1Hospital Ramón Y Cajal, Madrid, Spain. 2; 7Hospital Henares, Rheumatology, Majadahonda, Madrid, Spain; 8Hospital Universitario Severo Ochoa, Rheumatology, Leganés, Madrid, Spain; 9Hospital Puerta de Hierro Majadahonda, Rheumatology, Majadahonda, Madrid, Spain; 10Hospital 12 de Octubre, Madrid, Spain; 11Fundación Hospital Alcorcón, Rehabilitation, Alcorcón, Spain; 12Fundación Hospital Alcorcón, Clinical Investigation Unit, Alcorcón, Spain; 13Hospital Universitario Fundación Alcorcón, Rheumatology, Alcorcón, Spain; 14Hospital de Móstoles, Rheumatology, Móstoles, Spain

Background: Treatment with biological agents is recognized as a potential risk factor for the development of Progressive Multifocal Leukoencephalopathy (PML), a rare and often fatal demyelinating disease of the CNS caused by John Cunningham Virus infection.

Objectives: Analyze the incidence and trend of hospital admissions for PML in patients with RA, in Spain, during the period between 1999 and 2015.

Methods: Population study based on the analysis of a national administrative database that includes a Minimum Basic Data Set (MBDS) of the income of patients with RA (ICD 9 714). Period: January 1, 1999, to December 31, 2015. The cases of PML were identified due to the presence in the primary and secondary diagnosis of the codes ICD 9 046.0 to 046.9. The population at risk was estimated through the population census of the National Institute of Statistics, with an estimated prevalence of RA of 0.5% in both sexes (0.2% in men and 0.8% in women). Crude and adjusted rates were calculated at national level. The trend was analyzed using Generalized Linear Models (GLM) using the variable year as the analysis variable.

Results: Of the total of 338,343 hospital admissions in patients with RA during the 17 years of the study period, only 14 cases (0.004%) of PML were recorded, nine (64.3%) were women and five (35.7%) men. The mean age was 69.5 years (SD 16.8); 74.56 (SD 14.8) in women and 60.09 (SD 11.0) years in men (p = 0.145). Five patients (35.7%) died during admission (2 women and 3 men) (p = 0.266). The average of the Charlson index was 2.21 (SD 1.7); 3 (SD 2.5) in women and 1.78 (SD 1.1) in men (p = 0.227).

The crude incidence rate of PML was 0.54/100,000 inhabitants * year, 0.85/100,000 inhabitants * year in men and 0.37/100,000 inhabitants * year in women. The Relative Risk male: female was 2.34. The gross rate of PML increased from 0.32/105 * year in the period 1999-2002, to 0.74 between 2011 and 2015, both in women (from 0.19 in the period 1999-2002 to 0.52 from 2011 to 2015) as well as men (from 0.82 in the period 1999-2002 to 1.64 during 2011-2015). It is estimated that this increase is of 19.7% per year.

Conclusion: In Spain, between 1999 and 2015, there has been an increase in the incidence rate of PML in patients with RA. We estimate an annual increase of 19.7%.

CERTOLIZUMAB PEGOL EFFECTIVENESS IN WOMEN OF CHILDBEARING AGE WITH RHEUMATOID ARTHRITIS: RETROSPECTIVE ANALYSIS OF AN INTERNATIONAL MULTICENTRE COHORT

Ennio Giulo Pavali1, Andrea Becciolli2, Roberto Caporal2, Piercarlo Scirli Pallini2, Roberto Gorfa3, Piercarlo Scirli Pallini2, R. Ionescu4, S Rednic4, A Balanescu4, E Rezus4, C Mogosan5, Catalin Codreanu5, 1LORHEN Registry and Gaetano Pini-CTO Institute, Rheumatology, Milano, Italy; 2LORHEN Registry and University of Pavia, IRCCS PoliClinico San Matteo, Rheumatology, Pavia, Italy; 3LORHEN Registry and ASST Spedali Civili, Rheumatology, Brescia, Italy; 4RRBR Registry and University of Medicine and Pharmacy “Carol Davila” Bucharest, Bucharest, Romania; 5RRBR Registry and University of Medicine and Pharmacy “Iuliu Hatieganu” Cluj, Rheumatology, Cluj, Romania; 6RRBR Registry and University of Medicine and Pharmacy “Dr. Ioan Papa” Iasi, Iasi, Romania

Background: Even though certolizumab pegol (CZP) has been licensed for the treatment of rheumatoid arthritis (RA) a long time ago, observational data in real-life settings are still lacking. Moreover, recent data on the lack of transplacental passage (1) make CZP particularly appealing for the treatment of RA women with a desire of pregnancy.

Objectives: To evaluate in a real-life international cohort the frequency of use, the clinical response, and the retention rate of CZP in RA women of childbearing age.

Methods: Data were retrospectively extracted from the Italian LORHEN and the Romanian Registry of Rheumatic Diseases (RRBR) registries, which include all RA patients treated with CZP between December 2010 and October 2018. The analysis was limited to women who received CZP as first-line biologic agent. The study population was stratified according to childbearing age (18-49 versus >49 years). The 6-, 12- and 24-month clinical response was evaluated as the proportion of patients achieving Disease Activity Score 28 (DAS28) remission and compared between the subgroups by a chi-squared test. The 5-year retention rate was calculated by the Kaplan-Meier method and compared between the subgroups by log-rank test.

Results: The whole cohort included 630 RA patients treated with CZP. According to the inclusion criteria, the study population consisted of 308 female RA patients (mean [± standard deviation, SD] age 54±12.1 years; mean disease duration 8.7±8.4 years; baseline DAS28 5.25±1.72, female RA patients (mean [± standard deviation, SD] age 54.2±12.1 years; mean disease duration 8.7±8.4 years; baseline DAS28 5.25±1.72, ±7.2, respectively; p<0.001), no other significant differences in baseline characteristics between the childbearing (n=97, 31.5%) and non-childbearing women at each timepoint (39.4% vs 25.4, p=0.02 at 6 months; 52.8% vs 37%, p=0.014 at 12 months; 52% vs 34.2, p=0.014 at 24 months). The overall 5-year retention rate was 37.1%, with a higher (but not statistically significant) persistence in the childbearing versus non-childbearing subgroup (55.1% vs 37.1%).
CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS ADMITTED TO AN INTENSIVE CARE UNIT IN SPAIN FROM 2005–2015. TREND-AR STUDY

Alberto García-Vadillo1, Natalia Crespi-Villarías2, Carmen Barbabito3, Manuel Fernandez-Prada4, María Galindo-Izquierdo5, Hilda Godoy6, Angeles Herranz Varela7, Cristina Macia-Villa8, Concepción Morado Quiróga9, Jose Luis Morell Hita10, Elia Perez Fernandez11, Javier Quirós11, Virginia Villaverde11, María Espinosa11, Cristina Martinez-Prada11, Ramón Mazzucchelli11, Hospital Dr. La Princesa, Rheumatology, Madrid, Spain; 2Hospital de La Princesa, Rheumatology, Madrid, Spain; 3Hospital de la Campa de la Concepción, Rheumatology, Majadahonda, Spain; 4Hospital Universitario de Guadalajara, Rheumatology, Guadalajara, Spain; 5Hospital Universitat de Bellvitge, Rheumatology, Barcelona, Spain; 6Hospital Universitat de Bellvitge, Rheumatology, Barcelona, Spain; 7Hospital Universitat de Bellvitge, Rheumatology, Barcelona, Spain; 8Hospital de Bellvitge, Rheumatology, Barcelona, Spain; 9Hospital de Bellvitge, Rheumatology, Barcelona, Spain; 10Hospital Universitario de Bellvitge, Rheumatology, Barcelona, Spain; 11Hospital Universitario de Bellvitge, Rheumatology, Barcelona, Spain; 12Hospital de Bellvitge, Rheumatology, Barcelona, Spain; 13Hospital Universitario de Bellvitge, Rheumatology, Barcelona, Spain.

OBJECTIVES: To analyse the clinical features of patients with Rheumatoid Arthritis (RA) that were admitted to an Intensive Care Unit (ICU) from January 2005 to December 2015.

METHODS: A retrospective observational population study was conducted analysing the national database that includes the Minimum Basic Data Sets (MBDSs) of admissions of RA patients to an ICU during the 2005–2015 period. Demographic characteristics, length of stay, clinical course, outcome and the MBDS codes for the main reason of admission were recorded. The cases were detected by the presence of their CIE-9 codes in the primary or secondary diagnoses. Statistical analysis was performed with stata 15.0 software.

RESULTS: During the 11 years of the study, a total of 2719 RA patients required 2806 admissions to an ICU. Average age was 69.7 ± 10.8 years and women constituted 58.5% of the cases. 30% of the patients admitted to an ICU had requirement of ≥ 3 previous admissions and 11% required readmission within the next 30 days. Average Charlson index was 2.33 ± 1.4. Average length of stay was 9.3 ± 14 days and 64.2% died in the ICU during hospitalization. The main causes of hospitalization were cardiovascular events (45.7%), lung diseases (16%) and infections (10%). In the univariate analysis mortality was significantly increased in patients presenting infections (90%), lung disease (89%), severe hepatopathy defined by ascites and/or encephalopathy and/or gastrointestinal bleeding (88%), nephropathy/kidney disease (73%) and a higher Charlson index (2.4 vs 2.2). Multivariate analysis showed that mortality was increased among patients presenting respiratory complications and infections.

CONCLUSION: The most frequent hospitalization causes for patients with Rheumatoid Arthritis in Spain between 2005 and 2015 were cardiovascular, pulmonary and infectious diseases. RA patients that were admitted to the ICU showed an increased mortality. This increased mortality was mainly found in patients presenting respiratory or infectious conditions.

Changes in Left Ventricular Systolic Function Are Predicted by Disease Severity in Patients with Rheumatoid Arthritis Without Prior Cardiovascular Disease

Alessandro Giatl1, Giovanni Ciof2, Giovanni Orsolini3, Luca Idolazzi4, Antonio Carletto1, Andrea Dalbeni5, Federica Ogniben6, Elena Fracassi4, Davide Gatti7, Maurizio Rossini1, Ombretta Viapiana1, +University of Verona, Rheumatology Unit, Department of Medicine, Verona, Italy; 2University of Verona, General Medicine and Hypertension Unit, Verona, Italy.

Background: Occult left ventricular (LV) systolic dysfunction (LVSD) is associated with worse cardiovascular outcomes in asymptomatic patients with arterial hypertension and/or diabetes mellitus. In these patients, LV systolic function may worsen or improve overtime. However, little is known about the changes in LV function during follow up of patients with rheumatoid arthritis (RA).

Objectives: This prospective study analyzed incidence and factors associated with changes in LV systolic function in patients with RA without known cardiovascular disease.

Methods: One-hundred-forty outpatients with RA without overt cardiac disease were recruited between March and December 2014. Patients underwent clinical and echocardiographic evaluation at baseline and after a median period [min-max] of 35 [23-47] months of follow up. Stress-corrected midwall fractional shortening (sc-MFS) was used as measure of LVSD and considered impaired if <86.5%. Disease activity was assessed with the clinical disease activity index (CDAI).

Results: Impaired sc-MFS at follow up (sc-MFS-FU) was detected in 60/140 (43%) patients who were compared with 80 patients with normal sc-MFS-FU. Baseline sc-MFS did not differ significantly between the two groups, which appeared to diverge significantly soon after 1-year of follow up (figure). Baseline anti-citrullinated protein antibodies (ACPA) positivity, high disease activity (CDAI>10) and duration of RA were independently associated with impaired sc-MFS-FU at multiple logistic regression analysis. Among these parameters, ACPA had the highest sensitivity (80%) whereas high disease activity had the highest specificity (89%) for sc-MFS-FU. A predictive score including all three predictors (ACPA status, CDAI>10 and duration of RA) detected impaired sc-MFS-FU with a sensitivity of 76% and specificity of 82% (AUC 0.80 [IC 0.72-0.88], p<0.0001).

Conclusion: This study supports the hypothesis that changes overtime in LVSF in patients with RA are associated with ACPA, high disease activity and duration of disease.

Polypharmacy: A Rarely-Discussed Problem in Rheumatoid Arthritis. Data from a Large Real-Life Study

Ana Paula Gomides1, Cleandro Albuquerque1, Ana Beatriz Vargas-Santos2, Cláudio Brenda1, Ivair Pereira1, Karina Bonifio1, Manoel Bertolde1, Maria Raquel Porto1, Maria de Fátima Sauna1, Paulo Louzada1, Rina Giorgi1, Sebastião Radominski1, Licia Mota1, Geraldo Castelar2, +University of Brasilia, Brasilia, Brazil; 2JANS, Rio de Janeiro, Brazil; 3Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; 4Hospital Universitário – Universidade Federal de Santa Catarina, Florianópolis, Brazil; 5Hospital das Clínicas, Faculdade de Medicina da USP (HCFMUSP), São Paulo, Brazil; 6Faculdade de Ciências Médicas da Universidade Estadual de Campinas, Campinas, Brazil; 7Hospital das Clínicas da Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; 8Faculdade de Medicina – Universidade Federal do Paraná, Curitiba, Brazil; 9Hospital Federal do Paraná, Curitiba, Brazil;

Background: Polypharmacy is concomitant use of five or more drugs and is usually associated with various comorbidities and advanced age. The already demonstrated consequences of polypharmacy are increased side effects, drug interactions, increased hospitalizations, drug handling difficulties, reduced adherence, and even increased mortality. Rheumatoid arthritis (RA) is a chronic systemic disease with preferential involvement between the third and fifth decades. In the process of stabilizing disease andcomorbidities, patients with RA frequently require combined use of several drugs. Despite the possible negative consequences of polypharmacy in RA, there is a shortage of studies in literature.

Objectives: Evaluate prevalence and factors associated with polypharmacy in patients with RA in a real-life setting.

Methods: This is a cross-sectional part of the Rheumatoid Arthritis in Real Life (REAL) study that analyzed RA patients in a real-life context from August to October 2015 in 11 public health services in Brazil. Statistical analysis involved obtaining frequencies of the variables of interest and multiple Poisson regression analyses.

Results: We evaluated 792 patients, of whom 89% were women, with median age of 56.6 years. 78.73% had a positive rheumatoid factor and 55.2% had an erosive disease. The median Disease Activity Score was 3.52, the median CDAI score was 9. Of the patients, 67.9% used 5 or more drugs as follows: mean of 2.8 and maximum of 5 drugs for RA, mean of 2.7 and maximum of 9 different types of medications for comorbidities, and mean of 5.5 and maximum of 11 drugs in total. The most commonly used drugs, besides specific drugs for underlying diseases, were vitamin D (63.8%), folic acid (61.1%), calcium (57%), and antihypertensive drugs (47%). In the multivariate analysis, the use of corticosteroids, methotrexate, and biological DMARDs and number of comorbidities (all with P <0.001) were statistically significant. Age, smoking, rheumatoid factor positivity, and measures of activity by compound disease activity indexes were not associated with polypharmacy.

Conclusion: The prevalence of polypharmacy was high (67.9%) in this population with RA, much higher than that described for elderly populations and other chronic diseases. This data can serve as an alert for this important and rarely-discussed aspect of RA.

SPECIFICITY OF THERAPY FOR RHEUMATOID ARTHRITIS PATIENTS UPON THYROID INVOLVEMENT IN THE AUTOIMMUNE DISEASE

I. Zborovskaya1, Olga Paramonova2, Olga Rusanova2, O. Zborovskaya3, I. Gontar1.

Objectives: To study the specifics of therapy for rheumatoid arthritis patients upon thyroid involvement in the autoimmune disease.

Methods: The study included patients diagnosed with rheumatoid arthritis from 2010 to 2020, without any exclusion criteria. Rheumatoid arthritis activity was assessed utilizing DAS-28 Calculator.

The presence of thyroid lesion was evaluated by means of clinical workup, ultrasound examination, and laboratory tests, including measuring the concentration of TTH, free T3, T4, as well as anti-TPO. Antibodies to T3 and T4 (anti-T3 and anti-T4) were measured by enzyme immunoassay, and the findings were shown in absorbance units. The cut-off values of positive and negative findings for anti-T3 (0.098 absorbance units) and anti-T4 (0.093 absorbance units) were calculated by ROC curve analysis utilizing sera from relatively healthy donors (n = 39). The results were shown as an arithmetic mean ± standard error (M ± m).

Results: 72 patients with rheumatoid arthritis participated in the study. The mean activity of rheumatoid arthritis assessed by DAS 28 Calculator was 3.2 ± 1.4 points. Extra-articular presentations were detected in 20 patients, 5 of whom showed clinical manifestations of thyroid lesion. All five patients were marked by low TTH and a high activity of rheumatoid arthritis (4.8 ± 1.9 points of DAS28). In 73 patients antibodies to T3 were detected (0.128 ± 0.047 absorbance units). Apart from the thyroid gland, no clear association between these antibodies and lesions of other organs or systems were noted. A statistically significant tendency for an increase in X-ray stage linked to increased antibodies to T4 was noted (p = 0.034; ANOVA); an inverse relation was noted for antibodies to T3 (p = 0.034; ANOVA). The association with DAS 28 for antibodies to T4 (r=0.525, p=0.031) and for antibodies to T3 (r=-0.391, p=0.040) was also inverse and statistically significant. Besides, another statistically significant correlation was revealed between the value of DAS 28 and TTH concentration (r=-0.330, p=0.046).

Conclusions: The available findings demonstrate that a high activity of rheumatoid arthritis is associated with hypothyroidism development, despite the tendency for increased count of antibodies to T4 which is typical of rheumatoid arthritis. The possibility to modify the activity of rheumatoid arthritis by correcting thyroid dysfunction is very important both for developing a strategy of managing drug-resistant cases of rheumatoid arthritis, and for the management of this condition in general.

Cognitive Impairment and Rheumatoid Arthritis in Moroccan Patients

Azzouzi Hamida, Fadoua Chennouf, Eddarami Jalila, Ichchou Linda.

Muscle Mass Index less than 5.45 kg/m² in women and less than 7.26 kg/m² in men, while sarcopenic obesity was defined by the presence of sarcopenia more abdominal obesity. The GCs use and dosage (prednisone and methylprednisolone) were analyzed reviewing the clinical records. Anti-cyclic citrullinated peptides (anti-CCP) antibodies, rheumatoid factor (RF) levels, high sensitivity C reactive protein (hsCRP), erythrocyte sedimentation rate (ESR) were determinate. The morning stiffness, clinical activity of disease (DAS28-ESR score) and disability index functional (HAQ-DI) were measurement.

Results: In this study 86% of the population had sarcopenia and 44% sarcopenic obesity. The 62.8% under GCs therapy. The prednisone dosages was positively associated to sarcopenia (>5 mg/day; OR=4.3, p=0.003) and sarcopenic obesity (OR=3.2, p=0.06). The intramuscular pulse of methylprednisolone (40 mg/kg) was associated to sarcopenic obesity phenotype (OR=2.61, p=0.09). Regarding the clinical and serological markers in RA, high disease activity (DAS28-ESR score) was associated to sarcopenia (OR=6.6, p=0.01) and sarcopenic obesity (OR=6.3, p=0.02). The morning stiffness (p=0.03), RF (p=0.05), anti-CCP positive (p=0.01) and HAQ-DI score (p=0.04) were too associated, mainly to sarcopenic obesity.

Conclusion: Sarcopenia and sarcopenic obesity are associated to GCs dosage and with serological and disease activity markers in RA patients from southern Mexico. So that is needed promote monitoring and management of sarcopenia and sarcopenic obesity in RA patients.

CARdiovascular risk in the rheumatoid arthritis PATIents of the Gulf Corporation Council-GCC: what contribute to the carotid INTima media thickness

Suad Hannawi, Haifa Hannawi, Issa Al Salmi,

Background: Rheumatoid arthritis (RA) is a common inflammatory joint disease that occurs in 1-3% of population. RA patients are at higher risk of cardiovascular disease (CVD). This accelerated atherosclerosis can’t be fully explained by the traditional CVD risk factors. The CVD risk factors had never been investigated in the RA patients of Gulf Corporation Council (GCC).

Objectives: For the first time, this study assesses the CVD as manifested by carotid intima media thickness (cIMT) and the CVD risk factors (traditional and non-traditional) in RA GCC-population.

Methods: 216 RA (179 (83%) F and 37 (17%) M) GCC patients, who were free of atherosclerosis (CVD & Cerebrovascular diseases) included over 5 years (2013-2018). Diabetic, hypertensive, gout, renal and thyroid patients, pregnant, current smokers and those with history of smoking, and patients on diuretics medications were excluded. cIMT ultrasound (US) measurements were obtained using a real-time US scanner equipped with a 7.5-MHz linear probe. Blood tests (full blood counts, liver function, renal profile, and inflammatory markers), demography details, and body mass index (BMI) had been obtained within the same week of the cIMT scan. The correlation between cIMT and other variables were calculated using simple linear and multivariate regression analysis.

Results: The mean cIMT was 0.58 ± 0.11 mm (Min 0.28, Max 0.98). The mean age was 48 ± 13 years (48 ±12 yrs for females, 50±16 yrs for males, p= 0.279).

univariate regression analysis showed a positive linear relationship between cIMT and age of the participants (p=0.001, CI: 0.00, 0.01), total cholesterol (p=0.005, CI: 0.01, 0.01), high density lipoprotein (HDL) (p=0.001, CI: 0.00, 0.01). The mean level of education was significantly related to a-MMSE (p=0.0001).

Conclusion: It is certainly true that the interpretation and evaluation of cognitive functions in a difficult task, especially in an illiterate and disabled patient. However, in our study A-MMSE results were low even after test repetition, and in a state of disease remission. Although these results underscore the high frequency of cognitive impairment in RA patients, we estimate that further studies are eligible to confirm causality.

DURATION OF EXPOSURE TO BIOLOGICS AND BODY COMPOSITION IN MEN WITH RHEUMATOID ARTHRITIS

Background:

Higher inflammatory load associates with increased risk of cardiovascular events in patients with rheumatoid arthritis (RA). We recently reported that occult atherosclerosis burden on coronary computed tomography angiography (CCTA) predicted long-term cardiovascular events (CVE) in RA above and beyond cardiac risk factors or scores. We further showed that higher cumulative inflammatory burden independently predicted coronary plaque progression.

Objectives:

To explore whether the duration of exposure to biologic DMARDs and/or statins during the study period mitigates the effect of cumulative inflammatory load on coronary plaque progression.

Methods:

One hundred-one participants with a baseline CCTA underwent a follow-up evaluation in 8±3.6 months. Plaque burden was reported as segment involvement score (SIS, describing the number of coronary artery segments with plaque per patient) and coronary artery calcium (CAC), quantified by the Agatston method. Robust logistic and linear regression models evaluated effects of predictors on plaque (SIS) progression and CAC change, respectively. Predictors of interest were time-averaged c-reactive protein (CRP), duration of bDMARD exposure (years), duration of statin exposure (years), and their 2- and 3-way interactions. Models were controlled for age and baseline hypertension. Significant interactions were subsequently decomposed and examined based on a median split for the duration of biologic and statin exposure.

Results:

A significant interaction between inflammation and statin exposure duration was observed for plaque progression (p=0.019 (figure 1A); in patients with shorter statin exposure (<1 year), higher inflammation predicted a greater likelihood of plaque progression [odds ratio (OR)=1.90, 95% confidence interval (CI)=1.15 to 3.14, p=0.012. By contrast, longer statin exposure (>1 year) attenuated that risk [OR=0.57, 95% CI=0.35 to 0.80, p=0.001] in patients with longer exposure to statins (>1 year), inflammation was not related to plaque progression [OR=1.25, 95% CI=0.48 to 3.31, p=0.65] or CAC change [OR=1.06, 95% CI=0.43 to 0.21, p=0.52]. In patients with longer biologic exposure (>5 years) the length of treatment with statin did not moderate the effect of cumulative inflammation on plaque progression [p=0.229, figure 1].

Conclusion:

The relationship between cumulative inflammation, length of treatment with bDMARDs, statins and their ultimate impact on coronary plaque progression in RA are highly nuanced. The effect of the duration of statin exposure on coronary plaque burden progression seems relevant only in the context of insufficient biologic exposure; shorter treatment with statins in that setting allows for significant coronary plaque progression in response to higher cumulative inflammatory load. In contrast, longer statin exposure attenuates that risk.

DURATION OF EXPOSURE TO BIOLOGICS AND STATINS MODERATES THE EFFECTS OF CUMULATIVE INFLAMMATION ON CORONARY ATHEROSCLEROSIS PROGRESSION IN RHEUMATOID ARTHRITIS

George Karpouzas, Sarah Ormseth, Elizabeth Hernandez, Matthew Budoff. Harbor UCLA Medical Center, West Carson, United States of America

Background:

Rheumatoid arthritis (RA) is a chronic immune inflammation of the joints, leading to early disability of patients at high risk of cardiovascular events and osteoporotic fractures. This problem is important today in men with RA, because, due to more frequent severe disease and increased mortality in the year after the fracture. Reduction of bone mineral density (BMD) and muscle mass are significant predictors of fractures, which leads to the high importance of studying the state of BMD and body composition.

Objectives:

Improving the diagnosis of osteoporosis in patients with RA of the male gender with the regard of BMD and body composition.

Methods:

The study involved 110 male patients with a documented diagnosis of RA at the age of 59 [53; 65] years. Depending on the taking of glucocorticosteroids (GCS) all patients was allocated two groups: I subgroup - 60 patients who are not taking GCS and subgroup II - 50 patients who are taking GCS. The control group consisted of 30 healthy men comparable by the age and body mass index. The study of BMD at the lumbar spine (L1-L4) and femoral bone was carried out, using the «Whole body» («The whole body»). Assessment of body composition was carried out, using the «Whole body» (=The whole body). Sarcopenia was diagnosed as a decrease in lean mass index of less than 7.26 kg/m².

Results:

63.6% of patients with RA showed a reduction of BMD corresponding osteopenia/OP. OP was diagnosed in 28 (25.5%) patients with RA, and osteopenia - in 42 (38.2%). The detection rate of OP in the second subgroup was significantly higher (p<0.05), than in the first subgroup (48% and 5% respectively). The most significant decrease in BMD was observed in the neck of the femur in the main group as a whole and in individual subgroups. There was a negative correlation degree of activity of RA and indicators of BMD of the lumbar spine (r=-0.4, p<0.05) and proximal femur (r=-0.38, p=0.05). Assessment of body composition showed that patients of the main group were significant decrease in the total lean mass (LM) of the body, and the trunk and limbs of LM compared with patients of the control group (p<0.05). Sarcopenia detected in 66 (60%) of RA patients, whereas in the control group it was absent. In 44 (67.2%) male patients with RA with sarcopenia decreased BMD to the level of osteopenia (34.9%) and OP (31.8%). Obtained a negative

FR10052

BODY COMPOSITION IN MEN WITH RHEUMATOID ARTHRITIS

Artem Kondrashov, Nadezhda Shostak, Anaida Muradyants. Pirogov Russian National Research Medical University (RNRMU), Academician A.I. Nesterova chair of faculty therapy, Moscow, Russian Federation

Background:

Rheumatoid arthritis (RA) is a chronic immune inflammation of the joints, leading to early disability of patients at high risk of cardiovascular events and osteoporotic fractures.

Objectives:

To study the body composition at the lumbar spine (L1-L4) and femoral bone of male patients with RA and control men.

Methods:

The study of BMD at the lumbar spine (L1-L4) and femoral bone was carried out, using dual-energy x-ray absorptiometry using a bone mineral density –STRATOS dR® (DMS, France). Assessment of body composition was carried out, using the «Whole body» (=The whole body). Sarcopenia was diagnosed as a decrease in lean mass index of less than 7.26 kg/m².

Results:

63.6% of patients with RA showed a reduction of BMD corresponding osteopenia/OP. OP was diagnosed in 28 (25.5%) patients with RA, and osteopenia - in 42 (38.2%). The detection rate of OP in the second subgroup was significantly higher (p<0.05), than in the first subgroup (48% and 5% respectively). The most significant decrease in BMD was observed in the neck of the femur in the main group as a whole and in individual subgroups. There was a negative correlation degree of activity of RA and indicators of BMD of the lumbar spine (r=-0.4, p<0.05) and proximal femur (r=-0.38, p=0.05). Assessment of body composition showed that patients of the main group were significant decrease in the total lean mass (LM) of the body, and the trunk and limbs of LM compared with patients of the control group (p<0.05). Sarcopenia detected in 66 (60%) of RA patients, whereas in the control group it was absent. In 44 (67.2%) male patients with RA with sarcopenia decreased BMD to the level of osteopenia (34.9%) and OP (31.8%). Obtained a negative

Disclosure of Interests:

None declared, Matthew Budoff: None declared
correlation parameters LM and absolute 10 years risk of osteoporotic fractures (r=0.302, p<0.05) on FRAX. 

Conclusion: 63.6% of men suffering from RA, there was a decrease in BMD, the corresponding OP/osteopenia with a primary reduction of BMD at the femoral neck. Decrease BMD in patients with RA was significantly associated with a high degree of disease activity (r=0.4, p< 0.05). Taking GCS had no significant effect on BMD at the femoral neck. Analysis of body composition in 55% of patients with RA showed a reduction in the level of LM limbs sarcopenia. Obtained correlation lower BMD and LM limbs (p<0.05; r=0.28).

Thus, in patients with RA male along with OP/osteopenia showed a significant decrease in LM that given the biomechanics of movement can be an additional risk factor for falls and fractures.

FRID0053 ACCELERATED ATHEROSCLEROSIS IN PREMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS (15 YEARS PROSPECTIVE STUDY)

Melka Koren Krajnc 1, Radovan Hojić 2, Izot Holec 2, Artur Pahor 1, 1University medical Center Maribor, Dept. of Rheumatology, 2000 Maribor, Slovenia
2University medical Center Maribor, Dept. of Nephrology, 2000 Maribor, Slovenia

Background: Rheumatoid arthritis (RA) is chronic inflammatory disease, associated with increased mortality and morbidity due to higher cardiovascular risk in these patients.

Objectives: Traditional risk factors are not the only answer for accelerated atherosclerosis. In long term prospective study, we investigated the relationship between asymptomatic atherosclerosis and traditional risk factors as well inflammatory markers in patients with RA and matched healthy controls.

Methods: In 60 RA premenopausal women and 34 matched controls values of laboratory test results, concentrations of inflammatory mediators, matrix metalloproteases (MMP) and markers of inflammation were measured. Using B-mode ultrasonography carotid intima-media thickness (cIMT) and plaques occurrence (markers of asymptomatic atherosclerosis) as baseline and after 15 years of observation were defined in both groups. The differences in concentrations of inflammatory mediators, MMPs and markers of inflammation were compared. The relationship of inflammatory mediators and markers, MMPs and markers of asymptomatic atherosclerosis was examined using regression models.

Results: After the follow up statistically significant higher values of inflammatory markers like selective adhesion molecules ICAM & VCAM, interleukin 6 (IL-6), tumour necrosis factor alpha (TN alpha) and MMP-3 in patient’s group was found. Among traditional risk factors only sedentiation rate and CRP levels were statistically higher in patient’s group. More plaques were found in patients’ group (12.9% vs. 42.4%; p=0.005), patients had also higher values of cIMT (p=0.0001). Using multiple linear regression analysis only VCAM was found as independent prognostic factor for plaques occurrence (p=0.016), but not for cIMT (p=0.314) in RA patients after the follow up.

Conclusion: Asymptomatic atherosclerosis is accelerated in premenopausal women with RA patients. The results of our study showed the association between the inflammation and accelerated atherosclerosis, VCAM was found as independent risk factor for plaques occurrence in these patients.

FRID0054 CHARACTERISTICS OF PATIENTS WITH ELDERLY-ONSET RHEUMATOID ARTHRITIS AND INVESTIGATION OF DRUG THERAPY

Takeshi Kuroda1, Hiroe Sato1, Daitsuke Kobayashi1, Takeshi Nakatsume1, Yoko Wada1, Masaaki Nakano2, Ichiro Narita1, 1Niigata University Graduate School of Medical and Dental Sciences, Division of Clinical Nephrology and Rheumatology, Niigata, Japan; 2Niigata University, Faculty of Medicine, Niigata, Japan

Background: It is expected that the increase in average life expectancy in recent years would also be observed even in patients with rheumatoid arthritis (RA)

Objectives: We compared data for RA patients obtained between 1991 and 2018 to clarify the current clinical picture of RA in elderly patients.

Methods: We evaluated 429 and 368 RA cases seen at our department in 1991 and 2018, respectively. The patient ages and sex ratios in the two groups were first compared, and then the clinical features of 260 patients with younger-onset RA (YORA; onset age ≤65 years) and 108 patients with elderly-onset RA (EORA; onset age >65 years) in the 2018 group were evaluated. All patients satisfied the 1987 and 2010 Rheumatoid arthritis classification criteria for RA, and their data were obtained from the medical records. Patient data at the onset of RA were used. The study protocol was approved by the Institutional Review Board of Niigata University. All statistical analyses were performed with SPSS ver. 13 for Windows, and differences at p<0.05 were considered to be statistically significant.

Results: The peak age at RA onset was 50s-60s in 1991 and 60s-70s in 2018. In 1991, the male-female ratios in the <65 yr- and >65 yr-age groups were 0.14 and 0.19, respectively, whereas the corresponding ratios in 2018 were 0.25 and 0.38, respectively. Although the proportion of elderly patients increased, homogeneity testing of the odds ratio revealed no significant difference. Among the 368 RA patients in the 2018 group, initial involvement of large joints was more frequent in those with EORA, whereas initial involvement of small joints was more frequent in those with YORA (p<0.05). Statistical analysis demonstrated no significant inter-group differences in hemoglobin, WBC, BUN, uric acid, CRP, ESR or serum creatinine, but the estimated glomerular filtration rate was significantly higher in the YORA group (P<0.00). The frequencies of hematuria and proteinuria (>1.0 g/Cl) showed no inter-group differences. The frequency of RF positivity also did not differ between the groups, but the RF titer was higher in the YORA group (p<0.01). ACPA showed no inter-group difference in terms of either the frequency of positivity or titer. Among other features after diagnosis, AA amyloidosis was observed in only 7 (2.7%) of the YORA patients. RA proceeded PMR in 7 patients in each group, and the frequency of PMR was significantly (P<0.01) higher in patients aged >60 years. For therapy, MTX was used in about 70% of YORA patients, its use being more frequent than EORA patients (p<0.01), although the dose employed did not differ significantly between the two. About half of all patients received steroid, and neither the frequency nor the dose differed significantly between the YORA and EORA groups. Biological agents were used in 61% of YORA patients and 29% of EORA patients, the difference being significant (p<0.01). Abatacept was used significantly (p<0.05) more often in the EORA group because of the low frequency of severe infections, but the frequency of use of other biological agents and Jak inhibitors did not differ significantly between the groups.

Conclusion: The characteristics of EORA patients differ from those of YORA patients. Diagnosis requires attention to PMR. In YORA, attention to amyloidosis is also required in view of the fact that treatment was insufficient in the past. Pharmacotherapy should be based on the characteristics of aging in elderly patients with RA. The diagnosis and treatment of RA in elderly patients is an issue of future concern.
AN EQUATION FOR ESTIMATED CARDIORESPIRATORY FITNESS IN RHEUMATOID ARTHRITIS PATIENTS IS NEEDED

Marthe Halsen Lijff1,2, Mari Hoff1,3, Vibeke Videm1,3, 1NTNU – Norwegian University of Science and Technology, Trondheim, Norway; 2Levanger Hospital, Levanger, Norway; 3St. Olavs Hospital, Trondheim, Norway

Background: RA patients are deconditioned and on average have decreased cardiopulmonary fitness compared to healthy controls. The objective was to develop a new equation for eCRF specifically for RA patients, using previously reported measures of eCRF from healthy individuals.

Methods: Among participants with self-reported RA in the second and third surveys of the Norwegian population-based Nord-Trøndelag Health Study (HUNT2 and 3), RA patients were identified from hospital case files using standardized diagnostic criteria. The mean eCRF of participants with and without RA were calculated and the 95% confidence intervals compared.

Table 1. Mean eCRF (mL/kg x min) and 95% CIs of RA patients and participants without RA attending HUNT2 and 3. Age categories with n=8 RA patients in grey.

</table>

Mean eCRF (CI), n

Table 1. Mean eCRF (mL/kg x min) and 95% CIs of RA patients and participants without RA attending HUNT2 and 3. Age categories with n=8 RA patients in grey.

Conclusion: The eCRF CIs of RA patients and participants without RA were overlapping in all age categories except for men aged 60-69 years in HUNT 3 (Table1). This is contradictory to previous findings where RA patients were deconditioned compared to healthy controls (1). A probable explanation is that equations for eCRF were developed from healthy populations, and therefore overestimate eCRF in RA patients. For better CRD risk management including CRF as an important risk factor, an equation for eCRF developed specifically for RA patients is needed.

NESTED CASE-CONTROL STUDY: ASSOCIATED FACTORS WITH INSulin RESISTANCE IN A RHEUMATOID ARTHRITIS INCEPTION COHORT

Sara Manrique Arija, Natala Mena-Vázquez, Inmaculada Ureña, F. Gabriel Jiménez-Núñez, Clara Fuego-Varela, Antonio Fernandez-Nebro. UCG of Rheumatology at the Hospital Regional Universitario de Málaga (HRUM), Institute for Biomedical Research in Malaga (IBIMA), Malaga University 1, Malaga, Spain

Objectives: To assess insulin resistance (IR) in patients with rheumatoid arthritis (RA) and compare it with healthy controls and to analyze the association between the accumulated inflammatory burden in patients with RA and IR.

Methods: Design: Nested case-control study. Population: consecutive RA-patients (ACR/EULAR 2010 criteria), >16 years, selected from a prospective inception cohort (diagnosis of RA between 2007 and 2011). Patients with Diabetes Mellitus (according to ADA 2010 criteria) were excluded. Controls: sex-, age- and BMI-matched controls were collected from a health center in our hospital area. Protocol: Cases and controls were evaluated by a rheumatologist. Clinical data of disease activity (RA patients), analytical values and oral glucose tolerance test (OGTT) were determined. Main outcome: IR measured by the homeostasis model for insulin resistance (HOMA-IR) (IR=[2.29 μU/mmol x mL/mg] (Secondary outcome: IR measured by quantitative insulin sensitivity check index (QUICKI))<0.337) and by the homeostatic model assessment of β-cell function (HOMA β). Variables: Demographic, clinical-analytical variables, Disease Activity Score 28 points (DAS28-ESR), Health Assessment Questionnaire (HAQ), BMI (according to WHO classification) and glucose and insulin before and after OGTT values. Statistical analysis: Descriptive and paired T-test or Chi-square test followed by Multivariate Linear Regression in RA patients (Dependent variable: HOMA-IR).

Results: Two hundred subjects were studied, 31 of them were excluded after OGTT. Finally 169 subjects were included; 89 RA and 80 controls. The mean age of patients with RA was 56.6±10.3 years. Most of them were women (75.3%), with seropositive (FR 82.0% y ACPA 75.3%) and erosive (81.1%) disease. The average duration of the disease was 98 months (81.1 years). The delay in the diagnosis of RA was 10.9 months (5.4 - 25.6) with a mean DAS28 index since the beginning of the disease of 3.11 (0.8). Differences between clinical characteristics and in relation to IR between cases and controls are shown in Table 1. No significant differences in the proportion of subject with IR in cases and controls were observed and 28.1% of patients with RA had IR. Of the 25 patients with IR, the majority, 68%, presented a DAS28 score> 3.2 (moderate-high activity index). In multivariate analysis, the independent variables associated with IR in patients with RA were: Obesity [OR=6.01; β=1.795 (p=0.002), disease activity (CR=2.77; β=1.021 [p=0.009]) IL-1β [OR=1.59; β=0.484 (p=0.024)]. This model would explain 37.5% of the variability of the IR (R²=0.375).

Conclusion: We did not find an increased IR in patients with RA compared with healthy controls, which may be due to adequate treatment and good control of inflammatory activity in the most of patients with RA. Obesity, inflammatory activity (measured by mean DAS28 index) and IL-1β were the predictors of IR in patients with RA in our study.

FRID057 INSULIN RESISTANCE IN ELDERLY ONSET RHEUMATOID ARTHRITIS AND POLYMYALGIA RHEUMATICA

Melania Martínez-Morillo, María Luisa Granada, Águeda Prior-Espanol, Anahy Brandy-Garcia, Susana Holgado Pérez, María Aparicio-ESpinar, Laila Gilfe, Anne Riveros-Frutos, Clara Sangüesa-Gomez, Jordi Carmins-Fábregas, Ivette Casasalot-Sok, Arivika Nack, Alejandro Olive, Lourdes Mateo Soria. Hospital Germans Trias i Pujol, Rheumatology, Badalona, Spain

Background: Rheumatoid arthritis (RA) patients have a higher insulin resistance (IR) and some studies report that it is present at diagnosis. Systemic inflammation has been pointed out as the reason. However, data on polymyalgia rheumatica (PMR) are controversial.

Objectives: To analyse IR in a group of untreated patients with a recent diagnosis of RA and PMR, and to establish predictive factors related with IR.

Methods: Longitudinal observational study of patients older than 60 years, newly diagnosed with elderly-onset AR (ACR/EULAR 2010) and PMR (ACR/EULAR 2012) with healthy control group of the same age. Inclusion: consecutive and voluntary. Exclusion: patients with insulin-dependent diabetes. Follow-up time: 12 months. The clinical-epidemiological, anthropometric and analytical characteristics were collected. IR was calculated by HOMA-IR ([homeostatic model assessment of insulin resistance) = glucose (mg/dL) * insulin (mUI/L)/405] at baseline and at 12 months. HOMA-IR>2.75 was considered IR (according to Spanish data).

The statistical study was performed with Stata 15.1.

Results: We recruited 42 patients with RA, 18 with PMR and 18 healthy controls. None of them had received treatment with corticosteroids or with DMARD at the baseline visit. Baseline characteristics are summarized in the table.

At baseline visit, 66.7% of patients with elderly-onset RA had IR, compared with 33.3% of controls (p=0.024) and 27.8% of PMR (p=0.006). Therefore, the prevalence of IR in patients with RA doubled that of controls and patients with PMR before starting treatment. After 12 months of evolution and treatment, patients with RA and IR decreased from 66.7% to 51.2%, not being statistically significant (p=0.179). On the other hand, the percentage of patients with PMR and IR remained the same (27.8%). The differences in IR between RA and PMR at 12 months remained statistically significant (p=0.048).

The results we decided to analyze the predictive factors related with IR only in the 42 patients with RA. In the univariate logistic regression analysis, the predictors of presenting IR were the BMI, the abdominal perimeter and the scapular girdle involvement. Specifically for BMI, for each of 2 kg/m2 the probability of having IR was 1.24 times higher (OR=1.24, IC95%: 1.12-1.37). Patients with scapular girdle involvement had a 4-fold increased risk of developing IR (OR = 6.0, 95% CI: 1.3-26.6). And for every 5 centimetres of abdominal perimeter the risk increased almost 4 times more (OR=3.9, 95% CI: 2.9-5.1). In the multivariate analysis, the only independent factor to increase the IR was the abdominal perimeter (aOR = 1.23, IC95%: 1.07-1.41).

Conclusion: Patients with elderly-onset RA have a higher IR than the general population. High IR in RA is present at diagnosis. IR in AR is not exclusively mediated by systemic inflammation, since patients with PMR do not have this increase. The predictors of presenting IR in elderly-onset AR were BMI, scapular girdle involvement and abdominal perimeter. Only the abdominal perimeter was shown as an independent factor.

SOLUBLE RECEPTOR FOR ADVANCED GLYcation END PRODUCTS (sRAGE) AND RISK FOR CARDIOVASCULAR DISEASES IN FEMALES WITH RHEUMATOID ARTHRITIS

Marta Naudi1, Marta I. Bakowska2, Sofia Töyrä Silversward3, Malin Erlandsson2, Lovisa Lyngfelt4, Karin Me Andersson5, Rille Pullerits1, 1Institution of Medicine, Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2Institution of Medicine, Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden.

Background: Rheumatoid arthritis (RA) is strongly associated with increased frequency of cardiovascular disease (CVD), which remains the major cause of mortality in these patients. Current CVD risk assessment algorithms have limited predictive value for RA patients. Soluble receptor for advanced glycation end products (sRAGE) has recently emerged as a biomarker of inflammation with an inverse correlation with traditional CVD risk factors as age, hypertension and hypercholesterolemia.

Objectives: In a cohort of female RA patients with no previous history of CVD, we assessed whether sRAGE levels were associated with increased risk of CVD during a prospective 5 years follow up.

Methods: Serum sRAGE levels were measured in 171 female RA patients (median age 53; range 21-71) at the inclusion to the study. The CVD risk was estimated using the Framingham algorithm and both traditional and RA associated risk factors for CVD were measured. All the patients were prospectively followed up to 5 years for new CV events, type II diabetes and medication for hypertension and hyperlipidemia. Statistical analysis was performed to compare CVD risk and actual events in the patients with low sRAGE (<1700 pg/ml) vs. high sRAGE (>1700 pg/ml).

Results: The comparison of patients with low sRAGE (n=125) and normal-high sRAGE (n=46) found no significant differences in frequency of the traditional CVD risk factors including age>60 years (30% vs 41%), overweight (50% vs 41%), smoking (14% vs 11%), incident hypertension (16% vs 16%) and hypercholesterolemia (56% vs 67%) at baseline and led to similar estimated CVD risk (7.65% vs 8.45%). The RA-related CVD risk factors including disease duration >10 years (37% vs 39%), presence of autoantibodies (89% vs 95%), disease activity (DAS28, 46% vs 60%) were also similar in the low-and high sRAGE groups. At 5 years follow up, 11 new CVD events were registered. The events occurred with similar frequency in the low sRAGE and high sRAGE groups (5.6% vs 8.7%). Despite a lack of difference in CVD events, we did observe a significant increase in frequency of new medication for hypertension in the low sRAGE group (21.5% vs. 63%, p=0.01), but not in medication for type II diabetes or statins.

Conclusion: In this study, we found no association between serum levels of sRAGE and the estimated CVD risk or actually occurred CVD events in female RA patients.

THE CONTRIBUTION OF TENOSYNOVITIS OF SMALL JOINTS TO THE SYMPTOM MORNING STIFFNESS IN PATIENTS PRESENTING WITH UNDIFFERENTIATED AND RHEUMATOID ARTHRITIS

Aleid Boer1, Debbie Boeters1, Ellis Niemantsverdriet1, Annette van der Helm - van Mil2,2,1,1LUMC, Reumatology, Leiden, Netherlands; 2ErasmusMC, Reumatology, Rotterdam, Netherlands

Background: Morning stiffness (MS) is characteristic of Rheumatoid Arthritis (RA) that is associated with functional disability. Despite the known parallel in the circadian rhythm of MS and that of several hormones and pro-inflammatory cytokines in the systemic circulation, it is insufficiently known to what extent local inflammatory processes contribute to this symptom. The correlation between MS and the number of swollen joints is relatively weak but may be underestimated by insufficient sensitivity in measuring local inflammation. MRI is more sensitive in detecting local inflammation. Furthermore, MRI-detected tenosynovitis of small joints is increasingly recognized as early feature of RA which is also associated with functional impairments. Recently it was proposed that this may contribute to MS.

Objectives: We assessed the relationship between MS and MRI-detected inflammation of synovitis and tenosynovitis in particular.

Methods: 286 consecutive patients newly presenting with undifferentiated and rheumatoid arthritis underwent contrast-enhanced 1.5T-MRI of (2-5) MCP-, (1-5)MTP-, and wrist-joints. Scans were scored for tenosynovitis according to Haraldsdottir and for synovitis/tenosynovitis (AMARIS) methodology. MS was dichotomized as-as 60 minutes. Associations between MS and tenosynovitis/synovitis were tested with logistic regression and the presence of a biologic interaction was assessed categorically (singly or simultaneous presence of synovitis/tenosynovitis).

Results: MS was present in 40% of patients. Tenosynovitis was more often present in patients with MS than without MS (80% versus 65%), OR 2.11 (95%CI 1.21;3.69). Also synovitis was more often present in patients with MS (58% versus 44%), OR 1.63 (1.22;2.16). In categorized analysis the largest association was found for concurrent synovitis and tenosynovitis OR 2.43 (1.30;4.54); whereas single presence of synovitis was not associated (OR 0.85 (0.21;3.47)). The variance explained in all analyses on morning stiffness was small, ranging 3-6%.

Conclusion: Tenosynovitis, and simultaneous presence of tenosynovitis and synovitis in particular, was associated with MS. However, effect sizes suggested that the contribution of local inflammation to this symptom is rather limited.

Acknowledgement: E.C. Newsum and W.P. Nieuwenhuis are acknowledged for scoring MRI-scans.

INFECTIONS AMONG RHEUMATOID ARTHRITIS PATIENTS STARTING OR SWITCHING BIOLOGICAL AGENTS. A SYSTEMATIC LITERATURE REVIEW

Marta Novella-Nayar1, Alejandro Gomez-Gomez2, Maria Auxiliadora Martin-Martinez2, Mercedes Guerra-Rodriguez2, Enrique Rayas1, 1Hospital Universitario de Torrevieja, Rheumatology, Madrid, Spain; 2Hospital Universitario Infanta Sofia, Rheumatology, Madrid, Spain; 3Spanish Society of Rheumatology, Research Unit, Madrid, Spain; 4Hospital Universitario San Cecilio, Rheumatology, Granada, Spain

Background: The increased rate of infections is one of the most relevant issues regarding biologic therapies in Rheumatoid Arthritis (RA). There is a large number of studies comparing different biologic agents and biologic vs synthetic DMARDs in order to assess their safety profile. Nevertheless, the main question is whether biologics really increase the infection risk by themselves. Up to date, different studies tried to clarify the actual role that these drugs have in this potentially serious adverse effect, searching for other predisposing conditions related to patient clinical characteristics.

Objectives: To compare the risk of infections between patients starting biologic agents for the first time (naive) and patients with an inadequate response to a previous biologic agent (switchers).

Methods: A search strategy was performed by the Spanish Society of Rheumatology documentalist over Pubmed, Embase and Cochrane Library databases (from January 2008 to February 2018). All the references retrieved were managed using Endnote X7®. Screening of studies, data collection and data analysis was performed by 2 reviewers. Meta-analysis, systematic reviews of Randomized Controlled Trials (RCT), Clinical Trials or Cohort studies, comparing data from adult RA patients starting biologics and switching biologics, were selected. After the first screening, a critical review was performed using electronic FLC platform for critical appraisal tools (Osbea®) and The Scottish Intercollegiate Guidelines Network (SIGN) was considered to classify the scientific evidence of the selected studies. Studies including patients with chronic infections, tuberculosis reactivations or surgical infections were excluded.

Results: 8 studies were included: 1RCT, 2 Open label study, 1 Open label extension from RCT, 2 subgroups analysis from RCTs and 2 prospective cohort studies. Overall infection rate was higher in switchers than in naïve patients, with a mean variation between 0-9 and 1.8 100 PY, serious infections were also higher in switchers patients, 2.2 100PY. In both groups, ( naïve and switchers), patients treated with more cumulative dose of glucocorticoids (GC) had an increased risk of infections, and it was higher in patients with an inadequate response to previous biologic agents. Mean disease duration was longer in switchers, but this fact was not related to increase of infections.

Conclusion: This systematic review show that overall rate of infections is slightly higher in switchers than in naïve patients, but the fact of having received several biologic agents does not present itself as a risk factor for infections. However, the most important risk factor in the development of infections was the higher cumulative doses of GC.

Disclosure of Interests: None declared.

EFFECTS OF MALALIGNMENT AND DISEASE ACTIVITY ON SECONDARY OSTEOARTHRITIS PROGRESSION IN KNEES OF RHEUMATOID ARTHRITIS PATIENTS

Noriaki Okumura, Taku Kasawaki, Kosuke Kumagai, Mitsuhiko Kubo, Takafumi Yayama, Tomohiro Mimura, Tsutomu Maeda, Shini Imai. Shiga University of Medical Science, Orthopaedics Surgery, Otsu, Japan

Background: Recent advancements in treatment of rheumatoid arthritis (RA) with disease-modifying anti-rheumatic drugs (DMARDs) have been remarkable, with disease symptoms nearly disappearing due to their strong anti-inflammatory action and many patients achieving remission. As a result, the need for RA-related surgery has shown a yearly decreasing trend, especially knee surgery and synovectomy procedures [1]. On the other hand, cases of secondary osteoarthritis (OA) in knee joints as a symptom associated with RA following a total knee arthroplasty (TKA) are increasing.

Objectives: We investigated the morphology of osteophytes by quantitatively evaluating their size using images obtained prior to performing a TKA. Additionally, the relationships of osteophyte size with patient background, disease activity, and degree of inflammation were examined.

Methods: Radiographs of 35 consecutive knees in 30 RA patients (26 females, 4 males; mean age 63.0 years; median disease duration 15 years) who underwent TKA, including preoperative standing AP view radiographs of the knee joint, were retrospectively analyzed. Using the Image-J software package, osteophyte size in the medial femur (MF), medial tibia (MT), lateral femur (LF), and lateral tibia (LT) regions was determined. Written informed consent for data collection was obtained from all patients in accordance with the Declaration of Helsinki.

Results: Preoperative Larsen grade was 2, 3, 4, and 5 in 1, 12, 18, and 2 patients, respectively, while the mean range of motion of the knee joint was 118° for flexion and -10° for extension. The mean femoral-tibial indentation angle (FTA) was 178°±13.6°, with varus (FTA >180°; n=14) more frequently observed as compared to valgus (FTA <170°; n=7) cases. Mean osteophyte size in the MF, MT, LF, and LT regions was 37.2, 17.0, 27.2, and 4.57 mm², respectively, and significantly greater in the medial compartment (MF+MT) than the lateral compartment (LF+LT) (p<0.001). In the varus cases, osteophyte size in the medial compartment was significantly larger as compared to the normal and valgus cases (p=0.0016). Furthermore, osteophyte size in the medial compartment was negatively correlated with the inflammatory markers CRP (r=-0.492, p=0.0027) and ESR (r=-0.529, p=0.0016), whereas that in the lateral compartment was negatively correlated with disease activity (r=-0.589, p=0.0023).

Conclusion: Our results suggest that secondary OA is a more prominent symptom in RA patients in whom inflammation is controlled, while disease activity has effects on osteophyte size.
INCREASE OF RHEUMATOID ARTHRITIS AS A CONTRIBUTORY CAUSE OF DEATH IN THE ELDERLY. A NATIONWIDE STUDY IN ITALY, 2003–2015

Francesca Ometto1, Ugo Fedeli2, Costantino Botsios1, Leonardo Punzi1, Enrico Grande2,3

Background: Metanalyses failed to show a decrease of the mortality risk in cohorts of patients with rheumatoid arthritis (RA) between 1950 and 1980. Mortality rates obtained with the analysis of multiple causes of death (MCD) can provide a more complete estimate of the burden of mortality related to RA compared to analysis considering only the underlying cause of death (UCD). Such analyses are available from a limited number of countries, and trends for RA mortality based on MCD were divergent.

Objectives: The objective of the study was to evaluate trends of rheumatoid arthritis (RA) mortality reported as the underlying cause of death (UCD) and as multiple cause of death (MCD) in Italy between 2003 and 2015.

Methods: Analyses were carried out on the Italian National Cause of Death Register, managed by the Italian National Institute of Statistics (ISTAT). Diseases mentioned in the death certificate are coded according to the International Classification of Diseases, 10th Edition (ICD-10, 2009 version). Deaths from January 1, 2003 to December 31, 2015 with mention of RA were included. Time trends of age-standardized rates were analyzed for RA both as UCD and MCD; and the annual percent change (APC) was estimated.

Results: Overall 26,564 deaths with mention of RA were retrieved out of 7,595,214 deaths (0.35% of all certificates). The yearly number of RA-related deaths increased through the study period, meanwhile the probability of selection as the UCD decreased: MCD/UCD ratio was 3.7 in 2003-2006 and 4.8 in 2012-2015 in males; 3.0 and 4.1 in females (Tab.). Mortality rates based on the UCD decreased (males APC -3.1%, CI -3.9, -2.3; females APC -3.3%, CI -4.1, -2.4); while MCD rates for RA-related mortality were stable. Specifically, rates were stable or declined among younger subjects, whereas an increase was registered (APC) was estimated.

PATIENT-REPORTED PALINDROMIC SYMPTOMS IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT

Leah Ellingswood1, Orit Schier2, Marie-France Valois3, Susan J. Bartlett3, Louis Bassette2, Carol Hilchon4, Gilles Boire5, Glen Hazlewood5, Edward Keystone5, Diane Tin6, Carter Thorne3, Vivian Bykerk7, Janet Pope8,9,10,11 Canadian Early Arthritis Cohort.1 Western University, London, Canada; 2University of Toronto, Toronto, Canada; 3McGill University, Montreal, Canada; 4Laval University, Quebec, Canada; 5University of Manitoba, Winnipeg, Canada; 6Universite de Sherbrooke, Sherbrooke, Canada; 7University of Calgary, Calgary, Canada; 8Southlake Regional Health Centre, Newmarket, Canada; 9Hospital for Special Surgery, New York, United States of America; 10Western University, Rheumatology, London, Canada

Background: The frequency and characteristics of patients with Palindromic Rheumatism (PR) (transient acute attacks of articular inflammation) prior to early rheumatoid arthritis (ERA) are unknown.

Objectives: To compare ERA patients who did versus did not report a history of transient episodes of joint inflammation preceding RA diagnosis.

Methods: Study participants were patients with ERA or suspected RA (symptoms <1 year; 83% met 2010 ACR/EULAR criteria) enrolled in the Canadian Early Arthritis Cohort (CATCH) between April 2017 to March 2018 who completed a questionnaire on prior inflammatory joint symptoms that ‘come and go’. Chi-square and t-tests were used to compare characteristics in patients with versus without a reported history of prior palindromic symptoms. Simple, and multivari-

SAFETY OF THE ZOSTER RECOMBINANT ADJUVANTED VACCINE IN RHEUMATOID ARTHRITIS PATIENTS: A SINGLE CENTER’S EXPERIENCE WITH 300 PATIENTS

Emma Stevens, Michael E. Weinblatt, Elena Massarotti, Frances Griffing, Sonali Desai.
Brigham and Women’s Hospital, Division of Rheumatology, Immunology and Allergy, Boston, United States of America

Background: Patients with rheumatoid arthritis (RA) and other systemic rheumatic diseases (SRD) are at increased risk of developing Herpes Zoster (HZ) due to the diseases/or medications used to treat them such as corticosteroids methotrexate, biologic disease modifying agents, and JAK inhibitors. Released in 2018, the Zoster Recombinant Adjuvanted (ZRA) is a new vaccine with >90% efficacy and can be used in patients taking immunosuppressive therapy as compared to the live Zoster vaccine. There has been a concern about whether the potency of the adjuvant could trigger flares of the underlying SRD, and whether there will be more side effects in this population.

Objectives: Our goal was to study the impact of the new ZRA vaccine in RA and other SRD patients and to measure the risk of flare and incidence of side effects.

Methods: We performed a retrospective chart review from 2/1/2018 to 1/20/2019, on patients with RA and SRD seen at the BWH who had received the ZRA vaccine. Co-variates of interest were collected. A flare responded to treatment with low dose glucocorticoids, and did not warrant any change in immunosuppressive therapy. Analyses were performed using StatsDirect 3 software.

Results: 300 patients who received the new ZRA vaccine between 2/1/2018 and 1/20/2019 were identified. Mean follow up was 12.5 weeks ranging from 1-40 weeks following administration. Patient characteristics are identified in Table 1.

We identified a 3.00% (n=9) incidence of flare following the first dose and 2.86% (n=4) incidence following the second dose. One patient flared after both the first and second dose. All the flares were mild, self-limited, and 2.86% (n=4) incidence following the second dose. All the flares were mild, self-limited, and did not warrant a change in immunosuppressive therapy. 15.3% (n=46) patients experienced side effects such as soreness at the injection site, fever, stomach ache, and flu like symptoms. Of the patients who experienced side effects, 15.4% (n=40) occurred after the first dose and 8.59% (n=11) occurred following the second dose. Five patients experienced side effects from both. All side effects were regarded as mild and did not necessitate an emergency room visit. No cases of Zoster were reported.

Conclusion: In our experience with 300 patients who received the new ZRA (207 RA and 93 SRD) in 2018-2019, the incidence of disease flares was ≤ 3% and of side effects was 15% which is reassuring. Both flares and side effects were mild, self-limited, and did not require a change in DMARD therapy. No cases of Zoster were reported. Larger formal studies with longer term follow up are required to confirm our findings.

FREQUENCY OF EYE INVOLVEMENT IN INFLAMMATORY ARTHRITIS AND CONNECTIVE TISSUE DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Matthew Tufi1, Jacqueline Hayworth2, Tatiana Nevskaya1, Janet Pope1.
1University of Western Ontario, London, Canada; 2University of Toronto, Toronto, Canada

Background: Rheumatoid arthritis commonly presents with extraarticular manifestations. Along with other connective tissue diseases, these manifestations may include eye involvement.

Objectives: The purpose of our work was to determine the prevalence and type of eye involvement in rheumatoid arthritis and other connective tissue diseases through a meta-analysis and literature review.

Methods: A systematic review of the literature was performed using Medline, Web of Science, and the Cochrane library from their inceptions until January 7, 2019. Conjunctivitis, keratoconjunctivitis sicca, xerophthalmia, uveitis, eye hemorrhage, optic neuritis, papilledema, orbital disease, retinal artery/vein occlusion, macular edema, retinitis, choroioretinitis, scleritis, iridocyclitis, choroid hemorrhage, blindness and amaurosis fugax were searched for prevalence in patients with rheumatoid arthritis, systemic lupus erythematosus, antiphospholipid syndrome, dermatomyositis, polymyositis, systemic sclerosis, Snowden’s syndrome, undifferentiated connective tissue disease, giant cell arteritis, granulomatosis polyangiitis (GPA) formerly Wegener’s granulomatosis, systemic vasculitis, and sarcoidosis.

Results: 3394 studies were identified and 65 included. The prevalence of eye involvement was 18% in rheumatoid arthritis, 31% in systemic lupus erythematosus, 35% in antiphospholipid syndrome, 27% in giant cell arteritis, 26% in GPA and 27% in sarcoidosis. The most common manifestations was dry eyes (keratoconjunctivitis sicca) in most diseases analyzed with a frequency approaching 90% in Snowgen’s syndrome. Anterior and posterior uveitis were the most common OC in sarcoidosis occurring in 16 [3-28]% and 6 [3-9]% of patients respectively.

Conclusion: Eye involvement is present in approximately one fifth of rheumatoid arthritis patients, and one quarter to one third of patients with other rheumatic diseases.

FR0070 SHORT-TERM INFLAMMATORY AND LIPIDS CHANGES IN RHEUMATOID ARTHRITIS PATIENTS INFLUENCE CARDIOVASCULAR RISK ALGORITHMS: A MONOCENTRIC RETROSPECTIVE STUDY

vincenzo venenito, Marco Fornaro, Giuseppe Lopalo, Anna Abbruzzese, Sergio Colella, Maria Grazia Anelli, Giovanni Lapadula, Floreruo Iannone, Fabio Cacciapaglia, Polichinico di Barile, Rheumatology Unit, Department of Emergency and Organ Transplantations, Barile, Italy

Background: Chronic inflammation may change lipid profile, thus current EULAR recommendations for cardiovascular (CV) management in polyarthritis suggest to assess cholesterol status when disease activity is stable or in remission. To date it is still unclear whether inflammation mediated changes in lipids profile could impact on CV risk algorithms and what score should be considered the reference one for any disease activity status.

Objectives: The aim of this study was to evaluate the influence of lipid profile, disease activity and inflammation modifications on four CV risk calculators during Treat to Target strategy with biologic agents.

Methods: In this monocentric study we retrospectively evaluated all data recorded from Rheumatoid Arthritis (RA) patients with moderate/high CV disease activity, who had started for the first time and maintained a bDMARD agent for at least 6 months, in our Outpatient Clinic from the 1st January 2010 to 31st December 2017. Patients with a prior CV event have been excluded from the analysis. For each patient, we assessed the CV risk in a short time period (within 6 months) to estimate the specific weight of lipids and disease activity related variables, using the Italian CV “Progetto Cuore” score, the QRISK3-2018 score, the Reynolds Risk Score (RRS) and the Expanded Risk Score in RA (ERS-RA). The results of the “Progetto Cuore” and RRS algorithms were multiplied by 1.5, in accordance to the EULAR recommendations for algorithms that do not include specifically RA among variables. Wilcoxon signed-rank test was used to compare CV risk scores during follow-up.

Results: One-hundred thirteen RA patients (female n. 86 (76.8%), mean age (SD) 52.8 (12.9) years, median disease duration (IQR) 26 (13-72) months) were eligible for the analysis. CDAL and C-reactive protein levels decreased significantly either at 3 and 6 months follow-up (p<0.001). At 3 months, we observed a statistically significant decrease in mean total cholesterol (TC) from 197.3±38.2 mg/dl to 205.8±37.3 mg/dl (p<0.01), which returned close to baseline levels at 6 months (201.1±34.5 mg/dl - p=0.22 vs baseline). High density lipoprotein (HDL), TC/CHDL ratio and triglycerides changes did not reach the statistically significance. The estimated CV risk assessed by the “Progetto Cuore” and QRisk3-2018 did not change during the 6 months’ follow-up. RRS showed a decrease either at 3 and 6 months (p<0.04). Similarly, ESR-RA highlighted a decrease of CV risk either at 3 and 6 months (p<0.01) (see Table I).

Conclusion: All evaluated “Scores” are not influenced by short term lipid changes observed during bDMARDs treatment, being applicable at any status of disease activity. Interestingly, the RRS and ESR-RA scores, evaluating RA inflammatory items, are susceptible to disease activity changes. These results should be taken into account by rheumatologists choosing a CV risk algorithm in daily clinical practice.

Anti-citrullinated protein antibody specificities, rheumatoid factor isotypes and risk of major adverse cardiovascular events

Helga Westerlund1, Johan Rönnelid2, Monika Hansson1, Lars Alfredsson3, Linda Mathsson1, Guy Serre4, Martin Cornillet5, Rikard Holmdahl6, Per-Johan Jakobsson1, Karl Skirner6, Lars Kläreskog7, Saedis Saevasdottir8, Johan Asling1, Karolinska Institutet, Department of Medicine, Solna, Sweden; 2Uppsala University Hospital, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; 3Karolinska Institutet, Institute of Environmental Medicine (IMM), Stockholm, Sweden; 4Toulouse University, Laboratory of Epithelial Differentiation and Rheumatoid Autoimmunity, Toulouse, France; 5Karolinska Institutet, Department of Medical Inflammation Research, Stockholm, Sweden; 6Charité University Hospital, Department of Medicine, Berlin, Germany; 7Karolinska Institutet, Solna, Sweden

Background: The association and role of antibodies to citrullinated proteins (ACPAs) on the risk of cardiovascular (CV) comorbidity in patients with rheumatoid arthritis (RA) is incompletely understood. We have previously reported an association between high levels of CCP2 and risk of acute coronary syndrome (ACS) in RA1. Objectives: To further investigate any association between specific ACPA or rheumatoid factor (RF) isotypes, and CV events (ACS, stroke, CV death, and major adverse CV event (MACE)). Methods: 253 patients with RA from the Swedish EIRA study were tested for ACPA specificities on a custom-made microarray chip. All antibodies (Ab) detected with a prevalence >= 10% were included in the analysis. Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups. ACPA was also measured by a commercial anti-CCP2 assay and anti-CCP2 levels divided into <25, 25-<75, 75--<1500, and >1500 arbitrary units/mL, where <25 defines negativity, IgG and IgM RF positivity was assessed using EIA immunoassay. For each RF isotype, cutoff level was determined as above the 98th percentile among controls. The data was linked to the National Patient Register and the Cause of Death register, and events of ACS (ICD10=I20-0, I21, or cause of death listed as "I21"), stroke (ICD10=I60-964), CV death (cause of death listed as "I"), or MACE (any of the above) identified. We used Cox proportional hazard model, adjusted for sex, age and calendar period of RA diagnosis, to assess associations between ACPA/RF status and each CV outcome.

Results: Median age at diagnosis was 52 years, and median follow-up was 12 years. The incidences per 1000 person-years were 4.3 for ACS, 4.0 for stroke, 2.4 for CV deaths, and 9.4 for MACE. 66% were anti-CCP2 positive. This was associated with ACS, stroke, and MACE. There was a trend with increasing CV risk with increasing anti-CCP2 levels (Table). For RF, the pattern was markedly different across isotypes; IgM RF associated with ACS, stroke and MACE whereas IgA RF associated to ACS. No association to ACS remained when Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups. No association to ACS remained when Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups. No association to ACS remained when Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups. No association to ACS remained when Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups. No association to ACS remained when Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups. No association to ACS remained when Ab load was defined as the number of specificities expressed in an individual, and categorized into four groups.

Conclusion: In patients with RA, RF and ACPA are linked to CV risk. For RF, CV risks differ with isotype. For ACPAs, very high levels, and the number of individual ACPAs, are linked to CV risk, suggesting that Ab load may be more important than individual ACPAs.

Predicting sarcopenia and obesity by measuring thigh muscle and fat thickness by ultrasound in patients with rheumatoid arthritis: from the Chikara study

Yuta Yamada1, Masahiro Tada2, Koji Mandai1, Noraki Hidaka2, Kentaro Inui1, Hiroshi Nakamura1. 1Osaka City University Graduate School of Medicine, Osaka city, Japan; 2Osaka City General Hospital, Osaka city, Japan

Background: Rheumatoid arthritis (RA) patients often have sarcopenia. The thickness of the quadriceps muscle, easily measurable by ultrasound (US), is known to be related to skeletal muscle mass, and its decreased thickness may suggest sarcopenia.

Objectives: To investigate the utility of US for predicting sarcopenia by examining the anterior thigh in RA patients.

Methods: Ninety-four patients (66 female) enrolled in the prospective CHIKARA study (UMIN000023744) underwent US muscle (MT) and fat thickness (FT) examinations of the anterior thigh. Muscle and body fat mass were also examined by a body composition analyzer (MC-780A; TANITA, Tokyo, Japan). Whether MT and FT can predict sarcopenia and obesity was also examined. Sarcopenia was diagnosed based on the Asian Working Group on Sarcopenia definition, and obesity was diagnosed by% body fat (%BF).

Results: MT was significantly lower in RA patients with sarcopenia than in those without (24.8 ± 3.5 mm vs. 29.6 ± 3.8 mm; p=0.01). MT was related to sarcopenia (males r=0.56, p=0.02; females r=0.32, p=0.01). The MT cut-off value for sarcopenia was 24.7 mm in males and 19.7 mm in females on receiver operating curve (ROC) analysis. FT was correlated with%BF (males r=0.66, p=0.01; females r=0.62, p=0.001),%BF was estimated by 2.21FT+7.28 in males and 1.45FT+14.46 in females by a simple linear regression model. This means that FT>8.0 mm in males and FT>10.7 mm in females indicate obesity (Table 1). When assessing the accuracy of these cut-off values, the kappa values were 0.541 and 0.469, respectively.

Table 1. Relationship between%BF and FT. FT: the fat thickness (FT) at anterior thigh measured by ultrasound,%BF:% body fat measured by body composition analyzer.

Conclusion: Sarcopenia and obesity can be predicted by US examination of the anterior thigh in RA patients.

SWELLING OR TENDERNESS, WHICH ONE CORRESPONDS BETTER WITH ULTRASOUND-DETECTED SYNOVITIS?

Xiaoying Sun, Xuerong Deng, Weihui Xie, Yu Wang, Zhong Zhang, Peking University First Hospital, Beijing, China

Background: Ultrasound (US) is a sensitive method for detecting joint inflammation in patients with rheumatoid arthritis (RA). The relationship between tender or swollen joints and ultrasound-detected synovitis has not been well explored in patients with RA.

Objectives: The purpose of the present study was to compare the correlation between ultrasound-detected synovitis and joint tenderness or swelling at the wrists and hands in RA patients.

Methods: Twenty-two joints, including bilateral wrists, proximal interphalangeal (PIP) and metacarpophalangeal (MCP) joints, were respectively evaluated by physical examination (PE) and ultrasound scan in 258 RA patients. All patients had at least 1 tender or swollen joint out of 22 joints. Joint tenderness was assessed by using semiquantitative scoring systems (0-3) for grey scale (GS) and power Doppler (PD). Positive synovitis was defined as GS≥2 and/or PD≥1. All correlations among US variables and clinical variables were assessed using Spearman’s rank correlation test. Cohen’s kappa (κ) between clinical and sonographic findings was calculated.

Results: Their median age was 51.2 years, median disease duration was 57 months, with 83.33% females. The mean (SD) Disease Activity Score based on 28 joints (DAS28)-ESR and DAS28-CRP were 4.47±1.62 and 5.70±1.47, respectively. In a total of 5676 joints assessed, 968 swollen joints (17.05%) and 1296 tender joints (22.83%) were found, while on ultrasonography GS synovial hyperplasia was present in 801 (14.11%) joints, positive PD in 476 (8.38%) joints. There were more tender joints without swelling (n=574) than those swollen joints without tenderness (n=246). In all joints, higher κ coefficient was observed in joint swelling (κ=0.367, p<0.01) with ultrasound-detected synovitis compared with tender-joint (κ=0.281, p>0.01). Similarly, swollen joint counts of 22 joints showed higher Spearman’s correlation coefficient with either total GS scores (r=0.499, p<0.01) or total PD scores of 22 joints (r=0.430, p<0.01) than tender joint counts of 22 joints (r=0.354,0.308, p<0.01). GS and PD synovitis were more frequently detected in swollen joints without tenderness compared with tender joints without swelling. This discrepancy tends to be more significant in MCP2, MCP3, and MCP4 joints (p<0.05).

Conclusion: In RA patients with at least 1 tender or swollen joint of wrists and hands, a higher frequency of joint tenderness was observed than swelling. However, swelling had better agreement with ultrasound-detected synovitis compared with tenderness. Joint swelling is more associated with ultrasound-detected synovitis than tenderness. Without swelling, joint tenderness tends to be less associated with ultrasound-detected synovitis.

FR0075 SYSTEMATIC ANALYSIS OF INJECTION-SITE PAIN CAUSED BY SUBCUTANEOUS ADMINISTRATION OF THE ADALIMUMAB BIOSIMILAR FKB327 VERSUS ADMINISTRATION OF THE ADALIMUMAB REFERENCE PRODUCT VIA DIFFERENT DELIVERY METHODS

Rieke Alten1, Mark C. Genoves2, Malcolm Boyce3, Takuma Yonemura4, Takahiro Ito5, Herbert Kellner6.

1University Medicine Berlin, Berlin, Germany; 2Stanford University, Division of Immunology and Rheumatology, Palo Alto, CA, United States of America; 3Hammersmith Medicines Research, London, United Kingdom; 4Souseikai Sumida Hospital, Tokyo, Japan; 5Fujifilm Kyowa Kirin Biologics, Tokyo, Japan; 6Specialist Practice in Rheumatology and Gastroenterology, Munich, Germany

Background: FKB327 is a proposed biosimilar of the adalimumab reference product (RP). Several studies in both healthy volunteers and patients with active rheumatoid arthritis (RA) were undertaken, the results of which have been reported elsewhere. The formulation excipients of the biosimilar product differ from those of the RP, and different injection-site pain intensity with subcutaneous injection has been reported.

Objectives: The current meta-analysis examines pooled data from these studies in relation to the amount of injection-site pain resulting from using a prefilled syringe (PFS) versus an auto-injector (AI) versus a regular syringe (RS). In parallel, the proposed biosimilar, FKB327, versus the RP.

Methods: Data from 4 studies, FKB327-001, -002, -003, and -004, were pooled in an effort to compare injection-site pain upon subcutaneous administration of FKB327 versus the RP (citrate-containing formulation of the RP [40 mg/0.8 mL]). Study FKB327-001, in healthy volunteers (n = 180), involved a single subcutaneous dose of either FKB327 or the RP. Study FKB327-004 was a similar study in healthy Japanese volunteers (n = 130). Study FKB327-002 was a randomized (FKB327 with RS or the RP), double-blind, multiple-dose study in patients with active RA. This was followed by Study FKB327-003, in which patients were rerandomized to receive either FKB327 with PFS or the RP in the randomization phase, followed by an open-label extension phase of the study, in which AI was introduced. As patients continued receiving treatment or switched treatments during the course of the FKB327-002 and -003 studies, injection-site pain was assessed at the first dosing occasion of FKB327 or the RP (n = 691). Data from all 4 studies were examined by meta-analysis of the visual analog scale (VAS) using a 100-mm horizontal scale for FKB327 versus the RP and for comparison of AI, PFS, and RS.

Results: Data were analyzed from a total of 2007 assessments in 1001 subjects. A linear mixed model of the VAS in mm for the RP versus FKB327 across all 4 studies showed a 12.6-point lower pain score for FKB327 across all 4 studies showed a 12.6-point lower pain score for FKB327 versus the RP (95% confidence interval [CI], –13.4 to –11.8; P < .001). For the AI and PFS used for FKB327 administration, AI showed a 1.7-point lower pain score in the VAS compared with PFS (95% CI, –3.3 to –0.1; P = .035). Gender, age, body weight, and population (healthy subject or patient) were not identified for differences in injection-site pain intensity.

Conclusion: FKB327 showed a significant advantage in terms of injection-site pain intensity compared with the RP, as well as lack of inferiority for both AI and PFS versus RS.

psoriatic arthritis (PsA) and ankylosing spondylitis (AS) in North East Romania from 2003 to 2018.

Methods: We performed a hospital-based retrospective cohort study in consecutive adult patients receiving their first biologic agent (TNF or non-TNF drugs) according to local recommendations in two academic centers. Patients were classified based on the initial TB/latent TB screening test: the tuberculin skin test (positive if > 5mm, TST group) or interferon gamma release assays (positive if >0.35 IU/mL QuantiFERON-TB gold, QFT group); retesting was done regularly if negative initial.

Data about drug efficacy was recorded every 24-weeks based on standard scores (DAS28-ESR for RA, DAPSA for PsA, ASDAS-CRP for AS), while TB risks at the end of the study or prior to switching were determined as hazard ratio (HR) with 95% confidence interval (CI) using cox regression.

Statistical analysis was performed in SPSS-19, p<0.05, on subgroups of patients depending on whether positive TST or QFT at baseline.

Results: 673 patients (360 RA, 116 PsA, 95 AS) were recruited; 55 of them (33 RA, 13 AS, 9 PsA) had latent TB at baseline and received chemoprophylaxis with isoniazid before starting biologics according to local policy. Fourteen active TB were identified, the majority of them occurred within one year of biologics (ranging 6 to 52 months), as follows: three pulmonary TB in RA (in etanercept, one adalimumab), one case of pulmonary TB in PsA (infliximab) and ten cases of RA (six pulmonary TB in abatacept, two adalimumab, etanercept and two infliximab; one ganglionar infection with infliximab; one peritoneal under certolizumab; one pulmonary and pleural under adalimumab). The rate of active TB was 5.3/1000 patient-years for infliximab, 4.594.64 for adalimumab, 1.38.39 patient-years for certolizumab, 3.721.51 for etanercept and 1.21.12 patient-years for abatacept, respectively. We reported an increased risk of TB disease in anti-TNF monoclonal antibodies users vs. soluble receptor, with an incidence ratio of 2.66 (p<0.05). Interestingly, no significant TB risk factors were demonstrated in our cohort; baseline latent TB, previous active TB, chronic glucocorticoid use, high disease activity at baseline, comorbidities, concurrent synthetic drugs were not associated with increased risk (p>0.05). In addition, we described 18 new patients with positive QFT when TB retesting as per protocol, classified as latent TB and requiring chemoprophylaxis.

Conclusion: The risk of tuberculosis remains a reality in biologics, despite extensive screening and prevention methods. The risk is variable when TB retesting as per protocol, classified as latent TB and requiring chemoprophylaxis.

**Conclusion:** The real-world evidence suggests that treatment durability may be better for JAKi than TNFi (both monotherapy and combination). The majority of csDMARD patients switched to another csDMARD, which showed short durability of treatment, suggesting that switching MOA may benefit these patients.

Objectives: To assess the variation in serum trough levels of infliximab after the systematic application of flush physiological serum after drug administration.

Methods: The study was divided into two phases: a first phase in which the clinical and analytical variables (including the serum trough levels of infliximab) were measured before the application of the flush serum and a second stage in which the same variables were measured after the systematic implementation of an infusion of 500 ml of 0.9% sodium chloride following the administration of infliximab.

Results: A total of 35 patients were collected, including 6 rheumatoid arthritis (13.3%), 9 psoriatic arthritis (20%) and 20 ankylosing spondylitis (AS) (44.4%). Overall, 18 patients were women (40%), the mean age was 57.6 years (12.6) and the BMI was 30.5 (13.1). The mean dose of infliximab was 3.1 mg/kg (1.1) and the mean number of years of treatment was 10 (5).

23 patients were taking infliximab on monotherapy (51.1%). The mean trough serum levels of infliximab pre-intervention with the dragging serum was 3.13 mg/dl (3.1), while postintervention levels were 3.66 mg/dl (3.8) (p = 0.071). In the subgroup of patients with AS there was a significant decrease in BASDAI between the pre and post intervention visit (3.4 vs 2.6, p < 0.05).

Conclusion: The use of flush serum after infliximab infusion increased serum drug levels. In the subgroup of patients with AS there was a clinically significant improvement measured by BASDAI.

[6] Pascual-Salcedo D1, Plasencia C, Ramiro S, Nuño L, Bonilla G, Navarro-Compán P, et al. Anti-TNF safety of TNFi versus non-TNFi after discontinuing a previous TNFi in (non-TNFi), however little guidance on choosing one or another exists.

Objectives: To compare the long-term clinical response, survival and safety of TFNI versus non-TFNI after discontinuing a previous TNFI in pts with RA, both in the global cohort and in the subpopulations stratified by reason of discontinuation of 1st TNFI.

Methods: Observational study including 127 pts from La Paz University Hospital biological RA registry, who discontinued a first TNFI between 1999 and 2016 and subsequently were treated with a second biologic. Disease activity was assessed by DAS28 at the beginning of the second biologic and at 6 (m-6), 12 (m-12) and 24 months (m-24) follow-up. Primary outcome was the proportion of pts with good or moderate EULAR response (E-Resp). Sensitivity analysis to evaluate clinical response according to the reasons for discontinuation of the first TNFI was performed too. Pts were classified into primary and secondary failure based on the characteristics of the non-response and if possible on the measure of drug and anti-drug antibodies, which were measured by ELISA after 6 months of the first biologic treatment and before switching. Mann-Whitney U test and Fisher’s exact test were used to test statistical differences. Factors associated with clinical response were assessed using univariable and multivariable logistic regression analysis. Drug retention was compared using Cox proportional hazards models.

Results: Seventy-seven (61%) pts received a TNFI and 50 (39%) a non-TNFI as second biologic therapy. Mean age was 56 years, 84% were women and 58% were also treated with methotrexate. At baseline, no significant differences between groups were found, except for significantly higher CRP levels in non-TNFI group (Table 1). No statistical differences were observed in E-Resp between groups at m-6 and m-12. Nevertheless, at m-24 more pts achieved E-Resp in non-TNFI group (80% vs 52%; p=0.001, Figure 1). Likewise, 100% (n=6) of the pts who achieve remission with the second biologic were treated with a non-TNFI. In the univariable analysis, higher baseline DAS28 (OR=1.65, p=0.06) being ACPA positive (OR=3.6, p=0.02) and treatment with a non-TNFI (OR=3.5, p=0.01) were associated with E-Resp at m-24. In the multivariable analysis, baseline DAS28 (OR=1.65, p=0.01) and non-TNFI treatment (OR=3.7, p=0.02) remained associated. Drug survival was similar in both groups (1.6±0.7 in TNFI vs 1.6±0.6 years in non-TNFI, p=0.5). In the subgroup of pts who dropped out due to secondary inefficacy (n=76) no differences in response to the second biologic were found, however, pts who stopped the first TNFI for other reasons (primary ineffectiveness and adverse events) achieved more frequently E-Resp and switching to non-TNFI since the beginning of treatment (m-6: 54% in TNFI vs 86% in non-TNFI, p=0.04; m-12: 56% in TNFI vs 70% in non-TNFI, p=0.4; m-24: 47% in TNFI vs 86% in non-TNFI, p=0.04). The overall incidence of AEs was similar between TNFI and non-TNFI groups (21% in TNFI vs 14% in non-TNFI, p=0.9).

Conclusion: In our cohort of patients with RA and failure to a first TNFI, and mainly after primary failure and adverse events, treatment with a non-TNFI was more effective than a second TNFI at 24 months after switch, without significant differences in the survival of the two treatments. In the subgroup of patients who failed the first TNFI due to secondary inefficacy, both treatment options were equally effective. These data reflect how the reason for discontinuation of a first biologic can guide the response to a second treatment.

SURVIVAL ON SECOND-LINE BIOLOGIC THERAPY AFTER THE WITHDRAWAL OF AN ANTI-TNF TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS: EXPERIENCE IN A SPANISH TERTIARY HOSPITAL

Andrea Briones-Figueroa, Jaime Arroyo Palomo, Patricia Morán Álvarez, Javier Bachiller-Corral, Mónica Vázquez Díaz. Department of Rheumatology, Ramón y Cajal University Hospital, Madrid, Spain

Background: Patients with Rheumatoid Arthritis (RA) have been traditionally treated with other TNF inhibitors (TNFis) after the withdrawal of a first TNFi (cycling). However, due to the increase in the biological therapy options, changing to a biologic agent with different mechanisms of action (switching) is an alternative choice. More studies are needed to clarify the role of both strategies in order to guide treatment decisions.

Objectives: To analyze the survival of the second biological drug, TNFi or biologic with a different mechanism of action, in patients with RA non-responders to the first TNFi. To evaluate factors associated with the survival of the second-line therapy.

Methods: A retrospective, longitudinal, observational study was performed, which included patients diagnosed of RA and treated with biological therapies between 2008 and 2017, who discontinue a first-line TNFi and started a second-line biological therapy. The demographic and clinical data were obtained from their medical records. Kaplan Meier and Log-rank survival analysis were performed, as well as Cox regression to identify related factors.

Results: 69 patients were identified, 14 men (20.3%) with a mean age at the beginning of the treatment of 52.68 ± 19.79 years. Demographic and clinical data are shown in the table. The main cause of withdrawal of the first TNFi was secondary failure (47.8%), followed by side effects (34.8%) and primary failure (13%). Cycling was performed in 34 patients (49.3%) and switching in 35 (50.7%). During the follow-up, the main causes of withdrawal of the second line treatment were primary and secondary failure (10.1% in both cases). The survival analysis of the 42 patients who presented a primary or secondary failure to the first TNFi was stratified according to the cause of withdrawal of the second biological therapy. No differences were found in the withdrawal rate due to adverse effects among patients who performed switching or cycling (11.42% vs 5.88%, p=0.41).

Conclusions: The survival on second-line biologics after the withdrawal of the first TNFi was similar to cycling or switching strategies. These results may contribute to guide treatment decisions.

Background: The optimal sequencing of biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs) in Rheumatoid Arthritis (RA) is unknown. Evidence regarding the effectiveness of a 2nd non-TNFi bDMARD, as well as of TNFi, in patients whose 1st bDMARD has been a non-TNFi is limited.

Objectives: To characterize patients switching for medical reasons after failure of a non-TNFi used as 1st bDMARD, and to assess the effectiveness of rituximab (RTX), abatacept (ABA) or tocilizumab (TCZ) vs. a TNFi.

Methods: Patients from 5 national registers (Sweden, Norway, Denmark, Iceland and Finland) with RA who started treatment with a non-TNFi as a 1st bDMARD after 2010 and switched to a 2nd bDMARD within 3 months after the discontinuation of the 1st (with the exception of RTX for which a 6-month window was used), were identified. Clinical effectiveness was assessed by DAS28 change at 6 months.

Results: 611 patients were included in the analyses. 80% were female, which a 6-month window was used), were identified. Clinical effectiveness were explored for most switching strategies. 63% of patients were still on treatment with their 2nd bDMARD at 6 months after switch.

Conclusion: The six-month drug retention for a 2nd bDMARD in patients with RA switching due to failure of a non-TNFi bDMARD as 1st ever bDMARD was lower than two thirds (63%). More detailed analyses are exploring potential subgroups of patients for whom specific switching strategies are more effective.

Acknowledgement: The study was partly funded by a study grant from NordForsk and Forum.

THE IMPACT OF IL-6 AND TNF INHIBITORS ON HEMOGLOBIN LEVELS: AN ANALYSIS FROM RHUMADATA® CLINICAL DATABASE AND REGISTRY

Denis Choquette 1, Louis Bessette 1, Loïc Choquette Sauvageau 1, Isabelle Ferrand 1, Paul Harasoiu 1, Frédéric Massicotte 1, Jean-Pierre Pelletier 1, Jean-Pierre Raynauld 1, Marie-Andrée Rémiillard 1, Diane Sauvageau 1, Édith Villeneuve 1, Louis Coupal 1, Institut de Recherche en Rhumatologie de Montréal (IRRM), Rhumatologie, Montréal, Canada; 2Centre de l’Ostéoporose et de Rhumatologie de Québec (CORQ), Rhumatologie, Québec, Canada

Background: Anemia is a common feature of RA. Prior to the appearance of biologic treatments, improvement of hemoglobin (Hb) levels was unusual and inconsistent. With better control of the inflammatory process by cytokine inhibitors, it has been shown that Hb levels can improve substantially. Recently in the development of IL-6 receptor antagonists (sarilumab (SARI) and tocilizumab (TOCI)) data have shown improvement in Hb levels related to the downstream regulation of hepcidin. No direct comparison of Hb levels between TNF and IL-6 inhibition has been observed in observational data (1).

Objectives: This analysis compares the impact of TNF and IL-6 inhibitors on Hb levels over time.

Methods: Data collected since January 1, 2015 (when TOCI and SARI were available in Canada) at the Institut de Recherche en Rhumatologie de Montréal (IRRM) and the Centre de l’Ostéoporose et de Rhumatologie de Québec (CORQ) was extracted from the Rhumadata® clinical database and registry on January 7, 2019. Selected patients were those initiated on an IL-6 antagonist or a TNFi (adalimumab, certolizumab, etanercept, golimumab or infliximab) and had been treated for at least one year. Furthermore, patients were cancer free and had no diagnosis of Crohn’s disease or ulcerative colitis and had creatinine (Cr) and ALT levels within the normal sex-specific range. IL-6 patients were matched (ratio 1:2) to TNFi patients based on age at treatment initiation, gender and baseline Hb. The collected data included baseline characteristics (socio-demographic variables, concomitant and past medication, comorbidities and the Charlson comorbidity index (CCI)), variables measured over time (Hb and other laboratory test results, patient and physician-reported outcomes, and disease activity measures such as CDAI and DAS28(4)-ESR). The groups were compared to identify potential confounders.

Results: A total of 145 patients initiating an IL-6 antagonist since January 1, 2015 were matched with 286 patients prescribed a TNF inhibitor during the same time-period. Most patients were women (86%), the mean age at treatment initiation was 54.1 standard deviation: 11.7) years, and 16% were smokers. Baseline patient global, pain and fatigue assessments, made on a visual analogue scale ranging from 1 to 10, were 5.4 (2.5), 6.1 (2.5) and 5.5 (3.0) in the IL6 group and 5.1 (2.7), 5.5 (3.0) and 5.0 (3.2) in the TNFi group. Baseline disease activity was assessed as moderate or high/severe in 85.5% (IL6) and 85.9% (TNFi) of patients (DAS28(4)-ESR criteria). At treatment initiation, mean Hb level was 126.6 (12.4) g/L, and Cr and ALT levels were 66.2 (11.5) umol/L and 18.7 (6.5) U/L in the IL6 group and 67.0 (12.0) umol/L and 19.3 (6.8) U/L in the TNFi group. At three months, Hb had increased by 5.4 (10.2) g/L in the TNFi group and by 1.8 (13.9) g/L in the TNFi group (p-value=0.024). These respective changes at 12 months were 8.7 (11.4) g/L and 5.4 (9.2) g/L (p-value=0.042).

Conclusion: This analysis confirms that IL-6 inhibition provides a numerically and statistically superior increase in Hb over TNF.

China-manufactured adalimumab biosimilar, HLX03, demonstrated pharmokinetic equivalence and comparable safety to reference adalimumab

Jixun Sun1, Guiling Chen1, Min Wu2, Yiwen Han3, He Gao2, Tianli Zhang2, Xinjun Guo4, Xin Zheng5, Eugene Liu1, Aixin Lu6, Weixiao Ji4, Scott Lu7, Qimin Zhang1, Katherine Chai1, Yanhua Ding1, 1The First Hospital of Jilin University, Jilin, China; 2Shanghai Henlius Biotech, Inc., Shanghai, China

Background: Adalimumab was first launched in China in August 2010 with more than 10 million people having its indications.1, 2 However, the high cost of the biologic drug limits the treatment accessibility and reduces the quality of life in patients living with the chronic inflammatory disease like rheumatoid arthritis and psoriasis. In accordance with the China National Medical Product Administration (NMPA) biosimilar regulatory development pathway, biosimilar products require to demonstrate similarity in pharmacokinetics (PK) and safety profile compared to its reference drug, which could further address the unmet medical needs of adalimumab. HLX03 was developed as a proposed biosimilar to adalimumab with the potential to increase affordable treatment options for patients.

Objectives: The study was aiming to compare the pharmacokinetics (PK), safety and immunogenicity of the proposed adalimumab biosimilar HLX03 with reference product.

Methods: We conducted a randomised, double-blind, parallel-controlled clinical trial (NCT03057935) in China to compare the PK, safety and immunogenicity of HLX03 and China sourced adalimumab (CN-adalimumab). In this study, 211 healthy volunteers were randomised 1:1 to receive a single (40 mg) subcutaneous injection of HLX03 or CN-adalimumab. The primary PK endpoint was area under the curve from time zero to the last quantifiable concentration (AUC0-t) and maximum observed concentration (Cmax). The secondary PK endpoint was AUC from time zero to infinity (AUC0-inf). PK equivalence was established if the 90% confidence interval (CI) for the test-to-reference ratio fell within the 80-125% equivalence margin.

Results: Based on the analysis of 210 subjects in the per protocol population (PPS) and 211 subjects in the full analysis set (FAS), HLX03 demonstrated PK equivalence to CN-adalimumab for all primary endpoints (Table 1). The percentage of adverse events (AEs) between two treatment groups were similar, with treatment-emergent AEs (TEAEs) noted by 32.5 and 36.5% of patients in the HLX03 and CN-adalimumab group, respectively. One subject suffered non-drug-related severe AE (tuberculosis) in the HLX03 arm, and one subject occurred grade 4 AE (elevated creatine phosphokinase) in the CN-adalimumab arm. In the group of CN-adalimumab, 6 more incidents of positive anti-drug antibodies (ADA) were identified at day 7 and no further significant difference observed. Based on the established clinical PK equivalence and safety similarities, 262 patients with moderate-to-severe chronic plaque psoriasis were randomized in 21 centers at 1:1 ratio to conduct a double-blind, parallel-controlled phase 3 study (NCT03316781) to further evaluate the efficacy and safety profiles of HLX03 and reference adalimumab. The primary efficacy endpoint was the improvement rate of Psoriasis Area and Severity Index (PASI) over the baseline at week 16.

Conclusion: PK equivalence and safety similarities between HLX03 and CN-adalimumab were demonstrated which leads to a multi-center, randomised, double-blind, parallel-controlled phase 3 study to further evaluate the efficacy and safety of HLX03 as the proposed biosimilar of adalimumab in patients with moderate-to-severe plaque psoriasis.

Efficacy, safety, and immunogenicity results of the switch from reference adalimumab (refADL) to Sandoz biosimilar adalimumab (SDZ-ADL) from admYRA phase 3 study in patients with moderate-to-severe rheumatoid arthritis (RA)

Piotr Wieland1, Slawomir Jeka2, Ewa Dobrucka3,4, Juan Manuel Miranda Lomin1, Julia Jauch-Lembach1, Arjan Thakur5, Halfimunyazi Halidou6, Norman Gayl5,1

1Wrocław Eugenii Liú University, Wrocław, Poland; 2Collegium Medicum University Hospital, Bydgoszcz, Poland; 3MEDICAL PLUS s.r.o, Uherske Hradiste, Czech Republic; 4University of Veterinary and Pharmaceutical sciences, Faculty of Pharmacy, Brno, Czech Republic; 5RM Pharma Specialists, Mexico City, Mexico; 6Hexal AG, Höchbrück, Germany; 7Arthritis and Rheumatic Disease Specialties, Aventura, FL, United States of America

Background: SDZ-ADL is approved by EMA in all indications of refADL based on preclinical and clinical study results. EMA submission data included results of a Phase 3 study in patients with plaque psoriasis. ADMYRA was a Phase 3 study comparing efficacy and safety of SDZ-ADL and refADL in patients with moderate-to-severe RA with inadequate response to disease modifying anti-rheumatic drugs, including methotrexate (NCT02744755).

Objectives: The ADMYRA study was designed to compare the efficacy of SDZ-ADL and refADL over 24 weeks of treatment, and to evaluate long-term efficacy, safety, and immunogenicity of SDZ-ADL up to Week (Wk) 48. The study also investigated the effect of the switch from refADL to SDZ-ADL at Wk 24 on efficacy, safety, and immunogenicity up to Wk 48. This abstract focuses on the data after switch from refADL to SDZ-ADL.

Methods: Eligible patients were randomized 1:1 to receive 40 mg subcutaneous SDZ-ADL or refADL every other week from Wk 0–22. At Wk 24, patients in the refADL arm were switched to receive SDZ-ADL; treatment continued until Wk 46. The primary endpoint was change in Disease Activity Score-28 including high-sensitivity C-reactive protein (DAS28-ESR) from baseline at Wk 12. Secondary endpoints included mean changes in DAS28-CRP scores, the proportion of patients fulfilling EULAR response criteria, safety, and immunogenicity up to Wk 48.

Results: As reported previously, mean change in DAS28-CRP from baseline at Wk 12 was -2.16 for SDZ-ADL (N=140) and -2.18 for refADL (N=144).1 Efficacy in both treatment arms was maintained throughout the study, also after the switch from refADL to SDZ-ADL at Wk 24. Mean change in DAS28-CRP from baseline at Wk 48 was -2.90 and -2.92 for refADL/switched and SDZ-ADL groups, respectively. At Wk 48, the proportion of patients with moderate/good EULAR response was 29.6/68.0% in refADL/switched group and 29.0/69.2% in SDZ-ADL group. At Wk 48, the proportion of patients in EULAR remission was 54.4 and 51.4% and in Boolean remission was 21.6 and 16.8% for refADL/switched and SDZ-ADL groups, respectively. As previously reported, safety and immunogenicity were similar in both arms before switch.1 No new safety concerns were identified after switch. After switch, 32.5% of patients in the refADL/switched group and 36.5% of patients in the SDZ-ADL group experienced adverse events (AEs); serious AEs were reported by 3.6 and 2.5%, respectively. The proportion of patients reporting injection site reactions after switch was 1.2% in the refADL/switched group and 0.6% in the SDZ-ADL group, respectively. After switch, 26.3 and 24.0% of patients
were positive for antidrug antibodies (ADAs) in refADLswitched and SDZ-ADL groups, respectively. Of these, 81.0 vs 72.2% were neutralizing. ADA positivity had no clinically meaningful impact on safety.

**Conclusion:** After the switch from reference to biosimilar, the rates of EULAR remission response and Boolean remission were high and maintained until Week 48. Treatment switch from refADL to SDZ-ADL at Wk 24 did not impact efficacy, safety, or immunogenicity.

**SAFETY, IMMUNOGENICITY AND EFFICACY OF THE PROPOSED BIOSIMILAR MSB11022 (MODIFIED FORMULATION) COMPARED WITH ADALUMMA B REFERENCE PRODUCT IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE RHEUMATOID ARTHRITIS: AURIEL-RA, A RANDOMISED, DOUBLE-BLIND, PHASE III STUDY**

Christopher Edwards1, Veronica Chyrok2, Joëlle Monnet2, Martin Ullmann2, Panetis Vlahos2, 1University Hospital Southampton, Southampton, United Kingdom; 2Fresenius Kabi, Eysins, Switzerland; 3Cytel, Geneva, Switzerland

**Background:** Adalimumab is a fully human anti-TNF monoclonal antibody indicated for the treatment of multiple inflammatory disorders, including rheumatoid arthritis (RA). MSB11022 is a proposed adalimumab biosimilar that has been shown to be structurally and functionally similar to the adalimumab reference product. MSB11022 has been developed in two formulations, in a citrate-based buffer, and in a modified buffer and stabiliser. MSB11022 demonstrated bioequivalence and comparable safety, tolerability and immunogenicity profiles to reference adalimumab (both in citrate formulations) in a study in healthy volunteers. Subsequently MSB11022 was shown to be therapeutically equivalent to reference adalimumab (both citrate formulations) in terms of efficacy, safety and immunogenicity in psoriasis patients in the 52-week, Phase III, pivotal AURIEL-RA Patient baseline characteristics were comparable between treatment groups. Few adverse events of special interest were reported during the study. Numbers are n (%) or mean ± standard deviation. DAS28, Disease Activity Score-28; ESR, erythrocyte sedimentation rate; ITT, intention-to-treat set; SAF, safety analysis set; TEAE, treatment-emergent adverse event.

**SAFETY AND EFFICACY OF RADIONUCLIDE SYNOVECTOMY IN PATIENTS WITH PERSISTENT INFLAMMATORY OF SINGLE JOINT IN THE COURSE OF BIOLOGICAL THERAPY**

Anna Felis-Giennas1, Marek Chojnowski2, Julita Rejmer1, Leszek Królčik3, Marzena Oleśnińska1, 1National Institute of Geriatrics, Rheumatology and Rehabilitation, Connective Tissue Diseases Department, Warsaw, Poland; 2Public Central Teaching Hospital, Nuclear Medicine Department, Warsaw, Poland

**Background:** Radionuclide synovectomy (RSV) is a form of minimally invasive treatment of persistent joint inflammation. Primary indication for RSV is hypertrophic synovitis refractory to disease-modifying anti-rheumatic drugs (DMARDs), whether synthetic or biological, and intraarticular steroid injections. This procedure has a high rate of success with a low rate of adverse events and complications in properly selected patients. Moreover, due to bactericidal properties of the radionuclides, the risk of infection after RSV is insignificant, and incidence of post-injection septic arthritis is extremely low.

**Objectives:** To assess safety and efficacy of RSV in patients with inflammatory rheumatic diseases treated with biological disease-modifying anti-rheumatic drugs (bDMARDs).

**Methods:** We analyzed outcomes of 76 radionuclide synovectomy interventions in 47 patients (37 female and 10 male) ongoing biological therapy. The patients were diagnosed as follows: rheumatoid arthritis (RA) – 37, anklyosing spondylitis (AS) – 7, psoriatic arthritis (PsA) – 2 and juvenile idiopathic arthritis (JIA) – 1 patient. The majority of the patients were treated with TNF-alpha inhibitors (79%), which included: adalimumab (31.6%), etanercept (25%), golimumab (14.5%) and certolizumab (7.9%). The other patients were treated with interleukin-6 receptor antagonist tocilizumab (19.7%) and anti-CD20 monoclonal antibody rituximab (1.3%).

**Patients with overall good response to biologics and persistent inflammation of single joint confirmed by ultrasound PD examination, in case of no contraindications were qualified for RSV procedure. For the RSV following radiotherapeutics were used: rhenium-186 sulphide in 41 cases for shoulder (2), elbow (15), wrist (22), hip (2) and ankle (2) joints; yttrium-90 citrate in 27 cases for knee joints; erbium-169 citrate in 8 cases for small joints of hand and feet. All patients had a follow-up visit 3 and 6 months after RSV, during which a clinical and ultrasound examination of the treated joints were performed. Continuous adverse events collection was conducted.

**Results:** The most common indication for RSV was RA – 60 procedures (78.9%), followed by AS – 10 (13.2%), PsA – 4 (5.3%) and JIA – 1 procedure (2.6%). 27 patients had RSV intervention in one joint. 17

patients with satisfactory response to RSV in one joint required radioisotope treatment in another joint (between 2 and 4 different joints were treated in each patient – 13 patients in 2 joints, 5/3 and 2/4). Median patient age was 50 years (21 – 72). Duration of continuous bDMARD treatment preceding RSV was between 1 and 72 months. The intervals between bDMARD administration and RSV ranged from below 24 hours to 4 weeks. Satisfactory effects of RSV, defined as absence of clinical and ultrasound symptoms of inflammation, were observed after 55 (72.4%) interventions. In 11 (14.4%) cases after initial improvement, the inflammation symptoms recurred less than 6 months after RSV. In 10 (13.2%) cases RSV had no effect.

