etiology of juvenile idiopathic arthritis (JIA) remains unknown, despite a range of proposed mechanisms under investigation [1]. However, previous research has revealed biological differences depending on the age of onset of JIA, independent of the classification based on the number of joints involved [2].

**Objectives:** In this parent-led study, the age of onset of JIA by both disease subtype and sex of the child were explored, to identify whether there is a difference in age of onset of JIA between males and females.

**Methods:** An online survey was shared via social media, targeted at parents of children and young people (CYP) with JIA. Questions probed the age of symptom-onset and diagnosis (by single year of age), JIA subtype and Rheumatoid Factor (RF) status.

**Results:** Of the 409 CYP included, 296 had polyarticular (poly) or oligoarticular (oligo) JIA, including extended-oligo JIA (72% of all respondents). There were no differences between onset among these subtypes; therefore, they were grouped for further analysis, given comparable disease progression and genetic markers among these subtypes. There was no significant difference regarding age of symptom onset between RF-positive and RF-negative CYP. Amongst those with poly/oligo JIA, there was a clear peak of symptom-onset in the first few years of life, with over half experiencing symptoms before their third birthday, and 73% before the age of five years. Interestingly, the distribution of symptom-onset was significantly different in the poly/oligo JIA group between males and females (P = 0.0093), with the onset of poly/oligo JIA appearing to occur earlier in females (Figure 1). Given that some CYP with older-onset JIA are sometimes reclassified as having enthesitis-related arthritis (ERA) when examined in adolescent services, the Mann-Whitney U Test was repeated with only those CYP with JIA onset before the age of seven years. In this case, there remained a significant difference in age of onset of poly/oligo JIA between males and females (P = 0.0061).

**Conclusion:** The age of symptom-onset among CYP with poly/oligo JIA differs between males and females, with females tending to exhibit symptom-onset earlier. This appears not to be attributable to misclassification of JIA subtype, and so this knowledge may assist future diagnoses of JIA. Further research is required to identify which temporal-associated factors may be critical in JIA onset and development.

Building patient led organisations

PARE0018 ENABLING PATIENT-CENTRED CARE IN RHEUMATOID ARTHRITIS AND ASSOCIATED COMORBITIES

Neil Betteridge1, Alejandro Balasa2, Maya Bucht1, Maxime Dougados3, Patrick Durez4, Ennio Favalli5, Guillaume Favier6, Cem Gabay8, Rinie Geenen9, Ioanna Gouri-Berthold9,11, Frank van den Hoogen10,11, Alison Kent12, Lars Klareskog13, Mikkel Ostergaard14, Karel Pavelka15, Joaquim Polido-Pereira16, Anne Grete Semb17, Magnus Sköld18, Tore K. Kvien19,11,17,18, Bettridge Associates, London, United Kingdom; 1Hospital Uni La Paz, Madrid, Spain; 18Kapel Allerton Hospital, Leeds, United Kingdom; 2Cochin Hosp, Paris, France; 3Rheum, Clin Uni Saint-Luc, IREC, Brussels, Belgium; 4Gaetano Pini Inst, Milan, Italy; 5Global Strategy Group, KPMG LLP, London, United Kingdom; 6Geneva Uni Hosp, Geneva, Switzerland; 7Dept of Psychology, Utrecht Uni, Utrecht, Netherlands; 8Department of Endocrinology, Diabetes and Preventive Medicine, Uni Cologne, Cologne, Germany; 9Sint Maartenskliniek, Nijmegen, Netherlands; 10Salisbury NHS Foundation Trust Hosp, Salisbury, United Kingdom; 11Karolinska Institutet and Karolinska Uni Hosp, Stockholm, Sweden; 12Righospitalet, Copenhagen, Denmark; 13Inst Rheumatolog, Prague, Czech Republic; 15Hospital Santa Maria, Lisbon, Portugal; 16Diakonhemmet Hosp, Oslo, Norway

Background: Patients with rheumatoid arthritis (RA) have an increased risk of comorbidities such as diabetes (IR of 8.6 per 1000 person-years11; 20% prevalence2), interstitial lung disease (7.7% incidence3; up to 60% (interstitial lung abnormalities in early RA)4), depression (up to 200%; 16.8%5), and cardiovascular disease (40-70%; 5-12.9%6). However, despite advances in treatment there are few established recommendations on the management of RA-related comorbidities.

Objectives: This study aimed to identify examples of good practice in the care of RA and associated comorbidities meeting standards of patient-centred care, and consider how these could be implemented in other European centres.