No side effects or adverse events occurred after RSV and, most importantly, there were no local or systemic infections observed up to 6 months after the procedure.

Conclusion: RSV seems to be an effective single joint treatment method in patients with active synovitis refractory to bDMARDs. Despite increased susceptibility to infection in patients partially immunocompromised and biological treatment, no septic complications were observed after RSV. RSV does not require discontinuation of biological treatment, unlike surgical synovectomy.

FRID090 SINGLE CENTRE COHORT OF REFRACTORY RHEUMATOID ARTHRITIS ALSO IDENTIFIES A RARE SUBGROUP OF MULTIPLE TARGETED THERAPY CLASS NON-RESPONSE

John Filton 1,2, Andrew Melville 1,2, Kamran Naraghi 1,2, Jacqueline Nam 1,2, Shouvik Dass 3, Paul Emery 1,2, Maya Buch 1,2. 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Chapel Allerton Hospital, Leeds, United Kingdom; 2NIMR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3Leeds Teaching Hospitals NHS Trust, Rheumatology, Leeds, United Kingdom

Background: Refractory Rheumatoid Arthritis (RefRA) has emerged as an area of unmet need in the biologic era (1). Failure of 3 or more classes of targeted therapy or failure of both an anti-cytokine and a cell-targeted treatment have been proposed as possible definitions (1, 2). The BSRBR-RA reported 6% fulfilled RefRA criteria (due to lack of efficacy and/or toxicity; but only including a first line TNF inhibitor bDMARD cohort) (2).

Objectives: To evaluate the extent of multi-targeted therapy RefRA in our tertiary RA single-centre experience, and identify any patterns of drug sequencing associated with development of RefRA.

Methods: We used a prospective database of RA patients established on targeted therapy, supplemented with information from individual funding requests and a review of our specialised biologic clinic patient notes to identify those who have been prescribed 2 or more classes of targeted therapies. Data on number and type of targeted therapy, and where available, reason for failure has been recorded. Disease activity state and functional outcomes are currently being evaluated.

Results: Of a cohort of over 1500 RA patients that have received at least 1 targeted therapy, 172 patients have received 3 classes of targeted therapies (reasons for each drug discontinuation has been identified in 166 cases). An additional 50 patients have received multiple (2 or more) TNFi and at least 1 other class of targeted therapy (2). Table 1 details numbers in each category of targeted therapy.

Mixed NR and toxicity | 19 | 36 | 17 |
Multiple toxicity | 3 | 2 | 1 |

* 48 patients received one anti-cytokine and one cell-targeted bDMARD, 12 received two anti-cytokine bDMARD (TNF and tocilizumab) and 3 received two cell targeted treatments (rituximab and abatacept).

In those who had failed multiple anti-TNF drugs 39 were switched to a cell-targeted therapy (31 Rituximab, 7 Abatacept), the rest were switched from a TNFi to tocilizumab. 36 out of 39 patients have maintained a response to their cell-targeted therapy after failing multiple anti-cytokines. 5 Patients demonstrate at least 3 primary non-responses with a further 4 further patients with multiple primary non-response and only 1 adverse event.

Conclusion: Over 10% of our single-centre targeted therapy exposed cohort demonstrate multi-targeted therapy RefRA. The majority comprise mixed non-response, loss of response and drug toxicity. A rare subgroup of 6% of RefRA demonstrate lack of efficacy to multiple therapies. On-going investigations aim to identify the clinical phenotype, predictors and underlying biology.

FRID091 UNEMPLOYED FEMALE RHEUMATOID ARTHRITIS PATIENTS ARE LESS ADHERENT TO THE BIOLOGIC DMARD TREATMENT

FRISO LABR1, Francesca Ornetto1, Davide Astori1, Bernd Rahfelder1, Costantino Bortoli1, Daniela Azzolina1, Marta Favero1, Dario Gregori1, John Done4, Andrea Doria1, 1University of Padova, Rheumatology Unit – Department of Medicine (DIMED), Padova, Italy; 2University of Padova, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy; 3University of Padova, Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy; 4University of Hertfordshire, Department of Psychology and Sports Sciences, Hatfield, United Kingdom

Background: The 5-item Compliance Questionnaire for Rheumatology (CQR5) allows the identification of patients likely to be high adherers (HAs) to anti-rheumatic treatment (i.e. taking >80% of their medications correctly), or “low adherers” (LAs). An Italian version of the questionnaire was validated (I-CQR5) [1].

Objectives: The objective was to investigate what factors are associated with high treatment adherence according to I-CQR5 in RA patients treated with biologic DMARDs (bDMARDs).

Methods: RA patients (with disease duration >1 year, undergoing treatment with <1 self-administered biological disease-modifying anti-rheumatic drug (bDMARD), willing and capable of completing the questionnaire unaided) were enrolled in the study. I-CQR5 were anonymous and clinical data were collected from the local database. Factors included were demographic, social characteristics of the patients, clinical and treatment variables. Factors achieving a p<0.10 in univariate analysis were included in a multivariate regression analysis.

Results: Among 604 RA patients, 193 patients were included in the validation analysis. Median age of the patients was 57 years (46-65), 142 (73.4%) were females, median disease duration was 15 years (9-21); 82 (42.7%) patients were treated with low dose bDMARDs; 174 (91.1%) patients were in low disease activity or remission (Fig.1). HAs were 40.9% (79/193) of patients: 100% (193/193) of patients treated with bDMARDs and 22.4% (57/193) of those treated with bDMARDs in combination with conventional synthetic DMARDs. Female gender, no employment, lower education level, positive Rheumatoid Factor and/or Anti-Citrullinated Peptides Antibodies, low bDMARD dose, higher patient-VAS were significantly more frequent in LAs compared with HAs. In the multivariate analysis, employment was also positively and significantly associated with high adherence: OR 2.89 (1.3-6.44), p=0.009 (Tab.1).

Conclusion: As previously reported only one third of RA patients treated with bDMARDs were found to be HAs to treatment according to the I-CQR5. Employment status was the major determinant, increasing by almost 3-fold the likelihood of being adherent. Education level and female gender might be also taken into account as factors influencing treatment adherence.

SAFETY AND EFFICACY OF FILGOTINIB IN ACTIVE RHEUMATOID ARTHRITIS BY PRIOR BIOLOGICAL DMARD EXPOSURE IN PATIENTS WITH PRIOR INADEQUATE RESPONSE OR INTEGRATION TO BIOLOGICAL DMARDS (BDMARD-IR)

Mark C. Genovese1, Kenneth Kalunian2, Jacques-Eric Gottenberg3, Neelufar Mozaffarian4, Beatrix Bartok4, Franziska Matzkies4, Jie Gao4, Ying Guo4, Mark C. Genovese1, Kenneth Kalunian2, Jacques-Eric Gottenberg3, David Walker4, Kurt de Vlam5, Tsutomu Takeuchi5

Background: Filgotinib (Fil), an oral selective Janus kinase 1 (JAK1) inhibitor, significantly improved the signs and symptoms of rheumatoid arthritis (RA) in patients with a favorable safety profile in a global phase 3 study in bDMARD-IR patients with active RA (FINCH2).1

Objectives: To assess the safety and efficacy of FIL in the FINCH2 study by the number and type of prior bDMARDs.

Methods: FINCH2 enrolled 449 bDMARD-IR patients with moderate-to-severe active RA. Patients were randomized 1:1 to FIL 200 mg, FIL 100 mg or placebo (PBO) on a background of csDMARDs for 24 weeks. In this prespecified subgroup analysis, efficacy and safety were analyzed according to the number (<3 vs ≥3) of previous bDMARDs used.

Results: 448 patients received ≥1 dose of study drugs. Of these, 343 were previously exposed to <3 bDMARDs, while 105 were previously exposed to ≥3 bDMARDs. Table 1 shows demographics and baseline (BL) characteristics of patients in these 2 groups; efficacy and safety parameters (Table 2) were similar for both groups. There were no cases of opportunistic infection, active tuberculosis, malignancy, gastrointestinal perforation, or death.

Medical Surgical Center named after N.I.Pirogov

Background:
The new millennium biologic therapies e.g. tumor necrosis factor inhibitors (TNFi) have played a major role improving clinical outcomes in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA). A major limitation in many countries for pre-
scribing these drugs has been the high drug costs. The present time for sales of these TNFis e.g. infliximab, etanercept and adalimumab has ended and as a consequence biosimilar TNFis are now reaching the market. This has a cost saving potential for payers. In Norway, encour-
aged by the health authorities, non-medical switch from biologic originator drugs with biosimilar drugs available, including etanercept. To the best of our knowledge no longer than one year real life experienced real life evi-
dence data for non-medical switch from originator etanercept to biosimilar etanercept SB4 exist (ref.1).

Objectives:
At the participating outpatient clinics patients with RA, PsA and axSpA were monitored using a computer clinical system, as standard clini-
care. Demographic, clinical and treatment data were retrieved from the computer system for patients who started treatment with biosimilar etanercept SB4 between January 2016 and January 2019. Kaplan-Meier survival curves were used to explore drug survival. Survival differences between groups were tested using Breslow statistics.

Results:
At the participating outpatient clinics since 2016 a total of 474 RA, 249 PsA and 320 axSpA patients had a non-medical switch from biologic originator to biosimilar etanercept SB4. In RA, PsA and ax-
SpA patients the percentage of women was 68.2%, 42.6% and 30.3%, the percentage of current smokers 17.0%, 12.8% and 19.6%, mean (SD) age was 63.0 (13.1), 58.2 (11.3), 53.1 (12.1) years and disease duration 16.8 (9.8), 16.1 (9.7), 17.7 (9.0) years, respectively. In RA 80.0% were anti-CCP positive and in PsA and axSpA 34.4% and 90.8% were

1Immuno-Rheumatology research group, IDI-Paz. La Paz University Hospital, Madrid, Spain; 2Immunoology Department, Ramón y Cajal University Hospital and IRYCIS, Madrid, Spain; 3Rheumatology Department, Ramón y Cajal University Hospital and IRYCIS, Madrid, Spain; 4Rheumatology Department, La Paz University Hospital, Madrid, Spain; 5Immunoology Department. La Paz University Hospital, Madrid, Spain.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease with the typical characteristic of synovitis of small-sized and medium-sized joints that leads to cartilage and bone damage. TNF inhibitors (TNFi) are widely used for the treatment of rheumatoid arthritis (RA) however, there are still no objective indicators of clinical response to TNFi therapy.

Objectives: To analyse the change of peripheral blood mononuclear cells (PBMC) profile after 6 months (m) of treatment with TNFi in order to find cellular indicators of response.

Methods: Prospective bi-center pilot study including 100 RA patients receiving TNFi therapy. PBMC were isolated from patients at baseline and 6m of treatment, and were analysed by flow-cytometry. Clinical activity at baseline and 6m of TNFi treatment was assessed by DAS28. Clinical remission (DAS28<2.6) after 6m of treatment was considered as optimal response. The association between clinical remission and the percentage of change (Δ, 6m-0m) within each PBMC subset was analysed through univariate logistic regression model (odds ratio; 95% CI; β; p-value).

Results: Demographic characteristics before starting TNFi therapy are shown in Table 1. After 6m of TNFi treatment, 40% patients achieved clinical remission. Decreased percentage of B cells (ΔCD19+) was found after 6m of TNFi treatment in optimal responders, while suboptimal responders did not show differences with the baseline (OR: 0.78; 95% CI: 0.63-0.97; β: -0.25; p: 0.027) (Figure 1). This effect was essentially owing to a reduction of naïve B cells (OR: 0.76; 95% IC: 0.62-0.94; β: -0.27; p: 0.011) (Figure 1). No significant association was found between the other PBMC subsets (monocytes, NK cells, CD4+ T cells and CD8+ T cells) and clinical remission (Figure 1).

FRI0086 TNF CONCENTRATIONS DURING TREATMENT OF INFLAMMATORY DISEASES WITH GOLIMAMB
Femke Hooijberg1, Lea C. Berkhout2,3, Merel J. Lam1, Sadaf Aligi3, Michael Nurmohamed1, Arick de Vries3, Charlotte L. Krieckaert2, Theo Rispen3,2, Gert-Jan Wolbink1,2,3, Amsterdam Rheumatology and Immunology Center Reade, Amsterdam, Netherlands; 2Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands; 3Landsteiner Laboratory, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands; 4Biologics Lab, Sanquin Diagnostic Services, Amsterdam, Netherlands; 5Amsterdam Rheumatology and Immunology Center, location VUMc, Amsterdam, Netherlands

Background: Golimumab is a monoclonal antibody that binds TNF, countering its pro-inflammatory effects. Berkhout et al. (2019) described the development of a novel drug-tolerant assay to quantify TNF during TNF-inhibitor treatment. Using this assay, they analyzed the dynamics of TNF during treatment of rheumatoid arthritis (RA) patients with adalimumab and found that TNF levels shortly after treatment initiation predict nonresponse (1). Our study is the first to measure TNF levels during golimumab treatment, using the same drug-tolerant assay.

Objectives: To describe the dynamics of TNF in patients with RA, ankylosing spondylitis (AS) or psoriatic arthritis (PsA) during golimumab treatment.

Methods: Consecutive patients with RA, AS, or PsA starting golimumab treatment were included in this prospective observational cohort study, named the Reade Rheumatology Registry. Serum samples drawn during the study visits were analyzed for drug levels, anti-drug antibody (ADA) formation, and TNF concentrations using a regular enzyme-linked immunosorbent assay (ELISA), a radioimmunoassay, and a drug-tolerant competition ELISA, respectively. Regression analyses were used to analyze the data. Missing data was imputed using last observation carried forward.

Results: In total, 304 serum samples from 69 patients were included in this study. The median follow-up period was 52 (interquartile range (IQR) 16-130) weeks. Median TNF concentration at baseline was 4 (IQR 3-105) pg/ml and this increased to 68 (37-127) pg/ml four weeks after treatment initiation. During follow-up, TNF concentrations remained stable for the majority of patients (Figure 1). TNF levels at baseline were already high in the majority of patients (Figure 1). TNF levels at baseline were already high in the majority of patients (Figure 1). TNF levels at baseline were already high in the majority of patients (Figure 1). TNF levels at baseline were already high in the majority of patients (Figure 1). TNF levels at baseline were already high in the majority of patients (Figure 1). TNF levels at baseline were already high in the majority of patients (Figure 1).

Conclusion: Golimumab therapy was found to induce an increase in TNF concentrations, independent of disease activity. This is in line with what has been found for adalimumab treatment. However, TNF concentrations measured in this study were at least twice as low as TNF concentrations during adalimumab treatment (1). The high baseline TNF concentrations in 25% of the patients were also surprising, as it indicates that patients switch to golimumab while their TNF is still in complex with a previous TNF-inhibitor.

Background: Numerous biological DMARDs (bDMARDs) are used in RA treatment, however detailed knowledge of patients’ perceptions on drug use and the impact of adverse drug reactions (ADRs) is sparse.

Objectives: To gain insight into bDMARD-induced ADRs and their burden from the RA patients’ perspective.

Methods: The Dutch Biologic Monitor is an ADR-patient web-based questionnaire used for a prospective, multicentre, event monitoring cohort study including patients using a bDMARD for an immune-mediated inflammatory disease between January 1, 2017 and December 31, 2018. Patients were asked to complete questionnaires bi-monthly about used bDMARDs, indication and bDMARD-induced ADRs. ADRs were coded according to MedDRA terminology and their impact was measured on a 5-point scale, ranging from 1 (no burden) to 5 (very high burden). Per patient, every recurrent unique ADR was included as one ADR. ADRs regarding infections (INF), skin (SK), gastrointestinal (GI) and injection site (INJ) were clustered and analysed for the reported prevalence and burden. Fatigue and headache were separately analysed for prevalence and burden. The prevalence of clustered ADRs between the various bDMARDs was compared using a $\chi^2$ test and the average burden was compared using a Mann-Whitney U test.

Results: In the Dutch Biologic Monitor 583 consecutive (44.8%) RA patients were included (71.2% female, average age 59 years, SD=12.4) using the originator or a biosimilar of etanercept (ETN, 265), adalimumab (ADA, 196), tocilizumab (41), abatacept (35), certolizumab pegol (23), rituximab (19), infliximab (18), golimumab (15), sarilumab (2), secukinumab (1), anakinra (1). Almost half of the patients (276; 47.3%) reported at least one bDMARD-induced ADR with a total of 703 ADRs in 2,559 completed questionnaires. Patients reported 129 INJ reactions (129 ADRs/ 583 pts, prevalence of 22.1%, reported by 86 pts) with an average

Figure 1

Conclusion: Golimumab therapy was found to induce an increase in TNF concentrations, independent of disease activity. This is in line with what has been found for adalimumab treatment. However, TNF concentrations measured in this study were at least twice as low as TNF concentrations during adalimumab treatment (1). The high baseline TNF concentrations in 25% of the patients were also surprising, as it indicates that patients switch to golimumab while their TNF is still in complex with a previous TNF-inhibitor.

SWITCHING RATE OF BIOLOGICAL DMARDS IN RHEUMATOID ARTHRITIS PATIENTS: TREASURE – REAL LIFE DATA

Umut Kalyoncu, Ali İlhan Ertenli, Abdulsamet Erden, Orhan Küçükkahin, Timuçin Kaifoğlu, Ediz Dalıköç, Cemal Bes, Nüfils Alpay Kantel, Hakan Emmungil, Pamir Atagündüz, Bekir Nihan Coşkun, Burcu Yağış, Süleyman Serdar Koca, Muhammet Çiçoğlu, Aşkın Ateş, Servet Akar, Deddy Gerioğlu, Duygu Ersözü, Veli Yazıcı, Emre Emmungil, Süleyman Serdar Koca, Abdulsamet Erden, Orhan Küçükkahin, Süleyman Serdar Koca: None declared, Ali İlhan Ertenli: None declared, Pamir Atagündüz: None declared, Belkıs Alpay: None declared, Hakan Emmungil: Grant/research support from: MSD, Roche, Pfizer, Consultant for: MSD, Abbvie, Roche, UCB, Novartis, Speakers bureau: MSD, Abbvie, Roche, Pfizer, UCB, Novartis, Sander W. Tas: None declared, Harald Vonkeman: None declared, Jette van Lint: None declared, Naomi Jessurun: None declared.

Background: In rheumatoid arthritis (RA), biologic DMARDs are important treatment options in resistant patients. Inefficacy or side effects may cause switching between these drugs.

Objectives: This study aimed to determine features of patients switching from one biologic DMARD to another in RA treatment and to investigate associated reasons for switching.

Methods: This multicenter, prospective observational cohort study used the TReasure database in which web-based registration of RA and spondyloarthritis patients are being performed in 15 centers across different regions of Turkey. In this study, data of RA patients switching from one biologic agent to another were analyzed. Demographic and clinical data, follow-up duration, time to switch, and reasons for switching were retrieved from the database.

Results: Of the included 2115 RA patients, 829 (39.2%) switched between biologic agents (switched group) and 1286 (60.8%) continued to receive their current therapies (continued group). The median follow-up duration of all patients was 3.7 years and the median time to switch was 1.1 years. In the switched group, the proportion of females and the median HAQ-DI score were higher as well as disease duration was longer (Table 1). Among the biologic agents used at first, 60.9% of the patients were receiving an anti-TNF agent and 39.1% of the patients were receiving other biologic agents (Table 2, figure 1). In the switched group (n=829), the main reasons for switching were secondary inefficacy (n=269), primary inefficacy (n=238), and side effects (n=178) followed by primary or secondary unknown inefficacy (n=106), patient’s demand (n=21), physician’s request (n=16), willing to be pregnant (n=7), other (n=31), and unknown (n=54).

Conclusion: The patients in the Treasure database were followed-up approximately 4 years and about one-third of the patients had to switch from one biologic DMARD to another. The main reasons for this switching were primary (29.2%) and secondary (33.0%) inefficacy and 20% of the patients had to switch due to side effects. According to the switching pattern, about half of the patients using an anti-TNF agent at first switched to another anti-TNF agent and the other half switched to other biologic agents.

PREDICTIVE FACTORS FOR REMISSION ACHIEVEMENT BY TOCILIZUMAB MONOTHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER INADEQUATE RESPONSE TO METHOTREXATE: A POST HOC ANALYSIS OF THE SURPRISE STUDY

Masaru Kato1, Yuki Kanoke2, Yoshia Tanaka3, Masayuki Inoue4, Hitomi Kobayashi-Harakatsa1, Kichi Amari5, Masayuki Miyata6, Yokhu Murakawa7, Hidekata Yashuka7, Shintaro Hirata8, Nazile Sultan Yasil Bilge9, None declared, Zeynel Abidin Akar: None declared, Omer Karadag: None declared, Ayeş Bahar Kelesoglu Dincer: None declared, Sedat Yılmaz: None declared, Uluk Igen: None declared, Yavuz Pelihvani: None declared, Ender Terzioglu: None declared, Levent Kılıç: None declared, Şükran Ertan: None declared, Sedat Kızıra: None declared.

Methods: This is a post hoc analysis of the SURPRISE study, a 2-year randomized, controlled study comparing the efficacy of tocilizumab with (ADD-ON) and without methotrexate (SWITCH) in active RA patients despite methotrexate therapy. The primary endpoint was the DAS28-ESR remission (< 2.6) at week 24. The change in modified total Sharp score (mTSS/year) was also assessed as an end-point.

Results: In SWITCH (n = 96), CRP, SAA, RF and DAS28 at baseline showed predictive value for DAS28 remission at week 24 in univariate analysis. Multivariate analysis confirmed SAA, RF and DAS28 at baseline, but not CRP, as predictive factors, with SAA having the highest value (OR [95%CI] by decrease of 5.0 µg/mL = 1.011 [1.002-1.020], p = 0.01, ROC-AUC = 0.731). SAA of < 50.0 µg/mL showed extremely high predictive value for DAS28 remission (OR [95%CI] = 6.012 [1.997-18.096], p = 0.0088, ROC-AUC = 0.761). Furthermore, the structural remission (mTSS/year ≤ 0.5) rate at week 52 was significantly higher in patients with SAA of < 50.0 µg/mL than those with SAA of ≥ 50.0 µg/mL (71% vs 51%, p = 0.048). In contrast, in ADD-ON (n = 98), only DAS28 at baseline showed predictive value for DAS28 remission at week 24 in both univariate and multivariate analysis. In patients with SAA < 50.0 µg/mL, both DAS28 remission (75% vs 77%, p = 0.79) and structural remission (71% vs 68%, p = 0.71) rate were comparable between SWITCH and ADD-ON.

Conclusion: SAA levels at baseline can predict the necessity of concomitant methotrexate in tocilizumab initiation in patients with RA. Patients with low levels of SAA at baseline may benefit similarly from tocilizumab therapy with and without methotrexate in terms of achieving clinical and structural remission.

REFERENCE:
Background: Disease Modifying Anti-Rheumatic Drugs (bDMARD) tapering is possible in rheumatoid arthritis (RA) patients in sustained remission. However, only minimal data are available on progressive tapering of non-TNF bDMARD such as tocilizumab (TCZ) or abatacept (ABA). Objectives: The TOLEDO (Towards the Lowest Efficacious Dose) trial aimed to assess the impact on disease activity of progressive tapering of non-TNF bDMARD such as tocilizumab (TCZ) or abatacept (ABA). Patients: A total of 233 patients fulfilling ACR-EULAR 2010 criteria for RA were included in the TOLEDO trial. Methods: In this multicenter open-label non-inferiority randomized open-label controlled trial assessing tocilizumab or abatacept injection spacing in rheumatoid arthritis patients in remission.

Results: Of the 233 patients, 117 were randomized to the spacing arm and 116 to the maintenance arm. At all 2-year follow-up points, patients in the spacing arm achieved significantly better disease activity compared to patients in the maintenance arm. The non-inferiority of the spacing arm was maintained in the ABA and TCZ subgroups. The spacing arm was associated with a lower incidence of relapses and durable relapses compared to the maintenance arm. The spacing arm was also associated with a lower incidence of adverse events compared to the maintenance arm. Conclusion: The TOLEDO trial demonstrated the feasibility and safety of progressive tapering of non-TNF bDMARD in RA patients in sustained remission. Further studies are needed to confirm the long-term safety and efficacy of progressive tapering of non-TNF bDMARD in RA patients.
Non-Medical Switching from Originator to Biosimilar Etanercept – No Evidence for a Relevant Nocebo Effect – A Retrospective Analysis of Real-Life Data

Uta Kiltz1,2, Styliani Tsiami1,2, Xenofon Baraliakos1,2, Juergen Braun1,2.
1Rheumazentrum Ruhrgebiet, Herne, Germany; 2Ruhr-University, Bochum, Germany

Background: Real-world data about switching patients from originator product to a biosimilars are important to assess and to document the outcome of switches in clinical practice in order to confirm the low risk of major problems. It has been hypothesized that lack of efficacy and adverse drug events (ADEs) upon switching from reference biologics to biosimilar products are related to the nocebo effect [1].

Objectives: To evaluate the effectiveness and safety of systematic non-medical switching from innovator etanercept to biosimilar etanercept SB4 in adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (axSpA) in a real-life setting based on different information strategies before switching.

Methods: Data of all adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (axSpA) who had received innovator etanercept and were switched in our specialized center from innovator to biosimilar etanercept for economic reasons were retrospectively analysed. Whether or not patients were informed about the switch was left to the discretion of the treating physician. Disease activity and function were regularly assessed, and any changes were recorded in two consecutive visits at week 12 and 24. The scores documented at week 12 after switching were taken as primary outcome. AEs were documented.

Results: A total of 84 patients were included (44 RA, 25 axSpA and 15 PsA patients), 24 of which had received information about switching (28.5%). The scores at week 12 of both, disease activity and function, remained rather unchanged (Table 1). Whether patients had been informed about switching or not did not influence outcomes or AE. The retention rate of the biosimilar was 96.4% (n=81) at week 12 and 87.6% (n=71) at week 24 (Figure 1). While 7 patients were lost to follow-up, 6 patients discontinued due to inefficacy or AE, including one malignant melanoma. Overall, 18 AEs were reported in 10 patients (12%). In 3 patients (3.6%) who had 5 AEs in the first 12 weeks the innovator was successfully re-administered.

Conclusion: Systematic switch from innovator to biosimilar etanercept was not associated with changes in disease activity or function in all three indications within 12 weeks. This was independent of information on the switch transmitted to the patients.

GOLIMUMAB IMPROVES WORK PRODUCTIVITY AND ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA), ANKYLOSING SPONDYLITIS (AS) AND PSORIATIC ARTHRITIS (PSA): FINAL RESULTS FROM A NON-INTERVENTIONAL STUDY IN GERMANY (GO-ART)

Ines Klaudius1, Klaus Krueger2, Sven Remstedt3, Astrid Thiele1,4, MSD Sharp and Dohme GmbH, Haar, Germany; 1Praxisszentrum St. Bonifatius, Munich, Germany; 2Rheuma Praxis, Berlin, Germany; 3Krankenhaus St. Josef, Wuppertal, Germany

Background: Golimumab (GLM) has shown its efficacy and tolerability in various randomized clinical trials. Systemic data for GLM regarding health-economic parameters in daily clinical practice are essential not only for pharmaceutical companies but also for cost-benefit analyses in Germany.

Objectives: This prospective NIS was designed to evaluate the impact of GLM therapy on work productivity and activity as well as Quality of Life (QoL) in patients with RA, AS or PsA in Germany under routine settings over an observation period of 12 months, plus an additional voluntary extension period of 12 months (total 24 months) to collect long-term data on health economic parameters.

Methods: GO-ART was an observational prospective study on patients with RA, AS or PsA (biologic-naive and biologic-experienced) who started treatment with GLM at 63 sites of Germany. The primary endpoint was the change in work productivity/activity impairment as measured by Work Productivity and Activity Impairment (WPAI) questionnaire from baseline, measured primarily at month 3 and secondarily at months 6, 12 and 24. As secondary endpoint the change in quality of life (RAQoL for RA patients, ASQoL for AS patients and NAPPA-QoL for PsA patients) was assessed.

Results: 748 patients (RA=250, PsA=249, AS=249) started GLM therapy. The primary efficacy endpoint was analyzed in the modified intention-to-treat (mITT) subset of 493 patients (RA=158, PsA=157, AS=249) with full-time or part-time employment at baseline (mITT).

A total of 548 patients entered the additional 12-month observation period, of which 303 completed the 24-month assessment. By 3 months after initiation of Golimumab treatment, a marked improvement was seen in all 4 WPAI domain scores (‘presenteeism’, ‘total work productivity’, ‘total work productivity impairment’ (TWPI), and ‘activity impairment’) in daily living because of patient’s health problems related to RA, PsA or AS, as shown in Table 1 (all p-values <0.05).

The statistically significant improvements in the mean WPAI domain scores were maintained over the 24-month observation period in all 3 indications with a higher treatment effect regarding ‘activity impairment’ and ‘presenteeism’ compared to ‘absenteeism’ (Table 1). Quality of life improved significantly (p<0.0001) from baseline at month 3, 6, 12 and 24 in patients with RA (RAQoL), AS (ASQoL) and PsA (NAPPA-QoL) based on questionnaire data of 237 RA patients (RA-mITT), 228 AS patients (AS-mITT) and 235 PsA patients (PsA-mITT) indicating a clinically relevant improvement.

Conclusion: Treatment with GLM provided sustained improvement in WPAI and QoL in patients with RA, PsA and AS over the observational period of 24 months.

All scores of the WPAI showed a significant (p<0.05) reduction in mean score values in each indication at time points of 3, 6, 12 and 24 months after initiation of treatment with GLM. GLM leads to an improvement of work productivity and daily activities in patients already within the first 3 months of treatment.

as an ETN biosimilar. There is limited evidence on outcomes of transition from originator to biosimilar in a multi-country real-world setting.

**Objectives:** To provide real-world evidence on outcomes of transition from ETN to SB4 in routine clinical practice at EU sites.

**Methods:** Eligible patients had RA or axSpA and had initiated SB4 in routine clinical practice following a minimum of 6 months treatment with a stable dose of originator ETN, at clinics in France, Germany, Italy, and Spain. Data were captured from patient records prospectively and/or retrospectively for 6 months following transition. Outcome measures include clinical characteristics, disease scores (DAS-28 for RA, BASDAI for axSpA) and clinical management.

**Results:** Analysis of 533 eligible patients (347 RA, 186 axSpA) demonstrated no clinically significant change in disease score from baseline to 6 months post-transition; mean individual change was 0.0 (95% CI -0.1, 0.1) and 0.0 (95% CI -0.3, 0.2) at 6 months post-transition in RA and axSpA subjects respectively. Regarding dose regimen, 73.5% and 63.4% of RA and axSpA subjects transitioned from ETN 50mg QW to SB4 50mg QW, by 6 months post-transition, 73.5% and 63.4% of subjects were receiving SB4 50mg QW.

**Conclusion:** The results of this analysis show that treatment with CT-P13 across the 4 studies (RA = 670; AS = 819; PsA/PsO = 90). Mean age (years) of patients per RA, AS and PsA/PSO indication was 54.5, 40.3 and 52.9, respectively. Average exposure duration (days) to CT-P13 in patients with RA, AS and PsA/PSO was 280.3, 254.0 and 322.1, respectively, and the mean maximum dose of CT-P13 (mg/kg) with RA, AS and PsA/PSO patients was 3.77, 4.51 and 4.31, respectively. Treatment emergent adverse events (TEAEs) were reported in 50.15%, 37.73% and 26.67% for RA, AS and PsA/PSO, respectively. Incidence of TEAEs in RA indication is consistent with the historical rate in this population. Treatment emergent serious adverse events (TSEAs) were reported for 12.39%, 4.52% and 3.33% for RA, AS and PsA/PSO patients, respectively. Incidence of TEAEs leading to discontinuation were 8.81%, 3.42% and 7.78% for RA, AS and PsA/PSO. Two deaths and 1 death were reported among RA and AS patients, respectively. The causes of death in RA patients were acute respiratory distress syndrome (ARDS) and bronchopneumonia; the cause of death in the AS patient was unknown. AEIs of CT-P13 were analysed in safety population who were treated with CT-P13 at least once by the data cut point. No events of serum sickness, haematologic malignancy, demyelinating disorder, sarcoidosis/sarcoidosis-like reaction were reported.

FXR0105 EXPRESSION OF UNCOUPLING PROTEIN-1 IN SUBCUTANEOUS FAT IS INCREASED BY TOCILIZUMAB

Lovisa Lyngfelt1, Malin C. Erlandsson1,2, Karin Me Andersson1, Sofia Töyrä Silfverswärd1, Maria I Bokarewa1,2, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Adipose tissue is an important player in cardiovascular (CV) morbidity. Thermogenic brown adipocytes, rich with uncoupling protein 1 (UCP1), increase metabolic and CV health. (1)

Objectives: Study the impact of anti-rheumatic treatment on production of UCP1 in subcutaneous fat of RA patients.

Methods: Samples of subcutaneous fat were collected from 125 female RA patients by aspiration from periumbilical region. Expression of UCP1 and a reverse cholesterol transport protein ABCA1 were measured by qPCR and analyzed with respect to anti-rheumatic treatment and clinical disease activity. BT treatment, the patient comprised 4 major groups including tocilizumab (Tocilizumab: n=14), anti-TNF (n=29), methotrexate monotherapy (n=47) and methotrexate-sulfasalazine-hydroxychloroquine (triple therapy, n=15). CV risk was estimated using the Framingham risk algorithm.

Results: Measurable expression of UCP1 was found in 54.6% of the studied fat tissue samples. Patients on Tocilizumab had measurable expression of UCP1 in 79%, which was significantly more often than among TNFi-treated (45%, p=0.04) and MTX-treated patients (42%, p=0.02). Patients on triple therapy had also often measurable UCP1 levels compared to other groups (69% vs 43%, p=0.035). Tocilizumab patients have more lean body mass than patients treated with TNFi. This was based on lower BMI in Tocilizumab treatment patients compared to other groups at 24.1 vs 27.1, p=0.041; 23.6 vs 27.1, p=0.017; respectively). Additionally, the estimated muscle mass by creatinin/height ratio was significantly lower in TNFi than in triple therapy (p=0.034) and Tocilizeumab (p=0.008). Clinically, the treatment groups were similar in age, disease activity (DAS28) and disease duration with the exception for Tocilizumab. Tocilizumab patients were older (65 vs 57, p=0.004) and had numerically longer disease duration (17y vs 7y) and lower DAS28 (1.98 vs 3.11).

Notably, Tocilizumab patients had significantly higher TC compared to TNFi (p=0.027), and triple therapy (p=0.041). Triple therapy had the lowest TC levels (p=0.017). The differences were due to LDL, here patients on Tocilizumab had higher LDL than TNFi (p=0.09) and triple therapy (p=0.015). Serum HDL was similar. These differences in serum lipids were not related to expression of ABCA1 or UCP1. Despite the difference in the serum lipid profile, the estimated CV risk was significantly lower in Tocilizumab compared to MTX patients (4.10-87.57) vs 6.60(3.9-9), p=0.041.

Conclusion: In this study is Tocilizumab treatment is associated with persistent UCP1 production by adipose tissue. This was followed by lower estimated CV risk and favourable body composition in female RA patients.

FR0106 SARILUMAB AND TOCILIZUMAB RECEPTOR OCCUPANCY (RO), AND EFFECTS ON C-REACTIVE PROTEIN (CRP) LEVELS, IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

Christine Xu1, Patrick Nolan1,2, Guoqian Lui1, Anice Paccayla1, Melitza Iglesias-Rodriguez1, Gregory St John2, Chad Nivens3, Rafael Madonna1, Tomonori Ishii1, Ernest Choiy1, Vanaja Karamanulu1, Sanofi, Bridgewater, NJ, United States of America; Sanofi Aventis, Montpellier, France; Regeneron Pharmaceuticals, Inc., Tarrytown, NY, United States of America; Sanofi Genzyme, Cambridge, MA, United States of America; Pompeu Fabra University, Barcelona, Spain; Tohoku University Hospital, Sendai, Japan; Cardiff University School of Medicine, Cardiff, United Kingdom

Background: Objectives: The in vitro binding affinity of sarilumab (Kd 61.9 pM) for the human interleukin-6 receptor (IL-6R) is 15–22-fold higher than tocilizumab. We explored the relationship between IL-6R RO, relevant pharmacodynamic (PD) variables (eg CRP), and potential clinical relevance of the differences between sarilumab and tocilizumab.

Methods: Binding to total soluble IL-6R (sIL-6R) in vivo translates into the quasi-steady-state target-mediated drug disposition pharmacokinetics (PK) and indirect-response PD model with inhibition of elimination of sIL-6R and unbound sIL-6R concentration for both sarilumab and tocilizumab. PK/ PD models were used to simulate sIL-6R RO dynamic profiles (% RO over time) for: sarilumab after subcutaneous (SC) doses of 200 and 150 mg once every 2 wks (q2w); tocilizumab after SC doses of 162 mg q2w and once every wk (qw); and tocilizumab after intravenous (IV) doses of 4 and 8 mg/kg once every 4 wks (q4w). In addition, RO profiles were compared with changes in observed CRP levels in patients with RA following administration of sarilumab SC and tocilizumab IV (ASCERTAIN study; NCT01768572). In this study, 60.8% of patients required an increase in tocilizumab dose from 4 to 8 mg/kg IV during the study period, based on clinical response.

Results: Sarilumab SC 200 mg q2w achieved >90% RO after the first dose, which was maintained over the dosing interval throughout the 24-wk treatment course; at the lower dose of 150 mg q2w, RO was >90% from the second dose onwards. RO for tocilizumab SC, at 162 mg q2w, was >90% immediately after the first dose but dropped below 50% prior to the second dose. Similarly, for tocilizumab IV at 4 mg/kg q4w, the RO was high immediately after the first dose (>99% at Wk 1) but decreased over the dosing interval. At trough steady-state (Wk 24), RO was greater with sarilumab SC 200 mg q2w (98%) and 150 mg q2w (94%) compared with tocilizumab SC 162 mg q2w (84%) and IV 4 mg/kg q4w (60%). The higher doses of tocilizumab SC 162 mg q2w and tocilizumab IV 8 mg/kg q4w were able to maintain RO >99% at steady state, similar to sarilumab SC 200 mg at steady state. CRP levels in patients with RA were inversely associated with RO at trough; the greatest suppression in CRP was seen in patients who received sarilumab SC (at either dose) or the higher IV tocilizumab dose (Fig). However, proportionally smaller reductions in CRP levels were observed with the lower IV tocilizumab dose (4 mg/kg q4w), consistent with the lower RO of tocilizumab.

Conclusion: The higher binding affinity of sarilumab to IL-6R compared with tocilizumab translated into higher RO and greater reduction in CRP levels for sarilumab than tocilizumab, confirming the expected association between RO and PD effect. Sarilumab SC 200 mg q2w led to a rapid and sustained suppression of CRP over the 24-wk interval investigated; however, a higher dose (IV) or frequency of administration (SC) of tocilizumab was required to maintain the same degree of RO and CRP suppression. CRP may be a useful tool in clinical practice for patients treated with an IL-6R blocker.

Disclosure of Interests: Study funding and editorial support (Helen Johns, Adelphi) provided by Sanofi and Regeneron Pharmaceuticals, Inc.

Objective: To assess the effect of co-medication with MTX or other csDMARDs on drug survival of TNFi treated RA patients.

Methods: All adult patients with RA followed in the Czech national registry ATTTRA who started TNFi therapy after January 1st 2012 were considered. Six-year drug survival for patients on TNFi in combination with MTX, with other csDMARD or in monotherapy was analyzed using Kaplan-Meier method, log rank test was used to compare differences between groups. Reasons for TNFi discontinuation were analyzed. ATTTRA is a centralized prospective computerized registry of patients receiving biologic disease modifying anti-rheumatic drugs (bDMARD) therapy for rheumatic diseases collecting data on efficacy, safety and quality of life of all patients treated with bDMARDs in the Czech Republic. TNFi therapy is indexed for patients with RA who have failed treatment with at least one csDMARD.

Results: A total of 1841 RA patients initiated first bDMARD treatment during the studied period, with 1724 patients receiving TNFi. 1307 patients (76%) started TNFi therapy in combination with MTX, 267 patients (15%) with other csDMARD and 150 patients (9%) as monotherapy. Overall unadjusted TNFI drug survival was better in patients receiving MTX co-medication (median survival 53 months) compared to those receiving other csDMARD (median survival 36 months) or those being on monotherapy (median survival 21 months; p<0.001 for monotherapy vs MTX co-medication) (Figure). The most common reason for TNFi discontinuation was loss of efficacy (33%, 37% and 28% for MTX, csDMARD combination and monotherapy respectively) followed by primarily inefficacy (20%, 19% and 27%) and adverse events (19%, 15%, 23%).

Conclusion: In this registry study of patients with RA, use of MTX co-medication was associated with significantly better first TNFi drug survival compared to other csDMARD co-medication and to monotherapy.
Short-term efficacy of BCD-089, novel monoclonal anti-IL6 receptor antibody, in combination with methotrexate in patients with rheumatoid arthritis: 12-week results of phase 2 Aurora study

Background: In the previous phase 1 study, BCD-089 (INN: levilimab) was well-tolerated, had favorable safety profile and low immunogenicity. Here we report 12-week efficacy and safety results of ongoing phase 2 clinical study of BCD-089 in patients with active RA.

Objectives: This study is aimed to assess efficacy and safety of 2 dosing regimens of BCD-089 in patients with MTX-IR active RA.

Methods: During this multicenter double-blind placebo-controlled randomized clinical study (NCT03355842), 105 MTX-IR patients with active RA (ACR2010) were assigned (1:1:1) to receive 162 mg of BCD-089 subcutaneously (QW arm and Q2W arm) or PBO. MTX (10-25 mg/week) was used in all groups. After completion of 12-week blinded period patients from QW and Q2W arms continued the treatment, patients from PBO arm were switched to BCD-089 Q2W until Week 56. The primary efficacy endpoint was the rate of ACR20 at Week 12. Secondary endpoints included ACR50/70 and DAS28-CRP(4). The safety was routinely evaluated.

Results: The efficacy analysis showed that 95% confidence interval for BCD-089 treatment effect relative to PBO was [38.45 ≤ 63.4] for Q2W arm, which confirms the superiority to PBO of either dosing regimen. Summary of efficacy results is presented in Table 1.

The majority of adverse events (AE) were laboratory abnormalities. The spectrum of AEs is similar to other IL6R inhibitors (Table 2). Three serious adverse events (SAEs) were reported: community-acquired pneumonia (QW arm, treatment-related), acute cholecystitis (PBO arm, not related, did not lead to treatment discontinuation), and acute heart failure leading to death (Q2W arm, not related). One case of moderate local reaction (erythema) was reported in QW arm.

Conclusion: BCD-089 in combination with MTX had superior efficacy compared with MTX plus PBO in MTX-IR patients with active RA. BCD-089 showed safety profile consistent with other IL6R inhibitors. Further clinical studies are needed.

52.8% over 2.0 years of exposure to GLM and 45.2% over 1.6 year of exposure to GLM-IV.

Conclusion: In this real-world study of Canadian patients with RA, differences in baseline characteristics between patients treated with an anti-TNF switch over time and between agents show potential selection bias when selecting a given therapy and may impact the proportion of patients achieving a target-specific outcome. Treatment significantly reduced disease activity and improved functionality in a similar fashion and were also safe and well tolerated.

FR0110  RITUXIMAB BIOSIMILAR NON-MEDICAL SWITCH – DOES IT WORK?

Muhammad Khurram Nisar, Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom

Background: Since the introduction of anti-TNF biosimilars in routine clin- ical practice, there has been a drive to implement the switch program for all biosimilars at the point of availability. Rituximab biosimilar was granted marketing authorisation by the EMA in February 2017. Our Trust was one of the first centres to embrace a CQUIN which required adoption of biosimilar within three months for new patients and one year for switch- ers. This helped deliver significant savings to the NHS whilst achiev- ing similar clinical outcomes.

Objectives: We report our early experience of introducing rituximab biosim- ilar in people with RA.

Methods: A list of all patients prescribed rituximab was extracted through our BMIC system. A switch letter was drafted and sent to all patients includ- ing Truxima information sheet. Patients were given the opportunity to contact nurse helpline for information or if disease control worsened/adverse effects developed. We reviewed all relevant records and collected data on any adverse events and disease outcome on either side of the switch. Patients were reviewed as originally planned by their respective clinicians.

Results: 44 patients with RA on 2 g dose six-monthly were identified established on rituximab. Four had stopped treatment prior to switching. All 40 agreed to switch to Truxima that was completed by February 2018. Mean age of switchers was 58.6 (range 26-80 years). Eighty were men and remaining 32 (80%) were women. Fourteen (35%) were Asian, one Afro-Caribbean and the rest (62%) were White Caucasian. DAS28 scores were available for all participants. Prior to the switch median DAS28 was 3.0 (range 0.6-5.1). Following the switch it was 2.95 (range 1.5-5.7). Amongst these, eight (20%) reported adverse effects. Four had serum sickness reaction within the first week of the second dose with loss of efficacy. One required admission to ED (24 hrs) for further management. All decided against further biosimilar and three were swapped back to the originator with no further concerns. In one case the clinician decided to change the class of drug to a TNF inhibitor. Three patients had mild intolerance and agreed to continue Truxima with no fur- ther issues. One patient developed milky tuberculosis and was taken off biologic therapy.

Conclusion: Our experience of switching rituximab patients is certainly not as smooth as it was for infliximab and etanercept. All were happy to switch after receiving a letter and having the opportunity to contact if necessary. Substantial annual cost savings of nearly £140,000 were achieved once the switch process completed. At group level there were no significant differences in seven of eleven adverse events including serum sickness reaction with loss of efficacy and loss of confidence in the drug. One patient developed military TB despite having one previous originator cycle with no issues. We support the routine switching from originator to biosimilar rituximab however close monitoring is required cer- tainly in the first few weeks of dose administration.

FR0111  ASSOCIATION BETWEEN RHEUMATOID FACTOR STATUS AND DISCONTINUATION OF TUMOR NECROSIS FACTOR INHIBITORS DUE TO INEFFECTIVENESS IN RHEUMATOID ARTHRITIS

Yoosukha Okawa1, Nobunori Takahashi2, Toshfshi Kojima3, Naoki Ishiguro3,1. Nakatsuigawa Municipal General Hospital, Nakatsuigawa, Japan, 1. Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: As for the treatment of rheumatoid arthritis (RA), the influ- ence of rheumatoid factor (RF) positivity on the long-term efficacy of tumor necrosis factor inhibitors (TNFis) is controversial.

Objectives: We conducted an exploratory study in a large cohort of RA patients to evaluate the relationship between RF status and the discontinu- ation of TNFi treatment due to ineffectiveness in a clinical setting.

Methods: This study included bio-naive RA patients enrolled in the Tsuru- mai Biologic Communication Registry in Japan. The crude comparison of TNFi discontinuation due to ineffectiveness between seropositive and se- ronegative patients was analyzed using the cumulative incidence func- tion of competing events and Gray test. We assessed the associations between baseline patient characteristics and discontinuation of TNFi ther- apy due to insufficient response using Fine-Gray proportional hazard regression. Fine-Gray proportional hazard analysis considered competing events of interest, including insufficient response, adverse event, palliation, and personal reasons.

Results: Demographic and clinical characteristics of each group are summarized in Table 1. There was a higher discontinuation rate due to insufficient response in RF positive patients than in RF negative patients using Gray test (Figure). RF positivity was significantly predictive of the discontinuation of TNFi therapy due to ineffectiveness using Fine-Gray proportional hazard regression analysis after adjusting for baseline charac- teristics, including age, sex, stage, class, disease activity at baseline, methotrexate use, and prednisolone use (Table 2).

FRI0110
Conclusion: Using Fine-Gray proportional hazard regression, we demonstrated that RF positivity was related to a higher discontinuation rate of TNFi therapy due to ineffectiveness in bio-naive RA patients.

Disclosure of Interests: Yoshikazu Ogawa: None declared, Nobunori Taka-hashi Speakers bureau: AbbVie, Bristol-Myers Squibb, Chugai, Eisai, Mitsubishi Tanabe, and Pfizer. YS has received speakers fees from Astellas, Bristol-Myers Squibb, and Ono, Toshihisa Kojima Grant/research support from: Chugai Pharmaceutical (Investigator Initiated Study), Novartis, Nippon Kayaku, Eli Lilly, Eisai, Speakers bureau: AbbVie, Bristol-Myers Squibb, and Ono, Toshihisa Kojima Grant/research support from: Chugai Pharmaceutical (Investigator Initiated Study), Novartis, Nippon Kayaku, Eli Lilly, Eisai, Tanabe Mitsubishi, Naoki Ishiguro Grant/research support from: AbbVie, Asahi Kasei, Astellas, Chugai, Daichi-Sankyo, Eisai, Kaken, Mitsubishi Tanabe, Otsuka, Pfizer, Takeda, and Zimmer Biomet, Consultant for: Ono, Speakers bureau: Astellas, Bristol-Myers Squibb, Daiichi-Sankyo, Eli Lilly, Pfizer, and Taisha Toyama

Background: One of the most important complications of biological disease-modifying antirheumatic drugs (bDMARDs) is severe infection, and management of patients who develop severe infection during treatment with bDMARDs is a great concern. However, no consensus exists regarding bDMARDs readministration following treatment for bDMARDs-associated infection.

Methods: The study sample comprised patients with RA who were examined and prescribed bDMARDs at Osaka Minami Medical Center between January 2010 and December 2017, as part of the MiRAi cohort. The patients who developed severe infections during bDMARDs treatment were followed-up for 12 months. Logistic regression analysis was performed using baseline disease activity, baseline treatment, and disease activity and treatment during the 12-month period.

Results: Severe infections developed in 164 of a total of 1192 patients who were treated with bDMARDs during the study period, and the severe infection rate was 5.73/100 patients-years. Among the 164 patients, bDMARDs were readministered in 130 (79.3%), whereas treatment with bDMARDs was discontinued in 34 patients (20.7%). We observed 31 cases of patients with severe infections during the follow-up period (18.9/100 patients-years), of which 20 patients (15.4/100 patients-years) belonged to the bDMARDs readministration group and 11 (32.4/100 patients-years) belonged to the bDMARDs discontinuation group. The adjusted odds ratio (OR) for severe infection recurrence within 12 months in the bDMARDs discontinuation group was 0.39 [95% confidence interval (CI) 0.16-0.96]. At 12 months after infection, high-dose prednisolone treatment (adjusted OR 1.35, 95%CI 1.08-1.69), high C-reactive protein level (adjusted OR 1.28, 95%CI 1.02-1.62), and low serum albumin levels (adjusted OR 0.30, 95%CI 0.01-0.89) were associated with high risk of severe infection recurrence (Figure).

Conclusion: Patients who developed severe infection during bDMARDs treatment were at an extremely high risk for severe infection irrespective of the readministration or discontinuation of bDMARDs after infection. Discontinuation of bDMARDs, high dose of prednisolone 12 months after infection, high levels of C-reactive protein 12 months after infection, and low levels of albumin 12 months after infection were identified as risk factors for severe infection recurrence in these patients. However, bDMARDs readministration did not increase the risk of severe infection recurrence.

COMPARISON OF INFECTION-RELATED HOSPITALIZATION COSTS IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH ABATACEPT OR OTHER TARGETED DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS)

Damenmarie Paul, Francis Lobo, Varshaman Patel, Dhaval Patil, Bristol-Myers Squibb, US HEOR, Lawrence Township, United States of America

Background: Costs due to differences in risk of hospitalization infection associated with targeted disease-modifying anti-rheumatic drugs (DMARDS) in patients with RA have not been evaluated.

Objectives: Compare the risk and cost of infection-related hospitalizations in tumor necrosis factor inhibitor (TNFi)-experienced RA patients subsequently receiving DMARDS in the US.

Methods: A retrospective, observational study was conducted with 2 insurance claims databases (MarketScan and PharMetrics; January 1, 2009-June 30, 2017). Analyses were conducted in both datasets individually and in aggregate. The study population was adult TNFi-experienced RA patients initiating a subsequent DMARD (date of DMARD therapy-index date). Patients had 12 months of continuous enrollment prior to the index date (baseline period), and were required to have ≤1 outpatient medical claims on 2 different dates with a diagnosis code for RA. Patients with other autoimmune conditions were excluded. Follow-up began ≥12 months ending with the earliest of (1) end of insurance enrollment; (2) end of study period; (3) end of index treatment. Cohorts included (1) abatacept; (2) TNFi: adalimumab, certolizumab pegol, etanercept, golimumab, and infliximab; and (3) other non-TNFi: tocilizumab, rituximab, and tocilizumab. Hospitalized infection costs were measured on a per-patient-per-month (PPPM) basis (2016 USD). Two-part multivariable generalized linear models (GLMs) examined differences in costs. Baseline comorbidities, infection incidence, healthcare costs, payer type, age, gender, and geographic region were used as regression covariates. Log transformation and gamma distribution were applied in GLMs.

Results: Overall, most patients were female (79%) with an average age of 52 years. Although a higher percentage (4.5%) of patients in the abatacept cohort had a hospital visit for infection in the baseline period compared to TNFi (2.0%, P<0.001) and other non-TNFi (3.6%, P=0.02619), the trend reversed in the follow-up period (2.8% for abatacept vs 3.7% for TNFi and 5.2% for other non-TNFi, P<0.05). Regression results indicated a significantly higher risk for hospitalized infection for patients receiving a TNFi [HR: 1.6 (95% CI: 1.1, 2.2)] or other non-TNFi [HR: 1.9 (95%; 1.3, 2.8)] vs abatacept. Mean PPPM (95% CI) inpatient costs in the follow-up were $73 ($17-$158) for abatacept, $115 ($27-$224) for TNFi, and $125 ($29-$264) for other non-TNFi. Difference from baseline to follow-up PPPM inpatient costs was significantly lower for abatacept (difference of $42 for TNFi and $52 for other non-TNFi, P<0.05).

Conclusion: There were significantly lower infection-related hospitalizations and associated costs for TNFi-experienced RA patients who were switched to abatacept compared to patients switched to other therapies.

ABATACEPT IN EARLY RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

Damenmarie Paul1, Leticia Ferre1, Grace Crockett1, Lauren Mintzer2, Mr Sohail Fazeli2. 1Bristol-Myers Squibb, Princeton, NJ, United States of America; 2Doctor Evidence LLC, Santa Monica, CA, United States of America

Background: Rheumatoid arthritis (RA) is a wide-spread and debilitating disorder that is becoming increasingly relevant in an aging global population. Identifying and treating RA early in disease course is critical for preventing disability and joint damage.

Objectives: The goal of this systematic literature review (SLR) and meta-analysis was to compare the relative efficacy of abatacept (ABA) to other currently used recommended therapies for RA. Studies of interest were randomized controlled trials (RCTs) and observational studies. Outcomes included ACR50, DAS28, radiographic change, and adverse events where available. A search from January 1998 to June 2018 was performed on MEDLINE®, Embase, MEDLINE® and the Cochrane CENTRAL databases. Additional research was searched on US and European clinical trials registries from January 2005 to June 2018 and conference proceedings from ACR and EULAR from 2014 to 2018. A Bayesian network meta-analysis (NMA) was performed on the DCC Data™ platform for the RCTs with reported results on ACR50, DAS28 remission, total withdrawal, and withdrawal due to adverse events.

Results: We identified 90 publications on 69 unique trials reporting efficacy and safety outcomes in patients with early RA, including 43 RCTs and 26 observational studies. The included studies had low risk as assessed by the Cochrane Collaboration’s tool for assessing risk of bias. The studies were predominantly double-blind phase III or IV trials. Twenty-eight trials were included in the NMA evaluating ABA (n=1 trial), ABA+MTX (n=2), ADA+MTX (n=2), CTZ+MTX (n=2), ETN (n=1), ETN+MTX (n=1), HCQ+SSZ+MTX (n=1), HCQ+SSZ+Pred+MTX (n=1), IFX+MTX (n=4), MTX (n=2), MPred+MTX (n=2), MPred+Pred+MTX (n=1), Pred+SSZ+MTX (n=2), Pred+MTX (n=1), Pred (n=1), SSZ (n=4), SSZ+MTX (n=2), TCZ (n=2), TCZ+MTX (n=2), TOF (n=2), and TOF+MTX (n=2). Abatacept as monotherapy was similar to the combination of ABA and methotrexate for efficacy outcomes, ACR 50 (ABA vs ABA+MTX RR 0.82 [95% CI 0.51-1.35]), and DAS28 Remission (RR 0.76 [95% CI 0.39-1.49], as well as for all-cause withdrawal (RR 1.8 [95% CI 0.91-3.2]) and withdrawal due to adverse events (RR 2.35 [95% CI 0.69-7.38]). Both ABA as monotherapy and ABA+MTX were similar to all other comparators (as monotherapy or combination therapy) with respect to main efficacy and safety outcomes. Data reported in observational studies was not in line with the RCT analysis.

Conclusion: The results of this NMA similar efficacy between ABA and other biologics both as monotherapy and in combination with traditional DMARDS in early RA. Further investigation and comparison of different treatment options for early RA is warranted as the growing evidence base evolves in favor of using more novel therapies for RA. ABA-abatacept; ADA-adalimumab; CTZ-certolizumab; ETN-etanercept; HCQ-hydroxychloroquine, IFX-infliximab, MPred= methylprednisolone, MTX= methotrexate; Pred-prednisone, SSZ=sulfasalazine, TCZ= tocilizumab, TOF=tofacitinib.

TRAJECTORIES OF THE EQ-5D SCORE AMONG A LARGE COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH BIOLOGICAL DMARDS USING THE IORRA COHORT

Kumiko Sai1, Eichi Tanaka1, Eliseue Inoue2, Mai Abe1, Mikagawa1, Eri Sugano1, Naphiro Sugiland2, Meeo Okuhi1, Yoko Shinji1, Rei Yamaguchi1, Naoki Sugimoto1, Katsunori Ikari1, Ayako Nakajima2, Atsuo Tashigawa3, Hisashi Yamakana1, 1Tokyo Women’s Medical University, Tokyo, Japan; 2St. Marianna University School of Medicine, Kanagawa, Japan; 3Mie University Hospital, Mie, Japan

Background: Patient-reported outcomes are important for evaluating the disease status of patients with rheumatoid arthritis (RA). The EuroQol five-dimensional descriptive system (EQ-5D) has been used for health-related quality of life (QOL) in clinical research and pharmacoeconomic studies. RA is a chronic disease associated with pain, fatigue, disability, and functional loss, which can markedly decrease patient QOL.
The treatment strategies for RA and the QOL of RA patients, which is evaluated in daily practice using the EQ-5D, have changed significantly since the introduction of biological disease-modifying anti-rheumatic drugs (bDMARDs).

Objectives: To identify patient subsets with distinct EQ-5D trajectories among RA patients taking bDMARDs, and to examine the clinical features of patients whose QOL improved since bDMARD use in daily practice.

Methods: Since October 2000, we have established a large observational cohort of RA patients at our institute Institute Of Rheumatology, Rheumatoid Arthritis (IORRA). Essentially, all RA patients who attend our clinic are given questionnaires, including the EQ-5D, Disease Activity Score 28 (DAS28), and the Japanese version of the Health Assessment Questionnaire (J-HAQ), every 6 months. More than 5,000 RA patients are included in this cohort, of whom 785 patients who received bDMARDs for at least 3 years were enrolled in this study. The EQ-5D scores of these 785 patients were recorded biannually for 3 years, and latent class analysis of the temporal trends in the EQ-5D score based on posterior probabilities was performed after initiation of bDMARDs. The clinical characteristics of each latent class were then compared.

Results: The 785 patients (107 taking infliximab, 341 etanercept, 100 tocilizumab, 131 abatacept, 90 golimumab, and 16 certolizumab pegol) were classified into four classes based on time-related changes in their EQ-5D scores: Class 1 (n = 160), patients with a consistently low score < 0.6 despite use of bDMARDs; Class 2 (n = 314), patients with a consistently moderate score of 0.7; Class 3 (n = 229), patients whose score improved from 0.7 to 0.9 after use of bDMARDs; and Class 4 (n = 78), patients with a consistently high score of 0.9. When comparing the patients in Classes 2 and 3, whose EQ-5D scores before bDMARD use were similar, the patients in Class 3 had a younger age (<0.001), shorter disease duration (<0.001), higher DAS28 score (<0.001), lower J-HAQ score (<0.038), and more frequent use of non-steroidal agents (<0.002) than those of Class 2 patients.

Conclusion: The results of this study suggest that QOL is less likely to improve in patients with RA whose disabilities and QOL deterioration have already become established despite use of bDMARDs. We also determined the clinical features of RA patients whose QOL improved after initiation of bDMARDs.

FR0116 SUBCUTANEOUS TOCILIZUMAB IN MONOTHERAPY OR IN COMBINATION WITH CSDMARD IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS: OBSERVATIONAL STUDY TO DESCRIBE REAL-WORLD DRUG RETENTION RATE AT 12 MONTHS

Alain Sarau1, Thomas Barretche2, Guy Baudens3, Isabelle Idier4, Flore Delaporte5, Pascal Hilquin1,1. University Hospital La Cavale Blanche, Rheumatology, Brest, France; 2. University Hospital of Bordeaux, Rheumatology, Biostatistics, Bordeaux, France; 3. Private practice, Rheumatology, Valenciennes, France; 4. Chugai Pharma France, Medical, Paris La Defense, France; 5. TanIM STATS, on behalf of Roche, Statistics, Boulogne-Billancourt, France; 6. Hopital Sud Francilien, Rheumatology, Corbeil-Essonnes, France

Background: Rate of discontinuation and drug survival of biologic therapies in rheumatoid arthritis (RA) is about 60-70% in real life at one year. In France, all biologics 1st prescription and yearly renewal are reimbursed, restricted to hospital rheumatologists, with renewal and monitoring done by both office-based or hospital rheumatologists.

Objectives: To evaluate the 12-month drug retention rate, efficacy and tolerance of tocilizumab (TCZ) subcutaneous (sc) in RA patients (pts).

Study design: prospective, multicentre, observational 18-month study. Pts moderate to severe active RA requiring TCZ sc as prescribed in real life.

Primary endpoint: drug retention rate of TCZ sc at 12 months in pts followed by hospital- and office-based rheumatologists, estimated using Kaplan-Meier method. Secondary endpoints: pts characteristics, concomitant treatments, adherence to TCZ sc using the Compliance Questionnaire for Rheumatology (CQR5), efficacy, safety of TCZ sc and QoL using EQ-5D.

Statistical analysis: pts with ≥1 TCZ injection were analyzed for safety. Pts fulfilling inclusion and non-inclusion criteria were analyzed for efficacy.

Results: 291 pts were recruited, 286 were analyzed for safety and 285 for efficacy.

Baseline: mean age 56.2±12.5 years, females: 74.7%, at least 1 co-morbidity: 71.9%, mean RA duration 9.4±9.0 years, RF and/or ACPA: 60.8%, erosive RA: 60.8%, mean DAS28-ESR 4.77±2.12. Past RA treatments were csDMARDs in 94.4%, biologics in 62.8%, EQ-5D Health state was 0.53±0.19. TCZ Mono (i.e. without csDMARD) was initiated in 124 (43.5%), TCZ Combo in 158 (55.4%) pts, 64.8% of whom received MTX (17.3±4.4mg/w). Glucocorticoids (GCs) were used in 48.9% of the pts (9.9±9.3mg/d).

Follow up: 161 and 148 pts completed M12 and M18 visits. 138 pts withdrew including AE 61, lack of efficacy 37, pts/doctor wish 24. At M12, drug retention rate was 63.6%: 62.6% in Mono, 64.3% in Combo (Fig1); with similar results for pts ≥56 years old and for pts ≥30Kg/m². 5 Mono pts had ongoing csDMARD and 9 Combo pts had no csDMARD. 15.3% and 19.0% used GCs, 16.1±11.9mg/d in the Mono and 17.36±16.65mg/d in the Combo groups. Total number of TCZ injections was 36.7±25.84 done by pt in 54.0%. Mean time between 2 TCZ injections was 8.4±10.70 days. Adherence to TCZ was high in 86.5% of the 89 pts who completed CQR5 at month 12. It was 52.9% for the 121 pts who completed pts diary over the month 12-month 18 period. Mean time from injection to next visit was 2.12±1.14 respectively. EULAR good and moderate responses were respectively 61.3 and 7.7% in all: 67.2 and 4.9% in Mono; 56.8 and 9.9% in Combo pts. EQ-5D improved in all domains with a change from baseline of 0.11 to 0.29, 0.18 (81.8%) pts had at least 1 adverse event (AE), 46 (16.1%) had at least 1 serious AE including 11 infections, 2 GI perforations and 2 deaths (pneumopathy and bronchial carcinoma).

Figure 1. Kaplan-Meier curve of the drug retention rate by SC TCZ in mono vs combo - Efficacy population.
Conclusion: At 12 months, drug retention rate was 63.6% in patients receiving TCZ sc in real life, with no difference between Mono and Combo groups. EULAR good/moderate response was 69.0%. QoL improved in all EQ-SD domains. No new safety signal occurred.

THE COMPARATIVE RISK OF OSTEOPOROTIC FRACURES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TFN INHIBITORS VERSUS OTHER BIOLOGICS: A NATION-WIDE COHORT STUDY IN KOREA

Anna Shin1, Ya-Hui Dong2, Seungwhan Shin3, You-Jung Ha4, Yun-Jong Lee5, Eun Bong Lee5, Yeong Wook Song5, Eun Ha Kang6, 1Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Sungnam, Korea, Rep. of (South Korea); 2National Taiwan University Graduate Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan, Republic of China; 3Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis (RA) is associated with an increased risk of osteoporosis and osteoporotic fracture, but little is known about comparative risk of osteoporotic fractures between biologic agents.

Objectives: To investigate the comparative risk of osteoporotic fractures among RA patients who initiated TNF inhibitors, abatacept, and tocilizumab.

Methods: We identified patients aged ≥ 40 years with at least two ICD-10 diagnosis codes for RA who initiated TNF inhibitor, abatacept, or tocilizumab from the 2005-2015 Korean National Health Insurance Service datasets. The primary outcome was a composite osteoporotic fracture endpoint of spine, hip, forearm or humerus fractures requiring hospitalization. Secondary outcomes were spinal and non-spinal fractures. Follow-up period started from the day after the first dispensing date of the study drug to the earliest date among the following events: discontinuation of the study drugs, outcome occurrence, disenrollment, end of study dataset, or death. Propensity score (PS) matching with a variable ratio of 10:1 was conducted for TNF inhibitor versus abatacept initiators and for TNF inhibitor versus tocilizumab initiators to adjust for baseline confounding. We estimated hazard ratio (HR) and 95% confidence interval (CI) of osteoporotic fracture risks comparing TNF inhibitors to abatacept or tocilizumab by Cox proportional hazard models stratified by a matching ratio.

Results: We included 2,339 TNF inhibitor initiators and 594 abatacept initiators, and 2,486 TNF inhibitor initiators and 647 tocilizumab initiators in each PS-matched cohort. The incidence rates per 100 person-years for the primary outcome were 1.57 and 1.65 for TNF inhibitor and abatacept initiators, and 1.69 and 2.05 for TNF inhibitor and tocilizumab initiators, respectively. The HR (95% CI) for the primary outcome was 1.10 (1.54-2.23) comparing TNF inhibitors versus abatacept and it was 1.00 (0.53-1.92) comparing TNF inhibitor versus tocilizumab initiators. We also did not find any significant difference for secondary outcomes (Table1).

Table 1. Risk of osteoporotic fractures in TNF inhibitor initiators vs. abatacept initiators and tocilizumab initiators

FR0118 INFECTION OUTCOMES IN PATIENTS WITH RA TREATED WITH ABATACEPT AND OTHER DMARDS: RESULTS FROM A 10-YEAR INTERNATIONAL POST-APPROVAL STUDY

Teresa Simon1, Samy Suissa2, Mary Lou Skovron3, Thomas Frisell4, Johan Aukling5, Kaleb Michaud6, Sofia Pedro7, Anja Strangfeld7, Maarten Boers7, Diane Lacaille7, Marc Hochberg8, Veena Hoffman10, Andres Gomez1, 1Bristol-Myers Squibb, Princeton, United States of America; 2McGil University, Montreal, Canada; 3Karolinska Institutet, Stockholm, Sweden; 4University of Nebraska Medical Center, Omaha, United States of America; 5FORWARD, The National Databank for Rheumatic Diseases, Wichita, United States of America; 6German Rheumatism Research Centre, Berlin, Germany; 7Amsterdam University Medical Centers, Vrije Universiteit, Amsterdam, Netherlands; 8Arthritis Research Center, Richmond, Canada; 9University of Maryland, Baltimore, United States of America; 10Opuntia Epidemiology, Ann Arbor, United States of America

Background: The abatacept global post-marketing epidemiology programme consists of observational studies based on biologic disease registries and healthcare claims databases to assess infection and malignancy risks associated with abatacept treatment, as used in routine clinical practice.

Objectives: To evaluate the risk of infection in patients with RA treated with abatacept versus conventional synthetic (cs)DMARDs and other biologic (b) or targeted synthetic (ts)DMARDs.

Methods: Data were analysed from five cohorts: two biologic registries (the Anti-Rheumatic Therapy in Sweden register and the Rheumatoid Arthritis Observation of Biologic Therapy German registry), a disease registry (FORWARD, The National Databank for Rheumatic Diseases in the USA) and two healthcare claims databases (the population-based British Columbia Canadian RA Cohort and the US Optum Research Database). Crude incidence rates (per 1000 patient-years of exposure) with 95% CIs were estimated using multivariate models adjusting for demographics, comorbidities and other potential confounders within each database and were subsequently pooled between random effects model for meta-analyses.

Results: From all cohorts, patients treated with abatacept (6400), csDMARDs (137K) and other b/tsDMARDs (54K) were followed up for a mean of 2.3–3.7, 2.6–6.2 and 2.3–4.7 years, respectively. Patients were mainly female (71–86%), with a mean age ranging from 49–63 years, and 3–18% had a history of prior severe infections across treatment groups/cohorts. A greater number of abatacept-treated patients had a history of ≥2 prior biologics (44–85% vs csDMARDs, 11% [FORWARD] and other b/tsDMARDs, 0–19%). In abatacept-treated patients, incidence rates for hospitalised infections ranged from 16–56 and opportunistic infections from 0.4–7.8 (Table). Adjusted RR (95% CIs) for abatacept vs csDMARDs (range: 0.3 [0.2, 0.7] to 2.2 [1.3, 3.7]; pooled estimate: 1.2 [0.6, 2.2]) and abatacept vs other b/tsDMARDs (range: 0.5 [0.3, 0.8] to 1.3 [0.8, 2.1]; pooled estimate: 0.9 [0.6, 1.3]) showed no increased risk in hospitalised infections.

Conclusion: In this large, international post-marketing epidemiology programme, pre-specified infection risks were more frequent with abatacept than csDMARDs and b/tsDMARDs in some, but not all, cohorts. Increased risks for individual outcomes/cohorts may be attributed to prior biologic exposure, study design and practice pattern differences. These data are consistent with the current safety profile of abatacept.

FRI0119 PREDICTING REMISSION AMONG PATIENTS WITH RHEUMATOID ARTHRITIS STARTING TOCILIZUMAB MONOTHERAPY: MODEL DERIVATION AND VALIDATION USING CONVENTIONAL REGRESSION AND MACHINE LEARNING

Jamie Collins1, Fredrik Johansson2, Sara Gale3, Seoyoung Kim1, Swastina Shrestha1, David Sontag1, Jaklyn Straton1, Trinh Huong1, Chang Xu1, Elena Losina1, Daniel Solomon1

Background: Most rheumatoid arthritis (RA) patients strive to consolidate their treatment from methotrexate combinations to monotherapy with the goal of the most effective and simplified therapy. Tocilizumab (TCZ) appears to have similar efficacy when used with or without concomitant csDMARDs in RA. Thus, it is clinically useful to predict treatment benefit among patients with RA starting TCZ monotherapy.

Objectives: To identify RA patients most likely to achieve remission with TCZ monotherapy by developing and validating a prediction model through conventional regression and machine learning.

Methods: We followed the TRIPOD recommendations for derivation and validation of clinical risk prediction models. Four TCZ monotherapy randomized controlled trials (RCT) in RA were identified (ACT-RAY, ADACTA, AMBITION, and FUNCTION) – two were chosen for derivation of the prediction models and two for validation. Relevant data for individual subjects from the trials were obtained, including demographics, RA characteristics, prior treatments, comorbid conditions, and baseline disease activity. In the two derivation trials, we examined each potential predictor of remission at a time in logistic regression models, adjusted for age, sex, and baseline CDAI. The dependent variable in all models was odds ratio (OR) based (forwarding variables to multi-variable models if OR > 1.5 or < 0.66); AIC based (lowest AIC); and a machine learning approach that fit a logistic regression model to covariates selected by a LASSO-regularized logistic regression. Based on these different variable selection approaches, variables were included to the final multivariable model in the derivation cohort (DC). Age, sex, and baseline CDAI were forced into all models. We assessed discrimination with the area under the curve (AUC), model fit with the AIC and BIC, and calibration graphically using loess smoothing and with calibration slopes. We assessed model performance in the DC and in the validation cohort (VC), using variables selected in the DC.

Results: Baseline characteristics in the derivation (n=473) and validation (n=380) cohorts were generally similar: mean age 51.6 years in DC and 52.1 in VC; 77% female in DC and 83% in VC; mean baseline CDAI 39.8 in DC and 42.1 in VC; disease duration was longer in VC 3.6 years compared to 0.9 in DC. Seventy-eight patients (17%) reached remission in the DC, 49 (13%) in the VC. After testing possible variables in the derivation models, the variables selected as predictors of remission included younger age, male sex, lower baseline CDAI, shorter RA disease duration, region of world (Europe and South America increased odds of remission vs. Asia and North America), no previous exposure to DMARD/MTX, lower baseline HAQ-DI, and baseline hematocrit (see Table). In the DC, model fit and calibration were adequate in all three models, though discrimination was notably reduced under 10 fold cross-validation. The VC modeling suggested that all three models were similar in discrimination and were well calibrated (see Table).

Conclusion: Different modeling strategies selected similar variables to predict remission using TCZ monotherapy: shorter disease duration, lower HAQ-DI, and no prior DMARD/methotrexate use. While these results should be interpreted with caution, as the analysis combined different studies that may represent different populations, they may provide guidance to clinicians tailoring treatment options based on baseline characteristics.

Table: Factors for predicting remission in patients with RA starting TCZ monotherapy: results from three different modeling strategies in derivation cohort and validation cohort with AUC and BIC.

**FRIO120**

### HIGH LEVELS OF INTERLEUKIN-6 (IL-6) IN RA PATIENTS ARE ASSOCIATED WITH GREATER IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES (PROS) FOR SARILUMAB COMPARED WITH ADALUMAB

**Vibeke Strand**, Susan Boklage, Toshiba Kimura, Florence Joly, Anita Boyapati, Jérôme Msaid, Stanford University, Palo Alto, United States of America; Regeneron Pharmaceuticals, Inc., Tarrytown, United States of America; Sanofi, Chilly-Mazarin, France

**Background:** Increased levels of cytokines, including interleukin-6 (IL-6), reflect inflammation and are predictive of therapeutic responses in patients with RA. IL-6 has been implicated in fatigue, pain and depression in RA but a formal association with PROs has not been performed. Sarilumab, a fully human monoclonal antibody directed against IL-6Ra, is approved for treatment of moderate-to-severely active RA. The phase 3 MONARCH randomized controlled trial (NCT01061736) compared the efficacy and safety of sarilumab monotherapy vs adalumab in RA patients who should not continue methotrexate treatment due to intolerance or inadequate responses. Greater reductions in disease activity and improvements in the clinical signs of RA and physical function were demonstrated with sarilumab vs adalumab. Better understanding of the association between IL-6 levels and PROs is warranted to evaluate sarilumab vs adalumab in MONARCH.

**Methods:** Serum IL-6 levels were measured at baseline in 300/369 patients in the ITT population. Patients were categorized into high, medium, or low IL-6 tertiles. Between-group comparisons of differences at Week 24 in Short Form-36 (SF-36) physical and mental component summaries (PCS, MCS) and domain scores, Functional Assessment of Chronic Illness Therapy (FACT)-fatigue, and morning stiffness visual analog scale (VAS) measures were performed within each tertile using a linear fixed effect model. In order to evaluate the differential effect of sarilumab vs adalumab in the baseline high vs low IL-6 groups, an interaction test of treatment-by-baseline IL-6 group analysis was performed using low IL-6 group as the reference.

**Results:** At baseline, patients in the high IL-6 tertile presented a significantly worse MCS and morning stiffness scores (P < 0.05). The model interaction comparing high vs low IL-6 tertiles was significant for SF-36 PCS and physical functioning domains, and for morning stiffness. In patients with high IL-6, sarilumab treatment resulted in significant (P < 0.05) improvements vs adalumab in SF-36 PCS (LS mean [LSM] of the difference: 5.57, 95%CI (2.85, 8.28)) and physical functioning (PF, 16.59 (8.15, 25.03)), role physical (9.44 (0.78, 18.10)), bodily pain (BP, 10.87 (3.92, 17.81)), vitality (8.93 (1.11, 16.74)), and social functioning (12.82 (3.07, 22.58)) domains (all raw values in Figure). Sarilumab also showed significant (P < 0.05) effects vs adalumab in FACT-Fatigue (4.86 (1.06, 8.65)) and morning stiffness VAS (-19.93 (-30.30, -9.56)), with LSM changes exceeding minimum clinically important differences (MCID).

**Conclusion:** Evaluation of IL-6 biomarker associations with PROs indicate that patients with high IL-6 levels report better improvements with sarilumab vs adalumab with safety profile consistent with IL-6R blockade. The effects of adalumab treatment are stable based on IL-6 tertiles but higher with sarilumab, particularly in the high IL-6 tertile group. Effects on PCS scores are mainly driven by the PF domain, consistent with previous reports of marked improvements in pain with high IL-6 levels.

### IMPROVEMENT OF MATRIX METALLOPROTEINASE-3 AT 12 WEEKS IS AN INDEPENDENT PREDICTIVE FACTOR FOR ACHIEVEMENT OF LOW DISEASE ACTIVITY AT 52 WEEKS IN BIO-SWITCH RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT

Nibunori Takahashi, Toshihisa Kojima, Shuj Asal, Naoki Ishiguro, Nagoya University Graduate School of Medicine, Orthopedic Surgery, Nagoya, Japan

**Background:** Japanese post-marketing surveillance (PMS) data demonstrated that effectiveness of abatacept in rheumatoid arthritis (RA) patients with previous biologics treatment (bio-switch) was significantly lower than that in bio-naïve patients [1]. Useful predictive factors for good clinical response of abatacept is necessary especially in the bio-switch patients.

Serum matrix metalloproteinase-3 (MMP-3) is an enzyme produced by synoviocytes which can be used to predict clinical effectiveness and joint destruction in RA patients [2]. However, little is known about the relationship between MMP-3 and effectiveness of abatacept.

**Objectives:** This study aimed to study whether serum MMP-3 levels can predict good clinical effectiveness of abatacept in the bio-switch RA patients using data from a multicenter cohort.

**Methods:** Participants were consecutive 423 RA patients treated with abatacept, observed for longer than 52 weeks, and registered in the TBCR, a Japanese multicenter registry system for RA patients treated with biologics. Multivariate logistic regression analysis was used to study predictive factors for achievement of low disease activity at 52 weeks separately in bio-naïve and bio-switch group.

**Results:** A total of 189 bio-switch and 234 bio-naïve patients were included in this study. ROC analysis revealed that MMP-3 improvement rate at 12 weeks, compared to 4 and 24 weeks, had highest AUC and the best cut-off value was 20.0% at 12 weeks for predicting achievement of low disease activity (LDA) at 52 weeks in the bio-switch group (Figure 1, right panel). We performed multivariate logistic regression analysis to study independent predictive factors for LDA at 52 weeks using patients’ background factors as well as 20% improvement of MMP-3 at 12 weeks.

In the bio-naïve group, DAS28-CRP score at baseline was the only predictive factor, while the achievement of 20% improvement of MMP-3 at 12 weeks was a significant independent predictive factor, with the achievement of 20% improvement of MMP-3 at 12 weeks was an independent predictive factor (adjusted OR, 3.550, p=0.005) in addition to DAS28-CRP in the bio-switch group (Table). In the bio-switch group, patients that achieved 20% improvement of MMP-3 at 12 weeks demonstrated significantly higher achievement rate of LDA at 52 weeks compared to those that did not achieve 20% improvement (60.0% vs 33.3%, p=0.001) (Figure 2).

Conclusion: In the bio-switch patients, we sometimes have difficulty to obtain good clinical response of abatacept and it would be even more important to judge whether to continue abatacept or whether to add other anti-rheumatic drugs as early as possible [3]. Our results suggested that the improvement of MMP-3 at 12 weeks would be a key to predict good clinical effectiveness of abatacept at 1 year. We would be better to note not only the major clinical indices such as DAS28 but also the change of MMP-3 to obtain the best clinical results in the bio-switch patients treated with abatacept.

REAL-WORLD SAFETY DATA FROM PATIENTS WITH RHEUMATIC DISEASES TREATED WITH CT-P13, AN INFliximab BIOSIMILAR: AN INTERIM ANALYSIS FROM AN OBSERVATIONAL STUDY

Peter C. Taylor1, Robin Christensen2, Shahzad Moosa3, Pamela Selem4, Ruffy Gullatoc, Heather Fowler6, Claire Bombardier6, Boulos Harau5.1. University of Oxford, Oxford, United Kingdom; 2. The Parker Institute, Copenhagen and Odense University Hospital, Copenhagen, Denmark; 3. Pfizer Inc, New York City, United States of America; 4. Pfizer Inc, Manila, Philippines; 5. Pfizer Inc, Maidenhead, United Kingdom; 6. UHN/MSH, Toronto, Canada; 7. University of Montreal, Montreal, Canada

Background: CT-P13, an infliximab biosimilar, has been available in Europe and Canada since 2015, and real-world experience with CT-P13 is important to support the safety of this medication. PERSIST is an ongoing, observational cohort study evaluating CT-P13 as treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in a real-world setting.

Objectives: This interim analysis reports safety outcomes for patients who received CT-P13 as their first biologic (Biologic-naive) or who switched from infliximab reference product (IFX-RP) to CT-P13 (Switched) based on data collected from September 2015 to December 2017.

Methods: Patients were recruited during usual care at 38 academic and community sites in 6 European countries and Canada. Adult RA, AS or PsA patients prescribed CT-P13 or locally-sourced IFX-RP at the investi-
gator’s discretion and according to the approved label were eligible. Data were analysed descriptively.

Results: This analysis included 329 patients (RA, n=134; AS, n=110; PsA, n=85). Of these, 6 (1.8%) were not treated, 3 (0.9%) completed study treatment, 244 (74.2%) were ongoing and 76 (23.1%) discontinued study treatment, most commonly due to lack of response (30 [9.1%]). Demographics and baseline characteristics were generally similar between groups (Table 1). Most treatment-emergent adverse events (TEAEs; Table 2) were of mild or moderate intensity; 7/129 events were severe. Most commonly reported adverse events were related to infection (n=33; 10.2%); most frequently reported infection-related TEAEs were nasopharyn-
giits (n=6; 1.9%), respiratory tract infection (n=5; 1.5%) and pneumonia (n=4; 1.2%). No case of tuberculosis was reported. Eight (2.5%) patients reported infusion related reactions.

Conclusion: Incidences of TEAEs were similar and there was no discern-
able pattern across the most common TEAEs between groups. These interim analysis results from the PERSIST study conducted in a real-

world setting are consistent with the known safety profile of infliximab and do not demonstrate new safety information to change the bene-

fit-risk profile of CT-P13.

**Background:** Several biologic disease modifying anti-rheumatic drugs (bDMARDs) are currently available, but comparisons among these different drugs in clinical trials are rare and follow-up duration in trials is often limited. A comparison of these bDMARDs in daily practice can provide clinically relevant knowledge on treatment survival of all currently available bDMARDs.

**Objectives:** To assess the survival of each and every one of the biological therapies available in patients with rheumatoid arthritis (RA).

**Methods:** The METEOR registry is a multinational project that includes data on 40,000 patients with RA from its diagnosis and prospectively, with proven reliability, in clinical practice. Inclusion criteria: patients >18 years in biological treatment (bDMARD); Variables under study: disease onset date, bDMARD initiation and discontinuation date, bDMARD type (infliximab, certolizumab, adalimumab, golimumab, etanercept, rituximab, tocilizumab and abatacept), concomitant treatment, line of treatment. Clinical variables: TJC, SJC, ESR, CRP, BMI, patient onset date, bDMARD initiation and discontinuation date, bDMARD type.

**Results:** From the 47,263 patients registered in the total METEOR data-base, 11,132 were eligible for inclusion of the current study. Of these, 9,516 had sufficient data available and were included in the analyses. Included patients (n=9,516) less often smoked than non-included patients (n=1,616), but other baseline characteristics were very similar between groups (data not shown).

Baseline features of all patients were similar. Median time on bDMARD as 1st line treatment for each drug is shown in Table 1, infliximab showed the longest median time on treatment. Using infliximab as ‘reference’ treatment, Table 2 shows abatacept, certolizumab, rituximab and tocilizumab showed higher hazard risk to finish DMARD treatment. Median time after study entry (Q1-Q3) was 69 (37-96) months as by December 2018. Overall number of patients in drug-free remission was 34/141 (24.1%), 10/38 (26%) in the control group, 6/50 (12%) in the taper group and 18/53 (34%) in the taper/taper group. After adjustment for baseline risk factors in the likelihood to reach persistent drug-free remission between the groups (OR:0.76, 95%CI: 0.29-1.99) was highly uncertain. Positive ACNA (OR: 3.38, 1.01 – 11.31) and erosive-state (3.05, 1.32 – 7.06) at baseline were associated with a lower likelihood to reach persistent drug-free remission.

**Conclusion:** These data show that persistent drug-free remission can be reached in a subset of RA patients following a structured DMARD tapering approach after being in stable long-term DMARD control.

**Background:** Persistent drug-free remission of RA is a condition that is close to ‘cure’ of the disease. However, long-term drug-free remission is considered to be rare and very challenging to reach. Also, little data are available that report how often persistent drug-free remission can be achieved and what kind of clinical characteristics are associated with such state.
obtained. Furthermore, by using individual patient data (IPD), outcome definitions and methods can be harmonized for a valid combined analysis.

**Objectives:** To determine the effectiveness of treatment with TCZ on radiographic progression compared to MTX in RA patients over two years.

**Methods:** Randomized controlled trials in RA patients using TCZ as one of the treatment arms with radiographic damage assessed on radiographs at baseline and after two years were identified and IPD obtained.

The primary endpoint was defined as any radiographic progression over two years. Secondary endpoint was the amount of joint damage progression (points per time unit, expressed as incidence rate). Analyses were performed on total scores and for erosions and joint space narrowing (JSN) separately. TCZ strategies were compared with the control group.

**Results:** Five trials were identified, one trial using a fixed-treatment-tolarge approach, and the four other RCTs allowed the control group to start TCZ after 6 months or 1 year when the treatment target was not reached. Two trials were performed in early RA1–2. The dose of TCZ was tapered in two studies, IPD of 4 trials could be obtained and were included (n=2439 randomized to TCZ arm and n=791 to control arm, MTX in all cases)3–5. The radiographs, performed at baseline and after two years, were all assessed with the SdVdH method. Due to missing radiographic data, 1766 patients were evaluated in the TCZ arms and 543 patients in MTX arms. Patient characteristics are shown in Table 1. The occurrence of any radiographic progression was significantly less in the TCZ arms compared to MTX arms (pooled OR 0.76 [95%CI 0.67 to 0.86]). The effect for erosions (OR 0.77 [95%CI 0.67 to 0.88]) was stronger than for JSN (OR 0.88 [95%CI 0.78 to 0.98]) with both being in favour of TCZ.

**Conclusion:** Based on this individual patient data meta-analysis, radiotherapy for the amount of radiographic progression.

**Results:** Totally, 336 patients were included as shown in table 1. There were 100 IRRs out of 1893 infusions, among which 37 were at the first time of RTX infusion. Patients with SJ had showed higher rate of IRR in the first infusion compared with other disease (19.1% vs 8.1%, p=0.008). Considering grade 2 or more severe IRRs, patients with SJ still has higher IRR (p=0.004). SJ was an independent risk for
developing IRR (OR 2.5, 95% CI 1.3-4.7, p=0.006). Seventy (78.7%) of the patients with SjS had positive anti-SSA antibody, but the presence of anti-SSA antibody was not a significant risk for IRR after controlling for the diagnosis of SjS. The IRR per infusion did not relate to the RTX dose. The IRR in an infusion did not lead to stopping of the therapy, although infusion rate and premedication can be adjusted in the following therapies. Only 39.6% of the patients with an IRR had suffered from more IRR in the following infusions. Besides, male gender and the increasing cycles were associated with less IRR (p=0.029 and 0.007, respectively). In the 100 patients received more than 4 cycles, the rate of IRR decreased along with the cycles. No life-threatening IRR happened in the 1893 infusions.

Conclusion: Our study had found that patients with SjS had higher IRR compared to other diseases. Female had more frequent IRR might due to the sexual distribution of these diseases.

**IMPACT OF JANUS KINASE INHIBITORS ON RISK OF CARDIOVASCULAR EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS: SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS**

Wenhui Xie1, Shiyu Xiao2, Yanrong Huang1, Xiaoying Sun1, Yong Fan1, Zhuoli Zhang1, 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; 2Peking University Third Hospital, Department of Gastroenterology, Beijing, China

Background: Janus kinase inhibitors (JAKis) are emerging as novel therapies for patients with rheumatoid arthritis (RA). Two JAK inhibitors have been approved and more pipeline products are ongoing to be launched, but their safety profiles of cardiovascular events (CVEs) have not been fully-established yet.

Objectives: To identify the association between CVEs and JAKis therapies in adult patients with RA via a meta-analysis of randomized controlled trials (RCTs).

Methods: RCTs reporting safety issues in RA patients treated with JAKis were reviewed in PubMed, Embase, and Cochrane Library (from inception to October 2018). CINAHL and the major relevant congress (2016-2018) were searched for additional reports. Mantel-Haenszel fixed-effects method with odds ratios (ORs) and 95% confidence intervals (CIs) were performed on extracted data.

Results: Out of 405 references screened, 26 RCTs involving 11 800 patients were included. No statistically significant difference was observed in risk of CVEs associated with the use of JAKis in general (OR 1.04, 95% CI 0.61-1.76, p=0.89), tofacitinib (OR 0.63, 95% CI 0.26-1.54, p=0.31), baricitinib (OR 1.21, 95% CI 0.51-2.83, p=0.66), upadacitinib (OR 3.29, 95% CI 0.59-18.44, p=0.18), peficitinib (OR 0.43, 95% CI 0.07-2.54, p=0.35), decernotinib (OR 1.12, 95% CI 0.13-10.11, p=0.92) (Figure 1). Regarding frequently-used dosage, dose-ranging impact of JAKis on the risk of CVEs was not observed in tofacitinib (5mg vs. 10mg, twice daily), upadacitinib (15mg vs. 30mg, once daily), while baricitinib at 2mg once daily was found to be safer than 4mg (OR 0.19, 95% CI 0.04-0.88, p=0.03) (Figure 2).

Conclusion: The existing evidence from RCTs indicated that JAKis-based therapies are not related to statistically significant risk of CVEs in RA patients during the limited randomized controlled periods. However, a special focus on baricitinib 4mg once daily is needed concerning the cardiovascular safety in the future.

A NOVEL FORMULATION OF CT-P13 (INFliximab Biosimilar) for Subcutaneous Administration: 1-YEAR RESULTS FROM A PART 1 OF PHASE III RANDOMIZED CONTROLLED TRIAL IN PATIENTS with ACTIVE RHEUMATOID ARTHRITIS

Daehyung You1, Janusz Jaworski2, Ewa Matyksa-Piekarska3, Svitlana Smjyan4, Delina Ivanova5, Agnieszka Zielinska6, Eve-Kai Raussi7, Anastas Batalov7, Sangjoon Lee8, Jeehye Sul8, Noori Han8, Rene Westhovens9.

Background: Efficacy and safety of a new subcutaneous (SC) formulation (CT-P13 SC) up to Week 30 were comparable with intravenous (IV) formulation (CT-P13 IV) in both patients with rheumatoid arthritis (RA) [1] and Crohn's disease [2].

Objectives: This report is to further investigate pharmacokinetics, efficacy and overall safety of CT-P13 SC in patients with RA throughout the 1-year treatment period.

Methods: Patients with active RA (presence of 6 or more swollen and tender joints [of 28 assessed], and serum C-reactive protein [CRP] concentration >0.6 mg/dL) were treated with CT-P13 IV at Weeks 0 and 2, and then received CT-P13 SC 90 mg, 120 mg or 180 mg SC dose and were sufficiently higher than the target therapeutic concentration. These results show that the novel SC formulation of CT-P13 may enhance treatment options for use of infliximab biosimilar by providing high consistency in drug exposure.

Results: A total of 50 patients were enrolled, of whom 48 patients were randomly assigned at Week 6 into 4 cohorts (1:1:1:1 ratio). The mean C trough (pre-dose serum concentration of CT-P13 before next dose injection) of SC cohorts throughout the study visits were higher than those of IV cohort after randomization at Week 6. C trough levels increased with SC dose and were sufficiently higher than the target therapeutic concentration (1 μg/mL) throughout the study period (Figure 1). Overall, the efficacy results of CT-P13 SC up to Week 54 were comparable to those of CT-P13 IV.

Conclusion: The results from 1-year treatment suggest similar efficacy and safety of CT-P13 SC to CT-P13 IV in RA. The mean serum concentration in all SC cohorts consistently exceeded the threshold of target therapeutic concentration. These results show that the novel SC formulation of CT-P13 may enhance treatment options for use of infliximab biosimilar by providing high consistency in drug exposure.

Rheumatoid arthritis – non biologic treatment

Alyssa Morimoto1, Julie Rae1, Leslie Chin2, Nandini Ramamoothi2, Olivia Hwang1, Alexandra Ward1, D. James Hadden1, Caroline Looney1, Rupal Desai5, Balazs Toth6, Michael J. Townsend3. 1Genentech/ Roche, OMNI Biomarker Development, South San Francisco, United States of America; 2Genentech/Roche, Clinical Pharmacology, South San Francisco, United States of America; 3Yoo et al., Arthritis Research 18:82. 4ailed studies included RA patients (pts) on background methotrexate (MTX) with inadequate response to prior MTX (n=480, Cohort 1, MTX-IR) or anti-TNFs (n=98, Cohort 2, TNF-IR). Cohort 1 pts were randomized to receive PBO, adalimumab (ADA) 40 mg Q2W, or FEN 50 mg QD, 150 mg QD or 200 mg BID. Cohort 2 pts were randomized to receive PBO or FEN 200 mg BID. Clinical efficacy was assessed based on the proportion of pts achieving ACR50 at week 12. Pts for whom samples were available were assessed for levels of rheumatoid factor (RF), total IgM and IgG, CCL4, CXCL13, CRP and IL6.

Results: Primary study results are reported separately. Overall, treatment with FEN increased CRP (at week 12) and total IgM and IgG (at weeks 4-12) relative to PBO (Table 1). Early and sustained reductions of RF, total IgM and IgG, CCL4, CXCL13, CRP and IL6 were observed with FEN or ADA relative to PBO by week 1. CRP levels were significantly reduced with 200 mg BID FEN by week 8, and with ADA by week 2 relative to PBO. By week 12, there was a trend toward lower IL6 levels with FEN treatment relative to PBO, whereas ADA significantly reduced IL6 levels by week 1 relative to PBO in MTX-IR pts. In TNF-IR patients, IL6 was significantly reduced by FEN treatment by week 12 relative to PBO. PK-PD relationships were observed for multiple B and myeloid cell biomarkers. No single biomarker at baseline was associated with clinical response (at 12 weeks) in MTX-IR and TNF-IR pts. However, greater baseline RF titers were associated with increased FEN clinical response in TNF-IR pts.

Conclusion: Findings demonstrate that depression is associated with less robust short-term response to MTX, and despite clinical RA treatment, more persistent and severe pain. Depression in RA patients may be a risk factor for primary non-responder to MTX treatment, and interventions targeted at treating depression could result in better initial RA disease control and DMARD persistence.

Background: Depression is common in rheumatoid arthritis (RA) patients and exacerbates disease activity and may reduce response to first-line disease-modifying antirheumatic drugs.

Objectives: To determine whether depression affects disease activity in patients with early RA treated with methotrexate (MTX).

Methods: Patients in the Veterans Affairs Rheumatoid Arthritis registry with early RA (onset <2 years) receiving MTX were selected (n=268). Disease activity was measured using the 28 joint count disease activity score (DAS-28), tender and swollen joint counts (TJC and SJC), patient and provider global assessment (PTGA and PRGA), and erythrocyte sedimentation rate (ESR). Baseline confounders included sociodemographics, anthropometrics, concomitant treatments, and other clinical characteristics. Propensity score weights were used to equate the depressed and non-depressed participants on baseline confounders. Generalized linear survey models were used to compare disease activity trajectories between depressed (n=48) and non-depressed (n=220) patients over two years. Standardized causal mean outcome differences were estimated at 6 months and 1- and 2-years follow-up.

Results: Depression was associated with significantly greater DAS-28 at 6 months (β=0.36; 95% CI: 0.03, 0.69) but not at 1- or 2-years follow-up (Table 1). Associations for DAS-28 component measures were smaller in magnitude, decreased over time, and not statistically significant. Depression was also associated with significantly greater pain at both 6 months (β=0.47; 95% CI: 0.11, 0.82) and 1-year (β=0.42; 95% CI: 0.03, 0.82) follow-up but not the PRGA or MDHAQ at any assessed time interval.

Background: JAK inhibitors, including Upadacitinib (UPA), have been associated with increased serum levels of creatine phosphokinase (CPK) in patients with inflammatory disorders, but not in patients with myopathi- lative disease or in healthy subjects treated for a limited duration (1). While CPK increases can be indicative of muscle damage, there are no other indicators of muscle pathology observed with JAK inhibitors, suggesting that there may be another mechanism behind the increased CPK levels. Inflammatory diseases including rheumatoid arthritis are often asso- ciated with reduced muscle mass (sarcopenia), a process reversed with disease control (2).

Objectives: We hypothesized that one or more cytokines present in the inflammatory milieu may block differentiation of myoblasts into mature myocytes and that JAK inhibition restores differentiation and associated CPK expression. We focused on the gp130-mediated cytokines IL6, Oncostatin M (OSM), CNTF, and LIF as these have been shown to be involved in myoblast differentiation.

Methods: Human skeletal muscle myoblast (HSMM) cells were cultured in 10% fetal bovine serum, or were starved for 2% (horse serum) to induce differentiation into myocytes, with and without stimulation with OSM (1–100 ng/ml) and/or UPA (0.0007–1 μM) for up to 5 days. RNA was purified and expression of CPK (M-type) was determined by QPCR using GAPDH as a reference. CPK expression was also measured following stimulation of HSMM cells with other JAK inhibitors (Baricitinib and Tofacitinib).
Results: We have demonstrated that the gp130-mediated cytokine oncostatin M blocks myoblast differentiation into myotubes resulting in a decrease in CPK expression. Jak inhibition restores muscle differentiation and increased CPK expression (Figure 1A). Oncostatin M is highly expressed in RA synovium and other inflammatory milieu and may be one mechanism driving sarcopenia in RA. In addition to Upadacitinib, both Baricitinib and Tolactacinib restore myoblast differentiation suggesting that this is a class effect for Jak inhibitors (Figure 1B).

Conclusion: Our data studies suggest that the increase in serum CPK upon treatment with Jak inhibitors may represent recovery of muscle development via reversal of inflammation-associated inhibition of myoblast differentiation.

Background: Upadacitinib (UPA), an oral, Jak1-selective inhibitor showed efficacy over 12 weeks (wks) in patients (pts) with moderately to severely active rheumatoid arthritis (RA) and inadequate response to csDMARDs (SELECT-NEXT).

Objectives: We assessed safety and efficacy of UPA through Wk60 in an ongoing extension of the phase 3 SELECT-NEXT study.

Methods: Pts received once-daily (QD) UPA at 15 mg (UPA15), 30 mg (UPA30) or placebo (PBO) for 12 wks on stable background CSMARDs. From Wk12, the start of a long-term blinded extension, pts initially randomized to PBO at BL were switched to UPA15mg or 30mg per prespecified assignment at BL. Pts randomized to UPA continued their assigned dose. No dose adjustments of UPA were allowed; however, starting at Wk24, adjustments to background RA medications were permitted. Sites/subjects remain blinded to UPA dose throughout the extension period. Efficacy data up to Wk60 are reported “As Observed”. Adverse events (AE) per 100 pt yrs (PY) are summarized based on a cut-off date of Mar 22 2018.

Results: 611/61 (92%) pts completed Wk12 and continued on the extension. By the safety data cut-off date, 125/611 (20%) had discontinued study drug, 50 (8.2%) discontinued due to an AE, and 10 (1.6%) due to lack of efficacy. Cumulative exposure was 393.3 PYs and 372.4 PYs for UPA15 and UPA30 respectively. Based on AE Observed analysis, for pts who continued on UPA15 (262/310 [85%]) and UPA30 (243/301 [81%]), clinical and functional outcomes continued to improve or were maintained through Wk60, with 59% and 56% of pts achieving DAS28-CRP <2.6 and 35% and 32% achieving CDAI remission (≤2.8) with UPA 15 and 30 mg, respectively. Pts who switched from PBO to UPA15 or UPA30 showed comparable efficacy to those initially randomized to UPA (Table 1). The most frequently reported AE s were nasopharyngitis, urinary tract infection, upper respiratory tract infection, bronchitis, blood creatine phosphokinase increased, alanine aminotransferase increased, herpes zoster (HZ) and nausea. Most frequent AEs (≥8/100PYs) leading to premature study discontinuation were pneumonia, transaminase elevations, HZ and pyrexia. Event rates (E/100PYs) were numerically higher in UPA30 vs UPA15 for serious AE, AE leading to discontinuation, serious infections, HZ and malignancies, and were similar in UPA15 and UPA30 for adjudicated major adverse cardiovascular events and venous thromboembolic events (Table 2).

Conclusion: UPA15mg and 30mg on background csDMARD therapy demonstrated consistent efficacy and safety over 60 weeks in RA patients with inadequate response to csDMARDs. Both doses of UPA showed a similar efficacy profile at Wk 60, with numerically higher rates for certain safety events noted in the UPA30 group. An integrated safety analysis of upadacitinib across the phase 3 program is required to fully characterize the benefit:risk of UPA in RA.

Filgotinib (FIL), an oral selective JAK1 inhibitor, was safe and effective in FINCH2, a randomized, double-blind, placebo-controlled, phase 3 study in patients with active rheumatoid arthritis (RA) who had an inadequate response to biologic disease-modifying anti-rheumatic drugs (bDMARDs).

Objectives: A longitudinal study of cytokines from patients in FINCH2 was conducted to identify RA-associated biomarkers related to bone biology, immune cell migration, and inflammation that are altered by FIL therapy; and FIL-associated biomarkers that correlated with clinical response (DAS28 [CRP], swollen and tender joint counts, pain, and fatigue).

Methods: Plasma, serum, and urine samples from RA patients (n=449) who received FIL (100 mg, 200 mg) or placebo (PBO) once daily plus methotrexate were analyzed at baseline (BL) and week 12 for 42 disease-relevant cytokines using validated, commercially available single or multiplex assays. PBO-corrected on-treatment changes in cytokine levels from BL to week 12 were compared between treatment arms (Wilcoxon rank sum test). Spearman rank correlation was used to compare changes in cytokine level from BL to week 12 and clinical response. P-values <0.05 were considered significant.

Results: At week 12, 18 of 42 cytokines significantly decreased with FIL 100 mg treatment relative to PBO; FIL 200 mg decreased these cytokines to a similar or greater degree. An additional 6 cytokines were significantly decreased by FIL 200 mg. Conversely, 2 cytokines increased with FIL 200 mg (sIL-6R, IL-10, IL-2, leptin, and IL-17A). Biomarkers most significantly modulated by FIL 200 mg (p<0.0001) included markers related to immune cell migration, and inflammation that are altered by FIL therapy; and FIL impacts RA disease activity at a molecular level.

Conclusion: Twelve weeks of FIL treatment significantly reduced 24 disease-relevant cytokines associated with bone biology, immune cell migration, and inflammation in patients with active RA. These effects were dose-dependent and suggest a shift toward a restored immune homeostasis. These findings are consistent with the clinical efficacy of FIL in FINCH2.

REFERENCES:

Methods: This multicentre, randomised, double-blind, parallel-group, placebo (PBO)-controlled phase 3 study (NCT02308163) was conducted in Japan, Korea and Taiwan. All patients had RA diagnosed according to 1987 ACR or 2010 ACR/EULAR criteria. Patients with active RA (defined as ≥ 6 tender and ≥ 6 swollen joints and ≥ 6 swollen joints and ≥ 3 tender joints, respectively, and CRP > 0.50 mg/dL) and inadequate response to DMARDs (administered for ≥ 90 days) were randomised in a 1:1:1 ratio to 52 weeks' treatment with PBO, peficitinib 100 mg/day, or etanercept 50 mg/week (open-label reference arm). At week 12, patients initially assigned to PBO were switched (under blinded conditions) to either peficitinib 100 mg/day or peficitinib 150 mg/day until end of treatment. Concomitant stable dose of DMARDs was permitted. The primary efficacy variable was ACR20 response rate at week 12/early termination (ET). Results: In total, 507 patients were treated in the three arms and treated: PBO (n=101), peficitinib 100 mg/day (n=104), peficitinib 150 mg/day (n=102) and etanercept (n=200). Regarding efficacy at week 12/ET, significant differences were observed with peficitinib 100 mg/150 mg vs PBO (p<0.001) in the proportion of patients achieving ACR20, ACR50, ACR70 and DAS28-ESR ≤ 3.2). Patients were randomized 1:1:1 into liposomal peficitinib 75 mg vs. liposomal peficitinib 150 mg vs. methylprednisolone 120 mg. Two comparisons: 1) liposomal peficitinib 150 mg vs. methylprednisolone 120 mg; 2) liposomal peficitinib 75 mg vs. methylprednisolone 120 mg. The primary analysis involved 28 Joints (DAS28 3.2). Patients were randomized 1:1:1 into liposomal prednisolone 75 mg, liposomal prednisolone 150 mg and methylprednisolone 120 mg. Treatment was administered on Day 1 and Day 15. Patients treated with liposomal prednisolone IV received IM placebo injections; patients treated with methyl/prednisolone IM received IV placebo infusions. Evaluations were performed weekly for the first 4 weeks, and every second week thereafter. The primary endpoint was EULAR response rate (good and moderate combined) at Day 8. The primary analysis involved two comparisons: 1) liposomal prednisolone 150 mg vs. methylprednisolone 120 mg, 2) liposomal prednisolone 75 mg vs. methylprednisolone 120 mg. Safety results (AEs, vital signs, physical examinations, laboratory, ECG) were also evaluated. A total of 172 patients were screened and 150 were randomized to liposomal prednisolone 75 mg (N=49), liposomal prednisolone 150 mg (N=52) and methylprednisolone 120 mg (N=59). 144 (96%) patients completed the study; mean study duration was 82.9 days; adverse events or intercurrent illness was the primary reason for discontinuation. Results: EULAR response rate at Week 1 (Day 8) was 90.0% for liposomal prednisolone 150 mg and 85.7% for liposomal prednisolone 75 mg vs. methylprednisolone 120 mg treated patients (p-values of 0.007 and 0.018, respectively). Other secondary endpoints supported the primary endpoint results showing significant or clinically meaningful improvements in other EULAR response evaluations, as well as DAS28, VAS, ACR20/50/70, SF-36, HAQ and FACIT-F assessments. Similar numbers of patients reported at least one adverse event (AE) in each treatment group, 42 (86%), 46 (89%) and 39 (80%), respectively, for the liposomal prednisolone 75 mg, liposomal prednisolone 150 mg and methylprednisolone 120 mg groups. Most commonly reported AEs were nausea in the liposomal prednisolone groups and headache in all 3 treatment arms. Approximately 8%
of patients in the liposomal prednisone groups reported AEs related to study drug administration, versus 6% in the methylprednisolone group. Serious adverse events (SAEs) were reported by 4 (8.2%), 1 (1.9%) and 2 patients (4.1%) resp for the liposomal prednisone 75 mg, liposomal prednisone 150 mg and methylprednisolone 120 mg groups. Five of the 7 SAEs were treatment related; these included 4 events of hypersensitivity in the liposomal prednisone arms and one event of viral upper respiratory tract infection in the methylprednisolone group.

Conclusion: In this phase III trial, liposomal prednisone 75 mg and 150 mg were significantly more effective than 120 mg methylprednisolone in treating patients with a flare of their RA. The overall incidence of AEs was similar across treatment groups, although hypersensitivity appeared to be more common with liposomal prednisone.

THE EFFICACY AND SAFETY OF SIROLIMUS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A RANDOMIZED AND PARALLEL-CONTROLLED CLINICAL TRIAL

Jia Wang1, Sheng-xiao Zhang1, Fang Yuan Hu1, Xiao-Juan Zheng1, Ting Cheng1, Na-Na Yu1, Wen-Xian Yang1, Chong Gao2, Hong-Yan Wen1, Li Xiao-Feng1, The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: We have reported previously that the insufficient absolute number or functional defects of regulatory T cells (Tregs) in patients with rheumatoid arthritis (RA) can partly restore the reduced Tregs. Concomitantly, their usages of immunosuppressants to control disease activity without over-treatment and evaluable side effect. The further study is required using a large sample of RA patients treated with sirolimus for longer period.

Objectives: To investigate efficacy and safety of sirolimus combined with conventional immunosuppressants for RA treatment.

Methods: In this non-blinded and parallel-group trial, we randomly assigned 62 patients to receive conventional glucocorticoids and immunosuppressants with or without sirolimus at a dosage of 0.5 mg on alternate days for 24 weeks in a 2:1 ratio. The demographic features, clinical manifestations and laboratory indicators including peripheral blood lymphocyte subgroups and CD4+T subsets were compared before and after the treatment.

Results: Finally, 37 patients in sirolimus group and 18 in conventional treated group completed 6-month study. By 24 weeks, the patients with sirolimus experienced the significant reduction in disease activity indicators including DAS28, ESR, the number of tender joints and swollen joints (p<0.001). Notably, they had a higher level of Tregs as compared those

Conclusion: Low-dose sirolimus immunoregulatory therapy selectively up-regulated Tregs and partly replaced the usage of immunosuppressants to control disease activity without over-treatment and evaluable side effect. The further study is required using a large sample of RA patients treated with sirolimus for longer period.

UPADACITINIB IMPROVES PATIENT-REPORTED OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO METHOTREXATE: RESULTS FROM SELECT-COMPARE

Vibeke Strand1, Martin Bergman1, Namita Tundia2, Andrew Ostro3, Patrick Durez2, In-Ho Song2, Jose Jeffrey Enejosa3, Casey Schlacher3, Yan Song6, Roy Fleischmann7, Stanford University, Palo Alto, CA, United States of America; 2Drexel University College of Medicine, Philadelphia, PA, United States of America; 3AbbVie Inc., North Chicago, IL, United States of America; 4Cabrini Medical Centre, Monash University, Melbourne, Australia; 5Université Catholique de Louvain and Cliniques Universitaires Saint-Luc, Brussels, Belgium; 6Analysis Group Inc., Boston, MA, United States of America; 7University of Texas Southwestern Medical Center, MCRC Center, Dallas, TX, United States of America

Background: Upadacitinib (UPA), a selective JAK1 inhibitor, has demonstrated superior improvement in the clinical signs and symptoms of rheumatoid arthritis (RA) compared with placebo (PBO) and adalimumab (ADA). Objectives: To evaluate the effect of UPA vs PBO and vs ADA on patient-reported outcomes (PROs) at Week 12 in SELECT-COMPARE (NCT02629159), a randomised controlled trial (RCT) in an active RA population with inadequate responses to methotrexate (MTX).

Methods: Patients in SELECT-COMPARE, a phase 3 RCT, received UPA (15 mg once daily), PBO, or ADA (40 mg every other week) while on background MTX therapy. The following PROs were collected prospectively: Patient Global Assessment of Disease Activity (PGA) by visual analogue scale (VAS), pain by VAS, Health Assessment Questionnaire Disablity Index (HAQ-DI), duration and severity of morning (AM) stiffness, health-related quality of life by Short Form-36 (SF-36), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and Work Instability Scale for RA (RA-WIS). Least squares mean (LSM) changes from baseline (BL) to Week 12 were based on mixed-effects repeated measures

**FR013**
models. The proportions of patients reporting improvements ≥ minimum clinically important differences (MCID) from BL to Week 12 or scores ≥ normative values were determined with UPA, PBO, and ADA treatment; comparisons used chi-square tests.

Results: Data from 1629 patients (UPA: 651; PBO: 651; ADA: 327) were analysed. Mean age was 54 years; 79% were female; 54% had RA for ≥ 5 years. Baseline mean PRO scores were similar across treatment groups. At Week 12, UPA treatment resulted in statistically significant LSM changes from BL vs PBO across all PROs and statistically significant LSM changes from BL vs ADA in PIGA, pain, HAQ-DI, AM stiffness severity, FACIT-F, and SF-36 physical component summary (PCS) and 6/8 domain scores (Table). ADA treatment resulted in statistically significant LSM changes from baseline vs PBO in PIGA, pain, HAQ-DI, AM stiffness severity and duration, FACIT-F, and SF-36 PCS and 5/8 domain scores. Compared with PBO at Week 12, significantly more UPA-treated patients reported improvements ≥ MCID and scores ≥ normative values across all PROs with numbers needed to treat (NNTs) < 10. The proportions of UPA-treated patients reporting improvements ≥ MCID were similar or numerically higher than ADA-treated patients. Importantly, the proportion of UPA vs ADA treated patients reporting improvements ≥ normative values were significantly greater (all p < 0.05) in PIGA (36% vs 26%), HAQ-DI (21% vs 14%), SF-36 PCS (16% vs 11%), and SF-36 bodily pain (29% vs 21%) and vitality (42% vs 35%) domains.

LSM changes from baseline vs ADA ≥ MCID were statistically significant (all p < 0.05).

Conclusions: An active RA, treatment with UPA 15 mg QD on background MTX therapy for 12 weeks resulted in statistically significant and clinically meaningful improvements in PROs compared with PBO. Overall, PRO improvements with UPA treatment met or were superior to those reported with ADA, especially in key domains of pain, function, and vitality.

EXPOSURE-RESPONSE ANALYSES OF UPADACITINIB EFFICACY AND SAFETY IN RHEUMATOID ARTHRITIS – ANALYSES OF PHASE 2 AND 3 STUDIES

Mohamed-Essem Mohamed1, Ahmed Nader1, Insa Winzenborg2, Eva Doelger2, Peter Noertersheuser2, Ajeem Panang1, Ahmed Ottman1, AbbVie, North Chicago, United States of America; 1AbbVie Deutschland GmbH and Co. KG, Ludwigshafen, Germany

Background: Upadacitinib (UPA), an oral selective JAK1 inhibitor, demonstrated favorable efficacy and acceptable safety in two Phase 2 and five Phase 3 global studies in subjects with moderately to severely active rheumatoid arthritis (RA).

Objectives: To characterize relationships between UPA plasma exposures and different efficacy and safety endpoints using data from Phase 2 and Phase 3 RA studies.

Methods: Analyses were conducted using data from 3685 (for efficacy) and 4577 (for safety) subjects with RA enrolled in the Phase 2 and 3 studies. Relationships between UPA plasma concentrations and efficacy and selected clinically relevant safety endpoints were analyzed using Markov Chain models and logistic regression analyses, respectively.

Results: Percentage of subjects achieving ACR20, ACR50, ACR70, DAS28<3.2, and DAS28CRP < 3.2, and DAS28CRP < 2.6 increased with increasing UPA exposures, with maximum efficacy reached at exposures of 15 mg to 30 mg QD. Model-estimated efficacy responses are presented in Table 1. No relationships were observed between UPA exposure and pneumonia, herpes zoster infection, changes in platelet count (platelets > 600×10^9/L, platelets > 400×10^9/L), lymphopenia (Grade 4 or higher), and neutropenia (Grade 3 or higher) at Week 12/14 or Week 24/26. Shallow trends for exposure-response relationships were observed between UPA exposure and lymphopenia, grade 3 or higher at Week 12/14 or Week 24/26. No relationship with UPA exposure was observed for Grade 3 or higher lymphopenia at Week 24/26 (Figure 1).

Conclusion: Among patients with active RA, treatment with UPA 15 mg QD on background MTX therapy for 12 weeks resulted in statistically significant and clinically meaningful improvements in PROs compared with PBO. Overall, PRO improvements with UPA treatment met or were superior to those reported with ADA, especially in key domains of pain, function, and vitality.

surfactant tween 80 (polysorbate 80) and the squacline as an exception, through film hydration method and their potential as a drug delivery system for NPX.

Methods: We prepared niosomal Naproxen from the biocompatible surfactant tween 80 (polysorbate 80) and the squacline as an exception, through thin-film hydration method and their potential as a drug delivery system for NPX. The prepared system was characterized by Fourier transform infrared spectroscopy (FT-IR), UV-visible, photoluminescence (PL), field emission scanning electron microscopy (FE-SEM), and transmission electron microscopy (TEM).

Results: By using this method, the percent drug loading that resulted by the encapsulation of niosomes was found to be 99.5 ± 0.2% for 5% of NPX weight in total ingredients weight of niosomal vesicles (w/w). It was also seen that a slower rate of release of the NPX from the drug encapsulated noisome over 7 days, suggesting stable complexation of NPX. Cell toxicity assay was carried out by A549 and HeLa cancer cell lines and showed the half maximal inhibitory concentration (IC50) of NPX increased about 8.25 fold for A549 (from 3300 µM to 400 µM) and it decreases about 5.5 folds for HeLa (from 1920 µM to 350 µM) by nanof ormation.

Conclusion: Niosomal formulation has been evaluated as a safe drug delivery system. In this study, we showed that niosomal naproxen has more stability and more efficiently affect the cells. It can be explained by increasing the bioavailability of naproxen by niosomal nanocarriers which probably is based on more water solubility and more efficient cell entrance of drug. It seems that niosomal naproxen is a great candidate for future in vitro and in vivo researches for evaluating potential clinical applications.

Disclosure of Interests: None declared
of patients receiving monotherapy or combination therapy at treatment initiation.

Results: 1950 patients were included in the matched population (1300 bDMARD initiators; 650 tofacitinib initiators). Patients were predominantly aged 55 to 74 years (57.8%), and female (81.2%). At baseline, median disease duration was 107 and 120 months, with 16.1% and 17.3% of patients in DAS28-ESR defined disease remission for the bDMARD and tofacitinib groups respectively. After three months of treatment, 49.1% and 49.7% had achieved DAS remission and after 18 months of treatment 52.4% and 57.8% of patients had achieved DAS remission in the bDMARD and tofacitinib groups respectively. At 18 months the percentage of patients achieving CDAI/SDAI remission was similar with 29.2%/29.0% bDMARD patients and 30.9%/30.5% tofacitinib patients reporting CDAI/SDAI remission respectively. The median persistence of treatment was similar for bDMARD and tofacitinib groups: 33.8 (95% CI 28.8 to 40.4) and 34.2 (95% CI 32.2 to not reached) months respectively. In the overall population, more patients were prescribed tofacitinib as monotherapy (43.4%) compared to bDMARD monotherapy (33.4%).

Conclusion: In this analysis of a large real world dataset, tofacitinib demonstrated treatment effectiveness and persistence that was similar to bDMARDs. Overall, there was a trend for more use of tofacitinib as monotherapy than bDMARDs.

FRI0141 Efficacy of JAK-inhibitors versus biologic DMARDs on quality of life in rheumatoid arthritis: A meta-analysis of randomized controlled trials

Mamadaly Boudhabhay1, Thomas Barnetche2, Pascale Vergne-Salle1,1CHU de Limoges, Limoges, France; 2CHU de Bordeaux, Bordeaux, France

Background: Recent studies comparing JAK-inhibitors (Jak-i) and adalimumab seem to show a better efficacy of Jak-i on patient-reported outcomes in rheumatoid arthritis (RA).

Objectives: As there is no study comparing directly the Jak-i with other biologic DMARDs (bDMARDs), we performed a meta-analysis and compared the effect size of Jak-i and bDMARD versus synthetic DMARDs (sDMARDs) on quality of life.

Methods: We performed a systematic review of the literature until May 2018 using database including : MEDLINE (via PUBMED), EMBASE and abstracts from the ACR and EULAR congresses 2015-2017. We selected all randomized controlled trials (RCT) comparing quality of life (evaluated by SF36) in patient with rheumatoid arthritis treated with bDMARD or Jak-i versus sDMARDs. We performed meta-analysis comparing the effect size of Jak-i versus sDMARDs and bDMARD versus sDMARDs on PCS SF36 and MCS SF36 at 12 weeks. Statistical analysis determined in each study effect size. Pooled ES were computed by meta-analysis. Data were analyzed using the inverse variance approach.

Results: The literature search identified 240 articles plus one found by manual search and no congress abstract. Finally, 44 articles met the inclusion criteria. Jak-i and bDMARD showed higher level of quality of life than conventional therapies:

- For the SF36 PCS at 12 weeks: Jak-I: +4.82 IC95% [3.88, 5.77] and bDMARD: +3.99 IC95% [2.81, 5.18]
- For the SF36 MCS at 12 weeks: Jak-I: +3.42 IC95% [2.24, 4.60] and bDMARD: 2.99 IC95% [2.02, 3.96]

The range of the confidence intervals seems similar between Jak-I and bDMARDs.

SF36 PCS at 12 weeks:

FRI0142 Safety of the methotrexate-leflunomide combination in the Brazilian registry of biological therapies in rheumatic diseases (Biobadabrasil)

Background: The combination of methotrexate (MTX) with leflunomide (LEF), despite being effective in the therapy of rheumatoid arthritis (RA) [1], has not been widely accepted[2,3]. In spite of evidence that the MTX-LEF combination is generally safe [1,4,5], the relatively small number of patients and treatment courses have not permitted firm conclusions.

Objectives: To evaluate the safety of the combination MTX-LEF in Brazilian patients with RA included in BiobadaBrasil.

Methods: BiobadaBrasil is a multicentric prospective cohort study involving patients with rheumatic diseases who started the first biologic or a synthetic disease modifying anti-rheumatic drug (DMARD)[6]. This analysis includes RA (2010 criteria) patients recruited from Jan 2009 to Aug 2018, followed-up for one or multiple courses of treatment until censoring (latest date, September 03, 2018) or occurrence of the outcome of interest. The primary outcome was the incidence of any serious AE (SAE). Secondary outcomes were infectious, non-mycobacterial pulmonary infections, hepatic, hematologic and cardiovascular SAE. Multivariate Cox proportional hazards models (with DMARDs included as time-varying covariates) were used to estimate hazard ratios (HR) and 95% confidence intervals (CI); analyses were performed with the Survival package of R.
Results: Sample: 2055 RA patients, female=85.1%, mean disease duration=6.02 years; mean (SD) age=50.3 (12.1) years; mean (SD) DAS28=5.3 (3.1); seronegative RA=14.1%; median follow-up duration=3.9 years. In total, 565 patients received 664 courses of the MTX-LEF combination (median duration, 2.5 years/course; 2209 person-years). The incidence of SAE was 4.75/100 patient-years in the entire sample. There was no significant increase in the risk of any of the outcomes with the use of combined therapy (table 1) comparing with methotrexate (without leflunomide). The use of antimalarials was associated with reduced risk of SAE (adjusted HR=0.62, 95% CI 0.48 to 0.79, P<0.001), while sulfasalazine (adj. HR=1.78, 1.18 to 2.68, P=0.006) and biologic DMARDs/tofacitinib (adj. HR=1.67, 1.31 to 2.12, P<0.001) increased the risk of SAE.

FACTORS ASSOCIATED WITH NEAR REMISSION DIFFER BETWEEN AUTOANTIBODY-POSITIVE AND -NEGATIVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS TREATED WITH CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

Ludovico De Stefano, Serena Bugatti, Francesca Benaglio, Gaëtano Sakellaris, Antonio Marzo, Roberto Caporali, Carlomaurizio Montecucco, Division of Rheumatology, IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: Disease remission is recommended as the treatment target in patients with early rheumatoid arthritis (RA). According to the criterion, the proportion of patients classified as in remission considerably varies, with the Boolean-based definition being the most restrictive [1]. A considerable proportion of patients with established RA misses Boolean remission solely because of one of the 4 criteria (near remission) [2]. The frequency and the limiting variables to Boolean remission in real-life cohorts of patients with early RA are however unknown.

Objectives: To assess the feasibility and the limiting factors for fulfilling Boolean remission in early RA patients treated with csDMARDs according to a treat-to-target strategy.

Methods: The study population consisted of 578 early RA patients (<12 months of symptoms) consecutively recruited at our Early Arthritis Clinic, treatment-naïve at inclusion and prospectively followed-up upon initiation of therapy with methotrexate (MTX) aimed at the achievement of low disease activity (28-joints disease activity score [DAS28] <3.2). After 6 months of treatment, patients were classified as in remission or near remission according to the Boolean criterion as follows: (i) remission (PGA ≤22, TJC ≤2, CRP ≤0.3 mg/dl, DAS28 ≤2.6); (ii) near remission only one criterion was not met and the global remission index was ≤32. After 12 months of treatment, patients were classified as in remission (PGA ≤22, TJC ≤2, CRP ≤0.3 mg/dl, DAS28 ≤2.6) or near remission (one criterion not met and remission index ≤32). Missing criteria at 6 and 12 months were imputed according to the Boolean criterion. The proportion of patients classified as in remission considerably varies between autoantibody (AB)-positive and -negative patients -89.3% vs 69.4% at 6 months and 85.6% vs 65.8% at 12 months.

Results: Complete follow-up data after 6 months of treatment were available for 89.3% of the patients. Disease remission was achieved in 25.6% of the cases according to the DAS28, 16.7% according to the simplified disease activity index (SDAI) and 11.6% according to the Boolean criterion. One-hundred and thirty-three patients (25.8%) failed to reach Boolean remission (89.3% missing near remission). Reasons for missing Boolean remission were analysed in relation to disease variables. Complete follow-up data after 6 months of treatment were available for 89.3% of the patients. Disease remission was achieved in 25.6% of the cases according to the DAS28, 16.7% according to the simplified disease activity index (SDAI) and 11.6% according to the Boolean criterion. One-hundred and thirty-three patients (25.8%) failed to reach Boolean remission solely because of one of the 4 criteria (near remission) [2]. Of these, 45.9% were in DAS28 remission and 22.6% in SDAI remission. No differences in baseline demographic and clinical characteristics were found between patients in Boolean remission and patients in near remission. Use of prednisone co-medication and MTX starting dose were also comparable. Patients negative for both rheumatoid factor (RF) and anti-citrullinated protein autoantibodies (ACPA) were more frequently in near remission rather than in Boolean remission compared to autoantibody-positive patients (Fig. 1A). The missing criterion in near remission was SJC28 >1 in 49% of the cases, PGA >1 in 41%, and TJC28 >1 or CRP >1 mg/dl in the remaining 10%. Collectively, failure to achieve Boolean remission because of near remission was more common in RF and/or ACPA positive patients. Rather, autoantibody-negative patients more frequently missed remission due to PGA (Fig. 1B).

Conclusion: In patients with early RA treated with csDMARDs, near remission is up to two times more frequent than Boolean remission. Collectively, autoantibody-negative patients more commonly miss complete remission solely because of one criterion compared to autoantibody-
positive patients. Furthermore, in these patients, failure to achieve remission is mostly related to high PGA rather than to the persistence of joint inflammation. Altogether, these findings implicate that autoantibody-negative RA patients failing to achieve remission would require adjunctive tailored interventions rather than reinforcement of DMARD therapy.

Figure 1. Overall survival of JAKi and for biologic-naive and biologic-experienced patients

Conclusion: The current use of JAKi in Spain is mainly in RA and as 2nd line after bDMARDs. The use of JAKi in psoriatic arthritis is still scarce and a small group of patients are treated off-label. Less than half use combination therapy with MTX. Overall survival of JAKi is superior to 80% at 12 months. A longer follow-up is needed to continue analyzing the survival of JAKi in a real-world context.

Results: 149 patients, 75.2% women, were treated with JAKi, receiving a total of 152 cycles of treatment (50.7% tofacitinib, 49.3% baricitinib; 3 patients had both). The most frequent diagnosis was rheumatoid arthritis (RA, 92.6%), and there is a small number of off-label uses (6%), depicted at Table 1. Use on psoriatic arthritis is scarce (1.3%). Concomitant use of methotrexate (MTX) was registered in 68 patients (45.6%). Previous use of bDMARDs was high (n=124, 81.6%); drug survival rate for biologic-experienced patients was 81.7% and 78.7% at 6 and 12 months. None of the JAKi treatments in biologic-naive patients (n=18; 18.4%) were discontinued during follow-up. Pooled survival rate of JAKi was 85.0% and 82.5% at 6 and 12 months (Figure 1). Discontinuation was seen in 19 treatments (12.5%); the reasons were inefficacy (n=15, 9.9%) or adverse events (n=4, 2.6%).

*off-label use.

Background: In the SELECT-COMPARE study in rheumatoid arthritis (RA) patients (pts) with inadequate response to methotrexate (MTX), upadacitinib (UPA), a JAK1- selective inhibitor, was superior to placebo (PBO) or adalimumab (ADA) for treatment of signs & symptoms and for inhibition of radiographic progression vs PBO up to 26 weeks (wks). All pts were on stable background MTX.

Objectives: To report safety and efficacy of UPA plus stable background MTX up to 48 wks in this phase 3 study.

Methods: Pts were randomized to once-daily (OD) UPA 15mg, PBO, or ADA 40mg every other wk, with all patients continuing background MTX. The study was double-blind for 48 wks. Between Wks14-26, pts were rescued (from PBO to UPA, UPA to ADA, or ADA to UPA) if there was <20% improvement in tender/swollen joint count (Wks 14/18/22) or C Clinical Disease Activity Index (CDAI) >10 (WK26); all PBO pts who were not rescued were switched to UPA at Wk 26. Efficacy was analyzed by randomized group. Non-responder imputation (NRI) was used for binary endpoints for rescue prior to WK26. Last observation carried forth (LOCF).
forward (LOCF) was used for continuous endpoints and binary endpoints after Wk26. Treatment-emergent adverse events (AE) per 100 pts yrs (PY) were summarized up to July 6 2018 for pts with any exposure to ADA or UPA.

Results: In SELECT-COMPARE, 1629 pts were randomized at BL. Among 651 pts randomized to UPA, 38.7% were rescued between Wks 14-26; of those who remained on UPA, 86% completed Wk 48, while 58% and 0.3% discontinued study drug between BL and Wk 48 due to AE and lack of efficacy (LoE), respectively. Among 327 pts randomized to ADA, 48.6% were rescued between Wks 14-26; of those who remained on ADA, 76% completed Wk48, while 13.1% and 0 discontinued study drug between BL and Wk48 due to AE and LoE, respectively. The cumulative exposures were 1243.3 and 467.8 PYs for UPA and ADA, respectively. At Wk26, and Wk48, significantly more pts in the UPA vs ADA group achieved ACR20/50/70, low disease activity and remission (Table 1); this was also true for visits between Wks 26 and 48. Similarly, improvements in pain and function were significantly greater in the UPA vs ADA group through Wk48. At Wk26, there was significantly lower radiographic progression for UPA vs PBO, which was maintained through Wk48 (based on linear extrapolation). Adverse events are reported in Table 2 (in events per 100 PY). The rate of AE leading to discontinuation was higher with “any ADA” vs “any UPA”, while the rate of Herpes zoster was higher with “any UPA” exposure.

Conclusion: UPA continued to demonstrate superior clinical and functional responses vs ADA through Wk48. Inhibition of structural joint damage with UPA was also maintained through 48 wks vs PBO. Safety was consistent with observations in the first 26 wks.

From 41 persons with RA 32 patients, who never achieved low disease activity (DAS28<3.2) or remission (DAS28<2.6) followed the dosage enhancement (the visit before the switching). 

Objectives: The aim of the study was to evaluate the results of switching of TF's dosages in RA patients. 

Methods: were analyzed the data from Russian national register of patients with RA treated with TF (tofacitinib). 415 patients were included in the register (aug 2018). In statistical analysis were included data from 41 patients with RA (EULAR 2010), who switched dosage of TF at visit 3 and had complete clinical and laboratory data from 5 consecutive visits with an interval of 3 months between the visits. Demographic (age, sex, data), disease activity data DAS28 (Disease Activity score), C-reactive protein level were collected, table 1. Changes in disease activity were calculated to patients with switching of the tfa's dosage (the visit before and after the switching).

Results: 1.28 (68%) of patients were treated with NSAIDs, 24 (50%) with 5-10 mg of prednisolone, 34 (82.9%) with methotrexate (10-25 mg/week), biologics – 5 (4.2%).

From 41 persons with RA 32 patients, who never achieved low disease activity (DAS28<3.2) or remission (DAS28<2.6) elevated the dosage of tofa from 10 to 20 mg/day and 9 patients with DAS28 < 3.2 decreased the dosage from 20 to 10 mg/day. After escalation of TF dosage DAS28 decreased from 5.4±1.22 to 4.22 ±1.22 (p<0.00, n=32). In 10 patients escalation lead to DAS28-remission (DAS28<2.6) and in 12 patients to low disease activity (DAS28<3.2). 10 patients had no clinical or laboratory response on escalation of TF dosage. Interestingly, that responders before escalation of dosage had mean DAS28 3.54 (min 3.2 – max 4.9) and non-responders – 5.54 (min 5.3-max 6.8), p<0.000.

Conclusion: Escalation of dosage of TF in RA lead to improvement of the disease activity in non-complete responders, who achieved DAS 28 3.2-5.1, but not in patients with absence of any response (DAS28 before escalation 5.3-6.9). De-escalation of TF dosage in patients with DAS28 < 2.6 dose not lead to significant changes of RA's activity.

REFERENCES:
The relationship between the effectiveness of methotrexate (MTX) in rheumatoid arthritis (RA) and MTX polyglutamates levels (MTXPG) in red blood cells by tandem chromatography spectrometry (PILOT STUDY)

Gala Gridneva1, Yury Muraviev1, Alexander Lila2, Natalia Baymeeva2.1, VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Mental Health Research Center, Moscow, Russian Federation

Background: Therapeutic control of the level of MTXPGs in erythrocytes may be an objective marker of its effective dose in RA treatment.

Objectives: To evaluate the relationship between the level of MTXPGs in erythrocytes and the effectiveness of the dose of MTX used by RA patients.

Methods: The study included 60 random selected RA patients over the age of 19, 16 men and 44 women. The diagnosis in all cases met the criteria of the EULAR response to therapy. The groups were comparable in age, sex, alcohol intake, smoking, body mass index (BMI), ACPP-positivity, incidence of unwanted reactions to MTX, single therapy: 5.5 [2.0, 12.0] months in group 1 and 12.0 [3.0, 60.0] months in group 2; in group 2 patients received glucocorticoids (GK) orally 17 (57%) against 9 (30%) in group 1. Blood sampling was performed no later than 36 hours after the last administration of methotrexate. From each patient 2 ml of hemolysed blood were examined using an Agilent 6410 chromatograph (Agilent Technologies) - a quantitative measurement of methotrexate polyglutamate by liquid chromatography-spectrometry.

*Primary endpoint; †Secondary endpoint; *p (compared to PBO).

Results: It was established that the levels of total MTXPG and MTXPG1;2,3,5 in erythrocytes did not depend on the effectiveness of MTX, the dose of which was comparable in all patients. At the same time, the level of MTXPG4 was significantly higher (p = 0.023) in patients of group 1 (26.4 ± 6.1 nmol/l) compared with patients in group 2 (22.1 ± 6.8 nmol/l). Evaluation of the ROC curve showed that MTXPG4 values between 22.5 nmol/l corresponded to the absence of the therapeutic effect of MTX. The area under the curve was 0.672, (CI 0.539 - 0.808), p = 0.022. Sensitivity 65.4%, specificity 53.3%

Conclusion: More than 26% of patients who initiated MTX therapy either discontinued or may not restart MTX. There is a need to better understand the patterns of MTX use, the characteristcs of these patients, and how the patterns of use are related to outcomes.

TOFACITINIB

FRI0153 OPHTHALMOLOGICAL ADVERSE EVENTS UNDER JAK INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: CASE ANALYSIS OF THE EUROPEAN PHARMACOVIGILANCE DATABASE

Sophie Hecquard1, Marie Blanche Rabier2, Marion Lepelley2, Frank Verhoeven1, Anne Sophie Gauthier1, Clément Prati1, Bernard Delbosc1, Daniel Wendling1.

1Centre Hospitalier Universitaire de Besançon, Besançon, France
2Centre Hospitalier Universitaire de Grenoble, La Tronche, France

Background: Ophthalmological manifestations in rheumatoid arthritis (RA) include dry syndrome, scleritis, episcleritis, uveitis and peripheral ulcerative keratitis (PUK). Recently, a new class of synthetic molecules has been developed, called JAK inhibitors (JAKinhib). We observed one case of PUK occurring two months after the introduction of baricitinib treatment with corneal perforation with secondary improvement after discontinuation of JAKinhib.

Objectives: The aim of this study is to describe and characterize the ophthalmological side effects of JAK inhibitors (JAKinhib) in patients with rheumatoid arthritis (RA) from European pharmacovigilance (PV) data.

Methods: The ophthalmological manifestations that appeared under JAK inhib were extracted from the European PV database (May 2018), EUDRAVIGILANCE following a request addressed to the National Drug Agency in order to discuss the imputability of the treatment. A discontinuation of it seems justified pending an ophthalmological opinion.

Results: A total of 41 patients with ophthalmic adverse events (AEs) on JAK inhib were reported. Among patients, 12 were treated with BARICITINIB and 29 with TOFACITINIB. Of these AEs, 51% were reported by the medical profession, 39% by patients and 10% by paramedical teams. The database analysis revealed 4 scleritis, 3 corneal ulcers, 1 PUK and 1 corneal ulceration. The average time to onset of AEs was 13.2 months. The infectious causes had been eliminated.

Conclusion: Ophthalmological manifestations under JAKinhib seem to be rare but not exceptional, the rheumatologist must be aware of them in order to discuss the imputability of the treatment. A discontinuation of it seems justified pending an ophthalmological opinion.

FRI0154 SAFETY AND EFFICACY OF FILGOTINIB IN PATIENTS AGED 65 YEARS AND OLDER: RESULTS FROM A PHASE 3 STUDY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE OR INTOLERANCE TO BIOLOGICAL DMARDS (BDMARD-IR)

Kenneth Kakujiang1, Jacques-Éric Gottenberg2, Mark C. Genovese3, Neehufer Muzaffariani4, Beatrix Bartik5, Franziska Matzkies4, Jie Gao6, Ying Guo4, Tsutomu Takeuchi5, Kurt de Vlam6, David Walker7.

1University of California, San Diego, La Jolla, United States of America; 2Dept of Rheumatology, Strasbourg University Hospital, Strasbourg, France; 3Stanford University Medical Center, Palo Alto, United States of America; 4Gilead Sciences, Inc., Foster City, United States of America; 5Kio University School of Medicine, Tokyo, Japan; 6Universitair Ziekenhuis Leuven, Leuven, Belgium; 7Northumbria Healthcare, Newcastle upon Tyne, United Kingdom

Background: Filgotinib (FIL), an oral selective Janus kinase 1 (JAK1) inhibitor, demonstrated efficacy and safety vs placebo (PBO) in BDMARD-IR patients with active RA in a global phase 3 study (FINCH2, Clinical-Trials.gov NCT02873936).1

Objectives: We performed a prespecified subgroup analysis of the safety and efficacy of FIL in patients aged ≥65 years vs <65 years in FINCH2 to understand FIL effects in older patients.

Methods: 449 patients were randomized 1:1:1 to FIL 200 mg, FIL 100 mg, or PBO on a background of csDMARDs for 24 weeks. The primary efficacy endpoint was ACR20 response at week 12.

Results: Of 448 patients who received ≥1 dose of study drugs, 113 (25.2%) were ≥65 years of age; baseline disease characteristics were similar for both age groups. Safety and efficacy parameters by age group are in Tables 1 and 2. The most common treatment-emergent adverse events (TEAEs, by System Organ Class) category was infections and infestations; nasopharyngitis, upper respiratory tract infections, and bronchitis were the most common infections and infestations in the FIL arms in both age groups. There were no cases of opportunistic infection, active tuberculosis, malignancy, gastrointestinal perforation, or death. Efficacy outcomes were similar for both groups.

Conclusion: Overall, older age was not associated with higher incidence of safety events (serious infections, herpes zoster, MAC occurred in the group <65 yrs) and efficacy was similar in older and younger BDMARD-IR patients with active RA.

**Conclusion:** In this post hoc analysis, the efficacy of UPA in patients with RA appeared comparable whether administered in combination with MTX or non-MTX csDMARDs.
A PHASE 1, SINGLE AND MULTIPLE ASCENDING DOSE STUDY OF TAS5315 - A NOVEL HIGHLY SELECTIVE INHIBITOR OF BRUTON’S TYROSINE KINASE – IN HEALTHY MALE VOLUNTEERS

Yuji Kumagai1, Yoshiya Tanaka2, Misuru Murata2, Tsutomu Takeuchi3, 1Kitasato University School of Medicine, Kanagawa, Japan; 2University of Occupational and Environmental Health, Kitakyushu, Japan; 3Keio University School of Medicine, Keio University School of Medicine, Japan

Background: Bruton’s tyrosine kinase (BTK) is expressed in the cells of the immune system and osteoclasts, and plays an important role in inflammation and bone resorption. TAS5315 is a novel, highly selective inhibitor of BTK. In animal models, TAS5315 suppressed the inflammation at the joints and significantly suppressed extreme bone destruction, in a dose-dependent manner. It has the potential to become a treatment option in patients with rheumatoid arthritis (RA).

Objectives: To evaluate the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of TAS5315 in healthy male volunteers.

Methods: The single ascending dose (SAD) study, which was the first-in-human study, and the multiple ascending dose (MAD) study were conducted as randomized, double-blind, placebo-controlled and parallel-group comparative studies in a single center. In the SAD study, 70 subjects were enrolled and received 0.01–8 mg of TAS5315 or placebo. In the MAD study, 31 subjects were enrolled and received 1–8 mg of TAS5315 or placebo once daily for 7 days. The allocation ratio (TASS315: placebo) was 7:3 in the SAD study and 6:2 in the MAD study. The PD of TAS5315 was assessed by measuring the rate of BTK occupancy in peripheral blood mononuclear cells using a fluorescence probe.

Results: The observed PK profile of TAS5315 was linear in the dose range of 0.01–8 mg. TAS5315 was rapidly absorbed (median \(T_{\text{max}}\): 0.5–1.5 hr) and eliminated (mean \(T_{1/2}\): 1.00–1.37 hr). The maximum percent of BTK occupancy by TAS5315 increased dose-dependently at 0.01–2 mg in SAD study. The occupancy rate of BTK peaked at 2 mg and was almost 100% at 2–8 mg. 6 hr after administration and remained almost 80% or higher for up to 24 hr. The expression level of CD203c in peripheral blood basophils treated with anti-IgE antibodies was also measured with a flow cytometer. The SAD and MAD studies were reviewed and approved by the IRB of Kitasato University Hospital.

Conclusion: TAS5315 was well tolerated when administered as repeated doses of up to 8 mg once daily for 7 days. The inhibitory effect of BTK on BTK occupancy by TAS5315 was demonstrated in this study, and this provides the basis for an early Phase II study to evaluate the efficacy of TAS5315 in patients with RA.

effect profile compared to methotrexate at doses used in oncology.(3) Hence this study aimed to clarify why lower dose methotrexate carried a risk of hair fall.

**Objectives:** Determine the mean change in number of hair strands obtained by the hair pull test at the start of the trial and at 3 weeks, 2 months and 3 months among rheumatoid arthritis patients on methotrexate in comparison to healthy controls.

**Methods:** After ethics committee approval and informed consent, consecutive patients attending a rheumatology OPD and who were planned to be initiated on methotrexate were enrolled into the study. Patient relatives, hospital staff and healthy blood donors were recruited as healthy controls. Patients with prior exposure to methotrexate in the last 6 months, currently on other medications known to cause hair fall or those suffering from diseases which could predispose to alopecia were excluded.

**Results:** During the 6 month enrolment phase 98 patients and 82 controls were enrolled. Patients were 85% female with a mean age of 48.1 ±13.4. Rheumatoid factor positivity was seen in 59%. Average duration of the disease was 9.6 months (Range 15 days to 3 years). Patients were started on 10 to 15 mg of methotrexate which was escalated at the 1st visit at 3 weeks. Only 3 patients had received prior DMARDs. Controls also constituted predominantly women (90%) with an slightly lower average age of 44.4 ±10.9 years. The mean no of hair in the hair pull test at the start of the study was 1.21±2.01 (range 0-12) in patients vs 0.84 ±1.25 (range0-4) in controls. The mean change in the hair count in the same test repeated at 3 weeks, 2 months and 3 months was -0.29, -0.31 & -0.26 respectively (i.e. reduction in hair fall). In comparison healthy controls showed values of 0.31,0.11, 0.1 at the same follow up points. There was no statistical significant difference in the proportion of patients having more than 5 hairs in the test at the onset of treatment vs healthy controls or during any point during the follow up period.

**Conclusion:** Low dose methotrexate did not appear to predispose to increased hair fall during this short term study. In fact many patients showed reduction in the number of hair in the hair pull test on methotrexate.

**FR0158 COMPARISON OF THE EFFICACY AND SAFETY OF TOFACITINIB AND UPADACITINIB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS**

Young Ho Lee, Gwan Gyu Song. Korea University, Rheumatology, Seoul, Korea, Rep. of (South Korea)

**Background:** A class of targeted synthetic disease-modifying anti-rheumatic drugs (tsDMARDs) has emerged as an alternative treatment option for rheumatoid arthritis (RA). Tofacitinib is an orally administered Jak (Janus kinase) inhibitor with functional cellular specificity for Jak-1 and Jak-3 over Jak-2 and upadacitinib, a new Jak inhibitor, has been engineered to confer greater selectivity for Jak1 than for Jak2, Jak3, and Tyk2.

**Objectives:** The aim of this study is to assess the relative efficacy and safety of tofacitinib and upadacitinib at different doses were assessed in patients with RA with an inadequate response to conventional synthetic (cs) or biologic (b) DMARDs.

**Methods:** We performed a Bayesian network meta-analysis to combine direct and indirect evidence from randomized controlled trials (RCTs) to examine the efficacy and safety of tofacitinib and upadacitinib in combination with methotrexate (MTX) in RA patients with an inadequate cs- or b-DMARD response.

**Results:** Nine RCTs including 5,794 patients met the inclusion criteria. There were 15 pairwise comparisons including 10 direct comparisons of six interventions. Upadacitinib 15 mg+MTX and upadacitinib 30 mg+MTX were among the most effective treatments for active RA with an inadequate cs- or b-DMARD response, followed by tofacitinib 10 mg+MTX, tofacitinib 5 mg+MTX, and adalimumab 40 mg+MTX. Ranking probability based on the surface under the cumulative ranking curve (SUCRA) indicated that upadacitinib 15 mg+MTX and upadacitinib 30 mg+MTX had the highest probability of being the best treatment in terms of the ACR20 response rate (SUCRA = 0.820, 0.762), followed by tofacitinib 10 mg+MTX (SUCRA = 0.623), tofacitinib 5 mg+MTX (SUCRA = 0.424), adalimumab+MTX (SUCRA = 0.371), and placebo+MTX (SUCRA = 0.001). No significant differences were observed in the incidence of serious adverse events after treatment with tofacitinib+MTX, upadacitinib+MTX, adalimumab+MTX, or placebo+MTX.

**Conclusion:** In RA patients with an inadequate response to cs- or b-DMARDs, upadacitinib 15 mg+MTX and upadacitinib 30 mg+MTX were the most efficacious interventions and were not associated with significant risks of serious adverse events.

**FR0159 REAL-WORLD EVIDENCE OF EFFECTIVENESS OF SWITCHING FROM TOFACITINIB 5MG BD TO TOFACITINIB 11MG QD IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTER, OBSERVATIONAL STUDY IN TAIWAN**

Liang-Hung Lin1,2, Der-Yuan Chen1,4, Taichung Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Division of Allergy, Immunology and Rheumatology, Taichung City, Taiwan, Republic of China; Providence University, Department of Food and Nutrition, Taichung City, Taiwan, Republic of China; Providence University Hospital, Taichung City, Taiwan, Republic of China; Providence University, Department of Medicine, Providence University, Department of Medicine, Providence University Hospital, Taichung City, Taiwan, Republic of China

**Background:** Rheumatoid arthritis (RA) is a chronic autoimmune disorder, precipitating chronic inflammation of the joints, also affecting organs throughout the body. For chronic conditions, such as RA, a once-daily (QD) dosing option has the potential to optimize patient adherence, and may enhance patient convenience and ease of use. Real-world data on effectiveness of switching from tofacitinib 5mg QD to tofacitinib 11mg QD is scarce.

**Objectives:** This study aimed at evaluating the effectiveness and safety of RA patients switching from tofacitinib 5mg BD to tofacitinib 11mg QD in a real-world setting.

**Methods:** A retrospective chart review of patients with RA was performed at the rheumatology department of an integrated secondary teaching hospital in Taiwan. The following cohorts were defined: RA patients who switched from tofacitinib 5mg BD to tofacitinib 11mg QD between 1 July 2018 and October 2018, and the follow-up period was at least 3 months. The clinical demographics and laboratory variables were obtained from clinic records.

**Results:** As of December 2018, 71 patients were included (85% of women), with a mean (SD) age of 57.4 (12.7) years, 70.1% were biologic-experienced; 78.9% rheumatoid factor positive and 80.3% anti-citrullinated peptide antibody (ACPA) positive. At baseline (before patients initiated tofacitinib 5mg BD treatment), the mean (SD) DAS28-ESR was 5.0 (8.4% patients with low disease activity, and 2.8% in clinical remission), the mean CDAI was 23.0 (11.2% patients with low disease activity, and 0% in clinical remission). After an average duration of 20 months treatment on tofacitinib 5mg BD treatment, the mean DAS28-ESR was 3.3 (29.6% patients with low disease activity, and 2.8% in clinical remission).
the mean CDAI was 7.5 (84.5% patients with low disease activity, and 2.8% in clinical remission). While switching to tofacitinib 11mg QD for 3 months, no significant difference was observed in terms of the ratio of DAS28-ESR LDA or CDAI LDA, but numerically more patients achieved DAS28-ESR LDA or CDAI LDA (32 and 64, respectively). During the 3-month follow-up period, no new adverse events were present.

Conclusion: Our study showed that RA patients switching from tofacitinib 5mg BID to tofacitinib 11mg QD sustained the effectiveness with no adverse clinical impact.

The preparation and property of iguratimod

Iguratimod, a methanesulfonanilide, has obvious anti-inflammatory efficacy and increases the gastrointestinal side effects of drugs[2].

Methods:
NanoIguratimod@Hydrogel was prepared using the high-gravity anti-solvent precipitation (HGAP) technique, and its properties were tested. The NanoIguratimod-loaded Hydrogel Composite was prepared and the delivery of the payload was demonstrated. In vitro, the biological effects of Nanolirutamoid@Hydrogel on fibroblast-like synoviocytes (RA-FLS) were evaluated. In vivo, the pharmacokinetics of oral raw iguratimod or subcutaneous injection of Nanolirutamoid@Hydrogel was carried out in the healthy rats. Further, we evaluated the efficacy of Nanolirutamoid@Hydrogel in treating collagen-induced arthritis (CIA) rats.

Results: By the HGAP technique, we acquired the amorphous form Nanolirutamoid with an average size of 295nm, which had higher dissolution rates and higher stability. The release of iguratimod from hydrogel was completed within 24h.

Discussion of Interests: None declared

Disclosure: Of Interests: None declared

PREPARATION AND PROPERTY OF IGURATIMOD NANOSONE SUSTAINED-RELEASE SYSTEM

Zhenzhen Ma1, Cheng Tao2, Lin Sun1, Jianjun Zhang2, Jinxia Zhao1.

1University Third Hospital, Department of Rheumatology and Immunology, Beijing, China; 2Beijing University of Chemical Technology, College of Chemical Engineering, Beijing, China.

Background: Iguratimod, a methanesulfonanilide, has obvious anti-inflammatory activity and has been developed exclusively in Asia-Pacific countries. As a novel disease-modifying anti-rheumatic drug, iguratimod is effective in the treatment of RA, but some side effects, such as liver damage and gastrointestinal discomforts are the main concerns in clinical application[1]. Currently, iguratimod is practically insoluble in aqueous solvents and only available in oral dosage forms. The low solubility of drugs leads to incomplete absorption and bioavailability, which affects the clinical efficacy and increases the gastrointestinal side effects of drugs[2].

Objectives: In order to improve the bioavailability and alleviate the side effect of gastrointestinal reaction, we changed the dosage form of iguratimod to NanoIguratimod-loaded Hydrogel Composite.

Methods: Iguratimod nanoparticles (Nanolirutamoid) were prepared by using the high-gravity anti-solvent precipitation (HGAP) technique, and their properties were tested. The Nanolirutamoid-loaded Hydrogel Composite was prepared and the delivery of the payload was demonstrated. In vitro, the biological effects of Nanolirutamoid@Hydrogel on fibroblast-like synoviocytes (RA-FLS) were evaluated. In vivo, the pharmacokinetics of oral raw iguratimod or subcutaneous injection of Nanolirutamoid@Hydrogel was carried out in the healthy rats. Further, we evaluated the efficacy of Nanolirutamoid@Hydrogel in treating collagen-induced arthritis (CIA) rats.

Results: By the HGAP technique, we acquired the amorphous form Nanolirutamoid with an average size of 295nm, which had higher dissolution rates and higher stability. The release of iguratimod from hydrogel was completed within 24h compared with Nanolirutamoid. Nanolirutamoid@Hydrogel inhibited the proliferation, migration, and invasion of RA-FLS in a doses dependent manner. The pharmacokinetic parameters showed better bioavailability and longer half-life time with Nanolirutamoid@Hydrogel by subcutaneous administration than oral raw iguratimod. Animal experiments confirmed that subcutaneous injection of Nanolirutamoid@Hydrogel (10mg/kg every three days) and oral raw iguratimod (10mg/kg daily) showed similar efficacy in decreasing arthritis index score, pathological score, and expression of cytokines (IL-6, TNF-a and IL-1b).

Conclusion: Overall, our data suggested that Nanolirutamoid@Hydrogel provided new administration routes and extended the administration interval, it may serve as a promising drug delivery approach for the treatment of RA.

PHARMACOKINETICS AND SAFETY OF A SINGLE ORAL DOSE OF PEFICITINIB (ASP015K) IN SUBJECTS WITH NORMAL AND IMPAIRED HEPATIC FUNCTION

Daisuke Miyatake1, Tomohisa Shibata1, Junko Toyoshima1, Yuichiro Karako1, Kazuo Oda2, Tetsuya Nishimura1, Masataka Katashima1, Masashi Sakuki3, Kazuaki Inoue4, Takayoshi Ito5, Naoki Uchida6, Kenichi Furuita7, Akinori Urabe8.

1Astellas Pharma, Inc., Tokyo, Japan; 2Astellas Research Institute of America LLC, Northbrook, United States of America; 3Showa University School of Medicine, Tokyo, Japan; 4Showa University Fujigaoka Hospital, Yokohama, Japan; 5Showa University Koto Toyosu Hospital, Tokyo, Japan; 6Clinical Research Institute of Clinical Pharmacology and Therapeutics, Showa University, Tokyo, Japan; 7P-One Clinic, Keikokai Medical Corporation, Tokyo, Japan; 8Mediscience Planning Inc., Tokyo, Japan.

Background: Peficitinib (ASP015K), a novel oral Janus kinase inhibitor, demonstrated efficacy as once-daily therapy for moderate-severe rheumatoid arthritis in a phase 2b study (NCT01649999) and 2 phase 3 studies (NCT02308163, NCT02305849). Mean urinary excretion of peficitinib accounted for 9~15% of the oral dose. It produces 3 conjugated metabolites (H1, H2, H4), which show very weak in-vitro pharmacological action.

Objectives: To assess pharmacokinetics (PK) and safety of a single oral dose of peficitinib 150 mg in subjects with normal and impaired hepatic function.

Methods: This phase 1, open-label, single-dose, parallel-group study was conducted at six centres in Japan. Eligible subjects were aged 20–75 years, with body mass index >17.0–<30.0 kg/m². Hepatic impairment was defined as screening using Child-Pugh classification: Class A, mild (5–6 points); Class B, moderate (7–9 points). Subjects with severe hepatic impairment (Child-Pugh classification Class C, 10–15 points) were excluded. Subjects received a single oral dose of peficitinib 150 mg under fasting conditions, based on daily dose in the 2 phase 3 studies. Blood samples for plasma PK analysis of peficitinib and its metabolites were collected before and up to 72 h post dose. Safety was assessed throughout the study.

Results: 24 subjects were enrolled (70.8% male): 16 with impaired and 8 with normal hepatic function (Table 1): all received study medication.

CONCLUSION: Overall, our data suggested that Nanolirutamoid@Hydrogel provided new administration routes and extended the administration interval, it may serve as a promising drug delivery approach for the treatment of RA.

FR0162 BASELINE CHARACTERISTICS AND OUTCOMES IN PATIENTS WITH ANAEMIA IN CLINICAL STUDIES OF TOFACITINIB IN RHEUMATOID ARTHRITIS

RESULTS: The proportion of pts with G2A at BL was similar for tofacitinib (3.2%, 152 of 4736 pts) and PBO (2.4%, 27 of 1125 pts) groups. Pts with G2A at BL were more often female, Asian, younger, had never smoked and had a lower body mass index (BMI) and higher C-reactive protein (CRP) and ESR vs pts without G2A at BL; RA duration was generally similar across groups (Table). Tofacitinib seemed to improve anaemia more rapidly than PBO: in pts with G2A at BL, a lower proportion of those receiving tofacitinib had G2A at M1 and M3 vs those receiving PBO (48.8% vs 75.0%, respectively, at M1 and 36.1% vs 57.1%, respectively, at M3), while the proportions were similar at M6 (28.9% vs 30.6%, respectively). In pts receiving tofacitinib, mean Hgb levels gradually increased from BL to M6 in those with G2A at BL (1.25 g/dL change), but were relatively stable in those without G2A at BL (0.15 g/dL change). In tofacitinib-treated pts, DAS28-4(ESR) scores decreased from BL to M6 by -2.40 in those with G2A at BL and -2.42 in those without G2A at BL. DAS28-4(ESR) low disease activity (≤2.3) rate at M6 was lower in tofacitinib-treated pts with G2A at BL vs those without G2A at BL (18.3% vs 28.4%, respectively). Among pts receiving tofacitinib,

Conclusion: Peficitinib exposure in subjects with mild hepatic impairment was similar to that in subjects with normal hepatic function; subjects with moderate hepatic impairment had greater exposure. A single dose of peficitinib was well tolerated.

Number of subjects available for AUC and Cmax: n = 97; n = 97.

Hepatic impairment was defined according to Child-Pugh classification: class A: mild; 5–6 points; or class B: moderate, 7–9 points.

AUC and Cmax were based on the concentration-time curve from the time of dosing extrapolated to infinity and maximum concentration, respectively. PK parameters were estimated at the last non-missing post-dose observation (terminal elimination half-life (t1/2) and CL, t1/2, and CL were based on the least square means (LSM) of the parameter).
those with BL G2A had a higher incidence of TEAEs vs those without BL G2A in the following MedDRA system organ classes (with incidence $>20\%$ in pts who were either with or without BL G2A): gastrointestinal disorders (30.9\% vs 22.5\%, respectively) and infections and infestations (44.1\% vs 39.0\%, respectively).

**Conclusion:** In this post hoc analysis, more pts with BL G2A had a higher incidence of TEAEs vs those without BL G2A. The majority were females (89.3\%) and most had prior biologic use history (74.0\%). At baseline, no significant differences in disease activity and sociodemographic profiles were found between the two groups of patients with and without concurrent MTX use. Discontinuation was reported in 44 (33.6\%) of all TOFA patients with a median survival of 31.3 months. Overall retention of TOFA at 6, 12 and 24 months was 80.5\%, 63.1\% and 53.5\% respectively. These findings are very similar to the results reported from the RHUMADATA registry at ACR 2018. Fifteen (34.0\%) patients stopped their TOFA due to non-response/loss of response, 22 (50.0\%) due to adverse events, and 7 (16\%) due to other reasons. Patients also stayed on TOFA longer when they concurrently used MTX compared to TOFA without MTX.

**Conclusion:** We found that half of the RA patients remained on TOFA 31 months after initiation. Patients also stayed on TOFA longer when they concurrently used MTX compared to TOFA without MTX.

Mohammad Movahedi1, Angela Cesca1, LI Xiuying1, Claire Bombardier1,2, 1Toronto General Research Institute, University Health Network, Ontario Best Practices Research Initiative, Toronto, Canada 2University of Toronto, Mount Sinai Hospital, Rheumatology, Toronto, Canada

**Background:** Tofacitinib (TOFA) is an oral, small molecule drug which can be used as an alternative to biologic disease modifying anti-rheumatic drugs (bDMARDs) for rheumatoid arthritis (RA) treatment and is prescribed alone or with methotrexate (MTX).

**Objectives:** We aimed to evaluate the discontinuation rate of this drug, with and without concurrent MTX, with and without prior biologic use, in patients with RA using real world data from a Canadian (Ontario) observational cohort.

**Methods:** Patients enrolled in the Ontario Best Practices Research Initiative (OBDI) who started TOFA after its approval in Canada (June 2014) were included in this analysis. Patients were followed from TOFA initiation until discontinuation, death, lost to follow-up, or last visit, whichever came first. Time to discontinuation of TOFA, due to any reason, in patients 1) with and without concurrent MTX use; 2) with or without prior biologic use was assessed using Kaplan-Meier survival analysis.

**Results:** Among the 131 patients, 70 (53.4\%) received TOFA without MTX and 61 (46.6\%) TOFA with MTX. Mean (SD) age and disease duration were 60.2 (0.90) years and 13.7 (0.80) years, respectively. The majority were females (89.3\%) and most had prior biologic use history (74.0\%). At baseline, no significant differences in disease activity and sociodemographic profiles were found between the two groups of patients with and without concurrent MTX use. Discontinuation was reported in 44 (33.6\%) of all TOFA patients with a median survival of 31.3 months. Overall retention of TOFA at 6, 12 and 24 months was 80.5\%, 63.1\% and 53.5\% respectively. These findings are very similar to the results reported from the RHUMADATA registry at ACR 2018. Fifteen (34.0\%) patients stopped their TOFA due to non-response/loss of response, 22 (50.0\%) due to adverse events, and 7 (16\%) due to other reasons. At 6 and 12 months' follow-up, more patients remained on TOFA in the ‘TOFA with MTX’ group (88.3\% and 73.1\%, respectively) compared to the ‘TOFA without MTX’ group (73.9\% and 54.6\%, respectively) (Logrank p=0.05). There was no significant difference in TOFA discontinuation between the two groups of patients with and without prior biologic use (Logrank p=0.77).

**Conclusion:** We found that half of the RA patients remained on TOFA 31 months after initiation. Patients also stayed on TOFA longer when they concurrently used MTX compared to TOFA without MTX.

INCIDENCE RATE AND CHARACTERIZATION OF
HERPES ZOSTER IN PATIENTS WITH MODERATE-TOSEVERE RHEUMATOID ARTHRITIS: AN UPDATE FROM
BARICITINIB CLINICAL STUDIES

Yi-Hsing Chen1, Yi-Ming Chen1, Josef S. Smolen2, Tsutomu Takeuchi3,
Rudiger Muller4, David Walker5, Ran Liao6, Clementine Perrier6, Wen-Shuo Wu6,
Kevin Winthrop7. 1Taichung Veterans General Hospital, Taichung City, Taiwan,
Republic of China; 2Medical University of Vienna, Vienna, Austria; 3Keio University
School of Medicine, Tokyo, Japan; 4Aarau Kantonsspital, Aarau, Switzerland;
5
Freeman Hospital, Newcastle upon Tyne, United Kingdom; 6Eli Lilly and
Company, Indianapolis, United States of America; 7Oregon Health and Science
University, Portland, United States of America
Background: Baricitinib (BARI) is a selective inhibitor of Janus kinase
(JAK) 1 and JAK2, approved for the treatment of moderately to severely
active rheumatoid arthritis (RA) in adults in over 50 countries, including
the United States, Europe and Japan. Due to their disease and associated therapy with disease-modifying anti-rheumatic drugs (DMARDs), RA
patients (pts) have an increased risk of herpes zoster (HZ) compared
with the general population.1 Furthermore, the incidence of HZ is
increased in RA pts treated with BARI versus placebo (PBO).2
Objectives: To determine the long-term overall and geographical incidence, time to first event and risk factors for HZ in BARI-treated RA pts.
Methods: Data were pooled from nine completed Phase 1, 2, and 3
studies of BARI in RA pts, including six randomised, PBO-controlled studies (0–24 weeks in DMARD-inadequate responders, including RA-BUILD,
RA-BEACON and the long-term extension study, RA-BEYOND [data cut
off February 13, 2018]), and active-controlled studies with methotrexate
(MTX; RA-BEGIN study in DMARD-naïve pts) and adalimumab (RA-BEAM
study in MTX-inadequate responders). The HZ incidence was evaluated
for all RA pts who had ever received BARI (any dose) and the HZ incidence rate (IR) was calculated as the number of pts with an HZ event
per 100 patient–years of observation (PYO). Exposure included up to 28
days after treatment cessation, and was censored at the HZ event date.
Univariate and multivariate Cox proportional hazard regression models
were used to evaluate risk factors for HZ.

Results: Of 3770 RA pts treated with BARI, median age at study entry
was 54 years (range 20–90 years), approximately one-quarter were each
from North America (n=840; 22%), EU (783; 21%), Asia (959; 25%) and
Central America (760; 20%), median time from RA diagnosis was 5
years, 2938 (78%) and 1754 (47%) were on concomitant MTX or corticosteroids (CS; mean dose 6.2 mg/day), respectively. HZ was reported in
323 (9%) pts over 9892 PYO, with median BARI exposure of 1115
days. Of these pts, 12 (4%) had a history of HZ, and 256 (79%) and
168 (52%) were on concomitant MTX and CS, respectively. The median
time to first HZ event was 538 days and the overall IR of HZ was 3.3/
100 PYO, which did not increase significantly over time (Fig 1). Twentysix (8%) cases were multidermatomal, and no visceral disease was
reported. Eight (2%) pts showed involvement of the ophthalmic division of
the Vth cranial nerve and 9 (3%) experienced recurrent HZ during observation. Only 11 HZ pts (4%) had received prior HZ vaccination. Multivariate analyses showed that older age (hazard ratio [HR] 1.30, 95%
confidence interval [CI] 1.17, 1.43) and geographical region (Asia,

Friday, 14 June 2019
especially Japan, Taiwan and South Korea; HR 1.82, 95%
Fig 2) were associated with a higher risk of HZ.
Conclusion: HZ incidence in BARI-treated RA pts did not
time and the majority of HZ events were monodermatomal
cated. Pts who were older and those from Asia were at
of a HZ event.

To assess health-related quality of life (HRQoL) of Japanese patients with RA who had an inadequate response to MTX.

Methods: This multicentre, randomised, double-blind, parallel-group, placebo-controlled, phase 3 study recruited patients in Japan with active RA and inadequate response to MTX. Patients were randomised 1:1:1 to 52-week placebo+MTX (PBO), peficitinib 100 mg QD+MTX (PEFI 100 mg) or peficitinib 150 mg QD+MTX (PEFI 150 mg). The PBO group was switched to PUF 100 mg or 150 mg at Week 12 (for non-responders) or Week 28 (for remaining patients). Patient- and physician-reported outcome assessments included: Physician’s Global Assessment of disease activity (PGA); Subject’s Global Assessment of disease activity (SGA); and Subject’s Global Assessment of pain (SGAP) by visual analogue scale. Physical function was evaluated using Health Assessment Questionnaire-Disability Index (HAQ-DI). All assessments were conducted at each visit from baseline to the end of study.

Results: 519 patients were treated: PBO (n=170), PEF1 100 mg (n=175) and PEF1 150 mg (n=174). One PEF1 100 mg patient was excluded from the analysis due to protocol deviation. At Weeks 12/early termination (ET) and 28/ET, both PEF1 groups were associated with significant improvements in PGA, SGA, SGAP and HAQ-DI (Table 1). These outcomes were maintained or improved at end of treatment (EOT; Week 52/ET) when compared to placebo. Changes from baseline in PGA, SGA, SGAP and HAQ-DI in the PEF1 100 mg and PEF1 150 mg groups were: -38.41,-43.33; -29.34,-34.05; -28.94,-32.68; and -0.36,-0.51, respectively. Significantly greater proportions of patients achieved functional remission and a minimum clinically important (MCI) reduction in HAQ-DI score (>0.5 and reduction of >0.22, respectively) at Weeks 12/ET and 28/ET in both PEF1 groups than in the PBO group (p<0.001 vs PBO for both PEF1 doses; Table 1). In the PEF1 100 mg and PEF1 150 mg groups at EOT, functional remission occurred in 105/172 (61.0%) and 106/171 (62.0%) patients with MCI reduction in HAQ-DI score occurred in 99/172 (57.6%) and 120/171 (70.2%) patients, respectively.

Conclusion: Measures of PGA, SGA, SGAP and HAQ-DI in patients with RA who had an inadequate response to MTX demonstrated improved HRQoL with peficitinib; PEF1 150 mg QD showed similar or numerically greater changes in HRQoL than PEF1 100 mg QD. Improvements were maintained or improved to the EOT and demonstrated a significant benefit for patients with RA in Japan.
Methods: Adult (≥18y) patients with symptomatic, refractory inflammatory mono- or oligoarthritis were included for RSO with Yttrium-90 citrate as part of a phase-III, prospective, open-label non-controlled trial. All patients were required to have failed 6-months of medical therapy and 2 intraarticular injections and have minimal evidence of cartilage or bone destruction. Only large and medium-sized joints were included (i.e. knees, ankles, wrists and elbows). The dose of Yttrium was adjusted based on the size of joint. Follow-up evaluations were done at 3, 6 and 12 months after RSO. Safety was assessed by patient and clinician reported adverse events. Clinical response was measured by improvement in joint tender- ness, effusion and range of motion.

Results: A total of 74 patients and 83 joints (88% knees) were treated with Yttrium-90 citrate. The underlying diagnosis included 25.7% RA, 34% SpA, 11% IA, and 10.3% other inflammatory arthritis. Complications included 3 post-RSO flares, 1 septic joint and 2 injection site skin infec- tions. Joint tenderness was reported in 93.8% of joints at baseline, com- pared to 50.0% at 3mo (p<0.001), 55.6% at 6mo (p<0.001) and 40.4% at 12mo (p<0.001). Joint effusion was present in 95.1% of joints at base- line, 44.3% at 3mo (p<0.001), 51.4% at 6mo (p<0.001) and 47.4% at 12mo (p<0.001). 73.9% of joints had improvement in range of motion at 3mo, 55.9% at 6mo and 60.7% at 12mo.

Conclusion: These results confirm the clinical efficacy and safety of Yttrium-90-citrate RSO for refractory synovitis with a sustained clinical ben- efit at 12 months. This is the first such study in a Canadian cohort. RSO with Yttrium is a safe alternative to surgical synovectomy in refrac- tory cases.

FR0169 DOES INITIATING TOCILIZUMAB LEAD TO BETTER DISEASE CONTROL COMPARED TO INITIATING MTX WITH DOSE PREDNISONE IN EARLY RHEUMATOID ARTHRITIS? AN INDIRECT COMPARISON OF U-ACT-EARLY AND CAMERA-II TREAT-TO-TARGET TRIALS
Maxime Verhoeven1, Janneke Tekstra1, M Jacob. van Laar 1, Johannes WJ Bijlsma1, Attila Pelthoe-Schramm2, Michelle Born3, Floris Laleber1, Paco Welsing1. 1University Medical Center Utrecht, Utrecht, Netherlands; 2Hoffmann-La Roche, Basel, Switzerland; 3Roche Nederland BV, Woerden, Netherlands

Background: Treatment with methotrexate (MTX), often with concomitant glucocorticoids, is the cornerstone of early rheumatoid arthritis (RA) therapy. However, it may be less effective compared to (expensive) biological disease modifying anti-rheumatic drugs, such as tocilizumab (TCZ). Hitherto, the effectiveness and safety of MTX in combination with glucocorticoids have never been compared to TCZ with or without MTX.

Objectives: To compare effectiveness and safety of initiating TCZ, or TCZ with MTX (TCZ+MTX) to initiation of MTX with 10mg prednisone (MTX+Pred) all in a step-up treat-to-target treatment strategy in early RA patients.

Methods: Individual patient data of the U-Act-Early (n=237) and CAMERA-II (n=236) trials were used. Both were 2-year, double-blind, randomised, placebo-controlled studies evaluating step-up tight-control, treat-to-target treatment strategies with the opportunity to taper, in case of suspected, placebo-controlled studies evaluating step-up tight-control, treat-to-target treatment strategies with the opportunity to taper, in case of sustained remission, TCZ and/or MTX.

Using MTX (n=109+119) as the reference strategy, TCZ+MTX (n=106) and TCZ (n=103) were compared with MTX+Pred (n=117): primary outcome was the disease activity score (DAS28) over time. Secondary outcomes were remission, TCZ and/or MTX.

Conclusions: TCZ+MTX to initiation of MTX with 10mg prednisone (MTX+Pred) all in a step-up treat-to-target treatment strategy in early RA patients.

Conclusions: In early RA patients, TCZ-based strategies resulted in better DAS28 over time compared to MTX+Pred, as well as higher percentage of remission, part of these effects may be due to a specific effect of TCZ on APRs.

FR0170 PHYSICAL ACTIVITY LEVEL IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW
Charlotte Schouller1, Jean Francis Maillere2, Jean Marie Casillas3, Daniel Wending4, Frank Verhoeven5, CH Montreau, Rheumatology, Montceau Les Mines, France; 2CHU Dijon, Rheumatology, Dijon, France; 3CHU Dijon, Physical rehabilitation, Dijon, France; 4CHRU Besancon, Rheumatology, Besancon, France

Background: Rheumatoid arthritis (RA) is one of the most common inflammatory rheumatism characterized by an increased cardiovascular risk. Regarding the last EULAR recommendations, physical activity is an important part of the management of RA. The evaluation of physical activity level is needed to know RA patients practices. However, to our knowledge, there is no consensual measure tool of the physical activity level for patients suffering RA.

Objectives: The aim of this study is to evaluate the different methods of measurement of physical activity levels in RA.

Methods: This is a systematic review of literature realized on the PubMed and Cochrane databases and meeting the PRISMA recommendations. We used the following key words: - « physical activity », - « physical activity level » AND « rheumatoid arthritis » . We included only article written in English language and with RA patients older than 18 years old.

Results: We identified 190 studies with the key words, 51 words were selected on title and 23 articles have been identified as eligible. Finally, 19 studies were included in this review. In total, of the 19 selected studies, 13567 RA patients were evaluated on their level of physical activity. There were 73,4% female with a mean age of 56,1 years. In 10 studies, the BMI was available with results between 25 and 30 kg/m2. Two methods for measuring physical activity levels have been identified.
Questionnaires, a subjective tool, were used in 13 studies. It should be noted that 8 different questionnaires were used in these studies with recurrent use of the IPAQ (international validated questionnaire in general population) and SQUASH (validated in English language in RA). In these studies, responses at Wk 24 were generally sedentary with a proportion of patients meeting WHO physical activity recommendations ranging from 20 to 77%. It appears that Scandinavian patients are clearly the most active.

Concerning objective measurement tools, 9 studies evaluated the level of physical activity using activity tracker. 7 studies used the accelerometer, 1 used the VO2 max, 1 used an actimeter. All studies showed a sedentary behavior. In these studies, the results were expressed as energy expenditure and not as a percentage of patients meeting WHO recommendations. Thus, the comparison between the two methods is difficult but accelerometer showed a significant decrease in the level of physical activity in RA.

The oldest studies (2002 and 2007) showed that only 30% of patient met the WHO recommendations, but the recent studies (2017 and 2018) showed the same prevalence of sedentary behavior. The disease activity and the disease duration were comparable between the different studies.

Conclusion: Patients with rheumatoid arthritis present a sedentary behavior. Objective and subjective tools showed the low level of physical activity over the past decade. These data illustrate the necessity of the promotion of physical activity in rheumatoid arthritis.

FRIO171 CLINICAL RESPONSES IN PATIENTS WITH INADEQUATE RESPONSE TO BDMARDS UPON TREATMENT WITH UPADACITINIB

Michael Weinblatt1, Glen Thomson2, Kun Chen3, Sebastian Meerwein4, Casey Schlacher4, John Cushi5, Brigham and Women's Hospital, Boston, United States of America; 2MDSD Research, Winnipeg, Canada; 3AbbVie, North Chicago, United States of America; 4AbbVie Germany GmbH and Co. KG, Ludwigshafen am Rhein, Germany; 5Baylor University Medical Center, Dallas, United States of America

Background: Upadacitinib (UPA), a JAK1-selective inhibitor, demonstrated efficacy in the SELECT-BEYOND study in patients (pts) with moderate to severe rheumatoid arthritis (RA) on a stable dose of csDMARDs who had inadequate response (IR) or intolerance to bDMARDs.

Objectives: In this analysis we evaluated clinical responses among pts receiving UPA and placebo (PBO) based on the number and mechanism of action (MOA) of prior bDMARDs.

Methods: 498 pts were randomized to UPA 15mg or UPA 30mg once daily (QD) or PBO for 12 weeks (wks), after which pts on PBO received UPA 15 or 30mg QD from Wk 12 onwards. Pts were subgrouped by the number and/or MOA of bDMARD(s) received prior to enrollment: 1) lack of efficacy (LoE), 2) anti-TNF, 3) LoE to an anti-IL-6, and 4) LoE to an anti-IL-6, and those who had IR/intolerance to 1, 2 or 3 prior bDMARDs, with consistent safety profiles as to the overall study population.

Results: Overall baseline disease duration was 17.7 years, with 117 patients (23%) enrolled in the LoE population, including in pts with LoE to an anti-TNF or an anti-IL-6, and those who had IR/intolerance to 1, 2 or 3 prior bDMARDs, with consistent safety profiles as to the overall study population.

FRIO172 A PROSPECTIVE AUDIT OF A PATIENT COHORT PRESCRIBED HYDROXYCHLOROQUINE FOR RHEUMATOID ARTHRITIS AND OTHER INFLAMMATORY RHEUMATIC DISEASES IN ORDER TO PRIORITIZE RETINOPATHY SCREENING AND ESTIMATE THE NEED FOR DRUG EDUCATION APPOINTMENTS

Brandon Yeo1, Audrey Low2, Alexandra Chadwick2, Sarah Wills2, 1University of Manchester, Faculty of Biology, Medicine, and Health, Manchester, United Kingdom; 2Salford Royal NHS Foundation Trust, Rheumatology, Salford, United Kingdom

Background: Hydroxychloroquine (HCQ) is prescribed for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and inflammatory osteoarthritis (IOA). A potential side effect of HCQ is drug-induced retinopathy, with an increased risk reported for patients taking >5mg/kg/day and those who have renal impairment.

In the United Kingdom, the Royal College of Ophthalmologists (RCO) has published new screening guidelines for HCQ, recommending 1) patients receive doses <5mg/kg/day and 2) all patients planning to be on HCQ long term (>5 years) should receive baseline eye examination ideally within 6 months of starting HCQ and definitely within 1 year.

Objectives: This audit aimed to: 1) audit dose prescription by body weight, 2) estimate the screening burden on ophthalmology services, 3) estimate service needs for additional drug education appointments to counsel patients starting HCQ.

Methods: A list of all patients who were started on HCQ from January 2017 to February 2018 was obtained from the outpatient pharmacy at Salford Royal Hospital. Demographic and clinical data were extracted from electronic patient records. High-risk patients were defined as those who were prescribed an initial dose of >5mg/kg/day or those with an eGFR <50 ml/min/1.73m^2. Patients were followed until the most recent follow-up visit by July 2018 to determine drug persistence and reasons for HCQ cessation, if any.

Results: 177 patients were started on HCQ, with most (82%) diagnosed with rheumatoid arthritis (Table). Most patients were female (76%) and a third (35%) were older than 60 years old. 9 patients (5.1%) had impaired renal function. 83 patients (47%) were prescribed an initial daily dose of HCQ >5mg/kg/day. By July 2018 (follow-up duration 6-19 months), 127 patients (71.8%) remained on HCQ and will need baseline eye screening.

Disclosure of Interests: None declared
The remaining 50 patients (28.2%) stopped HCQ due to inefficacy (7.3%), GI disturbance (3.4%), rash (3.4%).

</tbody>
</table>

Conclusion: Clinicians need to be cognisant of recent guidelines and adjust HCQ dosing to the recommended 5mg/kg/day. Additional specialist pharmacist input for DED (12-13 extra appointments per month) is required. Almost a third of the patients had stopped HCQ by July 2018, mostly due to side effects and reported inefficacy. However, a large proportion (71%) of HCQ starters remain on the drug by 6-12 months and will need baseline screening. Ophthalmology services can estimate services and capacity required for baseline HCQ screening per annum.

SLE, Sjögren’s and APS – treatment

FR10173 HOW WELL DO CLINICAL TRIALS REPRESENT REAL WORLD LUPUS NEPHRITIS PATIENTS?
Sophie Collinson, Ben Parker, Eoghan Mccarthy, Ian N. Bruce, British Isles Lupus Assessment Group Biologics Register. Kellogg Centre for Rheumatology, NHRI Manchester Musculoskeletal Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background: Lupus nephritis (LN) represents a serious manifestation of systemic lupus erythematosus (SLE). LN therapies include glucocorticoids and conventional immunosuppressants as standard of care (SOC) or biological therapies. Rituximab (RTX) is used in some patients but published clinical trials have failed to meet their primary end-points. SLE trials have limitations including stringent eligibility criteria in an attempt to achieve homogeneity, however poor recruitment can lead to early termination as such, clinical trials may not reflect the disease population of interest and outcomes can be difficult to generalise.

Objectives: Our aim was to apply published trial eligibility criteria to patients with LN in a large UK-wide register to quantify how accurately LN clinical trials represent a real-world cohort.

Methods: A literature review of recent major published LN clinical trials was performed (n=6). Inclusion and exclusion criteria common across trials were applied to all patients registered in the BILAG-Biologics Register (BILAG-BR) with active LN, a UK-wide registry of patients with SLE. Active LN was defined as a BILAG score A or B. We applied available data to inclusion criteria including ACR/SLECC criteria for SLE diagnosis, positive dsDNA or ANA antibodies and a UPCR>100mg/mmol. Available exclusion criteria were active CNS lupus, a history of malignancy or CKD 4/5, hypogammaglobulinaemia, and cyclophosphamide use within 30 days of entry or previous B cell therapy within 12 months of entry.

Results: As of July 2018, 259/897 (28.9%) patients in BILAG-BR had active LN. In the RTX and SOC groups, 70/230 (30.4%) and 10/29 (34.5%) respectively did not meet all inclusion criteria (Table 1). Meanwhile 118/230 (51.3%) of RTX patients and 6/29 (20.7%) of SOC patients met one or more exclusion criteria. Overall 131/259 (50.6%) did not satisfy all inclusion and exclusion criteria and thus were ineligible for clinical trial entry. Of those patients deemed ineligible, the RTX patients were younger (median age 36 vs. 49 in SOC group, p=0.653) and the majority were non-Caucasian (n=71/121 (58.7%), p=0.251). The majority of patients in both treatment groups were female (p=0.089). UPCR <100mg/mmol (n=135) was the most common exclusion criteria missed whilst the commonest exclusion criteria were concomitant active CNS disease (n=22) and hypogammaglobulinaemia (n=24).

Conclusion: In a large national cohort of active LN we found that 50.6% of patients would not be eligible for clinical trial entry using published entry criteria. This poses significant implications on the study of LN treatment in patients with more severe disease. When designing clinical trials, the stringency of eligibility criteria should be reviewed in order to provide greater representation of the target disease population.

FR10174 SUBCUTANEOUS DOSING OF THE NOVEL ANTI-CD40 ANTIBODY ICX501 ACHIEVES TARGET DRUG EXPOSURE AND CLINICAL EFFICACY IN PRIMARY SJÖGREEN’S SYNDROME: RESULTS OF A PHASE IA RANDOMISED OPEN LABEL TWO ARM PARALLEL GROUP TRIAL

Benjamin Fisher1, Antonia Szanto2, Wan Fei Ng3, Michele Bombardieri4, Maximilian Posch5, Athena Papas6, Arwa Farag6, Thomas Daikeler7, Bettina Bannert7, Alan Kivitz8, Steven Carsons9, David Isenberg10, Francesca Barone1, Simon J. Bowman1, Pascal Espié1, Grazyna Wieczorek11, Pierre Moulin11, David Flicho11, Cyrielle Dupuy11, Amanda Nguyen11, Andrew Wright11, Michael Rottet11, James Rush11, Peter Grofely11, University of Birmingham, Birmingham, United Kingdom; University of Debrecen, Debrecen, Hungary; Newcastle University, Newcastle, United Kingdom; Queen Mary University of London, London, United Kingdom; Charité Research Organisation GmbH, Berlin, Germany; Tufts University, Boston, United States of America; University Hospital Basel, Basel, Switzerland; University of Alabama at Birmingham, Birmingham, United States of America; University of Toronto, Toronto, Canada; University of California, Los Angeles, United States of America; University of Southern California, Los Angeles, United States of America; NYU Winthrop Hospital, Mineola, United States of America; University College Hospital, London, United Kingdom; Novartis Institutes for Biomedical Research, Basel, Switzerland; Novartis Pharma AG, Basel, Switzerland

Background: Primary Sjögren’s syndrome (pSS) is a systemic progressive autoimmune disease characterised by formation of lymphoid structures and germinal centres within glandular tissue. Ixicalimab (CFZ533) is a novel monoclonal antibody that potently and selectively blocks CD40, a co-stimulatory pathway receptor important for germinal centre reactions.
**Objective:** To test IV versus SC loading doses of iscalimab followed by SC maintenance dosing, as a means of achieving target drug exposure and clinical efficacy.

**Methods:** Patients with clinically active pSS [EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) >6] were randomised to receive either 600 mg SC iscalimab weekly on 4 occasions, followed by 300 mg SC weekly until week 12, or a single IV dose of 10 mg/kg iscalimab on study Day 1, followed by 300 mg SC weekly until week 12. Subjects and investigator staff remained blinded to study treatment allocation until first dosing.

**Results:** Twenty-five patients were randomised; 13 in the SC loading and 12 in the IV loading arms. Baseline characteristics were similar to the previous phase IIa cohorts with mean ESSDAI scores of 12.7 (SD 6.1) and 10.4 (5.9) in the SC and IV loading arms respectively. In Arm 1 (SC) and Arm 2 (IV), the mean trough plasma concentrations were 169 µg/mL (SD 64.1, CV 38%) and 135 µg/mL (SD 70.9, CV 53%) on Day 85, respectively. Both values were well above levels previously reported to be sufficient for suppression of germinal centre development and T dependent antigen responses in cynomolgus monkeys. Consistent with this finding, clinically important improvements were seen in both arms with a mean decrease in ESSDAI scores of -5.5 (+/- SD: 5.5) and -7.6 (+/- 7.1) points from baseline to Day 85 in the SC and IV dosing arms. Improvements were also seen in EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI) scores: -1.67 (+/- 2.0) and -1.17 (+/- 2.3), respectively. Other secondary efficacy outcomes showed similar patterns of improvement. Treatment with iscalimab was associated with a reduction in the germinal centre-related serum biomarker CXC1L1 in both groups. Overall, iscalimab was safe and well-tolerated with no new safety signal emerging. One subject experienced three SAEs (hemarthrosis, worsening of right knee pain and swelling requiring arthroscopy) in the safety follow-up period, all unrelated to study drug.

**Conclusion:** These results further support the safety and efficacy of iscalimab in pSS and the suitability of SC dosing for future development.
Objectives: This Phase 2 study was designed to minimize background medications and placebo responses to improve interpretation of a small trial in a complex, heterogeneous disease.

Methods: SLE patients were enrolled with active disease, ameliorated during screening with >160 mg of IM Depo-Medrol. Improvement was required before randomization, defined by decrease in SLEDAI ≥4 points or ≥1 grade in a BILAG A or B score. Immunosuppressive drugs were stopped except antimalarials and/or ≤10 mg/day prednisone or equivalent. Subjects were randomized to IV XmAb5871 (5 mg/kg) or placebo and given Depo-Medrol 80 mg IM on Days 1 and 15, after which, steroid impact was expected to withdraw gradually. Study treatments were given Q14 days for up to 16 doses or loss of improvement (LOI), defined as SLEDAI increase ≥4 points OR new BILAG A or B, with investigator-determined significance. At LOI, patients could receive immediate standard treatments. The primary endpoint was the proportion with no LOI by Day 225 in the efficacy evaluable group (those completing Day 225 or withdrawn for LOI or drug-related adverse event).

Results: 104 subjects were randomized: 99 female, median age 45 (20–76) years. The primary endpoint was met by 21 (42%) of XmAb5871-treated patients vs 12 (28.6%) of the placebo group (p=0.18). All but one responder also fulfilled the SRI-4 response definition from screening to completion. Results did not differ in those with or without anti-dsDNA and/or ENA antibodies. Time to flare was significantly longer in the XmAb5871 group (p=0.025) (figure 1). XmAb5871-treated patients with LOI had less recurrent disease after IM steroid cessation than those in the placebo group: 6 (20%) of placebo patients developed BILAG A scores vs 3 (13%) in the active arm. 9 (30%) of worsening placebo patients had SLEDAI increase ≥7 vs 0 in the XmAb5871 group. SLEDAI scores were higher and increased sooner after disease nadir with placebo vs XmAb5871 (figure 2); 16 (30.8%) of XmAb5871 patients vs 7 (13.5%) placebo patients sustained LLDA (low disease) during months 6-8 (p=0.045). Transient, infusion-related gastrointestinal side effects occurred in XmAb5871-treated patients during the 1st or 2nd infusion. There were 8 SAEs in 7 XmAb5871-treated subjects, 5 in 4 placebo patients, no opportunistic infections, and no deaths. Infection rate was low compared to other SLE trials.

Conclusion: XmAb5871 was well-tolerated. Preliminary data from this small trial indicates suppression of disease recurrence after treatment withdrawal, supporting further evaluation of XmAb5871 in SLE.

CLUSTER PROFILING OF PATIENTS IN A REAL-WORLD DATASET WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND THEIR ASSOCIATED TREATMENTS

Zahi Touma1, Ben Hoskin2, Christian Atkinson2, David Bell2, Olivia Massey2, Jennifer H. Loffand2, Pam Berry2, Chetan Karyekar3, Karen Costenbader2.

1University of Toronto, Toronto, Canada; 2Adelphi Real World, Cheshire, United Kingdom; 3Janssen Global Commercial Strategic Organisation, Horsham, United States of America; *Janssen Global Services, LLC, Horsham, United States of America; 4Brigham and Women’s Hospital, Boston, United States of America

Background: Previous systemic lupus erythematosus (SLE) studies have identified potential clusters of SLE clinical manifestations. Objectives: To describe the presentation of SLE across different cohorts of patients and describe standard of care within clusters.

Methods: Cross-sectional study of 263 rheumatologists in the US and EUS. Data were collected from the Adelphi Real World 2015 Lupus Disease Specific Programme. Physicians completed patient record forms (PRFs) for the next 5 patients consulting with SLE; these patients completed patient reported outcome (PROMs) forms describing how SLE affected them. PRFs data include patient characteristics and management history. PROMs focused on similar data collection, including patient reported outcome measures on the humanistic burden. Principal-component factor analysis reduced 39 unique SLE symptoms to 8 factors. These factors were used as covariates in latent class analysis to provide discrete cohorts of patients. Chi-squared and Kruskal-Wallis tests compared patient outcomes across clusters.

Results: Data were extracted from 1376 PRFs. Factor analysis resulted in 8 clusters of concurrent symptoms: joint, haematological, constitutional/mental health, skin, circulatory, cardiovascular, renal, and musculoskeletal symptoms respectively. The four-cluster solution was selected. Cluster 1 displayed the lowest symptom burden, characterised by low skin involvement. Cluster 2 is characterised by joint and skin involvement. Cluster 3 & 4 had a high frequency of all factors, with cardiovascular involvement high in cluster 3 and renal/constitutional involvement high in cluster 4 (table 1).

Significant between-cluster differences were observed when comparing clinical and humanistic outcomes; physician/patient satisfaction were greatest in cluster 1 (physician satisfied 94.2% vs. 2: 90.8%, 3: 85.2%, 4: 74.4%, p<0.0001; patient 94.7% vs. 2: 93.9%, 3: 91.5%, 4: 79.2%, p<0.0001), whilst disease progression (deteriorating slowly 2.5% vs. 2: 12.9%, 3: 9.6%, 4: 25.5%, p=0.0001) and flaring in the last 12 months (flared 30.0% vs. 2: 54.8%, 3: 62.2%, 4: 70.8%, p<0.0001) differed significantly with worst outcomes seen in cluster 4.

Significant differences were also observed between clusters in relation to treatment proportions; anti-malarials (highest cluster 1: 70.5%), biologic DMARD (highest cluster 3: 17.5%), glucocorticoid and immunosuppressants (highest cluster 4: 85.5%, 74.5%).

Conclusion: This study adds to the evidence demonstrating the heterogeneous nature of SLE experienced within distinct patient clusters. Significant proportions of SLE patients experience high symptom burden and low levels of satisfaction. Additional analysis to understand limited biologic use in more severe patients is needed.

FRIO179 PREDICTION OF RESPONSE TO RITUXIMAB IN SLE USING A VALIDATED TWO-SCORE SYSTEM FOR INTERFERON

Adewunmi Alase1, Zoe Wigston1, Agata Burska1, Elizabeth Hensor1, M.D. Yuzualf M.D. Yusuf1, John Reynolds2, The Masterplans Consortium3, Miriam Wittmann1, Ian N. Bruce1, Edward Vital1, ’Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom; ’University of Manchester, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; ’University of Manchester, The MASTERPLANS project Team, Manchester, United Kingdom

Background: Rituximab (RTX) is used for resistant SLE but clinical response varies. We previously validated two interferon-stimulated gene expression scores (IFN-Score-A and IFN-Score-B) that improved prediction of clinical outcomes in SLE. IFN-Score-A included most commonly reported ISGs and predicted flares and glucocorticoid requirements. IFN-Score-B included ISGs that respond to multiple IFN subtypes and predicted development of SLE in At-Risk individuals. Diagnosis of SLE was associated with both scores, while only IFN-Score-B was elevated in RA. The British Society for Rheumatology Biologics Registry (BILAG-BR) collects samples for RTX-treated patients in the UK. MASTERPLANS is a consortium to identify predictors of drug response.

Objectives: To investigate whether IFN-Score-A and IFN-Score-B predict BILAG response to RTX at 6 months.

Methods: This is a preliminary analysis of the first RTX-treated patients in the BILAG-BR with complete data. Patients were recruited if they were starting within the first cycle of RTX for active SLE (BILAG A or 2xBILAG B) despite previous cyclophosphamide or mycophenolate mofetil. Disease activity was measured using BILAG-2004. Clinical response was defined as improvement by >=1 grade in active BILAG-2004 systems with no worsening in other systems. Whole blood was collected into TEMPUS tubes and RNA extracted. IFN-Scores were measured using a custom Taqman array as previously described [El Sherbiny et al., 2018]. Multivariate logistic regression was used to test IFN-Scores and baseline clinical covariates as predictors of BILAG response at 6 months.

Results: Samples were available from 147 patients, of whom 84 had complete baseline and 6 month clinical data available and were included in this analysis. 40/84 (47.6%) patients had BILAG response at 6 months. In univariate and multivariate analysis, high IFN-Score-B expression was significantly associated with clinical response (see table 1).

</tbody>
</table>
Conclusion: This preliminary analysis suggests that assessment of IFN activity has a role in predicting response to RTX. A novel IFN score (Score B) was more predictive than classic ISGs (Score A). These results add to a body of work showing that IFN-Score B predicts clinically significant outcomes independently of overall IFN activity. Future work will analyse this biomarker in a larger cohort of patients and integrate with other putative clinical and biological predictors of response.

FRI0180 OFF-LABEL USE OF RITUXIMAB IN RHEUMATIC DISEASES, A SWISS TERTIARY CENTRE EXPERIENCE
Alexandre Dumusc, Thomas Huegle, Pascal Zufferey, University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland

Background: Rituximab (RTX), a monoclonal antibody targeting CD20, is licenced for the treatment of rheumatoid arthritis (RA) for many years and more recently for ANCA-associated vasculitis. RTX is frequently used off-label to treat other auto-immune diseases (AID), especially connective tissue diseases (CTD). There are no published data about off-label use of RTX in AID in Switzerland.

Objectives: To describe off-label use of RTX in a real-life setting, when treating AID.

Methods: Retrospective cohort study of all patients treated with RTX in the Rheumatology Department between 2005 and 2017. Clinical efficacy of RTX after 12 and 24 months of treatment was evaluated with a semi-quantitative scale (no response (NR), partial (PR) and complete response (CR)); RTX discontinuation rate was also analysed using Kaplan-Meier method and log rank test to evaluate the difference between survival curves. Adverse events (AE), serious AE (SAE) were included in the safety analysis. Occurrences of hypogammaglobulinemia and anti-rituximab antibodies (ADA) were also reported.

Results: 178 patients treated with RTX could be identified: 28% for CTD, 63% for RA and 10% for other AID. Rituximab was used off-label in 73% of the patients according to official Swiss indications. No significant differences in terms of clinical response were observed in off-label indication after 12 months (NR: 15%/13%, PR:48%/52%, CR:3%/35%, n=108/31) and 24 months (NR:13%/9%, PR:3%/35%, CR:51%/57%, n=79/23) of treatment when compared with prescriptions following official Swiss indications, respectively. RTX discontinuation rate (HR 1.03 95% CI 0.71-1.49) was also similar between both groups.

Clinical response after RTX treatment did not differ significantly between patients with CTD and RA after 12 months (NR:10%/12%, PR:50%/52%, CR:40%/36%, n=4=84/24) and 24 months (NR:7%/9%, PR:32%/44%, CR:61%/47%, n=92/54, respectively). Detailed results are available in Table 1. Survival curves of rituximab treatment from CTD group closely matched that from RA group (HR 0.96 95% CI 0.65-1.44). Causes of RTX treatment discontinuation in patients with CTD (n=27) and RA (n=72) consisted of lack of efficiency (63%/56%), adverse event (19%/35%) and remission (19%/10%), respectively.

SAE (n=113) occurred in 33% of the patients and consisted mainly of infectious SAE (43%) and perfusion-related AE (6%). 6 patients died during RTX treatment. Low IgG levels were observed in 34% (50/149) of the patients graded as mild (20%), moderate (11%) or severe (3%). The nadir of IgG levels occurred after 4.5(3.5) years (mean (SD)) of RTX treatment. ADA were observed in 6/51 patients.

Disclosure of Interests: Alexandre Dumusc: None declared, Thomas Huegle Grant/research support from: AbbVie, Lilly, Novartis and Pfizer, Speakers bureau: AbbVie, Lilly, Novartis and Pfizer, Pascal Zufferey: None declared.

FRI0181 THE PLUTO STUDY: INTRAVENOUS BELIMUMAB IN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS
Nicolino Ruperto1, Carlos Abud-Mendoza1, Diego O. Viola1, Inmaculada Calvo1, Deborah M. Levy2, Julia Calderon Gallegos2, Manuel Fernandez2, Vyacheslav Chasnyk1, Vladimir Keltsev1, Jordi Anton1, Maria Gastanaga1, Michael Shishov2, Alina Boteanu1, Michael Henrickson2, David Roth3, Herbert Steunperme4, Mei-Lun Wang4, Alberto Martini3, Daniel J Lovel2, Hermine Brunner1.1Member of PRINTO, Istituto Gaslini, Genoa, Italy; 2Member of PRCSG, Cincinnati, United States of America; 3GSK, Philadelphia, United States of America; 4GSK, Stevenage, United Kingdom; 5GSK, Collegeville, United Kingdom; 6GSK, Research Triangle Park, United States of America

Background: Belimumab (BEL), a monoclonal antibody targeting the B-lymphocyte stimulator, is approved in adults with active systemic lupus erythematosus (SLE). This is the first clinical trial of belimumab in pediatric patients with childhood-onset SLE (cSLE).

Objectives: PLUTO, a Phase 2, randomised, double-blind trial (BEL114055; NCT01649765), evaluated the efficacy, safety and pharmacokinetics (PK) of intravenous (IV) BEL vs placebo (PBO), plus standard of care (SoC), in cSLE.

Methods: Patients with cSLE 5–17 years of age were randomised to BEL 10 mg/kg IV or PBO every 4 weeks, plus SoC. Primary endpoint: SRI4 at Week 52. Major secondary endpoints: PRINCIPALACR 30 and 50 cSLE evaluation criteria for improvement at Week 52; cSLE core response variables at Week 52; and sustained SRI4 and ParentGQA (patient well-being) responses (Weeks 44–52). Other endpoints: components of SRI4 at Week 52; and frequency of severe flares using the

Disclosure of Interests: Nicolino Ruperto: None declared, Carlos Abud-Mendoza: None declared, Diego O. Viola: None declared, Inmaculada Calvo: None declared, Deborah M. Levy: None declared, Julia Calderon Gallegos: None declared, Manuel Fernandez: None declared, Vyacheslav Chasnyk: None declared, Vladimir Keltsev: None declared, Jordi Anton: None declared, Maria Gastanaga: None declared, Michael Shishov: None declared, Alina Boteanu: None declared, Michael Henrickson: None declared, David Roth: None declared, Herbert Steunperme: None declared, Mei-Lun Wang: None declared, Alberto Martini: None declared, Daniel J Lovel: None declared, Hermine Brunner: None declared.
modified SELENA-SLEDAI Flare Index. Safety and PK were assessed. Analyses were performed on the intent-to-treat population. The study was not powered to test for differences between groups; p-values were not calculated.

Results: 93 patients were included (BEL, n=53; PBO, n=40). Groups (BEL vs PBO) were balanced at baseline for age (mean [standard deviation] 13.5 [2.59] vs 14.8 [2.17] years, respectively) and SELENA-SLEDAI score (10.3 [3.34] vs 10.4 [3.63], respectively). Compared with PBO, there were more SRI4 responders (including all 3 components of SRI4), and PRINTO/ACR 30 and 50 responders in the BEL group (Figure). Likewise, more BEL vs PBO recipients had sustained improvement of SRI and patient well-being (ParentGA) (Figure).

Changes in cSLE core response variables are shown in the Table. Serious harms were 62% less frequent with BEL vs PBO (hazard ratio: 0.38 [95% CI 0.18, 0.82]). PK: BEL exposures in cSLE were similar to adult SLE studies. 9/53 (17%) BEL patients had ≥1 serious adverse event vs 14/40 (35%) PBO patients. One PBO patient died of acute pancreatitis.

Conclusion: The benefit-risk profile of BEL IV plus SC in cSLE is generally consistent with BEL in adult SLE. The 10 mg/kg IV dose used in adults may be an appropriate dose in cSLE.

The concordance of the test abnormality with the retina expert opinion showed the following sensitivity and specificity, respectively: OCT 93%, 84%; ERG 100%, 51%; MP1 100%, 70%; and FAF 83%, 76%. The frequency of retinopathy increased with years of HCQ use [number of retinopathies per total patients (percent frequency)]: 5 years or less, 1/103 (0.97%); 6-10 years, 2/209 (1.83%); 11-15 years, 3/91 (3.30%); 16-20 years, 11/96 (11.46%); and 21 or more years, 6/75 (8.00%).

Conclusion: In agreement with the American Academy of Ophthalmology, OCT appears to be the optimum test for yearly monitoring (2). The frequency of retinopathy was much lower in our prospective study than estimated by the Kaiser-Permanente study. Our data also show the need for ophthalmologists with retinopathy expertise to interpret retinal testing, as screening tests are frequently abnormal due to causes other than HCQ retinopathy. Stopping HCQ based on an abnormal test without confirmation from a retinopathy expert could needlessly deprive an SLE patient of an important medication.

FRIO183

STUDY DESIGN FOR A MULTICENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY TO ASSESS THE EFFICACY AND SAFETY OF REPOSITORY CORTICOTROPIN INJECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS DESPITE MODERATE-DOSE CORTICOSTEROIDS

Anca Aaskanase, Enru Zhao, Julie Zhu, Erin Connolly-Strong, Richard Furie

Columbia University Lupus Center, New York, New York, United States of America; "Malinckrodt ARD, LLC, Bedminster Township, New Jersey, United States of America; "Zucker School of Medicine at Hofstra/Northwell, Great Neck, New York, United States of America

Background: Repository corticostropin injection (RCI) is a complex mixture containing purified porcine pituitary adrenocorticotropic hormone (ACTH)-an analogue with potential anti-inflammatory and immunomodulatory effects through the melanocortin receptors (MC1R, MC3R-MC5R) and endogenous steroid production. RCI is approved by the US FDA for the treatment of acute exacerbations (ie, disease flares) or as maintenance therapy in patients with systemic lupus erythematosus (SLE). In a pilot study, RCI was well tolerated with improvements in disease activity for lupus patients treated with RCI compared to those who received placebo (Furie et al, 2016).

Objectives: To discuss the design, demographics, and baseline characteristics of a clinical trial evaluating the role of RCI in the treatment of patients with inadequately controlled SLE disease activity.

Methods: This is a multicenter, double-blind, randomized, placebo-controlled, 24-week clinical trial aiming to determine the effect of RCI in reducing disease activity for patients with persistently active SLE despite moderate-dose corticosteroids (CSs). Patients are required to have SLE (>4 of 11 ACR criteria from 1997) and active disease (moderate to severe rash and/or arthritis) despite stable dose CSs > 4 weeks prior to screening (7.5 - 30 mg/day of prednisone or equivalent). Patients are treated with RCI 1 mL (80 U) subcutaneously (SC) or placebo 1 mL, every other day for 4 weeks followed by twice per week for 20 weeks. Randomization is stratified by study site location and prednisone or equivalent dose (<20 and > 20 mg/day). Patients remain on stable doses of CSs through Week 16, with tapering encouraged between Weeks 16 and 24. Efficacy is evaluated using the SLE Responder Index-4 (SRI-4) and changes from baseline in SLE Disease Activity Index-2000 (SLEDAI-2K), British Isles Lupus Assessment Group-2004 (BILAG-2004) scores, and Physician’s Global Assessment (PGA). The primary efficacy endpoint is the proportion of SRI-4 responders at Week 16. Secondary and exploratory endpoints include changes in disease activity scores over time, prednisone dose, and biomarkers (ie, complements, autoantibodies, inflammatory, bone turnover).

Results: As of 14 December 2018, 124 patients comprised the intent-to-treat (ITT) population. Target enrollment is 270 patients, of which 162 patients are expected to be randomized at approximately 60 sites globally. Demographic and baseline characteristics (Table 1) were collected, including circulating lymphocyte profiles (CD19+ B Cells, CD3+ total T cells, and CD4 Treg cells), which are consistent with the pilot study of RCI (Furie et al, 2016).

Conclusion: This on-going study assesses the efficacy and safety of RCI for the treatment of refractory SLE in a racially and ethnically diverse population. The rapid onset of action of RCI allows for a 16-week primary endpoint. Patients enrolled in this trial have moderate or high disease activity (as shown by the mean SLEDAI-2K, BILAG, and PGA) and are likely to provide valuable data on the role of RCI in refractory lupus. Bone turnover markers will further define the safety profile of RCI in lupus.

**SAFETY AND EFFICACY OF SPLENECTOMY IN THE TREATMENT OF ANTIPHOSPHOLIPID SYNDROME-ASSOCIATED CYTOPENIAS**

Ana Barrera-Vargas1, Juan Rangel Patiño2, Samuel Govea-Peláez1, Javier Merayo-Chalico1, Roberta Demicheli-Gómez2, Jorge Alocer-Varela1.

1Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Immunology and Rheumatology, Mexico City, Mexico; 2Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Hematology and Oncology, Mexico City, Mexico.

**Background:** Thrombocytopenia and autoimmune hemolytic anemia (AIHA) are common hematologic manifestations in primary antiphospholipid syndrome (APS). Although splenectomy is considered a second-line treatment in both primary immune thrombocytopenia (ITP) and idiopathic AIHA, its role in APS patients with either one of these manifestations has not been adequately defined, mainly because of the theoretically increased risk of thrombosis for patients with APS who undergo surgery.

**Objectives:** To determine the safety and efficacy of splenectomy for steroid-refractory thrombocytopenia or autoimmune hemolytic anemia in patients with primary APS, when compared to patients with ITP or idiopathic AIHA.

**Methods:** We performed a retrospective, single-center, case-control study. We included patients with primary APS and either thrombocytopenia, or autoimmune hemolytic anemia/Evans syndrome who underwent splenectomy between 2000 and 2018. The control group was made up by patients with primary immune cytopenias (ITP or AIHA) who also underwent splenectomy during that period. Cases and controls were adjusted by age, the hematologic manifestation and date of splenectomy. We recorded demographic, clinical and serologic characteristics at the time of surgery and during follow-up.

**Results:** We included 34 patients in each group. Thrombocytopenia was the indication for splenectomy in 53% of patients, with AIHA or Evans syndrome comprising the remaining 47%. Most patients were female (78%) and median age was 37 years. Among APS patients, 41% had triple antibody positivity. There were no differences regarding comorbidities between groups. Patients with APS received more immunosuppressive treatment lines before splenectomy compared to controls (p=0.02), and there was a trend for more high-dose steroid cycles in the APS group (p=0.07). Median time to splenectomy was 54 months in APS patients and 18 months in controls, but without statistical significance. Regarding splenectomy, most were laparoscopic (88%) and surgical complications were similar between groups (18%). However, patients with APS had a higher incidence of global non-surgical complications in the first month (59 vs 23%, p=0.04), most of them being infections (21 vs 3%, p=0.05). There was no difference in the incidence of postsurgical thrombosis, venous or arterial, between groups.

Most patients achieved a global response after one month (65% in APS group, 91% in controls, p=0.7). Complete response was observed in 65% and 79% of cases and controls, respectively (p=0.27). Median follow-up time was 52 months for APS patients and 41 months for controls. There were no differences regarding relapse which required any treatment adjustment between cases and controls (44% and 38%, respectively, p=0.8, Fig 1). However, 47% of APS patients received a prolonged maintenance immunosuppressive treatment, compared with 6% of controls (p=0.01). The incidence of infections and thrombosis during follow-up was similar between groups (p=0.15 and p=0.7, respectively; Fig 2).

**Conclusion:** Splenectomy is associated with adequate and long-lasting responses in APS patients with cytopenias, which do not differ from patients with non-APS-associated thrombocytopenia and AIHA. Thrombosis was not a common complication in our patients; however, there was a higher incidence of infections in APS patients. This could be related to the higher steroid doses and more intensive previous immunosuppressive therapies. Splenectomy could be considered an earlier treatment option for APS patients with refractory cytopenias, and this could reduce infection risk and post-surgical morbidity.

Durand, Buenos Aires, Argentina; 9Hospital Carlos G. Durand, Buenos Aires, Buenos Aires, Argentina, 10Bezhanijska Kosa, University Medical Center, Belgrade University, Serbia, Belgrade, Serbia, 11I.M. Sechenov First Moscow State Medical University, Moscow, Moscow, Russian Federation, 12UMC UTRECHT, UTRECHT, Netherlands; 13Rheumatology and Clinical Immunology Unit, University of Brescia, Brescia, Italy, Brescia, Italy; 14University of Milan, Milan, Italy; 15Hacettepe University, Ankara, Ankara, Turkey, 16APHP Saint Antoine, PAris, France, 17Hospital San Raaftele, Milan, Italy; 18Ghent University Hospital, Ghent, Belgium; 19Sao Joao Hospital, Porto, Alameda, Porto, Portugal; 20Emergency Clinical County, Cluj, Romania; 21University Hospital La Rabta, TUNIS, Tunisia, 22The Zakim-Batron Center for Autoimmune Diseases, affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Israel, Tel Aviv, Israel; 23University of Barcelona, Barcelona, Spain; 24Istituto Auxologico Italiano, Milan, Italy; 25APHP, PAris, France

**Background:** The relapse rate in antiphospholipid syndrome (APS) remains high, 20% at 5 years in thrombotic APS and 28% in obstetrical APS (1). Hydroxychloroquine (HCQ) appears as an additional therapy, with immunomodulatory and anti-inflammatory effects (2-5).

**Objectives:** The main aim of this trial is to assess the efficacy of treatment with Hydroxychloroquine in preventing new events in primary antiphospholipid syndrome patients.

**Methods:** We have performed a retrospective multicentre open-labelled study (2002-2018).

**Results:** 812 patients with APS from 53 international centres from 16 countries were included. In all cases, the previous standard treatment was inefficient. The mean follow-up was 20.2 months (8-144 mo), the mean age 39.5 years old. The type of clinical manifestations is described in figure 1.
The obstetrical manifestations were various as described in figure 2. The number of thrombotic events were 190 arterial and 187 venous. Triple antiphospholipid antibody (IaPL) positivity was found in 20% of patients and lupus anticoagulant (LA) in 22%. No bleeding was registered in 99.6% of cases with treatment by HCQ. HCQ use was associated with favourable outcome in 96% of cases (figure 3).

In multivariate analysis, age more than 65 years was associated with thromboembolic events (odds-ratio 0.13 95%CI 0.03-0.32, p 0.005).

Conclusion: HCQ could be effective in cases of refractory APS but prospective studies are necessary.

FRIO168 HYDROXYCHLOROQUINE ON THE TOP OF STANDARD TREATMENT WITH LOW DOSE ASPIRIN AND LOW MOLECULAR WEIGHT HEPARIN SIGNIFICANTLY REDUCES THE PROBABILITY OF PREGNANCY MORBIDITY IN WOMEN WITH MULTIPLE POSITIVITY FOR ANTI-PHOSPHOLIPID ANTIBODIES

Cecilia Chighizola1, Francesca Pregnolato1, Francesca Bartoli2,3, Maria Gerosa2,3, Chiara Corneto1,2, Maria Gabriella Raimondi1,2, Laura Trespidi1,2, Maria Orietta Borghi1,2, Mariella Wally Ossola1, Enrico Ferrazzi2,4, Pier Luigi Meroni1.

1Istituto Auxologico Italiano, Milan, Italy; 2University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 3ASST Gaetano Pini, Rheumatology, Milan, Italy; 4Fondazione Ca Granda, Ospedale Maggiore Policlinico, Department of Obstetrics and Gynaecology, Milan, Italy.

Background: Hydroxychloroquine is an anti-malarial drug that not only exerts immunomodulatory and anti-thrombotic properties, but also has been shown to reverse several effects mediated by anti-phospholipid anti- bodies (aPL) in models of obstetric anti-phospholipid syndrome (APS). Not surprisingly, HCQ, whose prescription during gestation is perfectly safe, has been proposed as an additional therapeutic tool in obstetric APS, but evidence of its efficacy is still scant.

Objectives: This study investigates how treatment with HCQ, prescribed in different combinations with low-dose aspirin (LDSA) and low-molecular weight heparin (LMWH), affects the probability of pregnancy morbidity (PPM).

Methods: Data on pregnancies in women with persistent aPL positivity at any titre, with or without autoimmune diseases, were retrospectively collected at a single centre.

A weighted generalized estimated equation (GEE) model was applied to quantify the effect of treatment with HCQ on PPM, allowing to: i) evaluate pregnancy outcomes over time using available longitudinal data; ii) account that pregnancies of the same woman are not independent events; iii) consider that women had a different number of pregnancies; iv) estimate the role of several confounders and predictors.

The model envisaged as dependent variable pregnancy outcome as a binary outcome, defined for each pregnancy as “obstetric complication yes versus no” (pregnancy loss before 10 weeks, pregnancy loss after 10 weeks, premature birth before 34 weeks, according to updated APS classification criteria).

Results: Three-hundred-eighty-one women were recruited in this study: 155 women with aPL positivity (100 women with positivity for criteria aPL and 55 women with low-titer aPL) and 226 women with autoimmune diseases but negative aPL. Data were collected on 847 pregnancies: 458 in women with positive aPL (172 in women with criteria aPL and 286 in women with low-titer aPL) and 389 in women with autoimmune disease and negative aPL.

PPM in untreated patients are presented in Table 1. Table 2 reports PPM in women receiving LDASA +/- HCQ, LDASA + LMWH +/- HCQ.

Conclusion: HCQ, when added to LDASA or on the top of standard treatment with LDASA and LMWH, allows to reduce PPM. Most importantly, HCQ plus the combo LMWH + LDASA leads to a significantly

Involvement: The obstetrical manifestations were various as described in figure 2. The number of thrombotic events were 190 arterial and 187 venous. Tri- plet antiphospholipid antibody (IaPL) positivity was found in 20% of patients and lupus anticoagulant (LA) in 22%. No bleeding was registered in 99.6% of cases with treatment by HCQ. HCQ use was associated with favourable outcome in 96% of cases (figure 3).

In multivariate analysis, age more than 65 years was associated with arterial events (odds-ratio 0.13 95%CI 0.03-0.32, p 0.005).

Conclusion: HCQ could be effective in cases of refractory APS but prospective studies are necessary.

PRELIMINARY EXPLORATION OF NEW METHODS TREAT TO PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: REGULATING TH17/TREG CELL BALANCE BY RAPAMICIN AND ALL-TRANS RETINOIC ACID

Yanfang Chu, Chunniao Zhao, Bingying Zhang, Xuxia Wang, Yiqi Wang, Junwei Chen, Li Xiaofeng, Yanfang Chu, Chunmiao Zhao, Bingying Zhang, Xuxia Wang, Yiqi Wang, Jia An, Junwei Chen, Li Xiaofeng, the Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Helper T cells 17 (Th17) and regulatory T cells (Treg) are two important immunoregulatory cells that act in opposite directions. Previous study has shown that Th17/Treg cell balance is one of the important pathogenesis of systemic lupus erythematosus (SLE). Further researches believed that rapamycin (RAPA) alone or in combination with all-trans retinoic acid (ATRA) can regulate Th17/Treg cell balance, and then alleviate the condition of SLE.

Objectives: To investigate effect of the use of RAPA alone or combined ATRA on Th17/Treg cell balance in patients with SLE.

Methods: Seventy patients with SLE (64 females and 6 males, mean age 31.9±10.12 years, mean duration 61.1±53.64 months) in our hospital from March 2016 to June 2018 were enrolled. All of them were in line with the standard of ACR in 1997. The patients were randomly divided into RAPA group (RAPA 0.5 mg/time, twice a week) and RAPA+ATRA group (RAPA and ATRA 10 mg/time, twice a week), 35 cases in each group. All were treated continuously for 24 weeks. The number of Th17 and Treg cells in peripheral blood before treatment and 6,12,24 weeks after treatment were measured. The SLEDAI scores and glucocorticoid dosage before and after the treatment were also observed to evaluate the differences of efficacy between the two groups.

Results: At different time in each group, the number of peripheral blood Th17 cells in SLE patients was decreased (P<0.05), the ratio of Th17/Treg cells induced (P<0.05), indicating a restored balance of them. The SLEDAI scores and the dosage of glucocorticoid were decreased significantly (P=0.001). There were no significant differences in the number of Th17 cells, Treg cells, SLEDAI scores and the dosage of glucocorticoid between two groups (P>0.05). Compared with pretreatment, the number of Th17 cells, the ratio of Th17/Treg cells and SLEDAI scores after 24 weeks treatment in SLE patients was decreased in RAPA group (P<0.05). Compared with pretreatment, the SLEDAI scores and the dosage of glucocorticoid after 24 weeks treatment in SLE patients was significantly reduced in RAPA+ATRA group (P<0.001).

Conclusion: Using RAPA or combined with ATRA could improve the condition of SLE patients by regulating Th17/Treg cells balance and reduce glucocorticoid dosage, which provided new directions for the pathogenesis and treatment of SLE.

**FRIO188 EARLY RENAL IMPROVEMENTS FOLLOWING RITUXIMAB IN LUPUS NEPHRITIS**

Sofie Collinson, Ben Parker, Eoghan McCarthy, Ian N. Bruce, British Isles Lupus Assessment Group Biologies Register. Kellogg Centre for Rheumatology, NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom

**Background:** Rituximab (RTX) is the monoclonal antibody of choice in patients with lupus nephritis (LN) who either fail to respond to, or cannot receive standard care (SOC) therapy. Despite its continued use in clinical practice, published clinical trials regarding its use in LN management have failed to show any clear benefit.

**Objectives:** We aimed to analyse renal outcomes of LN patients in a large national register.

**Methods:** Patients with active LN on recruitment into the BILOG-Biologies Register (BILOG-BR) were included. Active LN was defined as a BILOG A or B score in the renal domain. Patients are eligible for RTX if they have failed either MMF or cyclophosphamide. We defined renal response at 6 and 12 months as a change in BILOG score from A to B/C/D or B to C/D. Non-renal disease activity was also described.

**Results:** Overall 259/807 patients in BILOG-BR had active LN at baseline. Of these, 230 received RTX and 29 received SOC. 109/159 (68.6%) RTX patients and 15/19 (78.9%) of SOC patients had a renal BILOG response at 6 months (p=0.792) (Table 1). In those with sufficient response data at 12 months, 31/98 (31.6%) and 7/15 (46.7%) (p=0.084) demonstrated continued renal response in the RTX and SOC groups respectively. Both groups made improvements or remained stable in all other renal domains (UPCR, eGFR, creatinine) at 6 and 12 months. Oral steroid doses decreased in both treatment groups. Of note, baseline steroid doses in the SOC group were higher than RTX patients (30mg (20-40) vs. 12.5mg (10-25), p<0.001).

**Non-renal disease activity measures improved in both cohorts.**

</tbody>
</table>

**Conclusion:** In a large UK-wide, real-world, observational LN cohort we have shown that RTX does improve renal outcomes at 6 and 12 months in refractory SLE patients. RTX is a valid treatment option for many patients with renal disease in SLE.

**FRIO189 POOLED ANALYSIS OF THE REAL-WORLD EFFECTIVENESS OF BELIMUMAB IN TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS USING MULTI-COUNTRY DATA FROM THE OBSERVE STUDIES**

Christopher Collins1, Josefina Cortés-Hernández2, Mercedes García3, Johannes van Kempen2, Andreas Schwarting4, Zahi Touma5, Shannon Ferrant6, Milena Kurticzc7, Kenriv Rainy8, Washington Hospital Center, Washington, United States of America; 9 Va’id Hebron Hospital, Barcelona, Spain; 3 HGA San Martin La Plata, La Plata, Argentina; 5 Kantonsspital St. Gallen, St Gallen, Switzerland; 1 Johannes Gutenberg-University, Mainz, Germany; 4 Toronto Western Hospital, University of Toronto Lupus Clinic, Toronto, Canada; 5 GSK, Collegeville, United States of America; 6 GSK, Brentford, United Kingdom

**Background:** Real-world evidence of belimumab effectiveness in patients with systemic lupus erythematosus (SLE) has been reported separately for several countries through the OBSERVE (evaluation Of use of Belimumab in clinical practice SEttings) programme.

**Objectives:** To evaluate the effectiveness of belimumab in patients with SLE using pooled data from the individual OBSERVE studies.

**Methods:** This was a post hoc meta-analysis (GSK study 206351) of patients who entered data from six retrospective observational cohort studies (Argentina, Canada, Germany, Spain, Switzerland, United States of America). Physicians provided data for adults (>18 years; clinical diagnosis of SLE) who had initiated intravenous belimumab as part of their usual SLE care ≥6 months prior to enrolment and for whom reasons for belimumab initiation could be identified. Primary objective: physician-assessed overall clinical response to belimumab at Month 6, which reflected physicians’ impression of change in overall clinical manifestations, categorised as worse, no improvement, and improvement of ≤20%, 20–49%, 50–79%, and ≥80%. Secondary objectives included a description of patient characteristics at belimumab initiation (index); treatment patterns during the 6 months after index; and patient and treatment characteristics associated with an overall clinical response. Safety was not assessed.

**Results:** Data were pooled from all 830 patients (89.3% female; mean [standard deviation] age 41.9 [12.6] years) included in each of the OBSERVE studies. At index, most patients had moderate SLE (71.4%; physician-assessed) and serological indicators of high disease activity (82.8%; high anti-dsDNA and/or low complement). Of 345 patients for whom Safety of Estrogens in Lupus Erythematosus-National Assessment Trial-SLE Disease Activity Index baseline data were available, 60.0% had a score >10. At index, 72.0% of patients had musculoskeletal, 59.0% had mucocutaneous manifestations, and 16.5% had renal involvement. At Month 6, 82.8% of patients had ≤20% improvement and 48.1% had >50% improvement in their overall condition; only 4.7% had none or a worse response to belimumab therapy (Figure). In total, 81.4% of patients received steroids at a mean dose of 17.6 mg/day. At Month 6, the mean change in steroid dose was −9.7 mg/day. Of those receiving a dose >7.5 mg/day (78.4% of all patients receiving steroids at index), 54.5% had a dose reduction to ≤7.5 mg/day at Month 6. Effective previous treatment was the main reason for belimumab initiation (74.3%). Prior to Month 6, 4.4% of patients (n=12270) in Argentina, Spain, Germany and Switzerland discontinued belimumab, most frequently due to lack of efficacy and patient request (both 33.3%); OBSErve US and Canada excluded patients with <6 months’ belimumab treatment.

**Conclusion:** This study provides important insights into global real-world outcomes in a large number of patients with SLE treated with belimumab. After 6 months of treatment, most patients demonstrated clinical improvements in SLE; results were consistent across the pooled population and for patients with high disease activity. Belimumab was steroid sparing; most patients receiving steroids at belimumab initiation decreased their steroid dose after 6 months of belimumab treatment.

INCIDENCE OF ANTIMALARIALS-INDUCED RETINOPATHY IN INFLAMMATORY RHEUMATIC DISEASES, USING OCT AND VISUAL FIELD TEST: A SYSTEMATIC REVIEW AND META-ANALYSIS

CAGNY Hélène DE1, Jacques Morel1,2, Bernard Combe1,2, Cécile Gaujoux-Viala3,4, Cédric Lukas1,2, 1University of Montpellier, Montpellier, France; 2University hospital, Rheumatology, Montpellier, France; 3University of Nîmes, Nîmes, France; 4University hospital, Rheumatology, Nîmes, France

Background: Antimalarials (AM) are frequently used as first-line therapy in mild inflammatory diseases, because of a good benefit/risk ratio. Recently, their benefit on long term cardiovascular risk in RA patients has been demonstrated [1, 2]. Their most severe side effect is retinopathy, which can potentially lead to blindness, but remains reversible if detected early, provided the treatment is stopped. This complication has been described early [3], but its incidence remains uncertain. A recent update of the American Association of Ophthalmology (AAO) recommendations on screening for chloroquine and hydroxychloroquine retinopathy, suggests to screen patients under AM treatment, with a frequency depending on risk factors, and with the systematic and minimal use of Optical Coherence Tomography (OCT) and Visual Field (VF) test, completed by others tests if required [4].

Objectives: We aimed at estimating the exact incidence of AM-induced retinopathy, based on available published literature about this issue, with particular reference to detection performed with OCT and VF test.

Methods: A systematic literature search was conducted in Pubmed, Cochrane and Embase databases until April 6th 2018, completed by a manual search in references from the resulting selected articles. We first selected all publications about the incidence of AM-associated retinopathy in patients treated for inflammatory diseases and included them in the systematic literature search. Among them, and in order to minimize heterogeneity of results, we focused on those which had used at least OCT and VF test, as recommended by the AAO, to perform a meta-analysis. Analysis was conducted using MetaXL for Microsoft Excel, applying the Inverse of Variance method.

Results: Among the 3890 articles of potential interest, we selected 91 articles appropriately addressing the topic and included them in the systematic literature search. They were published between 1964 and 2018, with variable population sizes (10 to 3580 patients). Patients were treated with hydroxychloroquine, chloroquine or both for an inflammatory disease (usually lupus or rheumatoid arthritis). Mean treatment duration ranged from 1 to 14.1 years. Most of them were retrospectively designed, and diagnostic methods were diverse. For the aforementioned meta-analysis, we used data from 16 articles published between 2010 and 2018, in which every patient had at least OCT and VF Test. We found a pooled estimate of incidence of 6.05% (IC 95% [5.18 – 7.31]), with a I2 heterogeneity coefficient of 80%.

Conclusion: We found a pooled incidence of approximately 6% of AM-induced retinopathy when OCT and VF test are used. However diagnostic criteria are not consensually well-defined, leading to heterogeneous data.

FRID1019

TREATMENT OF REFRACTORY POOR APL-RELATED OBSTETRIC OUTCOMES WITH TNF-ALPHA BLOCKERS: MATERNAL-FETAL OUTCOMES IN A SERIES OF 18 CASES

Jaume Alipats-Reig1, Enriquè Estève-Valverdes2, Elisa Llurba3, Josep Mª Gris4, 1Systemic Autoimmune Diseases Unit, Department of Internal Medicine, Vall d’Hebron University Hospital, Barcelona, Professor of Medicine. Department of Medicine. Faculty of Medicine. Universitat Autonoma de Barcelona., Barcelona, Spain; 2Staff. Department of Internal Medicine. Althaia Network Health. Manresa, Barcelona, Spain; 3. Head. Obstetric and Ginecology Department. Sant Pau University Hospital. Universitat Autonoma de Barcelona., Barcelona, Spain; 4. Staff. Reproductive Medicine Unit. Obstetric Department. Vall d’Hebron University Hospital. Universitat Autonoma de Barcelona, Barcelona, Spain

Background: No absolute data on the treatment of antiphospholipid antibodies (aPL) related to refractory obstetric complications exist to date. TNF-α play a major role in this disorder.

Objectives: To assess the effectiveness of TNF-α blockers in 18 aPL-positive women with recurrent infertility after therapy with low-molecular-weight heparin (LMWH) plus aspirin (LDA) plus hydroxychloroquine (HCQ).

Methods: Prospective case-series of 12 women fulfilling Sydney criteria for obstetric antiphospholipid syndrome (OAPS) and 6 with incomplete forms (OMAPS). All women tested positive for aPL at least twice. Non-criteria aPL were tested in 15/18. Complement, TNF-α and IL-10 were also evaluated. Women were closely monitored for fetal well-being and possible malformations throughout gestation and the postpartum period.

Results: Sixteen patients were started on adalimumab and 2 on certolizumab. Twelve women completed gestation: 9 at term and 3 pre-term. Differences in laboratory categories and outcomes were observed when OAPS and OMAPS were compared. First trimester miscarriage or implantation failure recurred in 6 cases, all of the OAPS group. Malformations were not seen in the newborns.

Conclusion: Overall, good obstetric results were obtained in 70% of previous LMWH-LDA+HCQ refractory cases. TNF-α blockers were well tolerated without adverse effects. The combination of LMWH plus LDA plus TNF-α blockers appears to be a promising treatment for refractory obstetric complaints related to aPL; nevertheless, outcome differences between OAPS and OMAPS do exist.
A SYSTEMATIC LITERATURE REVIEW TO INFORM THE 2019 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS

Antonis Fanouriakis1, Myro Kostopoulou2, Alessia Alunno3, Martin Aringer4, Ingeborg Bajema5, John N. Boileau6, Riccardo Cervera7, Andrea Dorà8, Caroline Gordon9, Marcello Govoni10, Frederic Housiaux11, David Jayne12, Mario Koutsoukas13, Myrto Kostopoulou14, Ingeborg Troldborg15, Ronald van Vollenhoven16, Jörg Wenzel17, George Bertsias18

Objectives: Systematic review of the literature (SLR) to inform the 2019 update of the 2008 EULAR recommendations for the treatment of SLE.

Methods: SLR of PubMed from 2010 to 2017 for questions (selected through Delphi exercise) regarding: i) efficacy/safety of different drugs used in SLE, ii) treatment of specific manifestations, iii) monitoring and treatment goals and iv) comorbidities and adjunct therapy. Evidence was categorized based on design and validity of available studies [Oxford Centre for Evidence-Based Medicine 2011 Levels of Evidence (LoE) and strength of statements was graded [Grading of recommendation (GoR)] assessment, development and evaluations, GRADE)].

Results: Main topics supported by strong evidence base included: Association of hydroxychloroquine (HCQ) use with favourable outcomes (LoE 1b, GoR A), belimumab for extrarenal disease (LoE 1a, GoR A), efficacy of antimalarials in skin disease (LoE 1a, GoR A), mycophenolate mofetil (MMF) for induction and maintenance therapy of lupus nephritis (LN) and cyclophosphamide (CYC) in severe LN (LoE 1b, GoR A). Weak evidence supported the value of repeat kidney biopsies in refractory LN (LoE 4, GoR C), all second-line agents for skin disease (LoE 4, GoR C) and efficacy of most first and second-line treatments for thrombocytopenia (LoE 4, GoR C). Moderate LoE was found for all other questions (Table).

Conclusion: A SLR for the treatment of SLE found the highest LoE for benefits of HCQ, efficacy of belimumab for extrarenal disease and MMF and IV-CYC in LN.

Disclosure of Interests: None declared

Background: Recommendations for the treatment of systemic lupus erythematosus (SLE) were published by EULAR in 2008. Advances in treatment strategies and goals called for an update of these recommendations, capitalizing on strengths and experience from previous projects.

Objectives: To update the EULAR recommendations for the management of SLE.

Methods: Systematic literature review (01/2007-12/2017) followed by Delphi method to form questions, elicit expert opinions and reach consensus.

Results: Treatment in SLE aims at remission or low disease activity and renal disease (including the use of calcineurin inhibitors). SLE patients should be assessed for their antiphospholipid antibody status, infectious and cardiovascular diseases risk profile, and preventative strategies be tailored accordingly.

Conclusion: Updated EULAR recommendations provide physicians and patients with updated consensus guidance on the management of SLE, combining evidence-base and expert-opinion.
INTEGRATED SAFETY PROFILE OF ATACICEPT FROM ALL CLINICAL STUDIES TO DATE

Caroline Gordon1, Roberto Bassi2, Peter Chang3, Amy Kao4, David Jayne5, David Wolfe5, Victor Ora6, Patricia Fleurancau-More7,1, University of Birmingham, Birmingham, United Kingdom; GEM Serono Research and Development Institute, Inc., Billerica, United States of America; 7University of Cambridge, Cambridge, United Kingdom; 8University of California, San Francisco, United States of America

Background: We conducted an integrated analysis of pooled safety data from all 17 atacicept clinical studies across multiple indications to date.

Objectives: To characterize the overall safety profile of atacicept.

Methods: Analyses were based on 3 pooled datasets: double-blind placebo (PBO)-controlled set (DBPC-S) (n=1568; key endpoint: treatment-emergent AEs [TEAEs]); systemic lupus erythematosus set (SLE-S; n=761; key endpoints: IgG change and serious infection rates, and mortality); and full analysis set (FA-S; n=1845; key endpoint: exposure-adjusted mortality).

Results: Of 1568 patients (DBPC-S), 30.8% received PBO, and 8.2%, 24.5% and 36.5% received atacicept 25, 75 and 150 mg, overall. Baseline characteristics were balanced across treatment arms. Treatment exposure in patient-years (py) was similar for PBO and atacicept 75 and 150 mg but was lower with 25 mg (Table). Exposure-adjusted TEAE rates were generally higher with atacicept vs PBO; serious TEAE and infection rates were similar with atacicept and PBO (Table). TEAE-related discontinuation rates were higher with atacicept vs PBO (16.1 vs 10.9/100 py). Exposure-adjusted mortality rate (95% CI) was 0.30 (0.19–0.41) for atacicept 75, 150 mg and 0.44 (0.36–0.52) for PBO. In SLE patients, exposure-adjusted mortality rate/100 py were 1.45 (0.54–3.87) with atacicept 150 mg and 0.78 (0.29–2.07) across all atacicept-treated patients. The underlying disease and other causes were potential confounders in most cases.

Conclusion: In this integrated safety analysis of atacicept, no consistent association was found between atacicept dose and specific TEAEs or mortality. These results support further development and evaluation of atacicept in patients in whom potential benefits may outweigh risks.

Table: Exposure-adjusted TEAE rates by dose (DBPC-S)

EFICAC Y AND SAF ETY OF DAPR OZUMAB PEG O L (DZP) IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A RANDOMISED, PLACEBO (PBO)-CONTROLLED STUDY

Richard Furie1, Ian N. Bruce1, Thomas Dömer3, Manuel Gustavo León3, Piotr Leszczynski2, Murray B. Urowitz1, Birgit Hauer2, Teri Jimenez3, Catherine Babrey1, Jaiun Lu1, Christian Stach1, Northwell Health, Great Neck, United States of America; 2University of Manchester, Manchester, United Kingdom; 3Charité Berlin, Berlin, Germany; 4Investigaciones Clínicas, Lima, Peru; 5Poznan University of Medical Sciences, Poznan, Poland; 6Toronto Western Hospital, Toronto, Canada; 7UCB Pharma, Monheim, Germany; 8UCB Pharma, Raleigh, Unites states of America; 9Biogen, Baar, Switzerland; 10Biogen, Cambridge, United States of America

Background: CD40 ligand (CD40L) regulates interactions between T cells and CD40-expressing cells including antigen-presenting cells (APC) and B cells, thereby playing a critical role in autoimmune disease pathogenesis. DZP, a PEGylated monovalent Fab’ antibody fragment with specificity for CD40L, prevents CD40L engagement of CD40 and thus blocks intracellular signalling and APC activation.

Objectives: To report the 24-week efficacy and safety interim data of DZP in a phase IIb, randomised, double-blind, PBO-controlled, dose-ranging study in patients with SLE [NCT02804763].

Methods: Patients with moderately to severely active SLE (SLEDAI-2K score >6; ≥2 BILAG grade A or ≥2 BILAG grade B organ domain scores at screening) despite stable non-biologic standard of care treatment were randomised 1:1:1:1 to receive iv DZP 6, 24 or 45 mg/kg or PBO every 4 weeks for 20 weeks. Patients receiving corticosteroids (CS) ≤10mg/day prednisone equivalent were required to start tapering CS by Week 4; guidance was provided, but tapering schedules were ultimately determined by the investigators.

The primary objective was to establish a dose-response relationship across three doses of DZP and PBO based on BICLA response rates at Week 24. Four pre-specified dose-response models were tested by a statistical method (MCP-Mod), to determine whether any of the models fit the observed data with statistical significance (at a one-sided p<0.05). The secondary endpoint was a pairwise comparison of BICLA response rates at Week 24. Other endpoints included the SRI-4 and BICLA response rates at 12 and 24 weeks, mean changes from baseline in SLEDAI-2K scores at 12 and 24 weeks, percentage of patients with daily CS dose ≤7.5 mg/day at 12 and 24 weeks, pharmacodynamic (PD) markers and safety.

Results: 182 patients were randomised; 167 (91.8%) completed Week 24 of the study. Baseline demographics were similar across treatment groups. The primary endpoint was not met as none of the pre-specified dose-response models fit the observed BICLA response rates at Week 24 with statistical significance (p<0.06 for the most applicable model). BICLA response rates and other efficacy outcome measures at Weeks 12 and 24 were numerically higher for all DZP groups vs PBO (Table 1). Favourable biological effects were observed with improvements in relevant PD markers, including anti-dsDNA antibody levels, in DZP groups vs PBO. Treatment-emergent adverse events (TEAEs) and serious TEAEs were generally balanced across treatment groups (Table 2). More upper
respiratory tract infections were observed in patients treated with DZP vs PBO; the majority were mild. We observed four thromboembolic events: one in the 24 mg/kg DZP group and three in the PBO group.

Conclusion: DZP appeared to be well tolerated as TEAEs were generally balanced across the treatment groups. Numerically greater improvements relative to PBO were observed consistently across multiple efficacy endpoints and biomarkers; however, for the primary endpoint no pre-specified dose-response relationship model fit the observed BICLA response rates at Week 24 with statistical significance. The potential for deriving clinical meaningful outcomes and benefit from DZP in patients with SLE warrants further investigation.

DZP appeared to be well tolerated as TEAEs were generally consistent across the treatment groups. Respiratory tract infections were observed in patients treated with DZP vs PBO; the majority were mild. We observed four thromboembolic events: one in the 24 mg/kg DZP group and three in the PBO group.

Methods: This open-label multicenter dose escalation trial enrolled SLE pts (per Systemic Lupus International Collaborating Clinics Classification Criteria) with SLE Disease Activity Index (SLEDAI) ≥4 despite stable background immunosuppressant, antimalarial, and/or corticosteroid (≥20 mg prednisone equivalent) therapy. Patients received KZR-616 at 45 mg (Cohort 1) or 60 mg (Cohort 2) SC OW through Week 13 (W13) with 12 weeks of follow up. Cohort 2 is currently enrolling pts using intrapatient dose escalation from 30 to 60 mg. Safety data include AEs, vitals, electrocardiograms and laboratory tests. Efficacy measures include the SLEDAI, Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), 28 tender (T) and swollen (S) joint counts (JC), Physician Global Assessment (PhGA), and Patient Global Assessment (PtGA) in evaluable pts (receive ≥1 month of KZR-616; non-evaluable pts can be replaced).

Results: We enrolled 13 pts: 8 in Cohort 1, 5 in Cohort 2. The pts were 100% female; Baseline (BL) median SLEDAI was 10.0. All pts received at least 1 dose of KZR-616. In each cohort, 3 pts withdrew due to withdrawal of consent prior to W13. Overall, the 45 mg dose was well tolerated with no SAEs; all AEs were mild in intensity. The most common AEs were injection site erythema (62.5%), nausea (25%), and respiratory tract infections were observed in patients treated with DZP vs PBO; the majority were mild. We observed four thromboembolic events: one in the 24 mg/kg DZP group and three in the PBO group.

Conclusion: DZP appeared to be well tolerated as TEAEs were generally consistent across the treatment groups. Respiratory tract infections were observed in patients treated with DZP vs PBO; the majority were mild. We observed four thromboembolic events: one in the 24 mg/kg DZP group and three in the PBO group.

Methods: This open-label multicenter dose escalation trial enrolled SLE pts (per Systemic Lupus International Collaborating Clinics Classification Criteria) with SLE Disease Activity Index (SLEDAI) ≥4 despite stable background immunosuppressant, antimalarial, and/or corticosteroid (≥20 mg prednisone equivalent) therapy. Patients received KZR-616 at 45 mg (Cohort 1) or 60 mg (Cohort 2) SC OW through Week 13 (W13) with 12 weeks of follow up. Cohort 2 is currently enrolling pts using intrapatient dose escalation from 30 to 60 mg. Safety data include AEs, vitals, electrocardiograms and laboratory tests. Efficacy measures include the SLEDAI, Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), 28 tender (T) and swollen (S) joint counts (JC), Physician Global Assessment (PhGA), and Patient Global Assessment (PtGA) in evaluable pts (receive ≥1 month of KZR-616; non-evaluable pts can be replaced).

Results: We enrolled 13 pts: 8 in Cohort 1, 5 in Cohort 2. The pts were 100% female; Baseline (BL) median SLEDAI was 10.0. All pts received at least 1 dose of KZR-616. In each cohort, 3 pts withdrew due to withdrawal of consent prior to W13. Overall, the 45 mg dose was well tolerated with no SAEs; all AEs were mild in intensity. The most common AEs were injection site erythema (62.5%), nausea (25%), and injection site pruritus (25%). Cohort 2 (60 mg) enrollment was halted, as all pts experienced vomiting within 8-24 hours of their first dose, which typically resolved within 24 h. One pt had an SAE of thrombotic microangiopathy. Two pts permanently reduced their dose to 45 mg. After 2 doses at 45 mg, another pt successfully re-escalated to 60 mg.
Cohort 2a (n=5 to date), there has been 1 SA of localized herpes zoster. In pts, PK and PD were similar to that achieved for the same doses in HV1. Efficacy data for evaluable pts are shown in the table. Two (33%) and 2 (67%) evaluable pts in Cohorts 1 and 2, respectively, had a SLEDAI improvement of ≥4 points from BL at W13.

Conclusion: KZR-616 dosed at 45 mg SC QW appears to be safe and well tolerated and showed evidence of disease suppression at W13 in active SLE pts on stable background therapy. The Ph 2 doses in the first randomized placebo-controlled trial with KZR-616 in active LN pts on mycophenolate and prednisone will be 30 and 45 mg. Efforts are ongoing to evaluate KZR–616 doses ≥60 mg using step-up dosing.

FR0197 Efficacy data of MC2-03 (ciclosporin 0.03% and 0.06% eyedrops) in sjogren’s patients with severe keratitis: outcomes of the northern lights phase 2b trial
Frederic Gomez1, Johan Selmer1, Morten Praestegaard1, Miguel Teus2, Luis Pablo2, Maite Sainz de la Maza2, Steffen Heegaard2, MC2 Therapeutics, Horsholm, Denmark;1University of Alcalá, Madrid, Spain;2University Hospital Miguel Servet, Zaragoza, Spain; 1Institute Clinic of Ophthalmology, Hospital Clinic of Barcelona, Barcelona, Spain; 2Department of Ophthalmology/University Hospital Rigshospitalet, Copenhagen, Denmark

Background: Sjögren’s syndrome is one of the most common rheumatic autoimmune disorders (1). It is a chronic systemic autoimmune disease in which immunmediated inflammation, characterized by lymphocytic infiltration of exocrine glands and epithelia, causes secretory gland dysfunction leading to dryness of the main mucosal surfaces (2) including dry eye with severe keratitis. Ciclosporin is a well-known immunosuppressant with a long record in the treatment of various autoimmune disorders (2) including dry eye. The aim of this study was to evaluate the safety and efficacy of MC2-03 in the treatment of severe keratitis in Sjögren’s syndrome patients.

Objectives: To report the clinical efficacy of MC2-03 (ciclosporin 0.03% and 0.06% eyedrops) in Sjogren’s patients with severe keratitis from a 6-month clinical trial.

Methods: The NORTHERN LIGHTS trial is a randomized, double masked, controlled multicentre European trial that assessed MC2-03 0.03%, MC2-03 0.06%, vehicle and best-standard-of-care (BSC) for the treatment of moderate-to-severe dry eye disease (patients having baseline corneal fluorescein staining (CFS) score ≥4). The full analysis set consisted of a total of 255 patients with 66 patients having a documented history of Sjögren’s syndrome. The objective of the trial was to evaluate safety and efficacy of MC2-03 after treatment once daily for 6 months followed by a 3 month safety follow-up. The primary efficacy endpoint was the proportion of patients achieving ≥2-grade improvement in CFS. CFS was evaluated using the modified Oxford grading system: a 7-point ordinal scale (0, 0.5, and 1 to 5), where grade 0 represents complete corneal clearing (absence of staining dots).

Results: The 66 patients with documented history of Sjögren’s syndrome constituted 25.9% of the trial population with 90.9% of the patients being females (n=60). Among the Sjögren patients, 58% (n=38) had severe dry eye (CFS 4) at baseline. Data analyzed for observed cases showed that the proportion of Sjögren’s patients achieving 2-grade improvement of CFS (baseline CFS 3 and CFS 4) was higher in MC2-03 groups compared to the control groups (Table 1). When patients treated with any active were compared to patients treated with any control, a 2-grade improvement of the CFS was observed in 51.9% patients in the combined active group vs. 26.7% for the combined control group (p=0.0620).

Table 1. SJ patients with 2-grade reduction in CFS

<table>
<thead>
<tr>
<th>Cohort</th>

</tr>
<tr>
<td>BSC</td>
<td>3/14 (21.4%)</td>
<td>6/15 (40.0%)</td>
<td></td>
</tr>
</tbody>
</table>

Using the same approach, the most severe patients, having CFS 4 at baseline, had a statistically significantly higher responder rate of 64.3% in the combined active group versus 21.1% in the combined control group (p=0.0286).

Table 2. Severe Sjögren patients with 2-grade reduction in CFS

FR0198 Antimalarial agents diminish while methotrexate, azathioprine and mycophenolic acid increase BaFF levels in systemic lupus erythematosus
Boris Hernández-Breijo1, Alvaro Gomez2,3, Sofia Soukka2,3, Petter Johansson2,3, Ioannis Parodis2,3, La Paz University Hospital, Immuno-Rheumatology Research Group, IDiPaz, Madrid, Spain; 1Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden; 2Karolinska University Hospital, Rheumatology, Stockholm, Sweden

Background: Elevated levels of the B cell activating cytokine BAFF (also known as BLYS) have been associated with active systemic lupus erythematosus (SLE), and the anti-BAFF monoclonal antibody belimumab has been approved as an add-on to standard-of-care SLE treatment, the latter mainly comprising glucocorticoids, antimalarial agents (AMA) and other immunosuppressive treatments.

Objectives: To investigate the effect of AMA and three other commonly used in SLE immunosuppressive agents (methotrexate, azathioprine, mycophenolate mofetil/sodium) on serum BAFF levels.

Methods: Access to data from the phase III clinical trials of belimumab BLISS-52 (n=865; NCT00424476) and BLISS-76 (n=819; NCT00410384) was granted by GlaxoSmithKline (Uxbridge, UK); a total of 1684 SLE patients were analysed. Serum samples obtained prior to belimumab initiation of patients achieving 2-grade improvement in CFS was evaluated using the modified Oxford grading system: a 7-point ordinal scale (0, 0.5, and 1 to 5), where grade 0 represents complete corneal clearing (absence of staining dots).

Results: The 66 patients with documented history of Sjögren’s syndrome constituted 25.9% of the trial population with 90.9% of the patients being females (n=60). Among the Sjögren patients, 58% (n=38) had severe dry eye (CFS 4) at baseline. Data analyzed for observed cases showed that the proportion of Sjögren’s patients achieving 2-grade improvement of CFS (baseline CFS 3 and CFS 4) was higher in MC2-03 groups compared to the control groups (Table 1). When patients treated with any active were compared to patients treated with any control, a 2-grade improvement of the CFS was observed in 51.9% patients in the combined active group vs. 26.7% for the combined control group (p=0.0620).
EFFECTIVENESS AND SAFETY OF BELIMUMAB IN PATIENTSWITH ACTIVE SYSTEMIC LUPUS

Background: Belimumab is the unique biologic therapy available for patients with SLE.

Objectives: To investigate effectiveness and safety of belimumab in SLE patients in clinical practice.

Methods: 458 active SLE patients (ACR criteria) from 24 Italian Centers, mean±SD age 43.5±11.3 years; mean±SD disease duration 12.3±8.7 years, were treated with belimumab (10 mg/kg day 0, 14, 28 and then every 28 days), as add-on therapy.

Results: BAFF levels (mean, SD; pg/mL) were higher in patients receiving methotrexate (1835, 1617; n=212; P=0.001), azathioprine (1901, 1472; n=364; P<0.001) or mycophenolate mofetil/sodium (1994, 1544; n=175; P<0.001) and no immunosuppressive treatment other than the one investigated compared with patients receiving no immunosuppressive treatment (1593, 1929; n=860); AMA were allowed in both groups, in all comparisons. In contrast, patients on AMA displayed lower BAFF levels (1654, 1318; n=1085) compared with patients who did not use AMA (1942, 2408; n=1942; P=0.002). In linear regression, AMA use showed a consistent and independent association with lower BAFF levels in all models, whereas use of each one of methotrexate, azathioprine and mycophenolic acid was associated with higher BAFF levels. All models were adjusted for the use of immunosuppressive agents other than the one investigated.

Conclusion: Our data imply differential effects of antimalarial agents and other immunosuppressive treatments on BAFF levels; AMA diminished while methotrexate, azathioprine and mycophenolic acid increased BAFF levels. It is worth noting that methotrexate and mycophenolic acid are not approved for the treatment of SLE. Considering the importance of BAFF in B cell homeostasis and SLE pathogenesis, exploration of the biological significance of the differential effects of different immunosuppressive agents on BAFF levels is anticipated.

Acknowledgement: The authors would like to thank GlaxoSmithKline (Uxbridge, UK) for granting access to the data from the BLISS-76 and BLISS-52 trials (ClinicalTrials.gov identifiers NCT00424476 and NCT00410384, respectively) through the Clinical Study Data Request (CSDR) consortium.

FR1020

REVIEW OF HYDROXYCHLOROQUINE USE AND DEVELOPMENT OF A REGIONAL STRATEGY TO MINIMISE RETINAL TOXICITY

Ursula Laverty1, Gerard Reid2, Julie Silvestri2, Adrian Pendleton1. 1Musgrave Park Hospital, Belfast, United Kingdom; 2Royal Victoria Hospital, Belfast, United Kingdom

Background: Guidelines from the Royal College of Ophthalmologists in February 2018 were developed for retinal screening for patients on hydroxychloroquine, as recent evidence suggests the risk of retinal toxicity is higher than previously reported. The prevalence of retinal toxicity in long term use appears to be 7.5% and depending on dose and duration of therapy can increase to 20-50% after 20 years of therapy. Risk is increased for patients taking more than 5mg per kg per day of hydroxychloroquine, patients on Tamoxifen and those with renal impairment. The guidelines recommend the use of a standardised referral proforma to help identify patients who are high risk.

Objectives: 1. Audit of Hydroxychloroquine use and retinal screening in the Belfast Health and Social Care Trust (BHSCST)
2. Develop a regional referral proforma and screening service for retinal toxicity

Methods: Patients who were treated with hydroxychloroquine, under the care of a consultant rheumatologist were identified on the database. A proforma was used to aid data collection and patients’ electronic records were reviewed. We audited the use of hydroxychloroquine and retinal screening against current Royal College of Ophthalmology (RCO) guidelines. We designed a standardised referral proforma and regional screening strategy in conjunction with ophthalmology colleagues.

Results: There were 151 patients identified on hydroxychloroquine on the database. 40 of these patients had stopped hydroxychloroquine, 2 of which had retinal toxicity. Therefore the rate of retinal toxicity in this sample was 1.3% (2/151).

There were 111 patients who remained on hydroxychloroquine treatment with a female: male ratio of 9:1. Age range was from 22 to 84, with a mean age of 55. There were 44% of patients on hydroxychloroquine for rheumatoid arthritis, 25% had systemic lupus erythematosus, 8% had Sjogren syndrome, 6% had panniculitis rheumatoid arthritis and 13% had other connective tissue diseases. The majority (79%) of patients were on 200mg hydroxychloroquine daily and 19% were on 400mg daily. 6% of patients had an eGFR<60. No patients were on tamoxifen. 72% of patients were on hydroxychloroquine treatment for over 5 years. Retinal screening was overdue in 64% of patients.

Conclusion: In this sample, only 1.3% of patients had evidence of retinal toxicity, although 64% of patients were overdue retinal screening. We developed a referral proforma and a regional screening strategy in line with RCO guidelines. In order to meet the RCO guidelines, we recognise the need for substantial investment in regional ophthalmology services.

REAL WORLD MEDICATION USE IN INCIDENT SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS NEPHRITIS PATIENTS

Lin Xi1, Furaha Karubuyo1, Jarni Sahl1, Jennifer H. Lockhart2, Lj Nari3, 1STATinMED Research, Ann Arbor, United States of America; 2Janssen Global Commercial Strategic Organization, Horsham, United States of America; 3Janssen Research and Development, LLC, Horsham, United States of America

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that causes inflammation in connective tissues and can involve multiple organs systems. Lupus nephritis (LN) is an inflammatory kidney disease caused by SLE. There is a gap in the literature regarding the standard of care in SLE and LN patients.

Objectives: This study generated real world medication use among SLE and LN patients.

Methods: This retrospective study used data from two large administrative databases in the US: Truven Health MarketScan® and Optum® databases to identify adult patients (≥18 years of age) with ≥2 medical claims on different dates for SLE or LN diagnoses from 01JAN2013-31DEC2015. SLE was identified using the International Classification of Diseases, 9th and 10th Revision, Clinical Modification [ICD-9-CM] codes (710.0) OR ICD-10-CM (M32.10-M32.19, 32.8, 32.9). LN was captured as a subset of SLE using [ICD-9-CM: 710.0 AND (581.81 or 582.81 or 583.81); OR ICD-10-CM-M32.14)]. The first SLE or LN diagnosis was designated as the index date. Patients were required to have continuous health plan enrollment for 1 year pre-index date (baseline period) and 1 year post-index date (follow-up period) and no prior SLE/LN diagnosis claims or belimumab medical/prescription claim during the baseline period to ensure incident patients were captured. The Truven Health MarketScan® and Optum® databases were pooled together and duplicates were identified and retained in MarketScan® only. Patient demographics and clinical characteristics during the baseline period were assessed. SLE treatment used during the follow-up period was evaluated and the proportion of patients that used SLE medications and average number of medical/prescription claims (#Rx) for each medication were provided.

Results: A total of 31,345 patients were identified including 30,086 SLE and 1,259 LN patients. Key results are shown in Table 1. The mean age was 52.7 years for SLE and 48.3 years for LN patients. Over 80% of the patients were female, with a mean Charlson Comorbidity Index (CCI) score of 1.1 and 1.8 for SLE and LN patients respectively. The most common comorbidities at baseline were hypertension and infections. Corticosteroids (SLE=58.3%, #Rx=4.5; LN=66.2%, #Rx=6.5) and hydroxychloroquine (SLE=43.4%, #Rx=5.8; LN=40.7% #Rx=6.2) were the most commonly used SLE medications during 1-year follow up period. Approximately 2% of patients used biologics including belimumab (SLE=1.1%, #Rx=8.8; LN=1.4%, #Rx=8.3) and rituximab (SLE=0.9%, #Rx=4.2; LN=2.1%, #Rx=4.0).

Table:

Conclusion: Our findings indicate a nominal use of biologics (2%) among SLE and LN patients. Corticosteroids and hydroxychloroquine were the most commonly used SLE treatments. These data reveal an unmet need for availability of advanced therapy to treat SLE and LN. Future studies are warranted to understand the underlying causes.

1. Mucke J, Duesing C, Chehab G, Schneider M. The definition of an accurate target for a treat to target (T2T) approach in SLE has been challenging over the past years. Recently four definitions of remission were presented by the international DORIS task force. The aim of this study was to evaluate the frequency of remission in our outpatient SLE cohort and to assess feasibility and concordance of the remission definitions with the treating physician’s opinion regarding the patient’s state.

Disclosure of Interests: Jos captures the essence of the findings from a clinical study focusing on the treatment of refractory skin lupus lesions. The study was conducted at a tertiary center and included 216 patients with systemic lupus erythematosus (SLE) and 2,251 patients with lupus nephritis. The study aimed to evaluate the frequency of remission according to four different definitions proposed by the DORIS task force. The results showed that the definition of remission based on the treating physician’s opinion had the highest concordance rate among the four definitions. However, the study faced challenges in assessing the feasibility of implementing these definitions in clinical practice. The findings highlight the need for further research to improve the definition of remission in SLE and optimize treatment strategies.

The findings highlight the need for further research to improve the definition of remission in SLE and optimize treatment strategies.

Disclosure of Interests: Jos captures the essence of the findings from a clinical study focusing on the treatment of refractory skin lupus lesions. The study was conducted at a tertiary center and included 216 patients with systemic lupus erythematosus (SLE) and 2,251 patients with lupus nephritis. The study aimed to evaluate the frequency of remission according to four different definitions proposed by the DORIS task force. The results showed that the definition of remission based on the treating physician’s opinion had the highest concordance rate among the four definitions. However, the study faced challenges in assessing the feasibility of implementing these definitions in clinical practice. The findings highlight the need for further research to improve the definition of remission in SLE and optimize treatment strategies.
Results: A total of 233 patients were included (87.6% female). 88 (37.8%) patients fulfilled any of the four DORIS remission definitions, while 129 patients were in remission according to their physician’s judgement. Of the 88 in DORIS remission, 17 were in complete remission, 20 in clinical remission, 16 in complete remission on treatment (ROT) and 35 in clinical ROT. In most cases the treating physician agreed on their patient being in remission (94.1% for complete remission, 90.0% for clinical remission, 81.3% for complete ROT, 88.6% for clinical ROT). A total of 145 patient were not in any DORIS remission. We observed discordance in the assessment of remission in 58 patients (24.9%). 10/88 being not in remission according to their treating physician despite fulfilling the DORIS remission definition and 48/145 were considered in remission though not in DORIS remission. Reasons for failing DORIS remission in the patients with attested physician’s remission was an elevated cSLE-DAl Score (n=22), elevated (n=24) or missing (n=1) physician global assessment, and prednisolone dosage >5 mg (n=9).

Conclusion: DORIS remission proved an achievable target in our outpatient clinic. Still we found discordance regarding DORIS remission and the treating physician’s judgement with a greater number of patients considered in remission by their physicians. Main reasons were a cSLE-DAl>0 and physician global assessment >0.5. Further analyses are needed to better characterize cases of disagreement and to address the question, if the rather strict DORIS criteria are needed to improve long-term outcome.

FrHO204 SAFETY, TOLERABILITY, PHARMACOKINETIC AND PHARMACODYNAMIC EFFECT OF BIIB059, A MONOCLONAL ANTIBODY TARGETING BDCA2 FOLLOWING ADMINISTRATION OF SUBCUTANEOUS SINGLE DOESES IN JAPANESE HEALTHY VOLUNTEERS

Cristina Musselli, Francois Gaudreault, Himanshu Naik, Hua Carroll, Ankur Sharma, Xiaobi Huang, Nathalie Franchimont, BIOGEN, Cambridge, United States of America

Background: BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, when ligated inhibits the production of inflammatory media tors. BIIB059 is a fully humanized, IgG1 monoclonal antibody (mAb) which targets BDCA2. This study was performed to evaluate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of BIIB059 in Japanese healthy volunteers.

Objectives: This phase 1 study evaluated the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of BIIB059 in Japanese individuals (NCT02847598).

Methods: A total of 32 subjects from Japan were enrolled into 4 cohorts (8 BIIB059: 2 Placebo) to receive a single subcutaneous (SC) injection of 20-, 50-, 150- or 450 mg of BIIB059 or placebo. Blood samples were obtained to characterize PK and PD profiles and establish PK-PD relationships for BIIB059.

Results: BIIB059 was generally well tolerated; no SAEs were observed. Adverse events were reported by 9 subjects (37.5%) and none (0.0%) in the BIIB059- and placebo-treated subjects, respectively. Overall, 95.8% and 4.2% subjects reported AEs that were mild or moderate in severity, respectively. Three subjects (12.5%) experienced AEs considered related to study drug and mild in severity. All AEs resolved without treatment. There were no clinically significant findings on laboratory or physical examination. Following single SC BIIB059 administration, Cmax and AUC (0-inf) increased in a dose-proportional manner. Mean t1/2 ranged from 10 to 27 days. Eleven subjects (45.8%) treated with BIIB059 tested positive for anti-BIIB059 antibodies at ≥ 1 postdose timepoint (ADA).

FrHO2025 ANTIMALARIAL AGENTS IMPROVE PHYSICAL FUNCTIONING IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Joannis Panidis, 1,2 Sofia Soukka, 1,2 Alvaro Gomez, 1,2 Yvonne Enman, 1,2 Petros Chrismann, 2 Shazuddin Chaudhuri, 1,2 Katerina Chatzidionysiou, 1,2 Petter Johansson, 1,2 Sharzad Emamikia, 1,2 Katerina Chatzidionysiou, 1,2 Dimitrios Gaudreault, 1,2 Anup K. M. Kumar, 1,2 HImanshu Naik, 1,2 FRI0104

1Karolinska Institute, Division of Rheumatology, Department of Medicine, Stockholm, Sweden; 2Karolinska University Hospital, Rheumatology, Stockholm, Sweden

Background: Patients with systemic lupus erythematosus (SLE) suffer an impaired health-related quality of life (HRQoL), and the majority of them experience fatigue as a major problem. Traditionally, treatment of SLE has been symptomatic, and antimalarial agents (AMA) are considered a cornerstone of SLE treatment. In previous literature, results regarding the effect of antimalarial agents on HRQoL have been conflicting.

Objectives: In this study, we aimed at investigating the potential influence of AMA on SLE patients’ self-perception of HRQoL aspects.

Methods: We utilised pooled baseline data from the BLISS-52 and BLISS-76 clinical trials of belimumab (n=1684). Access to data was granted by GlaxoSmitKline. The patients’ HRQoL and fatigue were self-reported using the Medical Outcomes Study (MOS) short form 36 (SF-36) health survey, the functional assessment of chronic illness therapy (FACT)-Fatigue scale and the three-level EuroQual-5 Dimension (EQ-SD) questionnaire. Minimal clinically important difference (MCID) was set to ≥ 5.0 points for SF-36 scales, ≥ 2.5 points for SF-36 component summary scores, and ≥ 4 points for FACT-Fatigue scores. High disease activity was defined as a SELENA-SLEDAI score ≥10. Organ damage was assessed using the SLICC/ACR Damage Index (SDI). The non-parametric Mann-Whitney U test was used for comparisons between AMA users and non-users. Linear regression models were next used in order to adjust for possible confounding factors; these included age, sex, ethnic origin, SLE disease activity, SLE duration, organ damage, corticosteroid use and use of other immunosuppressive agents.

Results: Results are presented as mean values ± standard deviation. Patients receiving AMA (n=1098) performed better than patients who did not receive AMA (n=586) with regard to SF-36 physical component summary (PCS) scores (39.6 ± 9.5 versus 38.1 ± 9.9; P=0.001), physical
functioning (61.1 ± 24.9 versus 55.0 ± 26.5; P<0.001), role physical (53.2 ± 26.9 versus 50.3 ± 27.7; P=0.036), bodily pain (49.5 ± 23.8 versus 47.1 ± 25.3; P=0.016), FACIT–Fatigue scores (30.5 ± 11.8 versus 29.3 ± 11.9; P=0.046), EQ-5D scores (0.75 ± 0.18 versus 0.72 ± 0.19; P=0.004), and EQ-5D visual analogue scale (VAS) scores (64.6 ± 19.4 versus 61.7 ± 18.6; P=0.001). The difference in SF-36 physical functioning was the greatest one among the SF-36 parameters, exceeding the corresponding MCID (≥50 points). The association between AMA use and better physical functioning was still significant after adjusting for potential confounding factors (standardised coefficient, β=0.08; P=0.001).

In this analysis, Asian patients performed better in physical functioning (β=0.07; P=0.004) while African/African American patients performed worse (β=0.07; P=0.033). High disease activity (β=−0.09; P=0.001) and organ damage (β=−0.01; P=0.001) were also independent factors of worse physical functioning, whereas corticosteroid use independently improved the outcome (β=0.06; P=0.022).

Conclusion: AMA use contributes to better physical functioning in patients with SLE, independently of other factors.

Acknowledgement: The authors would like to thank GlaxoSmithKline (Uxbridge, UK) for granting access to the data from the BLISS-SC and BLISS-SD trials (ClinicalTrials.gov identifiers NCT01424476 and NCT00410394, respectively) through the Clinical Study Data Request (CSDR) consortium.

HYDROXYCHLOROQUINE BLOOD LEVELS PREDICT RETINOPATHY IN SLE

Michelle A. Petri1, Li Jessica1, Marwa Elkhalfia2, Daniel Goldman1, Laurence Magder1, Johns Hopkins University School of Medicine, Rheumatology, Baltimore, United States of America; 1Alexandria University, Medicine, Alexandria, Egypt; 2University of Maryland, Epidemiology and Public Health, Baltimore, United States of America

Background: Hydroxychloroquine (HCQ) retinopathy after 10 years or more of use is more frequent than previously appreciated. This led to new ophthalmology guidelines that changed the recommended dosing from 6.5 mg/kg to 5 mg/kg (1).

Methods: We analyzed data on 537 SLE patients from a clinical cohort who had repeated assessments of HCQ blood concentrations, and were evaluated one or more times for retinopathy (300 single retinopathy exam, 149 two and 88 three or more assessments). The patients were 92% female and 42% Caucasian. Hydroxychloroquine blood levels were performed as previously described. In our analysis, HCQ toxicity was defined dichotomously by a retina expert: all those with a value of “No” or “Possible” were categorized as not having HCQ toxicity, and those who had a “Yes” were categorized as having it. Mean and maximum HCQ blood concentration over all cohort visits prior to the final retinopathy assessment were calculated. Risk of HCQ toxicity was then assessed in tertiles defined by these variables.

Results: Our data show that the risk of HCQ retinopathy is higher in men and Caucasians. As expected, it is higher in older patients and with greater duration. We also found that BMI and hypertension were predictive of HCQ retinopathy. For the first time, our data show the utility of HCQ blood levels in predicting retinopathy. This would allow clinicians to either decrease dose or increase monitoring in those with high blood levels.

BASELINE LEVELS OF BAFF, APRIL AND CD8+ EFFECTOR MEMORY CELLS AS PREDICTORS OF SLEDAI RESPONSE TO BELIMUMAB THERAPY

Francesca Repida1, Silvia Piantoni1, Laura Andreoli1, Torsten Lowin2, Rajesh Kumar1, Paolo Airò1, Franco Franceschini2, Angela Tincani1, Georg Pongratz1, U.O. Rheumatology and Clinical Immunology, ASST Spedali Civili di Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy; 2University Hospital Düsseldorf, Department of Rheumatology and Institute for Rheumatology, Düsseldorf, Germany

Background: Systemic lupus erythematosus (SLE) patients show high circulating levels of BLyS (B lymphocyte stimulator, also known as BAFF) and of other cytokines belonging to the tumor necrosis factor (TNF) superfamily [1]. Belimumab is a monoclonal antibody against soluble BLyS used for treatment of refractory SLE. Although B cells are the main target of this therapy, a BLyS-dependent T cell activation pathway has also been demonstrated [2]. Clinical studies showed that high levels of anti-DNA antibodies and low complement at baseline are predictors of response to Belimumab treatment.

Objectives: Our study aims at exploring the role of biomarkers belonging to the TNF superfamily and of effector T-lymphocytes as predictors of response.

Methods: Twenty-one patients with SLE received Belimumab. Clinical evaluation and laboratory test were performed at baseline and after six and twenty months of therapy. Biomarkers belonging to the TNF superfamily (BAFF, APRIL, sBCMA, sCD40L, sTACI, TWEAK) were tested by high-sensitivity ELISA in all patients and lymphocyte immunophenotyping was performed by flow cytometry in ten subjects. SLE-disease activity was assessed by SLEDAI-2K score.

Results: BAFF and APRIL baseline serum levels and the number of CD3+CD8+ effector memory T cells were correlated positively with SLEDAI-2K improvement after 12 months of treatment (Pearson correlation=0.535 (p=0.015), 0.504 (p=0.023) and 0.654 (p=0.040)). After backwards exclusion of linear regression analysis including SLEDAI-2K, effector T cell relative number and BAFF or APRIL at baseline, only APRIL remained as significant independent predictor of SLEDAI-2K improvement after 12 months of therapy (adjusted R square=0.649, p=0.025). Moreover, after controlling TNF-family members serum levels and SLEDAI-2K at baseline, only BAFF showed the best predictive value (adjusted R 0.564, p<0.001).
Conclusion: In our cohort of SLE patients, baseline serum level of APRIL, together with percentage of CD3+CD8+ effector memory cells, or BAFF serum level alone resulted as best predictors of response to Belimumab. Considering that immunophenotyping is often not done in clinical practice, BAFF baseline serum levels alone could be used routinely as a good predictor of response to therapy, as suggested by post-hoc analyses of the BLISS study and shown by a recent “real-life” observational study [3].

FRIO208 IDENTIFYING LUPUS PATIENT SUBSETS AND SPECIFIC PHARMACODYNAMIC CHANGES THROUGH IMMUNE CELL DECONVOLUTION OF GENE EXPRESSION DATA IN ATACICEPT-TREATED PATIENTS IN THE APRIL-SLE STUDY

Eileen Samy1, Matthew Studham1, Amy Kao1, Philipp Haselmayer2, Peter Chang1, P. Alexander Rolfe1, David Wofsy3, Julie Demartino1, Robert Townsend1, 1EMD Serono Research and Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA, United States of America; 2Merck KGaA, Darmstadt, Germany; 3University of California, San Francisco, CA, United States of America

Background: The Phase 2/3 APRIL-SLE study evaluated the safety and efficacy of atacicept, a dual inhibitor of the B lymphocyte stimulator (BLyS) and a proliferation-inducing ligand (APRIL), in systemic lupus erythematosus (SLE).

Objectives: The goal of this post-hoc analysis was to use cell-based gene signatures on gene expression data from the APRIL-SLE study to identify clusters of patients with potential to flare and to assess clusters for differences in treatment effects of atacicept vs placebo.

Methods: A published immune cell deconvolution algorithm (Abbas et al. 2009) was applied to whole-blood gene expression data from APRIL-SLE patients to identify relative proportions of 17 immune cell types. Patients were then grouped into clusters based on these immune cell profiles using a k-medoid clustering algorithm and were compared to each other based on patient characteristics, biomarkers and clinical efficacy. In addition, baseline expression and change in expression of putative APRIL-responder genes were compared among clusters. APRIL-responder genes were identified by combining differential expression results from the APRIL-SLE study (Week 52 vs Day 1 randomization) and tabalumab (targets BLyS) Phase 3 studies (Week 52 vs baseline; GSE88887).

Results: Patient gene expression data (N=105; placebo, n=30; atacicept 75 mg, n=40; atacicept 150 mg, n=35) were used to group patients into five main clusters (P1-P5) by predominant characteristic cells: P1, T helper cells; P2, plasma cells; P3, neutrophils and B cells; P4, B cells; P5, activated dendritic cells. Patients in P2 and P5 were more likely to have positive anti-dsDNA antibodies (≥30 IU/ml), elevated BLyS; ≥1.6 ng/ml, and high interferon gene signature in the blood than other those in other clusters. Patients in P2 were most likely to have low complement C3 and C4 levels. Placebo-group flare rates in P2 (100%), P4 (100%) and P5 (83%) were markedly higher than in P1 (33%) and P3 (29%). In P2, P4, and P5 the median time-to-flare was much lower with placebo (85, 98.5, and 115.5 days, respectively) than with atacicept 150 mg (over 364 days for all three clusters). A comparison of differentially-expressed genes from clinical studies of SLE patients treated with atacicept and tabalumab revealed possible APRIL-responder genes: SDC1, PARM1 and MZB1. These genes had a higher baseline expression in P2 and P4 compared with other clusters. SDC1 was reduced from baseline more in P2, P4, and P5 after atacicept treatment, while PARM1 and MZB1 decreased after atacicept treatment in P2 and P4.

Conclusion: These post-hoc analyses revealed different subsets of SLE patients based on their molecular profiles. Atacicept may have different treatment effects in the identified patient subsets vs placebo, providing insights into potential mechanisms of flare in SLE.

FRIO209 LOW-DOSE GLUCOCORTICOID COULD AFFECT ADVERSE PREGNANCY OUTCOMES, ESPECIALLY IN PRETERM BIRTH, LIGHT-FOR-DATE NEWBORNs, PRETERM PREMATURE RUPTURE OF MEMBRANE IN CONNECTIVE TISSUE DISEASE PATIENTS

Hironi Shimada, Risa Wakaya, Mai Mahmoud Fahmy Mansour, Shusaku Nakashima, Mikiya Kato, Tachi Miyagi, Tonomiho Kameda, Hiroaki Dobashi. Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan

Background: Connective tissue disease (CTD) often occurs in women of child-bearing age, and flare-ups during pregnancy. Therefore, it is important to manage their disease activities with the treatment which have no influence on fetal growth and development. Among the treatment during pregnancy glucocorticoid is most often used for maintain or control to flare-ups of CTD disease activities. However, prolonged use of glucocorticoid during pregnancy is considered to increase the risk of adverse pregnancy outcomes (APOs) including preterm birth, intrauterine growth restriction, and premature rupture of membrane (PROM) (1, 2).

Objectives: The aim of this study is to reveal the dose of glucocorticoid which influences on APOs.

Methods: We investigated 164 pregnant patients complicated with CTD from March 2006 to January 2019. All these patients were managed their disease activities throughout pregnancy in our institute. APOs including preterm birth, light-for-date (LFD) newborns, PROMs in these pregnant patients were examined retrospectively. We analyzed the association between APOs and the incidence or mean dose of glucocorticoid use during pregnancy.

Results: Underlying CTD is Systemic lupus erythematosus (25.3%), Sjögren’s syndrome (24.9%), rheumatoid arthritis (18.1%), Antiphospholipid syndrome (6.8%), mixed connective tissue disease (6.7%), and others. Glucocorticoid was administered in 96 cases, which tended to be earlier gestational week at delivery (37.5±3.0 vs. 38.9±1.5, P<0.01) and lower birth weight of newborns (2601.9±603.0 vs. 3019.0±480.8, P<0.01) significantly. Compared with full-term birth, the cases of preterm birth had higher dose of glucocorticoid during pregnancy significantly (P<0.01). Logistic regression analysis for preterm birth revealed the cut-off value of mean prednisolone dose as 7.5 mg per day (Figure 1). Similarly, the
patients who delivered LFD newborns had higher dose of prednisolone (P=0.04), and logistic regression analysis revealed cut-off value as 6.7 mg per day (Figure 2). The cases with preterm PROM also had higher dose of prednisolone (P=0.01), and logistic analysis revealed cut-off value as 5.0 mg per day (Figure 3).

**Conclusion:** Glucocorticoid is often used for CTD patients during pregnancy, however, CTD patients who were treated with continuing high dose of glucocorticoid during pregnancy had high risks for APOs such as preterm birth, low birth weight of newborns, preterm PROM. Our data indicated that the cut-off dose of prednisolone values of preterm birth, LFD, preterm PROM was 7.5 mg, 6.7 mg, 5.0 mg per day respectively. It is important for rheumatologists to pay much attention for these risk of glucocorticoid use to CTD patients who hope to conceive and to manage the disease activity with appropriate dose of glucocorticoid. Recently, many immunosuppressants including biologics have been reported to be available for the safety use during pregnancy, and might be helpful to reduce the risk of APOs by glucocorticoid use.

A LOW AND PROMPTLY TAPERED STEROID REGIMEN CAN ACHIEVE EXCELLENT RESULTS IN LUPUS NEPHRITIS, WITH LESS ADVERSE EVENTS

Farah Tamirou1, Nathalie Demoulin2, Selda Aydin3, Frederic Houssiau1.
1Rheumatology Department, Cliniques universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium; 2Nephrology Department, Cliniques universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium; 3Pathology Department, Cliniques universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium

Background: The optimal use of glucocorticoids (GC) in lupus nephritis (LN) remains a topic of debate, especially the tapering protocol and the duration of treatment. To date, only one randomized controlled trial, MyLupus, has compared two oral prednisolone (P) regimens in LN (0.5 mg/kg/d) with fewer side-effects in the 0.5 mg/kg/d group. Importantly, Herpes zoster infections were only observed in the higher P dose group, with a lower number of non-responders. The one-year renal response was defined by achieving a proteinuria target <0.8g/d.

Methods: Data from the last 30 consecutive proliferative LN patients diagnosed at the Louvain Lupus Clinic (between 2015 and 2018) were reviewed retrospectively. In these patients, the 10 last consecutive patients received a low fixed dose of P (20mg/d) for 4 weeks, rapidly tapered as follows: 15mg/d for 2 weeks, 12.5mg/d for 2 weeks, 10mg for 2 weeks, 5mg/d from for 2 weeks and 2.5mg/d for 6 months. GC were withdrawn at week 52. The baseline and the follow-up data of these 10 patients were compared to the 20 previous consecutive LN patients followed in the same center but given a standardized P dose of 0.5 mg/kg/d. Both groups of patients received 750 mg methylprednisolone IV pulses on 3 consecutive days at baseline. The one-year renal response was defined by achieving a proteinuria target <0.8g/d.

Results: Clinical (BMI, gender, age, mean serum creatinine, mean proteinuria, SLEDAI-2K, non-steroid immunosuppressants) and pathological (ISN/RPS class) characteristics did not differ at baseline between the two groups. As illustrated in the Table, the mean uPCR ratios measured at one year were similar, as were the percentages of patients who achieved the proteinuria target. Importantly, Herpes zoster infections were only observed in the higher P dose group, with the difference reaching almost statistical significance.

Conclusion: In patients suffering from proliferative LN, an induction protocol with a low and rapidly tapered dose of P may be as effective as higher dose regimen to achieve the proteinuria target at one year, with fewer Herpes zoster episodes. These results deserve to be confirmed in a controlled trial.

FRIO213 RANDOMIZED PLACEBO CONTROLLED TRIAL OF ABATACET FOR NON-ORGAN THREATENING SYSTEMIC LUPUS WITH BACKGROUND MEDICATIONS WITHDRAWN

Aikaterini Thanou1, Cristina Arriens1, Teresa Aberle1, Eliza Chakravary2, Samaria Vaseer3, Joe Rawdon1, Judith A. James1, Joan Merrill1, 1Oklahoma Medical Research Foundation, Oklahoma City, United States of America; 2The University of Oklahoma Health Sciences Center, Oklahoma City, United States of America

Background: Abatacept (ABA) is a fusion protein of the extracellular domain of CTLA4 and the Fc domain of human IgG1, constructed to inhibit B/T cell co-stimulation. Previous studies of ABA in lupus failed to show benefit in overall disease activity, but improvement in arthritis was suggested.

Objectives: This 6-month randomized, double-blind, placebo-controlled (PBO) study withdrew background medications to facilitate the assessment of the effect of treatment in SLE patients with SLE arthritis.

Methods: Patients were entered with moderate to severe arthritis [BILAG A or B with ≥3 swollen and ≥3 tender joints (28 joint count)]. All DMARDs except prednisone (up to 20mg daily) were withdrawn by baseline and patients were randomized 1:1 to weekly sc ABA or PBO. One or more DepoMedrol injections (≥320mg total) was allowed by end of Month 2. Additional steroids or immune suppressants (IMS) at any time, or more DepoMedrol injections were allowed, but designated non-response. The primary endpoint was BICLA response at Month 6 compared to screening. Secondary objectives included SRI-4, SLEDAI 4-point improvement, SLEDAI arthritis resolution, BILAG A/B musculoskeletal (MSK) improvement, as well as low disease activity defined by either SLEDAI 2 or Lupus Low Disease Activity State (LLDAS) at Month 6. Flares were evaluated by the modified SELENA-SLEDAI flare index (1) in patients followed after baseline.

Results: 66 patients were randomized and received at least one dose of the study drug, 31 ABA and 35 PBO. 7 withdrew prior to Month 6. Flares were evaluable in 64 patients (31 on ABA, 33 on PBO). 14 (45%) patients on ABA vs. 18 (55%) on PBO had a moderate/severe flare by Month 6. 22 (71%) patients on ABA vs. 23 (70%) on PBO had experienced flare by Month 6. Rates of flare and treatment failure by Month 6 did not differ between groups (Log-Rank test, p=0.688 and p=0.631, respectively). The safety profile of ABA was consistent with known effects of the treatment.

Conclusion: ABA did not demonstrate improvement vs placebo in controlling disease activity or flare in SLE patients in a protocol that mandated IMS withdrawal. Placebo response rates of ≥23% support the validity of these results. Since some evidence suggests potential efficacy of ABA for certain biologic subsets of SLE (2), immunophenotyping may prove helpful.

FRIO214 EFFICACY OF RITUXIMAB AND CYCLOPHOSPHAMIDE TREATMENT IN PATIENTS WITH PRIMARY SJOGREN’S SYNDROME AND PAROTID GLAND MALT LYMPHOMA

Anna Torgashina, Bogdan Chalcev, Evgeniya Sokol, Vladimir Vasilev. Nasanova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Mucosa-associated lymphoid tissue (MALT) lymphoma occurred in a higher frequency and at an earlier age in primary Sjögren’s syndrome (pSS) than reported for MALT lymphoma in the general population. The optimal treatment of MALT lymphoma in pSS has not been defined.

Objectives: to analyze retrospectively the long-term clinical course of pSS in patients with MALT lymphoma.

Methods: 63 SS patients with MALT lymphoma were retrieved from our SSS database. Most of the 63 pSS-lymphoma patients were female (n=60; 95%), pSS was diagnosed at a mean age of 51 (43-58) years and lymphoma at a mean of 7 (2-10) years later. Total mean follow-up was 5 years (2-8). 14 patients received immunomodulator agents for SS before the development of lymphoma (low doses of prednisone - 8 patients, chlorambucil – 7, cyclophosphamide – 3 patients). In 43 patients, the diagnosis of SS and MALT - lymphoma were established simultaneously. Clinical features and treatment outcome of MALT - lymphoma as well as SS activity was evaluated.

All patients had features of autoimmune disease (ANA-100%, RF-90%, anti-Ro/o/anti-La antibodies-94%) and met the diagnostic criteria of the Association of Rheumatologists of Russia for primary Sjögren’s syndrome: salivary gland involvement (stimulated parotid flow rate ≤ 2 ml in 5 min, parotid sialography showing the presence of diffuse punctuate or globular shadows with a diameter > 1mm, histopathology: a focus score>2 per 4mm2 in minor salivary gland biopsy), keratoconjunctivitis sicca (stimulated Schirmer’s test ≤10mm in 5 min, tear break-up time < 10 seconds, rose Bengal test or fluorescent test >1+), presence of abnormal concentrations of at least one of the serum autoantibodies (anti-Ro/o, anti-La, anticardiolipin antibodies, IgM-rheumatoid factor). The histology and immunohistochemical diagnosis of lymphoma was performed with B-cell clonality determination in salivary gland tissue.

Patients were treated with RTX (25 patients) or RTX+CPH (38 patients). Patients received 2 1g intravenous infusions of RTX 2 weeks apart, then 375 mg every 3 months for 2 years. Cyclophosphamide 1000 mg was administered every two weeks for a period of 12 weeks.

Results: MALT lymphoma was localized in parotid glands in 60 cases, submandibular salivary glands – in 2 cases, lacrimal gland – in 1 case. Eleven patients showed systemic features (7-purpura, 1-ocular, 3 – nephritis). Blood serum and urine examination revealed monoclonal secretion in 16/56 patients (7- lgM, 4- lgG and IgA, 2-lgA and 3 - BJK). Nineteen of 56 (34%) patients had cryoglobulinaemia. After follow-up of 24 mo, complete clinical remission (CR) of MALT lymphoma (normalization of salivary gland size, disappearance of lymphadenopathy and cytopenia) was obtained in 25 (72%) in the group of RTX and 35 (92%) in the group of RTX+CPH (p=0.005). An erosion biopsy of the parotid gland before and after therapy was made in 21 patients. Complete disappearance of histological pattern of MALT lymphoma was shown in 50% of the RTX treated patients and in 66% patients with combined therapy. B-cell clonality in parotid glands disappeared in 1/5 cases after RTX monotherapy and in 1/4 cases after RTX with CPH therapy. Cryoglobulinaemia disappeared in 33% patients in group of RTX and 46% in group of RTX+CPH (p=0.6).

Conclusion: Complete clinical remission of the lymphomas was achieved significantly more often in the group treated with RTX plus cyclostatic agent in comparison with patients who had RTX monotherapy.

Disclosure of Interests: None declared

Background: Autoimmune thrombocytopenia (AITP) is common in systemic lupus erythematosus (SLE) patients and may be refractory to conventional therapies. SLE related thrombocytopenia (SLE-TP) patients have T-cell dysfunction that was reported to be associated with the activation of the mammalian target of rapamycin (mTOR). Rapamycin (RAPA) inhibits antigen-induced T-cell proliferation and has been developed as a medication named sirolimus.

Objectives: We assessed safety, tolerance, and efficacy of sirolimus in a prospective, open-label clinical trial.

Methods: We did a single-arm, open-label study of sirolimus in patients with refractory SLE-TP unresponsive to, or intolerant of, conventional medications at Peking Union Medical College Hospital (PUMCH, Beijing, China). We enrolled refractory TP patients (aged ≥18 years) with systemic lupus erythematosus (SLE) who visited our referral center since September 2017. We excluded patients with allergy or intolerance to sirolimus, patients with life-threatening manifestations of lupus, such as RPN, NPLE or PAH and patients with uncur ed infection. All eligible participants had signed informed consents. Patients received oral sirolimus at a starting dose of 2 mg per day for 3 days and a sequential dose of 1 mg per day, with dose adjustment according to tolerance and to maintain a therapeutic range of 6–15 ng/mL. Patients were treated with sirolimus for 6 months. Safety outcomes included tolerance as assessed by the occurrence of common side-effects. The primary efficacy endpoint was complete remission rate and partial remission rate at the sixth month. The secondary efficacy endpoint was treatment remission rates at the third month. The efficacy endpoints were assessed in all patients who completed 3 or more months of treatment, and all patients who received at least one dose of treatment were included in the safety analyses.

Results: Between September 2017 and November 2018, 12 lupus patients (1 male and 11 female) were enrolled with an average age of 33.3y, average disease duration of 8.4 years. All patients have achieved remission with front-line therapy, including corticosteroids, intravenous immunoglobulin and immunomodulatory agents, such as azathioprine, FK506, mycophenolate mofetil, and cyclosporine. After sirolimus therapy (2 weeks to 6 months), 5 of 12 patients achieved CR, 11 patients have finished 4 months’ assessment, and 9 of them achieved CR.

Conclusion: Sirolimus is effective for the treatment of refractory SLE-TP and can be a choice of the second-line treatment. Further prospective studies are needed to evaluate sirolimus as a therapeutic option for SLE-TP and to monitor for potential long-term side effects.

**RESULTS:**

**Conclusions:** Our study highlights that pharmacological inhibition of IRAK4 response can reverse two key components of lupus nephritis; the inflammatory and the fibrotic response.

**REFERENCES:**

**Disclosure of Interests:** Dania Rabah Shareholder of: Employee and shareholder of Biogen, Employee of: Biogen, Ramon Bonegio2, Agnes Gardel1, Holly Legault1, Ian Rifkin2, Ti Wang1, Chris Roberts1, Jeffery Vessels1, Norm Alliare3, Andrea Bertolotti-Ciarlet4, Kevin Guckian1. Biogen, Cambridge, United States of America, 1Boston University, Boston, United States of America; 2Cystic Fibrosis Foundation Therapeutics, Lexington, United States of America; 3Takeda, Cambridge, United States of America

**Background:** IRAK4 is an important signaling mediator of the innate immune system. IRAK4 regulates MyD88-dependent signaling from most TLRs and from IL-1R, resulting in downstream production of pro-inflammatory cytokines.

**Objectives:** Inhibition of IRAK4 kinase activity is a promising therapeutic approach for the treatment of autoinflammatory diseases, such as lupus. To this end, we identified a potent and highly selective inhibitor of IRAK4 kinase activity, BIIB-IRAK4i.

**Methods:** Recombinant kinase assays and DiscoveRx kinomescan were used to measure BIIB-IRAK4i kinase inhibition and selectivity, respectively. BIIB-IRAK4i-mediated proximal and distal pharmacodynamics effects (PD) were measured in both cell lines and whole blood assays. The ability of BIIB-IRAK4i to inhibit cytokine production induced by TLR ligands was measured in vitro and in vivo. Acute antibody-mediated lupus nephritis mouse model, which is a TLR-7 dependent and characterized by severe glomerular proliferative lesions with crescent formation, was used to determine the efficacy of BIIB-IRAK4i.

**Results:** BIIB-IRAK4i displayed equipotent proximal inhibition of MyD88 signaling and distal inhibition of cytokine production in vitro. BIIB-IRAK4i led to potent inhibition of cytokine production in whole blood assays stimulated with various synthetic TLR ligands as well as more physiologically relevant stimuli such as immune complexes, a hallmark of lupus pathogenesis. BIIB-IRAK4i inhibited TLR9-mediated cytokine production with similar potency in vitro and in vivo. In addition, BIIB-IRAK4i decreased both inflammation and fibrosis in an acute antibody-mediated lupus nephritis mouse model. BIIB-IRAK4i inhibited crescent formation as well as markers of tubulointerstitial fibrosis., which are both associated with decreased survival and adverse outcomes in human lupus nephritis.

**Conclusion:** Our study highlights that pharmacological inhibition of IRAK4 response can reverse two key components of lupus nephritis; the inflammatory and the fibrotic response.

**REFERENCES:**

[1] Phansenee, S., Sekararithi, R., Jatavan, P., & Tongsong, T. (2018). Prevention of immune flare may be life-threatening, and some of the medications that are used to treat SLE adversely affect fetus.[]

**Objectives:** To evaluate the pregnancy outcome in SLE patients and to determine the predictive factors for adverse fetal and maternal outcomes.

**Methods:** The study was conducted on the pregnant SLE patients attending the Rheumatology department, Zagazig University hospital in the period from January 2013 to January 2018. The data was collected retrospectively; demographically, laboratory and serological data on all patients, age at the onset of SLE, disease duration, systems affected, their disease activity using the Systemic Lupus Erythematous Disease Activity Index (SLEDAI), treatment received immunosuppressive regimen (dose and duration) before and during pregnancy, SLE flare during pregnancy, the fetal and the maternal outcomes.

**Results:** Fifty-four pregnancies were observed in 49 SLE patients with mean age of (27.5±5.6), mean SLE disease duration (3.7±2.2) and mean SLEDAI (5.4±6.1). 39 (75%) pregnancies with successful live births and 13(25%) fetal losses were observed. 36 of the live births (92.3%) were full-term and 3 (7.7%) were preterm births. Fetal losses included six spontaneous abortions, 3 stillbirths and 4 therapeutic abortions; 2 of them due to observed fetal anomalies and one due to life threatening lupus flare. We found SLEDAI significantly higher in patients with lost pregnancies (p=0.0001) than successful pregnancies. Proteinuria during pregnancy was a predictive factor for adverse fetal outcomes (odds ratio [OR] 19.7; P < 0.0001), also the presence of antiphospholipid antibodies (OR 15.3; P<0.0001), low C3 and C4 (OR 15.3; P=0.0001), anti-RO antibodies (OR 11.1; P=0.02), anti-LA (OR 4.7; P=0.03), chronic hypertension (OR 54.8; p=0.0001) and SLE flares (OR 32; P=0.0003). SLE flares occurred in 10 pregnancies (19.2%), mostly during the second trimester (60%). Renal involvement (70%) was the most common SLE flare during pregnancy. SLE flares during pregnancy were highly associated by nephritis prior to pregnancy (adjusted OR 9; P = 0.04) and the presence of antiphospholipid antibodies (adjusted OR 12; p=0.01).

**Conclusion:** Favorable pregnancy outcome was observed in Egyptian SLE patients; particularly in those with longer period of remission. Planned pregnancy is very important to reduce undesirable fetal and maternal outcomes in SLE patients. The presence of lupus nephritis, chronic hypertension, antiphospholipid syndrome, active disease at the onset of pregnancy, and proteinuria were highly associated with bad outcome.

[1] Yan Q, Du F, Huang X, Fu Q, Chen S, Dai D, et al. Prevention of immune flare may be life-threatening, and some of the medications that are used to treat SLE adversely affect fetus.[]
Objectives: Our objective here was to analyse a clinically well-phenotyped patients using a suite of immune assessments and identify inter-relationships between these features as well as subgroups of patients who may differ in response to therapy.

Methods: 143 SLE patients were evaluated for clinical phenotype using BILAG-2004, autoantibodies using radioimmunoprecipitation (IP, University of Bath), two interferon scores (IFN-Score-A and IFN-Score-B), flow cytometry for major circulating immune cell subsets, as well as the surface protein expression of tetherin on each subset, a cell-specific assay for IFN response.

Unsupervised hierarchical clustering was used to define autoantibody subgroups. IFN scores (reflected dCT) were compared between the groups using multivariate models. Other variables were compared using Kruskal-Wallis test with pairwise comparisons.

Results: Using IP, 141 patients could be divided into five subgroups: U1RNP/Sm only (n=23), Ro60+ only (n=8), U1RNP/Sm+Ro60+ (n=6), Ro60+Ro52+La (n=11), Ro52+ (n=16) and other ANA (n=77). Antibody subgroups was strongly associated with IFN-Score-A (F=4.39, p=0.001). Expression was lowest for “other ANA”, intermediate for single antibody groups, and highest with multiple positive antibodies. Multivariate linear regression, including interaction terms between antibody types, revealed that Ro60 and U1RNP/Sm were the independent predictors of IFN-Score-A level (p=0.051 and 0.009 respectively). There was no association between autoantibody status and IFN-Score-B (F=0.973, p=0.438).

In flow cytometry, the U1RNP/Sm group was notable for significantly lower numbers of CD4+T-cells and memory-B-cells. Memory B-cells were also lower in antibody-positive groups compared to “other ANA”. Tetherin expression was increased in antibody positive groups, but to a similar extent on most cell subsets. Memory B cell tetherin was significantly higher in the groups with multiple positive antibodies.

U1RNP/Sm+ was associated with renal involvement (p=0.004). Multicollinearity was greater in the Ro60+Ro52+La group (p=0.037).

Conclusion: This cohort revealed relationships between immune features. U1RNP/Sm antibody was notable for defining a group of patients with a cluster of immune abnormalities, including the greatest elevation of IFN activity, greater abnormalities on flow cytometry and clinical renal involvement. This was independent to the IFN-Score-B high status that predicts better clinical response to rituximab (presented elsewhere at this conference).

Future work in MASTERPLANS will investigate the significance of these subgroups for response to therapy.

Background: In Sjögren’s Syndrome (SS), ocular damage is mediated by inflammation induced by antibodies, enzymes, and other effectors that could be used as clinical indicators of the ocular surface damage. There is evidence suggesting that increased activity of matrix metalloproteinases (MMPs) is correlated with an increased ocular damage because of its potential inflammatory activity and could be used as a potential therapeutic target for dry eye.1,2 Very few studies have addressed the role between the ocular MMPs and the clinical parameters of SS.

Objectives: To determine the level of correlation between the serological profile of autoantibodies with ophthalmological parameters at the cornea level.

Methods: Cross-sectional, observational, and descriptive study. Sixty patients with a diagnosis of primary Sjögren’s syndrome (pSS) classified according to the ACR/EULAR 2016 criteria were included. The following measurements were made: Schirmer test, lacrimal osmolality, ocular staining score (OSS), and ocular surface disease index (OSDI) and metalloproteinase-9 (MMP-9) in tear and antibodies were measured in peripheral blood serum: RF isotypes (IgA, IgG, IgM), anti-SSA/Ro and anti-SSB/La proteinase-9 (MMP-9) in tear and antibodies were measured in peripheral serum: RF isotypes (IgA, IgG, IgM), anti-SSA/Ro and anti-SSB/La.

Results: Fifty-eight women participated (96.7%) with an average age of 53 years (±13.01) (Table 1). We found a positive correlation between OSS and RF-IgM (r=0.385 P<0.002), RF-IgA (r=0.256 P=0.049), and anti-Ro/SSA (r=0.302 P=0.019). We found a statistically significant association between the seropositivity of the Anti-SSA/Ro antibody and the presence of MMP-9 in tears (OR 4.38, CI 95% 0.877-21.92, P=0.057). A

Conclusion: A significant correlation was observed between serology, ocular surface damage (OSS), and ocular surface inflammation (MMP-9). The positivity of RF isotypes IgM and IgA could alert the clinician about the ocular damage to initiate a study directed to this organ. Nevertheless this present study shows preliminary outcomes, we need to enroll more patients to obtain better outcomes.

FR0221 CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME IN PREGNANCY: CASE SERIES

Nur Azizah Allameen, Aisha Lateef, Anita Yee Nah Lim, National University Hospital, Singapore, Division of Rheumatology, University Medicine Cluster, Singapore, Singapore

Background: Catastrophic antiphospholipid syndrome (CAPS) is a rare condition associated with high mortality. Prompt recognition and treatment is important for optimal outcomes. Clinical features of CAPS can overlap with obstetric complications, leading to diagnostic challenges.

Objectives: Describe two patients with CAPS during immediate post-partum period.

Methods: We report two cases in a single centre over two years.

Results: A 38 year old with obstetric Antiphospholipid syndrome (APS) presented with epigastric pain, transaminitis and thrombocytopenia in keeping with evolving HELLP syndrome. Spontaneous complete miscarriage ensued. Post-delivery, she developed worsening abdominal pain and transaminitis (Table 1). Imaging demonstrated hepatic infarcts and patchy ground glass lung opacities. She was treated for CAPS with intravenous steroids and anticoagulation, and recovered.

A 39 year old with primary APS (deep venous thrombosis and obstetric features) whose antenatal course was fraught with minor per vaginal bleeding (PVB) presented with heavy PVB at 22 weeks gestation requiring cessation of anticoagulation. She developed a deep venous thrombo sis. Risk of clot propagation versus bleeding prompted cautious anticoagulation. Labour was induced for declining maternal health and poor foetal prognosis at 24 weeks, 3 days. Post-delivery, she developed abdominal pain, headache, transaminitis and worsening thrombocytopenia with heavy PVB requiring uterine artery embolization. Given features that were consistent with micro thrombi and ischaemia (Table 1), she was treated as for CAPS and HELLP syndrome with intravenous steroids, plasma exchange (PLEX) and intravenous immunoglobulin (IVIG), and recovered.

FR0222 ANALYSIS OF CLINICAL AND SEROLOGICAL FEATURES OF PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME AND AN EARLY DISEASE ONSET AT AGE BEFORE 35 YEARS

Durania Aynnopoulou1, Andreas Goules1, Evangelia Zampeli1, Maria Mavromati1, Clio Mavragani1,4, Fotini Skopouli3,5, Haralampos M. Moutsopoulos1,2 6,

Method: Patients with primary SS (pSS) fulfilling the 2002 revised European/American International classification criteria for SS, were evaluated. The study group included 133 patients with disease onset ≤35 years old (mean disease duration, range: 10–32 years; group A) matched at 1:1 ratio according to gender and disease duration with 133 pSS patients with middle-age onset (mean disease duration, range: 10–32 years; group B) and 133 pSS patients with elderly onset (mean disease duration, range: 10–32 years; group C) matched at 1:1 ratio according to gender and disease duration.

Background: Primary Sjögren’s Syndrome (pSS) is a chronic systemic autoimmune disease with diverse clinical picture, extending from exocrinopathy to systemic disease and non-Hodgkin’s lymphoma (NHL). Usually, it affects middle aged women, but early disease onset (<35 years old) has been also observed. So far, there is a limited number of studies to explore whether the age of SS onset affects the clinical SS phenotype. To definitely answer this question a well-organized, large, harmonized cohort of patients with a continuous follow up is needed, through the ongoing European project (HarmonicSS, grant agreement no: 731944).

Objectives: To investigate whether the clinical and serological picture of pSS patients with early disease onset (<35 years old) differs to that of middle-age onset.

Methods: Medical records of 717 pSS patients, included in two Greek cohorts fulfilling the 2002 revised European/American International classification criteria for SS, were evaluated. The study group included 133 patients with disease onset ≤35 years old (mean disease duration, range: 10–32 years; group A) matched at 1:1 ratio according to gender and disease duration with 133 pSS patients with middle-age onset (mean disease duration, range: 10–32 years; group B) and 133 pSS patients with elderly onset (mean disease duration, range: 10–32 years; group C) matched at 1:1 ratio according to gender and disease duration.
age at disease onset 52±5 years; median disease duration, range: 10, 0-30; group B). Clinical and laboratory data were collected through an extensive clinical chart review. All parameters were compared by chi-square or Fisher's exact test, when appropriate.

Results: The two pSS groups had similar frequencies of non-specific clinical findings (chronic fatigue, arthralgias/myalgias, arthritis, Raynaud's phenomenon), peri-epithelial manifestations (interstitial nephritis, lung and liver disease), splenomegaly, leukocytopoiesis and neutrophil counts. However, patients with disease onset <35 years old, exhibited increased proportion of salivary gland enlargement (SGE; 43.8% vs 25.4%, p<0.003), lymphadenopathy (18.2% vs 7.6%, p=0.016), palpable purpura (20.3% vs 9.8%, p=0.025), anti-Ro/SSA antibodies (90.2% vs 74%, p=0.001), rheumatoid factor positivity (73.3% vs 53.6%, p=0.002), low C4 levels (64.5% vs 42.4%, p<0.001) and NHL (18% vs 8.3%, p=0.038).

Conclusion: Our findings suggest that young patients with pSS display increased prevalence of systemic features, B cell hyperreactivity, as well as heightened risk for lymphoma development. Further prospective studies with a larger number of patients are needed to address whether early disease onset may also serve as an additional risk factor for NHL development.

FRIO224

EXTRACELLULAR VESICLES AS A SOURCE OF BIOMARKERS IN SJÖGREN SYNDROME: A SWATH-MS PROTEOMIC APPROACH

Chiara Baldini1, Francesco Finamore2, Francesco Ferro3, Marta Mosca1, Stefano Bombardieri1, Silvia Rocchiccioli3, Antonella Cucchetti3, 1University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; 2Institute of Clinical Physiology, CNR, Pisa, Italy

Background: Primary Sjögren’s syndrome (pSS) is a multifactorial autoimmune disorder characterized by lymphocytic infiltration of the exocrine glands. In the recent past several proteomic studies attempted to look at valid biomarkers for pSS in whole saliva, however little is known about the composition of salivary extracellular vesicles (EVs), nor to what extent their content may reflect the phenotypic state of the disease.

Objectives: In this study, we search for pSS specific biomarkers by using a sequential window acquisition of all the theoretical fragment ion spectra (SWATH-MS) approach to monitor the dynamics of saliva EVs sub-proteome of pSS patients compared to healthy controls.

Methods: We included patients with a diagnosis of pSS made according to the AECG 2002 criteria and healthy volunteers as controls. Saliva was collected under standardized conditions. EVs were enriched by sequential ultracentrifugation steps from saliva samples. Peptide identification and quantification was performed by matching SWATH-MS data against an assay library of MS/MS spectra created from a previously acquired data-dependent acquisition (DDA) method. GO terms and protein-protein interaction network analysis were performed using Cytoscape software.

Results: We included 20 pSS patients (AECG 2002 criteria) and 10 healthy subjects. Quantitative data evidenced a distinct separation between the patient group and control group, indicating that pSS may modulate the phenotype of protein cargoes of salivary EVs. The majority of the proteins up-regulated in pSS compared to controls were found to be involved in several inflammatory processes. Particular emphasis was given to proteins converging to IL-12 signaling that included annexin A2, coflin, macrophage migration inhibitory factor (MIF), S100A8-A9 and plasmin-2 proteins.

Conclusion: Our results revealed that the inflammatory phenotype observed in pSS patients is also extended to salivary EVs, which protein content may represent a novel source for potentially useful biomarkers for pSS.

FRIO224

PREVALENCE OF SJÖGREN'S SYNDROME IN THE COMMUNITY OF MADRID

Jaimie Barrio Cortés1, Tomás Gómez Gascon1, M1 Dolores Esteban Vasallo1, Isabel Del Cura Giraldez1, Juan Antonio López Rodriguez2, Ana Clara Zoni3, María Felicitas Domínguez Berjón2, “Fundación de Investigación e Innovación Biomédica de Atención Primaria, Madrid, Spain; Dirección General de Salud Pública, Madrid, Spain; Unidad de Apoyo a la Investigación de la Gerencia de Atención Primaria, Madrid, Spain

Background: Several studies on the epidemiology of autoimmune diseases performed within the past several decades revealed a prevalence of Sjögren Syndrome (SS) between 0.3% and 4.83% (1). More recent studies revealed a lower prevalence between 31/100,000 to 49/100,000 (2). The exact prevalence of SS is unknown due to the heterogeneity of the populations and geographic areas studied, the utilization of different diagnostic tests or the lack of a unique classification criteria for the disease. Also, the disease may have an insidious onset and a variable course with a broad spectrum of clinical manifestations, so the diagnosis may be delayed or SS patients may be missed and misclassified as other rheumatic disease. Besides, SS can occur alone (primary SS) or in association with other specific systemic autoimmune rheumatic diseases (secondary SS).

Objectives: The aim of our study was to determine the prevalence of SS in the Community of Madrid (CM) and to describe the sociodemographic and clinical characteristics of these patients.

Methods: Population-based cross-sectional study in the CM, Spain. The information source for SS cases was the Registry of rare diseases in the CM (SIERMA). A descriptive analysis of the main sociodemographic and clinical characteristics of SS cases was performed. Prevalence per 10,000 inhabitants in people with 18 years of age and over, stratified by sex and their 95% confidence intervals (CI) were calculated for 2015. The denominator was the population registered in the Population Register in the middle of the period (July 2015).

Results: There were 4,778 cases of SS in SIERMA and 389 (8.1%) of them were already dead. 4434 (92.8%) were women. The median age was 64.7 years (15,4), and the maximum age was 103 years. The disease was most frequent in the sixth decade with 1079 cases (22.6%), in the seventh decade with 1120 cases (23,4%) and in the eighth decade with 935 cases (19.6%). 3116 cases (65,2%) were classified as primary SS (pSS) and 1662 (34.8%) as secondary SS (sSS).

Among the sSS the main rheumatological conditions associated were rheumatoid arthritis (58%), lupus (24,5%), systemic Sclerosis (10,5%); peripheral connective tissue (4%), inflammatory muscle disease (2%) and vasculitis (1%). The prevalence of SS in adults (≥ 18 years of age) was 8.4/10,000 with a 95% CI: 8.2 – 8.7 (14.9% in women and 0.8% in men). The prevalence of pSS was 5.9/10,000 (CI 5.3 – 5.7) and for sSS was 2.8/10,000 (95%CI: 2.7-3).

Conclusion: SS mainly affects females during the sixth, seventh and eight decades of life, and shows a female:male ratio of 9:1. Two out of three cases of SS identified were classified as pSS. The main rheumatological conditions associated were rheumatoid arthritis and lupus. The estimated prevalence of SS in the Community of Madrid population is lower than the observed in previous studies whereas the prevalence of pSS is similar than the observed in current studies.

THE EULAR/ACR 2018 AND SLICC 2012 HAVE INCREASED SENSITIVITY AGAINST THE ACR 1997 CLASSIFICATION CRITERIA AND CLASSIFY NON-OVERLAPPING GROUPS OF SLE PATIENTS: SIMULTANEOUS APPLICATION ASSURES THE GREATEST CAPTURE OF PATIENTS IN CLINICAL PRACTICE

Christina Adamichou1, Dionisis Nikolopoulos2, Irini Genitsarid1, Alessandra Bortoluzzi4, Antonis Fanouriakis2, Emmanouil Papastefanakis1, Eleni Kalogiannaki1, Irini Gergianaki1, Prodomos Sidiroupulos1, Dimitrios Bourtouzas1, George Bertsias1, 1Rheumatology, Clinical Immunology and Allergy, University of Crete, Heraklion, Greece; 2Rheumatology Clinic, University Hospital and BRFAA, Athens, Greece; 3Institute of Computer Science, Foundation for Research and Technology Hellas (FORTH), Heraklion, Greece; 4Section of Rheumatology, University of Ferrara, Cora (FE), Italy

Background: A joined EULAR/ACR initiative has proposed a new set of classification criteria for SLE based on weighted items and the use of ANA as an entry criterion.

Objectives: To compare the diagnostic performance of the old and new classification criteria against physician diagnosis in an early SLE cohort and examine phenotypic and prognostic differences among patients who are classified with the criteria.

Methods: Adult patients diagnosed by experienced physicians with SLE were classified with the criteria. Hazard models were used to calculate elapsed time between the earliest item (of any criterion) and classification. Severity of SLE (BILAG-2004 glossary) and the SLICC/ACR organ damage index were determined.

Results: The SLICC and EULAR/ACR had increased overall sensitivity as compared to the ACR criteria (91.3%, 88.6%, 85.7%, respectively; p<0.01), especially in early-onset (<3 years) disease (91.4%, 87.3%, 79.9%, respectively; p<0.001), with comparable specificity rates (ranging 91.0–92.7%). By combining the three criteria sets, 97.1% of patients were classified. Both the EULAR/ACR and the SLICC enabled earlier SLE classification (median time-to-classification: 7.1 and 7.6 months, respectively) than the ACR criteria (median 9.1 months). Nevertheless, disease classification was delayed by >3 months in 17.3–19.9% of cases, particularly in neurological SLE (20.0–26.8%). Comparative analysis of patients who were missed by the criteria revealed significant differences in rates of individual clinical and serological features (Table 1) suggesting that existing criteria may classify non-overlapping groups of patients. Importantly, unclassified patients presented with a high prevalence of moderate/severe disease (43.3–60%) and organ damage (30–50%).