Methods: Following a literature review, multidisciplinary teams including specialists in rheumatology, cardiology and internal medicine, nurses, physiotherapists, psychologists, patient liaisons and care coordinators at 12 selected specialist centres across Europe (1 centre per country) were interviewed (approx. 180 interviews). The models identified were critically reviewed by a group of experts including a patient representative, and the degree to which the interventions impacted patient care and could be implemented in other centres was evaluated.

Results: Several care model interventions were identified which may improve quality and the patient’s experience of care, e.g. fully integrates screening and diagnosis of comorbidities; coordination and sharing of care across different disciplines of comorbidity management; tailored individual education of patients and family members on lifestyle; enabling virtual engagement between patients on lifestyle management; and optimised con- venience for patients having to attend multiple specialty appointments.

Conclusion: This study identified and evaluated interventions that may improve patient outcomes and quality of care in RA and associated comorbidities. The next steps will be to disseminate and implement these examples of good practices in a variety of European healthcare systems and settings.

Patient information and education

PARE0019 LIVING WITH SYSTEMIC SCLEROSIS: EXPLORING ITS IMPACT ON CAREGIVERS: A QUALITATIVE STUDY

Rita Schriver1,2, Julia Spierings3, Jeska de Vries-Bouwstra3, Lisa De Puntend3, Ch.M.V. van den Erde4, Madelon Vork5, On behalf of the Arch Working group, 1NVLE, Utrecht, Netherlands; 2Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands; 3University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands; 4Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 5Haga Ziekenhuis The Hague, Department of Rheumatology, Den Haag, Netherlands; 6St Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands

Background: Systemic sclerosis (SSc) is a rare, chronic and heteroge- nous disease with many possible outcomes and an uncertain horizon which presents difficulties not only for patients, but also for caregivers.

Objectives: To gain more insight in the experiences and unmet needs of caregivers for people with SSc in the Netherlands.

Methods: The study had a qualitative design. Participants were recruited by the Dutch patient organization (NVLE) using social media. One focus group and two individual interviews with a semi structured approach were held. Participants were asked to note down their associations with the disease, which lead on to a group conversation moderated by two researchers (MRS, CHE). The focus group was audiotaped and trans-cribed. Individual telephone interviews were summarized. All participants verified and approved the reports afterwards.

Results: Eight caregivers (4 males, 4 females: 4 partners, 2 widowers, 1 parent and 1 friend) of patients with SSc participated. Six attended the focus group session, two were interviewed over the phone. The chal- lenges were reported by the participants. The first challenge is coping with the chronic disease course, unawareness of treatment options and lack of information about limitations in treatment modalities. Furthermore, the distress of patients’ decline, decreased independence, low energy levels and poor energy levels without being able to provide a cure, was experienced as a huge burden by caregivers. Aside from this distress, caregivers per- sonal lives are also affected; future opportunities are cut off, such as starting a family or continuing an active life style.

Caregivers addressed invalidation and the decrease in support from others due to misjudgment and misconceptions about severity, duration
EXERCISE FOR LUPUS PATIENTS

Jeanette Andersen; Lupus Europe, Romford, Essex, United Kingdom

Background: Up to 80% of all Lupus patients experience fatigue and most of them report this as the most severe symptom. One of the major causes of morbidity in SLE patients is chronic, debilitating fatigue, decreasing quality of life, increasing risk of work disability with associated cumbersome healthcare costs. Several research papers show that the only thing clinically proven to have an effect on Lupus fatigue is moderate exercise. If you tell this to a Lupus patient experiencing fatigue, however, you will find it very difficult to motivate them to exercise. The challenge is to make them realise that exercise does not necessarily mean running a marathon or going to the gym – a little movement goes a long way.

**Objectives:** To get lupus patients to exercise and thereby experience less fatigue/better manage their disease.

**Methods:** Develop an exercise program, that is approved by physiotherapists and leading lupologists, easy to do and inspires Lupus patients to keep active even when they feel exhausted.

**Results:** In collaboration with physical therapists Lupus Europe has developed an exercise program from our own experiences and had it approved by leading European lupologists. The program has five levels; from lying in bed up until being able to run and jump. All exercises can be done at home without training tools. In order to make it accessible we have planned to make five videos (with Lupus patients), showing how to do each exercise and five connected pamphlets. We have already recorded the first three levels and are planning to finish the entire “package” in 2019. The materials will be made available to all Lupus patients on the Lupus Europe web site and YouTube channel free of charge.

**Conclusion:** We have already seen good results within the Lupus community, where people are finding the program easy to use and a help to keeping them active. Our hope is, that researchers will use our program to investigate its effectiveness on Lupus fatigue.