Conclusion: Despite improved sensitivity and earlier classification with the EULAR/ACR and the SLICC criteria, still SLE diagnosis may be missed or delayed even in patients with moderate to severe disease, especially neurological-dominant disease. Simultaneous application in clinical practice assures the greatest capture of patients.

Disclosure of Interests: None declared

LOW EXPRESSION OF ESTROGEN RECEPTOR BETA IN RENAL TUBULAR EPITHELIAL CELL MAY CONtribute TO HYPERURICEMIA IN PREMENOPAUSAL STATES OF AMERICAN FEMALE SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Haifan Liu1,2, Xiaoyan Cai3,4, Lie Da5, MA Jianda6, Yingqian Mo7, Minyan Xie1
1Panyu Central Hospital, Department of Rheumatology, Guangzhou, China; 2Jinan University, Guangzhou, China; 3Guangzhou First People’s Hospital, Department of Rheumatology, Guangzhou, China; 4The Second Affiliated Hospital of South China University of Technology, Guangzhou, China; 5Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

Background: We have reported that the incidence of hyperuricemia of young female systemic lupus erythematosus (SLE) patients was higher than that of healthy young women11. Whether the estrogen receptor (ER) expressed in renal tubular tissue contributes to it? There are few reports yet.

Objectives: To investigate the expression of ERs in the renal tubular cells and their relationship with serum uric acid (UA) levels in premenopausal female SLE patients.

Methods: Eighteen kidney biopsy specimens of premenopausal female SLE patients served as the lopus nephritis group (LN group), and 12 specimens of premenopausal female IgA nephropaty patients served as the IgA group. Serum UA levels and kidney index were collected, and the expression of ERs in the renal tubular epithelial cell of the two groups were determined by immunohistochemistry. According to the
percentage of the positive stained cells, the semiquantitative analysis was made. The expressions of ERs, including ERα and ERβ, of the two groups were compared, and the relationship between the expression of ERs and serum UA levels were analyzed with linear regression analysis.

Results: 1. The mean ages of the LN group and the IGA group were 27.39±8.09 years and 33.08±5.45 years, respectively, with significantly different (t=-2.128, P=0.042). There was no renal failure subject in both groups (CRE level above 120 mol/l), and all the SLE patients were at stage of onset.

2. Mean UA level of the LN group was significantly higher than that of the IGA group (t=-3.149, P=0.004), and the CRE level of the two groups were similar (t=-0.109, P=0.914) (table 1).

3. In each group, ERβ was well expressed in the tubular epithelial cells, and no in kidney glomeruli. In contrast, ERα was not expressed in the renal tissues of both groups (figure 1).

4. The median score of ERβ expression in the LN group was remarkable lower than that of the IGA group (z=-2.080, P=0.038, table 1).

5. Linear regression analysis indicated that ERβ expression scores of the total 30 patients had significantly negative correlation with serum UA levels (r=-2.141, P=0.041, table 2).

Conclusion: 1. Low expression of ERβ in renal tubular epithelial cell may contribute to hyperuricemia in premenopausal female SLE patients, association with potential or existing renal damage. Eur J Innflamn,2018;16:1-6.

prevalence of pulmonary involvement, including interstitial lung disease (ILD), in patients with primary SS widely varies from 8% to 20%. Patients with SS with ILD have high morbidity and a fourfold increase in mortality.

Objectives: Krebs von den Lungen-6 (KL-6) is a mucin-like, high-molecular-weight glycoprotein; it is expressed in regenerating type II pneumocytes. Serum KL-6 is highly associated with the activity of ILD in patients with radiation pneumonitis, idiopathic pulmonary fibrosis, hypersensitivity pneumonitis, sarcoidosis, rheumatoid arthritis, polymyositis, dermatomyositis and systemic sclerosis. The increase in serum KL-6 level might reflect the increase in the number of regenerating type II pneumocytes secondary to pulmonary damage. We hypothesise that an early pulmonary damage occurs before clinical or radiological evidence of ILD in patients with SS.

Methods: In this retrospective case-control study, patients who were diagnosed with primary SS and fulfilled the American-European Consensus Group Criteria for Sjögren’s Syndrome were included. Clinical information, laboratory results on inclusion, images and pulmonary functions test results were recorded via electronic medical records review. Pulmonary radiography including chest X-ray and chest computed tomography was reviewed by a chest physician.

Results: Of the 39 patients with SS, 21 (53.85%) developed ILD at the end of follow-up. The follow-up period was 2.65 ± 1.88 years. The time to diagnosis of ILD was 2.72 ± 1.74 years in the ILD group. The serum KL-6 level was 1920.10 ± 1974.26 U/ml in the ILD group and 894.11 ± 788.53 U/ml in the non-ILD group (p = 0.001). The diffusing capacity of the lungs for carbon monoxide was 70.76 ± 19.63 ml/min and 91.88 ± 12.02 ml/min in the ILD group and non-ILD group, respectively (p < 0.001).

Conclusion: Serum KL-6 level is significantly higher in patients with primary SS developing ILD and may represent an early non-radiographic pulmonary damage. Serum KL-6 can be a valuable biomarker in predicting the development of ILD in patients with primary SS.

**Objectives:** Determine prevalence of MIN in SLE (LLC). Compare clinical and echocardiographic (echo) features of patients with and without MIN. Identify echo predictors of MIN.

**Methods:** A prospective cross-sectional study was done at Tygerberg Hospital, Western Cape, South Africa. Adult inpatients, fulfilling the 2012 SLICC criteria were screened. Echo analyses included STE and regional function (wall motion score (WMS)). Patients were grouped according to evidence of MIN (absent criteria [AC]; single criterion [SAC]; fulfilling LLC), comparing clinical, laboratory and echo data. Logistic regression and ROC were used to determine predictors of MIN.

**Results:** 49/106 SLE patients screened were included (Figure 1). 46.9% of patients had MIN (≥1 criterion); 12.2% fulfilled LLC for LM and 34.7% had a SAC. SLE disease activity (SLEDAI) (p=0.047) was higher in patients fulfilling LLC, but not in the SAC group. A clinical and echo diagnosis of LM was made in all patients fulfilling LLC, in 17.6% of patients in the SAC group and none in the AC group (Table 1). Anti-DsDNA and anti-B2GP1 were more frequently positive in SAC vs the AC group (p=0.054 and 0.081). WMS was higher in LLC and SAC groups (p=0.006 p=0.083) with mid and basal STE more impaired in patients with MIN (p=0.047 p=0.043). LVIV and mid STE score combined was the best predictor of MIN (Table 2; Figure 2).

**Conclusion:** CMR evidence of MIN is common in SLE, even in the absence of clinical myocardial dysfunction or high lupus activity. Impaired echo regional and global function occurs more frequently in patients with MIN. STE combined with LVIV predicts MIN detected by CMR and has potential as a cost effective screening tool. CMR is limited by a high exclusion rate in SLE, mainly due to renal impairment.

PATIENT PERCEPTION OF SLE BURDEN: THE ROLE OF ORGAN DAMAGE

Elena Elefante1,2, Chiara Tani3, Francesco Ferro1, Chiara Stagnaro3, Alice Parma1, Linda Carl1, Viola Signorini1, Marta Mosca1, University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; 2University of Siena, Department of Medical Biotechnology, Siena, Italy; 3AOU Pisana, Rheumatology Unit, Pisa, Italy

Background: physician-based assessment of Systemic Lupus Erythematosus (SLE) may not be able to capture the real disease impact on patients’ life. In the literature, the impact of disease damage on patients’ quality of life (QoL) is controversial.

Objectives: Objective of our study was to investigate the role of organ damage in determining patient perception of SLE burden.

Methods: this is a cross-sectional study that enrols patients with a diagnosis of SLE (ACR 1997 criteria). For each patient, demographics, comorbidities, treatment, clinical and laboratory data were collected. Disease damage was evaluated with the SLICC-Damage Index (SDI) and a score >2 was defined as “severe damage”. The BILD (Brief Index of Lupus Damage) was used for patient self-evaluation of organ damage. Finally, the Lupus Impact Tracker (LIT) questionnaire was used to assess patient perception of SLE burden.

Results: we included 246 adult SLE patients (94.7% Caucasian, 93.1% female, mean age 45.3±13.2 years, mean disease duration 14.3±9.8 years). As for cumulative organ involvement in our cohort, the most prevalent was articular involvement (67.5%), followed by cutaneous (54.1%), hematological (51.2%), renal (43.9%) and serositis (17.9%); 11.8% had a history of NPSLE. Among comorbidities, 10.9% of patients had a concomitant fibromyalgia. 48.8% of patients was presenting at least one organ damage; among those patients, the median SDI was 2 (IQR 1-3); 16.3% of patients had a “severe damage” and among them median SDI was 4 (IQR 3-6). The most frequent items of organ damage in our cohort were: cataract (19.9%), deforming or erosive arthritis (10.2%) and osteoporosis with fracture (8.5%). Moreover, a significant number of patients (18.3%) met the criteria for neuro-psychiatric damage, mainly cerebrovascular accidents (7.3%), seizures (5.3%) and cognitive impairment (4.1%). Finally, a not negligible number of patients had premature gonadal failure (4.5%) and malignancy (6.5%).

As far as patients’ perception is concerned, the median LIT score in the cohort was 22.5 (IQR 7.5-40) and median BILD was 1 (IQR 0-2).

In a multiple linear regression analysis, we found a direct positive correlation between the SDI score and age at enrollment and disease duration (p<0.001). Severe damage resulted associated with a history of serositis (p=0.01) and NPSLE (p=0.001). We also found a positive linear correlation between the SDI score and the patient’s self-reported damage (BILD score; p=0.001) and with the patient’s perception of disease burden (LIT; p<0.01), irrespective of age and disease duration. In particular, in the multivariate analysis, higher SDI scores were significantly associated with a poorer perception of disease burden in terms of: future planning (p<0.001), usual activities, family responsibilities, discomfort due to physical appearance (p<0.01) and drug side effects (p<0.05), irrespective of fibromyalgia and age at enrollment.

Among the different types of organ damage, we found that cognitive impairment, cerebrovascular accidents and premature gonadal failure mainly contributed to determine SLE burden. In fact, they were significantly associated with higher LIT scores (p<0.05).

Conversely, SDI score was not related with health-related quality of life and fatigue as measured by SF-36 and FACIT respectively, neither with fibromyalgia.

Conclusion: disease damage seems to have a role in determining patient perception of SLE burden, mainly affecting patients’ ability to plan the future and to fulfill daily activities and family responsibilities. In particular, neuropsychiatric damage exerts the greatest influence on patient perception of SLE impact.

MORTALITY IN SLE PATIENTS COMPARED TO POPULATION CONTROLS IN FINLAND IN YEARS 2000–2015

Pia Elbing1, Hannu Kautiainen2,3,4, Laila Virta5, Olli Kaijser-Hepponen6, Kari Puzakka7, Kuopio University Hospital, Department of Medicine, Kuopio, Finland; 2Helsinki University Central Hospital, Unit of Primary Health Care, Helsinki, Finland; 3University of Helsinki, Department of General Practice, Helsinki, Finland; 4Kuopio University Hospital, Unit of Primary Health Care, Kuopio, Finland; 5Social Insurance Institution, Research Department, Turku, Finland; 6Kuopio University Hospital, Department of Medicine, Kuopio, Finland; 7South Karelia Central Hospital, Department of Medicine, Lappeenranta, Finland

Background: It is well established from a variety of studies that systemic lupus erythematosus (SLE) patients have a shortened life expectancy. The literature on SLE has highlighted the impact of cardiovascular diseases (CVD) on increased mortality. However, there is lack of studies comparing results to the background population.

Objectives: Aim of the study was to clarify, whether incident SLE patients have an excess mortality compared to population controls.

Methods: The study included all adult (age >17 years), incident, SLE patients who were entitled to a special reimbursement for SLE medication in years 2000 – 2014 in Finland. For each patient, the Population Registry Centre identified 3 population controls matched for age, sex and place of residence. Comorbidities at baseline were obtained from the Care Register for Health Care of the National Institute for Health and Welfare. Data on education at baseline and deaths until the end of 2015 were retrieved from the Statistics Finland.

Results: A total of 1006 incident SLE patients (84% females) and 3005 population controls were found. During the follow-up (mean 8.8 years), 98 patients (mean age at death 70±14 years, 65% females) died. The 5-, 10-, and 15-year survival rates in SLE patients were 95.0% (95%CI 93.9-96.2%), 88.8% (86.2-91.0%) and 82.1% (77.9-85.8%), respectively. The number of deaths among controls was 187. Crude hazard ratio (HR) was 1.61 (95% CI: 1.26 to 2.06), p=0.001, adjusted for education and comorbidities 1.14 (95% CI: 0.88 to 1.48) p=0.32. Main causes of deaths in patients were CVDs (33%), malignancies (27%) and neurological diseases (10%). Ten-year cumulative mortality rate due to CVD was in SLE patients 3.3% (95CI 2.2 to 4.9%) and in controls 2.6% (2.0-3.3) and 15-year rate 6.7% (95%CI 4.2 to 9.8) and 4.9% (3.6 to 12.0), respectively. Crude HR for CVD deaths was 1.28 (95% CI: 0.85 to 1.93), p=0.34, adjusted 0.88 (95% CI: 0.56 to 1.39), p=0.05.

Conclusion: SLE patients had a slightly increased risk for overall and cardiovascular related mortality compared to population controls. After adjusting for education and comorbidities, the difference was not statistically significant.

Disclosure of Interests: Pia Elbing Speakers bureau: Mylan Finland Oy, Abbvie Oy, UCB Pharma Oy Finland, Hannu Kautiainen: None declared, Laila Virta: None declared, Olli Kaijser-Hepponen: Speakers bureau: Boehringer Ingelheim, Karl Puzakka: None declared
### FACTORS ASSOCIATED WITH THE DEVELOPMENT OF NEOPLASIA IN PRIMARY SJÖGREN’S SYNDROME

Monica Fernandez Castro1, Carlos Sánchez-Piedra2, José Luis Andreu1, Jose Rosas3, Victor Martínez Taboada4, Alejandro Olivé5, Hospital Puerta de Hierro Majadahonda, Rheumatology, Madrid, Spain; 2Research unit of the Spanish Society of Rheumatology, Madrid, Spain; 3Hospital Marina Baixa, Rheumatology, Alicante, Spain; 4Hospital Marqués de Valdecilla, Rheumatology, Santander, Spain; 5Hospital Germans Trias i Pujol, Rheumatology, Barcelona, Spain

**Background:** Primary Sjögren’s syndrome (pSS) is characterized by lymphocytic infiltration of the exocrine glands. These patients have a higher risk than the general population of developing non-Hodgkin lymphoma (NHL). This risk also increases with the time of evolution of the disease. pSS is also associated with the development of non-hematological cancer such as thyroid, digestive or gynecological among others.

**Objectives:** The aim of the study is to explore the association between the development of neoplasia and demographic, clinical or therapeutic factors in pSS.

**Methods:** The SJOGREN registry is a multicenter, cross-sectional study of patients with pSS who meet the American-European consensus criteria of 2002, of 33 Spanish rheumatology units. The demographic, clinical, analytical, therapeutic and neoplastic data were collected through review of the clinical records and interviews with the patients. Previously, all the patients signed informed consent and the approval of the local ethic committees was obtained. Descriptive statistics was used for the analysis of the data. The chi-squared test was used to establish the statistical associations and it was considered a $p<0.05$ as significant. Bivariante logistic regression models were used to identify the effect of each independent variable on the main variable (neoplasia); the multivariate analysis was used to establish the independent effect of the patient characteristics associated with the dependent variable.

**Results:** Four hundred and thirty-seven patients were included in SJOGREN-SEr Registry (female gender 95.19%; median age 58.3 years). We found 30 patients (6.86%) with neoplasia (3 of them with more than one neoplasia); 7 with lymphomas (23.3%); 2 Hodgkin’s lymphomas, 1 immunocytoma, 9 with gynecological neoplasia (30%), 2 with digestive malignancies, 2 with lymphomas, 6 with malignancies in other locations, 3 with multiple myeloma and 2 patients with Waldenstrom macroglobulinemia. The results of the bivariate analysis are shown in the table. The factors significantly associated with the development of neoplasia were older age, glandular inflammatory involvement, lung involvement and use of rituximab. The age at diagnosis of the disease tended to be higher in the group with neoplasia (50.1 (± 12.9) vs 54.7 (± 11.7), $p = 0.059$). In the multivariate analysis, positive associations with neoplasia included for this analysis 345 patients with an active follow-up, 31 males and 314 females, with a male to female ratio of 1:10. A higher number of male had male disease onset (13% vs 1.6%) and diagnosis (16% vs 1.6%) after 60 years compared to female ($p=0.001$; OR 9.1; 95% CI 1.92-42.56 and $p<0.0001$; OR 11.8; 95% CI 2.73-51.56 respectively). The most relevant differences among male and female patients are reported in the table 1. Males more frequently presented discoid lesions, renal involvement, polyneuropathy and leukopenia compared to female SLE. No difference regarding disease activity during the last 12 months measured by SLEDAI was found. Regarding the damage index, males showed a higher mean SDI and number of patients with a severe damage (SDI>2) compared with women. Analyzing treatment prescribed since the diagnosis of SLE we collected some relevant differences: antimarial were less prescribed in males than females (87% vs 97%, $p=0.02$; OR 0.19; 95% CI 0.051-0.825), whereas mycophenolate mofetil was more frequently used in males (69% vs 36%; $p=0.005$ OR 3.0 95% CI 1.13-6.8). Finally, significant differences regarding the ongoing treatment are reported in table 1: mycophenolate mofetil was more frequently prescribed in males (84.2 vs 25.6) and a highly suggestive trend of significance toward a greater use of steroids in males was also found.

**Conclusions:** Thirty (6.86%) patients with pSS from the SJOGREN registry developed some neoplasia; the most frequent was gynecological, followed by lymphoproliferative processes. Older age, glandular inflammatory involvement and use of rituximab (presumably indication bias) were associated with the presence of neoplasia.

### DIFFERENCES BETWEEN MALE AND FEMALE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A SINGLE CENTER EXPERIENCE OVER 20 YEARS OF FOLLOW-UP

Micaela Fredi1,2, Federica Tomasoni1, Laura Andreoli1,2, Ilaria Cavazzana1, Angela Tincani1,2, Franco Franceschini1,2, U.O. Rheumatology and Clinical Immunology, ASST Spedali Civili di Brescia, Brescia, Italy; 2Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy

**Background:** Systemic lupus erythematosus (SLE) is a chronic inflammatory disease of unknown etiology involving multiple organ systems. It affects predominantly women, and according to different reports only 4–22% of the lupus population is male. Sex differences may influence the clinical and serological expression, therapy and outcome, but the current results varies among different countries and different ethnic groups (1-3).

**Objectives:** The aim of this work was to analyze our male and female SLE patients with an ongoing follow-up.

**Methods:** Cumulative clinical, serological manifestations, concomitant diseases of patients belonging to the historical SLE cohort with at least one evaluation in the past 15 months were collected from clinical charts. For these patients data regarding the overall and ongoing treatments, damage index (SDI), activity index (SLEDAI-2K) during the last 12 months were collected. For statistical analysis was used Chi-squared test, Fisher exact test, Student T test or Wilcoxon-Mann Whitney when appropriated.

**Results:** Out of the 550 SLE patients registered until may 2018 we have included for this analysis 345 patients with an active follow-up, 31 males and 314 females, with a male to female ratio of 1:10. A higher number of male had male disease onset (13% vs 1.6%) and diagnosis (16% vs 1.6%) after 60 years compared to female ($p=0.001$; OR 9.1; 95% CI 1.92-42.56 and $p<0.0001$; OR 11.8; 95% CI 2.73-51.56 respectively). The most relevant differences among male and female patients are reported in the table 1. Males more frequently presented discoid lesions, renal involvement, polyneuropathy and leukopenia compared to female SLE. No difference regarding disease activity during the last 12 months measured by SLEDAI was found. Regarding the damage index, males showed a higher mean SDI and number of patients with a severe damage (SDI>2) compared with women. Analyzing treatment prescribed since the diagnosis of SLE we collected some relevant differences: antimarial were less prescribed in males than females (87% vs 97%, $p=0.02$; OR 0.19; 95% CI 0.051-0.825), whereas mycophenolate mofetil was more frequently used in males (69% vs 36%; $p=0.005$ OR 3.0 95% CI 1.13-6.8). Finally, significant differences regarding the ongoing treatment are reported in table 1: mycophenolate mofetil was more frequently prescribed in males (84.2 vs 25.6) and a highly suggestive trend of significance toward a greater use of steroids in males was also found.

**Conclusion:** Our study confirmed the presence of differences between male and female SLE patients, both on clinical manifestations and also during the disease course. Our results on currently followed male SLE confirmed that these patients have a more severe disease, in particular with renal or neurological manifestations, that could justify the higher use of mycophenolate mofetil and the higher SDI compared to female SLE.

MIGHT A 12-WEEK AEROBIC EXERCISE INTERVENTION IMPROVE PATIENT-REPORTED OUTCOMES IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS?

Blanca Gavilán Carrera1, Jose Antonio Vargas-Hitos2, Pablo Morillas-de-Laguno1, Franco Franceschini: None declared, Laura Andreoli: None declared, Ilaria Cavazzana: None declared, Micaela Fredi: None declared, Federica Tomasoni: None declared, Gabriela Hernandez-Molina, Carlos Castréjon-Morales, Omar Granados-Portillo, Ivette Cruz-Bautista, Narly Ruiz-Quintero, Ililana Manjarrez, Diego Hernández-Ramírez, Guadalupe Lima, Miguel Astudillo-Angel, Luis Lorrente. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: Despite the relevant advance in treatment options and survival rates in systemic lupus erythematosus (SLE), patient’s quality of life (QOL), and other patient-reported outcomes (PROs) do not seem to improve accordingly [1]. PROs provide valuable information about the patient’s perceptions across a variety of domains that should be considered in a successful management of this condition [2]. Exercise seems to be a safe way to improve cardiopulmonary fitness [3], and could have also a positive influence on PROs in SLE.

Objectives: To evaluate the effects of 12-week aerobic exercise intervention on PROs (QOL, depression, stress, and fatigue) in women with SLE.

Methods: These are secondary outcomes of a non-randomized clinical randomized Controlled Trial (NCT03107442). A total of 58 participants with SLE were assigned to exercise group (n=26) or control group (n=32). The exercise intervention followed the American College of Sports Medicine guidelines, and consisted of 12-week progressive aerobic exercise on a treadmill (3 sessions/week) between 40%-75% of the individual’s heart rate reserve [3]. Attendance of ≥75% was set for inclusion in the analyses. The control group received verbal information about a healthy lifestyle. At baseline, and at week 12, PROs were assessed including the physical and mental summary scores of the 36-item Short-Form Health Survey (SF-36), depression (Beck Depression Inventory; BDI-II), perceived stress (visual analogue scale) and fatigue (Multidimensional Fatigue Inventory; MFI-20). A total of 49 women with SLE (age: 44.5±14.2 years) completed all the assessments (exercise=21; control=28) and were included in the per-protocol (primary) analyses. The exercise and control group were comparable in age, disease duration and SLE activity, sociodemographic characteristics, and BMI at baseline, although there were differences in BDI-II scores. Baseline values and BDI-II values were used as covariates in the analyses.

Results: In comparison to the control group, the exercise group showed a significant reduction in general fatigue (mean difference -2.11 units; 95% CI -4.18 to -0.04; P= 0.046) and physical fatigue (mean difference -3.90 units; 95% CI -6.3 to -1.5; P= 0.005) following the intervention. There were no between-group differences in the changes from baseline to week 12 either in physical (P=0.828) or mental (P=0.767) QOL, depression (P=0.498), perceived stress (P=0.247) or other fatigue dimensions (mental, reduced motivation, reduced activity, all P>0.05).

Conclusion: The results of this study suggest that 12 weeks of progressive aerobic exercise might improve relevant dimensions of fatigue in women with SLE, despite absence of effects on QOL, depression or perceived stress.

REFERENCES:

Background: Patients with systemic lupus erythematosus, especially lupus nephritis (LN), have higher risk of thrombosis than the general population. Since use of corticosteroids also increase the risk of thrombosis, the risk of thrombosis (SPT) may increase the risk of thrombosis in patients with LN. However, few studies examined this association.

Objectives: To compare risk of thrombosis between patients with and without SPT in LN.

Methods: This retrospective, propensity score-matched cohort study was conducted using claims data provided by Medical Data Vision Co., Ltd (Tokyo, Japan). We defined individuals as LN cases if they met all of the following: 1) were diagnosed as LN; 2) had a dose of corticosteroids (CS) over 30 mg/day during hospitalization between April 2009 and January 2018; 3) were 16 years old or over. Cases with central neurological lupus, alveolar hemorrhage, or pregnancy at baseline were excluded. Cases with plasmapheresis or antplatelet therapies at the start of observation, warfarin within a year, direct oral anticoagulants within a month, major surgery or lower limbs operation within three months, past thrombosis within a year, and prophylactic treatment of thrombosis from the observation starting month were also excluded from the study population. LN cases were divided into 2 groups; receiving SPT (SPT group, n=692) or not receiving SPT (non-SPT group, n=525). The start of observation was defined as commencement of CS treatment during hospitalization. Observation stopped either on April 2018 or the month cases were withdrawn from the database or developed first thrombosis, whichever came first. Thrombosis was defined as follows: at least one of three disease names (thrombosis, embolisms and infarction) and prescription of thrombosis within a year, and prophylactic treatment of thrombosis from the observation starting month were also excluded from the study population. The mean age of the patients was 55.7 years, and twenty (50%) were male. The underlying rheumatic diseases and PCP between October 2015 and October 2018 in a tertiary referral center. PCP was diagnosed via a positive sputum Pneumocystis jirovecii PCR in the presence of a compatible clinical presentation. The clinical characteristic, underlying rheumatic diseases, comorbidity, immuno-suppressants, adjunctive glucocorticoid dose, and outcome were evaluated. Chest X-ray (CXR) was evaluated as a radiographic score (0-18), and a higher score suggested a more severe lung involvement. The prognostic factors of mortality were analyzed by multivariate logistic regression model.

Results: The annual rate of thrombosis was 12.8% in LN cases. The mean age of the patients was 51.7 years and the proportion of female was 76%. There were no statistically significant differences in baseline variables between the two groups after propensity-score matching (both groups; n=434). The percentage of cases with thrombosis in both groups at each month were similar (SPT vs non-SPT at Month 1, 2, 3, and 4: 3.0% vs 4.4% (p=0.28), 3.5% vs 5.1% (p=0.24), 3.9% vs 5.3% (p=0.331), and 4.6% vs 5.5% (p=0.536), respectively). There were no significant differences in cumulative incidence rates of thrombosis between the two groups (P=0.265 by log-rank test). Univariate analysis revealed five risk factors of thrombosis: activity of daily living (p=0.004), hepatic failure (p=0.001), malignancy (p=0.02), and use of methylxtrate (p=0.038) and oral contraceptive (p=0.037). After adjusting for covariates, OR of SPT was 0.82 (95%CI 0.44-1.52), which was not significantly elevated.

Conclusion: This study revealed that SPT did not increase the risk of thrombosis in patients with LN.

REFERENCES:
Background: Pregnancies in women with inflammatory and autoimmune diseases are considered high-risk pregnancies, so close and ideally multidisciplinary control is necessary. Given the advances in treatment and identification of risk factors a higher percentage of patients manifest gestational desire.

Objectives: To describe our experience in a multidisciplinary unit (integrated by Rheumatologists and Obstetricians) and assess the complications in the evolution of pregnancies and treatments used in patients with inflammatory and autoimmune diseases.

Methods: Retrospective study of pregnancy outcome in patients with rheumatic diseases and follow-up in a multidisciplinary unit for 15 years (January 2003-December 2018). Demographic characteristics, maternal disease, comorbidities, previous abortions, presence of autoantibodies (AAb), number of births, fetal losses and abortions during follow-up, previous treatment and treatment during pregnancy and maternal and fetal complications were collected.

Frequencies and percentages were used in qualitative variables, mean ±SD in quantitative and for the comparison between groups Chi2 test (or Fisher test if appropriate) was used in categorical variables and Student T test (or U of Mann-Whitney if appropriate) in quantitative variables. Data was analysed using IBM SPSS v23.

Results: 141 patients (194 pregnancies) were registered with maternal average age at rheumatic disease diagnosis of 29.14 ± 6.6 years and average age at abortion/childbirth of 34.82 ± 4.63 years. 12.8% were smokers and 21.1% had comorbidity (hypothyroidism:10.8%, dyslipidemia:2.1%). Maternal diseases are collected in table 1. 50 abortions were registered prior to follow-up in our unit (0.35 abortions/mother). During follow-up 19 abortions were registered (0.13 abortions/mother). Frequencies of abortions/births are specified in table 1.

The frequency of different AAb is found in table 2. Intrauterine growth restriction (IUGR) was observed in 7 cases (3.7%) and pre-eclampsia in 6 (3%) being more frequent among patients with SLE (n:3 and n:2 respectively), APS (n:1 and n:1) and asymptomatic women (p = 0.047).

Treatments used prior to and during pregnancy are shown in table 3. In our series, as previously described in the literature, women with systemic autoimmune and inflammatory diseases have higher risk of abortion, pregnancy complications and instrumental delivery than general population. SLE and APS are most associated with these complications. Multidisciplinary close follow-up of these patients improves pregnancy outcomes.

Intrauterine growth restriction (IUGR) was observed in 7 cases (3.7%) and pre-eclampsia in 6 (3%) being more frequent among patients with SLE (n:3 and n:2 respectively), APS (n:1 and n:1) and asymptomatic women (n:2 and n:1). No difference was observed in complications rate between anti-Ro positive and anti-Ro negative women (p = 0.047).

Treatments used prior to and during pregnancy are shown in table 3. In our series, as previously described in the literature, women with systemic autoimmune and inflammatory diseases have higher risk of abortion, pregnancy complications and instrumental delivery than general population. SLE and APS are most associated with these complications. Multidisciplinary close follow-up of these patients improves pregnancy outcomes.

without SLE. On the other hand, the pregnancy adverse outcomes are common in pregnant women with SLE. However, the pregnancy rates in women with SLE was not fully understood. In addition, comparison of the pregnancy adverse outcomes with general population is limited.

Objectives: We estimated the pregnancy rates and adverse pregnancy outcomes in Korean women with SLE and compared them with women without SLE.

Methods: Among all women aged 15-49 years in the Korean National Health Insurance claim database from January 2013 to December 2015, pregnant women were identified by using ICD-10 code for delivery and abortion. Pregnant women were categorized into women with SLE and control group. Adverse pregnancy outcomes classified into five categories as follows: fetal loss, intrauterine growth retardation (IUGR), preterm delivery, pre-eclampsia or eclampsia, and gestational diabetes mellitus. Crude incidence rates (IRs) of pregnancy and adverse pregnancy outcomes were calculated. Incidence rate ratios (IRR) of those were estimated and adjusted for age.

Results: In SLE, 994 pregnancy cases were observed during the study period. The crude estimated IRs of pregnancy were lower in SLE patients than general population (Table 1). Age-adjusted IR was also lower in SLE patients (Table1). The adjusted-IRR of live birth in SLE pregnant women was 0.92 (95% CI 0.85 - 0.99) compared with control group. The adjusted-IRR of fetal loss, IUGR, and preterm delivery was 1.27 (95% CI 1.11 - 1.45), 4.52 (95% CI 3.45 - 5.91), and 3.25 (95% CI 1.62 - 6.52), respectively. The IRR of pre-eclampsia or eclampsia was 3.21 (95% CI 2.52 - 4.08), but those of gestational diabetes mellitus was not significant (IRR 0.89, 95% CI 0.80 - 1.00).

Conclusion: Pregnancy rates in SLE women were lower about 30% compared with general population. Pregnancy adverse outcomes were higher in SLE pregnant women with more than 4-fold IUGR and pre-eclampsia/eclampsia. 3.2-fold preterm delivery.

SUBPOPULATION COMPOSITION OF INFLAMMATORY INFILTRATES OF THE MINOR SALIVARY GLAND AS AN ADDITIONAL DIAGNOSTIC CRITERION FOR PRIMARY SJOGREN’S SYNDROME

Eugeni Kuvarena1, Irina Gilgor’eva1, Irina Bekhtereva2, Valentina Myachikhina1

1Federal State Budgetary Institution “Almaazov National Medical Research Centre” of the Ministry of Health of the Russian Federation, Saint-Petersburg, Russian Federation; 2Federal State Budgetary Institution «North-Western State Medical University named after I.I. Mechnikov», Saint – Petersburg, Russian Federation, Saint-Petersburg, Russian Federation

Background: Primary Sjogren’s syndrome (pSS) is frequent nosological forms among the diffuse connective tissue diseases. Histological examination of the minor salivary gland (MSG) is important diagnostic method. The currently established histological criteria for pSS indicates 61.2-93.7% sensitivity and 61.2-100% specificity respectively, which makes the search for additional hallmark highly relevant. Immunohistochemical study of MSG is the most appropriate for this purpose.

Objectives: To study the qualitative and quantitative compositions of cellular subpopulations minor salivary gland mononuclear foci as additional biomarker of pSS.

Methods: The study included 56 patients with a definite diagnosis of pSS according to the criteria of ACR/EULAR 2016. The control group consisted of 19 healthy volunteers. The biopsy of the minor salivary gland was performed for all the subjects, followed by an immunohistochemical study to evaluate the expression of CD3, CD4, CD8, CD20, CD21, CD68, CD138. A statistical analysis of the data obtained during the study was carried out using the SPSS 23 statistical software for Windows (IBM, United States of America). Diagnostic threshold for each biomarker was determined by ROC analysis. Operating characteristic curve, area under the curve (AUC), specificity, sensitivity, diagnostic accuracy (DT), diagnostic thresholds (DP), positive likelihood ratio (LR+) and negative likelihood ratio (LR-) were also calculated. The construction of classification models, including several markers, was performed using linear discriminant analysis.

Results: The largest AUC were observed in CD3 - 0.795 (95% confidence interval (CI) 0.687 - 0.893) and CD20 - 0.796 (95% CI 0.698 - 0.894), which at the specified DP corresponded to the sensitivity of 67.9% (95% CI 54.04 - 79.71) and 71.4% (95% CI 57.79 - 82.7), specificity of 95% (95% CI 73.97 - 99.87) and 95% (95% CI 73.97 - 99.87). The CD21 marker was detected only in the pSS group. AUC for this biomarker was 0.652 (95% CI 0.525 - 0.778), sensitivity - 30.4% (95% CI 18.78 - 44.1), specificity - 100% (95% CI 82.35 - 100).

Using the method of discriminative analysis, we designed classification models that included various combinations of the markers under study. The combination of the decimal logarithms CD3 and CD68 had AUC 0.873 (95% CI 0.794 - 0.953), sensitivity - 76.8% (95% CI 63.58 - 87.02), specificity - 95% (95% CI 73.97 – 99.87).

Conclusion: CD3 and CD20 can be considered as additional histological criteria for pSS. CD21 was observed only in patients with pSS. The combined quantitative assessment of CD3 and CD68 had a greater diagnostic value compared to CD3 and CD68 separately.

FRI0243

RECOVERY OF RENAL FUNCTION IN PATIENTS WITH LUPUS NEPHRITIS AND REDUCED RENAL FUNCTION

Jung Sun Lee1, Wook Jung Seo2, Ji Seon Oh1, Seokhong Han1, Yong-Gil Kim1, Chang-Keun Lee1, Bin Yoo2

1University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Rep. of (South Korea); 2Veterano Health Service Medical Center, Seoul, Korea, Rep. of (South Korea)

Background: Reduced renal function is associated with worse renal outcomes in patients with lupus nephritis (LN). However, there is insufficient knowledge regarding renal function recovery in patients with LN with reduced baseline renal function.

Objectives: The present study aimed to investigate renal function recovery and related factors in patients with reduced baseline renal function.

Methods: The present retrospective longitudinal cohort study included patients with LN and reduced renal function. Reduced renal function was defined as an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m². Recovery of renal function was determined by eGFR >60 mL/min/1.73 m² at 6 months after baseline, and factors associated with it were evaluated using logistic regression analysis.

Results: We included 90 patients with LN, with a mean eGFR value of 37.2 (± 13.9) mL/min/1.73 m². Forty-six patients (51.1%) recovered their renal function after 6 months. On multivariate analysis, hydroxychloroquine use (OR: 3.891, 95% CI: 1.196-12.653, p = 0.024), prolonged LN (OR: 0.926, 95% CI: 0.874-0.981, p = 0.009), and high-grade tubular atrophy (OR: 0.451, 95% CI: 0.208-0.829, p = 0.013) were associated with renal function recovery. During follow up, 25 patients were on end stage renal disease (ESRD). Kaplan-Meier analysis revealed that renal function recovery after 6 months and lower probability of ESRD are associated.

Conclusion: In patients with LN and reduced renal function, renal function recovery at 6 months was associated with use of hydroxychloroquine and inversely related to longer duration of LN and higher grade of tubular atrophy.

MATHEMATICAL PROCESSING IS AFFECTED BY DAILY BUT NOT CUMULATIVE GLUCOCORTICOID DOSE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Anastim Mak1, Rachel Teo2, Nien Yee Kow1, Preeti Dhanaresukar1, Sen Hee Tay1, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; 2Lee Kong Chian School of Medicine, Singapore, Singapore

Background: The impact of glucocorticoids on neurocognitive performance in patients with SLE is not fully understood.

Objectives: We aimed to study the effect of daily and cumulative doses of glucocorticoids on neurocognitive performance in patients with SLE using the computer-based Automated Neuropsychological Assessment Matric (ANAM).

Methods: Consecutive patients with SLE and gender- and age-matched (±5 years) healthy control subject (HC) were studied. In a quiet and comfortable room, each subject underwent the 45-minute ANAM test under supervision which comprises simple reaction time (SRT) that probes neuromuscular efficiency, and 8 domains of neurocognitive assessment including 3 code substitution tests (probing learning and recall), spatial processing (probing visual perception and mental rotation), matching to
sample (probing short-term memory and attention), continuous performance test (probing sustained attention), mathematical processing, and memory search (probing working memory). Anxiety and depression were assessed by the Hospital Anxiety and Depression scale (HADS). The total and individual-domain throughput scores (TPS) were compared between both groups using Student’s t test. The presence of cognitive dysfunction, defined as total TPS <1.5 SD below the mean TPS of HC, was compared between both groups by χ² test. Within the SLE group, the relationships between prednisolone dose (daily [mg]) and cumulative ([g]) and individual-domain TPS were first explored by bivariate correlations. Independent association between glucocorticoid dose and individual-domain TPS that showed significant bivariate associations with prednisolone dose was determined by multiple linear regression, with adjustment for potential clinically- and demographically-important confounders.

Results: Ninety-six SLE patients and 96 HC were studied, 16 men (16.7%) were present in each group. The mean age±SD of SLE patients and HC were 36.5±7.1 and 33.6±1.06 years (p=0.073), respectively. The mean±SD duration of SLE, SLEDAI and daily and cumulative prednisolone doses were 98.85±87.4 months, 3.37±3.4, 11.01±13.0mg and 16.92±18.5mg, respectively. SLE patients had a significantly higher mean HADS-anxiety score than HC (6.25±3.3 vs 4.62±3.0, p=0.001) while the mean HADS-depression score was comparable between both groups (p=0.093). SLE patients had significantly shorter duration of education (12.92±3.92 vs 15.86±2.5 years, p<0.001), scored significantly worse across all the 8 ANAM domains, had a significantly lower mean total TPS (337.23±94.4 vs 395.62±87.6, p<0.001) and were significantly more prevalent of cognitive dysfunction as compared to HC (25.0% vs 7.3%, p<0.001). In SLE patients, a statistically significant negative correlation was found between daily prednisolone dose and TPS of mathematical processing (r=-0.248, p<0.015), while no significant correlation between cumulative glucocorticoid dose and any of the individual ANAM domain was found. In multivariate regression, daily prednisolone dose remained independently associated with lower TPS of mathematical processing (β=-0.208, p=0.024) after adjusting for age, gender, SLEDAI, total HADS, total TPS, serum albumin and 25-DH hydroxyvitamin D levels and duration of education in SLE patients.

Conclusion: Daily, but not cumulative glucocorticoid dose has an independent impact on the working memory of SLE patients. While how daily glucocorticoid dose affects working memory mechanistically requires further investigation, its impact on neurocognitive assessment in SLE patients cannot be underestimated.

Disclosure of Interests: None declared

FRIO245
RHEUMATOID FACTOR IN IGA, IGG AND IGM IMMUNOGLOBULIN CLASSES IN PRIMARY SJÖGREN’S SYNDROME

Małgorzata Mańkowska, Agnieszka Ciach, Robert Pleciński, Piotr Nowak, Magdalena Słowińska, Anetta Kowalczyk, Anna Marciniec, Dorota Szydłowska

Background: Primary Sjögren’s syndrome (pSS) is an autoimmune disease with the autoantibodies overproduction, including rheumatoid factors (RF). An association of RFs with the disease activity has been already described, with RFs in IgA, IgG immunoglobulin classes suggested as potential biomarkers of immunological/clinical pSS features.

Objectives: Examining correlations of RF in IgM, IgA and IgG immunoglobulin classes with other autoantibodies, dry eye tests and histopathological assessment (focus score) of salivary gland inflammation.

Methods: We studied 76 patients, mean age 53 (SD=13); (67Female/9Male) with pSS diagnosis (criteria ACR/Eular 2017); mean disease duration from diagnosis 2.24 year. Laboratory tests performed: ESR, C-reactive protein(CRP), concentrations of gamma globulins (g/dl), RF serum concentration assessed using ImmuLisa Enhanced™ RF IgA, IgG, IgM Antibody ELISA IMMCO Diagnostics, Inc. As positive result of the RF-IgA and RF-IgG concentration > 25 EU/mL was considered, as positive RF-IgM > 12.5 EU/mL; a highly positive result set as > 100 EU/mL. The study was approved by the proper ethics committee.

Results: 55% (n=42), - 45%(n=34), ++ 9% (n=7); RF-IgM: + 88% (n=67), - 12% (n=9), + 5% (n=42). In comparison of patients’ groups: RF-IgA (+) vs. RF-IgA (-): no difference in term of FS, OSS and Schirmer’s test; in RF-IgA+ group significantly higher anti SS-A antibodies (p=0.002); a significant difference in anti SS-A antibodies level (p=0.028) RF-IgA(+) and lower positive group (less than 100EU/mL); iRF-IgM(+) vs. RF-IgM(-): RF-IgM (+) significantly higher anti -SS-A antibodies (p=0.007); ii/RF-IgG (+) vs. RF-IgG(-): RF-IgG(+): RF-IgG(+) significantly higher anti SS-B antibodies (p=0.015). Positive correlation was found between: RF-IgA(+) and RF-IgG(+) (rho=0.647) and RF-IgM(+) (rho=0.669); RF-IgG(+) and RF-IgM(-) (rho=-0.429). Surprisingly no correlations found in studied group between concentrations of RF- IgA, IgG and IgM and WBC, C4, C3 complement component, FS, OSS, and Schirmer’s test.

Conclusion: 1. rheumatoid factors in main three classes of gammaglobulins, particularly RF-IgA, strongly associate with anti-SSA and anti-SSB autoantibodies production. 2. RF – IgM and RF- IgA dominate over RF- IgG in pSS. 3. both RF-IgA and RF-IgM may be used as diagnostic tool for pSS. 4. Further research is needed to distinguish activity and role of RF- IgA based upon its presence in serum vs. saliva.

FRIO246
CELLULAR/FIBROCELLULAR CRESCENT IS A 52-WEEK AND LONG-TERM POOR PROGNOSTIC FACTOR OF ACTIVE LUPUS NEPHRITIS

Avy Nawata, Kazuhiisa Nakano, Shingo Nakayamada, Yoshiya Tanaka. University of Occupational and Environmental Health, Japan. The first department of internal medicine, Kitakyushu, Japan

Background: Lupus nephritis (LN) is one of the most serious manifestation of systemic lupus erythematosus (SLE), associated with poor prognosis. LN exhibits a variety of histological findings including both inflammatory lesions such as crescent formation and immune complex (IC) deposition lesions. In current INS/RPS 2003 classification, all of them are classified as class III, IV and V. Recently, in the 2016 update of Oxford classification of IgA nephropathy, crescent formation (C) was added as an independent prognostic factor. Further examination of pathological and clinical prognostic factors for LN is required.

Objectives: To identify renal remission rate and clinicopathological characteristics associated with renal non-remission at 52 weeks (52w) in LN patients

Methods: A single center retrospective study. We enrolled Japanese 152 patients of LN class III, IV, and V those who could observe for 52 weeks or more.

Results: The detection of RF in examined sera: RF- IgA(+) positive(+) 66% (n=50), negative (-) 34%(n=26); highly positive (+) 51%(n=39); RF-IgG: + 55% (n=42), - 45%(n=34), ++ 9% (n=7); RF-IgM: + 88% (n=67), - 12% (n=9), + 5% (n=42). In comparison of patients’ groups: RF-IgA (+) vs. RF-IgA (-): no difference in term of FS, OSS and Schirmer’s test; in RF-IgA+ group significantly higher anti SS-A antibodies (p=0.002); a significant difference in anti SS-A antibodies level (p=0.028) RF-IgA(+) and lower positive group (less than 100EU/mL); iRF-IgM(+) vs. RF-IgM(-): RF-IgM (+) significantly higher anti -SS-A antibodies (p=0.007); ii/RF-IgG (+) vs. RF-IgG(-): RF-IgG(+): RF-IgG(+) significantly higher anti SS-B antibodies (p=0.015). Positive correlation was found between: RF-IgA(+) and RF-IgG(+) (rho=0.647) and RF-IgM(+) (rho=0.669); RF-IgG(+) and RF-IgM(-) (rho=-0.429). Surprisingly no correlations found in studied group between concentrations of RF- IgA, IgG and IgM and WBC, C4, C3 complement component, FS, OSS, and Schirmer’s test.

Conclusion: 1. rheumatoid factors in main three classes of gammaglobulins, particularly RF-IgA, strongly associate with anti-SSA and anti-SSB autoantibodies production. 2. RF – IgM and RF- IgA dominate over RF- IgG in pSS. 3. both RF-IgA and RF-IgM may be used as diagnostic tool for pSS. 4. Further research is needed to distinguish activity and role of RF- IgA based upon its presence in serum vs. saliva.

REFERENCES:

Results: Baseline data: mean age 39 years, 135 females, 18 men, historically class III, 53 cases, IV: 58 cases, pure V: 12 cases, III/IV + V: 30 cases. At 52w after biopsy, SLEDIAI (16 → 2), BILAG (17 → 2) score is significantly decreased. Dose of PSL was reduced (48 → 9 mg). At 52w, all patients were classified as RR (125 cases, 82%) and NR (27 cases, 18%) by ACR/LUNAR remission criteria. Surprisingly, all cases of pure V reached remission. Class III or IV LN (RR 114 cases; 91% vs NR 27 cases; 100%, p = 0.01) and cellular/fibrocellular crescent formation (RR 51 cases; 40% vs NR 19 cases; 66%; p = 0.01) were significantly higher in NR. Clinically, long disease duration (p = 0.02), coexisting hypertension (RR 7 cases; 6% vs NR 9; 33%, p <0.01) and TMA (RR 1 case;0.7%, NR 2 cases;7%, p = 0.02), baseline urine protein (RR 1.5g vs NR 2.2g, p=0.01), baseline low WBC (p = 0.03); baseline low IgG (p = 0.02) were detected. About therapeutic drugs, IVCY significantly improved remission rate (RR 84 cases 68% vs. NR 9 cases 41%, p = 0.03). After long-term observation, 52w NR was significantly lower eGFR level (RR 81 vs NR 50, p <0.01, median observation period of 138 months). 3 cases developed lupus nephrotic syndrome with peritoneal involvement. In LN, more frequently than in LN in NR, the presence of interstitial infiltrate was detected. The therapeutic response was relatively better in cases with IC deposition less than those with intense inflammatory histological pattern. In LN, more frequently than in LN in NR, the presence of interstitial infiltrate was detected. The therapeutic response was relatively better in cases with IC deposition less than those with intense inflammatory histological pattern.

Disclosure of Interests: Aya Nawata: None declared, Kazuhiisa Nakano: None declared, Enago: Grant/research support from: Enago, Research support from: Enago, Masaaki Kato: Grant/research support from: Enago, Research support from: Enago, Yukiho Tanaka: Grant/research support from: Enago, Research support from: Enago, Eriko Yamasaki: Grant/research support from: Enago, Research support from: Enago, Tatsuya Ohno: Grant/research support from: Enago, Research support from: Enago.

Conclusion: As histological factors contributing to 52w-NR, class III or IV and crescent formation were detected. This result suggested that the therapeutic response was relatively better in cases with IC deposition less than those with intense inflammatory histological pattern. Previous studies have demonstrated that the presence of tubulo-interstitial infiltrate is associated with a worse outcome in response to therapy. Our data highlight the importance of tubulo-interstitial damage, scarcely considered in the current classification criteria, since it represents a key point to predict long-term prognosis.

PROGNOSTIC ROLE OF TUBULO-INTERSTITIAL INFILTRATE IN PATIENTS AFFECTED BY LUPUS NEPHRITIS

Viviana Antorella Pacucci, Francesca Spinelli, Konsantinos Giannakakis, Simona Truglia, Fulvia Ceccarelli, Francesca Morello, Cristina Garufi, Viviana Anteo Pacucci, Francesca Spinelli, Konsantinos Giannakakis, Cristina Garufi, Cristiano Airessani, Guido Valesini, Fabrizio Conti, Sapienza University of Rome, Rome, Italy

Background: Lupus nephritis (LN) occurs up to 50% of patients affected by Systemic Lupus Erythematosus (SLE) representing one of the major causes of morbidity and mortality in lupus population (1). Kidney biopsy is a fundamental tool for the diagnosis and management of lupus nephritis (LN). The presence of pathological changes such as inflammatory infiltrate in glomeruli and/or in tubulointerstitium are relevant in terms of prognosis and response to therapy (2).

Objectives: The aim of the study was to correlate the clinical and laboratory parameters with the response to therapy and with the presence of glomerular and/or interstitial infiltrate in kidney section of patients with a biopsy-proven LN.

Methods: Kidney sections of patients with SLE undergoing a renal biopsy for diagnostic purposes were studied; samples were classified according to the 2004 International Society of Nephrology/Renal Pathology Society classification criteria (3). Clinical, laboratory and histological data were collected in a standardized, computerized and electronically filled form, including demographic, autoimmune profile, previous and concomitant treatments. We assessed the disease activity by using SLEDAI-2K and remission in response to therapy was defined as the absence of renal impairment and as a score 0 of renal SLEDAI (proteinuria <500mg/24 hours, absence of haematuria and urinary casts) (4). All patients underwent to cyclophosphamide or mycophenolate treatment (S-L and 6-MP). Two to three micron thick sections from paraffin-embedded blocks routinely stained with hematoxylin-eosin (HE) and Periodic acid-Schiff (PAS) for light microscopy investigation were re-evaluated. Predictive value of the presence of interstitial infiltrate on renal remission was evaluated. The results were expressed as mean±standard deviation (SD) depending on the distribution of the variables. The values of P < 0.05 were considered statistically significant.

Results: We evaluated 53 kidney samples from patients with LN (F:M = 51:2, mean age at biopsy 35±7.7 years; mean disease duration at date of biopsy 8±3.8 years). Class IV (46%) was the most common class followed by class III (29%), class II (13%), class V (11.5%) and class VI (0.5%). Tubulo-interstitial infiltrate was found in 33 kidney specimens, with germinal centres (GC)-like features in 13 renal samples (Figure 1). During the follow up (6±3.8 years) the tubulo-interstitial infiltrate, either diffuse or with GC-like feature, was negatively correlated with renal remission (P=0.03).

Conclusion: Assessment and management of patients with LN are greatly facilitated by information obtained by renal biopsy. In the present study we demonstrate that the presence of tubulo-interstitial infiltrate is associated with a worse outcome in response to therapy. Our data highlight the importance of tubulo-interstitial damage, scarcely considered in the current classification criteria, since it represents a key point to predict long-term prognosis.

ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY IN PRIMARY SJÖGREN SYNDROME: A MARKER OF EROSIONS ON HIGH RESOLUTION ULTRASOUND OF HANDS AND WRISTS

Lissiane Guedes, Elaine Leon, Margarete Vendramini, Tamytis Bocare
Karina Borjigoli, Elisa Bonzi, Sandra Pascho, Hospital das Clínicas, Faculdade de Medicina da USP (HCFMUSP), Rheumatology, Sao Paulo, Brazil

Background: Cyclic citrullinated peptides antibodies (anti-CCP) were described in primary Sjögren’s syndrome (pSS). However, its possible associations with joint erosions, synovitis and tenosynovitis on high resolution ultrasonography of hands and wrists (US) in pSS are uncertain.

Objectives: To assess in pSS the US findings, and their possible associations with anti-CCP.

Methods: We have evaluated 97 consecutive pSS patients (2016 ACR/EULAR Classification Criteria), of both sexes, aged 18-76 years, and without meeting the 1987 ACR classification criteria for rheumatoid arthritis (RA). Twenty RA patients (disease duration <5 years, and without joint deformities), and 80 healthy controls with comparable mean age, gender and ethnicity were also included in a case-control study. Clinical evaluation was performed through a standardized protocol with interview and physical examination. Disease activity was measured according to EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI). US was done in 36 joints and 36 tendon areas of wrists and hands, by the same rheumatologist with expertise in ultrasonography, and blinded to autoantibody profile. Patients and controls also underwent X-ray of hands and wrists. Anti-CCP was determined by ELISA using a commercially available kit.

Results: Frequency of tenosynovitis on US was higher in the pSS group than in healthy controls (36.1 vs. 3.8%, p<0.001). Moreover, the number of tenosynovitis was higher in the former group (p=0.001). Importantly, the presence of erosions on US (27.8 vs. 7.5%, p=0.001) and their number (p=0.005) were greater in the pSS group than in healthy controls, with predominance of small erosions (p=0.015). Comparative analysis between RA patients and pSS revealed that the frequency (p=0.001) and number (p<0.001) of synovitis on US were greater in the former group. The number of grade 1 synovitis was comparable between RA and pSS patients (p=0.354). However, the number of grade 2/3 synovitis were higher in RA than in pSS patients (p=0.001). Similarly, the number of erosions on US was higher in the RA group compared to pSS group (p<0.001), particularly of moderate/large erosions.
RESULTS:

Table 1 presents the pooled risk ratio (RR) estimates and summary statistics for VTE in SLE patients compared to the general population. The meta-analysis of the VTE studies showed a significantly increased RR of 3.67 (95% CI: 2.10 to 6.42) for patients with SLE compared to the general population. Removal of the two cross-sectional studies increased RR of 3.67 (95% CI: 2.10 to 6.42) for patients with SLE compared to the general population. The robustness of the results was tested using the leave one out function. The leave one out function confirmed the robustness of the results.

CONCLUSION: Overall, the risk of VTE was found to be significantly higher, over three- to six-fold higher, among patients with SLE compared with the general population. Future research should focus on assessing the impact of traditional and SLE-specific modifiable risk factors on VTE to further identify SLE patients most at risk to support targeting prevention and treatment strategies.

SUBCLINICAL ATHEROSCLEROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: COMPARABLE EFFECT OF TRADITIONAL CARDIOVASCULAR RISK FACTORS WITH RHEUMATOID ARTHRITIS

Himera Sánchez-Pérez1, Juan Carlos Quevedo-Abeledo2, litigo Ruíz-Figueroa3, Beatriz Tejera-Segura4, Vanessa Hernández-Hernández5, Antonia de Vera-González6, Alejandra Delgado-González7, Raquel López-Mejías8, Soledad Cidúa9, Miguel A González-Gay9, Iván Ferraz-Amaro10. 1Hospital Universitario de Canarias, División de Rheumatología, Tenerife, Spain; 2Hospital Universitario de Gran Canaria Dr Negrín, División de Rheumatología, Las Palmas de Gran Canaria, Spain; 3Hospital Universitario Insular de Gran Canaria, División de Rheumatología, Las Palmas de Gran Canaria, Spain; 4Hospital Universitario de Canarias, Central Laboratory Division, Tenerife, Spain; 5DIVAL, Santander, Spain

Background: Both rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients are associated with an increased and premature

with an I² ranging between 92% and 99%. Visual examination of the funnel plots showed evidence of publication bias, however this was not supported by the Egger's test. The leave one out function confirmed the robustness of the results.

FRID0249

THE RISK OF VENOUS THROMBOEMBOLIC EVENTS IN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: SYSTEMATIC REVIEW AND META-ANALYSIS

Nick Pooley1, Jinoos Yazdany2, Julia Langham3, Lindsay Nicholson4, Sue Langham5, Nina Embleton1, Xia Wang3, Barnabas Desta3, Volkan Barut4, Edward R. Hammond3. 1Maxverex Limited, Manchester; United Kingdom; 2University of California, San Francisco, CA, United States of America; 3AstraZeneca, Gaithersburg, MD, United States of America; 4AstraZeneca, Cambridge, United Kingdom

Background: Although observational studies suggest people with systemic lupus erythematosus (SLE) have a heightened risk of venous thromboembolic events (VTE), meta-analyses that integrate evidence across studies to estimate the pooled risk have not been performed.

Objectives: To conduct a systematic review and meta-analysis to estimate the risk of VTE including pulmonary embolism (PE) and deep vein thrombosis (DVT) in patients with SLE.

Methods: We conducted a systematic review using MEDLINE and EMBASE from inception to March 2018 to identify observational studies (cohort and cross-sectional) that evaluated the risk of several major cardiovascular outcomes in patients with SLE compared to a general population or healthy controls (protocol published in PROSPERO 2018 CRD42018098690). Here we report the results for venous thromboembolic outcomes. Studies were included that provided effect estimates (relative risks or hazard ratios) for the calculation of pooled effect estimates. Random effects models were used to calculate pooled risk ratios (RR) and 95% confidence intervals (CI) separately for VTE, PE and DVT. Visualization of funnel plots and the Egger test were used for evaluation of publication bias. The robustness of the results was tested using the leave one out function. Sensitivity analysis assessed the impact of removing high risk of bias studies (i.e. cross-sectional).

Results: A total of 9 studies were identified for inclusion into the meta-analysis; 7 for VTE (including two cross-sectional studies), 3 for DVT and 4 for PE. Meta-analysis of the VTE studies showed a significantly increased RR of 3.67 (95% CI: 2.10 to 6.42) for patients with SLE compared to a general population. Removing the two cross-sectional studies did not impact the results (RR 4.06 [95% CI: 3.12 to 5.28]). The pooled RRs for PE and DVT were 4.47 (95% CI: 1.79 to 11.15) and 5.51 (95% CI: 2.27 to 13.39), respectively. The statistical heterogeneity was high.

prevalence of atherosclerosis. This has been characteristically attributed to the inflammation present in both diseases.

**Objectives:** To analyze the differences in the role of traditional cardiovascular risk factors in the subclinical atherosclerosis between the two diseases and the effect of the presence of carotid plaque when univariate interaction was performed. After final adjustment for demographics, the presence of other traditional cardiovascular factors, and disease related data, no differences were found in the influence of hypertension, diabetes, dyslipidemia or current smoking over cIMT or the presence of carotid plaque. Moreover, the effect of the addition of various cardiovascular risk factors on the subclinical carotid atherosclerosis did not differ between both diseases.

**Conclusion:** The influence of traditional cardiovascular risk factors (hypertension, diabetes, dyslipidemia and smoking) over cIMT and carotid plaque is equal in RA and SLE. No interaction was found between traditional cardiovascular risk factors and disease related data in the effect of the former on subclinical atherosclerosis.

RENAL TRANSPLANTATION IN LUPUS NEPHRITIS VS NON-AUTOIMMUNE TRANSPLANTATION. LONG TERM FOLLOW-UP. STUDY FROM A SINGLE TERTIARY CENTER

Lara Sánchez Bilbao, Iñigo González-Mazón, Marina de Cos-Gómez, Belén Aleniza-Mateo, José Luis Martín-Varillas, Monica Calderón-Goecke, D. Prieto-Peña, Juan Carlos Ruiz-San Millán, Miguel A. González-Gay, Ricardo Blanco, Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain. 2Nephrology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

Background: Lupus nephritis (LN) is a severe complication of systemic lupus erythematosus (SLE), affecting up to 30-40% of patients. Unfortunately, approximately 10-20% of LN develop end stage renal disease (ESRD) and need replacement therapy. Renal transplantation may be a good option. However, concerns about LN recurrence after renal transplantation have been reported.

Objectives: In a series of patients with first renal transplantation due to LN our aim was to assess a) long-term post-transplant survival and, b) comparison of post-transplant survival with a control group due to a non-autoimmune nephropathy, the polycystic kidney disease (PCKD).

Methods: We study two groups of patients with first renal transplantation: a) LN and b) control group with PCKD. All these patients were transplanted in a single reference University Hospital. The main outcome variables were a) graft and patient survival up to 20 years and b) evolution of renal function (serum creatinine and proteinuria) in the first 5 years of follow-up. Cumulative survival rates after transplantation were estimated by the Kaplan-Meier method and compared between groups using the log-rank test. Mann-Whitney test was used to compare quantitative variables.

Results: We included a total of 53 patients with renal transplant; a) LN group (n=51), b) PCKD group (n=32). No significant differences were found in terms of sex and cardiovascular risk factors. Significant differences were found in terms of age at kidney transplantation, with a mean of 39.80±11.27 years in LN group and 46.59±5.01 years in the PCKD group (p=0.004). Renal biopsy had been performed in 16 patients with LN: type II LN (25%), type III (25%) and type IV (50%), (according to the World Health Organization and International Society of Nephrology/Renal Pathology Society classification). From 48 patients (of 53) in which a renal biopsy was performed during the first-year post-transplant, rejection was found in 21 patients (43.7%) without significant differences between the 2 groups (p=0.444). The evolution of serum creatinine and proteinuria after renal transplantation is shown in TABLE 1. Regarding serum creatinine, significant differences were found in creatinine levels only at the 6th month post-transplant (p=0.032) with no differences in the following measurements. In LN group, 3 patients (14.3%) developed a lupus flare: 2 cases presented as extrarenal disease and only 1 case with histological recurrence in the graft. No significant differences were found in terms of patient or graft survival between the two groups in 20 years of follow-up (Figures 1 and 2).

Conclusion: Despite concerns about LN recurrence after renal transplantation, data obtained in our sample indicate that this procedure as a safe alternative therapy for ESRD in this population and can provide a long-term survival.

COMBINED PANEL OF NINE TESTS HAS THE GREATEST SENSITIVITY BUT THE LOWEST SPECIFICITY TO DETECT ANTIPHOSPHOLIPID Antibody Syndrome in Patients with Systemic Lupus Erythematosus

Saika Sharmeen, Katalin Barki, András Perl. 1State University of New York, Upstate Medical University, Medicine, Syracuse, United States of America; 2State University of New York, Upstate Medical University, Clinical Pathology, Syracuse, United States of America

Background: Antiphospholipid antibody syndrome (APS) is an autoimmune hypercoagulable state caused by antiphospholipid antibodies (aPL) which represent a diagnostic criterion and underlie significant comorbidities in patients with and without systemic lupus erythematosus (SLE). Although several tests exist for APS diagnosis, their utilization has been highly variable among laboratories and physicians.

Objectives: We have evaluated a panel of nine tests and conducted a retrospective study to determine their sensitivity and specificity for supporting the diagnosis of APS in SLE at our Institution between 2010 and 2018.

Methods: 1633 SLE patients, who satisfied the ACR criteria for a definitive diagnosis [1,2], were evaluated for the presence of APS as earlier described [3]. Lupus anticoagulants were assessed by Staclot LA hexagonal phase phospholipid neutralization assay (HPPNA; delta >8 seconds), Staclot diluted Russell viper venom test (dRVVT; <1.2 normalized ratio).
obtained from Stago ( Parsippany, NJ, United States of America). Platelet neutralization procedure (PNP; delta < 1 second) has been performed using a STA-R Evolution instrument by Stago [4, 5]. IgG and IgM antibodies against α2-glycoprotein 1 (α2-GP1-IgG, α2-GP1-IgM) and cardiolipin (αCL-lgG, αCL-lgM) were measured in house while IgA isoforms (α2-IgA-lgA, α2-IgA-lgG) were tested by LabCorp Diagnostics (Burlington, NC). Sensitivities, specificities, and positive (PPV) and negative predictive values (NPV) for detection of APS were calculated and compared by 2-tailed chi-square tests using GraphPad software.

Results: 222/1633 SLE patients had APS when using a combination of nine tests. Table 1 shows the frequency of positive and negative test results and p value for each assay. The greatest sensitivity was seen when all nine tests were performed together for detecting APS in SLE patients (74%; p<0.0001). In contrast, combining all tests had the lowest specificity (52%; p<0.0001). Importantly, the 2nd most sensitive test for detection of APS was the HPPNA at 52%, this tests also had the second lowest specificity (66%). Similar trends were seen when individual APS comorbidities, such as deep venous thrombosis (DVT), pulmonary embolism (PE), and stroke or TIA, were separately analyzed. Among the charts reviewed, the complete 9-test panel was only performed in 550 of 1633 patients (Table 1).

Conclusion: This study demonstrates that utilizing a combined 9-test panel has the greatest sensitivity but lowest specificity for detecting APS in SLE subjects. This failure to employ the complete panel may lead to exclusion of patients who may meet criteria for identifying patients with APS who need long-term anticoagulation for preventing life-threatening thrombotic events.

LOW ATTENUATION NON-CALCIFIED CORONARY PLAQUES AND POSITIVE REMODELING INDEX: MARKERS OF VULNERABLE CORONARY PLAQUES IN SYSTEMIC LUPUS ERYTHEMATOSUS

George Stojan1, Li Jessica1, Laurence Magder1, Matthew Budoff1, Michelle A. Petri1, Johns Hopkins University School of Medicine, Baltimore, United States of America; 2University of Maryland, Baltimore, United States of America; 3UCLA, Los Angeles, United States of America

Background: The presence of low attenuation noncalcified plaque (LANCP) and positive remodeling index (RI) are characteristic vessel changes in unstable coronary plaques. LANCP (<30 Hounsfield Units) contain necrotic cores that are characterized by endothelial dysfunction, oxidative stress, and inflammation. They have been shown to be a better predictor of future cardiovascular events compared to traditional cardiovascular risk factors in the general population. Coronary arterial remodeling describes changes of vessel size at the site of lesion. Positive remodeling (expansion) of early lesions maintains lumen size despite plaque accumulation. This explains why these lesions might pass undetected by conventional angiography. Plaque rupture is often apparent at sites with only modest luminal stenoses but marked positive remodeling.

Accelerated atherosclerosis leading to premature coronary artery disease remains the major cause of late death in SLE.

Objectives: We sought to characterize LANCP and positive RI in patients with systemic lupus erythematosus.

Methods: A total of 72 patients who met the ACR or SLICC classification criteria for SLE had CT angiograms, 30 of which had follow up CT angiograms. A total of 100 healthy controls who had two CT angiograms were included in the study. Each noncalcified plaque (NCP) detected within the vessel wall was evaluated for minimum CT density and vascular remodeling index. A LANCP was defined as an NCP with a density <30 Hounsfield units. Lesions with remodeling 0% were considered to have positive RI. T-test was used to evaluate baseline characteristics between lupus patients and controls. Paired t-test or Wilcoxon signed rank test was used to compare LANCP volume and RI between baseline and follow-up. Fisher’s exact test was used to evaluate the association between change in LANCP, RI, demographic and clinical variables.

Results: Lupus patients had a significantly higher burden of LANCP at baseline compared to healthy controls in all age subgroups except in those >60 years of age. LANCP volume was associated with age (p<0.01) and body mass index (p<0.01). No significant differences were observed between RI in lupus and controls at baseline. Despite a significant progression of the total noncalcified plaque burden in lupus compared to controls (p<0.0001), the LANCP in lupus patients regressed (p<0.001). No demographic or clinical differences were observed between lupus patients whose LANCP progressed and those whose LANCP regressed. Lupus patients who were not treated with statins had a more significant progression of their LANCP burden (p<0.01) compared to controls who were on statins, while lupus patients who were taking statins had a significant progression (p<0.01). There were only 5 cardiovascular events in the studied group and there were no differences in remodeling index or low density noncalcified plaque observed but the number of events was small.

Conclusion: Lupus patients have a significantly higher burden of LANCP at baseline compared to healthy controls in all age subgroups except in those >60 years of age. The LANCP burden regresses more rapidly over time in lupus compared to controls. Surprisingly, the most significant LANCP plaque volume regression was seen in lupus patients who were never treated with statins, while the most significant progression was observed in those taking statins. Positive RI was ubiquitous, with no evidence of progression or differences compared to controls. These characteristic vessel changes may identify SLE patients at need for more frequent noninvasive cardiac monitoring.

ASSESSING THE PREVALENCE AND USE OF VALIDATED SYSTEMIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY METRICS IN REAL WORLD PRACTICE

Karen Costenbader1, Ben Hoskin2, Christian Atkinson3, David Bell4, Olivia Massey2, Jennifer H. Loftand5, Pam Berry5, Chetan Kanyakar1, Zaih Touma6, 1Brigham and Women’s Hospital, Boston, United States of America; 2Adelphi Real World, Cheshire, United Kingdom; 3Janssen Global Commercial & Organization, Horsham, United States of America; 4Janssen Global Services, LLC, Horsham, United States of America; 5University of Toronto, Toronto, Canada

Background: Disease activity metrics for systemic lupus erythematosus (SLE) are not widely used in real world clinical practice.

Scientific Abstracts
Objectives: To assess the use and drivers of SLEDAI and BILAG index in real world clinical practice.

Methods: A cross-sectional study of rheumatologists in the US and EU. Data were collected from the Adelphi Real World 2010/2013/2015 Lupus Disease Programmes (DSP). Physicians were asked to complete an attitudinal survey and patient record forms (PRFs) for the next 5 patients consulting with SLE; the same patients were asked to complete patient self-completion (PSC) forms describing how SLE affected them.

Results: Physicians provided 263 surveys, extracted from the 2015 DSP, indicating that 131 were aware of but did not use the BILAG index, and 92 of physicians were aware of but did not use the SLEDAI. Physicians provided 1376 record forms for SLE patients, extracted from the 2015 DSP; 71 (5.2%) had a BILAG index (1305, 94.6% had no BILAG index), and 373 (27.1%) had had a SLEDAI calculated prospectively (1003, 72.8% had No SLEDAI). Patients with SLEDAI had longer disease duration that patients who did not have a SLEDAI (mean: 6.3 vs. 5.2 years, p<0.007), were less likely to have been described as mild at diagnosis (no SLEDAI mild: 18.7%; SLEDAI mild: 11.3%, p=0.0004) and consulted more with health care professionals in the past 12 months (no SLEDAI mean visits: 6.5, SLEDAI mean: 7.7, p<0.001).

Conclusions: The use of SLEDAI and BILAG index in clinical practice is limited and seemingly reserved for use in more severe patient cohorts; understanding the ongoing impact of this selective use on the treatment and management of SLE would be beneficial. Additionally, understanding the drivers and barriers to the use of disease activity metrics is important for the improvement of management of SLE in the future.

Background: Different neurological manifestations have been observed in 20-25% of patients affected by Sjögren’s syndrome (SS). Among them, CNS demyelinating diseases, Neuromyelitis optica (NMO) and NMO spectrum disorders (NMOSD) with anti-aquaporin4 antibodies (anti-AQ4P4) positivity have been described.

Objectives: The aim of the present study was to assess the clinical characteristics and seroimmunological correlations in patients with Ro-SSA antibodies and Central and peripheral nervous system (CNS and PNS) involvement.

Methods: We retrospectively reviewed clinical records, laboratory and Magnetic Resonance Imaging (MRI) reports of patients followed-up at a tertiary level immunohematology and neuroimmunology clinic. We included patients showing an anti-SSA antibodies positivity and concomitant neurological symptoms at diagnosis. We excluded patients fulfilling SLICC criteria for SLE. We recorded clinical and laboratory and MRI data for all patients.

Results: Out of 9598 clinical records reviewed, we identified 511 patients with anti Ro/SSA positivity. 11 patients had prevalent neurological manifestations. 8 (72.7%) patients were women. The median age was 56 years [IQR 31 years]. CNS involvement was the main clinical feature in 7 patients (63.6%); 3 of them (27.3%) also had NMS manifestations. 4 patients showed exclusively PNS involvement.

LUPUS NEPHRITIS

Background: Serological immune abnormalities such as anti-double strand DNA (dsDNA) antibodies (Abs) and hypocomplementemia (HC) are characteristic of lupus nephritis (LN). International Society of Nephrology/Renal Pathology Society (ISN/RPS) Classification of LN defines pathological active lesions (ALs) as including endocapillary hypercellularity, karyorrhexis, fibrinoid necrosis, cellular/fibrocellular crescents, and wire-loop lesion/hyaline thrombi. We reported these abnormalities are associated with individual pathological ALs. The association between serological abnormalities and pathological ALs in LN is not well characterized.

Objectives: To identify the clinicopathological association between serological immune abnormalities and pathological ALs in LN.

Methods: We enrolled 126 Japanese LN patients who were subjected to renal biopsy in 11 hospitals from 2000 to 2018. We determined various clinical parameters at the time of renal biopsy, including creatinine (Cr), estimated glomerular filtration rate (eGFR), total protein (TP), IgG, IgA, IgM, C3, C4, CH50, anti-nuclear antibodies (Abs), anti-double strand DNA (dsDNA) Abs, anti-Sm Abs, anti-RNP Abs in the sera, urinary findings, presence of comorbidities (antiphospholipid antibody syndrome, hyperlipidemia, diabetes mellitus, and hyperuricemia), and use of any immunosuppressive medications before renal biopsy. Renal biopsy findings were classified by ISN/RPS Classification including ALs. Immune deposits were evaluated by immunofluorescence. Elevation of serum anti-dsDNA Abs level [dsDNA Abs (+)] was defined as >12 IU/mL. HC was defined by C3 <0 g/dL. In patients of all pathological classes, we analyzed the association between serological abnormalities and ALs by univariate and multiple regression analyses.

Results: Of 126 patients (104 females; mean age 41.8 years), dsDNA Abs (+) and HC (+) were found in 83 (65.9%) and 80 (63.5%), respectively. There were no significant differences in renal function, comorbidities, immune deposits or immunosuppressive medications before renal biopsy. Multiple regression analysis showed that patients with dsDNA Abs (+) had a higher frequency of endocapillary hypercellularity, karyorrhexis, fibrinoid necrosis, and wire-loop lesion/hyaline thrombi than patients without dsDNA Abs (+) (OR = 4.0; 95% CI: 1.6-9.9). Patients with HC (+) had a higher frequency of endocapillary hypercellularity, karyorrhexis, fibrinoid necrosis, and wire-loop lesion/hyaline thrombi than patients without HC (+) (OR = 3.2; 95% CI: 1.4-7.3). Patients with both dsDNA Abs (+) and HC (+) had a higher frequency of endocapillary hypercellularity, karyorrhexis, fibrinoid necrosis, and wire-loop lesion/hyaline thrombi than patients without both dsDNA Abs (+) and HC (+) (OR = 6.3; 95% CI: 2.5-15.3).

Conclusion: Serum anti-dsDNA Abs and HC were associated with fibrinoid necrosis and karyorrhexis, respectively. These results document that individual serological immune abnormalities associate with specific ALs, suggesting that pathophysiological differences underlie each AL.

REFERENCES:
Background: Risk factors for treatment failure in patients with giant cell arteritis (GCA) are poorly understood.

Objectives: To identify predictors of treatment failure in GCA patients receiving tocilizumab (TCZ) or placebo (PBO) in combination with prednisone in a randomized controlled trial.

Methods: Two hundred fifty GCA patients received weekly or every-other-week TCZ plus a 26-week prednisone taper (TCZ+pred) or PBO plus a 26- or 52-week prednisone taper (PBO+pred). Patients who achieved and maintained clinical remission (CR) from week 12 to week 52 while adhering to the protocol prednisone taper were classified as responders. CR, adjudicated by investigators, was defined as the absence of disease flare (GCA signs or symptoms, and/OR ESR elevation attributable to GCA that required further treatment [eg, rescue prednisone]) regardless of CRP level. Treatment failure was defined as failure to achieve CR by week 12 or occurrence of flare between weeks 12 and 52. Both TCZ groups and both PBO groups were combined for this analysis. Potential predictors investigated included baseline demographics, disease- and treatment-related factors, and health-related quality of life (HRQOL) measures. Univariate and multivariate analyses were performed.

Results: Overall, 45% (113/250) of patients were responders: 27% (27/101) in the PBO+pred groups and 58% (86/149) in the TCZ+pred groups. In contrast, 44% (111/250) of patients experienced treatment failure: 66% (67/101) in the PBO+pred group and 30% (44/149) in the TCZ+pred group. The other 10% (26/250) of patients were nonresponders for reasons other than treatment failure: 7 in the PBO+pred group and 19 in the TCZ+pred group. In univariate analysis, female sex and lower baseline SF-36 Physical Component Summary (PCS), Mental Component Summary, and FACIT-Fatigue scores were associated with treatment failure among PBO+pred–treated patients, whereas higher patient global assessment of disease activity scores and lower SF-36 PCS, FACIT-Fatigue, and EQ-5D scores were associated with treatment failure among TCZ+pred–treated patients (Figure 1). Among TCZ+pred–treated patients, no treatment response difference according to sex was observed. Age, previous relapse, starting prednisone dose, and GCA clinical features (cranial or polymyalgia rheumatica symptoms) were not associated with treatment failure in either group based on univariate analysis. Multivariate logistic regression demonstrated that PBO+pred treatment, female sex, worse FACIT-Fatigue scores at baseline, and historical CRP >2.5 mg/dL all independently increased the risk for treatment failure (Figure 2).

Conclusion: Female GCA patients responded particularly poorly if treated with prednisone alone according to univariate analysis. Female sex, impaired HRQOL at baseline, history of elevated CRP, and treatment with prednisone alone are independent risk factors for treatment failure in GCA. These factors may be considered when determining which treatment would be best for a particular patient.

REFERENCES:
Clinical Outcomes of Patients with Giant Cell Arteritis with Polymyalgia Symptoms Only vs Cranial Symptoms Only Treated with Tocilizumab or Placebo in the GIACTA Trial

Background: GIACTA, a randomized, double-blind, placebo (PBO)-controlled trial, demonstrated the efficacy and safety of tocilizumab (TCZ) in patients with giant cell arteritis (GCA).1 Growing evidence has shown that TCZ is also effective for the treatment of polymyalgia rheumatica (PMR); however, data on this are limited.2,3

Objectives: To evaluate the efficacy of TCZ in patients with GCA presenting with cranial symptoms only or PMR symptoms only in GIACTA.

Methods: GIACTA randomized 251 GCA patients to receive weekly or every other week TCZ plus a 26-week prednisone taper (TCZ + prednisone) or PBO plus a 26- or 52-week prednisone taper (PBO + prednisone) in a post hoc analysis.1,2 In this post hoc analysis, baseline characteristics, sustained remission rate, number of flares, annual flare rate, time to flare, cumulative prednisone dose and safety were assessed in patients with PMR symptoms only and patients with cranial symptoms only at diagnosis. Disease flare was defined as the recurrence of signs or symptoms of GCA (including PMR) or an elevation in erythrocyte sedimentation rate attributable to GCA.

Results: Of 146 patients included in the analysis, 52 had PMR symptoms only and 94 had cranial symptoms only at diagnosis. Demographics and other patient characteristics are shown in Table 1. The hazard ratios for flare in patients receiving TCZ vs PBO were 0.77 (99% CI, 0.26-2.32) for patients with PMR symptoms only and 0.37 (99% CI, 0.13-1.01) for patients with cranial symptoms only. Of patients with PMR symptoms only, 18 flares occurred in 13/31 patients (41.9%) in the TCZ group and 20 flares occurred in 12/21 patients (57.1%) in the PBO group. Of patients with cranial symptoms only, 19 flares occurred in 12/58 patients (20.7%) in the TCZ group and 25 flares occurred in 17/36 patients (47.2%) in the PBO group (Table 2). For both the PMR and cranial symptoms only groups, annual flare rates were lower in patients receiving TCZ compared with those receiving PBO. The occurrence of adverse events and serious adverse events was similar between groups (Table 2).

Conclusion: TCZ improved clinical outcomes in patients who presented with PMR symptoms only or cranial symptoms only at diagnosis as indicated by a reduced incidence of flares. These findings suggest that TCZ is effective in patients with GCA with PMR or cranial symptoms.

Granulomatosis with Polyangiitis, (GPA): Cardiovascular Morbidity and Mortality in a Population-Based Cohort: A Danish Register Study

Background: In order to understand and ultimately prevent cardiovascular (CV) morbidity and mortality in systemic inflammatory disorders we studied the epidemiology of CV disease in ANCA associated Vasculitis (AAV). There is growing evidence that both premature and pronounced atherosclerosis is associated with ANCA associated vasculitis (AAV).1-3 However, the exact mechanisms for CV involvement are unknown and probably multiple.

Methods: A population-based cohort study was performed using the Danish Civil Registration System, the Danish National Patient Registry (all inpatient and outpatient contacts are registered with ICD diagnosis since 1995) and the Danish Cause of Death Register. Patients registered twice or more with a diagnosis of GPA (ICD8: 446.29 and ICD10: M31.3) during 1995-2016 were included. Annual incidence rate (IR), point prevalence (PP) and standardized mortality ratio (SMR) were calculated. The entire adult population in Denmark served as control population. CV morbidity was divided into heart failure (HF) (ICD-10 code I21, I50, J81 and I110) and myocardial infarction (MI) (ICD-10 code I21-25). Death caused by CV disease (ICD-10 code I1-999) was registered.

Results: We identified 1829 individuals with GPA. The median annual IR was 20.5/1,000,000 and PP was 277/1,000,000 in 2015. Overall SMR was 2.14. Among patients with GPA 171 had a hospital diagnosis of MI. Compared to the control population, the hazard ratio (HR) of MI was 2.47 (95% CI 4.55-11.46) during the first 3 months after the GPA diagnosis. From 3 months to one year declining to 1.41 (95%CI 0.80-2.49) and after 10 years the HR was still slightly increased to 1.64 (95%CI 1.20-2.23). The risk of a diagnosis of HF was markedly increased with a HR at 7.22 (95% CI 4.55-11.46) during the first 3 months after a GPA diagnosis, after three months up to one year 2.94 (95%CI 1.87-4.69), and 2.07 (95% CI 1.54-2.78) after 10 years. The total number of CV deaths in the GPA cohort was 307. During the first three months after a GPA diagnosis, the HR was increased to 9.51 (95%CI 7.12-12.70) declining to 2.51 (95% CI 1.77-3.58) after one year, but still increased to 1.56 (95% CI 1.23-1.98) after 10 years.

Disclosure of Interests: Helle Laursen Grant/research support from: Odense University Hospital, Roukemtology, Odense, Denmark; Odense University Hospital, Rheumatology, Odense, Denmark
Conclusion: In a population-based study we found an overall increased SMR. The risk of CV morbidity and of CV death among patients with a register diagnosis of GPA was increased. There was a striking temporal relation between a high HR of CV morbidity and mortality during the first year after the diagnosis of GPA. Nevertheless, the HR of CV morbidity and mortality was albeit lower still increased after 10 years with a diagnosis of GPA. The result indicates a strong association between systemic vascular inflammatory disease and CV involvement. A time of diagnosis of GPA systemic inflammatory activity usually is present and the results point towards an association of inflammation with CV risk-factors probably including premature and pronounced atherosclerosis. The persistence of increased HR of CV involvement after 10 years indicates a permanent influence on the risk factors.

FRID0264

ADVERSE EVENTS DUE TO HIGH DOSE GLUCOCORTICOIDS – LESSONS FROM ANCA-ASSOCIATED VASCULITIS AND OTHER INFLAMMATORY DISEASES

Peter Rutherford, Dieter Götte. Vifor Pharma, Medical, Zurich, Switzerland

Background: High dose glucocorticoids (GCs) are a component of induction remission and maintenance regimes in ANCA-associated vasculitides (AAV) and are used in other inflammatory disorders. The adverse event (AE) profile of GC is well known and in AAV is believed to link to early mortality risk from infection as well as long term organ/tissue damage. However, it is known GC AE reporting is incomplete and EULAR made specific recommendations for such reporting in clinical trials (Van der Goes 2010).

Objectives: This systematic literature review aimed to examine AE rates and outcomes related to high dose GC use in AAV and to quantify AE risk in terms of GC dose and duration.

Methods: A systematic literature review was performed of studies published between 1 Jan 2007 and 30 January 2018. Data on GC-related AEs (defined as any untoward medical occurrence) and serious AEs (defined as any untoward medical occurrence that resulted in death, was life threatening, required or prolongation of hospitalization, was organ system specific or resulted in persistent or significant disability or incapacity) were extracted from identified trials. The initial AAV search demonstrated incomplete GC data collection compared to EULAR recommendations in most AAV studies so the search strategy was extended to include other inflammatory disorders in which similar GC regimes and doses are used namely systemic lupus erythematosus, glomerulonephritis, pemphigus and giant cell arteritis.

Results: Three hundred and eleven studies of these 5 conditions were selected for a detailed AE analysis on the basis of their inclusion of full description of GC regime, actual delivered GC dose and patient exposure. Of the 62,630 patients enrolled in the 38 studies, 35,587 were exposed to GCs. 21 studies reported serious AEs, while 17 studies reported AEs only. The most common serious AEs related to specific organ damage - particularly musculoskeletal, ocular and neuropsychiatric - but mortality and infection were also observed. The most common AEs were metabolic conditions, with diabetes related events comprising 72% of the metabolic AEs, and weight gain comprising 15%.

Conclusion: GC-related AE reporting in clinical studies of high dose GCs could be improved. Serious AEs including organ damage, infection and mortality were reported and both total GC dose and therapy duration are important risk factors mortality and infection. Metabolic and musculoskeletal events are a particular patient burden. New therapeutic options for AAV and other disorders should aim to reduce this AE profile.

FR10266 ABERRANT PD1 AND VISTA EXPRESSION ON CD4+ TH-CELLS IN GIANT CELL ARTERITIS
Rebeca Hid Cadena1, Rosanne Reitsema2, Wayel Abdulahad2,3, Minke G. Huising2, Annemieke Boots1, Peter Heijmans1, Elisabeth Brouwer1,2.
Vascularis Expertise Center Groningen. 1University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands; 2University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands.

Background: The immune system controls immune responses by balancing positive and negative immune checkpoint (IC) molecules in cell-cell interactions. These co-stimulatory and co-inhibitory molecules allow complete T-cell activation and T-cell effector functions giving rise to an optimal immune response while preventing autoimmunity (1). Failure of tolerance results in the initiation and propagation of pathogenic T-cell responses leading to the development of autoimmune diseases such as Giant Cell Arteritis (GCA). The latter is a complex illness of multiple pathogenic factors with important contributions of both innate and adaptive immunity in its initiation and perpetuation (2,3). Recently, a loss of inhibitory checkpoints on immune cells has been implicated in the immunopathology of GCA (4,5). The possible contribution of IC pathways to the dysregulation of Th-cells in GCA could aid in our understanding of GCA immunopathology.

Objectives: In this study, we aimed to investigate the expression of different IC molecules and their ligands by circulating monocytes, and functionally distinct populations of CD4+ T-cells in peripheral blood samples from GCA-patients in comparison to healthy controls (HCs).

Methods: In a cross-sectional study, fresh blood samples were obtained from 30 GCA-patients with/without immunosuppressive treatment (glucocorticoids) and 18 sex and age-matched HCs. The frequency of the expression of different IC including CD80/86, PD-L1, PD2 and V-domain Ig suppressor of T-cell activation (VISTA) were determined on total monocytes and subsets (classical, intermediate and non-classical). In parallel, expression of the corresponding receptors CD28, Cytotoxic T-Lymphocyte-associated antigen 4 (CTLA-4), Programmed death-1 (PD-1), and VISTA were determined on total CD4+ and subsets of Th-cells defined by CD45RA and CD25 expression of GCA-patients and HCs by flow cytometry.

Results: The frequencies of CD80/CD86+ and VISTA+ monocytes were decreased in GCA-patients compared to HCs. Proportions of circulating CD4+ Th-cells in GCA-patients were not different when compared to HCs. The frequencies of CD28 and CTLA-4 expressing CD4+Th-cells did not differ between GCA-patients and HCs. In contrast, proportions of PD-1 and VISTA expressing Th-cells were significantly decreased in GCA patients. Memory T-cells showed decreased expression of IC molecules. Interestingly, naïve T-cell populations already demonstrated loss of PD-1 and VISTA.

Conclusion: In GCA, lower frequencies of CD80/CD86+ and VISTA+ circulating monocytes were found. Likewise, decreased proportions of PD-1+CD4+ and VISTA+CD4+ Th-cells were noted. Decrease of negative IC on the surface of immune cells could add to the persistent activation of CD4+T-cells seen in GCA.

REFERENCES:
[1] Ceeris S, Nowak EC, Noelle RJ. B7 family checkpoint regulators in CD4+ and VISTA+CD4+ Th-cells were noted. Decrease of negative IC molecules and their ligands by circulating monocytes were found. Likewise, decreased proportions of PD-1 and VISTA. Interestingly, naïve T-cell populations already demonstrated loss of PD-1 and VISTA.

FR10267 DIAGNOSING POLYMALGIA RHEUMATICA: THE IMPACT OF FAST-TRACK CLINIC AT HOSPITALIZATION RATES
Stavros Chrysidis1, Nikolalet Giannoutsou1, Philip Lage-Hansen1, Andreas Diamandopoulos2,3. South-west Jutland Hospital, Esbjerg, Esbjerg, Denmark; 2Martha Hensens Hospital, Oslo, Oslo, Norway.

Background: Polymyalgia Rheumatica (PMR) is a common inflammatory autoimmune rheumatic disease, with the highest incidence rates seen in Scandinavia.

One of the challenges in the diagnosis of PMR is the lack of diagnostic tests specific for the disease. The diagnosis may require exclusion of other conditions that can present with polymyalgia symptoms and may lead to hospitalization. Only limited data on hospitalization rates among patients with PMR exists (1).

Ultrasonography is likely to be in differential PMR from non-inflamatory conditions and can be used for the diagnosis of concomitant Giant Cell Arteritis (GCA).

GCA Fast Track Clinics (FT) using US as the main diagnostic tool have shown both improvement in patient outcomes and decrease in the cost of care(2).

Objectives: To investigate the admission rates of patients diagnosed with PMR and the impact of the FT on these rates.

Methods: A FT clinic for patients suspected to have PMR was established at rheumatological outpatient clinic of South-West Jutland Hospital (serving 250,000 inhabitants) in January 2018. Collaboration with the Emergency Medical department was established and patients with PMR symptoms referred to the hospital were examined at FT within 0-1 days, thereby avoiding hospitalization. Similarly, patients referred with PMR symptoms to the outpatient clinic by a GP, were examined at FT within 1-2 days. At FT a thorough history and clinical examination were performed including musculo-skeletal and vascular US. Retrospectively data from patients diagnosed with PMR from 2013-2018 was analyzed.

Results: In a 6 years’ period, 336 patients were diagnosed with PMR. 54 patients were diagnosed during hospitalization. Hospitalized patients were older (mean values ± standard deviation) 73.61±18.96 vs 70.94 ±7.97 years, p=0.024, with significantly higher initial C-reactive protein (CRP, mg/l) levels 99±58.8 vs 43.9±37.p<0.0001 and a shorter duration of symptoms (6.92±5.5 vs 13.6±13.7 weeks, p=0.0018). No differences were found regarding gender, PMR related symptoms, initial prednisolone dose and response to treatment. An equal annual distribution of the number of new diagnosed cases and hospitalizations rates during the first 5 years was found. After the implementation of the FT at January 2018 a significant decrease in hospitalization rates (19.4% vs 3.5% p=0.0001) and inpatient days of care (4.15±3.1 vs 110, p<0.0001) was observed. The time from symptoms debut to diagnosis was also significantly decreased from 13, 74 to 6, 79 weeks (Table).

FRID0268 CLINICAL FEATURES OF TAKAYASU'S ARTERITIS FROM AN INCEPTION COHORT: EARLY DISEASE IS CHARACTERIZED BY ‘SYSTEMIC INFLAMMATION’
Fatma Alibaz-Oner, On behalf of Turkish Takayasu Arteritis Study Group. Marmara University Faculty of Medicine, Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: There is only retrospective and very limited data for the long term prognosis of Takayasu’s Arteritis (TAK), a rare large-vessel vasculitis.

Objectives: In this study, we aimed to present the preliminary results of a Takayasu Inception Cohort settled for long term, prospective follow-up of only newly-diagnosed patients with TAK.

Methods: Patients fulfilling the American College of Rheumatology 1990 criteria for TAK and diagnosed in the last 12 months were included to the study. Patients’ data were recorded in an electronic database of an international ‘Takayasu’s Arteritis Registry’ requiring baseline and at least annual visits. Data is compared with an historical Turkish cohort previously published (Biçakçigil et al., 2009).

Results: The study included 170 patients (age: 38.5±13.1 years, F/M: 143/27) with TAK from 15 tertiary Rheumatology centers in Turkey. The mean symptom duration of patients was 5.2 years at diagnosis. According to the angiographic classification, 68.2% of the study group had type I and only 18.3% had type V disease. When we compared our results to our retrospective cohort (previously published by Turkish Takayasu Arteritis Study Group), constitutional symptoms (115/165=69.6% vs 66%) and limb claudication (87/131=66.4% vs 48%) were observed to be more frequent, whereas pulselessness (45/130=34.6% vs 88%) was less in the inception cohort. Carotidynia was present only in the inception cohort (Table 1). Cardiodynamics was observed 78% of patients. At least one relapse was observed 40% of patients mycophenolate mofetil and 5 (2.9%) patients biologics at disease-onset.

Disclosure of Interests: None declared

FRID0269 COMPARATIVE STUDY OF INFlixIMAB VERSUS ADALUMAB IN REFRACTORY UVEITIS DUE TO BEHÇET’S DISEASE. NATIONAL MULTICENTER STUDY OF 177 CASES

Background: Uveitis is one of the major causes of disability of Behçet’s disease (BD). According to the “Expert panel recommendations”, anti-TNF therapy with infliximab (IFX) or adalimumab (ADA) may be considered as first- or second-line therapy for patients with BD-opthalmic manifestations.

Objectives: To compare IFX versus ADA as first biologic drug in refractory uveitis due to BD for 1-year period.

Methods: Multicenter study of BD-associated uveitis refractory to conventional biologic treatment. Dosing schedule: IFX 3-5 mg/kg iv at 0, 2 and 6 weeks and then every 12-16 weeks, and ADA 40 mg/sc/ever other week. Main comparative outcome measures: safety and efficacy, assessing the intraocular inflammation, macular thickness, visual acuity, degree of immunosuppression load, drug retention, and glucocorticoid-sparing effect.

Results: 177 patients (316 affected eyes) were included. IFX was used in 103 and ADA in 74. No significant differences at baseline were observed regarding main demographic features, previous therapy and ocular severity. After 1 year of therapy, we observed an improvement in all ocular parameters in IFX vs ADA groups: AC inflammation (78.18% vs 68.5%), 218/248 (88%) Pulsoless, 22/184 (12%) Respiratory manifestations, 156/248 (63%) Neurologic manifestations, 141/248 (57%) Cardiac involvement, 7/166 (4.1%) Mortality rate was 4.1% (3/73 patients) during a mean annual visits. similarly, mucocutaneous symptoms also seem to be a feature of newly-diagnosed disease (30/162=18.5% vs 8.8%). Regarding comorbidities at diagnosis, the rate of dyslipidemia was 17.6% (30/165)%, diabetes mellitus 15.1% (25/165)%, smoking 20% (34/164)% and obesity (BMI>30) 14% (22/157)% among TAK patients. All patients were given oral corticosteroid (CS) therapy (0.5-1 mg/kg) at diagnosis, 17 patients (17/180-10%) also having CS pulses. In addition to CSs, 68 patients (50.6%) were given methotrexate, 31 patients (18.2%) azathioprine, 3 (3.5%) cyclophosphamide, 12 patients (7.1%) iflamamide, 2 (12.1%) patients mycophenolate motil and 5 (2.9%) patients biologics at disease-onset (2 tocilizumab, 2 infliximab, 1 adalimumab). Biologic agents were chosen for 7 patients (7/32) at last visit(1 adalimumab, 4 tocilizumab, 2 infliximab).

REFERENCES:

Background: Behçet’s disease (BD) is a variable vessel vasculitis with a wide and heterogeneous set of signs and symptoms. The inhibitor of phosphodiesterase-4 Apremilast (APR) has demonstrated efficacy in the treatment of oral and/or genital ulcers.

Objectives: To assess the efficacy and safety of APR in BD patients with manifestations different from mucocutaneous ulcers.

Methods: National multicenter retrospective study on 32 BD patients treated with APR at maintained standard dose of 30 mg twice daily.

Results: From a cohort of 49 patients with oral and/or genital ulcers related to BD and refractory to conventional and/or biological treatment, we selected the cases with another clinical manifestation(s) (n=32, 23 women/9 men), mean age of 46.3±5.05 years. Non-aphthous manifestations present at apremilast onset were: arthralgia/arthritis (15), furunculosis/pseudofolliculitis (12), asthenia (7), erythema nodosum (3), furunculosis (2), paradoxical psoriasis by TNFi (2), itilits (2), deep venous thrombosis (2), erythematosus and scaly skin lesions (1), fever (1), eating disorder (1), fibromyalgia (1), unilateral anterior uveitis (1) and neurobehçet (1). APR was used in monotherapy (n=3) or combined (n=29) with oral corticosteroids (20), colchicine (17), methotrexate (5), azathioprine (3), dapson (3), tocilizumab (1), hydroxychloroquine (1) and/or mesalazine (1). The outcome of the different clinical symptoms is shown in TABLE. The patient with neurobehçet kept stable (paresthesias) during the 6 months of follow-up. The 2 cases of deep venous thrombosis and the case of anterior uveitis resolved with anticoagulants and adjuvant topical treatment, respectively. Furunculosis, folliculitis/pseudofolliculitis and itilits were the manifestations that improved completely and rapidly. The cases of arthritids experienced improvement, while those with arthromyalgia presented a torpid evolution.

Conclusion: Our data show an improvement of the cutaneous follicular and intestinal clinic with APR and a stability of the neurological clinic, while the musculoskeletal manifestations were mostly refractory.

FRI0272 USE OF CONTRAST ENHANCED ULTRASOUND SONOGRAPHY (CEUS) IN LARGE VESSEL VASCULITIS (LVV)

Raoul Bergner, Jan Splitthoff, Daniel Wadsack, Klinikum Ludwigshafen, Medizinische Klinik A – Sektor Rheumatologie, Ludwigshafen, Germany

Background: C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are important parameters in the monitoring of LVV. Since Toilлизумab is approved for treatment of LVV these cheap and easy repeatable parameters are worthless because of their normalisation by Tocilizumab. The limitation of our study is the small number of patients, the missing blinding of the investigator and the method intrinsic fact, that you can’t investigate all involved vessels by ultrasound/CEUS.

Objectives: CEUS can increase the visibility of tissue perfusion, particularly if there is a very slow bloodflow, which cannot be detected by power-doppler sonography.

Methods: In this proof of concept study we investigated patients with active and inative LVV (alLV/II VKV) with CEUS. After injection of ultrasound contrast agent we measured the contrasted area of large vessels in a transverse section first if the lumen was completely contrasted and once again 4-8 seconds later. If the vessel wall incorporated the contrast agent the contrasted area increased (Fig 1). The increase of the contrasted area (CA) was correlated with CRP and ESR. Patients were only included if they were not treated with Toilлизумab and therefore ESR and CRP were usable to evaluate the disease activity.

Results: Investigated were 16 patients (13 female, 3 male), 8 with alLV and 8 with II VKV, respectively. The mean CA was 66.6±44.6 (alLV) vs. 2.4±6.6% (II VKV) (p<0.0001). The increase correlated significantly with the CRP r=0.87, p<0.0001. An increase of the CA was 66.6±44.6 (alLV) vs. 2.4±6.6% (II VKV) (p<0.0001). The mean daily dose of OGCs measured over 6 months post-index among this patient sample (Q1: £ 1.00 to £ 1.00; Q2: £ 2.00 to £ 3.00; Q3: £ 15.00 to £ 25.00 mg; Q4: > 50.00 mg). Potential AEs were cerebrovascular disease, diabetes, chronic pulmonary disease, and renal disease. Mean daily OGC dose was 28.9 mg during the first 6 months post-index. Mean daily OGC dose was 28.9 mg during the first 6 months post-index. Mean (SD) CRP and ESR during the 12-month follow-up ranged from 7.5% to 24.5% from OGC daily dose Q1 to Q4 cohorts. The proportion of patients with glucose level, serious infections, cataracts, gastrointestinal bleeding or ulcer and increases in body mass index (BMI). Actual OGC use by patient could not be confirmed and is a limitation of this study.

Results: Mean age of the 785 eligible patients was 76 years (SD 9); 70% were female. Mean Deyo Charlson Comorbidity Index score at base-line was 1.57 (SD 2.01). The most common baseline comorbid conditions were cerebrovascular disease, diabetes, chronic pulmonary disease, and renal disease. Mean daily OGC dose was 28.9 mg during the first 6 months post-index. Mean (SD) CRP and ESR during the 12-month follow-up ranged from 7.5% to 24.5% from OGC daily dose Q1 to Q4 cohorts. The proportion of patients with glucose level, serious infections, cataracts, gastrointestinal bleeding or ulcer ranged from 6.0% in Q1 to 11.8% in Q4. An increase in BMI of 5 ranged from 4.1% to 6.4% from Q1 to Q4.

Conclusion: In patients with GCA, potential OGC-related AEs increased with increased daily OGC dose. This highlights the need for effective therapies that reduce the exposure and potential risk of OGCs.

SURVEYING PATIENTS WITH TAKAYASU ARTERITIS WITH A DELAYED DIAGNOSIS

Irina Borodina1, Artem Popov2, Yevgeny Bogdanov1, Vitaly Voinov2, 1Ural State Medical University, hospital therapy, Yekaterinburg, Russian Federation; 2ural State Medical University, HOspital therapy, Yekaterinburg, Russian Federation

Background: Takayasu arteritis (TA) is a well known, but rarely identified variety of large vessel vasculitis. Frequency of initial misdiagnosing in TA patients has been reported to reach 80%. Up to 80% of TA cases are correctly diagnosed only 2 to 11 years after the symptoms presentation. Objectives: to study possible reasons for misdiagnosing in TA patients with a delayed diagnosis.

Methods: cross-sectional survey included 30 TA patients. All subjects met ACR criteria for TA and more than 12 months since the onset of the clinical manifestations delayed diagnosis. The subjects were asked to recall if vessels auscultation (VA), measurement of both arms and legs blood pressure (BP), assessment of BP and pulse asymmetry (PA) were performed during their first physician visit following the symptoms onset. Recall if vessels auscultation (VA), measurement of both arms and legs blood pressure (BP), assessment of BP and pulse asymmetry (PA) were performed during their first physician visit following the symptoms onset. Results: 19 (67%) patients reported no VA during the initial examination, only 3 (10%) subjects confirmed the test performed, 5 (17%) were not sure and 3 (10%) did not apply for medical aid during the first year of the symptoms occurrence. Arms BP asymmetry was not assessed in 13 (43%) patients, in 6 (20%) subjects correct BP tests were performed, 8 (27%) responders were not sure and 3 (10%) had not consulted any physician timely. PA was assessed in 7 (23%) cases, PA was not tested in 12 (40%) patients, and 8 (27%) subjects were not sure. Arms and legs BP was not assessed in 26 (87%) patients during their initial examination.

Conclusion: the data obtained confirm paramount importance of proper physical examination during initial physician’s consultation for timely and correct Takayasu arteritis diagnosis.

HIGH ANGIOPOIETIN-2 LEVELS ASSOCIATE WITH ARTERIAL INFLAMMATION AND LONG-TERM GLUCOCORTICOID REQUIREMENT IN POLYMYALGIA RHEUMATICA

Yannick van Sleen1, Anniemiek Boets2, Wayel Abdulaahad3, Johan Bijzet4, Maria Sandovici5, Kornelis van der Geest6, Elisabeth Brouwer6,1, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 3University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 4University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 5University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 6University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Polymyalgia rheumatica (PMR) frequently co-occurs with giant cell arteritis (GCA). So far, a simple biomarker for detecting concomitant arteritis or PMR pattern lacking. Furthermore, biomarkers predicting disease course in PMR are awaited.

Objectives: We here investigated the diagnostic and prognostic value of acute-phase markers (ESR, CRP, IL-6, serum amyloid A) and angiogenesis markers, except angiopoietin-1, angiopoietin-2 in isolated PMR and PMR/GCA overlap patients.

Results: We prospectively included 39 treatment-naive PMR patients, of which 10 patients also showed evidence of large vessel GCA on FDG-PET/CT. Anterior healthy controls (N=13) and infection controls (N=32) were included for comparison. Serum marker levels were measured by ELISA or Luminex. ROC and Kaplan Meier analyses were used to assess diagnostic and prognostic accuracy, respectively.

Conclusions: All acute-phase and angiogenesis markers, except angiopoietin-1, were higher in isolated PMR patients compared to HCs. Angiopoietin-2, ESR and soluble Tie-2 were significantly higher in patients with PMR/GCA overlap compared to isolated PMR patients. Angiopoietin-2, but not soluble Tie-2, outperformed ESR and CRP in discriminating patients with and without overlapping GCA (AUC 0.90). Moreover, high angiopoietin-2 levels were associated with long-term glucocorticoid requirement.

Luis Hernández, Miguel A González-Gay, Ricardo Blanco. Rheumatology, Internal Medicine and Pathology Units, Santander, Navarra, Madrid, Torrelavega, León, Pontevedra, Barcelona, Mondragón, Santiago de Compostela, Vigo, Alicante, Lugo, Badalona, Palencia, Alicante de San Ju A Coruña, Granada, Bilbao, Avilés, Castellón, Salamanca, Zaragoza, Valencia, Menorca, Málaga, Ávila, Gijón, Ourense, Tenerife, Sevilla, Lérida, Spain

Background: In Giant Cell Arteritis (GCA) two dominant cytokine clusters have been linked to disease activity, IL-6 – IL-17 axis (Th17) and IL-12 – IFN-γ axis (Th1). The first one related to systemic symptoms and the second route responsible for ischemic symptoms. Tocilizumab (TCZ) performs its effect mainly by inhibiting Th17 axis and ternary Th1 route. Objectives: Our aim is to evaluate the effect of TCZ on ischemic and systemic symptoms throughout the follow up.

Methods: Retrospective, multicenter study of 134 patients diagnosed of GCA on treatment with TCZ. We evaluate the efficacy of TCZ by improving ischemic (visual involvement, headache, jaw claudication) and systemic symptoms (fever, constitutional syndrome, polymyalgia rheumatica (PMR)).

Results: We evaluated 134 patients (101 w/33 m) and its main symptoms at TCZ onset. TABLE 1. (54.5%) patients presented PMR followed by headache in 70 (52.2%) cases, constitutional syndrome in 31 (23.1%) and visual involvement in 28 (20.5%) patients. After one month of treatment there was an important clinical improvement, persisting in 12.3% of patients PMR, 10.6% headache and 10.6% visual involvement. Throughout the follow-up, the improvement of ischemic symptoms was slower. At month 12, in 5.6% (4) of patients, visual involvement impairment, and 2.8% (2) patients presented headache and constitutional syndrome. However, the analytical improvement was statistically significant from the first month and sustained during follow-up.

Conclusion: According to the results of our study, we can conclude that in clinical practice, ischemic symptoms last longer to improve than systemic symptoms; being visual affectation the most frequent symptom after 12 months of follow-up.

Background: Eosinophilic granulomatosis with polyangiitis (EGPA), formerly known as Churg-Strauss syndrome, is a small-vessel necrotizing vasculitis associated with eosinophilia and asthma. Glucocorticoids (GCs) usually control the disease, but relapses and GC-dependant asthma are frequent, leading to potential biological therapy use.

Objectives: We examined off-label biological therapy use for relapsing/refractory EGPA.

Methods: Remission was defined as the absence of asthma and vasculitis manifestations with a prednisone dose ≤5 mg/day, and partial response as the absence of manifestations requiring prednisone dose between 6 and 10 mg/day.

Results: One hundred and eighteen patients (66 men, 52 women; median age 50.5 years) were included. Fifty (42%) patients received rituximab (RTX), 38 (32%) methylprednisolone (MEPO), and 30 (26%) benznidazol (OMA).

Previous treatments were: oral GCs (98%), methylprednisolone infusions (51%), azathioprine (68%), cyclophosphamide (47%), methotrexate (30%), mycophenolate mofetil (8%).

At inclusion, median (interquartile range) BVAS in the RTX, OMA and MEPO groups were 8 (4.5-13), 2 (1.5-4) and 2 (2-5), respectively, median (IQR) daily GCs dose were 20 mg/day (15-40), 20 mg/day (10-37.5), 10 mg/day (7.5-20). GC-dependant asthma was found in 39 (78%) of the RTX group, 36 (95%) in the MEPO group and 28 (83%) in the OMA group.

After median follow-up of 22.8 months (IQR 10-47), remissions, partial responses and therapeutic failures, respectively, were noted in 50%, 16% and 34% for RTX recipients, 17%, 38% and 45% for the OMA group and 84%, 3% and 13% for the MEPO group.

Median BVAS dropped to 0 at 6 and 12 months and at last follow-up in all groups. A GC-sparing effect seemed more important with RTX and MEPO. Median GCs dose decreased from the baseline 20 mg/day to 8.5 at 6 months, 7.5 at 12 months and 5 at last follow-up in the RTX group, from 20 mg/day to 12 at 6 months, 10 at 12 months and 10 at last follow-up in the OMA group, and from 10 mg/day at 5 to 6 months, 3 at 12 months and 5 at last follow-up in the MEPO group.

In the MEPO group, no difference was noted between patients receiving 100 mg and those 300 mg monthly. Nineteen (18%) patients stopped RTX because of refractory disease, and 12 (24%) experienced adverse events, including severe infections in 5. Thirteen (43%) stopped OMA because of severe infusion reaction in one and refractory disease in 12, and 4 (13%) patients receiving OMA experienced adverse events. Three (8%) patients stopped MEPO because of adverse events in 2 (one severe infusion reaction and one because of paresthesia), because of pregnancy in one. Seven (18%) additional patients receiving MEPO experienced adverse events, mainly asthenia.

Conclusion: The results suggest that RTX may be effective in 50% of patients with vasculitides relapses related to EGPA, with an acceptable safety profile, while MEPO is highly effective with a good GCs-sparing effect and safety profile in patients with steroid-dependent asthma.

BAFF AND APRIL GENE EXPRESSION IN PATIENTS WITH ANCA ASSOCIATED VASCULITIS

Saket Jha1, Jagdeep Singh2, Ranjana Minz2, Aadhah Dhoria1, Gorsik Naidu1, Rajiv Kumar1, Manish Rath1, Sanjay Jain1, Shashi Anand2, Amarn Sharma1. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Clinical Rheumatology and Immunology wing, Department of Internal Medicine, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, India; 3Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Nephrology, Chandigarh, India

Background: Neutrophil activation is the central step in the pathogenesis of ANCA associated vasculitis (AAV). Activated neutrophils are an important source of tumor necrosis factor (TNF) ligands involved in the B cell development and survival, namely, B cell activating factor (BAFF) and a proliferating ligand (APRIL)1. They have been postulated to have a role in the pathogenesis of AAV but presently there is limited data2, 3.

Objectives: To study the expression of BAFF and APRIL genes in patients with AAV and healthy controls and their correlation with disease activity.

Methods: This was a prospective case-control study. Gene expression of BAFF and APRIL was studied in 20 patients of AAV (10 each with AAV and healthy controls and their correlation with disease activity.

Results: Out of 20 AAV patients 16 were GPA and 4 MP. Mean age of patients in active (8 GPA and 2 MP) and remission (8 GPA and 2 MP) group was 34.5 ± 16.1 and 39.9 ± 16.6 years respectively. The sex distribution in both groups was 1:1. Mean BVASv3, ESR and CRP of patients and controls.

There was no significant APRIL gene expression in patients with AAV. Associated with ANCA associated vasculitis (AAV). Activated neutrophils is significantly expressed in patients with AAV.

Figure 1: Box and whisker plot of BAFF expression in active AAV patients, AAV in remission and controls.

Conclusion: BAFF gene is significantly expressed in patients with ANCA associated vasculitits. Among AAV patients there is significantly higher expression of BAFF in patients with active disease than disease activity.

There is no significant APRIL gene expression in patients with AAV.

REFERENCES:
Results: There was no statistically significant correlation between HLA B51 and systemic manifestations or disease activity or Doppler findings nor capillary parameters and morphology. There was statistically significant relation between HLA B51 and ankle brachial index. There was statistically significant difference between patients and controls in EDV, RI of the carotid artery, and arterial, venous lumens of the capil- lary, also the capillary lobe and length with lower values in the patients. There was statistically significant difference between patients and controls in carotid intima media thickness with higher values in patients, inspite of the absence of significant difference in lipid.

Conclusion: HLA B51 didn’t link to different clinical presentation in BD; it is related to peripheral arterial affection only. BD patients had poor arter- ial compliance and increased arterial stiffness, there is precldiual arteri- osclerosis in BD not to related to the level of lipid profile.

FRIO282 STATINS REDUCE RELAPSE RATE IN TAKAYASU ARTERITIS
Oh Chan Kwon1,2, Wook Jang Seo3, Ji Seon Oh4, Min-Chan Park2, Seokchan Hong1, Chang-Kee Lee1, Bin Yoo1, Yong-Gil Kim1, 1University of Ulsan College of Medicine, Asan Medical Center, Division of Rheumatology, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 2Yonsei University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3Seoul Veterans Hospital, Division of Rheumatology, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 4University of Ulsan College of Medicine, Department of Rheumatology, Asan Medical Center, Division of Biomedical Informatics, Seoul, Korea, Rep. of (South Korea)

Background: Takayasu arteritis (TAK) is a chronic inflammatory disease, mainly affecting aorta and its major branches. Despite treatment with glu- cocorticoid and adjunctive immunosuppressive agent, relapse is common. Considering the high relapse rate, it is important to identify additional medications that may help sustain remission. Statins, as having anti-inflamatory and immunomodulatory effects, may be one such possibility.

Objectives: To investigate the effect of statins on relapse of Takayasu arteritis (TAK), which frequently occurs after achievement of remission.

Methods: We conducted a retrospective study on TAK patients with active disease, diagnosed between 2012 and 2017. Relapse was defined as recurrence of active disease after achieving remission. Demographic and clinical parameters of patients who experienced relapse were com- pared to those who did not. To identify factors associated with relapse, multivariate Cox regression analysis with stepwise backward elimination was performed. Inverse probability of treatment weighting (IPTW)-adjusted analysis was used to evaluate the influence of statins on relapse.

Table. Multivariate Cox proportional hazard regression analysis estimating risk of relapse

</tr>
</tbody>
</table>

Abbreviation: LDL; low density lipoprotein

Results: Of the total 74 TAK patients, 40 (54.1%) patients received statins, whereas 34 (45.9%) patients did not. Relapse was observed in 36 (48.6%) patients of the total 74 TAK patients. Compared with patients who did not experience relapse, patients who experienced relapse were younger (44.5±13.5 years vs. 34.1±12.6 years, p=0.001), had lower preva- lence of hypertension (63.2% vs. 38.9%, p=0.037), more commonly had carotidhyia (7.9% vs. 27.8%, p=0.025), had higher LDL-cholesterol (84.8 ±18.8 mg/dl vs. 100.5±26.1 mg/dl, p=0.010), and were less commonly tak- ing statins (71.1% vs 36.1%, p=0.003). These variables were included in multivariate Cox regression analysis. The use of statins was significantly associated with lower risk of relapse (adjusted hazard ratio 0.260, 95% confidence interval 0.120–0.563, p=0.001). Furthermore, IPTW-adjusted analysis confirmed that statin use was associated with a lower risk of relapse (IPTW-adjusted hazard ratio 0.153, 95% confidence interval 0.038–0.616, p=0.008).

Conclusion: In TAK, statins can be beneficial in reducing relapse rate after achieving remission.

Covariates: Age (continuous), hypertension (yes/no), carotidhyia (yes/no), LDL-cholesterol (continuous), and statin use (yes/no)

FRIO283 PRESENTATION AND MANAGEMENT OF GIANT CELL ARTERITIS IN A REAL-WORLD SETTING (ARTEMIS STUDY)

Alfred Mahr1, Marc Paccaudil, Eric Hachulla2, Isabelle Idier4, Varly Devauchelle- Pense3, Hospital Saint Louis, University Paris Diderot, Paris, France; 1University Hospital, Department of Geriatric Medicine, Poitiers, France; 2University Lille Nord de France, Department of Internal Medicine, Lille, France; 3Chugai Pharma France, Medical, Paris La Défense, France; 4University Hospital, Department of Rheumatology and Unit of Immunology, Brest, France

Background: We have little real-world data in France on the natural his- tory and management of patients with GCA.

Objectives: The objective of this retrospective observational study, named ARTEMIS, was to describe the characteristics and management of patients with GCA in real-life settings in France.

Methods: This was a cross-sectional, non-interventional, multicentre, single- centre survey, conducted among hospital-based physicians specialized in internal medicine or rheumatology. Investigators enrolled consecutive patients ≥ 50 years old seen for GCA and currently under treatment. Information on medical practices, such as patient characteristics and diag- nostic journey, diagnostic methods and specific GCA treatments, were collected on an eCRF. GCA activity was assessed on a 100-mm VAS completed by the patients (PIMA) and physicians (PGA). GCA was con- sidered active for VAS scores ≥10 mm. Newly diagnosed GCA was defined as diagnosis (Dg)-to-visit interval -6 weeks. Onset of symptoms- to-Dg interval was classified as “short” (<1 month), “intermediate” (1–3 months) and “long” (>3 months). Descriptive statistics were used for quantitative and qualitative variables.

Results: Over the 3-month inclusion period (August-November 2018), 306 patients were recruited (females: 67.3%, age at Dg: 70 years, 72.5%); 260 (85.0%) and 46 (15.0%) were followed by internists or rheumatolo- gists, respectively. Overall, 39 (12.7%) had newly diagnosed GCA, 267 (87.3%) had a GCA duration ≥ 6 weeks (mean follow-up 24±2.70 months). Original referral of patients to specialized centres was from GPs (55.9%), ophthalmologists (10.1%), neurologists (6.9%), emergency physici- ans (5.6%), internists (4.2%) and rheumatologists (4.9%). Mean time to Dg was 3.3±6.9 months, with an “intermediate” Dg interval for 57.5% of patients. The most common prior medical histories were hypertension (45.8%), psychiatric disorders (10.1%), dyslipidemia (11.8%), diabetes (9.5%) and osteoporosis (5.9%); during follow-up psychiatric disorders, diabetes and osteoporosis were more often reported: 12.1%, 14.7% and 8.5% of patients respectively. Initial GCA presentations included cranial symptoms (89.5% of patients), constitutional symptoms (73.9%), polymyal- gia rheumatica (48.4%), and other extra-cranial manifestations (34.0%). Initial mean ESR and CRP level were 73.0±30.7 mm/hr and 87.3±68.3 mg/l. Temporal artery biopsy, high-resolution temporal artery Doppler ultra- sonography, 18FDG-PET and aortic angio-CT were performed for 84.7%, 31.2%, 26.4% and 29.7% of patients, respectively, and contributed to diagnostic journey, diagnostic methods and specific GCA treatments, were consid- ered active for VAS scores ≥10 mm. Newly diagnosed GCA was defined as diagnosis (Dg)-to-visit interval -6 weeks. Onset of symptoms- to-Dg interval was classified as “short” (<1 month), “intermediate” (1–3 months) and “long” (>3 months). Descriptive statistics were used for quantitative and qualitative variables.

Results: Of the total 74 TAK patients, 40 (54.1%) patients received sta- tins, whereas 34 (45.9%) patients did not. Relapse was observed in 36 (48.6%) patients of the total 74 TAK patients. Compared with patients who did not experience relapse, patients who experienced relapse were younger (44.5±13.5 years vs. 34.1±12.6 years, p=0.001), had lower preva- lence of hypertension (63.2% vs. 38.9%, p=0.037), more commonly had carotidhyia (7.9% vs. 27.8%, p=0.025), had higher LDL-cholesterol (84.8 ±18.8 mg/dl vs. 100.5±26.1 mg/dl, p=0.010), and were less commonly tak- ing statins (71.1% vs 36.1%, p=0.003). These variables were included in multivariate Cox regression analysis. The use of statins was significantly associated with lower risk of relapse (adjusted hazard ratio 0.260, 95% confidence interval 0.120–0.563, p=0.001). Furthermore, IPTW-adjusted analysis confirmed that statin use was associated with a lower risk of relapse (IPTW-adjusted hazard ratio 0.153, 95% confidence interval 0.038–0.616, p=0.008).

Conclusion: In TAK, statins can be beneficial in reducing relapse rate after achieving remission.

Covariates: Age (continuous), hypertension (yes/no), carotidhyia (yes/no), LDL-cholesterol (continuous), and statin use (yes/no)

RESULTS OF A SYSTEMATIC LITERATURE REVIEW INFORMING THE 2018 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF LARGE VESSEL VASCULITIS: EVIDENCE TO GUIDE THE MANAGEMENT OF GIANT CELL ARTERITIS

Sara Monti1,2, Ana Filipa Agueda3, Raashid Lugman4, Frank Buttgerelli5, Maria C. Cad6, Christian Dejaco7, Alfred Mah8, Cristina Ponte9, Caro Salvarani1, Wolfgang A. Schmidt1, Bernhard Hellmich1,1, IFFCCS Policlinico S. Matteo Foundation, University of Pavia, Department of Rheumatology, Pavia, Italy; 2University of Pavia, PhD in Experimental Medicine, Pavia, Italy; 3Centro Hospitalar do Baixo Vouga E.P.E., Department of Rheumatology, Aveiro, Portugal; 4University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 5Charité University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 6University of Barcelona, Institute of Research in Clinical Biochemistry, Barcelona, Spain; 7South Tyrol Health Trust, Hospital of Bruneck, Department of Rheumatology, Bruneck, Italy; 8Hospital Saint Louis, Paris, France; 9Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, Department of Rheumatology, Lisboa, Portugal; 10Azienda USL-IRCCS di Reggio Emilia and University of Modena and Reggio Emilia, Department of Rheumatology, Reggio Emilia, Italy; 11Immuneure Krankenhaus, Klinik für Innere Medizin, Rheumatologie und Klinische Immunologie Berlin-Buch, Berlin, Germany; 12Akademisches Lehrkrankenhaus der Universität Tübingen, Klinik für Innere Medizin, Rheumatologie und Immunologie, Vaskulitis-Zentrum Süd, Medius Kliniken, Kirchheim-unter-Teck, Germany

Background: The latest EULAR recommendations for the management of large vessel vasculitis (LVV) were published in 2009 (1). Since then, imaging has become a reliable diagnostic tool and new therapeutic options are available for giant cell arteritis (GCA), supporting the need to update the recommendations.

Objectives: To analyse the current evidence for the management (diagnosis/monitoring and treatment) of LVV to inform the 2018 update of the EULAR recommendations.

Methods: A systematic literature review (SLR) dealing with diagnosis/monitoring and treatment strategies for LVV, respectively, was performed. Medline, Embase and Cochrane databases were searched from inception until 31st December 2017. Evidence on imaging was excluded in light of recent published EULAR recommendations (2). We reviewed data relevant to GCA. Level of Evidence (LoE), was assessed in accordance with the 2009 Oxford Centre for Evidence-based Medicine.

Results: We identified 283 papers from the SLR. The implementation of a fast-track approach to diagnosis significantly lowered the risk of permanent visual loss compared to historical cohorts (Level of evidence – LoE 2b). The SLR confirmed the efficacy of prompt initiation of glucocorticoids (GC). There was no high-quality evidence on the most appropriate start-dose, route of administration, tapering and duration of GC (LoE 4). Patients with GCA are at increased risk of dose-dependent GC-related adverse events (LoE 3b). The addition of methotrexate (MTX) (LoE 1a) or tocilizumab (TCZ) (LoE 2b) reduced relapse rates and GC requirements (LoE 1b). There was no consistent evidence that anti-platelet agents given at the time of GCA diagnosis prevented future ischaemic events (LoE 2a).

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) (Churg-Strauss) is a small-vessel necrotizing vasculitis characterized by blood and tissue eosinophilia and asthma. Glucocorticoids (GCs) represent the treatment cornerstone. So far, EGPA management is based on conventional immunosuppressants, but GC-dependence remains frequent. Recently, therapies targeting B cells and interleukin-5 have been prescribed, but data on large cohorts are lacking.

Objectives: This study aimed to describe therapeutic management and efficacy of treatments in EGPA patients.

Methods: We set up a multicenter European cohort that included 636 EGPA patients. Treatments used, complete remission rates and vasculitis relapse-free survival were recorded. Complete remission was defined as absence of EGPA relapses and prednisone dose ≤5 mg/d at last follow-up. Efficacy to treat GC-dependent asthma/ENT signs was defined as the absence of asthma/ENT symptoms and prednisone dose ≤5 mg/d within the 6 months after initiation.

Results: For induction, cyclophosphamide (CYC) was the most frequently prescribed immunosuppressant (36.2%), more often in patients with FFS (≥1 P<0.001). GCs alone were used in 37.4%, azathioprine (AZA) in 15.6% and methotrexate (MTX) in 6.2%. No difference was found in the 10-years overall survival between patients with FFS<0.05, FFS=1 and FFS≥2.

Complete remission rates were similar between conventional immunosuppressants (CYC, AZA or MTX) and GCs alone. Vasculitis relapse-free survival was also similar between CYC, AZA or MTX and GCs alone. Similar results were observed for first vasculitis relapse treatments. During follow-up, GC-dependent asthma and/or ENT manifestations were treated with AZA (40%), MTX (25%), cyclophosphamide (6%), rituximab (RTX) (21%), CYC (9%), cyclosporine (6%), omalizumab (5%), rituximab (5.5%), allowing GC-tapering (RTX) (21%), CYC (19%), cyclosporine (6%), omalizumab (5.9%), allowing GC-tapering (RTX) (21%), CYC (19%), cyclosporine (6%), omalizumab (5.9%). Conventional immunosuppressants were mostly used in first and second line, while eosinophil-targeted biotherapies were used in 4th or 5th lines.

Conclusion: In EGPA patients, the response to conventional immunosuppressants, in addition to GCs, is often disappointing compared to GCs alone, without clear benefit on complete remission rates and relapse-free survival. In contrast, notwithstanding a small number of treated patients, eosinophil-targeted therapies seemed promising to treat asthma and/or ENT manifestations.

FRI0288

OPHTHALMOLOGICAL MANIFESTATIONS AND ENDOTHELIN-1 PLASMA LEVELS IN PATIENTS WITH SYSTEMIC NECROTIZING VASCULITIS (SNV)

Lubov Petelivska1, Oleg larenko2, Kateryna larenko2, Bogomolots National Medical University, The Department of Internal Medicine and Surgery, Kyiv, Ukraine; 2Olexandrovitska City Clinical Hospital, The Laboratory Department, Kyiv, Ukraine

Background: Inflammatory eye disease is described in 50% to 60% of patients with ANCA-positive vasculitis and in 10–20% of patients with polyanasthetic nodosa, and for 8% to 16% of patients it is an initial manifestation [1,2]. Endothelin-1 (ET-1) as a potential participant in the local regulation of intraocular pressure, ocular blood vessel tone, and iris smooth muscle tone, suggesting that it may be an important mediator in the development of ocular pathologic conditions [3]. The lower ET-1 plasma levels were found in the optic neuropathy [4].

Objectives: to provide a more complete description of the ocular disease in patients with systemic necrotizing vasculitis (SNV), to evaluate the serum level of ET-1 in patients with SNV with and without eye involvement.

Methods: The study included 36 patients with SNV (polyarthritis nodosa - 8, ANCA - associated vasculitis - 28) and healthy controls (n=26). The 17 patients with SNV had ophthalmological manifestations. Clinical activities of patients were calculated according to the Birmingham Vasculitis Activity Score (BVAS). The serum levels of ET-1 (pmol/L) were determined by immunassay analysis using the kits of Biomedica. The outcomes of this study were the differences in marker levels between SNV patients with and without eye involvement and healthy controls estimated by analysis of the absolute changes in marker levels and the areas under receiver operating characteristic (ROC) curves (AUC).

Results: The ocular manifestation of patient with SNV included episcleritis (n=1), anterior uveitis (n=3), ischaemic optic neuritis (n=3) and exudative retinal vasculitis (n=1). All patients had active disease (BVAS>11). There were no significant differences of BVAS, ESR and CRP between SNV patients with and without eye involvement. In 14% patients with SNV eye involvement was an initial manifestation. The level of ET-1 (M ± σ) in group of SNV patients with eye involvement (n=17) was 0.28 ± 0.13 and did not differ significantly from the control group (0.27 ± 0.10, p>0.05). At the same time, in patients without eye involvement (n=19), it was significantly elevated (0.36 ± 0.34) compared with control group and with group of SNV patients with eye involvement (p = 0.001). ROC analysis showed that the AUC for ET-1 was 0.50±0.10 (p=0.98), which indicates not acceptable capacity for ET-1 differentiate groups of patients with ocular involvement and patients without ocular involvement (sensitivity - 59%, specificity - 57%).
Conclusion: The most common ocular manifestation in patients with SNV was episceritis, which occurred in almost one third of patients. The serum levels of ET-1 were decreased in patients with SNV with eye involvement compared with patients without eye involvement, but this cannot be used for diagnostic purposes.

FRI0289 THE CYCLOPHOSPHAMIDE-SPARING ROLE OF AN INTENSIFIED B-CELLS DEPLETION PROTOCOL IN ANCA-ASSOCIATED VASCULITIS

Dario Roccatello1,2, Savino Sciascia2, Roberta Feroglio1, Daniela Rossi2, Giovanni Bosco Hospital, Turin, Italy; 2University of Turin, Turin, Italy

BACKGROUND: ANCA-associated vasculitis (AAV) are systemic diseases with relapsing chronic course. The management of AAV requires the use of immunosuppressive drugs whose use is associated with potential toxicity.

OBJECTIVES: This case-control study aims to evaluate the immunosuppressive-sparing effect of rituximab (RTX) used with cyclophosphamide (CYC), compared to a traditional regimen based on high-dose CYC.

METHODS: 26 patients (pts) with AAV with a necrotising extracapillary glomerulonephritis were prospectively enrolled. 13 pts received the intensified protocol of B-lymphocyte depletion therapy (IBCDT) “4+2” with RTX and CYC (4 weekly infusions of RTX followed by 2 monthly followed by prednisone tapered to 5 mg/day in 3 months). 13 pts treated with the high-dose CYC treatment protocol followed by azathioprine as maintenance therapy were enrolled as controls.

RESULTS: In the 13 cases treated with the IBCDT we observed a significant reduction in mean values of parameter of disease activity. After administration of RTX, a significant reduction of the mean s-creatinine values and BVAS was observed. All pts had full B-cell depletion on peripheral blood after the first IBCDT protocol after 1 year. No further maintenance therapy was given. In the cases, a response was observed in 8/13 cases. 4 pts did not respond and a death was observed for cardio-vascular causes. No significant difference was observed in terms of response to therapy between the two groups. The IBCDT allows a significant reduction in the cumulative dose of CYC to which each patient was exposed during follow-up, reaching statistical significance levels (p <0.001). Calculated on a monthly basis, the “4+2” protocol allowed an average reduction in the CYC cumulative dose equivalent to 827 mg/month.

Conclusion: In a selected sample of patients with AAV with renal involvement, the IBCDT regimen appeared to be non inferior in terms of the efficacy when compared to CYC-based standard regimens. Moreover, the IBCDT regimen allowed a net reduction in the cumulative average dose of CYC to which pts are exposed, quantifiable in approximately 1g/month.

RENAL TRANSPLANTATION DUE TO RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS (RPGN). COMPARATIVE STUDY WITH NON-AUTOIMMUNE TRANSPLANTATION AND LONG-TERM FOLLOW-UP. STUDY FROM A SINGLE TERTIARY CENTER

Lara Sánchez Bilbao, Marina de Cos-Gómez, Ifiño González-Mazón, Belén Alienza-Mateo, José Luis Martín-Vanillas, Monica Calderón-Goercke, D. Prieto-Peña, Juan Carlos Ruíz-San Millán, Miguel Á. González-Gay, Ricardo Blanco. Rheumatology. Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain; Nephrology. Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

Background: Rapidly Progressive Glomerulonephritis (RPGN) is characterized histologically by the presence of crescents and clinically by a rapid and severe decline in kidney function. Thus, this entity may lead to end stage renal disease, with kidney transplantation. RPGN can be primary, without extra-renal involvement (RPGN-renal-limited), or secondary to systemic autoimmune disorders (RPGN-SAD), infectious diseases or drugs. Kidney transplantation in RPGN-SAD may be associated to a worse outcome.

Objectives: In a series of patients with first transplantation due to RPGN our aim was to assess a) long-term post-transplant survival in RPGN-SAD, b) comparison of post-transplant survival between RPGN-SAD and RPGN-renal-limited and c) comparison of both RPGN (SAD and renal-limited) with a control group of non-immunological disorder, the polycystic kidney disease (PCKD).

Methods: We study three groups of patients: a) RPGN-SAD due to granulomatosis with polyangiitis (n=3), microscopic polyangiitis (n=6) or Goodpasture syndrome (n=2), b) RPGN-renal-limited and c) control group of patients with PCKD. All these patients were transplanted in a single reference University Hospital. The main outcome variables were a) graft and patient survival up to 20 years and b) evolution of renal function (serum creatinine and proteinuria) in the first 5 years of follow-up. Cumulative survival rates after transplantation were estimated by the Kaplan-Meier method and compared between groups using the log-rank test. Kruskal-Wallis test was used to compare quantitative variables and chi2/Fisher’s exact test for qualitative variables.

Results: We included a total of 100 patients with renal transplant: a) RPGN-SAD group (n=11), b) RPGN-renal-limited group (n=32), and c) PCKD group (n=57). No significant differences at baseline were observed between the two RPGN groups regarding sex, age and cardiovascular risk factors. Compared to the PCKD group, patients with RPGN presented higher cholesterol levels at the time of the transplant (p=0.041) with no other significant differences. Renal biopsy had been performed in the 43 patients with RPGN: type I (27.9%), type II (4.7%), type III RPGN (41.9%) and 25.6% of patients had not classified RPGN (no immunofluorescence was performed at the time of the biopsy). From 89 patients (of 100) in which a renal biopsy was performed during the first-year post-transplant, rejection was found in 33 patients (37.1%) without significant differences between the 3 groups (5 cases in the RPGN-SAD group, 11 cases in the RPGN-renal-limited group and 17 cases in the PCKD group; p=0.592). The evolution of serum creatinine and the proteinuria after the transplant is shown in Table 1. There were no significant differences between the three groups in the serum creatinine values during at 1st, 6th, 12th, 36th and 60th months post-transplant. Neither differences were found in terms of graft and patient survival between the 3 groups in 20 years of follow-up (Figures 1 and 2).

Conclusion: Our study shows similar graft and patient survival as well as renal outcome in renal transplant due to RPGN-SAD and RPGN-renal-limited. These outcomes were also similar in non-immune renal disease. Therefore, renal transplantation could be the best option for patients with end stage renal disease due to RPGN regardless of systemic manifestations.

A MULTI-CENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PARALLEL GROUP STUDY TO EVALUATE THE EFFICACY AND SAFETY OF SIRUKUMAB IN THE TREATMENT OF PATIENTS WITH GIANT CELL ARTERITIS

Statement of the study: To evaluate the efficacy and safety of sirukumab (SIR) in giant-cell arteritis (GCA) and other diseases.

Methods: This 2-part phase 3 study enrolled subjects with active GCA (NCT02531633). Subjects were randomized in a 3:3:2:2:2 ratio to one of 5 treatment arms: SIR 100 mg SC q2w + 6-mo prednisone taper (SIR100+6mo), SIR 100 mg SC q2w + 3-mo prednisone taper (SIR100+3mo), SIR 50 mg SC q4w + 6-mo prednisone taper (SIR50+6mo), placebo (PBO) SC q2w + 6-mo prednisone taper (PBO+6mo), PBO SC q2w + 12-mo prednisone taper (PBO+12mo), for 52-week treatment (Part A). Following completion of Part A, subjects could enroll into the study extension with option for open label SIR treatment (Part B). The primary endpoint was the proportion of subjects in sustained remission at Week 52. Secondary endpoints included sustained remission over time, disease flare, and safety. As a result of the early study termination due to administrative reasons, the revised primary endpoint intent-to-treat analysis (revised ITT, N=55) included only subjects who received at least 1 dose of the SC investigational product and had completed 52 weeks (N=28) or had discontinued the study prior to study termination (n=27).

Results: A total of 161 of planned 204 subjects were randomized (mean age 69.6 years, 77.0% female, 98.1% white, 55.9% with new-onset disease). Baseline prednisone dose was >30 mg/day in 50.9% of subjects. The proportions of subjects with disease flares from Week 2 (N=155) to Week 52 were lower in the SIR100+6mo (18.4%), SIR 100+3mo (28.2%) and SIR50+6mo (30.8%) arms compared to the PBO+6mo (40%) and PBO+12mo (37%) arms.

Conclusion: As a result of early study termination, only a few subjects, all in SIR treatment arms, achieved the primary endpoint of sustained remission at Week 52. The proportion of subjects with flares from Week 2 – 52 were higher in the PBO arms compared to SIR arms. The overall safety was consistent with the known SIR safety profile. Study funded by GSK.

Factors Associated With First-Year and Overall Mortality in ANCA Associated Vasculitis; Patients With Renal Limited Vasculitis Makes No Better Than Microscopic Polyangiitis

Onay Gercik1, Zeki Soy pronounced2, Fulya Çakalaşoğlu1, Gokhan Kabadayi1, Idil Kurut1, Dilek Solma3, Servet Akar1, Izmir Kaplı Calbı University, Faculty of Medicine, Rheumatology, Izmir, Turkey; Izmir Kaplı Calbı University, Faculty of Medicine, Nephrology, Izmir, Turkey; Izmir Kaplı Calbı University, Izmir Ataturk Education and Research Hospital, Pathology, Izmir, Turkey

Background: Overall mortality in ANCA-associated vasculitis (AAV) over the last two decades has been reported to be decreasing with the use of immunosuppressive therapies. However, mortality rates remain high and most of the deaths occur in the first year after diagnosis despite treatment.

Objectives: In this study, we aimed to determine the prevalence of mortality in our AAV patients and to investigate the factors that may be associated with first-year and overall mortality.

Methods: Patients followed up in one center with the diagnosis of AAV were included in the study. Diagnostic subgroups were: granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), eosiinophic granulomatosis with polyangiitis (EGPA), and renal-limited vasculitis (RLV). The clinical and demographic characteristics of the patients were collected retrospectively. Factors predictive of mortality were evaluated by Kaplan-Meier method and the Cox proportional hazard model.

Results: In total 104 (45.5%) female and mean age 54.9 ± 15.4 years AAV patients (51 GPA; 25 MPA; 27 RLV and 1 EGPA) were included in the analysis. ANCA positivity was detected in 81 (77.9%) patients with IIF and/or ELISA. ESRD had developed in 31 (32.3%) of AAV patients and in 37.8% of patients with renal involvement. Mortality rate was 14.4% in the first year after diagnosis and 27.9% during a median follow-up period of 1289 (5-5804) days. The age at diagnosis was the only significant predictor of first-year mortality (p=0.001) and the Cox proportional hazard model. Univariate analysis revealed that overall mortality was associated with AAV subgroups (p = 0.035), renal (p = 0.046) and ENT (ear-throat) involvement (p = 0.025). ESRD (p = 0.025) and hemodialysis at the time of diagnosis (p = 0.040). However Cox regression analysis showed age at diagnosis as the only significant predictor also of the overall mortality (P=0.001).

Conclusion: Our findings suggest that there could be some survival differences between AAV subgroups and patients with or without renal and ENT involvement. However, the age at diagnosis seems to be the only significant predictor of first-year and overall mortality in our AAV patients.
Large vessel vasculitis (LVV) and use of granulocyte colony-stimulating factor (G-CSF) and/or chemotherapy by describing our six patient cases and a systematic review of the literature.

Objectives: To evaluate the rare connection of LVV and anticancer therapy by describing our six patient cases and a systematic review of the literature.

LVV and chemotherapy fulfilling our study criteria. Altogether 22 cases were analyzed. Mean age was 59 years (range 40-77 years). In 14/22 patients receiving chemotherapy present similar clinical symptoms with LVV should be kept in mind as differential diagnosis. LVV is a serious condition which may lead to vessel wall damage. Published few case reports and adverse event reports suggest causal association between LVV and use of granulocyte colony-stimulating factor (G-CSF) and/or chemotherapy (1).

Objectives: To evaluate the rare connection of LVV and anticancer therapy by describing our six patient cases and a systematic review of the literature.

Methods: Between 2016-2018 we identified six patients with probable drug induced LVV associated with chemotherapy and G-CSF. All patients had breast cancer. Systematic literature review was performed according to PRISMA guidelines using comprehensive search terms for breast cancer, chemotherapy, LVV and G-CSF.

Results: In our case series, 5/6 patients developed LVV symptoms within two weeks after administration of docetaxel and G-CSF. Vasculitis symptoms disappeared after drug cessation or drug change. Literature search identified 16 published case reports with association of LVV and chemotherapy fulfilling our study criteria. Altogether 22 cases were analyzed. Mean age was 59 years (range 40-77 years). In 14/22 cases data from G-CSF administration was available. Time delay from drug administration to LVV symptoms was average 10 days (range 1-42 days) with G-CSF and median 12 days (range 2-310 days) with chemotherapy. Most prevalent cancer types were breast cancer (8/22), hematological malignancies (7/22) and lung cancer (3/22). Most common clinical LVV symptom were fever (18/22), neck pain (11/22) and chest pain (8/22). Diagnosis was confirmed with imaging studies showing vasculitis in various large vessels in upper body. Notably, four cases had vascular inflammation only in carotid region and this was recognized by radiologist as carotidynia/ transient perivascular inflammation of the carotid artery (TIPIC) syndrome.

Conclusion: Large vessel vasculitis is a possible serious rare adverse event associated with chemotherapy (possibly docetaxel) and G-CSF. Since signs and symptoms are non-specific, we assume this condition is underdiagnosed and should be kept in mind when treating oncological patients. Successful management requires early identification and cessation of the drug. When diagnosed and treated properly, the recovery is usually fast.

Disclosure of Interests: Kirsu Taimen Speakers bureau: Pfizer, Novartis, Abbvie, Roche (lectures); Samu Heino: None declared, Laura Pirilä: None declared, Heikki Relas: Speakers bureau: Pfizer, Riikka Huovinen: Consultant for: MSD, Abbvie, Roche, UCB, Novartis, Pfizer, Amgen, Speakers bureau: Pfizer, Roche, Amgen, Novartis, Amo Hänninen Speakers bureau: Roche, Laura Pirilä Consultant for: Abbvie, Novartis, Eli Lilly, MSD Finland, Pfizer, UCB, Roche, Jansen- Citag, Sangdon, Speakers bureau: Pfizer, Doktor, Novartis, Pfizer, Roche, Amgen, Speakers bureau: Pfizer

Methods: NIS is a publicly available inpatient database that contained data for over 7 million hospital stays, which are a 20% stratified sample of over 4,000 non-federal acute care hospitals across all the regions of the United States of America. The primary outcome was hospitalization costs and charges. The most common reasons for hospitalization were PAN itself (15.3%), sepsis (6.9%), acute kidney injury (4.8%) and acute respiratory failure (2.5%). For the primary outcome, the inpatient prevalence of PAN was found to be 14.9 cases per 100,000 admissions. For secondary outcomes, patients with PAN displayed increased adjusted odds of mortality (OR:1.60, p<0.01), shock (OR:1.81, p<0.01), ICU admission (OR:2.06, p<0.01) and multiorgan failure (OR:3.45, p<0.01) compared to patients without PAN. Patients with PAN also displayed significantly higher hospital costs (additional adjusted mean [aAM]: $10,780, p<0.01), hospitalization charges (aAM: $39,915, p<0.01) and LOS (aAM: 4.2 days, p<0.01) compared to patients without PAN. Patients with PAN displayed a significant association with several comorbidities.

Conclusion: The inpatient prevalence of PAN was higher than what would be expected from the overall prevalence. The mean total hospital costs and total hospitalization charges for patients with PAN were higher than patients without PAN. Analysis of comorbidities found significantly higher odds of several comorbidities even after adjusting for potential confounders.

FRI0296 INPATIENT PREVALENCE, MORTALITY, EXPENDITURES AND COMORBIDITIES OF POLYARTERITIS NODOSA: NATIONWIDE INPATIENT SAMPLE 2014

Patompong Ungprasert1, Kam Wijampreecha2, Wisi Cheungpasitporn3, Chirat Thongprayoon4, Paul Kroner2.

1Pharmacology, Mahidol University, Bangkok, Thailand; 2Mayo Clinic, Rochester, Rochester, United States of America; 3University of Mississippi Medical Center, Jackson, United States of America; 4University of Mississippi Medical Center, Jackson, United States of America; 5Mayo Clinic Rochester, Rochester, United States of America

Background: Polyarteritis nodosa (PAN) is a systemic necrotizing vasculitis that characteristically affects medium-sized arteries of the intestine, kidneys and soft tissue. Little is known about the inpatient burden, expenditures and association with comorbidities of PAN.

Objectives: To investigate the inpatient prevalence, expenditures and comorbidities of patients with PAN using a national inpatient database. Methods: Patients with PAN were identified from the Nationwide Inpatient Sample (NIS) database of the years 2014 using ICD-9 diagnostic code. NIS is a publicly available inpatient database that contained data of over 7 million hospital stays, which are a 20% stratified sample of over 4,000 non-federal acute care hospitals across all the regions of the United States (US). Data on patient characteristics, comorbidities, resource utilization and expenditures was collected. The primary outcome was determining the inpatient prevalence of PAN in hospitalized patients in the US. Secondary outcomes included determining inpatient mortality, inpatient morbidity (measured by shock, ICU admission and multi-organ failure), comorbidities, hospital length of stay (LOS) and total hospital costs and charges. The most common reasons for hospitalization were utilization of the top principal diagnoses in patients with PAN. A cohort of patients without PAN was also identified from the same database to serve as comparators for analysis of comorbidities. Multivariate regression analysis was used to adjust for age, gender, ethnicity, Charlson Comorbidity Index, income, hospital region, location, size and teaching status.

Results: A total of 5,255 patients with PAN were included in the study. The mean age was 58.8 years, and 57% were female. The top reasons for hospitalization were PAN itself (15.3%), sepsis (6.9%), acute kidney injury (4.8%) and acute respiratory failure (2.5%). For the primary outcome, the inpatient prevalence of PAN was found to be 14.9 cases per 100,000 admissions. For secondary outcomes, patients with PAN displayed increased adjusted odds of mortality (OR:1.60, p<0.01), shock (OR:1.81, p<0.01), ICU admission (OR:2.06, p<0.01) and multiorgan failure (OR:3.45, p<0.01) compared to patients without PAN. Patients with PAN also displayed significantly higher hospital costs (additional adjusted mean [aAM]: $10,780, p<0.01), hospitalization charges (aAM: $39,915, p<0.01) and LOS (aAM: 4.2 days, p<0.01) compared to patients without PAN. Patients with PAN displayed a significant association with several comorbidities (Table 1).

FRI0297 CLINICAL FEATURES, TREATMENT MODALITIES AND RELAPSE RATES IN GREEK PATIENTS WITH RETROPERITONEAL FIBROSIS

Aliki Venetsanopoulou1, Evangelia Zampeli2, Sophia Christaki3, Ourania Argyropoulou1, Kyrtaki A. Rodi4, Menelas N. Manousakis5, Foteni N. Skopoul1, Athanasios Tsoufas1, Haralampos M. Moutsopoulos6.

1School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; 2Athens Medical School, Sotiria General Hospital, 3rd Internal Medicine Department, Athens, Greece; 3Europolic Hospital, Department of Internal Medicine and Clinical Immunology, Athens, Greece; 4Stimanoglou Hospital, 3Rheumatology Unit, Athens, Greece; 5Academy of Athens, Athens, Greece

Background: Retroperitoneal fibrosis (RPF) is a rare disease of unknown etiology characterized by deposition of fibro-inflammatory tissue around the infra-renal abdominal aorta. The process may involve adjacent structures leading to complications, the most frequent being ureteral obstruction [1]. RPF is mainly idiopathic (IRPF), yet it might be secondary to malignancies, infections, drugs, or radiotherapy [2]. Recent data argue that IRPF could be part of the IgG4-related diseases [3]. Diagnosis is aided by imaging studies (abdomen CT/MRI), but in patients with newly diagnosed RPF, excluding malignancy is mandatory [2].

Objectives: The aim of our study was a) to describe the presenting clinical, laboratory, imaging features and treatment modalities used in patients
with IRPF from four tertiary medical units in Greece and b) to evaluate factors potentially associated with disease relapse. 

Methods: Medical records of patients diagnosed with RPF from 2000-2018 in four rheumatology units (Laiko, Euroclinic, Sismanoglion and Sotira Hospital) were retrospectively evaluated. Sixty-seven patients with IRPF were included in the study. 

Results: The median age at diagnosis was 56 years (IQR:52.0-60.0), with median disease duration 6.0 years (IQR:3.0-11.0), 56% were smokers and 75% males. Patients more often presented with constitutional symptoms (57%), low back pain (63%), raised inflammatory markers (78%), anemia (43%) and compromised renal function (15%). Commonest imaging findings were periarticular-periiliac mass (46%), periarticular mass (33%), periarticular (25%) and hydrophrenic (36%) with envelopment of one (31%) or both ureters (18%). Tissue biopsy was requested in all patients, but was performed in only 10, with 3 having marked numbers of IgG4-positive plasma cells. Serum IgG4 was measured in 36/67 and 36% had elevated levels at diagnosis (median 224 mg/dL, IQR:174-328). Clinical/laboratory/radiological presentation did not differ between patients with elevated and normal serum IgG4 levels. Steroids were first-line treatment in 93% of patients. Other immunosuppressives used as steroid-sparing agents were azathioprine (70%), cyclophosphamide (19%), mycophenolate-mofetil (18%), D-penicillamine (12%) and methotrexate (8%). Relapse occurred in 19% of patients at a median of 36 months (IQR:18-66) after diagnosis with 69% of them being under therapy. Relapse did not correlate to initial imaging findings or to any treatment modality, yet patients with increased serum IgG4 tended to have higher relapse rate (26% vs 11%, p=0.071). 

Conclusion: Diagnosis of IRPF was mostly based on imaging studies in our cohort. Steroids were used as first-line treatment. Relapse occurred in one-in-five of patients independently of initial clinical/radiographic presentation or treatment modality used. RPF patients with initially elevated serum IgG4 levels tended to have a higher relapse rate.

FRID298

ABNORMALITY OF PERCENTAGES AND ABSOLUTE NUMBERS OF CD4+ T SUBSETS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS AND ITS CORRELATIONS WITH CLINICAL INDICATORS

Yarlin Wang, Xiang-Cong Zhao, Jing Luo. The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: ANCA-associated vasculitis (AAV) is a heterogeneous autoimmune disease with unknown etiology [1-2]. During the last decade, a panel of CD4+ T subsets have been identified. However, the exact role and quantitative status of these subsets in AAV patients remains unclear. 

Objectives: We therefore investigated these T cell subsets in AAV patients. 

Methods: AAV patients (n = 54) and healthy controls (HCs) (n = 19) were enrolled. Of them, ten patients initially presenting with active disease were assessed again after remission was achieved. In addition, 38 patients were renal vasculitis. Proportions and absolute numbers of peripheral blood CD4+ T cell subsets and expression of multiplex cytokines were determined by flow cytometry (FCM). Correlations of clinical indicators with the CD4+ T cell subsets were systematically analyzed. 

Results: Percentages of naive T cells (TN) (p<0.001), terminally differentiated effector (TEMRA) T cells (p=0.027) and activated T cells (aTreg) in AAV patients were decreased, but those of effector memory T-cell subpopulation (TEM) (p<0.001), regulatory T cell (Treg) cells and FoxP3lowCD45RA− T cells were increased. Similar results were observed when we compared absolute numbers of the above corresponding cells in AAV patients and HCs, except TEM. Furthermore, the percentage of aTreg (p=0.043) was decreased while that of Th17 cells (p=0.027) was increased in renal vasculitis patients. A significant correlation was observed between the ratio of Th17 to Treg subset and creatinine or BUN, as well as the ratio of Th17/aTreg was significantly increased in active and renal vasculitis patient. In addition, we found that cytokine IL-2 and IL-4 exhibited a downward while IL-6, IL-10, TNF, IFN-γ and IL-17A trend upward in AAV patients. 

Conclusion: There were abnormally quantitative changes in CD4+ T subsets and cytokines in AVV patients, especially the decrease in the relative and absolute number of aTreg (activated Tregs), which indicates an imbalance of pro- and anti-inflammatory T cells. These T subsets might be associated with the ANCA-related autoimmune response and can be used as diagnosis markers for disease activity and as targets for potentially powerful therapy of AAV.

THE PREVALENCE OF NON-VASCULAR PULMONARY MANIFESTATIONS IN PATIENTS WITH TAKAYASU' ARTERITIS: A RETROSPECTIVE MULTI-CENTERED COHORT STUDY

Ayten Yazici1, Ayse Cefe1, Sema Kaymaz Tahra2, Nübler Alpay Kantez2, Mete Kara3, Oran Gerçik4, Handan Yarkan Tugba5, Fatih Onen1, Servet Aka5, Kenan Akisu2, Gökhan Koseler2, Fatma Altabaz-Onen6, Haner Direskeneli2, 1Kocaeli University School of Medicine, Rheumatology, Kocaelı, Türkiye; 2Marmara University School of Medicine, Rheumatology, Istanbul, Türkiye; 3Yoz University School of Medicine, Rheumatology, Istanbul, Türkiye; 4Ege University School of Medicine, Rheumatology, Izmir, Turkey; 5Dokuz Eylul University School of Medicine, Rheumatology, Izmir, Türkiye; 6Koç University School of Medicine, Rheumatology, Istanbul, Türkiye. 

Background: Takayasu’ arteritis (TAK) is a rare vasculitis characterized by inflammation and obliteration of intermediate to large-size arteries. Even though more than 50% of patients with TAK have pulmonary artery involvement, non-vascular involvement and symptoms are uncommon. 

Objectives: We aimed to investigate the frequency of non-vascular pulmonary involvement in TAK. 

Methods: We assembled a retrospective cohort of patients with TAK from six different centers in Turkey. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records, and the computed tomography findings were evaluated for pulmonary manifestations. 

Results: As of January 2019, 197 TAK patients were recruited (mean age: 42.7±13.9 years [min-max: 17-75] to the cohort, and 88.3% of them were female. Twenty-four patients had cough and/or dyspnea and four had hemoptysis as pulmonary symptoms. In CT assessment, parenchymal infiltrations were present in four (2%), pleural effusion in five (2.5%), nodule/cavity in one (0.5%), and pulmonary hemorrhage in one (0.5%). The patient who had pulmonary hemorrhage had also pleural effusion at the same time. In the whole cohort, 11.2% of patients (n=22) had pulmonary hypertension (PAH), three of them had cough and/or dyspnea and four of them had hemoptysis as a pulmonary symptom. Among patients with PAH, any pulmonary involvement in CT was more frequent compared to the rest of the patients (22.7% vs 5.1%, p<0.0001) (Table 1). 

Conclusion: In this first assessment of Turkish TAK cohort, we observed non-vascular pulmonary involvement in about 5% of our patients and half of them were pleural effusions. The second most common manifestation was parenchymal infiltration with a frequency of 2%. Although rare, non-vascular pulmonary manifestations should also be investigated in TAK patients, especially in patients with pulmonary hypertension.

Scleroderma, myositis and related syndromes

FRIO300 IMPACT OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS IN A COMPLETE, NATIONWIDE COHORT
Anna-Marie Hoffmann-Vold1, Håvard Fretheim1, Anna-Kristine H Halse1, Marit Seip2, Helge Bitter3, Marianne Wallenius4, Anne Salberg5, Torhild Garen1, May Britt Lund1, Trond M Aaleken1, Øyvind Midveld1, Øyvind Molberg1, 1Oslo University Hospital, Oslo, Norway; 2Haukeland University Hospital, Bergen, Norway; 3University Hospital of Northern Norway, Tromsø, Norway; 4Hospital of Southern Norway, Kristiansand, Norway; 5St. Olav’s University Hospital, Trondheim, Norway; 6Lillehammer Hospital, Lillehammer, Norway

Background: Interstitial lung disease (ILD) represents a clinical challenge in systemic sclerosis (SSc) and associates with high mortality. The presence of severe lung fibrosis is a strong predictor for early mortality. There is substantial progress in SSc-ILD research, but precise, population-based data on cumulative incidence, range of severity and predictive value of clinical risk factors are lacking. Such data are vital for clinical decision making, and highly warranted as background information for appropriate development of screening and management strategies for SSc-ILD.

Objectives: To assess cumulative incidence of ILD, range of ILD severity and mortality risk predicted by baseline pulmonary function tests (PFT) and ILD extent by CT in a complete, nationwide SSc cohort.

Methods: The Norwegian SSc cohort study (Nor-SSc) includes all the 630 incident and 185 prevalent SSc patients from 2000-2012 meeting SSc classification criteria. A baseline PFT was recorded in 703 (86%) patients, and 650 (80%) had high resolution computed tomography (HRCT) images available for analyses. Extent of fibrosis was scored on 10 sections from each HRCT and expressed as percentage of total lung volumes. For the survival and mortality analyses, all Nor-SSc patients diagnosed from 2000-2012 (the 630 incident cases) were included and compared with 15 age- and gender matched controls per patient drawn from the national population registry. Vital status was available for all patients and controls at study end (January 2018). Descriptive statistics and standardized mortality rates (SMR) were estimated.

Results: Of the 815 patients in the total Nor-SSc cohort, 682 (84%) were female and 629 (77%) had limited cutaneous SSc. Mean age at SSc diagnosis was 53 yrs, with mean time from SSc onset to diagnosis of 3.8 yrs. We observed ILD on HRCT in 324/650 patients (50%), and the majority of these had <5% lung fibrosis (Figure 1A). Mean FVC at baseline was 94% of expected value, and nearly half of the patients (42%) had an FVC>100% (Figure 1B). Proportionate distribution of FVC

(PAH: pulmonary arterial hypertension, CT: computed tomography)
nintedanib versus placebo in patients with SSc-ILD were investigated in the SENSCIS trial. Methods: Patients with SSc-ILD with onset of first non-Raynaud symptom ≤7 years were randomised to receive nintedanib 150 mg bid or placebo double-blind. Dose reductions to 100 mg bid and treatment interruptions were allowed to manage adverse events. AEs reported over 52 weeks of treatment were coded using preferred terms in the Medical Dictionary for Regulatory Activities and analysed descriptively. A questionnaire was used to collect additional information on diarrhoea AEs. Results: A total of 576 patients (288 per group) received ≥1 dose of nintedanib or placebo. Over 52 weeks, 13.9% and 7.3% of patients treated with nintedanib and placebo discontinued study treatment due to AEs. The most frequent AEs in patients treated with nintedanib were diarrhoea (75.7% vs 31.6%), nausea (31.6% vs 13.5%) and vomiting (24.7% vs 10.4%). Serious diarrhoea AEs were reported in 2 patients (0.7%) in each group, and serious vomiting AEs were reported in 2 patients (0.7%) in the placebo group and none in the nintedanib group. Of the 218 nintedanib-treated patients who experienced a diarrhoea AE, most experienced events that were at worst of mild (49.5%) or moderate (44.3%). Most (70.2%) experienced 1 or 2 events, and the duration of diarrhoea AEs was ≤9 days for 50% of the events reported over 52 weeks. Among nintedanib-treated patients who experienced ≥1 diarrhoea AE, 26.1% had a permanent dose reduction and 9.2% discontinued study treatment due to the AE. Among the 91 patients in the placebo group who experienced ≥1 diarrhoea AE, the duration of diarrhoea AEs was ≤3 days for 50% of the events reported over 52 weeks, 2.2% had a permanent dose reduction and 1.1% discontinued study drug due to the AE. Conclusion: In patients with SSc-ILD, the gastrointestinal AEs associated with nintedanib were manageable for most patients and consistent with its known safety and tolerability profile in patients with IPF. FRI0302 SAFETY AND EFFICACY OF RITUXIMAB BIOSIMILAR IN SYSTEMIC SCLEROSIS: AN ITALIAN MULTICENTER STUDY

Cennado Campolonghi1, Giacomo De Luca2, Maria Grazia Lazzaroni2, Silvia Laura Bosello2, Maria De Santis3, Adriana Cariddi4, Carlo Stellm5, Elisa Grems6, Paolo Arlo3, Marco Matucci-Cerin7, Lorenzo Dagn8, 1IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; 2Special Civil and University Hospital of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy; 3Fondazione Policlinico Universitario A. Gemelli, Division of Rheumatology, Rome, Italy; 4Humanitas Research Hospital, Division of Rheumatology and Clinical Immunology, Milan, Italy; 5University of Florence, Division of Rheumatology AOUC, Florence, Italy

Background: recent data support the use of rituximab(RTX) in Systemic Sclerosis(SSc). RTX biosimilar(RTX-B) offers a more affordable option but its efficacy and safety have not yet been evaluated.

Objectives: To assess the safety and efficacy of RTX-B in SSc.

Methods: Data about SSc patients treated with RTX-B(1gr repeated every 2 weeks) and with a follow-up >6 months were retrospectively collected from 5 Italian centres. Both SSc patients naïve to RTX(RTX-Bn) or already treated with ≥1 course of RTX originator(RTX-O) and switched to RTX-B(RTX-Bs) were considered. A comprehensive assessment of disease features and organ involvement was available at baseline and at final follow-up for all patients. Non parametric tests were used.

Results: Data of 21 SSc patients(20 female, mean age 50.5±11.8 years) were collected/mean disease duration at RTX-B therapy was 7.6±4.8 yrs. Eleven patients(52%) had diffuse cutaneous SSc(dSSc), 12(57%) were anti-topoisomerase-1 antibodies positive, 11 patients(57%) were RTX-B and 9 RTX-Bs(43%). In RTX-B patients, the median number of previous RTX-O courses was 3(range 1 – 8). RTX was decided because of skin progression in 11(52%), intestinal lung disease(LD) worsening in 9(43%), arthritis in 6(29%), myocarditis and myositis in 1 patient each. All patients had been previously treated with immunosuppressants: mycophenolate mofetil(MMF) 14(67%), methotrexate(MTX) 7(33%), cyclophosphamide 6(29%), azathioprine 4(19%), tocilizumab and etanercept 1(5%) patient each. At RTX-B introduction, 14(87%) patients were on concomitant immunosuppressant: 10(48%) MMF and 4(19%) MTX; 15 patients(71%) were also on steroids(mean dose:3.1 ±2.1mg/day). At 6 months after RTX-B treatment, a significant reduction of the modified Rodnan skin score(mRSS), DAS28 and erythrocyte sedimentation rate(ESR) was observed in the entire cohort (p<0.001, p<0.028, p<0.003, respectively); mRSS was significantly reduced also in RTX-Bn (p<0.011) and RTX-Bs patients(p<0.046)(Table 1). No significant changes were observed for lung function tests. Only 1 RTX-Bs patient experienced a transient neutropenia 3 months after the 2nd RTX-B infusion whilst on MTX.

Conclusion: in agreement with previous data published on RTX-O, also RTX-B seem efficient in improving skin and joint involvement and in stabilizing lung function, either in RTX-B and in RTX-Bs SSc patients.

INTERSTITIAL LUNG DISEASE ASSESSMENT BY ULTRASOUND: RESULTS FROM A DELPHI PROCESS AND WEB-RELIABILITY EXERCISE BY THE OMERACT ULTRASOUND WORKING GROUP (WG)

Andrea Delle Sedie1, Lene Terslev2, George Brugn3, Tomás Cazeniev4, Stavros Chrysidis5, Mario Diaz6, Marco Di Carlo7, Marilena Frigato8, Carlos Pineda9, Francesco Porta10, Viviana Ravagnani11, Carlo Alberto Scirè12, Teodora Serban13, Kate Smith14, Maria-Antonietta D Agostino15, Maria Antonietta D Agostino16, Alain Soare17, Stefanie Weber18, Simon Rauber19, Thomas Wohlfahrt20, Guer Scmitt21, Jörg Distler22, Andreas Ramming23, Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and Universität Ulm, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany

Background: Intersitial lung disease (ILD) evaluation is challenging, given the low sensitivity of X-ray and pulmonary function tests, and limited accessibility and radiation linked to repetitive HRCT. Lung Ultrasound (US) has shown potential in the evaluation of ILD of autoimmune diseases including systemic sclerosis.

Objectives: To define and assess the reliability of definitions of US-detected findings in ILD.

Methods: A taskforce (TF) within the OMERACT US WG performed a literature review (LR) to identify US lesions in ILD, a Delphi exercise to define these lesions and a web-based exercise to test the reliability of these definitions by using either intraclass correlation coefficient (ICC) or kappa statistics. Prior to the Delphi exercise all participants received training files and were subsequently asked to provide clips on BL, PLI and normal findings. Based on the results of the LR, which identified B-lines (BL) and pleural line irregularity (PLI) as main US findings in ILD, the Delphi exercise contained statements on US definitions on BL and PLI. After reaching agreement (> 75%) on the above mentioned items, a set of 80 high-quality clips (30 for PLI, 50 for BL) was selected and distributed to the TF members in order to score them (semiquantitatively, 0-2 for PLI and total number for BL).

Results: The 3 Delphi rounds and the web-based exercise were completed by 24 and 22 sonographers, respectively. Final definitions are reported in Table I. The web-based exercise showed moderate inter-reader reliability for both BL (ICC=0.61) and PLI (Kappa=0.69).

Table I: definitions of PLI and BL

Pleural line irregularity (PLI): a loss of regularity that may be associated with an increase in thickness, focal, diffuse, or nodular

Conclusion: US is a candidate imaging modality to identify and monitor ILD in rheumatic diseases; US consensus based definitions of main US findings were defined and endorsed. Further development is planned for validating US as an outcome measurement instrument for ILD.

OBJECTIVES: We sought to characterize the in vivo effect of lenabasum on inflammatory cells and cytokines thought to be involved in the itch and disease pathogenesis of dermatomyositis (DM).

METHODS: 22 adult patients with refractory, skin-predominant DM on stable standard-of-care treatments were recruited for a double-blind, placebo-controlled, randomized trial. Treatment was initially administered orally at a dose of 20 mg a day for 4 weeks, and subsequently raised to 20 mg twice a day for an additional 8 weeks. In a subset of subjects, lesional skin biopsies were collected at baseline and at Week 12. Tissues were stained via immunohistochemistry for IFN-beta, IFN-gamma, IL-4, IL-13, IL-33, IL-31, IL-31 RA, CB2 receptor, PPAR-gamma, CD4, CD8, CD69, CD11c, and mast cells. RT-PCR for IFN-beta, IFN-gamma, IL-31, IL-4, STAT6, and ST2 was performed on tissue RNA. Protein expression was quantified either by percent area positive or cells per HPF in the dermis. Statistical analyses were performed using the Wilcoxon signed-rank test.

RESULTS: CD4 expression in the skin biopsies from lenabasum-treated subjects significantly decreased at Week 12 compared to the placebo group (p<0.05). There were significant reductions in IFN-beta mRNA and protein, as well as IFN-gamma mRNA and protein at Week 12 in subjects on lenabasum compared to placebo (p<0.05). IL-31 protein (p<0.01) was reduced at Week 12 in subjects who received lenabasum, but IL-31RA protein did not change. CB2 protein decreased significantly in the lenabasum group compared to placebo. There were no changes in IL-4, IL-13, IL-33, and PPAR-gamma protein, or the number of CD8, CD69, CD11c, or mast cells in either group. There was no significant difference in IL-31, IL-4, STAT6, or ST2 mRNA expression.

Conclusion: Lenabasum reduces Type 1 and 2 interferon levels as well as T-helper cell inflammation in subjects with DM. These effects have the potential to inhibit underlying disease pathways in DM, thus contributing to clinical improvement.

REFERENCES:
Objectives: This study aimed to analyze the serum levels of neopterin in patients with dermatomyositis (DM) in association with clinical manifestations, laboratory data and patient prognosis.

Methods: One hundred and eighty-two consecutive DM patients and 30 healthy controls were retrospectively enrolled in the study. Serum levels of neopterin were detected by using the ELISA method. Clinical and laboratory data and patient prognosis were obtained and analyzed in association with serum neopterin.

Results: Serum levels of neopterin were significantly increased in DM patients (median 21.2 nmol/L; IQR 13.9-35.2 nmol/L) compared to healthy controls (median 4.3 nmol/L; IQR 2.9-5.6 nmol/L, P < 0.01). High serum neopterin levels were associated with anti-MDA5 antibody, rapidly progressive interstitial lung disease (RP-ILD), and cutaneous involvement including skin ulcer and heliotrope rash. Longitudinal assessment of serum samples revealed that the serum neopterin levels were closely correlated with disease severity. In addition, a significant increase in serum neopterin concentration of non-survivors (median 38.7 nmol/L; IQR 23.5-65.3 nmol/L) was observed when compared to that of survivors (median 19.0 nmol/L, IQR 12.5-28.0 nmol/L) (P < 0.001). ROC curves showed that serum neopterin could distinguish non-survivors and survivors at an optimal cut-off level of 22.1 nmol/L with a sensitivity and specificity of 0.804 and 0.625 respectively (P = 0.01). Kaplan-Meier survival curves revealed that DM patients with serum neopterin > 22.1 nmol/L had a significantly higher mortality compared to patient group with serum neopterin < 22.1 nmol/L (logrank P = 0.01). Multivariate Cox regression analysis identified high serum neopterin concentration to be an independent risk factor for poor prognosis in DM (adjusted HR = 4.619, 95% CI: 2.092-10.195, P < 0.01).

Conclusion: Increased serum levels of neopterin were significantly associated with RP-ILD and reduced survival in DM patients, suggesting it as a promising biomarker in the disease evaluation of DM. These findings highlight the role of cellular immune activation and macrophage activity in the pathogenesis of DM.

PREVALENCE AND CLINICAL MANIFESTATIONS OF ERASMUS SYNDROME IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

Serjia Acevedo1, Joanna Neves2, Daniela Faria1, Joana Silva1, Joana Rodrigues1, Daniela Prieto1, José Taveira-Costa1, Sérgio Alcino1, Camilo Alves1, Filipa Teixeira1, Unidade Local de Saúde do Alto Minho, Rheumatology department, Ponte de Lima, Portugal; 2Hospital de Braga, Rheumatology department, Ponte de Lima, Portugal

Background: Erasmus syndrome (ErS) is defined by the association of exposure to silica with the subsequent development of systemic sclerosis (SSc), with or without associated silicosis.

Objectives: The objectives of this study were, on one hand, to evaluate the prevalence of ErS in a population of SSc patients and to characterize the cases and, on the other hand, to evaluate the clinical and laboratory characteristics of SSc patients with or without exposure to silica.

Methods: We performed a cross-sectional study of the patients with SSc in our department. Demographics, clinical and laboratory data were collected from all patients with SSc diagnosed according to ACR/EULAR criteria. Moreover, a telephone call was made in order to detail the professional activity and possible exposure to silica.

Results: The prevalence of ErS in this population was 15.3% (9/59). All cases identified were male, corresponding to 75% of men with SSc followed at our department. There was a statistically significant association between ErS and male gender (p<0.001), initial pulmonary manifestation (p=0.025), history of digital ulcers (p=0.014) and smoking (p=0.047). On the other hand, a lower risk of gastrointestinal involvement was found in ErS cases (p=0.008). All patients with ErS had positive autoantibodies (mainly anti-Sc170 and anti-centromere) with titers tending to be higher than SSc without ErS, although without statistically significant differences. In addition, although with no statistical significance, we found that pulmonary artery systolic pressure (PASP) estimated by echocardiogram was higher in patients with ErS.

Conclusion: In our study, prevalence of ErS was higher than data from previously published literature. For a more accurate ErS diagnosis it is necessary to be aware of and investigate less intense silica exposures, which may have occurred many years before diagnosis. Statistically significant differences were found between ErS and SSc without exposure to silica; this fact may have impact in diagnosis, treatment and prognosis.

Conclusion: a significant improvement in endothelial function and microvascular involvement was achieved after three months of HCQ treatment.

It is a novel finding in SSC which can represent a new therapeutic possibility for the prevention of microvascular complications of the disease.

FR00315 DIFFERENTIAL PERFORMANCE OF NAILFOLD VIDEO CAPILLAROSCOPIC PARAMETERS IN THE DIAGNOSIS AND PROGNOSIS OF SYSTEMIC SCLEROSIS
Vasilli-Kalliopi Bounia 1, Konstantinos Kottas 1, Stylianos Panopoulos 1, George Konstantinos 1, Alexios Ilipoulos 1, Athanasios Tzoufas 1, Petros Silkakis 1, Panayiotis Vlachoyiannopoulos 1, National and Kapodistrian University of Athens, Medical School, First Department of Pneumopaealic and Internal Medicine, Athens, Greece; 2Veterans Administration Hospital (NIMTS), Department of Rheumatology, Athens, Greece; 3National and Kapodistrian University of Athens, Medical School, Pathophysiology, Athens, Greece

Background: The role of Nailfold Video Capillaroscopy (NVC) in the identification of patients with Raynaud phenomenon (RP) at risk to develop systemic sclerosis (SSc) is well-established. However, it is not clear if certain capillaroscopic indices perform better than others at predicting SSc development and which NVC parameters have a prognostic value in established SSc.

Objectives: To comparatively assess the performance of different NVC parameters in predicting development of SSc, very early diagnosis of SSc (VEDOSS), or mixed connective tissue disease (MCTD) in patients with RP. Also, to longitudinally examine the consistency of clinical correlations of NVC parameters in SSc patients at two different time points and evaluate the prognostic capacity of NVC in SSc.

Methods: Consecutive RP patients referred to our department for NVC (138 with SSc, 12 with VEDOSS, 6 with MCTD, 36 with primary RP, and 50 with non-SSc secondary RP) were evaluated at baseline, both clinically and capillaroscopically. 175 were reevaluated after a mean±SD of 3.34±1.48 years. Sixty-two healthy volunteers served as controls. Qualitative assessment of NVC images permitted categorization of patients to a normal, early, active or late capillaroscopic pattern. Capillary loss, dilatation score, giant or ramified capillaries and micro-hemorrhages were evaluated by a semi-quantitative score (0-3), derived as the mean of three evaluated fields of each of the 2nd, 3rd, 4th and 5th finger of both hands. FVC and DILCO were recorded, if performed within 6 months of NVC. FVC and DILCO deterioration were considered clinically significant if >10% and >15%, respectively. Skin thickening was measured using the modified Rodnan Skin Score (mRSS). MRSS deterioration was considered clinically significant if >3.5. First occurrence of digital ulcers in patients with no prior such history and vital status were also recorded at follow-up.

Results: Capillary loss score had the highest diagnostic accuracy at discriminating patients with an SSC-spectrum disorder from patients with RP of different etiology and from controls, as defined by ROC curve analysis [AUC (95% CI)=0.925 (0.893-0.956)], followed by dilatation score [AUC (95% CI)=0.904 (0.807-0.938)] and giant score [AUC (95% CI)=0.856 (0.810-0.902)]. By contrast, micro-hemorrhages [AUC (95% CI)=0.727 (0.669-0.786)] and ramification scores [AUC (95% CI)=0.588 (0.521-0.654)] did not perform equally well. Notably, clinical correlations of capillaroscopic parameters in SSc were found not to be consistent over time, when longitudinally assessed at two different time points by univariate and multivariate analysis. Binary logistic regression analysis indicated that baseline capillaroscopic pattern could predict occurrence of a combined adverse disease outcome (FVC deterioration>10% and/or DILCO deterioration>15% and/or mRSS deterioration>3.5 and/or first occurrence of digital ulcers and/or death), after a mean±SD follow-up of 3.28±1.45 years in 94 SSc patients with available follow-up data (OR=3.43, p=0.031 for active versus early pattern, OR=8.778, p=0.007 for late versus early pattern).

Conclusion: Dilatation score performs best of all semi-quantitative NVC parameters in diagnosing SSc and although clinical correlations of capillaroscopic findings change over time, an active or late capillaroscopy pattern at baseline is associated with an adverse prognosis.

Disclosure of Interests: Vasilli-Kalliopi Bounia: None declared, Konstantinos Kottas: None declared, Stylianos Panopoulos: None declared, George Konstantinos: None declared, Alexios Ilipoulos: None declared, Athanasios Tzoufas Grant/research support from: ABBVIE, Pfizer, Amgen, Novartis, GSK, Petros Silkakis: None declared, PANAYIOTIS VLAPOULOPOULOS: None declared DOI: 10.1136/annrheumdis-2019-eular.4393

FR00314 SENSITIVITY TO CHANGE AND RESPONSIVENESS TO TREATMENT OF RENAL RESISTIVE INDEX (RRI) IN SYSTEMIC SCLEROSIS (SSC)
Cosimo Brunì1, Edoardo Rosato2, Antonietta Gigante2, Vanessa Maestri2,1, Giulia Tesi2,1, Marco Chiostri2,1, Gemma Lepri2,1, Silvia Bellando Randone2,1, Serena Guiducci1, Sergio Castellani1, Maria Boddi1, Marco Malucci-Cerinici2,1
1Careggi University Hospital, Firenze, Italy; 2Sapienza University of Rome, Roma, Italy

Background: RRI may identify any problem with the blood flow in the renal artery and in the parenchyma. It was shown to be increased in SSc patients and being in relationship with both vascular and fibrotic SSc-related manifestations.

Objectives: to test sensitivity to change and responsiveness to treatment of RRI in SSc.

Methods: patients fulfilling the 2013 ACR/EULAR classification criteria for SSc were enrolled from two SSc-care units, if RRI was determined at least twice since being diagnosed. Data regarding SSC clinical manifestations, instrumental and laboratory evaluation for renal, cardiac and cardiovascular involvement, as well as ongoing immunosuppressive and vasoactive vasodilating treatment, were collected both at baseline and follow-up RRI measurements.

Results: 230 patients [aged 57 (48-67) years, 12.6% males] were enrolled in the study, with baseline RRI value of 0.68 (IQR 0.07). In a mean 3.4 years follow-up, RRI showed a median change (ΔRRI) of 0.02 (IQR 0.05). ΔRRI was significantly correlated with ΔsPAP (R=0.173, p=0.023) and it was significantly higher in patient with new onset of pulmonary arterial hypertension (0.06±0.02 vs 0.03±0.05; p=0.038). On Cox univariate regression analysis, time from disease onset, ΔsPAP and ΔRRI predicted new PAH, while ΔsPAP was the only independent predictor at multivariate regression analysis. Regarding treatment, Sildenafil exposure determined a significantly lower increase in ΔRRI, with a progressive long-term effect. Conversely, CCBs and ifoprost treated patients showed a significantly higher increase of ΔRRI, which was determined by a higher DU burden. No difference was seen when immunosuppressive treatment was evaluated.

Conclusion: RRI is sensitive to change and reflects, in particular, the worsening of cardio-pulmonary vascular involvement (increase in ΔsPAP and new PAH onset). Moreover, it shows a possible protective effect of Sildenafil in reducing pulmonary vasculature manifestations.

Disclosure of Interests: Cosimo Brunì: None declared, Edoardo Rosato: None declared, Antonietta Gigante: None declared, Vanessa Maestri2,1: None declared, Giulia Tesi2,1: None declared, Marco Chiostri2,1: None declared, Gemma Lepri2,1: None declared, Silvia Bellando Randone2,1: None declared, Serena Guiducci1: None declared, Sergio Castellani1: None declared, Maria Boddi1: None declared, Marco Malucci-Cerinici2,1: Grant/research support from: Actelion, MSD, Pfizer, BMS, Chemomab, Sanipeedia, Speakers bureau: Actelion, BMS, MSD, Janssen DOI: 10.1136/annrheumdis-2019-eular.3515
Background: Systemic sclerosis (SSc) is a disease orphan of effective disease modifying agents. The diffuse cutaneous subset (dcSSc) is targeted in most clinical trials. Nevertheless, the high variability in clinical outcome at 12 months is limiting effective RCTs design and interpretation. The Global Ranked Composite Score (GRCS) and the Composite Response Index in SSc (CRISS) are the most recent attempts to capture overall response to treatment in dcSSc [1, 2]. Activation of interferon type 1 (IFN) pathway is associated with severe clinical manifestations in SSc. Several studies have indicated that the serum concentration of CCL2, CCL8, CCL19, CXCL9, CXCL10 and CXCL11 are the most relevant to measure IFN induction of PBMCs [3-4].

Objectives: Here we aimed to determine whether the IFN pathway activation measured by a serum test could be used to stratify patients with dcSSc for severe clinical outcome at 12 months as measured by GRCS and CRISS.

Methods: Serum concentration of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11 was measured by Luminex xMAP technology (Myriad RBM) in 143 SSc patients and 35 healthy controls (HC). IFN score was calculated as the average of the natural logarithm of the above chemokines. IFN score was measured by Luminex xMAP technology (Myriad RBM) in 143 SSc patients and 35 healthy controls (HC). IFN score was calculated as the average of the natural logarithm of the above chemokines. IFN score was measured by Luminex xMAP technology (Myriad RBM) in 143 SSc patients and 35 healthy controls (HC). IFN score was calculated as the average of the natural logarithm of the above chemokines. IFN score was measured by Luminex xMAP technology (Myriad RBM) in 143 SSc patients and 35 healthy controls (HC). IFN score was calculated as the average of the natural logarithm of the above chemokines. IFN score was measured by Luminex xMAP technology (Myriad RBM) in 143 SSc patients and 35 healthy controls (HC).

Results: All chemokines had a higher serum concentration in SSc vs HC (p<0.0001 for all). Median IFN score was higher in SSc than HC (5.26 vs 4.70, p<0.0001). There was no difference associated with disease duration or enrollment criteria in a RCT we analyzed the 12 months outcomes of the dcSSc patients with c6 years disease duration. Sixty-six 12-month outcome data were available. 37 were IFN HI and 29 IFN LO at baseline. The IFN HI group had a higher mRSS (median 9.5 vs 5, p=0.03), CRP (10.2 vs 5, p=0.003) and NT-proBNP (195 vs 50.5, p=0.001). We recorded 7 deaths for SSc and 5 lung failures (3 PVC drop, 2 DLCO drop); 3 had worsening of PVC, 4 improvement and 49 no change; 11 had worsening of HAQ-DI, 5 improvement and 43 no change; 9 had worsening of mRSS, 7 improvement and 43 no change (table 1). CRISS ranged from -59 to 64 and was negative in 29 (21 IFN HI, 8 IFN LO) and positive in 37 (16 IFN HI, 21 IFN LO). IFN HI patients had a worse outcome at 12 months with GRCS median score of -12 vs 15 in IFN LO (p=0.0271) (fig. 1). According, GRCS favored IFN LO in 68.4% of 1073 (37%29) pairwise comparisons versus 31.6% of IFN HI (p=0.0001). CRISS was 0 in 46 (38 IFN HI, 18 IFN LO) and <0 in 20 (9 IFN HI, 11 IFN LO). Spearman’s rank correlation of the two scores was r=0.5113. Consistent with GRCS data, CRISS was 0 in 76% of IFN HI vs 62% of IFN LO (P=0.046).

Conclusion: Serum IFN Score predicts worse clinical outcome at 12 months in dcSSc. Stratification for IFN score could aid both in clinical trial design and clinical management. Moreover, we here show that GRCS and CRISS may be sufficiently sensitive to measure difference in composite outcome at 12 months in dcSSc in an observational setting and they correlate with each other in this observational setting.

Improvement 2 2 1 4 3 4
PBC or other autoimmune liver disease or manifested elevated liver function tests.

Conclusion: The expression of the PDC antigenic components is variable both in SSc patients with AMA positive PBC and in SSc patients AMA positive without PBC or altered liver function tests, but we could not identify a clinical significance of this variability. It may be necessary to maintain a strict follow-up of these patients and to perform longitudinal studies to determine the diagnostic value of this variable expression of PDC components in the onset of PBC.

NOVEL CLASSIFICATION OF IDIOPATHIC INFLAMMATORY MYOPATHIES BASED ON DISTINCTIVE FEATURES AND AUTOANTIBODIES: ANALYSIS OF 67 KOREAN PATIENTS

Sang Wan Chung1, Seol Yoo2, Su-Jin Yoo2, Jinhyun Kim2, Seong-Wook Kang2, Seungcheol Shim1, Mihe Kwon2, Chung-I Joung3, Seung-Jae Hong1, Yeon-Ah Lee1, Kyung Hee University Medical Center, Seoul, Korea, Rep. of (South Korea); Chungnam National University College of Medicine, Daejeon, Korea, Rep. of (South Korea); College of Medicine, Konyang University, Daejeon, Korea, Rep. of (South Korea)

Background: Since Bohan and Peter first described their diagnostic criteria for idiopathic inflammatory myopathies (IIM) in 1975, new discoveries such as myositis-specific and myositis-associated autoantibodies (Abs) have been made.

Objectives: To investigate correlations between specific myositis Abs and their frequencies and clinical associations across different IIM groups, collectively demonstrating the utility of the new clinicoserologic classification in Koreanadult IIM patients with IIM.

Methods: We conducted a multicenter cohort study including 67adult patients (age ≥18 years) who have been diagnosed as IIM by ENMC criteria. Immunoblot assay with Euroline strip(EUROIMMUN, Germany) was performed using the sera of definite dermatomyositis (DM, n=36), definite polymyositis (PM, n=25), amyopathic DM (n=4), DM sine dermatitis (n=1), and immune mediated necrotizing myopathy (IMNM, n=1). Patients were classifiedbased on three classifications: 1) novel clinicoserologic classification suggested by Troyanov et al. in 2017. 2) 2017 EULAR/ACR classification criteria. 3) 2004 European neuromuscular center (ENMC) criteria. Associations of myositis Abs and clinical subsets of IIM were investigated.

Results: The distribution of the various IIM differed strikingly from those using the 3 classifications (Fig1). According to the 2004 ENMC classification and 2017 EULAR/ACR classification criteria, DM and PM was the most and the second frequent entities (DM: 55.2%, 56.7%; PM: 35.6%, 37.8%). But, using the new clinicoserologic classification, the overlap myositis (OM) is the major type of IIM and the frequency of PM is significantly decreased. Anti-ARS Abs specificity included anti-Jo-1(16.4%), -OJ(4.6%), -EJ(6.2%) -PL-7(3.1%), and -PL-12(4.8%). Interstitial lung disease was closely associated with anti-MDA5 and anti-ARS Abs, while DM-specific skin lesion was frequently observed in patients with anti-TIF1y and anti-ARS Abs. Seven patients with cancer-associated DM were identified. They were positive for anti-TIF1y (5/7) and anti-SRP(3/7) (table 1).

FRI0318

THROMBOCYTOPENIA AND MULTI-ORGAN INVOLVEMENT MIGHT BE POOR PROGNOSTIC FACTORS FOR SYSTEMIC SCLEROSIS CARDIOMYOPATHY

Xueling Wei, Lijuan Yang, Donghui Zheng, Lei Dai, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

Background: Systemic Sclerosis (SSc)-cardiomyopathy is associated with a high mortality in SSc. It is important to identify potential prognostic factors for SSc-cardiomyopathy.

Objectives: To describe the clinical characteristics and identify potential prognostic factors for patients with SSc-cardiomyopathy.

Methods: We retrospectively reviewed the clinical data of SSc-cardiomyopathy patients hospitalized at Sun Yat-Sen Memorial Hospital from January 1992 to November 2018. SSc-cardiomyopathy was defined as structurally and functionally abnormal of heart muscle in SSc patients with cardiac symptoms. Coronary artery disease, hypertension, valvular disease and congenital heart disease were excluded. The Chi-square test was used to compare the differences between the death group and the survival group.

Results: 1. There were 903 SSc patients recruited and 20 patients (2.2%) of them were SSc–cardiomyopathy. Among these 20 patients, 65% were females, with an age of 52.8±13.2 years, disease duration was 3.1±2.3 years, duration from SSc onset to cardiomyopathy occurred was 2.8±2.3 years. 2. SSc-cardiomyopathy developed in 18 patients (9%) with diffuse cutaneous SSc (dcSSc), and in 2 patients (10%) with limited cutaneous SSc (lcSSc). Eleven patients (55%) had pulmonary fibrosis, 7 patients (35%) had pulmonary arterial hypertension (PAH), 5 patients (25%) had scleroderma renal crisis (SRC) and esophageal involvement, respectively.

Conclusion: Novel classification based on distinctive features and new myositis Abs reflects the clinical phenotype of IIM better. Establishment of a system routinely available to screen myositis Abs is needed. This will be beneficial to provide more precise diagnosis and proper management for patients with IIM.

REFERENCE:
patients (30%) manifested thrombocytopenia and 4 patients (20%) manifested anemia.

3. Cardiac symptoms included shortness of breath (n=18), palpitation (n=6), edema of lower extremity (n=4), fatigue (n=5) and/or cough (n=3). All patients were found to have cardiomegaly by echocardiography (UCG) or chest radiography. Left ventricular ejection fraction (47±15%) were decreased. Ventricular wall motion abnormality was found in 5 patients (25%) by UCG. 15 patients (75%) manifested cardiac arrhythmia in electrocardiogram, with frequent premature ventricular contractions were the most common (n=10, 50%). Myocardial injury was found in 14 patients (70%) by electrocardiogram. Myocarditis was found in 7 patients (35%) by myocardial enzyme assay.

4. Nine patients (45%) died, the causes of death were heart failure (n=4, 45%), sudden death (n=3, 33%) and ventricular tachycardia (n=2, 22%). 5 patients (55.6%) died within 1 month after the onset of cardiac symptoms. 3 patients died within 2 month, and one patient with implantable cardioverter defibrillation (ICD) died 2 years after ICD implanted. Ten patients survived in a mean 6 (1-10) years follow-up.

5. Six patients (67%) manifested thrombocytopenia and 4 patients (44%) manifested anemia in the death group. However, only one patient (9.1%) in survival group manifested thrombocytopenia (p=0.007) and anemia (p=0.059).

There were more organs and systems involved in the death group, compared to the survival group (4±2 vs 2±1, p=0.044). 4 patients had SRC in death group, while 2 patients had SRC in survival group. 6 patients had pulmonary fibrosis in death group, while 5 patients in survival group (Table 1).

Table 1. Comparison between the death group and the survival group in Systemic Sclerosis cardiomyopathy patients.

ESOPHAGEAL EROSIONS PREDICT PROGRESSION OF LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS

Enrico De Lorenzen1, Gerlando Natalello1, Laura Gigante1, Lucrizza Verardi1, Umberto La Porta2, Giovanni Battista Canevari1, Ludovica Berardini2, Silvia Laura Bosello3, Elisa Gremsi4,5,1,2 Catholic University of the Sacred Heart, Institute of Rheumatology, Rome, Italy; Fondazione Policlinico Universitario A. Gemelli IRCCS, Department of Respiratory Medicine, Rome, Italy; Fondazione Policlinico Universitario A. Gemelli IRCCS, Department of Rheumatology, Rome, Italy

Background: Intestinal lung disease (ILD) is the leading cause of death in Systemic Sclerosis (SSc) but its pathogenesis is not fully understood. Esophageal disease is common in SSc and micro aspiration of both acid and non-acid gastrointestinal reflux could be involved in the pathogenesis of ILD. Esophagogastrroduodenoscopy (EGD) is an essential tool to evaluate disease severity of upper gastrointestinal tract involvement in SSc.

Objectives: The objective of the present study is to assess the role of EGD in predicting pulmonary functional deterioration in SSc patients.

Methods: One hundred and fifty patients with SSc and suspected esophageal involvement underwent EGD. Pulmonary function tests were performed at baseline and after a 36-months follow-up. Patients were characterized for disease phenotype, BMI, smoking exposure and medical history. A significant ILD progression was defined as a relative decline >10% of FVC or a concomitant decline >5% of FVC and >15% of DLCO.

Results: One hundred and thirty-six patients (90.5%) were female with a mean age of 55.6 ± 13.8 years and 12.1% were active smokers. Fifty

patients (33.3%) had a diffuse cutaneous disease; 37.4% and 40.8% were positive for anti-centromere and anti-Scl70 antibodies respectively. The mean disease duration from the first non-Raynaud symptom was 5.9 ± 6.7 years. Sixty-one patients (40.8%) showed EGD signs of reflux esophagitis. Among them, 31.3% had an erosive form (19.5% grade A, 15.6% grade B, 4.8% grade C and 1.4% grade D according to Los Angeles classification). At the baseline, 23.1% of the patients had a FVC <80% and 45.6% had a DLCO <50%. Patients with erosive esophagitis did not differ in terms of sex, age, duration and disease variant, positivity for anti-centromere, skin score values, FVC and DLCO at baseline compared to patients without erosions, but had a lower prevalence of anti-Scl70 (2.8 vs 52.5%, p=0.005) and active smoking (20.0 vs 8.4%, p=0.05). At follow-up, patients with esophageal erosions showed a greater relative decrease in FVC (3.4±19.3% vs 1.7±12.0%; p=0.013) after paired correction for sex, age, duration of disease, auto-antibodies, skin involvement variant, baseline FVC and DLCO, smoke exposure and therapy with immunosuppressants, proton pump inhibitors, prokinetics, antiplatelet agents and prostanoids.

Conclusion: SSC patients with erosive esophagitis present a higher risk of progression of interstitial lung disease. This evidence supports a role of micro-aspiration of gastric contents in the development of inflammation and fibrosis of the airways.

CREASE OR SPORADIC INCLUSION BODY MYOSITIS

Lousie Pynt Davidichner1,2,3, Sine Sendegaard Korsholm1, Line Vinderlevs Larsen1, Christoffer Tandrup Nielsen2, Marie-Louise From Hermansen2, Søren Jacobsen2, Nanna Wilting1, Markus E Krogager1, Tina Friis1,1, Odense University Hospital, Department of Rheumatology, 5000 Odense, Denmark; Rigshospitalet, Department of Rheumatology, DK-2100 Copenhagen, Denmark; Bispebjerg Hospital, Department of Dermatology, DK-2400 København NV, Denmark; Rigshospitalet, Department of Neurology, Copenhagen, Denmark; Statens Serum Institut, Department of Autoimmunology and Biomarkers, DK-2300 Copenhagen S, Denmark

Background: Sporadic inclusion body myositis (sIBM) is a subgroup of the idiopathic inflammatory myopathies (IMs) and is characterized by both degenerative and autoimmune features. Unlike other IMs, myositis-specific autoantibodies had not been found in sIBM patients until recently.

Objectives: We aimed to establish the prevalence and clinical associations of anti-CN-1A in a large Danish cohort with connective tissue disease (CTD).

Methods: In a cross-sectional study design, a total of 568 participants (183 IMs (55 sIBM, 128 non-sIBM: dermatomyositis (DM), polymyositis (PM), immune-mediated necrotizing myopathy (IMNM)), 184 systemic lupus erythematosus (SLE), 121 systemic sclerosis (SSc), and 100 blood donors (BD)) were tested for the presence of: a) CN-1A autoantibodies using a commercial Anti-CN-1A ELISA and b) myositis specific and associated autoantibodies (anti-Jo-1, anti-PL-7, anti-PL-12, anti-OJ, anti-EJ, anti-SS-A, anti-SS-B, anti-DNA, anti-PM/Scl75, anti-PM/SC100, anti-Ro52, anti-Ku) using a commercial line blot kit. The patients were classified according to the ACR classification criteria for IMs (2017), SLE (1997) and SSc (1980), respectively. Clinical features were compared between anti-CN-1A positive and anti-CN-1A negative patients using two-sample t-test and Mann-Whitney test for continuously normal and non-normally distributed data and Chi-square test for categorical data, as appropriate.

Results: CN-1A antibodies were predominantly found in IM patients. In the sIBM cohort, 24 patients (43.6%) were anti-CN-1A positive vs. 25 (19.5%) in the non-sIBM myositis cohort and 17 (10%) in the SLE cohort. None of the participants in the SSc or the BD cohorts had
presence of anti-cN-1A. Anti-cN-1A positivity had a sensitivity of 43.6% and a specificity of 91.8% for sIBM. The positive and negative predictive values were 36.4% and 93.8%, respectively.

There was no significant difference in gender, age at study entry, age at symptom onset, duration of symptoms or max creatine kinase (CK) levels during disease course between the anti-cN-1A positive and negative sIBM patients. Dysphagia was present in 19 (79%) of the anti-cN-1A positive and in 17 (55%) of the anti-cN-1A negative sIBM patients (P = 0.06).

Conclusion: The antibodies against cN-1A are the first and so far the only serological marker for sIBM. Our data showed that cN-1A autoantibodies are specific for sIBM and further corroborate the potential diagnostic role of cN-1A autoantibodies in this distinct subgroup of myositis.

FR0321 PERFORMANCE OF DIFFERENT PULMONARY HYPERTENSION SCREENING ALGORITHMS IN PATIENTS WITH SYSTEMIC SCLEROSIS PATIENTS

Mustafa Erdogan1, Burcak Kilickiran Avci2, Yagmur Ensoy2, Cansu Ebrun2, Zeki Ongen3, Gul Ongen4, Vedat Hamuryudan5, Gulen Hatemi5, 1Istanbul University -Cerrahpasa Medical Faculty, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Istanbul University -Cerrahpasa Medical Faculty, Department of Cardiology, Istanbul, Turkey; 3Istanbul University -Cerrahpasa Medical Faculty, Istanbul, Turkey; 4Istanbul University -Cerrahpasa Medical Faculty, Department of Pulmonary Diseases, Istanbul, Turkey

Background: Pulmonary hypertension (PH) is an important cause of morbidity and mortality in patients with systemic sclerosis (SSc). Different screening strategies have been proposed for identifying patients who have a high probability of PH and require right heart catheterization (RHC), which is the gold standard for diagnosing PH.

Objectives: To compare the performance of PH screening algorithms in our patients with SSc.

Methods: Forty-eight consecutive patients, fulfilling ACR/EULAR 2013 SSC criteria, were screened for PH using the 2015 ESC/ERS, DETECT and ASIG algorithms. Pulmonary function tests (PFT), diffusing capacity of the lung for carbon monoxide (DLCO), trans-thoracic echocardiography, serum NT-proBNP, uric acid assay and high-resolution computed tomography (HRCT) were performed as needed. Patients with known PH, severe interstitial lung disease and severe left ventricular dysfunction were not included. RHC was performed in all patients with positive screening according to any one of the screening algorithms. Patients with PH were classified according to the updated PH classification criteria. Sensitivity and specificity of the 3 screening algorithms were evaluated according to the established cut-off value of 25 mmHg for mean systolic pulmonary artery pressure and for the recently proposed cut-off value of 20 mmHg.

Results: Among the 48 SSc patients, 15 were excluded due to already diagnosed PH (n=4), left ventricular dysfunction (n=4), no measurable tricuspid regurgitation velocity (TRV) (n=5) and coexisting lung cancer (n=2). Among the remaining 34 patients, 16 required RHC according to at least one of the screening algorithms. Demographic and clinical features of remaining 34 patients were summarized in Table 1. Number of patients who had suspected pulmonary hypertension and required RHC according to ESC/ERS 2015, DETECT and ASIG were 8 (%25), 9 (%26) and 13 (%41) respectively (Figure 1). Among the 14 who had RHC, PH was present in 3 patients according to the 25-mmHg cut-off (Group 1 in 1, Group 2 in 1, Group 3 in 1) and in 8 patients according to the 20-mmHg cut-off (Group 1 in 5, Group 2 in 2, Group 3 in 1). The sensitivity and specificity of each algorithm is presented in Table 2. Sensitivity was similar at 100% for the 3 algorithms, but the ESC/ERS algorithm had better specificity, when PH was diagnosed with the 25-mmHg cut-off. For the 20-mmHg cut-off, both the sensitivity and the specificity were better with the ESC/ERS algorithm.

Conclusion: The ESC/ERS algorithm seems to have a better performance for detecting PH in patients with SSc. A limitation of this study was that RHC was not performed in patients who did not fulfill criteria according to any of the screening algorithms. The sensitivities may be lower than what we propose if there are patients with PH who are asymptomatic and not captured with any of the algorithms.

FR0322 AUTOANTIBODIES PROFILE INFLUENCE ON SYSTEMIC SCLEROSIS INTERSTITIAL LUNG DISEASE. A TERTIARY SPANISH HOSPITAL EXPERIENCE

Antía García Fernández1, Iván del Bosque Granelo1, Laura Calvo Sarac2, Nicolás Almeida Arostegui1, Luis Gorospe Sarasúa1, Carlos De la Puente Bujidos1, 1Ramón y Cajal University Hospital, Rheumatology, Madrid, Spain; 2Ramón y Cajal University Hospital, Radiology, Madrid, Spain

Background: Systemic Sclerosis (SSc) is a rare and heterogeneous connective tissue disease (CTD) characterized by skin fibrosis, vasculopathy/vascular damage and potential visceral impairment. Interstitial lung disease (ILD) constitutes the leading cause of mortality and requires close periodical assessment and follow-up. Diffuse cutaneous sclerosis and specific autoantibody profile (anti SCL70, anti Th/To, Anti U3 RNP and anti PmScl) are considered ILD development risk factors. In contrast, positivity to centromere has been considered as a protective factor to develop a clinical significant ILD.

Objectives: To assess ILD frequency and severity (extension and functional impairment) in SSc patients, analyzing the association with the different autoantibodies.

Methods: Retrospective, descriptive study of patients meeting EULAR/ACR 2013 SSc criteria and had a HRTC performed at a tertiary Spanish hospital from 1975 to 2018. One hundred and eight patients were included. HRTCs were graded by two radiologists according to Goh et al semi-quantitative score. Three groups were established according to the presence of different autoantibodies: anticientromere (ACA), antipmScl (ATA), and positivity to other ANAs (nucleolar pattern and other specificities).

Results: Clinical and laboratory characteristics are presented in table 1. Thirty-three patients had pulmonary involvement, 6 were ACA+, 18 ATA+ and 9 had other ANA specificities. The probability of not having pulmonary involvement among ACA+ and of having pulmonary involvement among ATA+ showed statistic significance (p<0.001 and p<0.001). Usual Intestinal Pneumonia (UIP) was the most frequently reported pattern (6 patients), followed by Non-Specific Intstitial Pneumonia (NSIP) (11 patients); Six patients did not meet the radiological criteria for neither UIP or NSIP. No statistical significant difference was found among radiological pattern and autoantibody profile. Regarding extension: 15 patients...
had non-extensive involvement (ACA: 2, ATA: 7, ‘other ANAs’: 6) performing Goh et al score with the FVC correction. ExtensiveILD was found among 18 patients (ACA: 4, ATA: 11, ‘other ANAs’: 3). Despite the fact that ATA+ group was more likely to have an extensive involvement no statistical significance was met. About pulmonary function tests (PFT) the mean FVC was 98.45% on ACA group, whereas on ATA and other ANAs groups the mean FVC were 89.97% and 81.43% respectively. Statistical differences were found between first and third group, however this difference was not found when only patients with pulmonary involvement were analyzed.

Conclusion: In our cohort, ATA and other ANAs groups were more likely to develop pulmonary interstitial disease and to need immunosuppressant treatment. Although the prevalence of ILD among ACA+ was only 10%, 50% of them required, due to the functional impairment or extension, immunosuppressant treatment. In spite of the low ILD-ACA+ incidence this complication should be kept in mind and periodical screening and assessment must be carried out as in other autoantibodies profiles.

EVALUATION OF LIPID PROFILE AND Atherosclerosis IN TREATMENT-NAIVE PATIENTS DIAGNOSED WITH UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE (UCTD)

Giorgos Papamichal1, Athanasios Geognadis2, Theodora Markatseli2, Charalampos Millios1, Alexandros Drosos2, Paraskevi Voulgar2. Internal Medicine, University of Ioannina, Greece, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece; Rheumatology Clinic, University of Ioannina, Ioannina, Greece;

Background: Patients with UCTD cannot be definitely diagnosed with a well-characterized systemic rheumatic disease. These patients often exhibit one of several disease patterns, manifesting multiple nonspecific clinical or serologic abnormalities, sometimes of more than one defined rheumatic disorder.

Objectives: The aim of this study is to investigate lipid profile and atherosclerosis in UCTD patients.

Methods: This is a prospective, observational study which included 30 treatment-naive UCTD patients. Thirty patients and 30 healthy matched-controls were compared for total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c) and triglycerides (TGs). Furthermore, in order to describe endothelial dysfunction and presence of atherosclerosis, we assessed intima-media thickness (IMT) of common carotid artery with the contribution of an experienced sonographer. We also measured Apolipoprotein A1 (ApoA1), Apolipoprotein B (ApoB), Apolipoprotein E (ApoE), Lipoprotein A (LpA), erythrocyte sedimentation rate (ESR), high-sensitivity C-reactive protein (HSCRP) and fibrinogen in the group of patients only.

Results: Thirty UCTD patients were studied. There were 11(36.7%) men, 19(63.3%) women and 7(23.3%) smokers. The mean (SD) age was 54.1 (13.1) years and disease duration was 17.3(10.4) years. All reported Raynaud’s phenomenon, 22(73.3%) had esophageal disorders, 21(70%) had pulmonary fibrosis and 3(10%) pulmonary hypertension. Arthritis was present in a great majority of these patients (93%). The immunological evaluation showed that 4(13.3%) had positive anticardiolipin antibodies and 11(36.7%) had scl-70 (+). The comparison of IMT between patients and matched-controls revealed an increased IMT in UCTD patients [0.82 (0.32) vs 0.6 (0.13) mm; p<0.001]. There was also a significant difference in mean (SD) TC [204(4.33) vs 238(4.14) in patients vs 238(4.14) in controls; p value=0.004] with respective reduced levels of mean(SD) HDL in patients [50.69(5.9) vs 61.1 (13.3); p value=0.002]. No statistically significant difference was found for LDL-c and TGs.

Conclusion: These patients had mean (SD) ApoA1 146.9(27.6), ApoB 94.9(25.6), ApoE 42.1(10.7), LpA 12.8 (15.9), HSCRP 7.5(13.5), ESR 28.9 (22.6) and fibrinogen 422.9(101.3).

FR10324

DISEASE ACTIVITY INDICES IN SYSTEMIC SCLEROSIS-WHICH TO USE IN DAILY PRACTICE?

Laura Gioseffi1,2; Sonora Petrescu1, Ana Balanescu1,2, Daniela Opris-Belca1,2; Violeta Bojinca1,2, Floriana Benghea1,2, Ioana Saulescu1,2, Sanziana Daia-Iliescu1,2, Diana Mazilu1,2, Andreea Borangiu1,2, Cosmin Constantinescu1,2, Maria Magdalena Negru1,2, Miha Abobuli1,2, Violeta Vlad1, Ruxandra Ionescu1,2, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 1St Maria Clinical Hospital, Bucharest, Romania

Background: Currently there is no fully validated index for assessing overall disease activity in patients with systemic sclerosis (SSc).

Objectives: To estimate the effect of disease activity as measured by 4 disease activity indices on the risk of subsequent organ damage in an EUSTAR center cohort.

Methods: Longitudinal observational study; European Systemic sclerosis study group disease activity index (ESCG DAI), revised EUSTAR disease activity index (r-EUSTAR DAI), 12 point activity index proposed by Minier (12point DAI) were calculated for all patients; the CRiSS (The Combined Response Index for Systemic Sclerosis) only for patients included after 2016. Student t-test/Mann-Whitney test, chi-square test were used to evaluate differences across subgroups; Pearson’s bivariate correlation/Spearman’s rank correlation coefficient to evaluate the association between variables. The predictive value of various variables for major organ involvement was assessed by Roc curves and univariate regression.

Results: 91 patients were selected,77 females (84.61%), 51,65(13,20) years old at diagnosis, 49,45% diffuse subset. Disease activity scores were all higher in male patients and in patients with diffuse cutaneous involvement, digital ulcers(DU), lung fibrosis, scleroderma renal crisis (SRC), amythiasma, muscle atrophy, gastric involvement, antiproliferosera 1 positive, EscSG DAI correlated with forced vital capacity (FVC)(r=0.73,p<0.001), DLCO(r=0.68,p<0.001), DU(2)= 3.08, p=0.05), lung fibrosis(2x0.10,3.20), systolic pulmonary arterial pressure (sPAP) (>0.54,p<0.001), muscle atrophy (x2=11.58,p<0.001), diffuse subset (x2=11.46,p<0.001), R- EUSTAR DAI correlated with FVC(r=0.6,p<0.001), DLCO(r=0.58, p=0.001), diffuse subset(2x=9.52,p<0.01), contractures(2x=11.23,p<0.001), muscle weakness(2x=6.67, p=0.01), muscle atrophy (x2=10.19, p<0.001), SRC (2x=4.74, p=0.02) and sPAP(r=0.5,p<0.001).

12 point DAI correlated with FVC(r=0.57,p<0.001), DLCO(r=0.66,p<0.001) and sPAP(r=0.42,p=0.001).

EscSG predicted well lung fibrosis (AUC=0.79,p<0.001), DU (AUC=0.66, p=0.001), gastric involvement (AUC=0.73, p=0.01) and SRC (AUC=0.9, p=0.01). R-EUSTAR index also lung fibrosis (AUC=0.76, p<0.001), DU (AUC=0.82,p<0.01) and SRC (AUC=0.84, p=0.04).

12point DAI was a good predictor for lung fibrosis(AUC=0.74,p<0.001), DU (AUC=0.78,p<0.05), gastric involvement(AUC=0.76,p<0.01).

In the regression analysis, lung fibrosis(bbeta=0.595CI=1.21-2.56,p<0.01), muscle atrophy (beta=1.49, 95%CI=1.02-2.19,p=0.03) and rhythm and conduction disturbances (beta=1.48, 95%CI=1.31-2.99,p=0.001) were independent predictors for disease activity evaluated by EScSG. For 12point DAI none of the evaluated parameters proved to independently contribute to disease activity. For 12point DAI items independently
contributing to disease activity were gastric involvement (beta=-2.46, 95% CI=1.19-5.09, p=0.01) and muscle atrophy (beta=-2.05, 95%CI=1.03-4.08, p=0.03).

The CRISS cohort included 35 patients, 32 females (91.42%), 48.48±14.24 years old, 62.85% diffuse subset, medium disease duration 11.88±(7.9 months). 8 patients were excluded due to new onset or worsening of lung fibrosis or SRC. None of the patients had a CRISS score with a probability of improvement>0.6.

Conclusion: We could not conclude that there is a gold standard to measure disease activity; for daily practice especially EsgSG and r-EUSTAR DAI quantify and predict major organ involvement. CRISS can be useful as an outcome measure for patients with short disease duration and closely monitored in clinical studies.

Background: Early identification of patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD) at risk of progression could help tailor management and aid cohort enrichment in clinical trials to improve outcome.

Objectives: To assess the frequency of progressive SSc-ILD in the total ILD cohort and in subgroups enriched by risk factors in the EUSTAR database.

Methods: Patients from the EUSTAR database registered after 2010, ≥18 yrs old, fulfilling SSc classification criteria, with serial lung function and HRCT assessments were eligible. The following risk factors for progressive SSc-ILD available in the EUSTAR database were chosen as enrichment criteria: low forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO), diffuse cutaneous SSc, antitopoisomerase I antibody (ATA), short disease duration, older age, male sex, increased C-reactive protein, and presence of respiratory symptoms and reflux disease. Eligible patients with progressive ILD were assessed in the cohort and in subgroups enriched by the risk factors. Progressive SSc-ILD was assessed as absolute changes in predicted and defined as: significant progressive (FVC decline >10%, or FVC decline 5–10% and DLCO decline >15%), moderate progressive (FVC decline 5–10% or stable (>5% FVC change in either direction). The follow-up period was defined as time from baseline to last available lung function test.

Results: 6004 patients fulfilled the main entry criteria; of these, 1822 (30.3%) had ILD. At baseline, mean age was 57 yrs, 17.4% were male, 48.2% had diffuse SSc, 53.5% were ATA-positive, mean baseline FVC 80% and DLCO59%, mean disease duration 9.8 yrs, and follow-up was 2.5 yrs. In the total ILD cohort (30% eligible patients), 21% showed progressive ILD. Enriching with single risk factors reduced the number of eligible patients down to 6%, while the frequency of progressive ILD stayed stable (Figure). Combinations of risk factors did not result in increasing numbers of progressive ILD patients, but in further decreasing numbers of eligible patients.

Conclusion: There is still an unmet need to identify SSc-ILD patients at risk of progression with efficient risk factors. For clinical trials, it is a challenge to balance feasibility of recruitment and enrichment.

Background: The hallmark of systemic sclerosis (SSc) is fibrosis of the skin. The interstitial matrix is rich in type I and III collagen while type IV collagen is the main collagen of the basement membrane. These two types of matrix are anchored together by other matrix proteins such as type VI collagen. Tissue turnover is in a delicate equilibrium of tissue formation and degradation, which may be altered in pathologies such as SSc, in which there is a net increase in tissue. By using advanced serological biomarkers tissue turnover, tissue formation and tissue degradation may be assessed separately, to quantify the tissue balance. The hypothesis of the current study was that the tissue balance was altered in SSc as compared to healthy, and that limited and diffuse SSc would present with different turnover rates.

Objectives: The objective was to quantify the tissue turnover balance in a cross-sectional study in limited and diffuse SSc.

Methods: Forty-three patients fulfilling the 2013 ACR/EULAR criteria for SSc were included. The study included limited (lcSSc, n= 20) and diffuse SSc (dcSSc, n=23) (recruited at Lund University, approval number Dnr 590/2008). Ten healthy controls were included. Biomarkers of type III, IV and VI collagen formation (PRO-C3, PRO-C4, PRO-C6) and degradation (C3M, C4M, C6M) were measured cross-sectional in serum samples by competitive ELISAs. The fibrotic index of collagen (FICol) was examined (formation/degradation). Difference between groups were tested by Mann-Whitney U test and correlations by Spearman’s correlation (rho).

Results: There was no significant difference in gender, age or BMI between lcSSC and dcSSC. The mean age of the population was 53.5 years and 75.2% female. lcSSC had a longer disease duration (lcSSC: 32.3 month (SD: 41.0), dcSSC: 13.5 month (SD 14.9), P=0.05) and a lower modified Rodnan skin score (mRSS, lcSSC: 4.25 points (SD: 3.1), dcSSC: 20.3 points (11.7), P=0.0001) compared to dcSSC as expected. Types I and III collagen formation were both significantly increased in dcSSC compared to lcSSC (PRO-C3: 18.6 ng/ml (SD: 10.0) vs 13.0 ng/ml (SD: 6.5) (P=0.01), PRO-C6: 16.7 ng/ml (SD: 6.6) vs 12.1 ng/ml (SD: 4.9) (P=0.01)). Figure 1). Type III collagen degradation were decreased in dcSSC compared to lcSSC (C3M: 13.3 ng/ml (SD: 2.9) vs 17.4 ng/ml (SD: 7.5) (P=0.03)). Neither type IV collagen formation nor type III, IV or VI collagen degradation were significantly different. The fibrotic index of type III and VI collagen (FICol3 and FICol6) were significantly increased in dcSSC compared to lcSSC (FICol3: 1.4 (SD: 0.6) vs 0.8 (SD: 0.3) (P=0.0001), FICol6: 1.2 (SD: 0.5) vs 0.9 (SD: 0.3) (P=0.03), Figure 2). The fibrotic index of type IV collagen (FICol4) were not different between the two groups but were both 1.5 times higher than the levels of healthy (healthy: 6.9, lcSSC 10.4 (SD: 3.3), dcSSC: 10.5 (SD:3.1)).

Both type III and VI collagen formation correlated moderately with mRSS with rho’s of 0.53 (P=0.0003) and 0.4 (p=0.008), respectively. FICol3 correlated with a rho of 0.59 (P=0.0001) and FICol6 with a rho of 0.35 (P=0.04).

Conclusion: The tissue turnover balance was clearly altered in both limited and diffuse SSc as compared to healthy controls. In addition, diffuse SSc presented with a more screwed balance in the fibrotic index towards tissue formation and disease progression. This study shows the importance of looking at both collagen formation and degradation. The collagen tissue turnover could be beneficial in following patients’ fibrosis development and possibly identifying if they are progressing or in regression.

Branching Chain Amino Acids in the Treatment of PolyMyositis and Dermatomyositis: Results from the BTOUGH Study
Naoki Kimura, Hitoshi Kohsaka, Tokyo Medical and Dental University (TMDU), Department of Rheumatology, Tokyo, Japan

Background: Muscle functions of patients with polymyositis and dermatomyositis (PM/DM) remain often impaired even after successful control of the immune-mediated muscle injury by immunosuppressive therapy. The only effort at the present to regain muscle functions except for the immunosuppression is rehabilitation, which is carried out systematically in limited institutes. No medicines for rebuilding muscles have been approved. Branched chain amino acids (BCAA) promote skeletal muscle protein synthesis and inhibit muscle atrophy. They thus have positive effects on muscle power, but have never been examined for the effects on PM/DM.

Objectives: To assess the efficacy and safety of BCAA in the treatment of PM/DM for official approval of their use in Japan.

Methods: Untreated adults with PM/DM were enrolled in a randomized, double-blind trial to receive either TK-98 (drug name of BCAA) or placebo in addition to the conventional immunosuppressive agents. One package of TK-98 (4.15g) contained L-isoleucine 952mg, L-leucine 1490mg, and L-valine 1144mg (molar ratio is 1:2:1.35), and 6 packages were administered daily in 3 divided doses. After 12 weeks, patients with average manual muscle test (MMT) score less than 9.5 were enrolled in an open label extension study for 12 weeks. The primary end point was the change of the MMT score at 12 weeks. The secondary end points were the disease activity evaluated with myositis disease activity core set (MDACS) and the change of functional index (FI), which evaluates dynamic repetitive muscle functions.

Results: Forty-seven patients were randomized to the TK-98 (24 patients [12 with PM and 12 with DM]) and placebo (23 patients [11 with PM and 12 with DM]) groups. The baseline MMT scores were equivalent (7.97±0.92 [mean±SEM] in the TK-98 group and 7.84±0.86 in the placebo group). The change of MMT scores at 12 weeks were 0.70±0.19 (mean±SEM) and 0.69±0.18, respectively (P = 0.98). Thirty-one patients from the TK-98 group and 12 from the placebo group were enrolled in the extension study. The MMT scores in both groups improved considerably throughout the extension study. The increase of the FI scores of the shoulder flexion at 12 weeks was significantly larger in the TK-98 group (27.9±5.67 and 12.8±5.67 in the right shoulder flexion [P < 0.05]. 27.0 ±5.44 and 13.5±5.25 in the left shoulder flexion [P < 0.05]). The improvement rate of the average FI scores of all tested motions (head lift, shoulder flexion, and hip flexion) through the first 12 weeks was larger in the TK-98 group. No difference was found in the disease activity throughout the study period. Frequencies of the adverse events until 12 weeks were comparable.

Conclusion: Although BCAA exerted no effects in the improvement of the muscle strength evaluated with MMT, they were effective in the improvement of dynamic repetitive muscle functions in patients with PM/DM without significant increase of adverse events.

Disclosure of Interests: None declared.

MALIGNANCIES IN SYSTEMIC SCLEROSIS
PATIENTS WITH ANTI-PM/SCL ANTIBODIES: AN EUSTAR CASE-CONTROL STUDY

Maria Grazia Lazzaroni1, Stefania Zingarelli2, Desla Vries-Bouwstra2,3, Eric Hachulla4, Elisabetta Zanatta5, Simone Barsotti6, Marie-Elise Truchetet7,8, Giacomo De Luca9,10, Francesca Ingegno11, Cristian Cajani12, Silvia Bellando Randone12, Enrico Colombo12, Angela Ceribelli12,13, Franco Frascinelli14, Yannick Allarone15, Paolo Arigi16,17, Brescia, Italy,18, Leiden, Netherlands,19, Lille, France,20, Padova, Italy,21,22, Bordeaux, France,23, Milano, Italy,24, Ghent, Belgium,25, Leuven, Belgium,26, Lund, Sweden,27, Verona, Italy,28, Firenze, Italy,29, Sassari, Italy,30,31,32, Rozzano, Italy,33,34, Paris, France

Background: The main clinical associations of anti-PM/Scl in Systemic Sclerosis (SSc) include calcinosis, joint and muscle involvement, interstitial lung disease (ILD), and, possibly, scleroderma renal crisis (1,2). A possible association of anti-PM/Scl with cancer was reported in single-centre SSc series (2,3), but was never analysed in large multicentre studies. Moreover, the characteristics of malignancies, in particular their temporal association with the onset of SSc, were not explored.

Objectives: To evaluate the association of anti-PM/Scl with malignancies in a large, international, multicentre cohort.

Methods: 16 EUSTAR centres provided data on anti-PM/Scl+ SSc patients in their cohorts (cases), and on anti-PM/Scl-negative controls, matched for age at onset (±5 years), cutaneous subset, and disease duration (≥24 months). Only SSc patients with age ≥16 years at disease onset were included in this analysis. Anti-RNA Polymerase3+ patients were not included in controls, given the known association with synchronous cancer. Malignancies diagnosed between 2 years before and after the onset of SSc were defined as “synchronous” to the onset of SSc.

Results: 123 anti-PM/Scl+ SSc patients and 160 matched anti-PM/Scl controls (28% anti-Topoisomerase I, 40% anti-centromere, 32% others) were compared (Table 1): anti-PM/Scl+ patients had a higher prevalence of myositis (p=0.0001) and ILD (p=0.0001), and a lower prevalence of oesophageal symptoms (p=0.0001). The frequency of malignancies was not significantly different between the 2 groups (14/120 (12%) vs. 9/155 (6%), p=0.12). Only 7 malignancies synchronous to SSc onset were identified: 4 among anti-PM/Scl+ cases and 3 among controls (3 breast cancers; 3 other solid tumours; 1 multiple myeloma). Mean age at SSc onset was significantly higher in patients with synchronous malignancies compared to those without (64.9±7.2 vs. 48.4±14.3 years; p<0.003), irrespective of the anti-PM/Scl status.

Conclusion: In this EUSTAR multicentre case-control study, the association of anti-PM/Scl with malignancies in SSc patients could not be confirmed. Patients with older age at SSc onset seems to be at higher risk for synchronous malignancies, regardless the autoantibody status.

HISTORY OF SILICA DUST EXPOSURES AND ASSOCIATION WITH CHEST HRCT AND CLINICAL CHARACTERISTICS IN SYSTEMIC SCLEROSIS

Alice Baller1, Catherine Cavaillon2, Mathieu Ledernier2, Amélie Nicolas3, Ronan Garlantezec4, Stéphane Jouveaux5, Céline Cazales6, Nicolas Bethommé7, Paul-André Rosentat4, Patrick Jegou4, LESCOAT Alcain7, SILICOSIS project, ERC Advanced Grant. 1Univ Rennes, CHU Rennes, INSERM, EHESS, Institut de recherche en santé, environnement et travail – UMR_S 1085, Rennes, France, 2Centre d'études européennes de Sciences Po, 79363, Paris, France, 3CHU Rennes, Univ Rennes, Radiology, Rennes, France, 4CHU Rennes, Univ Rennes, Radiology, Rennes, France, 5CHU Rennes, Univ Rennes, INSERM, EHESS, Institut de recherche en santé, environnement et travail – UMR_S 1085, Rennes, France, 6CHU Rennes, Univ Rennes, Internal medicine and clinical immunology, Rennes, France, 7CHU Rennes, Univ Rennes, Internal medicine and clinical immunology, Rennes, France, 8SILICOSIS project, ERC Advanced Grant, Centre for European Studies, Sciences Po and National Institute for Demographic Studies (INED), Paris, France

Background: The association of a history of silica exposure with precise chest high-resolution computed tomography (HRCT) features is still to be determined in SSc patients fulfilling the 2013 EULAR/ACR classification criteria. A recent study highlighted that mediastinal lymph node involvement (ILD) (1). Nonetheless, the links between mediastinal lymphadenopathies (LA) and silica exposure in SSc patients have never been studied to date.

Objectives: The aim of this study was to assess the association of exposures to inorganic particles on the whole life course, with the HRCT characteristics in an unselected population of SSc patients.

Methods: A specific questionnaire based on a multidisciplinary approach (social sciences, epidemiology, occupational health and medicine) was used to assess occupational and non-occupational exposures to inorganic particles, with a specific interest on silica exposures in 100 SSc patients fulfilling the 2013 EULAR/ACR classification criteria. Clinical characteristics and chest HRCT at diagnosis were evaluated to assess the association of dust exposure with disease characteristics. The most recent chest HRCT was also evaluated and compared to HRCT at diagnosis to assess pulmonary evolution. All HRCT were evaluated by 3 experts, blinded for the results form dust exposure questionnaire.

Results: Men had significantly higher global and occupational dust-exposure scores than women. Sixty-five percent of men with SSc (n=17) had an occupational exposure to silica. Thirty-five percent of patients had thoracic LA and 12% an association of mediastinal and hilar LA. Male gender, history of tobacco use, dcSSc, positivity for ATA, thoracic LA and pneumoconiosis were significantly associated with occupational exposure to silica (p<0.05 for all). The presence of mediastinal and hilar LA was also associated with occupational exposure to silica (p=0.0001, OR=13.45, 95%CI=3.46-52.27). After stratification on gender, higher occupational dust-exposure score in men remained associated with mediastinal and hilar LA (p=0.046, OR=6.5, 95%CI=1.09-38.63). Mediastinal and hilar LA were also significantly associated with a more severe evolution of pulmonary involvement in SSc when considering extensive ILD at diagnosis, the use of immunosuppressive drugs, a fibrotic evolution with change of SSc-ILD pattern in the course of the disease, and an increase of pathological parenchyma extent above 10% since diagnosis.

Conclusion: By using a dedicated highly detailed questionnaire, this study underscores the high prevalence of silica exposure in SSc patients, especially in men. Mediastinal and hilar LA, considered as a bad prognostic factor in ILD, were frequent and associated with silica exposure.
IL-2 RESTORED THE REDUCED ABSOLUTE NUMBER OF TREG CELLS IN THE PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHY

Yuying Liang1, Hong-Yan Wen2, Yanan Duan2, Yang Lu3, Zhen Yu3, Chong Gao3.
1The Second Hospital of Shanshi Medical University, Rheumatology, Taiyuan, China; 2The Second Hospital of Shansi Medical University, Rheumatology, Taiyuan, China; 3Shanshi Dayi Hospital Affiliated to Shansi Medical University, Rheumatology, Taiyuan, China.

Background: Idiopathic inflammatory myositis (IM) is a group of skeletal muscle non-suppurative inflammatory disease, including polymyositis (PM), dermatomyositis (DM), inclusion body myositis (IBM), DM/PM associated with malignancy and so on. The latest studies suggest that there is an increase of Th17 cells levels and a decrease of regulatory T cells (Tregs) levels in IM, which lead to the Th17/Treg imbalance. IL-2 promotes the proliferation and differentiation of several subsets of CD4+ T cells and inhibits Th17 cells. It is provided to Tregs from IL-2-producing cells such as activated CD4+CD25hi T cells, NK and NKT cells. Tregs express IL-2Ra (II-Ig) receptor complex. Therefore, Tregs may be selectively stimulated by low-dose IL-2 and amplified.

Objectives: To explore the quantitative changes of peripheral Th17 cells and Tregs in IM before and after receiving treatment with low-dose interleukin-2 (IL-2) and analyze the relationship between peripheral Th17 cells and Tregs and clinical indicators disease activity.

Methods: Total 151 IM patients were enrolled, and 196 healthy adults were used as normal controls. Of them, 76 cases were treated with low dose IL-2 (5.0*10^5 international units (IU) for 5 days). The absolute number of peripheral T, CD4+ T, CD8+ T, Th1, Th2, Th17 and Treg subsets were analyzed by flow cytometry. Laboratory examinations were analyzed retrospectively. Since the data was disregarded from the normal distribution, the median four quantile method was used for statistical description. Multiple samples were compared with Kruskal-Wallis H test, and the correlation between variables was Spearman rank correlation analysis.

Results: (1) In the patients, the absolute number of Treg cells was significantly decreased as compared with that in the control group (P<0.05) and increased by treated with a low dose IL-2. After IL-2 treatment, the absolute numbers of T, CD4+ T, CD8+ T, Th1, Th2 and Th17 cells and the ratio of Th17/Treg were still significantly lower than that in the control group (P<0.05). (2) The peripheral Th17 cells levels were negatively correlated with ESR, CRP, LDH and HBDH (r=-0.42, r=-0.28, r=-0.21, r=-0.20, P<0.05); the ratio of Th17/Treg was negatively correlated with ESR (r=-0.23, P<0.05).

Conclusion: The absolute number of peripheral Th17 cells and Tregs declined significantly in IM, and had correlation with ESR, CRP, LDH and HBDH. However, after receiving treatment with low-dose IL-2, the Tregs levels elevated, which means that IL-2 may plays an essential role in the differentiation and development of Tregs. It also provides new thought and strategy for the therapy of IM.

ASSESSING SYSTEMIC SCLEROSIS CARDIAC INVOLVEMENT USING MAGNETIC RESONANCE T1-MOLLI MAPPING

Sue-Ann Ng1,2, Stephanie Marchesseau2, John Carson Allen Jr3, John Tolman3, Andrea Loe1,2, Singapore General Hospital, Rheumatology and Immunology, Singapore, Singapore; 3Duke-National University of Singapore, Singapore, Singapore; 4Clinical Imaging Research Center, A*STAR and National University of Singapore, Singapore, Singapore

Background: Patients with systemic sclerosis (SSc) and symptomatic cardiac involvement have a disease-associated mortality of 20% in 10 years. Prevalence of subclinical cardiac involvement is 15%-35%. Early diagnosis and monitoring is therefore critical in the management of SSc-associated cardiac involvement. Conventional cardiac magnetic resonance imaging (cMRI) T1-weighted sequence with late gadolinium contrast has good accuracy for detecting localized fibrosis but not diffuse fibrosis that occurs in SSc. Modified look-locker inversion recovery (T1-MOLLI) mapping, a novel cMRI sequence, has been used to detect and quantify diffuse fibrosis in aortic stenosis. T1-MOLLI values have also been correlated with the degree of biopsy-quantified fibrosis.

Objectives: To investigate whether cMRI T1-MOLLI is able to detect fibrosis associated with SSc cardiac involvement.

Methods: We recruited 16 patients fulfilling the 2013 ACR/EULAR criteria for SSc and 17 healthy age-matched (within 5 years) controls. Patients underwent cMRI T1-MOLLI mapping on the Siemens Biograph mMR 3.0T (Erlanger, Germany).

T1-MOLLI values were compared between SSc patients and healthy controls using student t-test and statistical significance was taken to be p<0.05.

Results: Demographics and clinical features of our study cohort are as shown in Table 1. Two (12.5%) SSc patients were symptomatic with palpitations or had arrhythmia requiring treatment. Eleven (68.8%) SSc patients had elevated T1 MOLLI values, using a normal cut-off threshold of 1284 ms.

Mean cardiac T1 values were significantly higher in SSc patients (1329 ± 88.0 ms) than in controls (mean T1 = 1238 ± 93.7 ms, p=0.0075), indicating the presence of cardiac fibrosis.

Conclusion: cMRI T1-MOLLI mapping demonstrated that SSc patients who were predominantly asymptomatic showed evidence of cardiac fibrosis. cMRI T1-MOLLI is potentially a useful diagnostic and monitoring tool for SSc cardiac disease.

Abstract number: FR00334

PERFORMANCE OF THE SCLERODERMA SKIN PATIENT-REPORTED OUTCOME (SSPRO) IN A PHASE 2 TRIAL WITH LENABASUM

Ada Man1, Nancy Ogletuck2, Brian Conley2, Barbara White3, ‘University of Manitoba, Winnipeg, Canada; 2Corbus Pharmaceuticals, Inc, Norwood, United States of America

Background: Skin thickening is a distressing feature of systemic sclerosis (SSc). The severity and extensiveness of skin thickening, as traditionally
assessed by mRSS, may not directly correlate with its effect on patients’ health related quality of life (HRQoL). The Scleroderma Skin Patient-reported Outcome (SSPRO) was specifically developed to assess the skin-related HRQoL in SSc. No skin-specific PRO in SSc has been prospectively validated in a clinical trial.

Objectives: Validate the SSPRO prospectively in a clinical trial.

Methods: The SSPRO, Patient Global Assessment (PiGA), Physician Global Assessment (MDGA), HAQ-DI, mRSS, FVC%, predicted, PROMIS-29 questionnaire, and ACR CRiSS were assessed prospectively in a Phase 2 study of lenabasum in dcSSc. SSPRO has 18 items that assess four SSc skin-related HRQoL domains. The Phase 2 study of lenabasum had a 4-month double-blinded portion (N = 41 completers) followed by an open-label extension (N = 38 entered). Spearman correlations of baseline values and change values were determined for SSPRO and other outcome measures. Mean change in SSPRO scores were determined in subjects with increasing levels of improvement in other efficacy outcomes.

Results: At baseline, SSPRO correlated moderately with all other outcome measures except for FVC%, as expected, with stronger correlations with PiGA, HAQ-DI, and PROMIS-29 pain interference and social role domains (Table 1). The mean change in SSPRO scores at 3 and 12 months correlated mostly moderately (r = 0.25 to 0.62) with the mean change in other outcome measures, but correlations were low or inconsistent with mRSS, FVC%, and PROMIS-29 anxiety domain (Table 1). Significance of correlations in some outcomes was hampered by small magnitudes of change. Mean SSPRO generally increased in subjects with increasing levels of improvement in HAQ-DI, PiGA, mRSS, and ACR CRiSS, although less consistently with mRSS and ACR CRiSS at 3 months (Table 2).

Conclusion: SSPRO score correlates with both physician and patient-reported outcomes at baseline, though correlations with the latter were stronger. Change in SSPRO reflects changes in how the patient feels reported outcomes at baseline, though correlations with the latter were stronger. Change in SSPRO reflects changes in the patient feels baseline SSPRO score correlates with both physician and patient-reported outcomes at baseline, though correlations with the latter were stronger. Change in SSPRO reflects changes in how the patient feels and other outcome measures. Mean change in SSPRO scores were determined in subjects with increasing levels of improvement in other efficacy outcomes.

1Rheumatology, University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy; 2Pneumology, University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy

Background: Intestinal Pneumonia with Autoimmune feature (IPAF) is a recently defined disease that includes Intestinal Lung Disease (ILD) in patients with features of autoimmunity, not satisfying any of the established classification criteria for connective tissue diseases (CTD). Even if IPAF patients share clinical and serological findings with CTD, we are unaware about the clinical evolution of IPAF patients.

Objectives: To define the characteristics and evolution of IPAF patients in a multidisciplinary setting.

Methods: We selected patients with a diagnosis of IPAF referring to a multidisciplinary Rheumatology/Pneumology/Radiology team at our hospital. We excluded from the analysis patients positive for antisynthetase antibodies, as diagnosed with antisynthetase syndrome. Data were retrospectively collected from our hospital medical records.

Results: We analyzed 25 patients (19 females, 76%, 6 males, 24%), with a median onset age of 67 years (interquartile range, IQR, 59-74) and a follow-up of 32 months (IQR 22-69). ANA test was positive in 23 (92%) cases (fig 1), whereas cytoplasmic positivity was observed in 17 (68%). Anti-ENA screen was positive in 9 patients (36%) (7 [28%] anti-Ro52 and 2 [8%] anti-RNP). One patient (4%) was positive for anti-PM-Scl, 1 (4%) for anti-Mi2 and 1 (4%) for anti-Ku antibodies. These 2 latter antibodies are not included in the serological domain of IPAF. Patients had mainly a Non Specific Intestinal Pneumonia (NSIP) pattern (19 [76%]; fibrosis in 7 [28%], and with concomitant organizing pneumonia (OP) in 3 [12%]. Three (12%) patients had Usual Interstitial Pneumonia-like and 3 (12%) an OP pattern. The majority of patients (15 [60%]) satisfied only the morphological and serological domains. Clinical domains satisfied were: arthritis (4 [16%]), Raynaud’s phenomenon (5 [20%]), palmar telangiectasias (2 [8%]), mechanic’s hands (1 [4%]) and hiiker’s feet (1 [4%]). We observed other findings not included in IPAF criteria but suggestive for CTDs, both clinical (inflammatory myopathy 3 [12%]; dry eye1 [4%]; sclerodericytly 1 [4%], and instrumental (scleroderma pattern at nailfold capillaroscopy 1 [4%]; dilated esophagus at barium X-rays 2 [8%]). Clinical spectrum time course was variable in 5 (20%) cases: 3 (12%) patients developed arthritis after ILD, and 2 (8%) developed ILD respec-

*ACR CRiSS score is absolute, not change, score.*
tively after arthritis and inflammatory myopathy onset. Three (12%) patients were admitted to the Intensive Care Unit for Rapidly Progressive (RP) ILD and 2 died (respectively 2 months and 54 months after ILD onset), whereas the alive patient had 2 ICU admission for RP-ILD. Five (20%) patients, including the only 1 dismissed from ICU, needed home O2 therapy. Ongoing and previous therapies are reported in figure 2.

Conclusion: We showed that the prognosis of IPAF is highly variable, with patients experiencing RP ILD, other slow progressive worsening of respiratory functions and other a substantially stable disease. Furthermore, we showed other findings, laboratory, clinical and instrumental, that could help clinicians in a better identification and stratification of IPAF patients. As a matter of fact, at present, IPAF appears as a generic term including very different conditions that can be further differentiated according to clinical and serological data.

FRIO337 INCIDENCE AND PREVALENCE OF MYOSITIS ASSESSED BY MULTISOURCES CAPTURE-RECAPTURE METHODOLOGY

John McLaren1, Paul Alcock1, Michael Hearn1, Elizabeth Furr1, Sarah Hallwood1, NHS Fife, Fife Rheumatic Diseases Unit, Kirkcaldy, United Kingdom; 1NHS Tayside, Immunology Laboratory Service, Dundee, United Kingdom

Background: Precise epidemiology of myositis epidemiology remains largely unknown (1). Surveys based solely on administrative claims benefit from large case ascertainment but may be influenced by misclassification and misdiagnosing. The use of medical records with charts review benefit from accurate diagnosis but exhaustive ascertainment is difficult to achieve because numerous specialists are involved and cases may concern both inpatients and outpatients.

To overcome these difficulties we undertook a capture-recapture survey that takes advantage of a multi-sources case ascertainment to estimate the number of cases missed by any one source and to correct the prevalence rate (2).

Objectives: To assess the incidence and prevalence of myositis in Alsace, a region of eastern France.

Methods: Alsace, region of eastern France, is home to about 2 million inhabitants benefiting from high access to healthcare and a labialized referral center for myositis. Seeking care outside is uneasy because of peculiar geography. Myositis patients were retrieved through three separate sources: i) all general practitioners and community specialist ii) Muscle pathology center records, iii) all public and private hospitals records, iv) all public and private laboratory records. Incidence and prevalence cases fulfilling the ACR/EULAR criteria for myositis were included.

Results: The responses to the questionnaires sent to the physicians (>150), yielded 105 potential myositis cases. All hospital centres contacted (n=13) participated in the study and 135 potential myositis patients were recorded by this source. We thus received 1683 records of suspected myositis after excluding duplicates within each sources. The thorough review of the corresponding medical charts is currently ongoing and at this stage 10% of the potential cases fulfilled the ACR/EULAR criteria for myositis.

Conclusion: This first study based on a multi-sources capture-recapture methodology and ACR/EULAR criteria is very likely to provide an accurate estimation of myositis epidemiology.

ANTI-MDA5 IDIOPATHIC INFLAMMATORY MYOSITIS (IIM) CONFRS POOR PROGNOSIS BUT NEGATIVE MYOSITIS SPECIFIC ANTIBODY (MSA) IS NOT BENIGN EITHER

Sin Nea Ng, Chun Man Ng, Chi Ol Clang, Moon Ho Leung, Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong (SAR)

Background: MSA test is useful to diagnose IIM and subcategorize patients by disease phenotypes.

Objectives: The study aims to evaluate the survival of IIM patients of different MSA patterns.

Methods: An IIM registry had been set up in a tertiary referral centre since 2014 by recruiting prevalent and incident cases. Patients were followed up prospectively. This study included patients fulfilling the 2017 EULAR/ACR classification criteria for IIM and excluded those aged < 18 at disease onset. Immunoblot EUROLINE autoimmune inflammatory myopathies 16 antigens strip (EUROIMMUNE AG, Lubeck, Germany) was used. Information including baseline demographic data, disease manifestations, MSA results, co-existing malignancy, duration of survival and causes of death were collected. IIM patients were divided into seven groups, which included 1) anti-aminoacyl tRNA synthetase (ARS) 2) anti-MDA5, 3) anti-TIF1γ/anti-NXP2, 4) double positive MSA, 5) other MSAs, 6) negative MSA/MAA (myositis associated antibodies) and 7) positive MAA only.

Results: Among 112 IIM patients, 79 (70.5%) were female, and the median age of onset was 55 (18-90) years old; 63.4% were dermatomyositis (DM), 17.9% polymyositis (PM) and 18.8% clinically amyotrophic DM (CADM). Co-existing interstitial lung disease (ILD) was common and found in 65 (58%) patients; 16 (14.3%) had rapidly progressive interstitial lung disease (RPILD), and 16 (14.3%) died within the observed period. Overall, the commonest cause of death was RPILD, followed by infection and malignancy. While anti-MDA5 was strongly associated with RPILD (odds ratio = 33.0 [95% CI: 7.2-151.8], p<0.001), anti-MDA5 group had the worst survival, with 1-year and 5-year survival both at 43%, compared to above 80% in all other groups (log-rank test p<0.001) (Table 1). There were nine patients with double positive MSA and 28 had negative MSA/MAA. Analysis between MSA subgroups found that the double positive MSA and anti-MDA5 group had the worst survival, with 1-year and 5-year survival both at 43%, compared to above 80% in all other groups (log-rank test p<0.001) (Table 1).

Conclusion: Anti-MDA5 associated RPILD was the leading cause of mortality in IIM. However, those tested negative for both MSA and MAA by current immunoblot technique also had guarded prognosis related to the risk of infection and malignancy.

ANTIBODIES IN DERMATOMYOSITIS/POLYMYSITIS

Marko Cagava-Momohara, Yoshinori Muro, Masashi Akiyama, Nagoya University Graduate School of Medicine, dermatology, Nagoya, Japan

Background: The anti-Ro52 antibody, found in numerous systemic autoimmune conditions, is one of the most common autoantibodies in inflammatory myositis. It is known to be associated with interstitial lung disease (ILD) and to coexist with anti-Jo-1. There are two spliced forms: Ro52α and Ro52β. Ro52β was originally reported in 1995 as a spliced form of Ro52α in the human heart. Ro52α antigen cDNA has a defective exon 4, which encodes part of an autoepitope hotspot.

Objectives: We investigated the clinical and laboratory characteristics of anti-Ro52α and anti-Ro52β. We also analyzed the characteristics of anti-Ro52αβ in each coexisting inflammatory myositis specific autoantibody (MSA) group to reduce the influences of coexisting MSA characteristics.

Methods: Among 229 dermatomyositis (DM) and polymyositis (PM) patients, 167 patients (DM 152, PM 10, juvenile DM 5) fulfilled the criteria of Bohan and Peter, and 62 clinical amyopathic DM cases fulfilled the criteria of Sontheimer. Anti-Ro52α and anti-Ro52β antibodies were detected by ELISA.

Results: 46 of the 229 patients were anti-Ro52α-positive (20%). ILD was a frequent complication in the anti-Ro52α-positive patients (35/42: 76%) (P=0.0016), and anti-Ro52α was highly positive in the anti-aminoacyl tRNA synthetase (ARS) antibody-positive group (19/32: 60%) (P<0.0001) (Table 1). However, the ILD frequencies of anti-Ro52α-positive and anti-Ro52α-negative patients within each group of coexisting MSA (anti-ARS, anti-TIF, anti-MDA5, etc.) were almost same (P=1). The anti-Ro52α-positive rates were similar to the positive rates of anti-Jo1 (61%) and other anti-ARS (52%) (P=0.7).

Of the 46 anti-Ro52α-positive patients, 26 patients were anti-Ro52β-positive. No patient was only anti-Ro52β positive. The anti-Ro52α-positive and anti-Ro52β-positive groups were older than the anti-Ro52α-only-positive group (P<0.009), and the average of maximum creatine kinase was higher in both of the positive groups (P=0.065). The 6 patients without coexisting MSA were all both anti-Ro52α-positive and anti-Ro52β-positive (P=0.03) (Table 2).

Conclusion: Anti-Ro52 is highly positive when anti-ARS antibodies are present, but it is anti-Jo-1-specific. Anti-Ro52 positivity is not associated with elevated risk of ILD in any of the MSA-positive groups. The anti-Ro52αβ antibody might be an indicator of myositis.

REFERENCES:
To assess a long-term follow-up primary RP patient and has proven to be useful in identifying patients with secondary RP. Identify the presence of secondary RP is important to perform an the presence of scleroderma or other connective tissue diseases (CTD).

Main pathologies observed after follow-up were: Scleroderma/Systemic sclerosis (n=3), Systemic Lupus Erythematosus (n=3), Rheumatoid arthritis (n=2). The main capillaroscopic patterns were predominant among SSc patients presenting LUTS (both UI and OAB), although not any statistical correlation was found.

**LOWER URINARY TRACT SYMPTOMS PREVALENCE IN SYSTEMIC SCLEROSIS PATIENTS: RESULTS FROM A COMPREHENSIVE ANALYSIS**

Greta Pacini1, Amelia Chiara Trombetta1, Federica Goeangi1, Sabrina Paolino1, Carmen Pizzorno1, Elsa Alessandri1, Massimo Patane1, Emanuele Gotehi1, Giorgia Ferraro1, Francesco Cattelan1, Massimo Gin1, Andrea Casabella1, Vanessa Smith1, Maurizio Cutolo1. 1IRCCS San Martino Polyclinic Hospital, Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy; 2Ghent University Hospital, Department of Internal Medicine, Belgium Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium

Background: Lower urinary tract symptoms (LUTS) are a seldom-reported manifestation of systemic sclerosis (SSc). Although LUTS have been described in SSc patients with a higher prevalence than in the general population, no controlled studies have been reported to date [1-3].

Objectives: To compare LUTS prevalence and severity in SSc patients and in healthy subjects and mainly to explore their association with SSc clinical and diagnostic parameters.

Methods: This study evaluated 42 SSc consecutive patients (median age 61 years, range 21-85) and 50 matched healthy subjects (median age 57 years, range 28-93). SSc diagnosis was based on the 2013 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria. LUTS were assessed through validated self-reported questionnaires derived from the International Conference on Incontinence (ICIQ-FLUTS, ICIQ-MLUTS and ICIQ-OAB) [4]. General comorbidities and/ or medication potentially related to LUTS, as well as lower urinary tract infections, were evaluated in order to exclude confounding factors. Non-parametric tests and chi-squared test were performed to compare LUTS distribution, namely of urinary incontinence (UI) and overactive bladder (OAB), in the two populations, then linear and logistic regressions were used to test the association between SSc disease and LUTS prevalence and severity. In SSc population, linear and logistic regressions were performed to test the association between LUTS and SSc variables, includ- ing nailfold videocapillaroscopy (NVC) patterns ("Early", "Active", "Late", SSc-related autoantibodies and dual X-ray absorptiometry (DXA) parame-
ters. Multivariate analysis was performed to adjust the associations for potential confounders. A p value < 0.05 and a confidence interval (CI) of 95% were considered statistically significant.

Results: SSc patients showed significantly higher prevalence and severity of UI and OAB than healthy controls (p < 0.005, p< 0.01). SSc was a strong predictor of LUTS, independent of demographic data, comorbidities and treatments (OR 5.57, 95% IC 1.64-18.88). In SSc patients sarcopenia positively correlated with OAB (p< 0.001) and reduced bone mineral dens-
ity (BMD) positively correlated with OAB (p< 0.05) and UI (p< 0.001). UI positively correlated with anti Scl70 Abs (p< 0.05) and cyclosporine treatment (p< 0.001) and negatively with anti RNA polymerase III Abs (p< 0.05); OAB positively correlated with calcinosis (p< 0.005) and negatively with methotrexate treatment (p< 0.05). NVC "Active" and "Late" pat-
tens were predominant among SSc patients presenting LUTS (both UI and OAB), although not any statistical correlation was found.

Conclusion: For the first time urinary tract involvement was found to be significantly higher in SSc patients than in healthy matched controls. In addition, sarcopenia, bone damage and calcinosis appeared significantly correlated with LUTS, suggesting a possible interplay.

EROSIVE OSTEOARTHRITIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Cristina Pigan Morata1, Jaime Arroyo Palomo1, Carlos de la Puente Bujidos1
Hospital Universitario Ramón Y Cajal, Rheumatology, Madrid, Spain

Background: Erosive osteoarthritis (EO) is a rare but aggressive variant of hand osteoarthritis. Its prevalence in Europe is 3.3% in men and 9.9% in women, affecting 15.5% of patients with hand osteoarthritis. EO causes a significant loss of function in the hands, with more severe inflammatory signs and affecting almost exclusively thePIP and DIP joints, usually avoiding the TM and MCP. In systemic sclerosis (SSc), hands are commonly affected with pain and joint deformity that, added to sclerodactyly and the presence of digital ulcers, produce an important functional limitation. It has not been established yet whether the presence of the disease determines an increased risk for the development of erosive osteoarthritis.

Objectives: To determine the frequency of EO in patients with SSc seen in our hospital in Madrid and to compare it with the frequency observed in the large cohorts of healthy population (Framingham study). Secondly analyze both the clinical and analytical factors that may be related to the presence of EO in these patients.

Methods: A descriptive, observational cross-sectional study was conducted. We included all patients with a diagnosis of systemic sclerosis attended in our Rheumatology Unit. A database was created including clinical and epidemiological data and all the available imaging tests to assess the presence of findings compatible with EO in interphalangeal hand joints were reviewed. Acroosteolysis lesions were not considered as EO. Finally, a descriptive analysis was carried out.

Results: The prevalence of EO in our cohort of SSc patients, although low, is higher than the estimated in general healthy population according to the large European studies, with 8.16% (12/147) of the patients affected. All the patients with EO were female, with a higher age of presentation of SSc compared to patients without EO (66.72 vs 50.72 years). The disease was more prevalent in patients with limited skin involvement (75% vs 62%) and they had a higher frequency of telangiectasias in the typical locations. Likewise, patients with EO had more frequently positive AMA (25% vs 8.8%) and calcinosis (33% vs 17.7%). The frequency of ANA, Raynaud’s phenomenon and interstitial lung disease was similar in both groups. No patients with positive Ro or La presented EO.

Conclusion: Although it is an uncommon variant of hand osteoarthritis, in our cohort a higher prevalence of EO was observed in patients with SSc compared to the healthy general population. In our group, the most associated risk factors were female sex, advanced age at the diagnosis of SSc, the presence of AMA and calcinosis, regardless of its location. The frequency of pulmonary involvement and Raynaud’s phenomenon was similar in both groups.

EVALUATION OF CAROTID HEMODYNAMIC PARAMETERS AND PLAQUES BY DOPPLER ULTRASOUND IN PATIENTS WITH SYSTEMIC SCLEROSIS

Isidro Sanz Pérez1, Fernando Martínez-Vale2, Alfredo Guillén del Castillo3, Olimpia Orozco-Galvez2, Eduardo L. Gallegos-Morga4, Vicent Fonollola-Pal2, Carmen Pilar Simón-Azna5, Vall d’Hebron, Internal Medicine. Unit of autoimmune diseases, Barcelona, Spain; 2Hospital Parc Taulí, Internal Medicine. Unit of autoimmune diseases, Sabadell, Spain

Background: Carotid Doppler-ultrasound is useful for the detection of subclinical atheromatosis, and also for the evaluation of hemodynamic characteristics of carotid arteries.

Objectives: The aim of this study is to evaluate the hemodynamic parameters of carotid arteries and its relation with vascular related Systemic Sclerosis (SSc) complications and subclinical atheromatosis.

Methods: 157 patients with SSc of the cohort of Vall d’Hebron Hospital were included according to the ACR/EULAR 2013 criteria and LeRoy classification.

The left and right common carotid arteries (CCA), bulb and internal carotid arteries (ICA) were scanned using Doppler ultrasound for the detection of plaques and for the measurement of the Peak Systolic Velocity (PSV), End Diastolic Velocity (EDV), Pulsatility Index (PI), Resistance Index (RI) and Systole/Diastole ratio (S/D), using the software incorporated in GE Healthcare’s Vivid 1 equipment.

Results: 157 patients were included, 132 women (84.1%), the mean age was 56 years old (range 20-83) and the mean of years of disease evolution was 19 years (range 3-57). 64.2% were SSc limited subset, 20.9% SSc diffuse subset, 9.5% SSc sine sclerodactyly and 4.7% early SSc subset. 49.3% had digital ulcers, 41.9% had interstitial lung disease and 14.2% had pulmonary hypertension.

There were no statistically significant differences in hemodynamic parameters in relation to Raynaud’s phenomenon, digital ulcers or pulmonary hypertension.

Seventy-five patients (47.7%) had carotid plaques. Patients with plaques had lower CCA PSV (66.8cm/s vs 76.7cm/s, p <0.01, CI 6.2-14.5), lower CCA EDV (15.3 cm/s vs 19.99cm/s p <0.01, CI 2.88-6.49), higher CCA PI (1.69 vs. 1.55, p < 0.05, CI 0.02-0.26) and higher CCA RI (0.77 vs 0.73 p <0.01 CI 0.02-0.05). These patients also had lower ICA EDV (22.9cm/s vs 26.5cm/s, p <0.01, CI 1.01-6.11), higher ICA PI (1.43 vs 1.32, p <0.05 CI 0.01-0.22) and higher RI0.71 vs 0.68 p <0.05 CI 0.01-0.05), without statistically significant differences in ICA PSV (79.75cm/s vs 84.24cm/s p: 0.21) nor in the ratio PSV/EDV.

Ratio ICA PSV/CCA PSV was calculated, without showing significant differences in the presence of plaques or vascular manifestations of the SSc.

The PSV greater than 120cm/s, as an isolated measure, did not show statistically significant differences related to the presence of plaques. The PSV greater than 150 showed statistically significant differences (p <0.01, CI 0.05-0.23), showing a large specificity 0.98 but a very low sensitivity 0.15 for the detection of plaques.

Conclusion: In our study we have not found relation between carotid hemodynamic parameters and microvascular related SSc complications such as Raynaud’s phenomenon, the presence of digital ulcers or pulmonary hypertension.

Patients with SSc and atherosomative disease have a characteristic carotid hemodynamic profile consisting in lower PSV and EDV, and higher PI and RI, both at CCA and at ICA. The presence of increased PI and RI in patients with plaques, could suggest a primary damage of the vascular wall in patients with SSc. More studies are needed to determine if these data are the cause or a consequence of the presence of plaques.

In our study the PSV greater than 150 cm/s isolated shows a high specificity for the presence of plaques.

SEXUAL FUNCTION IN GERMAN WOMEN WITH SYSTEMIC SCLEROSIS COMPARED TO WOMEN WITH SYSTEMIC LUPUS ERYTHEMATODES AND EVALUATION OF A SCREENING TEST

Marc Schraulings1, Lena Friederike Nauf1, Michael Gernert2, Eva Christina Schwancke2, Sebastian Saur2, Hans-Peter Tony1, Melanie Henes3, Jörk Henes3,1University Hospital Würzburg, Rheumatology/Clinical Immunology, Würzburg, Germany; 2University Hospital Tübingen, Rheumatology, Tübingen, Germany; 3University Hospital Tübingen, Gynaecology, Tübingen, Germany

Background: Few studies have been conducted to address the impact of systemic lupus erythematoses (SLE) or systemic sclerosis (SSc) on sexual function (1,2), and so far none in Germany.

Objectives: The aim of this study is to evaluate the sexual function of women with SSc and SLE and to compare it with healthy women.

Methods: Sexual function was assessed in 157 women (aged 32-79 years) with SSc and in 49 women (aged 18-73 years) with SLE. At the same time, a sexual function questionnaire was administered to a group of 112 healthy women (aged 21-87 years).

Results: The prevalence of SSc was significantly higher in women with SSc than in women with SLE (p <0.01). The prevalence of SSc was significantly higher in women with SSc than in women with SLE (p <0.01). The prevalence of SSc was significantly higher in women with SSc than in women with SLE (p <0.01). The prevalence of SSc was significantly higher in women with SSc than in women with SLE (p <0.01).

Conclusion: The prevalence of SSc was significantly higher in women with SSc than in women with SLE (p <0.01).

Objectives: To assess and compare sexual dysfunction (SDF) in female patients with SLE or SSC, to correlate sexual function with disease characteristics and depression, and to evaluate a short questionnaire (Qualisex) as a screening test.

Methods: Female patients with systemic lupus erythematosus or systemic sclerosis in two German tertiary university hospitals were evaluated with a self-designed questionnaire on various sexual and gynaecological characteristics and depression, and to evaluate a short questionnaire (Qualisex), the 9-item questionnaire Qualisex, and the Beck’s depression inventory in a prospective study.

Results: 171 female patients were included into the study. Among them 83 suffered from SSc (mean age 48.50 years), and 88 from SLE (mean age 39.65 years). Organ involvement and immunosuppressive medication was frequent in both groups. 34.9% of SSC patients and 28.4% of SLE patients ever received cyclophosphamide. Disease duration was significantly longer in SLE patients (13.17 vs 9.85 years in SSC patients, p=0.021). No significant differences between SSC and SLE were found as to educational background, BDI depression categories, marital status, or number of children. Only 9.6% of SSC patients and 14.8% of SLE patients had ever discussed sexual problems with their physician, whereas 52% of all patients thought that these were relevant in relation to their disease. Significantly more SSC patients would wish to discuss sexuality with their physician more intensively (37.3% vs 28.4% in SLE patients, p=0.011). 79.5% of SSC patients and 79.4% of SLE patients were in a constant relationship; 62.6% (52 of 83) of SSC patients and 67.0% (59 of 88) of SLE patients were sexually active. Impeding factors like vaginal stenosis, sicca, impaired mobility of pelvis, or pain did not differ significantly between SSC and SLE. Among the 51 sexually active and evaluable SSC patients a mean FSFI of 25.53 (±5.06) was found, with a FSFI value below the cut off defining SDF (26.55) in 49% of patients, which did not differ significantly compared to SLE patients (n=59, mean FSFI 26.92 (±5.17), SDF in 45.8%). More patients who suffered from SDF had at least mild depression defined by BDI than patients without SDF (71.2% vs 46.4%, p=0.016). SSC patients showed a numerically better Qualisex than SLE patients (2.98 (±2.24) vs. 3.16 (±2.45) with 0 meaning no impairment and 10 severe impairment). The Qualisex correlated significantly with the FSFI (r=-0.367; p<0.001) with numerically better correlation in SSC patients (r=-0.407, p=0.001 vs r=-0.340, p=0.004).

Conclusion: Sexual Dysfunction (SDF) is a frequent problem in female patients with SSC and SLE. Frequency and nature are comparable between the two entities. Addressing sexual issues during medical consultation is an unmet need. The Qualisex constitutes a short questionnaire, which is suitable for SDF screening.

REFERENCES:

Capillary dimension has been evaluated in 2 studies, with no unequivocal results [3,4]. Corrado et al. found abnormal morphology to be more commonly associated with SSC-PAH [4]. No association was found between presence of haemorrhages and SSC-PAH [4]. Ricci et al. found that NVC scores were more commonly associated with SSC-PAH [5]. Concerning qualitative assessment, severe NVC patterns have been unequivocally found to be more commonly associated with SSC-PAH [4,5].

Conclusion: This is the first systematic literature review to investigate the role of NVC in SSC-PAH using standardized definitions as proposed by the EULAR SG MC/RD. Unequivocal associations with incident SSC-PAH were found in longitudinal studies between capillary density, abnormal morphology and NVC pattern. Unequivocal associations with SSC-PAH were not found in cross-sectional studies between capillary density and severe NVC pattern.

FR10346 PERFORMANCE OF THE 2017 EUROPEAN LEAGUE AGAINST RHEUMATISM/AMERICAN COLLEGE OF RHEUMATOLOGY (EULAR/ACR) CLASSIFICATION CRITERIA FOR ADULT IDIOPATHIC INFLAMMATORY MYOPATHIES IN A HONG KONG COHORT

He SQ1, Tak Lung Victor Wong1, Tommy Lam1. 1Kwong Wah Hospital, Kowloon, Hong Kong (SAR); 2Princess of Wales Hospital, New Territories, Hong Kong (SAR)

Background: The new classification criteria for idiopathic inflammatory myopathy (IIM) endorsed by the European League Against Rheumatism and American College of Rheumatology (EULAR/ACR) were published in 2017 [1]. However, the majority of the patients in the development cohort were Caucasians. External validation in other populations were advised. With the increasing availability and experience of myositis specific autoantibodies (MSAs) testing, the inclusion only anti-Jo-1 antibody is apparently insufficient.

Objectives: The objective of the study was to evaluate the performance of the 2017 EULAR/ACR classification criteria in a cohort of Hong Kong adult IIM patients. The secondary objectives included examining the level of agreement between the new criteria and the traditional criteria and assessing the effect of including other MSAs into the criteria.

Methods: This was a multi-centre retrospective cross-sectional study. Consecutive patients with a clinical diagnosis of IIMs and MSA tested seen in the rheumatology clinic and admitted to the rheumatology wards of the participating hospitals in Hong Kong up till August 2018 were recruited. Patients with juvenile onset myositis were excluded. Clinical parameters required by the two criteria will be collected by reviewing the medical records. A commercial line blot immunoassay kit (EUROMMUN) was used to detect the MSAs.

Results: Two hundred and four patients with IIM were recruited. The mean age was 59.3 years. There was a female predominance of 76.5%. The subgroups of the patients were: polymyositis 40.7%, dermatomyositis 38.2%, clinically amyopathic dermatomyositis patients 21.1%. MSAs were detected in 59.3% of the patients with anti-Jo-1 antibody being the commonest (13.2%). The new 2017 EULAR/ACR Criteria could classify 96.1% of the patients as having definite or probable IIM. The Bohan and Peter criteria could only classify 76.0% of the patients. When combining with the Sontheimer’s criteria for CADM, 93.1% of the patients could be classified. The percentage agreement of the new and the Bohan and Peter criteria also increased from 77.0% to 93.1% when the latter was supplemented with the Sontheimer’s criteria. If the presence of any MSAs is considered one of the criteria, the performance of the 2017 criteria improved to 97.5% while the combined Bohan and Peter/Sontheimer’s criteria to 96.1%. However, the new criteria still failed to highlight the important subtype of IIM associated with anti-MDA5 autoantibody.

Conclusion: In a population with a significant proportion of CADM patients, the new 2017 EULAR/ACR classification criteria outperformed the old criteria. Finally, a clinico-serological criteria for “anti-MDA5 syndrome” is proposed in which a patient must have positive serologic testing for an anti-MDA5 autoantibody, plus one of the following conditions:

myositis by the new EULAR/ACR criteria, interstitial lung disease or typical rash (skin ulceration, palmer papules).

TUBERCULOSIS IN SYSTEMIC SCLEROSIS

Thursday, 13 June 2019 703

Apichat So-Ngern, Ajanee Mahakkanukrauh, Siraphop Suwannaraj, Ratanaavadee Nanagara, Chingching Foocharoen, Scleroderma Research Group, Khon Kaen University, Department of Medicine, Khon Kaen, Thailand

Background: The tuberculin skin test (TST) is a screening tool for detection of occult or remote tuberculosis infection. Although skin lightness is a classic manifestation in systemic sclerosis (SSc), there are no reports vis-a-vis any limitation of the TST in SSc patients nor a definition on the cut-off for a positive TST test size for a diagnosis of tuberculosis.

Objectives: Our aims were to determine (a) the indurated reaction size of the TST, (b) the cut-off size for the indurated TST, and, (c) the sensitivity and specificity of the test for the diagnosis of tuberculosis in SSc patients.

Methods: A cross-sectional study was conducted among Thai adult SSc patients, followed up at the Scleroderma Clinic, Khon Kaen University, Thailand between November 1, 2016 and November 30, 2017. The TST was performed using 0.1 ml purified protein derivatives (PPD) injected intradermally (Figure 1), and interpreted 72 hours after testing.

Results: A total of 168 SSc patients were enrolled (male to female ratio = 1.8:1). The median age and duration of disease was 57.2 and 6.4 years, respectively. The majority (71.8%) was the diffuse cutaneous SSc subset. Seventeen cases (10.1%) were defined as tuberculosis infection. All of the patients had a history of BCG vaccination at birth. An indurated skin reaction size TST of 20 U/L had a high specificity for tuberculosis (99.3%; 95%CI 96.4-100) (Kappa 0.86; p=0.03). The modified Rodnan skin score (mRSS) had a significant negative correlation with the indurated skin reaction size (Rho -0.23; p=0.003). While other clinical parameters—such as BMI, SSc subset, serum albumin level, steroid or immunosuppressant use—were not correlated with the TST result (p=0.06, 0.14, 0.09, 0.23 and 0.89, respectively).

Conclusion: Indurated skin reaction size ≥ 20 mm indicated a high specificity for tuberculosis infection in SSc patients with history of BCG vaccination. The high mRSS resulted in a smaller skin reaction size when using the TST. The TST is thus less useful as a diagnostic tool for tuberculosis among SSc patients, especially among those with severe skin tightness.

Objectives: To describe the efficacy of intravenous immunoglobulin (IVIG) therapy in different organic conditions of Systemic Sclerosis (SSc).

Methods: Retrospective multicenter observational study that enrolled patients with SSc treated with IVIG. We collected epidemiological data, SSC complications, treatments and functional tests. Regarding IVIG treatment in different organic conditions of Systemic Sclerosis (SSc).

Results: 41 patients (83% women) were recruited, with a mean age of 58 ± 18 years. The age of diagnosis was 48 ± 18 years old. The diffuse cutaneous SSc was the most frequent in the sample (61%) and the mean of cycles was 10. 37% of patients had a history of use of corticosteroid therapy. When evaluating the degree of skin involvement (mRSS) patients showed a significant improvement of -2.49 ± 5.29 (-0.03) at the end of the follow-up. Indeed we observed better results in the groups of patients with myositis. No differences were observed in the% FVC or DLCO outcomes during the follow-up. However, when we compared patients with or without overlap syndrome we found differences in FVC values at the beginning of the study that were not present at the end of the follow-up. Patients with antiScIg70 seemed to have less response to IVIG therapy.

Conclusion: Our results suggest that IVIG can be useful for the management of some conditions in specific profiles of patients with SSc.

mineral content (BMC), and bone mineral density (BMD) in seven body areas (head, upper limbs, lower limbs, trunk, spine, ribs, pelvis). Sarcopenia was diagnosed in patients with reduced skeletal muscle index (RSMI) below 5.45 Kg/m² for females and 7.25 Kg/m² for males. Statistical analysis was performed by non-parametric tests.

Results: The mean age of patients was 64.11 years, mean disease duration 19.2 ± 7.6 years, mean Rodnan skin score (mRSS) 11.5±9.3, and mean RSMI 63.1±10.5 g/cm². All the patients showed a NVC “scleroderma pattern”: in particular 15 patients showed the “Late” pattern, 15 patients the “Active” pattern and 8 patients the “Early” NVC pattern. The “Late” NVC pattern group comparing to “Early/Active” group showed significantly lower total mass (5828±8217 vs 6723±11437 g, p = 0.02), lean mass (35249±3646 vs 41220±7954 g, p = 0.05), RSMI (5.8±0.92 vs 6.6±1.02 g/ cm², p = 0.02), BMC (1839±339 vs 2183±502 g, p = 0.04), trunk BMD (0.70±0.12 vs 0.87±0.13 g/cm², p = 0.05) and spine BMD (0.91±0.17 vs 1.08 ±0.18 g/cm², p = 0.008). No statically significant difference between the two group was observed regarding total fat mass, total body BMD and BMD at upper limbs, lower limbs, head, ribs and pelvis. Interestingly, 24% of SSc patients were found affected by sarcopenia, and the most of sarcopenic patients showed the “Late” NVC pattern (67%). Comparing age, disease duration, mRSS between sarcopenic and non sarcopenic patients there was no difference between the groups, but sarcopenic patients presented a statistically significant lower BM (p<0.02).

Conclusion: This study demonstrates in SSc patients a relationship between a more severe microvascular damage (“Late” SSc pattern) and the body composition, characterized by lower weight, total lean mass, bone mineral content and sarcopenia, without any significant variation in total fat mass. These clinical conditions seem not to be associated with severity of skin involvement and/or disease duration.

FRI0350
THE FREQUENCY OF LOW MINERAL DENSITY, FALLS AND FRACTURES IN PATIENTS WITH SYSTEMIC SCLEROSIS

Olga Dobrovolskaya, Nikolay Demin, Oxana Desinova, Natalia Toropsova.

Background: Systemic sclerosis (SSc) is a severe connective tissue disorder causing vascular, immune, and fibrotic changes in the skin and internal organs. Patients with SSc may have an increased risk of osteoporosis and fractures due to chronic inflammation, latent malabsorption or malnutrition, immunization, and use of corticosteroid therapy.

Objectives: to determine the frequency of low mineral density, falls, low energy fractures and 10-year probability of new fracture in patients with SSc.

Methods: 191 patients with SSc were enrolled in the study: 160 women (mean age 51±13 yrs), among them 107 postmenopausal, and 31 men (mean age 53±14 yrs). Bone mineral density (BMD) was measured at lumbar spine (LS), femoral neck (FN) and total hip (TH) by dual energy X-ray absorptiometry (DXA, Hologic 4500A). BMD decreasing grade was determined in accordance to WHO criteria. All patients were interviewed on a special questionnaire and assessment of 10-year probability of new fracture by FRAX® was performed. Vitamin D level was measured in 104 patients.

Results: Low BMD was found in 68% women and 55% men: osteopenia in 30% and 32% and OP in 36% (21% in reproductive age and 50% in postmenopausal) and 23%, respectively. BMD in LS, FN and TH associated with body mass index (r=0.3, p=0.003; r=0.41, p=0.0027; r=0.49, p=0.0002, respectively) and duration of postmenopausal period in women (r=0.56, p=0.023; r=0.66, p=0.006; r=0.63, p=0.009, respectively). BMD of LS and FN correlated with age (r=0.22, p=0.045; r=0.23, p=0.016, respectively), duration of SSc (r=0.32, p=0.037); r=0.31, p=0.046, respectively), glucocorticoid cumulative dose for LS only (r=0.31, p=0.024). Mean 25(OH)D level was 19.8±11.06 ng/ml. Normal vitamin D level had 9% of SSc patients. No correlation between BMD and 25(OH)D level was found.

46 (24%) patients reported falls in the year prior to the interview, among them in 2 patients the fall led to fracture. A total of 48 (25%) patients had low energy fractures in the past, among them 8 (4%) of women had two or more fractures. Frequency of low energy fractures was 35%, 43% and 25% among postmenopausal women, women of reproductive age and men, respectively. The mean age at which the fracture occurred was 55±11 yrs. in postmenopausal women, 30±12 yrs. in young women and 60±12 yrs. in men. The most frequent were the fractures of distal forearm and vertebrae: 13 (7%) and 26 (14%) patients, respectively. Five patients each (3%) had ankle and humerus neck fractures and 7 – other localizations. Nobody reported the fracture of the proximal femur. Patients with abnormal BMD (OP or osteoporosis) had a risk of falls and low energy fractures more than 2 times higher than patients with normal BMD (OR 2.93 [95% CI 1.11; 8.01], p=0.016 and OR 2.58 [95% CI 1.04; 6.6], p=0.025, respectively). 10-year probability of any major osteoporotic fracture was 18.4 ± 9.6% in women and 9.7 ± 8.6% in men and of hip fracture - 3.5 ± 3.7% and 1.5 ± 3.9%, respectively. Among all patients, 55% of women and 4% of men had a high risk of subsequent fractures using the FRAX® algorithm.

Conclusion: Low BMD was diagnosed in 68% of women and 55% of men with SSc. The correlations between BMD and age, body mass index, the duration and glucocorticoid cumulative dose. Reduced BMD was associated with an increased risk of falls and fractures. 55% of women and 4% of men had a high risk of subsequent fractures.

**DIFFERENCES IN ANTISYNTHETASE SYNDROME DEFINITION AND RELATED DIAGNOSTIC PERFORMANCE. A SYSTEMATIC LITERATURE REVIEW INFORMING THE NEW ACR/EULAR CLASSIFICATION CRITERIA**

Giovanni Zanframundo1, Sara Faghhi Kashani2, Lorenzo Cavagna1, Rohit Aggarwal3, Cafrumaurizio Montecucco1, Carlo Alberto Sciri4, Garafilla Sakellarious1, 1University and IRCCS Policlinico S. Matteo Foundation, Division of Rheumatology, Pavia, Italy; 2University of Pavia School of Medicine, Division of Rheumatology and Clinical Immunology, Department of Medicine, Pavia, Italy; 3University of Ferrara, Rheumatology Section, Department of Clinical Sciences, Ferrara, Italy

**Background:** Antisynthetase syndrome (ASSD) lacks of established clinic-serological classification criteria. A taskforce by EULAR and ACR is working on to develop and validate classification criteria for ASSD.

**Objectives:** To systematically upraise literature to retrieve the available definitions of ASSD and to evaluate their diagnostic performance.

**Methods:** This systematic review followed a pre-specified protocol. Two research questions (Q1: how is ASSD defined; Q2: what is the diagnostic performance of the definitions) were rephrased into PICOs terms to create search strategies. Studies on patients with suspect or confirmed ASSD, including a definition of the disease with any study design, excluding case-reports and narrative reviews, were eligible for inclusion. The diagnostic performance had to be tested against the reference standard of expert opinion. PubMed and Embase were searched from 01/01/1984 to 06/11/2018. Moreover, the ACR and EULAR congress abstracts (2017-2018) were hand searched. The titles and abstracts of the retrieved studies were screened by pairs of reviewers, the full-text of studies fulfilling the inclusion criteria was assessed to confirm eligibility. The references of the included studies were also evaluated in search of additional studies. Data from primary studies were extracted into a pre-specified extraction form and, if possible, 2x2 tables to assess diagnostic performance were completed. Sensitivities, specificities, positive and negative likelihood ratios (LR) were calculated for each study. If the diagnostic performance of a definition or variable was assessed in at least 4 studies, a meta-analysis of diagnostic performance was undertaken. The risk of bias (RoB) was assessed using the most appropriate tool depending on study design.

**Results:** After the exclusion of duplicates, the searches retrieved 4358 studies, of which 375 suitable for full-text review. Finally, 77 studies were included, along with 1 additional study from hand search and 3 congress abstracts. 72 studies were included in Q1 and 9 in both Q1 and 2. The presence of antisynthetase antibodies (70 studies), mainly anti-Jo1 (57 studies); myositis (51 studies), mainly defined clinically (32 studies); and interstitial lung disease (38 studies) were the variables most frequently used to define ASSD. Other variables, such as arthritis (19 studies), Raynaud’s phenomenon and skin manifestations (10 studies each) were evaluated less frequently. Most commonly, ASSD was defined by a combination of clinical and serological variables. However, no study evaluated the diagnostic performance of such combined definitions. Most of the studies included in Q2 (6) evaluated specific variables of muscle biopsy, one evaluated MRI and 2 clinical variables, with a wide variability in the studies included in Q2 (6) evaluated specific variables of muscle biopsy, one evaluated MRI and 2 clinical variables, with a wide variability in the performance of each item. It was possible to meta-analyze data only to assess the performance of perifascicular necrosis/atrophy: pooled sensitivity (95%CI) was 0.53 (0.33;0.72) and specificity 0.63 (0.47;0.76), pooled LR+ 1.45 (0.72;2.89) and LR- 0.73 (0.40;1.34).

**Conclusion:** ASSD is defined according to a variety of combinations of serological, clinical and histological variables. The performance of these combined definitions however has not been tested, and from the limited evidence available single muscle biopsy variable (perifascicular necrosis/atrophy) seem to perform poorly. The systematic review confirms the need of data and consensus driven classification criteria for ASSD.

**Disclosure of Interests:** Giovanni Zanframundo: None declared, Sara Faghhi Kashani: None declared, Lorenzo Cavagna: None declared, Rohit Aggarwal: None declared, Cafrumaurizio Montecucco: Speakers bureau: AbbVie, Bristol-Monsquibb, Celgene, Sanofi, Genzyme, Lilly, MSD, Pfizer, UCB, Carlo Alberto Sciri: None declared, Garafilla Sakellarious: None declared

**COMPARISON OF TWO ILOPROST REGIMENS IN TERMS OF ECONOMIC IMPACT AND EFFECTIVENESS**

Alessandra Della Rossa1, Simone Barsotti2, Marco Di Battista1, Lorenzo Puccetti1, Valentina Lorenzoni3, Giuseppe Turchetti4, Marta Mosca1, 1Azienda Ospedaliero Universitaria pisana, UO REUMATOLOGIA, Area Medica e Oncologica, Pisa, Italy; 2SSSUP, Pisa, Italy

**Background:** Systemic sclerosis (SSc) is an autoimmune chronic disease characterized by prominent vascular involvement. Intravenous iloprost (IV ILO), according to the recently updated EULAR recommendations, is indicated for SSc Raynaud’s phenomenon (RP) after failure of oral therapy. Moreover, IV ILO could be useful in DU healing and may represent a potential disease modifying medication. However, there are no uniform data regarding type of regimen (dosage, duration and frequency) and infusion modality.

**Objectives:** The purpose of this study was to compare effectiveness (in terms of Du) and direct costs, of two regimens of IV ILO infusion in the same cohort of consecutive SSc subjects.

**Methods:** Protocol A (A): the patient was admitted and 100 mcg of ILO was diluted in 500 ml of normal saline or 5% dextrose solution and infused continually at the maximum tolerated dose until exhaustion. Protocol B (B): the patient was followed as outpatient at infusion clinic and 50 mcg of ILO was diluted in 250 ml of normal saline or 5% dextrose and infused at a dose range from 0.5 to 1.5 mg/Kg/m. The dose was escalated at 30 minutes intervals and maintained at the maximum tolerated dose for 5 consecutive hours for two consecutive days. The intervals between the infusions were between 6-8 weeks in both protocols depending on clinical response and availability of places at the Unit. 44 patients who received long term IV ILO as inpatients (Cohort A), after a wash out of 3 months, were switched to ambulatory administration (Cohort B). Thereafter, after one year of follow-up 24 patients of the protocol B were lost to follow-up and 20 patients were maintained on this regimen. Comparison was made between Cohort A (44 patients=A44) in the period between March 2015 and October 2016 (period A), Cohort B (44 patients=B44) between October 2016 and March 2017 (period B44), Cohort B (20 patients=B20), between October 2017 and March 2018 (period B20). Comparison between groups was made by non parametric tests and contingency table analysis when appropriate. Costs were estimated multiplying data related to resource use (drug consumption, hospital stay, outpatient visits, management of complications, etc) by unit cost obtained from the accounting office of the Hospital. All costs were expressed in Euro.

**Results:** Mean number of DUs at the end of period A was 0.37±0.98 in A44 as compared to 0.90±1.39 of period B44 cohort B44 (p<0.045) and 0.55±0.95 of period B20 Cohort B20 (p=n.s.). Cumulative number of DUs was 9/44 in Cohort A (20.5%) as compared to 20/44 in Cohort B44 (45% p=0,002) and 7/20 in cohort B20 (35% p=0.05). High number of drop outs (24/44) in protocol B was due mainly to statistical significant difference in tolerability (adverse events 11% protocol A vs 42% protocol B p< 0,01). Direct costs were higher in protocol A (3132±883 Euros vs 2687±556 Euros) as compared to protocol B, despite the differences were not statistically significant between the two modalities.

**Conclusion:** Protocol A seems to represent a regimen better tolerated and more effective than protocol B. Moreover, protocol B is affected by high rate of drops out due mainly to worse tolerability. Admitting SSc-patients for continuous IV ILO infusion seems to represent a better tolerated and more effective choice than following them as outpatients at infusion clinic, with substantially comparable direct costs in the same SSc cohort.

Spondyloarthritis – etiology, pathogenesis and animal models

**FRI0353** MISREGULATION OF BMP/TGF SHEDS LIGHT ON THE PATHOGENICITY OF HLA-B27 IN Spondyloarthritis

Benjamin Grandon1, Auroe Rinchеваl2, Nadège Jah2,3, Jean-Marc Corsi1, Luiza M. Araújo1,2, Simon Glätzy1,2, Delphine Roche1, Gilles Chiocchia1,2, Isabelle Guénal1, Sébastien Gaumer1, Maxime Breban1,2,4,5,6, University of Versailles Saint-Quentin; INSERM, Team Chronic Inflammation and Immune System, Montigny-le-Bretonneux, France; 2UMR 1173 University of Versailles Saint-Quentin-INSERM, Team Chronic Inflammation and Immune System, Montigny-le-Bretonneux, France; 3University Paris Diderot, Sorbonne Paris Cité, INFLAMEX, Laboratoire d’Excellence, Paris, France; 4Ambroise Paré Hospital, Rheumatology, Boulogne-Billancourt, France

**Background:** The class I MHC allele, HLA-B27 is the main genetic factor predisposing to ankylosing spondylitis (AS) and related spondyloarthritis (SpA), a group of osteo-articular disorders combining inflammation with ossification. Until now, hypotheses to explain such striking association discovered 45 years have speculated either on the presentation of particular peptides to CD8+ T cells or on aberrant behaviors of the HLA-B27 molecule independent of its antigen presenting function, including slow folding and homodimers formation.

**Objectives:** To unravel aberrant function(s) of HLA-B27 independent of antigen presentation that may explain its pathogenicity.

**Methods:** Drosophila transgenic for SpA-associated HLA-B*27:04 or HLA-B*27:05 or non-SPA-associated HLA-B*07:02, alone or in combination with human β2-microglobulin (hβ2m) were produced. Genetic interaction tests were used to identify altered pathway(s). Protein-protein interactions were evidenced by proximity ligation assay. Phosphorylation of Smad2/3 was tested on CD4+ T cells from HLA-B27+ SpA patients and HLA-B27- healthy controls (6-10/group) by PhosFlow.

**Results:** Drosophila transgenic for HLA-B*27:04 or HLA-B*27:05 but not for control HLA-B*07:02 allele, in the presence of hβ2m that allows expression of well-folded HLA-B molecules at the cell surface, developed crosswitness phenotype. This was due to a disturbance of BMP signaling by HLA-B27/hβ2m which repressed Saxophone (Sax) BMP type I receptor (BMPR1) function, resulting in widening of phosphorylated Mad, the Drosophila receptor-mediated Smad, gradient, and increased expression of its target genes dpp and comb. Consistently, HLA-B27/hβ2m well-folded conformers co-localized with Sax at the surface of Drosophila cells and also with Sax mammal ortholog ALK2, on immune cells from SpA patients. As predicted, given that Sax orthologs ALK1 and ALK2 are known to exert antagonistic function on TGFβ/BMP signaling, we found heightened p-Smad in response to TGFβ or Activin A in CD4+ T cells from HLA-B27+ SpA patients (p<0.05).

**Conclusion:** The pathogenic role of HLA-B27 in SpA may result from a TGFβ|BMP signaling misregulation due to specific antagonistic interaction with ALK1/ALK2 BMPR1, at the crosstalk between inflammation and ossification. Interestingly, ALK2 mutations are responsible for the rare mendelian disorder, Fibrodysplasia Ossifians Progressiva that mimicks AS (Ref).

**FRI0354** ASSESSING THE ROLE OF TENDON-T CELL INTERACTIONS IN THE DEVELOPMENT OF CHRONICITY IN SPONDYLOARTHRITIS

Emma García-Melchor1, Giacomo Cafaro1, Lindsay AN Crowe1, Michael Motlean1,2, James H. Reilly1, Iain Mccinnes1, Moed Akbar1, Neal L. Millar1,2, Institute of Infection, Immunity and Inflammation, College of Medicine, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom; 2Department of Orthopaedic Surgery, Queen Elizabeth University Hospital Glasgow, Glasgow, United Kingdom

**Background:** Enthesitis is a hallmark of spondyloarthropathies[1], with mechanical stress or damage in the tendon being proposed as a trigger for the development of inflammation at the enthesis that propagates to the synovial compartment through what has been termed “synovio-enthesal complex[2].” Increasing evidence supports the role that stromal cells play in the shift of the inflammatory process towards chronically promoting T cell migration, retention and survival[3]. Therefore, we hypothesize that after tendon damage the crosstalk between stromal and immune compartments contributes to the development of chronic inflammation.

**Objectives:** We aimed to assess the effect of tendon stromal cells (tenocytes) on T cell migration and activation and the impact of these activated T cells on the stroma.

**Methods:** Tenocytes were explanted from tissue obtained from anterior cruciate ligament (ACL) reconstructions. The effect of damage on tenocytes and tenocytes conditioned media from tendon explants or IL-1β was evaluated by qPCR. A transwell membrane system was used to test the impact of conditioned media from tenocytes on T cell migration. T cells and tenocytes were co-cultured with or without the presence of a transwell membrane to quantify T cell activation (CD69 by FACS and IFNγ by ELISA). Changes in gene expression on tenocytes after co-culture with activated T cells were analysed by qPCR.

**Results:** In the presence of damage, tenocytes upregulated inflammatory mediators (IL-6, COX2), chemokines (CCL2, CCL5, CXCL10, CXCL12) and adhesion molecules (ICAM-1). Conditioned media, particularly after stimulation with IL-1β, from tenocytes induced T cell migration. Co-cultures of tenocytes and T cells resulted in activation of T cells that was contact dependant. In turn, these activated T cells upregulated the production of inflammatory mediators in tenocytes and increased the COL3/COL1 ratio.

**Conclusion:** Our results support a communication between the stromal and immune compartment within the tendon that could be involved in the progression towards chronicity in the context of spondyloarthritis. Following damage, tendon stromal cells are able to induce the recruitment of T cells, that once enter the tissue interact with the stroma. Stromal cells are then further activated to produce inflammatory cytokines and chemokines that amplify and maintain this inflammatory response.

**DOI:** 10.1136/annrheumdis-2019-eular6970
MUCOSAL ASSOCIATED INVARIANT T-CELLS ARE DRUG-INDUCED REMISSION AND SUBCLINICAL DIFFERENTIAL EXPRESSION OF HUMAN GERMLINE. A growing body of research has associated the differential expression in inherited remnants of ancient retroviruses that infected the ancestral lineage, including HERV-K and IL-17A. MAIT cells are enriched at mucosal surfaces and have been implicated in the pathogenesis of spondyloarthropathies (SpA) (1) and inflammatory bowel disease (IBD). Although the human enthesis is not a mucosal surface it is the primary site of inflammation in SpA which has strong association with IBD.

Objectives: To investigate if a population of MAITs is present at the normal human enthesis thereby establishing a potential link between gut and joint inflammation.

Methods: Healthy interosseous ligament and spinoous process were harvested from patients undergoing elective surgery for correction of mechanical spinal defects. Enthesal soft tissue (EST) and peri-entheseal bone (PEB) were separated and cells were harvested by enzymatic and mechanical digestion respectively. The proportion of cells expressing HERV-K, CXCL10, CCR6 and IL-23R transcript were measured by flow cytometry in EST, PEB and matched blood. Expression of CD69 and CD45RA were examined for phenotypic analysis. Transcript analysis for IL-23/IL-17 axis and immunomodulatory genes was performed on sorted entheseal MAITs and analysed by TaqMan array.

Results: As a proportion of total T-cells, MAITs were of approximately 3 fold and 2.5 fold greater abundance in EST and PEB respectively in comparison to matched peripheral blood (both p<0.034). MAITs in entheseal tissue had an overlapping resident memory phenotype (CD45RA+CD69+CD45RO+/CD69-CD45RA-) median 4.3% (range 2.4 – 7.8%) in EST and 5.9% (4.5 - 8.2%) in PEB compared to those from blood 17.7 (6.8 – 69.4%). MAITs robustly expressed RORC, CCR6 and IL-23R transcript. Compared to conventional entheseal T-cells, MAITs expressed significantly less TGF-β (6-fold, p>0.001) and significantly more IL-23R (29-fold, p=0.004).

Conclusion: Healthy human enthesal tissue contains an enriched population of MAITs that strongly express IL-23R transcript at a frequency comparable to that reported in the colon (2). The majority of these cells express a resident memory phenotype suggesting that they are a distinct population residing in enthesial tissue. These observations are potentially relevant to SpA pathogenesis and the observed link between SpA and IBD.

DIFFERENTIAL EXPRESSION OF HUMAN ENDOGENOUS RETROVIRUSES IN PSORIATIC DISEASE

Remy Pollock1, Rohan Machhar1, Laila Zaman1, Dalna D Gladman1, 2, Vinod Chandran1, 2, 3, 4, 5, 6, 7, 8, 9, 10

Krembil Research Institute; University Health Network, Psoriatic Disease Research Program, Toronto, Canada; 2Faculty of Medicine, University of Toronto, Division of Rheumatology, Toronto, Canada; 3University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada; 4Memorial University, Faculty of Medicine, St. John’s, Canada

Background: Human endogenous retroviruses (HERV) are the stably inherited remnants of ancient retroviruses that infected the ancestral genome. A growing body of research has associated the differential expression and regulation of HERVs with a number of diseases, including systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). HERVs are thought to contribute to the pathogenesis of autoimmune diseases by modulating the expression of host immune-related genes, molecular mimicry, or cross reactivity of host proteins with HERV encoded products.

Objectives: To compare the expression of 4 HERVs previously associated with autoimmune disorders (HERV-K, HERV-K10, HERV-W, and HERV-H) in whole blood, CD3+ T cells, and CD14+ monocytes of patients with cutaneous psoriasis without arthritis (PsC), psoriatic arthritis (PsA), and healthy controls.

Methods: PsC, PsA patients satisfying the CASPARI criteria, and healthy controls were recruited for the study. RNA was extracted from whole blood collected in Tempus tubes and HERV expression was measured by quantitative real time PCR (qRT-PCR) or droplet digital (dd)PCR with normalization to GAPDH. HERV expression in whole blood RNA from 40 PsA patients was compared to 40 age and sex matched PsC patients and 40 age and sex matched healthy controls. Subsequently, HERV expression in 55 PsC patients who progressed to develop PsA (converters) was compared to 55 age and sex matched PsC patients who did not develop PsA over the same duration of follow-up (non-converters).

Results: In whole blood, HERV-K was significantly differentially expressed between 40 PsA and 40 PsC patients (fold change [FC]=1.57, p<0.008). HERV-K was also significantly differentially expressed in baseline samples from 55 converters compared to 55 non-converters (FC=1.93, p<0.003). No other HERV genes were differentially expressed between these groups in whole blood. Significant expression differences were more evident in purified cells (Table 1).

Table 1. Differential expression of HERV's in purified T cells and monocytes.

Conclusion: In whole blood, expression of HERV-K differentiates PsA and PsC patients, and its expression is significantly elevated in PsC patients prior to the development of PsA. HERV expression differences between the groups are also evident in purified T cells and monocytes. These data suggest a role for HERV-K in the pathogenesis of psoriatic disease and their potential use as prognostic markers of arthritis in patients with psoriasis.

ENDOGENOUS RETROVIRUSES IN PSORIATIC DISEASE

Maria Maddalena Angioni, Enrico Mascia, Daniela Perra, Silvia Pimpaniga, Ignazio Cangemi, Piero Massa, Mattia Conga, Alberto Floris, Matteo Piga, Alessandro Matheiu, Alberto Cau. Università degli Studi ed AOU di Cagliari, Dip.to Scienze Mediche e Sanita’ Pubblica, Unità di Reumatologia, Monserrato (Cagliari), Italy

Background: Remission is an important goal of therapy in psoriatic arthri-

tis (PsA), but data on molecular players of clinical remission and effective
disease inactivation are scarce. Gene expression profiling analysis could be useful to elucidate the pathogenic mechanisms of diseases, and different gene expression analysis between diverse disease conditions produces gene signatures characteristic of the state or disease being studied. 

Objectives: Our aim was to compare the transcriptional profiles of patients with clinically active versus inactive remission state) PsA (peripheral joint subset), and healthy controls (HCs).

Methods: From a cohort of around 300 patients affected by PsA according to CASPAr criteria, we first selected 20 patients (peripheral arthritis subset) with active disease state (without biologic treatment ongoing) A) and 20 patients with >1-year remission induced by TNFα antagonism (R), as assessed by DAPSA > 14, and DAPSA ≤ 4 scores respectively, and from 20 HCs matching for age and gender ratio. Both PsA groups were not on corticosteroid treatment. RNA from peripheral blood was extracted and, following quality analysis by Agilent Bioanalyzer, each condition has been profiled using RNAs pools in biological duplicates by distinct Affymetrix Human GeneChip HTA 2.0, for a total of 6 arrays. Data analysis was performed using the commercial software Partek Genomics Suite, V 6.6. To identify a transcript as differentially expressed, a value of fold change 1.5 and p-value 0.05 has been set.

Results: The Venn diagram shows all comparative groups (A vs R, A vs HC, R vs HC) with their relative amount of transcripts differentially expressed, generated using abovementioned parameters, and the relationship between sets (fig1, panel A). Using the list of transcripts differentially expressed in at least one of the aforementioned comparison, a hierarchical clustering was carried out to highlight the intra-condition expression profile. We have identified (arbitrarily) 4 clusters of transcripts with analogous transcriptional profile and to each of them a color code has been assigned (Heatmap in Fig1, panel B). For these clusters and for all lists of transcripts differentially expressed founded by our comparative study, we carried out the Gene Set Enrichment Analysis by Gene Ontology (GO), in order to identify how molecular functions, cellular components or biological processes occurs more frequently than expected in a reference list of transcripts.

Conclusion: Observing the amount of differentially expressed transcripts, it is evident that while active disease state (A) has a clear-cut different profile, the drug-induced remission (R) is more similar with HCs condition. However, in the hierarchical clustering this trend of similarity does not appear in all clusters of transcripts, as shown particularly in the red, orange and green clusters. Again, the Gene Set Enrichment Analysis Score showed us that mRNA transcripts dysregulated in the R condition vs HCs, are involved in several biological processes related to immune system, development, response to stimulus, localization and others. Our next step will be to validate, by Real Time PCR in a large cohort of patients, the most interesting dysregulated genes covering biological functions eventually sustaining subclinical activity in PsA.

Disclosure of Interests: None declared

ROLE OF MiRNA-21-5PAS A POTENTIAL BIOMARKER FOR THE INFLAMMATION PATHWAY IN PSORIATIC DISEASE AND RESPONSE TO METHOTREXATE TREATMENT

Rohan Machhar1, Remy Pollock1, Justine Ye2, Vinod Chandran2,3,4, Dafna D. Gladian2,3,4, Krembil Research Institute, University Health Network, Psoriatic Arthritis Program, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto, Canada; 1Faculty of Medicine, University of Toronto, Division of Rheumatology, Toronto, Canada; 2University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada; 3Memorial University of Newfoundland, Faculty of Medicine, Newfoundland, Canada

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis occurring in patients with psoriasis. Several studies have shown links between altered miRNA expression with the pathogenesis of several autoimmune disorders. We previously demonstrated that miR-21-5p was upregulated in PsA compared to psoriasis without arthritis (PsC) and healthy controls (HC) and is thus a potential biomarker for PsA.

Objectives: 1) To determine whether miR-21-5p is differentially expressed in PsC patients who convert to PsA vs non-converters and validate the previous results in an independent cohort. 2) To determine the role of miR-215p in the response to methotrexate treatment (MTX) 3) To determine whether miR-21-5p modulates inflammation in psoriatic disease.

Methods: Serum & whole blood RNA samples were collected from 54 converters and 54 non-converters (matched for age, sex, psoriasis duration), 40 patients with early PsA (>2 years’ disease duration and not receiving biological therapy), 40 patients with PsC (>10 years disease duration, not receiving biologic therapy, and matched to PsA patients on age, sex, psoriasis duration, and age of psoriasis onset), and 40 HCs (matched to patients based on age, sex). RNA was extracted using the Tempus Spin RNA Isolation Kit. miR-21-5p was validated using droplet digital PCR (ddPCR). Serum IL-17, CXCL10, IL-23, TGFB1 were measured by commercially available ELISA kits. Mann- Whitney test, Wilcoxon signed rank test and Spearman correlations were performed.

Results: The expression of miR-21-5p was significantly higher in converters compared to non-convertors (Fold change(FC)=2.16, p=0.002). miR-21-5p was upregulated in PsA compared to PsC (FC=3.22, p=0.001) and HC (FC=15.7, p=0.0001) in the validation cohort. miR-21-5p was significantly down regulated 24 weeks post-MTX treatment in 30 PsA patients (FC=-1.9, p=0.008), which correlated with swollen (r=-0.49, p=0.003) and tender joint counts (r=-0.41, p=0.02) supporting a possible role in inflammation pathway in PsA patients. IL-17 levels in PsA & PsC were significantly higher from HC (p<0.03), but not different between PsA & PsC.

Conclusions: our results suggests a role of miR-21-5p as a potential biomarker for PsA. In the presence of upregulated miR-21-5p, IL-17 and IL-23 are upregulated while TGFB1 is down regulated. When miR-21-5p is decreased IL-17 and IL-23 downregulated, with up regulation of TGFB1. We have thus determined the role of miR21-5p as a potential biomarker for inflammation pathway in psoriatic disease and response to MTX possibly through modulation of CXCL10 and IL-17/IL-23 axis.

344
ANALYSIS OF BLOOD MONOCYTE TRANSCRIPTOMES INNATE VERSUS ADAPTIVE IL-17A PRODUCING CELLS

into blood. Bone marrow analysis shows a left shifted granulopoiesis in late myelopoiesis and G-CSF triggered mobilisation from bone marrow. These transcripts suggested alterations in mitochondrial activity, peptide binding, and TLRs.

Conclusion: AxSpA monocyte transcriptomes reflect weak immune activation vs. CO facet joints (p<0.01). Of MPO+ cells indicative of left shifted granulopoiesis was found in AS patients and controls regarding gene expression profile of neutrophils, CD8+ T cells and 2 adaptive cell populations (CD4+ T and CD8+ T) after cell stimulation by PMA + A23187 (calcium ionophore) and CD8+T after cell stimulation by PMA + A23187 (calcium ionophore). Published literature suggests the involvement of MAIT, γδ T, and neutrophils as IL-17A producing cells in AxSpA (1–3). However, even though they may be responsible for IL-17A-mediated inflammation, it is still unclear which is the major IL-17A-producing cell population in this disease.

Objectives: To assess and compare gene expression profiles of neutrophils, MAIT, γδ, CD4+ and CD8+ T cells from AxSpA patients.

Methods: We recruited 5 healthy donors and 10 patients with a diagnosis of AxSpA according to the ASAS criteria. We compared the gene expression profiles of 5 sorted cell populations: 3 innate cell populations (neutrophils, MAIT and γδ T cells) and 2 adaptive cell populations (CD4+T and CD8+T) after cell stimulation by PMA + A23187 (calcium ionophore) + β1,3 glucan (extracted from Aspergillus fumigatus hyphae). Published data suggested that neutrophils stimulation by Aspergillus fumigatus induces IL-17A production by these cells(4). For each of these cell populations, cytokine production and the expression of a panel of 755 genes (Autoimmune discovery panel from Nanostring including 43 genes for T cells) and 2 adaptive cell populations (CD4+T and CD8+T) were compared by a multigroup comparison. Results: There was no significant difference between patients and controls regarding gene expression profile of neutrophils, γδ T, CD4+T and CD8+T. We observed that 34 genes were differentially expressed between patients and controls in MAIT cells (p = 0.03, q = 0.1). In particular, T cell activation genes (TBX21, AHR, ZAP70) and cell interaction genes (ITGAV6, CNTNWB1, ICAM2, ITGB2, SEL1) were decreased in patients. Among AxSpA patients, MAIT cells were those significantly showing the highest level of IL-17A expression. IL23R and RORC were also more expressed by MAIT compared to others cell populations. IL-17A expression was very low in neutrophils but we observed that 18 out of the 43 AS associated genes were mainly expressed by neutrophils (p
<0.05, q = 0.02), supporting the idea that they should be involved in the pathophysiology of the disease.

Conclusion: These preliminary data confirm that the innate immune cells do not appear to participate in the production of IL-17A, but the high expression of AS linked genes in these cells suggests their involvement in AxSpA.

FR10363 AUTOANTIBODIES TO THREE NOVEL PEPTIDES IN EARLY AXIAL SPONDYLOARTHROPATHY IN TWO INDEPENDENT COHORTS

Dana Quaden1, Patrick Vandermael2, Piet Geusemans2,3, Johan Vanhoof4, Kurt de Vlam1,5, Yvette Somers1, Pieter Van den Berg1, Medical Center, Department of Development and Regeneration, Leuven, Belgium

Background: Diagnosis of axial spondyloarthritis (axSpA) is challenging since clinical manifestations, such as inflammatory back pain, peripheral arthritis, enthesitis and inflammatory bowel disease, often overlap with other disorders. Current laboratory markers for axSpA, Human Leukocyte Antigen (HLA)-B27 and C-reactive protein (CRP) are not sufficiently specific for diagnosis. Despite being considered a “seronegative” disease, emerging evidence supports the involvement of antibodies in axSpA.

Antigen (HLA)-B27 and C-reactive protein (CRP) are not sufficiently specific for diagnosis. Despite being considered a “seronegative” disease, emerging evidence supports the involvement of antibodies in axSpA. Therefore, we investigated the potential of autoantibodies in axSpA patients to establish a novel classification tool for diagnosis.

Methods: Using enzyme-linked immunosorbent assays (ELISA), presence of antibodies to the 9 novel UH axSpA peptides in axSpA patients and controls from 2 independent cohorts.

Results: Antibody reactivity against at least one of 9 novel UH axSpA peptides was found in 54% (41/76) of early axSpA patients, 26% (24/94) of LBP, 60 early rheumatoid arthritis patients (RA) and 94 healthy controls (HC).

Conclusion: Antibodies to 3 UH axSpA peptides were significantly more prevalent in early axSpA patients compared to controls. The latter group showed a specificity of 95% and a positive likelihood ratio of 2.7, which is the same as for the currently used laboratory marker CRP. Assuming a 5% pretest probability of axSpA, the LR+ for confirming axSpA using antibodies to these 3 UH axSpA peptides was 2.7, which is the same as for the currently used laboratory marker CRP. Assuming a 5% pretest probability of axSpA, the LR+ for confirming axSpA using antibodies to these 3 UH axSpA peptides was 2.7, which is the same as for the currently used laboratory marker CRP. Assuming a 5% pretest probability of axSpA, the LR+ for confirming axSpA using antibodies to these 3 UH axSpA peptides was 2.7, which is the same as for the currently used laboratory marker CRP.

FRI0364 T REGULATORY CELLS AS BIOMARKER OF DISEASE ACTIVITY AND RESPONSE IN PSORIATIC ARTHRITIS PATIENTS: RESULTS FROM APREMILAST-TREATED COHORT

Fulvia Ceccarelli1, Ilenia Pacella2, Arianna Forniti2, Francesca Spinelli1, Enrica Cipriano2, Carlo Periconi2, Simona Truglia1, Francesca Miranda1, Rossana Scivo2, Cristiano Alessandri2, Vincenzo Bambasè2, Guido Valesini1, Silvia Piconese3, Fabrizio Cordi1,1 Sapienza Università di Roma, Sapienza Arthritis Center, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Roma, Italy; 2Sapienza Università di Roma, Cellular and Molecular Immunology Unit, Dipartimento di Medicina Interna e Specialità Mediche, Roma, Italy

Background: The PDE4-inhibitor apremilast has been recently introduced in the treatment of Psoriatic Arthritis (PsA). It acts by down-regulating intracellular inflammatory mediators synthesis by elevating cAMP levels. Tregs, a subset of FOXP3+ CD4 T cells, play a key role in preventing immune responses and could exert their suppressive function via cAMP (1). Reduced frequencies of circulating Tregs have been observed in inflammatory disorders, nonetheless very few data are available on PsA patients.

Objectives: We evaluated peripheral Tregs in a cohort of PsA patients treated by apremilast.

Methods: Seventeen PsA patients (M/F 3/14; median age 56.0 years, IQR 20.0; median disease duration 15.0 years, IQR 11.0) with polyarticular PsA were enrolled, without active inflammation. Tregs were assessed at baseline in comparison with non-responder patients (median 4.8, IQR 1.2 versus median 2.9, IQR 1.1; P=0.02).

Conclusion: The results of our study demonstrate that%Treg is a marker of disease activity in PsA patients. Moreover, the baseline value of Tregs could predict the response to apremilast after 12 weeks of treatment.

FRI0365 PDE4 TARGETING SELECTIVELY INHIBITS INFLAMMATORY-DRIVEN OSTEOCLASTOGENESIS

Yannick Debboet1,2, Iain Mohnes1, Carl Goodyear1. 1Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2CHU de Toulouse – Université Toulouse III, Centre de Rhumatologie, Toulouse, France

Background: Patients suffering from Psoriatic arthritis (PsA) commonly develop bone erosions and inflammatory-induced bone loss. This process is mediated by osteoclasts derived from monocyctic precursors, and modulated by inflammatory cytokines (i.e. TNF, IL-1, IL-6, IL-17, IL-10 and GM-CSF) from immune and stromal cells. In immune cells (including CD14+ osteoclast pre-cursors), PDE4, an enzyme responsible for hydrolysing cyclic AMP to inactive AMP, drives inflammatory effects [1]. Importantly, Apremilast (APR, a selective PDE4 inhibitor) has known efficacy in PsA [2], and decreases pro-inflammatory mediators whilst increasing anti-inflammatory mediators (IL-10) [3]. Although published data indirectly suggest a positive impact of APR on bone in PsA, data is lacking with regards to the impact on bone disease activity in PsA patients.

Objectives: To evaluate the impact of a selective inhibition of PDE4 by APR on osteoclastogenesis from human CD14+ precursors.

Methods: Osteoclasts were differentiated from primary human CD14+ blood monocytes (healthy controls) with RANKL and MCSF, in the presence or absence of APR. To specifically study the impact of APR on osteoclastogenesis in an inflammatory context, osteoclastogenesis was also undertaken in the presence of: (i) TNF, (ii) Supernatants from activated Peripheral Blood Mononuclear Cells (PBMC) or activated CD3+ T cells, treated with or without APR, (iii) Co-culture with activated PBMC or activated CD3+ T cells, treated with or without APR, APR+ multinucleated cells (mature osteoclasts) were enumerated via microscopy.

Results: In a non-inflammatory context, PDE4 inhibition by APR did not affect the differentiation of CD14+ precursors into mature osteoclasts. However, TNF-enhanced osteoclastogenesis was significantly decreased by APR (>-30.0% +/- 14.9; p=0.0279). The treatment of either activated PBMCs or purified CD3+ T cells with APR substantially reduced cellular activation. In PBMCs this decrease in cellular activation resulted in a decrease in conditioned media-driven osteoclastogenesis (-49.7% +/- 13.2; p=0.0385). In comparison, APR treatment of purified CD3+ T cells did not reduce their osteoclastogenenic potential.

Conclusion: The results of this study reveal that PDE4 targeting potently inhibits inflammatory-driven osteoclastogenesis. Moreover, these data also suggest that CD3+ T cells are not the main target of PDE4 inhibition in this context. In summation, our study supports the hypothesis that APR can modulate bone integrity in inflammatory condition such as PsA.

Disclosure of Interests: YD received a fellowship from the Société Française de Rhumatologie

Yannick Debboet: Grant/research support from: Celgene PARTNER Fellowship, Iain Mohnes: Grant/research support from: AstraZeneca, Celgene, Comupgen, Novartis, Roche, UCB Pharma, Consultant for: AbbVie, Celgene, Galvani, Lilly, Novartis, Pfizer, UCB Pharma,
Background: The hallmark of advanced axial spondyloarthropathy (SpA) is spine ankylosis, due to an excess of bone formation. Our hypothesis was that pathways of bone formation regulators changed over time and that their changes were related to inflammation or use of “anti-inflammatory” drugs (like non-steroidal anti-inflammatory drugs (NSAIDs) and/or Tumor Necrosis Factor inhibitors (TNFi)).

Objectives: This prospective study aimed to describe the 5-year serum changes of bone formation regulators markers (sclerostin, bone morphogenic protein 7 (BMP-7) and Dickkopf-1 (DKK-1)) in early axial SpA.

Methods: The DESIR cohort is a prospective, multicentre French study of 708 patients (34 ± 9 years, 58% HLA B27 positive, BASDAI 45 ± 20) with early (> 3 months and < 3 years) inflammatory back pain suggestive of axial SpA. Sclerostin, BMP-7 and DKK-1 serum levels were assessed at baseline, two and five years. Change in bone formation regulators over time was analysed using mixed linear models, first in complete-cases and then in available-cases analysis. Determinants of serum biomarkers change were analysed using mixed linear models and we searched for an interaction between time and determinants of serum biomarkers.

Results: Serum levels of each biomarkers at baseline, two and five years are reported in Table 1. Serum BMP-7 significantly increased over time, with a mean of 0.17 pg/mL per month (Figure 1A). Median relative change of BMP-7 at five years was 53.0% (IQR -31.6%, 286.8%). Serum BMP-7 levels was undetectable in 337 patients (59.6%) at baseline, in 111 patients (48.0%) at two years and in 59 patients (20.2%) at five years. At baseline, serum sclerostin was significantly correlated with age (r = 0.28, p < 0.001), weight (kg) (r = 0.10, p = 0.007), CRP level (mg/mL) (rS = -0.14, p < 0.001), mSASSS (r = 0.08, p = 0.03), number of syndesmophytes (r = 0.15, p < 0.001), bone mineral density in hip and lumbar spine (r = 0.19, p = 0.001 and r = 0.18, p = 0.001 respectively).

Conclusion: Serum BMP-7 levels significantly increased over time with a rapid and substantial change. Serum sclerostin levels significantly increased over time decrease with the duration of TNFi use (-0.04 per month of TNFi use, p < 0.001). Unlike in serum BMP-7, serum sclerostin significantly increased over time, with a mean of 0.001 ng/mL per month (Figure 1B). Median relative change of sclerostin at five years was 14.8% [7.9%, 41.4%]. Serum DKK-1 did not significantly vary over time. In multivariate analysis, serum BMP-7 increased with moderate or high disease activity (ASDAS-CRP) (0.19 pg/mL per month, p = 0.01), in men (5.3 pg/mL, p = 0.004) and decreased with the duration of TNFi use (-0.04 per month of TNFi use, p < 0.001). Unlike in serum BMP-7, there was not a significant interaction between time and determinants of serum sclerostin. In multivariate analysis, serum sclerostin increased with time (0.001 ng/mL per month, p < 0.001), age (0.007 ng/mL per year, p < 0.001) and in men (0.05 ng/mL, p = 0.001) but decreased with the use of TNFi (-0.037 ng/mL, p < 0.001), in patients with a Z score ≤-2 at least one site (-0.036 ng/mL, p = 0.005) and with serum BMP-7 levels (<0.0006 ng/mL per unit of serum BMP-7, p = 0.03).
contain significantly more IgD^+CD95^- germinal center B cells (P < 0.01) with a higher expression of the costimulatory molecules CD80 and CD86 compared to WT. The vertebral also contained more CXCXR5/PD-1^+/FoxP3^+/CTLA4^+ T regulatory cells and a trend towards an increase in CXCXR5/PD-1^+/FoxP3^+/CTLA4^+ T follicular helper cells in tmtNFg tg mice. Meanwhile, B cell development in the BM of tmtNFg tg hind limbs was not altered. Furthermore, BM, spleen and vertebrae from tmtNFg tg mice contained significantly more IgA^+ plasma cells compared to WT littermates. Of note, tmtNFg tgFoxP3^+/- mice did not display lymphoid aggregates or HEVs in the BM, while tmtNFg tgFoxP3^+/- mice did, although to a lesser extent than tmtNFg tg mice.

Conclusion: tmtNFg overexpression in mice results in extensive lymphoid aggregates in the BM that are often organized in ELs, which may be mediated via TNF-RI signaling. These ELs might result in an increase of IgA^+ plasma cells in tmtNFg tg mice. Ongoing studies will look further into this and may indicate whether these findings contribute to the pathology observed in these mice.

**FRI0368**

**VASCULAR CALCIFICATION BY INFLAMMATION COULD BE AN IMPORTANT CAUSE OF CARDIOVASCULAR DISEASE IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

Seung Yun Lee1, Seong-Ryul Kwon1, Su-Ah Yoon1, Kyong-Hee Jung1, Won Park1, Shin-Goo Park2, Je-Min Lim2, Inha University Hospital, Division of Rheumatology, Department of Internal Medicine, Incheon, Korea, Rep. of (South Korea); 2Inha University Hospital, Division of Occupational and Environmental Medicine, Incheon, Korea, Rep. of (South Korea)

Background: Patients with ankylosing spondylitis (AS) have a higher risk of cardiovascular disease. Atherosclerosis is a main pathological process of cardiovascular disease and calcified plaque is a characteristic feature of atherosclerosis. Inflammation plays a potential role in vascular calcification. There is no previous study revealing the mechanism of vascular calcification in AS.

Objectives: We investigated the relationship between vascular calcification and inflammation in patients with AS.

Methods: Sixteen male patients aged over 20 years with AS were enrolled. They fulfilled the modified New York criteria and each of their ankylosing spondylitis disease activity score was more than 2.1. Sex and age matched non-healthy controls were also recruited. Mouse MOVAS (American Type Culture Collection, ATCC®, CRL-2797TM) vascular smooth muscle cells were stabilized in maintenance medium for 24 hours. Then the amount of serum equivalent to 10% of maintenance medium from subjects was added and cells were stimulated for another 72 hours. We exchanged this medium with calcification medium every third day and cells were cultured for another 11 days. After 2 weeks, cells were stained with Alizarin Red S and the optical density (OD) was measured while being compensated by cell viability. For Western blotting, cells were stabilized for 24 hours and stimulated for another 72 hours through the same procedure as that of Alizarin Red S staining. Then we measured the level of protein expression in PPAR-gamma, beta-catenin, TNF-a, interleukin (IL)-23, and MMP7.

Results: The level of OD of MOVAS cells treated with serum from AS patients (19.503 ± 6.422, mean ± SD) was significantly higher than that from controls (12.724 ± 5.746) (P = 0.027, Mann-Whitney test). The level of MMP7 expression of MOVAS cells treated with serum from AS patients (1.921 ± 0.702) was significantly higher than that from controls (0.779 ± 0.191) (P = 0.000, Mann-Whitney test). The level of beta-catenin expression of MOVAS cells treated with serum from AS patients (1.292 ± 0.356) was significantly higher than that from controls (0.887 ± 0.310) (P = 0.005). There was negative correlation between PPAR-gamma and TNF-a (rho = -0.762, p = 0.028, Spearman rank correlation coefficient), and between PPAR-gamma and IL-23 (rho = -0.601, p = 0.039); positive correlation between MMP7 and TNF-a (rho = 0.833, p = 0.010), and between MMP7 and IL-23 (rho = 0.797, p = 0.002).

Conclusion: Serum from AS patients showed increased calcification of vascular smooth muscle cells than serum from controls. The level of vascular calcification marker from vascular smooth muscle cells treated with serum from AS patients was significantly higher than that from controls. There were negative relationship between inflammatory markers and inhibitor marker of vascular calcification but positive relationship between inflammatory markers and stimulatory marker of vascular calcification.

These findings suggest that vascular calcification by inflammation could be an important cause of cardiovascular disease in AS patients.

**TOWARDS MORE PRECISE ESTIMATES OF THE FAMILIAL AGGREGATION AND HERITABILITY OF ANKYLOSING SPONDYLITIS – A SWEDISH NESTED CASE-CONTROL STUDY**

Malinka Moris; Karin Hellgren, Thomas Frisell. Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine, Stockholm, Sweden

Background: Ankylosing spondylitis (AS) is known to have strong familial aggregation, but studies quantifying the familial risk are few and have reached varying results. Familial risks reported from population-based studies range from 17 to 94 in first-degree relatives of AS cases.1 2 The heritability (i.e., the proportion of variance in AS liability explained by genetic variation) has been reported to >90%, based on very small studies of twins.3

Objectives: To assess the familial aggregation and heritability of AS among all Swedish AS patients, and to investigate if risks vary by type of first-degree relative or sex.

Methods: We identified all patients with an ICD-10 code of AS in the Swedish National Patient Register (NPR) between 1 January 2001 and 31 December 2016. To increase validity, index patients were required to have two or more visits listing an AS diagnosis, and at least one of the visits being to a specialist in rheumatology or internal medicine. Each index patient was matched on sex and birth year to 50 general population controls from the Total Population Register. First-degree relatives of index patients and controls were identified through the Multi-generation register. Their disease status was ascertained from the NPR in a similar manner as for index patients. Familial risks of AS among first-degree relatives were calculated as odds ratios (ORs) with conditional logistic regression. Based on the familial risks, the corresponding heritability was calculated for a range of plausible prevalence estimates.

Results: We identified 13,795 patients that met the inclusion criteria. Of their siblings, parents, and children, 3.6, 2.3, and 2.1%, respectively also had AS. The overall familial OR when having one affected relative was 19.4 (95% CI 18.1-20.8). The estimates were similar for relatives of different kinds (see table), but having more than one affected relative resulted in a higher risk (OR 68.0 (95% CI 51.3-90.1)). Heritability, estimated from sibling risk, was 77%. There were no clear-cut differences between the sexes, but women tended to have an elevated familial risk if the affected relative was female, and slightly lower heritability compared to males. These estimates can be considered as an upper limit of heritability, as shared environmental factors have not been taken into account in calculations.

Conclusion: Familial risks of AS were similar between different types of first-degree relatives, and no significant gender difference was seen on the heritability scale. Although high compared to most other diseases, the familial risks and heritability were lower than previous reports from other countries, though in line with earlier Swedish findings using in part the same data source. The heritability proposed here might still be an over-estimate of the true influence of genetics on disease risk. Thus, efforts should also be directed at identifying other risk factors for AS that are not of genetic origin.

REFERENCES:
**Background:** With our increasing understanding of cross-talk between the immune system (immune cells, cytokines) and extracellular matrix (ECM) of the affected tissues, ECM destruction and turnover has gained a lot of attention in inflammatory arthritis. ECM mainly consists of interstitial matrix (rich in type I and III collagens) and basement membrane (mainly composed of type IV collagen), both of which are affected in inflammatory arthritis. We hypothesize that inflammatory milieu in Psoriatic Arthritis (PsA) leads to accelerated ECM destruction and remodeling, and the release of ECM metabolites into circulation, that can be measured in serum as biomarkers of tissue remodeling and may give insight to pathologic processes at the tissue level.

**Objectives:** This prospective study aimed to use serological biomarkers for evaluation of the extent of damage to, and changes in turnover of ECM in patients with PsA and to investigate their relation to inflammatory biomarkers and disease activity.

**Methods:** Patients with PsA (n=145) fulfilling the CASPAR criteria and above 18 years of age with any disease activity were recruited through outpatient department in Aalborg University Hospital, Denmark. Exclusion criteria were pregnancy, treatment with biological DMARD, or with oral corticosteroids and other comorbidities. Clinical disease parameters were recorded, and blood samples were collected at baseline and 24 weeks follow-up. Inflammation-related ECM remodeling was measured by serological biomarkers of type I, III and IV collagen formation (Pro-C1, Pro-C3 and Pro-C4, respectively) and MMP-mediated degradation (C1M, C3M and C4M respectively). The chronic inflammation was measured by CRP (MMP degraded metabolite of CRP). All biomarkers were measured by competitive ELISAs and levels were compared to the reference levels of healthy individuals. The biomarker data was log2 transformed for normalization and standard parametric statistical methods were applied.

**Results:** We found that there was an increase in the degradation of interstitial matrix (represented by C1M and C3M) which was uncompensated with either decreased (Pro-C1) or unaltered (Pro-C4) formation in patients with PsA as compared to healthy individuals. On the contrary, there was a compensated increase in basement membrane remodeling in patients with PsA as represented by increase in both C4M and Pro-C4 in comparison to healthy individuals (Table 1). Interestingly, there was a strong correlation between baseline C4M and Pro-C4 (r=0.703, p<0.0001), and 24-week changes in both biomarkers (r=0.468, p<0.0001) pointing towards coupling between the two processes which was either lost or was weak in cases of interstitial collagens. As baseline values and changes in C1M, C3M, C4M and Pro-C4 showed a strong correlation with changes in inflammatory biomarkers, we believe that ECM remodeling in PsA is, at least partly, driven by inflammation. Furthermore, baseline values and changes in these ECM turnover biomarkers correlated positively with changes in composite disease activity scores (Table 2) that may indicate their clinical importance as potential diagnostic or disease activity markers.

**Conclusion:** Chronic inflammation underlying PsA pathology results in an increased amount of ECM turnover that correlates with clinical progression and can be measured by serological biomarkers.

1. Clinical and laboratory characteristics of the three groups (Table 1)
Background: Disease-modifying anti-rheumatic drugs (DMARDs) are introduced for the treatment of spondyloarthritis (SpA) after failure of non-steroidal anti-inflammatory drugs (NSAIDs). In Finland, try out with a conventional synthetic DMARD (csDMARD) is required before initiation of biologics (bDMARD). The patients with DMARDs are eligible for a higher reimbursement for the cost of medication. Opioids are not recommended for arthritis pain.

Objectives: To report the current DMARD and pain medication use among newly-onset SpA patients in Finland.

Methods: From the nationwide reimbursement register maintained by the Social Insurance Institution of Finland we collected all incident adult patients with SpA (ICD-10 codes M45-46) between 2010-14 and divided them into two groups depending on whether bDMARDs were subsequently initiated (group B) or not (group A). Patients’ drug purchases between 2009-15 were obtained from the Drug Purchase Register. Opioid use by these patients was evaluated one year before and after the index date (ID; the date when special reimbursement for antirheumatic drugs use by these patients was evaluated one year before and after the index date). We identified 3577 SpA patients, 23% of which started a self-injected bDMARD during the observation period. More of the patients in group B needed pain medication, prednisolone, methotrexate, or other csDMARDs than sulphasalazine, which was more frequent in group A (table 1).

Conclusion: Altered expression of IncRNA-NR_003542 and NR_026756 in peripheral blood of AS patients might be involved in the pathogenesis of AS, higher expression of IncRNA-NR_003542 and lower expression of NR_026756 might be as the biomarkers for the disease activity of AS, further study would be needed to expound on the exact role of the two IncRNAs in AS.

5-YEARS TREATMENT EFFECT OF TNF ALPHA INHIBITOR IN EARLY AXIAL SPONDYLOARTHRITIS AND ASSOCIATED FACTORS: AN INVERSE PROBABILITY WEIGHTING ANALYSIS OF THE DESIR COHORT

Marion Pons 1,2, Sylvie Chevreau 2, Karine Briot 1,2, Maria-Antonietta D’Agostino 3, Christian Roux 1,2, Maxime Dougas1,2, Anna Molto 3,1, University Paris Descartes, Cochin Hospital, Rheumatology, Paris, France; INSERM U-1153, CREPS Paris-Sorbonne, Paris, France; Ambroise-Pare Hospital, Rheumatology, Biostatistics, Boulogne-Billancourt, France

Background: Only scarce data is available on the long-term treatment effect in a real-life setting (i.e. effectiveness) of TNFi in early axial SpA forms and its predisposing associated factors; furthermore, unbiased evaluation of treatment effect in non-randomized clinical trials is challenging, and new methods have been developed to overcome prescription bias. Objectives: a) to estimate the probability to initiate a TNFi over 5 years of follow up in real life setting using novel statistical methods to overcome prescription bias; b) to determine the long-term effectiveness of first TNFi and its predictive factors.

Methods: Observational prospective French cohort (DESIR) with 5 years of follow-up, including 708 TNFi-naive patients early axial spondyloarthrits. Study visits were scheduled every 6 months in the first two years of follow up then yearly up to 5 years. Treatment (TNFi or other) was at the discretion of the treating rheumatologist(s). The probability to initiate a TNFi was estimated by the Kaplan Meier Method, assuming non informative dropouts. Effectiveness of the first TNFi was defined as the probability to reach an ASAS40 response in both groups (TNFi vs. any other treatment) after at least 10months of exposure. To evaluate treatment effect and overcome prescription bias repeatedly occurring over time, we have applied an iterative method based on inverse propensity score (PS) weighting using a marginal structural model, that allows the integration of the repeated weights derived from the propensity score at each visit (i.e. the probability to receive the treatment at each visit). The structural model used for this analysis was a PS-weighted cox regression, to estimate the probability to present an ASAS40 response after at least 10 months of treatment. Factors predicting first TNFi effectiveness, were explored by Cox (univariate and then multivariate) regression models.

Results: Of the 708 patients included in the analysis, 258 patients initiated a first TNFi during the first five years of follow up. The probability to initiate a TNFi treatment was 41.3% [95%CI 37.2-45.1]. Among the 258 patients who received a first TNFi, 163 (63.2%) were exposed for at least 10 months. On the original data, ASAS40 response was observed in 50/163(30.7%) vs. 58/450(12.9%) patients from the TNFi and usual care groups, respectively. The likelihood of an ASAS40 response was greater in the TNFi exposed group (HR= 3.2[95%CI 2.9-3.8], p <0.0001). Male gender (HR=1.59[95%CI 1.1-2.1]), HLA B27 (HR= 1.4 [95%CI 1.1-2.0]) and the presence of at least one objective sign of inflammation (MRI or CRP) or structural damage (radiographic sacroiliitis) (HR= 1.7 [95%CI 1.2-2.4]) were both predictive of an improved outcome.

THE RISK OF INFECTION BY TUMOR NECROSIS FACTOR INHIBITORS AND ITS ASSOCIATED FACTORS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULT FROM KOREAN NATIONAL HEALTH INSURANCE DATA

Bong-San Kang 1, Yu-Ched Lim 2, Min-Young Lee 3, Ja-Yeon Jeon 3, Hyun-Jeong Yoo 1, In-Sun Oh 3, Ju-Yong Shin 2, Eui-Kyung Lee 3, Tae-Hwan Kim 2, University Seoul Paik Hospital, Inje University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); Sungkyunkwan University School of Pharmacy, Suseo, Korea, Rep. of (South Korea); Alpaca, Sheung, Korea, Rep. of (South Korea); Pfizer Inc, Seoul, Korea, Rep. of (South Korea); Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: Tumor necrosis factor inhibitors (TNFi) are effective in patients who do not respond to non-steroidal anti-inflammatory drugs, or disease modifying anti-rheumatic drugs, and have been widely used in patients with ankylosing spondylitis (AS). However, there is some evidence that treatment with TNFi can increase the risk of infection in patients with AS.

Objectives: The aim of this study was to investigate the risk of infection in patients with AS treated with TNFi.

Methods: Data was obtained from insurance claims database of the Health Insurance Review & Assessment Service (HIRA) in South Korea. Patients who have been prescribed a TNFi such as etanercept (ETN), adalimumab (ADA), golimumab (GLM), and infliximab (IFX) to treat AS from 1 January 2012 to 30 June 2017 were enrolled. We evaluated the incidence rate (IR) and hazard ratio (HR) of serious infections including pneumonia, tuberculosis, and herpes zoster in each TNFi treatment group by using cox proportional hazard model. We further analyzed the HR of infection by sex.

Results: A total of 2,515 patients were included in the study, and they were prescribed ETN (n=526), ADA (n=914), GLM (n=628), or IFX (n=447). The IRs of serious infection were 1.66/100, 1.49/100, 1.58/100, and 1.39/100 per 1,000 person years (py) in ETN, ADA, GLM, and IFX treated groups, respectively. There was no significant difference in HR of serious infection between the TNFi groups. In the subgroup analysis of major infections, there was no difference in the HR of pneumonia between TNFi groups. However, the HR of tuberculosis with IFX group was significantly higher than that with ETN (adjusted HR 8.95, 95% CI: 1.12-71.4). In herpes zoster infection, there was no difference between TNFi groups in all patients, but the adjusted HRs significantly increased with GLM (adjusted HR 15.40, 95% CI: 6.4-144.34) and IFX (adjusted HR 10.02, 95% CI: 1.12-89.9) treatment as compared to ETN in female patients.

Conclusion: Patients receiving IFX had a higher risk of contracting tuberculosis than those receiving ETN. Moreover, the risk of herpes zoster was higher in female patients treated with GLM and IFX than in those treated with ETN in Korea.

FRIO375 SITE-SPECIFIC EFFECTIVENESS OF TNF INHIBITORS FOR ENTHESITIS IN DMARD-NAIVE PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Thomas Huegle1, Burkhard Moeller2, Adrian Ciurea3, Michael Nissen4, Patrick Zueger5, Martin Schulz6, Fabiana Ganz7, Almut Scherer2, Eleftherios Papagiannoulis2,3,2. Lausanne University Hospital (CHUV), Lausanne, Switzerland, 2University Hospital of Bern, Bern, Switzerland, 3University Hospital Zurich, Zurich, Switzerland, 4Geneva University Hospital, Geneva, Switzerland, 5AbbVie Inc., North Chicago, United States of America, 6AbbVie AG, Baar, Switzerland, 7Swiss Clinical Quality Management in Rheumatic Diseases Foundation, Zurich, Switzerland

Background: Enthesitis is a hallmark of spondyloarthritis (SpA), with substantial impact on quality of life. Although pathophysiological mechanisms of enthesitis may include both mechanical and autoimmune features, improvements upon initiation of TNF-inhibitors (TNFi) across individual enthesis sites have not been reported in real-world patients with axial spondyloarthritis (axSpA).

Objectives: To investigate the effectiveness of TNFi in axSpA patients without prior DMARD treatment at specific enthesis sites, including spine, thoracic cage, Achilles tendon and the plantar fascia.

Methods: This was a retrospective cohort study using the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) registry. AxSpA patients initiating TNFi without previous DMARD (biologic or conventional synthetic DMARD [csDMARD]) use and with available Maastricht Ankylo- spondylitis Enthesitis Score (modified to include the plantar fascia, and the Achilles tendon. Plantar fascia, and the Achilles tendon.

Results: 781 DMARD-naive patients with axSpA who initiated TNFi were identified. At baseline, patients (57% male) were a median of 40 (interquartile range [IQR] = 31-50) years of age with a median disease duration of 9 (IQR = 3-18) years and mean Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) of 3.4 (IQR = 2.8-3.9) at treatment initiation. A subgroup of 160 TNFi patients had active enthesitis at baseline (MASES: mean = 4.14, standard deviation [sd] = 2.87) and a 6-month follow-up visit available (MASES: mean = 2.07, sd = 2.82). At the 6-month follow-up, complete enthesitis resolution was observed for 72 (45%) of patients. Enthesitis resolution rate was the most frequent among the following sites: the costochondral sternalum, the costochondral joint, the lumbar vertebra, the pelvic crest, and the iliac crest posterior (Figure 1). Limited resolution of enthesitis was observed in the spine iliacus anterior, plantar fascia, and the Achilles tendon.

Conclusion: Our results suggest that for real-world DMARD-naive axSpA patients, TNFi are generally effective for resolving enthesitis. Significant resolution was observed for enthesitis of the spine and thoracic cage though resolution was more limited for plantar fascia or Achilles tendon enthesitis. Lower limb entheses are more prone to mechanical strain and may therefore require alternative or more prolonged therapy. A study was funded by AbbVie Inc. All authors were involved in the study design, review, data interpretation and approval of the abstract.

FRIO376 DIFFERENCES IN PHYSICAL ACTIVITY BETWEEN AXIAL SPONDYLOARTHRITIS PATIENTS WITH AND WITHOUT PHYSICAL THERAPY

Bas Hilberg1, Florus van der Giessen1, Tha Viet Vien2, Floris A. van Gaalen3, Karel Ronday1, Andreas Peeters5, Salma van Weely1, 1Leiden University Medical Center, Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; 2Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 3Haga Hospital, The Hague, Netherlands; 4Reiner de Graaf Gasthuis, Delft, Netherlands

Background: Physical activity (PA) according to public health guidelines is effective and safe for people with rheumatic and musculoskeletal diseases, including axial spondyloarthritis (axSpA), and should be promoted by healthcare providers.1 In axSpA, in particular high intensity aerobic PA is beneficial, yet this was found to be incompletely implemented in physical therapy programs.2 Studies describing aerobic PA in axSpA patients with and without physical therapy are lacking.

Objectives: To describe the amount, frequency and intensity of aerobic PA in axSpA patients with and without physical therapy treatment.

Methods: A survey, which included questions on patient characteristics, current physical therapy use (individual or group), PA (Short QUestionnaire on Assessment of Physical Activity, SQUASH) and health status (Assessment of Spondyloarthrits International Society Health Index (ASAS HI)), was sent by postal-mail to 456 axSpA patients registered in three hospitals in the Netherlands. From the SQUASH, besides amount (minutes/week) of all PA and meeting the PA guideline between patients with and without physical therapy. For moderate-intensity aerobic PA, both the amount and frequency were significantly greater in the group with physical therapy, whereas for vigorous intensity aerobic PA there were no differences in the total amount and the proportion meeting the guideline between patients with and without physical therapy. For moderate-intensity aerobic PA, both the amount and frequency were significantly greater in the group with physical therapy, whereas for vigorous intensity aerobic PA there were no differences between the groups (Table 1).

Conclusion: More than half of people with axSpA were physically active according to public health PA guidelines. People using physical therapy engaged in significantly more moderate intensity, but not high intensity aerobic PA than those without physical therapy. These results indicate that high intensity aerobic PA should be more intensively advocated and implemented, also in physical therapy treatment.

Methods: Bio-naïve patients with axial spondylarthritis (axSpA) attending primary care or out-patient setting were included in the study. The primary endpoint was treatment persistence after one year of infliximab (INF) treatment. Secondary endpoints were the probability of treatment persistence after two years, as well as safety and efficacy outcomes. Baseline characteristics were compared between the INF and CT-P13 groups.

Results: 1,319 patients were included in the study, of whom 1,229 completed the one-year follow-up. The treatment persistence rate was comparable between INF and CT-P13 after one year (95%CI: 38-50% and 38.68%, respectively). After two years, the treatment persistence rates were 44% (95%CI: 38-50%) for INF and 46% (95%CI: 42-51%) for CT-P13. The survival probability curves for INF and CT-P13 were identical (Figure 1), indicating that the treatment persistence rates were similar in the two groups.

Conclusion: The treatment persistence rates were comparable between INF and CT-P13 after one and two years of treatment. The similarity in survival probability curves suggests that the treatment persistence rate is not influenced by the choice of INF or CT-P13.

Disclosure of Interests: None declared.

Acknowledgement: This study was funded by the Nordic Arthritis Society.
Background: Tumour necrosis factor inhibitors (TNFi) are efficacious in patients with axial spondyloarthritis (axSpA), but some patients switch to a different TNFi because of adverse effects (AE) or lack of effect (LOE). The EuroSpA Collaboration has previously demonstrated a 1-year retention rate of 79% and 6 months LUNDEX adjusted BASDAI<4 of 59% in patients initiating the first TNFi treatment. Little is known about the effectiveness of switching to a second and third TNFi in patients with axSpA.

Objectives: Firstly, to investigate retention and response rates at 6, 12 and 24 months in patients with axSpA initiating the 2nd and 3rd TNFi in clinical practice across Europe. Secondly, to investigate whether the outcomes were associated with the reason for withdrawal (AE or LOE) from the previous treatment.

Methods: Prospectively collected data on axSpA patients in routine care from 12 European registries were pooled. Kaplan-Meier estimation was used to investigate TNFi retention rates. LUNDEX adjusted response rates were calculated for BASDAI<4 and ASDAS inactive disease (ASDAS-c1.3). Group comparisons were performed by Chi-square test. Results: A total of 7953 patients initiating their 2nd TNFi and 2782 patients initiating their 3rd TNFi were included. Baseline characteristics are shown in the Table. The overall retention rates for both 2nd and 3rd TNFi at 12 months were 72% (Figure). Corresponding retention rates for the individual registries ranged from 52-90% and 54-89%, respectively. In both patients who stopped their 1st TNFi due to AE or LOE, 12-month retention rate for the 2nd TNFi treatment was 68%. In patients who stopped the 2nd TNFi due to AE or LOE, 12-month retention rates for the 3rd TNFi treatment were 68% and 69%, respectively. For the 2nd and 3rd TNFi, 6 months LUNDEX adjusted BASDAI<4 were 44% and 37% (p=0.001), respectively, and for ASDAS inactive disease 18% and 13% (p=0.003) (Table).

Conclusion: Data from 12 European countries demonstrated decreasing response rates with increasing number of previous TNFi, although with only minor difference between 2nd and 3rd. Patients who had withdrawn from the previous TNFi due to LOE had retention rates and remission rates similar to those who had withdrawn due to AE.

- Speakers bureau: Abbvie, BMS, Boehringer-Ingelheim, Celgene, Eli Lilly, Hospira, Janssen, Merck, Novartis, Omni, Orion, Pfizer, Regeneron, Roche, and UCB

Background: Evaluation of long-term efficacy and safety for treatments for ankylosing spondylitis (AS) is important. Secukinumab, a fully human monoclonal antibody that directly inhibits interleukin-17A, has shown significant and sustained improvement in the signs and symptoms of AS through 3 years in the MEASURE 2 study (NCT01649375).1

Objectives: We report the 5-year end-of-study results of subcutaneous (s.c.) secukinumab 150 mg in the MEASURE 2 study. Methods: AS patients (pts; N = 219) were randomised to receive s.c. secukinumab 150 mg, 75 mg or placebo at baseline, Weeks (Wks) 1, 2 and 3 and every 4 wks from Wk 4. At Wk 16, placebo-treated pts were re-randomised to receive secukinumab 150/75 mg or placebo at baseline. Week 16 (N = 106). An optional dose escalation from secukinumab 75 mg to 150 mg was initiated beginning Wk 140. Outcome measures at Wk 260 included ASAS20/40, BASDAI50, BASMI, BASFI, SF-36 PCS and ASAS partial remission. Analyses were stratified by anti-TNF status, anti-TNF-naive and anti-TNF inadequate response [IR].1

Results: The safety profile at Wk 260 was 77% (82/106) for secukinumab 150 mg across all endpoints through 5 years (Table). Improvements were maintained regardless of prior exposure to anti-TNF therapy with greater responses in anti-TNF-naive pts. A total of 49 pts on secukinumab 75 mg (46.7%) escalated dose to 150 mg after Wk 140; efficacy responses improved in pts whose dose was escalated. Over the entire study period, the mean exposure (±SD) to secukinumab was 1459.1 ± 597.8 days. Improvements were observed for all endpoints at W52 (Table).

Conclusion: Secukinumab 150 mg provided sustained improvement in the signs, symptoms, and physical function in pts with AS through 5 years of treatment. The safety profile of secukinumab remained consistent with previous reports.1–3

Disclosure of Interests: Liseth de Wolff: None declared, Suzanne Arends Grant/research support from: Grant/research support from Pfizer, Freke Wink Consultant for: Abbvie, Janssen, Elisabeth Brouwer Speakers bureau: Dr. Brouwer as an employee of the UMCG received speaker fees and consulting fees from Roche which were paid to the UMCG, Anneke Spoorenberg Grant/research support from: Received unrestricted grants from Pfizer, Novartis and Abbvie pharmaceuticals. They had no influence in design and conduct of the study., Consultant for: Abbvie, Pfizer, MSD, UCB, and Novartis

Objectives: The aims of our study were to assess the 10-year survival of the first TNF-i, to compare retention rates of different anti-TNF drugs in real life settings and to identify factors associated with drug retention in active axSpA.

Methods: We performed a hospital-based retrospective cohort study on consecutive adult axSpA suboptimally controlled by standard therapy, starting their first biological agent with infliximab (IFX), adalimumab (ADA), etanercept (ETA) or golimumab (GLM) according to local policy, recruited at three academic centres between 2003 and July 2018. Drug efficacy (BASDAI, ASDAS-CRP) as well as reasons for discontinuation were evaluated every 24 weeks. Drug survival was calculated using the Kaplan-Meier analysis, while univariate and multivariate regression was used for predictors of persistence and withdrawal (p<0.05). Subanalysis was done for different disease durations.

Results: Of the 241 axSpA were recruited, 104 (43.15%) cases received ETA (original, biosimilar), 100 (41.49%) ADA, 26 (10.78%) IFX (original and biosimilar) and 11 cases (4.58%) GLM. Significant improvement was demonstrated (ASDAS-CRP, BASDAI, BASFI) in all patients, those with higher disease activity and functional impairment at baseline presenting earlier and higher response rate (p<0.05).

We reported high long-term persistence of the first biological agent in axSpA patients under 5 years on the same drug after 140 months. The retention rates of ETA, ADA and IFX were 70%, 68% and 57% after 3 years; 68%, 48% and 53% after 5 years; 35%, 30% and 27% after 10 years. Overall, retention to ETA was superior to that of monoclonal antibodies (p<0.05), with a total drug-exposure of 625.43 patient-years for ETN, 415.26 for ADA, 221.53 for IFX. In addition, survival of the second TNF-i drug was good but inferior to the first TNF-i (p<0.05).

Male sex, age under 40, high baseline C reactive protein, low initial BASFI and disease duration under 5 years were associated with retention rate in multivariate analysis (p<0.05), while the presence of syndesmophytes and obesity with higher withdrawal (p<0.05).

Conclusion: We reported high long-term persistence of the first biological agent in axSpA patients, with higher retention compared to ETA compared to monoclonal antibodies. Predictors for higher retention advocate the rationale for the drug choice in different axSpA settings.

FR01384 IMPACT OF INTERLEUKIN 17 BLOCKING AGENT ON CLINICAL OUTCOME IN SAPHO PATIENTS

Gunter Assmann1, Joerg, Thomas Bitterling1, Annette D. Wagner2, Martin Schreiber3, Konstantinos Christoyiannakis1, Ulrike Hufnegg4, Claudia Plötzler1, Frank Neumann5, 1University Medical School of Saarland, Medicine I, Oncology and Rheumatology, Homburg, Germany; 2University School of Medicine Hannover, Department of Nephrology, Hannover, Germany; 3Hospital of Worms, Department of Radiology, Worms, Germany; 4University Medical School of Erlangen, Human Genetics, Erlangen, Germany; 5University Medical School of Saarland, Department of Dermatology, Homburg, Germany; 6University Saarland Medical School, Jose Carreras Center for Immunogenetics, Homburg, Germany

Background: SAPHO syndrome has to be considered as a rare subtype of seronegative spondyloarthritis (SpA) showing typical manifestations with palmoplantar pustulosis and osteitis with hyperostosis; the clinical response of conventional or biological disease modifying drugs (DMARDs) in SAPHO syndrome are often disappointing. Whereas in SpA peripheral arthritis and inflammatory back pain represent the leading symptoms, the SAPHO patients often complain painful osteitis with hyperostosis in the sternal region as well as the palmoplantar pustulosis accompanied by synovitis preferentially in large joints including sacroiliitis. Recently, the detection of higher numbers of CD4+IL17+ lymphocytes in the peripheral blood of SAPHO patients has arisen the hypothesis that Th17 helper cells with their secretion of interleukin 17 (IL17) could be involved in the development of inflammation in SAPHO syndrome (1).

Objectives: Here we present an observational study of 12 SAPHO patients which were treated with the IL 17 blocking agent secukinumab. In addition, the fraction of CD4+IL17+ lymphocytes in peripheral blood specimen has been monitored on treatment.

Methods: Between January 2015 and February 2017 clinical activity of disease were measured in 37 SAPHO patients with a disease duration of 11 years (median). The disease activity were evaluated by the osteitis

PAMIDRONATE IN CHRONIC NON-BACTERIAL OSTEOITIS: A RANDOMIZED, PLACEBO-CONTROLLED PILOT TRIAL

Caroline Marie Andreasen1, Anne Grethe Jurik2, Bent Deleuran3,3, Troels Bille Folkman4, Hans Christian Horn5, Troels Herlitz5, Ellen Margrethe Haugen1,7, 1Aarhus University Hospital, Dept. of Rheumatology, Aarhus, Denmark; 2Aarhus University Hospital, Dept. of Radiology, Aarhus, Denmark; 3Aarhus University Hospital, Dept. of Oral and Maxillofacial Surgery, Aarhus, Denmark; 4Odense University Hospital, Dept. of Rheumatology, Odense, Denmark; 5Aarhus University Hospital, Paediatrics, Aarhus, Denmark; 6Aarhus University, Dept. of Clinical Medicine, Aarhus, Denmark

Background: Chronic non-bacterial osteitis (CNO) is an autoinflammatory disease often associated with seronegative spondarthritides. Osteitic bone lesions in adults are predominantly located in the anterior chest wall, the spine and pelvis. Case series suggest that the amino-bisphosphonate pamidronate may be effective in improving bone inflammation, pain, and disability. No randomized controlled trials have been conducted in CNO.

Objectives: In a randomized double-blinded, placebo-controlled trial we hypothesized that pamidronate reduces radiological signs of bone inflammation assessed by whole-body magnetic resonance imaging, improve pain, disability and reduces systemic markers of bone inflammation and bone turnover in blood.
score and skin score (ranging from 0 to 6, assessed by physician), the HAQ score (ranging from 0 to 3, assessed by patient), and MRI of the osteitis lesion (activity score 0-3, analogously to 3 domains of OMERACT RAMRIS scoring synovitis, bone marrow edema, and erosions; assessed by radiologist). In this period of time 12 of them showed disease activity due to osteitis and/or skin disease, at which time the treatment of secukinumab at dosage of 300mg as monotherapy has been started, re-evaluated after at least 12 weeks (ranging from 12 to 18 weeks). For monitoring blood specimens were derived to assess the CD4+IL17+ lymphocyte subpopulation using immunofluorescence technique. We thank the patients who participated. This study was funded by UCB Pharma, medical writing by Hinal Tanna, Costello Medical, UK.

Disclosure of Interests: None declared

OBJECTIVES: To report the incidence and association of active inflammation and chronic lesions in the spine of pts with axSpA treated with CZP over 4 years

METHODS: RAPID-axSpA (NCT01087762) was double-blind and placebo (PBO)-controlled to Week (Wk)24, dose-blind to Wk48, and open-label to Wk204. CZP-randomised pts (either 200mg every 2 weeks [Q2W] or 400 mg Q4W) continued their assigned dose throughout; PBO-randomised pts received CZP from Wk24, or if non-responders, from Wk16 onwards. Blinded spinal MRI scans at baseline (BL) and Wk12, 48, 96, and 204 were assessed by 2 central readers to evaluate the presence/absence of active INFLs (Short T1 Inversion Recovery [STIR] sequence) and FLs, sclerosis and erosions (T1 sequence) in vertebral edges (VEs). We used MMRM analyses with repeated measures (MMRM), fitted on observed data from all randomised pts. Associations between INFLs and FLs at the VE level for CZP-and PBO-randomised pts were described using cross-tabulations.

RESULTS: Of 325 randomised pts, 136 were eligible for these analyses. In pts randomised to CZP at Wk0 (n=89), active INFLs were reduced, and FL counts only slightly increased by Wk12; both were sustained at a low level to Wk204 (Table A). Very few VEs with sclerosis and erosions were observed at BL, and no changes in their frequency were observed over 4 years’ treatment (Table A). Over 4 years’ CZP treatment, the risk of developing a new FL was greater in VEs with vs without INFLs at BL, regardless of changes to INFLs in these VEs post-BL. The prevalence of FLs was greater in pts with >3 vs ≤3 years’ symptom duration and there were more new FLs in the >3 years subgroup during CZP treatment (data not shown).

CONCLUSION: Long-term CZP treatment in axSpA pts was associated with rapid and sustained reduction in active inflammation and a negligible increase in FLs in VEs. More FLs developed in VEs with INFLs at BL than without, but this was not affected by resolution of INFLs. There was no increase in sclerosis and erosions in VEs over 4 years’ CZP treatment.

LONG-TERM CERTOLIZUMAB PEGOL TREATMENT OF AXIAL SPONDYLOARTHRITIS IS ASSOCIATED WITH RAPID AND SUSTAINED REDUCTION OF ACTIVE INFLAMMATION AND MINIMAL STRUCTURAL CHANGES IN THE SPINE: 4-YEAR MRI RESULTS FROM RAPID-AXSpA

Xenophon Baraliakos1, Sebastian Kruse2, Simoné Auter3, Natasha de Peyrecave4, Tommi Nummit5, Thomas Kunke6, Bengt Hoepken7, Juergen Braun1.

1Rheumazentrum Ruhrgebiet and Ruhr-University Bochum, Herne, Germany; 2UCB Pharma, Brussels, Belgium; 3UCB Pharma, Monheim, Germany

Background: In patients (pts) with axial spondyloarthritis (axSpA), inflammation of the spine is believed to trigger a repair mechanism that results in syndesmophyte formation.1,2 Fatty lesions (FLs) in the bone marrow and erosions in the axial skeleton, both visible on magnetic resonance imaging (MRI) T1 sequences, are post-inflammatory changes that have been shown to contribute significantly to models predicting new bone formation.3 It has previously been shown that resolution of inflammatory lesions (INFLs) in pts with axSpA treated with anti-TNF therapy may be associated with an increase in FLs.4 However, it is not known whether CZP treatment coincides with changes in FLs, sclerosis, and erosions.

N, total number of patients with ASDAS.
Background: AxSpA is a chronic condition that has a negative impact on health-related quality of life (HRQoL). Secukinumab (SEC), a fully human anti-IL-17A monoclonal antibody, has been shown to effectively control AS symptoms and improve HRQoL.

Objectives: To evaluate the impact of SEC on HRQoL, assessed by the Short Form-36 Health Survey (SF-36), in pts with active AS stratified by time since first diagnosis (<2 or ≥2 yrs).

Methods: Pts were randomized to placebo (PBO) or SEC in MEASURE 1 (10 mg/kg intravenously followed by 150 or 75 mg SC), MEASURE 2 (150 or 75 mg SC) and MEASURE 4 (150 mg SC with/without SC loading). At Wk 16 or Wk 24, depending on ASAS 20 response, pts on (150 or 75 mg SC) and MEASURE 4 (150 mg SC with/without SC loading). Pts were randomized to placebo (PBO) or SEC in MEASURE

| **Table 2: flare, medications at preconception visits and medications initiated during pregnancy in patients with and without flares** |
| **Pt. with flare** | **Pt. without flare** |

*Two pregnancies ended in miscarriage were not considered.
assessed. Missing data were recorded as non-response and Fisher’s exact test was used to compare the proportion of responders between groups at Wk 16. Only pooled data for pts receiving the licensed dose of SEC (150 mg) are shown.

Results: Overall 739 patients were included, with 427 and 312 in the SEC 150 mg and PBO groups, respectively. Of those, 37% and 36% of the SEC and PBO groups, respectively, were classified as <2 yrs since first AS diagnosis (Overall: 37%). The mean time since AS diagnosis was similar for the PBO and SEC treatment groups in both the <2 yrs (approx. 0.80 yrs) and the ≥2 yrs subgroups (approx.11 yrs). The least squares mean (LSM) changes in PCS from BL to Wk 16 were increased with SEC 150 mg compared with PBO, in both <2 yrs (PBO: 2.11; 150 mg: 6.44, p<0.0001) and ≥2 yrs since diagnosis (PBO: 3.03; 150 mg: 5.82, p<0.0001). Significant increases were also reported in LSM changes in MCS scores from BL to Wk 16 with SEC 150 mg in patients <2 yrs since diagnosis (PBO: 2.10; 150 mg: 5.53, p<0.01), but not in the ≥2 yrs group. Analysis of individual SF-36 domain scores showed improvements with SEC vs PBO in the overall population and in both time since diagnosis subgroups, except Role-Emotional and Mental Health in the ≥2 yrs group (Figure). At Wk 16, the proportions of PCS responders were significantly higher with SEC 150 mg vs PBO, regardless of time since diagnosis (<2 yrs: PBO = 50.0%, SEC = 73.6%, p<0.01; ≥2 yrs: PBO = 45.0%, SEC = 69.8%, p<0.0001). MCS responses were not significantly different with SEC vs PBO in either subgroup. Overall, improvements in SF-36 scores and clinically meaningful MCID responses with SEC were more prominent in the <2 yrs since diagnosis compared with the ≥2 yrs group. Improvements in PCS, MCS, individual SF-36 domains and overall MCID responses were sustained to Wk 52 with SEC 150 mg.

Conclusion: Treatment with SEC 150 mg resulted in significant, clinically meaningful, and sustained improvements in HRQoL. Although reported improvements in SF-36 scores and clinically meaningful MCID responses with SEC were more prominent in the <2 yrs since diagnosis compared with the ≥2 yrs group, improvements in PCS, MCS, individual SF-36 domains and overall MCID responses were sustained to Wk 52 with SEC 150 mg.

Conclusion: The mean disease activity on patients starting biologic therapy is high. A clinically important improvement is met after 12 months of therapy, irrespectively of the index used or the prior use of biologics. The delta in DAI is bigger in the biologic-naive group who received the 1st BT. The biologic-naive group also reaches a higher percentage of low disease activity and inactive disease. Further analysis is needed to see if these tendencies remain after separating the groups per type of biologic drug.
DRUG THERAPY OF ANKYLOSING SPONDYLITIS (AS) DURING PREGNANCY IN REAL CLINICAL PRACTICE

Zuleykhna Gandasheva, Olga Krichetskaya, Tatiana Dubinina, Federal State Budgetary Scientific Institution “Research Institute of Rheumatology named after V. A. Nasonova”, Moscow, Russian Federation

Background: The emergence of new drugs for the treatment of AS and improvement of life quality of patients led to an increase in the number of pregnancies and births in women with AS. However, the prescription of medication during pregnancy is still a difficult decision for both doctors and patients, and the unreasonable abolition of therapy can lead to increased activity of the AS.

Objectives: was described the frequency of use of various groups of drugs before and during pregnancy, determine the relationship between the abolition or change in the mode of taking nonsteroidal anti-inflammatory drugs (NSAIDs) and the dynamics of back pain.

Methods: the survey involved 86 women with AS, having pregnancies that ended in childbirth, not earlier than 2016. The average age is 34.0 ± 5.8 years and the average duration of the AS is 120 ± 73.5 months. The median term of delivery is 39 (38; 40) weeks, the weight of newborns is 2941.1 ± 484.6 g. During pregnancy, 58 (67.4%) women noted deterioration of health. Among them: increased back pain in the first trimester was 66.7%, in II – 84.6%, in III – 72.2%.

Results: Before pregnancy, NSAIDs were taken by more women (63.4%) as compared to taking in a month of conception (37.2%) and taking during gestation (in trimesters - 25.6%; 34.8%; 9.3%, respectively), p < 0.05 in both cases. “On demand”, NSAIDs were taken before pregnancy by 41.6% of women, at conception - 37.5%, in trimesters — 50%, 40% and 25%, respectively. There was a tendency for more frequent increase of back pain during pregnancy in women who abolished NSAIDs in the month of conception, or switched to “on demand” (65%), compared with taking NSAIDs daily (50%). Patients who took NSAIDs “on demand” in the first trimester (group 1), more often noted deterioration of health in the second trimester - 34.6%, compared with patients constantly taking NSAIDs (group 2) - 18.2%. In addition, patients in group 1, as well as women who didn’t take NSAIDs in the first trimester, more often complained of back pain (54.6% and 53.1%) during gestation compared with patients in group 2 (38.4%). Group 1 patients in the second trimester noted increased back pain during pregnancy in 83.3%, whereas group 2 patients - in 58.3% (p < 0.01). Glucocorticoids were taken more often during pregnancy (16.3%; 20.9%; and 22.1% - in trimesters) than before (7%) and at conception (9.3%), p < 0.01 in both cases. Sulfasalazine before pregnancy was taken by 16% of women, at conception - 8%, during pregnancy - 3.5% (p < 0.01 in both cases). Before pregnancy, only 12.8% of women received biological therapy; at the time of conception (adalimumab, etanercept) - 6.9%, in I and II trimesters – by 2.3% (p<0.01).

Conclusion: During pregnancy and the month of conception, the number of women receiving NSAIDs, sulfasalazine, biological therapy, decreases compared to the period before pregnancy. Glucocorticoids in preparation for pregnancy and gestation are prescribed more often than before pregnancy. Withdrawal of NSAIDs or switch to mode “on demand” in the first trimester is associated with an increase in the frequency of back pain during pregnancy, but due to discrepant data on the safety of continuous use of NSAIDs in the first trimester, correction of therapy with the prescription of low-risk drugs is necessary.

Disclosure of Interests: None declared

NetaAkimab IMPROVES PATIENT-RELATED OUTCOMES IN PATIENTS WITH RADIOLOGICAL AXIAL Spondylarthropathies: RESULTS FROM RANDOMISED PHASE 3 TRIAL (ASTERA)

Inna Grydyukova1, V Mazurov2, Shandor Eides2, Tatiana Dubinina2, Olga Nevemyerova3, Evgenia Ilivanova3, Alena Kunzer3, Nikolaj Sokora4, Ekaterina Dokukina1, Anna Erremeeva3, Ekaterina Chernyeva1, Roman Ivanov2
1Mechnikov North-Western State Medical University, St-Petersburg, Russian Federation; 2Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 3Regional Clinical Hospital, Cheboksary, Russian Federation; 4Leningrad Region Clinical Hospital, St-Petersburg, Russian Federation; 5Healthcare Institution Municipal Clinical Hospital No. 1, Minsk, Belarus; 6Scientific and Practical Center of Surgery, Transplantology and Hematology, Minsk, Belarus; 7JSC BIOCAD, St-Petersburg, Russian Federation

Background: chronic pain, stiffness, fatigue and limited spinal mobility significantly affect quality of life (QoL) in patients (pts) with axial spondyloarthritis (axSpA). There is increasing evidence that IL-17 blockade is highly effective in this pts’ population and show benefits in terms of multiple patient-reported outcomes (PROs) in both non-radiological (nr) and radiological (r) axSpA.

Objectives: To evaluate early effects of netakimab (NTK) on PROs in pts with active r-axSpA, based on data of 16-week observation from ongoing phase 3 ASTERA study (NCT03447704).

Methods: ASTERA is a phase 3 international double-blind placebo (PBO)-controlled clinical study. After completion of screening 228 eligible adult pts with r-axSpA (mNew York criteria, 1984), which remained active (BASDAI ≥ 4.0) despite the standard non-steroidal anti-inflammatory drugs (NSAIDs), were randomly assigned (1:1) to receive 120 mg NTK or placebo (PBO) at Week (WK) 0, 1, 2 and then q4wk through WK 16. After WK 16 all patients will continue/be switched to receive NTK up to week 52. PROs were total back pain (10-item numerical range scale), BASDAI, BASFI. Work productivity and QoL were also assessed by Work Productivity and Activity Impairment (WPAI) and 36-item Short Form Health Survey (SF-36), respectively.

Results: Baseline characteristics were similar between treatment arms. The mean age at baseline was 39.1±9.9 years, 75.88% of patients were male and the mean symptoms duration was 4.3±4.48 years. All patients had active (mean BASDAI: 6.2±1.55) r-axSpA. 78.6% of patients were naïve to any biological treatment. Mean total back pain score at baseline was 6.7±1.6 in NTK group and 6.8±1.5 in PBO arm. At WK1 the difference in total back pain score between study arms became statistically significant (Figure 1). At WK 16 use of NTK was associated with statistically significant improvements from baseline in BASDAI (2.8 vs 0.2, p<0.0001), BASFI (-0.9 vs 0.9, p<0.0001) and physical component of SF36 (6.3 vs. -2.6, p<0.0001) (Figure 2). WPAI response in NTK arm was significantly better at WK 16, as compared with PBO (Table 1).

Conclusion: NTK in treatment of patients with r-axSpA showed rapid improvement in PRO, WP and QoL and was accompanied with improvement in physical function and disease activity.

A total of 4 overarching principles and 10 recommendations were presented to the experts and recommendations were formulated after thorough discussions and voting.

Management of enteropathic arthritis may be challenging due to differences in treatment response of inflammatory bowel diseases and arthritis to different therapeutic modalities, which may even cause worsening of some manifestations while improving others. Enteropathic arthritis was not addressed in the management recommendations for spondyloarthritis.

Methods: A task force was formed that included ten rheumatologists and gastroenterologists and other clinicians dealing with enteropathic arthritis.

The aim of this project was to develop a set of evidence based recommendations for the management of patients with enteropathic arthritis: A RHEUMATOLOGY, GASTROENTEROLOGY COLLABORATIVE INITIATIVE

EVIDENCE BASED RECOMMENDATIONS FOR THE MANAGEMENT OF ENTEROPATHIC ARTHRITIS: A RHEUMATOLOGY, GASTROENTEROLOGY COLLABORATIVE INITIATIVE

EVIDENCE BASED RECOMMENDATIONS FOR THE MANAGEMENT OF ENTEROPATHIC ARTHRITIS: A RHEUMATOLOGY, GASTROENTEROLOGY COLLABORATIVE INITIATIVE

Patients with active inflammatory bowel disease, active disease regarding both inflammatory bowel disease and arthritis, and among patients in remission. Final voting showed good agreement among the group on all recommendations.

Conclusion: These recommendations are intended to help rheumatologists, gastroenterologists and other clinicians dealing with enteropathic arthritis and to point out to the shortcomings of the available data on the management of this challenging condition.

EVIDENCE BASED RECOMMENDATIONS FOR THE MANAGEMENT OF ENTEROPATHIC ARTHRITIS: A RHEUMATOLOGY, GASTROENTEROLOGY COLLABORATIVE INITIATIVE
MAINTAINED CLINICAL REMISSION IN ANKYLOSING SPONDYLITIS PATIENTS SWITCHED FROM REFERENCE INFLIXIMAB TO ITS BIOSIMILAR, AN 18-MONTH COMPARATIVE OPEN-LABEL STUDY

Evripidis Kaltoumpas1, Eleftherios Pelechias2, Paraskevi Voulgar1
Alexandros Diosos1. We have no working group for this abstract.
1Rheumatology Clinic, University of Ioannina, Ioannina, Greece
2Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece

Background: switching from reference infliximab (RI) to biosimilar infliximab (BI) has no detrimental effects on efficacy and safety compared to continuous RI. However, long-term follow-up data is missing. Objectives: the aim of this study was to evaluate if BI is equivalent to RI to maintain patients with Ankylosing Spondylitis (AS) in clinical remission, in a long-term fashion.

Methods: one hundred and nine consecutive unselected AS patients were investigated. All, followed-up at predefined times receiving RI (5mg/kg/8 weeks) and were naïve to other biologics. Patients who were in clinical remission were asked to switch from RI to BI using the same therapeutic dose. Patients switched to BI were compared with a matched control group receiving continuous RI. During follow-up the demographic, clinical, laboratory parameters and comorbidities were all recorded for at least 18 months. Disease activity was measured using the Bath Ankylosing Spondylitis activity index (BASDAI), and the Ankylosing Spondylitis disease activity score (ASDAS), using the C-reactive protein. Remission was defined if patients achieved BASDAI ≤4 and ASDAS ≤1.3. Results: twenty-one patients were excluded, nine because had no clinical remission and twelve because refused to switch. Thus, 88 were evaluated. From those, 45 switched to BI, while 43 continued receiving RI. There were no differences between groups regarding demographic, clinical and laboratory parameters. All patients were in clinical remission (BASDAI ≤4 and ASDAS ≤1.3). During follow-up, five patients from the switched group and three from the maintenance group discontinued the study. Four patients receiving BI presented nocebo effects and were switched back to the RI. Three responded well, while the fourth did not. After 18 months of treatment, all patients in both groups remained in clinical remission. No significant adverse events were noted between groups.

Conclusion: BI is equivalent to RI in maintaining AS in clinical remission for at least 18 months.

Methods: This multicenter, prospective observational cohort study used the TREasure database in which web-based registration of rheumatoid arthritis and SpA patients are being performed in 15 centers across different regions of Turkey. In this study, data of SpA patients switching from one biologic agent to another were analyzed. Demographic and clinical data, follow-up duration, time to switch, and reasons for switching were retrieved from the database. Kaplan-Meier analysis was performed to show drug retention rates and Cox regression analysis was performed to investigate the factors affecting switching.

Results: Of the included 3138 SpA patients, 1165 (37.1%) switched to another biologic agent (switched group) and 1973 (62.9%) continued to receive their current therapies (continued group). The median follow-up duration of all patients was 3.8 years and the median time to switch was 1.0 years (0-13.4 years). According to the distribution of comorbidities, the rates of patients having diabetes mellitus, hyperlipidemia, asthma, gastrointestinal bleeding, and cancer were significantly higher in the switched group than those of in the continued group (8.4% vs. 5.6%, p=0.006; 14.5% vs. 9.2%, p=0.001; 15.6% vs. 6.2%, p<0.001; 3.2% vs. 1.8%, p=0.018; and 1.0% vs. 0.3%, p=0.019, respectively). Features of the patients are presented in Table 1. Cox regression analysis revealed that female gender HR 1.47 (95% CI 1.24-1.75), p<0.001, disease duration HR 1.016 (95%CI 1.00-1.03), p<0.009, and BASDAI score HR 1.095 (95%CI 1.05-1.14), p<0.001 were the significant increasing factors for switching from one biologic agent to another.

In the switched group (n=1165), the main reasons for switching were secondary inefficacy (n=351), primary inefficacy (n=328), and side effects (n=287) followed by primary or secondary unknown inefficacy (n=57), physician's request (n=45), patient's demand (n=36), willing to be pregnant (n=9), other (n=37), and unknown (n=70).

Conclusion: In SpA patients, switching was frequent between anti-TNF agents and the median time to first switch was 1 year. Female gender, short disease duration, and lower BASDAI score were found to be the significant factors affecting switching from the anti-TNF agent used at first. The main reasons for this switching were primary (29.0%) and secondary (31.0%) inefficacy followed by side effects (23.6%). Switching between subcutaneous anti-TNF agents is generally less than switching from infliximab to another biologic agent.

CHARACTERIZATION OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN THE ANKYLOSING SPONDYLITIS COHORT PRIOR AND DURING ADALIMUMAB TREATMENT: DATA FROM A LARGE GERMAN NON-INTERVENTIONAL STUDY

Michaela Köhn1,2, Marc Schmalzing3, Eva Christina Schwannek4, Holger Gnann4, Hans-Peter Tony5,6, Gerd Greger5, Annika Boas5, Harald Burkhardt1,2,6, Frank Behrens1,2,6,7, Hans-Peter Tony,5,6, Frank Behrens,2,6,7, Rheumatology Department, University Hospital Goethe-University, Frankfurt, Germany;8 Frank Behrens, Rheumatology and Immunology, University Hospital, Würzburg, Germany;9,10 GKM, München, Germany;5,8 AbbVie, Wiesbaden, Germany;< Centre of Innovative Diagnostics and Therapeutics, Rheumatology/Immunology at Goethe-University, Frankfurt, Germany

Background: Spondylarthritides (SpA) are characterized by different disease manifestations such as arthritis, enthesitis, dactylitis and associated to concomitant diseases like inflammatory bowel diseases (IBD) including ulcerative colitis (UC) and crohn’s disease (CD). IBD might have a specific role to SpA due to common pathophysiological pathways. Characteristics of the rheumatic disease and response to treatment may differ within the phenotypic manifestation and with and without associated diseases. Adalimumab (ADA) is a monoclonal antibody inhibiting TNF alpha which has demonstrated efficacy in both, nraxSpA and ankylosing spondylitis (AS) as well as for UC and CD.

Objectives: To evaluate patient baseline characteristics prior to and treatment response on different disease manifestations in a cohort of AS patients with IBD compared to an AS without IBD during ADA treatment.

Methods: Data from a large German multicenter prospective observational non-interventional study (n=3,756) of patients with active AS who initiated ADA therapy during routine clinical care were analyzed with focus on specific patient groups: (1) patients with AS and IBD at baseline (n=166) and (2) patients with AS without IBD at baseline (n= 3,590). Patient characteristics and data of efficacy on different disease manifestations and prevalence of concomitant IBD over 24 months were analyzed.

Results: Of 3,756 patients in the main analysis set, 166 (4.4%) were identified to suffer from concomitant IBD at baseline. Baseline characteristics showed differences in gender distribution, proportion of patients with enthesitis, psoriasis and uveitis showing a higher proportion of each for the IBD group (Table). After 24 months of ADA treatment, both groups had similar decreases for BASDAI, BASMI, BASFI and dactylitis improvement. The IBD group had a fast decrease in BASDAI at M6 to its maximum (95.2%) of patients with active AS who initiated ADA therapy during routine clinical care were analyzed with focus on specific patient groups: (1) patients with AS and IBD at baseline (n=166) and (2) patients with AS without IBD at baseline (n= 3,590). Patient characteristics and data of efficacy on different disease manifestations and prevalence of concomitant IBD over 24 months were analyzed.

Patient characteristics and data of efficacy on different disease manifestations and prevalence of concomitant IBD over 24 months were analyzed.
52.7% (r-axSpA/AS: 52.6%; nr-axSpA: 52.9%) had inactive disease (ASDAS<1.3; LORCF; Table B). The treatment-emergent adverse event (TEAE) rate/100 patient-years was 224.2; 3.9% patients discontinued CZP due to TEAEs. No new safety signal was identified.

Conclusion: The run-in phase of C-OPTIMISE shows that similar and continued CZP due to TEAEs. No new safety signal was identified.

ANKYLOSING Spondylitis: An integrated
Analysis of COAST-V and COAST-W

Helena Marzo-Ortega1, Eduardo Myster2, Tetsuya Tomita3, Jeffrey Lisse4, Carlo Sakoara4, Sergio Schwartzman5, NHIR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust and LIIRM, Univ of Leeds, Leeds, United Kingdom; 2Organización Médica de Investigación, Buenos Aires, Argentina; 3Osaka Univ Graduate School of Medicine, Osaka, Japan; “Eli Lilly and Company, Indianapolis, United States of America; 4Klinikum Bielefeld, Germany; 5Avenida USL-IRCCS and Univ di Modena e Reggio Emilia, Reggio Emilia, Italy; “The Hospital for Special Surgery, New York, United States of America

Background: The efficacy and safety of ixekizumab (IXE) in patients with radiographic axial spondyloarthritis (r-axSpA) were investigated in the COAST trial program.

Objectives: To report the long-term safety of IXE in r-axSpA patients using integrated safety data from the COAST trials program.

Methods: Safety data for r-axSpA patients treated with IXE were integrated from COAST-V (biologic-naive; NCT02696785) and COAST-W (Inadequate responders or intolerant to 1 or 2 TNF inhibitors; NCT029696798) studies. Patients fulfilled the AGS criteria for axial spondyloarthritis and met mNY criteria for ankylosing spondylitis. Trial eligibility criteria were previously reported.1,2 In these studies, participants were randomized to placebo (n=191), adalimumab (n=90, active reference arm, COAST-V only), or ixekizumab (n=376). Study participants initially randomized to IXE in both trials were treated with a starting dose (80-mg or 160-mg) and then 80-mg IXE every 2 weeks (IXE2W) or 4 weeks (IXE4W). Patients initially treated with placebo or adalimumab were re-randomized at Week 16 to receive either IXE2W or IXE4W following a 160-mg starting dose. The analysis population included all ixekizumab-exposed patients in both trials. Incidence rates (IR) per 100 person years with 95% confidence intervals (CI) and the number of patients are reported. Adverse Event (AE) codes were derived from MedDRA (v21.0). Integrated safety data are presented here include all data collected between May 6, 2016 and Sept, 20, 2018.

Results: The integrated population consisted of 641 patients with 749.6 total patient-years of exposure to IXE. Mean follow up time was 427 days. Mean baseline age was 43.8 ± 12.3 years. Mean and median baseline disease symptom duration (since onset) were 17.2 ± 10.8 years and 15.5 years (Min: 1.1, Max: 56.2), respectively. Safety data are presented in Table 1. Among these patients, 489 (76.3%) reported ≥1 treatment event.
886

Friday, 14 June 2019

emergent AEs with an IR of 65.2. Serious AEs (1) were reported for
51 (8.0%) patients with an IR of 6.8. Discontinuations due to AEs were
reported for 38 (5.9%) patients with an IR of 5.1. One death was
reported, a suicide, in a patient with a documented prior history of
depression and judged by the blinded principal investigator to be unrelated to the investigational product. The overall infection IR was 39.4,
with both serious and opportunistic infections reported with an IR of 1.7.
Among opportunistic infections, no Tuberculosis infections or reactivations
were reported and the Candida infection IR was 1.2. No infections were
associated with grade 3 or 4 neutropenia. The confirmed major adverse
cardiovascular events IR was 0.1. The malignancy IR was 0.4 with acute
promyelocytic leukemia, bladder cancer, and ovarian cancer reported. The
depression IR was 0.8. The adjudicated inflammatory bowel disease (IBD)
IR was 1.5 with 4 of 11 patients having prior history of IBD. The Anterior uveitis (AU) IR was 3.9 with 24 of 29 patients having prior history
of AU. The injection site reaction IR was 11.3.

Conclusion: The reported safety profile for IXE in r-axSpA is consistent
with the profile reported for other indications. During the extension period,
the overall safety profile of ixekizumab remained consistent with that
observed during the double-blind period of COAST-V and COAST-W.1,2

EFFECT OF LONG-TERM TREATMENT WITH
SECUKINUMAB ON LIPID PROFILE IN PATIENTS WITH
ACTIVE ANKYLOSING SPONDYLITIS AND PSORIATIC
ARTHRITIS: POOLED 4 YEAR ANALYSIS

Iain McInnes1, Dafna D. Gladman2, Atul Deodhar3, Corinne Miceli Richard4,
Peter Nash5, Abhijit Shete6, Daren Asquith7, Hanno Richards6, Luminita Pricop8,
Jianyuan Wang6. 1University of Glasgow, Glasgow, United Kingdom; 2University of
Toronto, Toronto, Canada; 3Oregon Health and Science University, Portland,
United States of America; 4Cochin hospital, Paris, France; 5University of
Queensland, Brisbane, Australia; 6Novartis Pharma AG, Basel, Switzerland;
7
Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom; 8Novartis
Pharmaceuticals Corporation, East Hanover, United States of America
Background: Systemic inflammation may adversely affect the lipid profile
in AS and PsA patients (pts)1. Treatment with some TNF and JAK inhibitors have reported increased total cholesterol (TC) and triglycerides (TG)
despite reduction in inflammation2-3. Secukinumab (SEC), a fully human
monoclonal antibody that directly inhibits IL-17A, has demonstrated a sustained efficacy and consistent safety profile in pts with AS and PsA4
Objectives: To evaluate the long-term effect of SEC on key lipid parameters in AS and PsA pts from pooled phase 3 clinical trials, through 208
weeks (wks)
Methods: This post hoc analysis included pooled data from MEASURE 1-4
(SEC 150 mg) in AS (N = 892) and FUTURE 2-5 studies (SEC 150/300
mg) in PsA (N = 2049), from pts treated with SEC or placebo (PBO).
Serum TC, TG, LDL- and HDL-cholesterol and TC/HDL-C levels were
assessed at baseline (BL), Wks 16, 104 and 208 in overall population and
in sub-groups by prior anti-TNF therapy, concomitant methotrexate (MTX)
and BL statin usage. Shift of common terminology criteria for adverse
events (CTCAE) grade from BL through Wk 208 were also analysed
Results: BL characteristics were comparable across SEC and PBO
groups. Lipid levels were stable in SEC treated AS and PsA pts through
Wk 208 (Table) with mean change (mmol/L) from BL in AS: TC = ±0.1,
TG = 0.1-0.2, LDL-C = ±0.1, HDL-C = ±0.04 and TC/HDL-C = ±0.2 and
PsA: TC = ±0.2, TG = 0.001-0.2, LDL-C = ±0.2, HDL-C = ±0.06 and
TC/HDL-C = ±0.2. Stable lipid values were also seen across key subgroups by prior anti-TNF therapy, concomitant MTX and BL statin usage,
which remained stable through Wk 208. No Change in CTCAE lipid
grades was observed in >90% of SEC-treated pts through Wk 208
Conclusion: SEC did not adversely affect the lipid profile and TC/HDL-C
ratio in pts with AS and PsA, over 4 years. The lipid profile remained
stable with SEC treatment and was sustained irrespective of prior antiTNF status, concomitant MTX and BL statin usage

FRIO0402 **SECUKINUMAB FOR AXIAL SPONDYLOARTHRITIS: DRUG SURVIVAL IN REAL-WORLD SETTING AND RESPONSE FACTORS**

Carolina Merino Argumánez1, Valentina Emperiale1, María Joven-Ibáñez5, Ana Pérez Gómez6, José 2Hospital Príncipe Asturias, Alcalá de Henares, Spain

BACKGROUND: IL-17 inhibition has been proved effective in patients with ankylosing spondylitis (AS) in clinical trials and it has been added to the most recent national and international treatment guidelines. However, real-world data of its use is still scarce.

OBJECTIVES: This study aims to analyze drug survival of secukinumab for axial spondyloarthritis (AxSpA) in a real-world setting and identify response factors.

METHODS: Multicentric observational, retrospective, longitudinal study conducted in 4 tertiary hospitals of the Madrid region. Patients over 18 y.o. with clinical diagnosis of AxSpA and having received at least one dose of secukinumab between January 2016 and October 2018 were included. Medical records were reviewed to collect demographic and clinical data related to AxSpA, its features and treatment. Statistical analysis was performed including bivariate analyses (considering withdrawal of drug during study period or not) and survival analysis with Kaplan-Meier and Cox regression. Reasons for discontinuing therapy are described. To detect influential variables, demographic characteristics, HLA-B27 positivity, radiographic features, previous biologic therapies, comorbidities and extra-articular involvement were analyzed.

RESULTS: Out of 143 patients included, 89 (62%) maintained secukinumab therapy at the end of the observation period (Dec 31, 2018), with an average drug survival time of 17 ± 8.2 months. 54 patients (38%) withdrawn therapy, due to primary ineffectiveness (26%), secondary ineffectiveness (14), adverse events (7) and other reasons (7). Median time to withdrawal was 6 months (0-21). No significant differences were found between groups, but a tendency to higher number of female patients in the group with higher drug survival time (41%, p = 0.07), non-radiographic AxSpA (35% vs 27%, p = 0.053) and lower HLA-B27 positivity (50% vs 65%, p = 0.052) was noted in the group withdrawing therapy. Previous exposure to biologic therapy did not differ (75% vs 71%, p = 0.37). Number of bDMARDs before Secukinumab therapy was also similar in both groups; the proportion of patients with previous exposure to 2 or more bDMARDs were 17% vs 22% (p = 0.373). Neither differences were found in all other variables studied (demographic, hip arthropathy, syndesmophytes, extra-articular involvement –uveitis, psoriasis, inflammatory bowel disease– or in comorbidities (tobacco exposure, hypertension, diabetes mellitus, dyslipidemia, ischemic heart disease, malignancy).

Conclusion: This study assessing drug survival of secukinumab in real-world setting showed a trend to lower drug survival in comparison to clinical trial data. No differences were found in the treatment withdrawal group. Population in which secukinumab is prescribed in real-world setting differs from clinical trials, with higher previous exposure to bDMARDs and higher comorbidity.

FRIO0403 **HIGH BASELINE PATIENTS COMPARED WITH EVALUATOR’S GLOBAL ASSESSMENT IS ASSOCIATED WITH LOWER RETENTION AND REMISSION RATES OF FIRST TNF INHIBITOR IN AXSPA PATIENTS – DATA FROM THE EUROSPA COLLABORATION**

Briqitte Michelsen, Lykke Ørnbjerg, Anne Gitte Loft, Joseph Sexton, Adrian Ciurea, Henrik Mann, Karl Esklund, Aylen Yazici, Maria Jose Santos, Johan Askling, Ziga Rota, Bjorn Gudbjornsson, Manuel Pombo-Suarez, Catarina Codreanu, Irene van der Hurst-Bruinsma, Eirik Kristianslund, Michael Nissen, Karel Pavelka, Nina Trokovic, Nevun Inanc, Elisa Vieira-Sousa, Daniela Di Giuseppe, Maria Tomasic, Ann Jon Gelsom, Marleen van der Sande, Florence Iannone, Carlos Sánchez-Piedra, Gareth T. Jones, Lise Hyldstrup, Niels Steen Krogh, Merete L. Hetland, Mikkel Florenzo Iannone, Carlos Sánchez-Piedra, Gareth T. Jones, Lise Hyldstrup, Niels Steen Krogh, Merete L. Hetland, Mikkel Østergaard. EuroSpa Research Collaboration, on behalf of DABIO (Denmark), ARTIS (Sweden), SCQM (Switzerland), NORD-OARMD (Norway), ATTPRA (Czech Republic), Reuma.pt (Portugal), BIOBADASER (Spain), ROB-FIN (Finland), bion.szl (Slovenia), ICEBIO (Iceland), TURKIBIO (Turkey), RFBF (Romania), ARC (Netherlands), BSRBR-AS (UK), GISEA (Italy), Denmark

BACKGROUND: Discordance between baseline patient’s and evaluator’s global assessment of disease activity is common.1 However, the impact of such discordance on retention and remission rates of TNF inhibitor (TNFi) therapy in axial spondyloarthritis (axSpA) patients remains unexplored.

OBJECTIVES: To assess the impact of baseline discordance, defined as “patient’s minus evaluator’s global assessment of disease activity” (ΔPEG), on retention and remission rates of first TNFi in female and male axSpA patients across Europe.

METHODS: AxSpA patients from 10 European registries participating in the European Spondyloarthritis Research Network Collaboration (EuroSpa) were included. Retention rates after 6/12/24 months (55% retention rate for both male and female patients) were assessed with Kaplan-Meier analyses, with comparison between baseline ΔPEG quartiles with log rank test, stratified by gender. Proportions of patients in BASDAI remission (≤42) and ASDAS inactive disease (<1.3) after 6/12/24 months were derived for different ΔPEG quartiles compared with Chi-square test, stratified by gender.

RESULTS: A total of 9013 axSpA patients were included. Mean(SD) age for women(n=3639)/men(n=5374) were 42.7(12.0)/41.7(12.0) years, disease duration 5.1(7.4)/9.8(7.7) years, median(25-75 percentiles) baseline ΔPEG

Science Abstracts

Friday, 14 June 2019 887
TNFi retention rates as well as proportions of patients achieving BASDAI<4 was achieved by 49% and ASDAS<1.3 by 9% of the patients. Results: Data from axSpA patients treated with secukinumab in routine care from 12 countries in the European Spondyloarthritides Research Collaboration (EuroSpA) were pooled. Time from treatment initiation to data cut was >= 6 months. Group comparisons were performed with independent t-test, Mann-Whitney U-test, ANOVA, Kruskal-Wallis and Chi-square test, as appropriate. Kaplan-Meier analyses with log rank test were performed for comparison of secukinumab drug survival. Results: A total of 1556 axSpA patients were included. Overall, 6-month BASDAI<4 was achieved by 49% and ASDAS<1.3 by 9% of the patients. bDMARD naïve compared with non-naïve secukinumab starters had shorter disease duration, higher baseline disease activity, a higher proportion were men and a higher proportion achieved crude and LUNDEX adjusted 6-month BASDAI<4 but not ASDAS<1.3 (table).
Drug retention was higher for bDMARD naïve compared with non-naïve patients (figure 1a). Baseline characteristics and disease activity (data not shown) as well as drug retention differed in-between the European registries (figure 1b).

Figure 1a. Pooled 6-month secukinumab retention rates for axSpA patients in EuroSpA, as well as compared between the bDMARD naïve and non-naïve patients (log rank test; p<0.001).

Figure 1b. Pooled 6-month secukinumab retention rate as well as compared across 11 registries in EuroSpA (log rank test; p=0.001). ICEBIO was excluded from the Kaplan-Meier plot (<10 patients).

Conclusion: This study of >1500 patients in 12 European countries provides real-world data on the effectiveness of secukinumab in patients with axSpA, adding evidence to existing RCTs. A majority of the patients was previous bDMARD users and had long disease duration. BASDAI <4 was achieved by 49% of the patients and ASDAS <1.3 by 9% at 6 months. Overall retention rate was 83% at 6 months, with significant differences across the registries and higher retention rates for bDMARD naïve compared with non-naïve axSpA patients.

FRI0405 AQUILA STUDY IN GERMANY – REAL WORLD DATA ON SECUKINUMAB’S EFFECTIVENESS IN PSORIATIC ARTHRITIS PATIENTS – RESULTS FROM AN INTERIM ANALYSIS

Uta Kiltz1, Daniel Peterlik2, Veronika Winkelmann2, Hans-Peter Tony3, on behalf of the AQUILA Study Group, 1Rheumazentrum Ruhrgebiet, Herne, and Ruhr University, Bochum, Germany, 2Novartis Pharma GmbH, Clinical Research Immunology, Hepatology and Dermatology, Nürnberg, Germany, 3Medizinische Klinik II, Universitätsklinik, Rheumatology/Immunology, Würzburg, Germany

Background: Psoriatic arthritis (PsA) is a chronic, progressive, inflammatory disorder of skin and joints, it impacts both physical and emotional well-being, and increases the risk of comorbidities. Thus, improvement of disease activity as well as emotional well-being is of utmost importance in treatment of PsA patients (pts). In clinical trials, secukinumab, an anti-interleukin (IL)-17A monoclonal antibody, has shown to significantly improve signs and symptoms of PsA.

Objectives: To evaluate real-world interim data on the effectiveness of secukinumab on treatment outcomes and quality of life (QoL) in pts with PsA.

Methods: AQUILA is an ongoing, 52-week (wk) non-interventional study enrolling 2000 pts with active PsA and ankylosing spondylitis. Here, we report interim results of effectiveness in a subgroup of PsA pts treated with secukinumab.

Validated questionnaires were used to measure effectiveness of secukinumab on:

- disease activity
- Physician’s Global Assessment (PhGA, 0=no disease activity, 10=most intense disease activity),
- Psoriasis Area and Severity Index (PASI),
- American College of Rheumatology (ACR) joint count and C-reactive protein (CRP),
- and QoL.
- Psoriatic Arthritis Impact of Disease 12–item score (PsAID–12),
- Medical Outcomes Study (MOS) SLEQ scale and Beck’s Depression Inventory II (BDI–II).

Pts who were already under secukinumab treatment or just about initiating secukinumab therapy, based on medical therapeutic need, were included; in both scenarios, disease activity at start of secukinumab treatment was used as starting point for analysis. Treatment decision was made independently of participating in this study. Pts were observed from...
Results: At BL, 641 PsA pts were included of whom 385 (60.1%) com-
pleted 52 wks so far (i.e. at the time of data cut-off for this interim anal-
ysis; 58.5% (n=375) of the pts were female and 41.5% (n=266) were
male, mean age was 52.6 years. About 66% (n=424) were pre-treated
with biologics. Mean PhGA improved from 5.3 at BL (n=571, 89.1%) to
2.5 at wk 52 (n=341, 53.2%). Mean absolute PASI improved from 8.1 at
BL (n=211, 32.9%) to 1.2 at wk 52 (n=147, 22.9%). More than half of
the documented pts (51 out of 94) achieved a 100% reduction (PASI
100) in skin symptoms at wk 52. The mean number of tender/swollen
joints (ACR) was reduced from 7.6 (n=436, 68.0%) to 3.9 (n=437, 68.2%) to
3.0 (n=241, 37.6%) at wk 52. The percentage of pts with CRP >3mg/L dropped from 43.0% at BL (n=230) to 36.6% at wk
52 (n=112). Mean PsA-ID improved from 5.0 at BL (n=602, 93.9%) to
3.3 at wk 52 (n=343, 53.5%). The percentage of PsA pts with high dis-
 ease activity (score ≥ 5) assessed by PsA-ID decreased from 61.0% at
BL (n=387) to 26.2% at wk 52 (n=90). MOS sleep scales did not change
relevantly over time. With respect to pts with a BDI-II reduction of
at least 3 score points, the mean value improved from 16.4 (mild
depression) at BL to 8.0 (no depression) at wk 52 (n=123, 19.2%).
Conclusion: Secukinumab reduced disease activity and improved QoL
already within this subgroup of PsA pts. Thus, real-world data from the
AQUILA study show that, in clinical routine, secukinumab treatment up to
one year provides a clear benefit for PsA pts in clinical and QoL
parameters.

AQUILA STUDY IN GERMANY – REAL WORLD DATA ON EFFICACY AND SAFETY OF SECUKINUMAB IN ANKYLOSING SPONDYLITIS PATIENTS – RESULTS FROM AN INTERIM ANALYSIS

Uta Kiltz1, Daniel Peterlik2, Veronika Winkelmann2, Hans-Peter Tony3; on behalf of the AQUILA Study Group. 1Rheumazentrum Ruhrgebiet, Herne, and Ruhr
University, Bochum, Germany; 2Novartis Pharma GmbH, Clinical Research
Immunology and Dermatology, Nürnberg, Germany; 3Medizinische Klinik II, Universitätsklinik, Rheumatologie/Immunologie, Würzburg, Germany

Background: Ankylosing spondylitis (AS) is characterized by chronic
inflammation of the spine and is at high risk to cause inflammation, pain,
and stiffnessextraspinally as well. Thus, important aims in therapy of AS
are pain reduction and maintenance of physical functioning. Secukinumab,
a fully human monoclonal antibody that selectively neutralizes interleukin
(IL)-17A, has already shown significant efficacy in the treatment of AS in
clinical trials.1

Objectives: The aim of this interim analysis is to evaluate the effective-
ness of secukinumab on disease activity, physical functioning and quality
of life in AS patients (pts) in a real world setting.

Methods: AQUILA is an ongoing, multi-center, 52-week (wk) non-interven-
tional study enrolling 2000 pts with active AS and psoriatic arthritis in
Germany. Here, we report interim results of effectiveness in a subgroup
of AS pts treated with secukinumab. Validated questionnaires were used to measure the effectiveness of secu-
kunumab on:

- disease activity
- Physician’s Global Assessment (PhGA: 0=no disease activity, 10=most
  intense disease activity),
- Bath Ankylosing Spondylitis Disease Activity Index (BASDAI),
- C-reactive protein (CRP)
- physical functioning
- global functioning: Assessment of Spondyloarthritis Health Index, (ASAS
  HI), and key aspects of sleep
- Medical outcomes Study Sleep Scale (MOS),
- severity of depression
- Beck’s Depression Inventory Version II (BDI-II).

Pts who were already under secukinumab treatment or just about initiat-
ing secukinumab therapy, based on medical therapeutic need, were
included; in both scenarios, disease activity at start of secukinumab treat-
ment was used as starting point for analysis. Treatment decision was
made independently of participating in this study. Pts of hip joints treated
from BL up to wk 52 according to clinical routine. Real-world effectiveness
of secukinumab was assessed prospectively and analyzed as observed.

Results: This interim analysis describes 311 AS pts who were included at
BL and of whom 178 (57.2%) have completed wk 52 so far (i.e. at the
time of data cut-off for this interim analysis). 63.3% (n=197) of the
pts were male and 36.7% (n=114) female, mean age was 47 years. About
70% (n=221) of the pts were pre-treated with biologics. Physicians
reported a mean PhGA value of 5.9 at BL (n=282; 90.7%) which
improved to 2.6 at wk 52 (n=168; 54.0%). Mean BASDAI value was
reduced from 5.6 at BL (n=301, 96.6%) to 4.0 at wk 52 (n=171, 55.0%).
With regard to inflammation parameters, the percentage of pts with a
CRP of >3mg/L decreased from 54.7% (n=140) to 40.0% (n=58) at wk 52.
Further, mean ASAS-HI value decreased over time from 8.2 at BL (n=274,
88.1%) to 6.3 at wk 52 (n=156, 50.2%). MOS sleep scale did not change
time over time, yet only few BL documentations for these scales were
available (range n=26 to 44). Regarding depression mood of the
pts, while at BL 40.7% (n=101) of the pts suffered from mild to severe
depression (BDI-II score between 14 and 63), 30.3% (n=46) did so in
wk 52. This is reflected by a drop of mean BDI-II value from 13.0 at
BL (n=248, 79.7%) to 10.6 at wk 52 (n=152, 48.9%).

Conclusion: This is a limited subset of AS pts, secukinumab reduced
disease activity and improved quality of life for up to one year as
reported by validated physicians’ as well as pt-reported outcomes.
Overall, this interim analysis gives promising insights into treatment effects
of secukinumab on pts’ physical and mental well-being under real-world
conditions.

FRID0407

TWO-YEAR ULTRASOUND CONTROLLED STUDY OF HYALINE CARTILAGE AND SYNOVIAL LAYER STRUCTURE OF HIP JOINTS IN PATIENTS WITH ANKYLOSING SpondyLitis DURING TREATMENT WITH ADALIMUMAB

Andrey Petrov1, Aistle Gafarovaa1, Aleksey Petrov2, 1, Jana Shevnin3, 1, Crimean
Federal University, Medical Academy, Simferopol, Russian Federation; 2Crimean
Clinical Hospital n.a. N.A. Semashko, Simferopol, Russian Federation

Background: The impairment of hip joints has significant prognostic value
on functional status of patients with Ankylosing spondylitis (AS) [1]. One
of possible yearly marker of hip joints structure damage in patients with
AS may be changing in volume of hyaline cartilage [2]. Objectives.

Objectives: To investigate changes in width of hyaline cartilage and syn-
ovial layer of hip joints in patients with coxitis, associated with AS under
treatment with adalimumab (ADA) during 2 years.

Methods: The 28 patients with AS and clinical, ultrasonic and radi-
ographic signs of coxitis (21 male, 7 female, average age is 35.4 years
old, duration of disease is 12-132 months) were included into study. All
patients were being treated by NSAIDs at least 3 months before they
started to take ADA (40 mg subcutaneously every 2 weeks). Treatment
with ADA was continued during 24 months. Patients were observed at
month 0, 12 and 24 months of treatment including measurements of pain
visual analog scale (VAS) in hip movements, maximal distance between
ankles, pelvic X-ray and sonography of hip joints by 10-18 MHz probe.
BASRI-Hips index was applied for radiographic estimation of structural
damage of hip joints [3]. During sonography width of hip joint capsule
and hyaline cartilage were measured. The Mann-Whitney-U test was used
for comparison of changes in clinical and sonographic data between two
groups of patients.
Results: It was determined that painVAS at hip movements was decreased (23.1 [12.3; 32.3] mm at month 12 and 19.7 [11.8; 32.9] mm at month 24 vs 73.7 [59.5; 82.6] mm at month 0, p<0.05) and maximal distance between ankles was increased (112.5 [94.7; 122.2] mm at month 12 and 116.2 [91.2; 125.0] mm at month 24 vs 78.7 [63.4; 86.8] mm at month 0, p<0.05) in observed patients under treatment with ADA. It was also found that ultrasound measured width of hip joint capsule was decreased from 11.8 [10.3; 12.7] mm at month 0 to 8.7 [8.1; 9.4] mm at month 12 (p<0.05) and 7.5 [6.6; 8.5] mm at month 24 (p<0.05). The ultrasound measured width of hyaline cartilage in observed patients was increased from 0.8 [0.6; 1.1] mm at month 0 to 1.0 [0.8; 1.2] mm at month 12 (p<0.01) and 1.2 [1.0; 1.7] mm at month 24 (p<0.05) under treatment with ADA. The BASRI-Hips index had not changed in observed patients at the end of 24-months period. The differences in changes of hip cartilage width between patients with joint capsule width at month 24 less than 9 mm and more than 9 mm was determined (p<0.05): +0.6 [0.3; 0.8] mm vs +0.1 [-0.1; 0.2] mm.

Conclusion: Treatment with ADA leads to decrease of clinical and sonographic signs of coxitis in patients with AS and improves of hyaline cartilage structure. The increase of width of hip hyaline cartilage was observed in patients with absence of ultrasound signs of hip joints synovial inflammation in patients with AS. MRI-controlled studies are needed to confirm ability of THF inhibitors to restore cartilage volume in patients with coxitis, associated with AS.

FEMALE ANKYLOSING SPONDYLITIS PATIENTS HAVE A SUBSTANTIALLY LOWER TNFI TREATMENT RESPONSE THAN MEN

Tamara Rusman1, M.T. Nurmoahmed2, S.E. Hoekstra1, J.C. van Denderen2, Mariëtte Ter Wee3, Irene van der Horst-Bruinsma1, Amsterdam UMC location VUmc, Department of Rheumatology, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology Center, location Reade, Amsterdam, Netherlands; 3Amsterdam UMC location VUmc, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands

Background: Accumulating data revealed difference in treatment efficacy in biologicals in women with axial spondyloarthritis (axSpA) (1). Objectives: The aim of this study was to assess gender differences in TNFI inhibitor treatment response up to a five year biological treatment Methods: Radiographic axSpA patients (AS) were recruited from the Amsterdam Spondyloarthritis cohort (the AmSpA cohort) of the VU University center and Reade. This prospective, observational cohort study included consecutive AS patients who were treated with TNFI inhibitors (TNFI) (infliximab, adalimumab, etanercept or golimumab). Data of this cohort was collected between January 2000 until December 2018. Inclusion criteria were: AS diagnosis according to the modified New York criteria and start with a first TNFI. Patients were evaluated at baseline, three months, six months and once yearly up to five years follow-up.

Disease activity was determined with the Ankylosing Spondylitis Disease Activity Score (ASDAS) and the Bath Ankylosing Spondylitis Index (BASDAI). Multivariable GEE analyses were performed to assess the delta difference between baseline and 1 year.

Results: 389 AS patients were included in the AmSpA cohort. Thirty-three of these 389 patients were excluded since they were not TNFI naive or their treatment status was unknown (7.5%), of whom the majority was never treated with TNFI (infliximab, adalimumab, etanercept or golimumab). Data of this cohort was collected between January 2000 until December 2018. Inclusion criteria were: AS diagnosis according to the modified New York criteria and start with a first TNFI. Patients were evaluated at baseline, three months, six months and once yearly up to five years follow-up. Disease activity was determined with the Ankylosing Spondylitis Disease Activity Score (ASDAS) and the Bath Ankylosing Spondylitis Index (BASDAI). Multivariable GEE analyses were performed to assess the delta difference between baseline and 1 year.

Conclusion: In radiological axial SpA, female patients had significantly lower level of TNFI treatment response at six and twelve months on the ASDAS-CRP and had a higher drop-out rate compared to males. This strongly indicates an important gender difference in especially the twelve first months of TNFI treatment.

TFR0410 TNFI THERAPY REDUCES SPINAL RADIOGRAPHIC PROGRESSION IN AXIAL SPONDYLOARTHRITIS (PARTIALLY) BY DECREASING DISEASE ACTIVITY

Alexandre Sprangro1, Sofia Ramiro1, Stephanie Wichuk1, Praveena Chowiencikawaliki1, Tertie Macosoumar1, Joel Paschke1, Desiree van der Heijde1, Robert B.M. Landewe2, Walter P. Maksymowych1,3, 1LUMC, Leiden, Netherlands; 2University of Alberta, Edmonton, Canada; 3Mahidol University, Bangkok, Thailand; 4CARE Arthritis, Edmonton, Canada; 5ARC, Amsterdam, Netherlands

Background: Recent observational data suggest that TNFI reduce spinal radiographic progression in radiographic axial spondyloarthritis (r-axSpA) mostly by inhibiting disease activity. Yet, resolution on the controversial effect of TNFI on structural progression is yet to be achieved.

Objectives: To investigate whether in r-axSpA TNFI have an indirect (through ASDAS) and/or direct effect on spinal radiographic progression.

Methods: Patients (pts) with axial spondyloarthritis (axSpA), fulfilling the modified New York criteria (mNY) were included in this prospective, observational cohort (ALBERTA FORCAST). Clinical and imaging data were collected at baseline and every 2 years up to 10 years of follow-up. Radiographs of the spine were independently scored by 2 central readers and one adjudicator (if disagreement), with known chronological order but blinded to clinical data, using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). The indirect effect of TNFI on mSASSS progression was evaluated by testing the interaction between TNFI and ASDAS at the start of each 2-year interval. If significant (p<0.15), the association between mSASSS at t and mSASSS at the end of the interval (t+1) was assessed in 3 groups of exposure to TNFI: i) treatment in all visits; ii) treatment in some visits; and iii) never treated.

Results: In total, 314 pts were included (74% males, mean symptom duration 17.8 (SD 11.7) years, 83% HLA-B27 positive and 7% previously treated with ≥1 TNFI). The interaction between ASDAS and TNFI at t was significant (p=0.10). A gradient was seen for the effect of ASDAS at t on mSASSS at t+1, which was more than 2 times higher in patients never treated with TNFI (β (95% CI): 0.41 (0.13; 0.68) compared to those always treated (β (95% CI): 0.16 (0.00; 0.31)) (Figure), showing that treatment with TNFI diminishes the effect of ASDAS on mSASSS. In addition to the indirect effect, TNFI also directly associated with less mSASSS progression: Pts receiving TNFI at t had on average 0.87 mSASSS-units less on t+1 compared to those not treated (β (95% CI): -0.80 (-1.37; -0.22)) and this was noted independently of ASDAS. Importantly, this effect remained significant after PS-adjustment (β (95% CI): -0.80 (-1.37; -0.22)).

Conclusion: This data is in line with previous evidence showing that treatment with TNFI limits spinal radiographic progression in pts with r-axSpA by decreasing disease activity. Additionally, a direct effect of TNFI reducing mSASSS progression, and independent of ASDAS inflammation, is also seen suggesting that other mechanisms also contribute to the structural effect of TNFI.

FR0411 COMPARABLE CLINICAL RESPONSES BUT HIGHER TREATMENT ADHERENCE OF SECUKINUMAB COMPARED TO TNF INHIBITORS IN SPONDYLARTHROPSIS PATIENTS: LONG-TERM PROSPECTIVE OBSERVATIONAL STUDY IN A TERTIARY HOSPITAL OF GREECE

Irini Flouri, Argyro Repa, Nestor Avgulisidis, Nikolaos Kougkas, Christina Adamichou, Anastasios Eskihtis, Paraskevi Kyridou, Ainour Molla Ismail Sall, Styliani Polia, Maria Terizaki, Aggeliki Koukounti, George Bertsias, Panagiotis Siderogeorgis, University Hospital of Heraklion, Crete, Rheumatology, Clinical Immunology and Allergy, Heraklio, Greece

Background: Data regarding effectiveness and persistence to therapy with anti-IL17 agent secukinumab (SEC) in spondyloarthritis (SpA) patients of real world clinical practice are very limited.

Objectives: To assess characteristics of SpA patients starting therapy with SEC versus tumor necrosis factor inhibitors (TNFi) in routine clinical care and compare clinical responses and treatment retention at 2 years.

Methods: All patients starting a bDMARD in the Rheumatology Department of the University Hospital of Heraklion, Crete, are included in a prospective observational study after their written informed consent. Data concerning disease activity at pre-specified time-points, drugs, comorbidities and any adverse events are recorded. For the present study we analyzed all consecutive patients with axial (AxSpA) or peripheral SpA (pSpA) starting or switching bDMARD therapy, either a TNFi or SEC from 1/2015 till 12/2018. We excluded patients with IBD-related SpA, starting or switching from a bio-originator to a biosimilar TNFi. We compared disease activity scores improvement at 6 months using linear regression analysis and treatment retention using Kaplan-Meier survival curves with log-rank test and Cox regression. Inverse propensity score weighting (IPW) was used to adjust for the potential confounding of gender, age, disease duration, previous bDMARDS and csDMARDS number, diagnosis (AxSpA vs pSpA), presence of peripheral arthritis and co-therapy with csDMARDs.

Results: A total of 239 patients with SpA started/switched bDMARD (SEC:69, TNFi:170). SEC was the >3rd bDMARD in 63% of patients compared to 17% of TNFi (p<0.001). Patients’ characteristics at baseline were comparable except for disease duration (median (IQR): 5 (1.5-11) years in SEC vs. 0.9 (2.4-6) in TNFi, p=0.001). AxSpA was the diagnosis in 78% patients starting SEC and 79% starting TNFi while peripheral arthritis was slightly more common with SEC (81% vs 76% in TNFi). Monotherapy tended to be more common with SEC compared to TNFi (52% vs 42%, p=0.16). Baseline disease activity regarding both axial and peripheral arthritis was comparable in the two groups. Unadjusted 2-year treatment retention was similar in the two groups, both overall (SEC: 63%, TNFi: 56%, p=0.18) and due to failure or adverse events. However, when we selected only patients on 1st or 2nd bDMARD (SEC:26, TNFi:131), 2-year survival of SEC was higher than that of TNFi (95% vs. 95%, p=0.027). Similarly, SEC tended to have higher TNFi in patients with pSpA (p=0.11). After IPW, SEC administration was an independent predictor for higher bDMARD retention overall (HR (95%CI)=0.48 (0.33-0.69), p=0.001) and specifically due to discontinuation for failure (HR=0.58 (0.38-0.88), p=0.011) and for adverse events (HR=0.21 (0.08-0.62), p=0.004).

Mean BASDAI and ASDAS improvements at 6 months were similar in patients with AxSpA receiving SEC or TNFi [Mean (SD) bBASDAI: 1.6 (2.5) vs 1.4 (2.5), respectively (p=0.78) and ASDAS: 0.7 (1.4) vs 1.0 (1.5), p=0.44]. Similarly, in patients with peripheral arthritis, IADAS28 at 6 months was comparable in the two groups (p=0.88). Adjusted linear regression with IPW provided similar results to the unadjusted analyses in both axial and peripheral disease.

Conclusion: In SpA patients of real-world, administration of SEC results in similar clinical responses but higher treatment adherence compared to TNFi, especially if Secukinumab is the 1st or 2nd bDMARD. Larger number of patients and longer follow-up is needed to confirm these data.

FR0412 SPINAL AND SACROILIAC JOINTS INFLAMMATION IN PATIENTS WITH RADIOPHAGIC AXIAL SPONDYLOARTHROPSIS TREATED WITH NETAKIMAB – 16-WEEKS RESULTS OF MULTICENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE III ASTERA STUDY

Alexander Smimov et al. Inna Gaydukov, Vladimir Mazurov, Shandr Erdes, Tatiana Dubrina1, Olgas Nesmyeyanova2, Elena Ivanova1, Elena Kundra2, Nikolaj Soroka3, Anna Eremerova1, Ekaterina Chemyaeva1, Roman Ivanov1, 1Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Mechnikov North-Western State Medical University, St-Petersburg, Russian Federation; 3Chelyabinsk Regional Clinical Hospital, Chelyabinsk, Russian Federation; 4Leningrad Regional Clinical Hospital, St-Petersburg, Russian Federation; 5Healthcare Institution Municipal Clinical Hospital, Minsk, Belarus; 6Scientific and Practical Center of Surgery, Transplantology and Hematology, Minsk, Belarus; 7USC BIOCAD, St-Petersburg, Russian Federation

Background: Efficacy and safety of netakimab (NTK), a humanized anti-interleukin 17A antibody, have been previously established in two phase 2 clinical trials in patients with radiographic axial spondyloarthritis (r-axSpA)1 and psoriasis2. ASTERA is a randomized, double-blind, placebo (PBO)-controlled phase III trial, aimed to demonstrate efficacy and safety of NTK in subjects with r-axSpA (NCT03447704).

Objectives: To evaluate the effect of NTK on inflammation in spine and sacroiliac joints (SIJ) at Week (Wk) 16 in ongoing ASTERA study in patients with active r-axSpA.

Methods: 228 eligible adults with active r-axSpA were randomized into 2 study arms (1:1) to receive 120 mg of NTK or PBO, administered as SC injections at Wk 0, 1, 2, and then q2wk through Wk 16. After Wk 16 all patients will start to receive NTK up to week 52. Inflammation in spine and SIJ was assessed with magnetic resonance imaging (MRI) at baseline and Wk 16. The following scoring methods were used: the Berlin spine score (derived from Ankylosing Spondylitis Spine MRI Activity (ASpi-MRI-a) Score for spine assessment and the SPARC score for SIJ assessment. All images were evaluated by central reader, blinded to treatment.

Results: Both arms were comparable in the Berlin spine score (4.18 ± 4.58 in NTK arm vs. 4.19 ± 4.32 in PBO arm) and the SPARC score (5.67 ± 8.33 in NTK arm vs. 5.23 ± 7.86 in PBO arm) at baseline (p=0.05). Data analysis at Wk16 revealed that NTK arm achieved significant decline in bone marrow edema in direct comparison with PBO arm: by Wk 16 the mean change from baseline in the Berlin spine score was -2.16 ± 2.87 in NTK arm vs. -0.30 ± 1.55 in PBO arm (p=0.001) and the mean change from baseline in the SPARC score was -3.80 ± 6.68 in NTK arm vs. -1.82 ± 4.12 in PBO arm (p=0.01).

Conclusion: the treatment with NTK at a dose 120 mg leads to improvement in spine and SIJ inflammation in patients with active r-axSpA by Wk16, as compared with PBO.

The frequencies of ADA and NAb positive were similar between the two groups at different time points. Through week 24, 79.13% of 412 patients in HS016 and 79.91% of 229 patients in adalimumab group developed ADAs, and 17.48% of 412 in HS016 and 18.78% in 229 in adalimumab group developed NABs.

Conclusion: The results of efficacy, PK, safety, immunogenicity from the study conducted in Chinese AS patients support a high similarity between HS016 and the adalimumab.

The geometric means for steady-state maximum plasma concentration (Cmax) and area under the plasma concentration-time curve from time zero to infinity (AUCinf) were similar between HS016 group and adalimumab group. The proportions of treatment-emergent adverse events, serious adverse events and injection site reactions were similar between the two groups (table 2).

Disclosure of Interests: None declared

Methods: A multicenter, randomized, non-inferiority, double-blinded, ADA controlled clinical trial with 24 weeks of follow-up was conducted in China. Participants with active AS defined as BASDAI ≥ 4 and average back pain score (VAS 0-10) ≥ 4 were eligible for participation. Participants were randomly assigned to receive BAT1406 (40mg q2w) or adalimumab (40mg q2w) at a ratio of 2:1 for 24 weeks. Primary outcome was the proportion of patients achieving ASAS20 response at 12 weeks. Inclusion of the 95% CI of the ASAS20 response difference within a ± 15% margin was required for equivalence. Secondary outcomes included ASAS40, ASAS5/6, BASDAI50 response, patient reported outcomes, safety and immunogenicity. This trial is approved by China Food and Drug Administration (number 2015LS05751).

Results: 554 eligible patients were enrolled from Jan 2017 to Aug 2017 and randomly assigned to receive BAT1406 (n=363) or Adalimumab (n=191) participants, 514 completed the study. Patients (86.5% of whom were male and whose mean age was 31.6 years) had a mean disease duration was 5.82 years. Over 12 weeks, 75.69% of patients in BAT1406 group and 73.68% in ADA group (between group difference 1.6%, 95% CI [-0.9% to 0.1%]) achieved ASAS20 response (per-protocol set; adjusted treatment difference 2.16%, 95% CI [-6.9% to 11.22%]). Outcomes for secondary end points were consistent with the primary efficacy finding. The frequency of adverse events (AEs) was comparable between groups ([BAT1406 318[87.1%] vs ADA 162 (85.3%)), as well as serious AEs, adverse drug reactions and discontinuations due to AEs. Similar positive rate was found in two groups for anti-drug antibodies up to week 24.

Conclusion: The study met the primary endpoint of demonstrating equivalent efficacy of BAT1406 and ADA. BAT1406 was comparable in tolerance, safety and immunogenicity with ADA in active AS patients.

Background: The first symptoms of ankylosing spondylitis (AS) patients usually begin prior to 45 years, but can occur later in life.

Objectives: The purpose of this study is to evaluate the efficacy and safety of anti-TNFα treatment in late-onset AS (LoAS) patients in comparison to those with adult onset AS (AoAS).

Methods: We studied AS patients in TURKBio registry between the dates of January 2011 and November 2018. All the patients fulfilled the modified New York criteria for AS and were classified into 2 groups based on their age at symptom onset: AoAS (age>16 but ≤45 years); and LoAS (age>45 years). In both groups, the following data were compared: (1) epidemiological variables; (2) clinical manifestations, including signs and symptoms at diagnosis; (3) laboratory results; (4) disease activity markers and follow-up parameters (BASDAI, ASDAS-CRP and HAQ); (5) radiographical parameters at baseline. The frequency of using drugs and adverse events were compared.

Results: A total of 2551 AS patients (91.1% with AoAS and 8.9% with LoAS) were included in the study. LoAS group had more female patients, older age, shorter disease duration and diagnostic delay, higher disease activity, and symptoms at diagnosis; (3) laboratory results (4) disease activity markers and follow-up parameters (BASDAI, ASDAS-CRP and HAQ); (5) radiographical parameters at baseline. The frequency of using drugs was similar between the groups (Table 1). The frequency of using drugs was higher in the LoAS group than in the AoAS group, as the use of glucocorticoids and sulfasalazine was more common in the LoAS group. The LoAS group had a higher frequency of anti-TNFα treatment, the mean improvement in BASDAI was significantly higher in the LoAS group compared to the AoAS group.

Conclusion: Our data showed that almost 8.9% of the patients with AS had late-onset of symptoms. The results suggested that LoAS patients might have different demographic, clinical features, disease activity parameters at baseline. The frequency of anti-TNFα use and response rate to the treatment was also similar in LoAS to those in AoAS patients. The LoAS patients seem to have more common severe adverse events compared to the AoAS patients possibly related to their older age.

References:
who were on a stable NSAID dose for ≥2 weeks. In Period 1, all patients received ETN (50 mg/week) plus NSAID for 24 weeks. At week 24, patients who achieved inactive disease qualified for Period 2 and were withdrawn from ETN treatment for 40 weeks. In Period 3, patients who experience a flare during Period 2 will be retreated with ETN for 12 weeks. Efficacy outcomes for Period 1 included the proportions of patients achieving inactive disease and 20% and 40% improvements in ASAS disease activity (ASAS20 and ASAS40), as well as the changes from baseline in the Spondyloarthritis Research Consortium of Canada (SPARCC) scores for the sacroiliac joint (SPARCC-SIJ) and the spine (SPARCC-Spine). Efficacy analyses presented here were performed on the observed cases.

Results: Of 209 treated patients, 112 (54%) were men, 186 (89%) white, 142 (68%) had MRI-evident sacroiliitis, and 162 (76%) were HLA-B27-positive. The mean baseline score for ASDAS-CRP was 3.5, 8.5 for SPARCC-SIJ, and 2.7 for SPARCC-Spine. Twenty-one (10%) patients discontinued the trial. A significant decrease in ASDAS-CRP score was observed at all post-baseline visits (Panel A). At Week 24, 62% (117/190) and 76% (144/190) achieved ASAS20 and ASAS40, respectively, and there was a significant reduction from baseline in SPARCC-SIJ (-5.8; P<0.001) and SPARCC-Spine (-1.5; P=0.002). Seventy-nine (38%) patients experienced TEAEs, and 1 (0.5%) patient experienced a serious TEAE (cellulitis).

Conclusion: Majority of patients with active nr-axSpA and an inadequate response to NSAIDs achieved inactive disease and reduction of inflammation in both the SJ and the spine with 24-week open-label ETN treatment. There were no unexpected safety signals.

Outcomes of Dose Reduction of TNF-Inhibitors in Axial Spondyloarthritis at 24 Months

Liz Van Rossum, Claire Harris, Annie Gilber, Raj Sengupta, Cathal Boyle, Karl Gaffney, Karl Machado, Andrew Keef, East Kent Hospital University Foundation Trust, Canterbury, United Kingdom; 2Northwick Park Hospital, London, United Kingdom; 3AKGfellyert, Brighton, United Kingdom; 4Royal National Orthopaedic Hospital, Bath, United Kingdom; 5Norfolk and Norwich Hospital, Norwich, United Kingdom

Background: Some patients with inflammatory arthritis who respond well to TNF inhibitor (TNFi) treatment continue to do so after dose reduction. In Axial Spondyloarthritis (axSpA) dose optimisation is desirable but the extent of benefit is unclear and predictors of therapeutic response to dose reduction are unknown.

Objectives: To observe responses to dose reduction of TNFi treatment in axSpA patients and to seek preliminary predictors of low-dose therapeutic response.

Methods: AxSpA Patients at 4 UK centres were allowed to reduce their doses of TNFi therapy if they had met UK (NICE) response criteria and remained well for at least 6 months and wished to do so. There was no pre-determined dose-reduction schedule. The proportion of dose reduction was calculated as a percentage, in mg per month, of the original, standard dose. All patients completed BASDAI and BASFI questionnaires at each visit with annual BASMI measurement. CRP levels were measured frequently. Individuals who continued to take reduced-dose treatment throughout the 24-month period were designated “Remainers” (REM) and those who reverted to full-dose treatment were designated “Reverters” (REV). Data were collected at 6 timepoints: 1: immediately before starting TNFi treatment; 2: at the point of dose reduction; 3: at the point of reversion to full-dose treatment (REV only); 4: 6 months after dose reduction; 5: 12 months after dose reduction; 6: 24 months after dose reduction.

Results: 58 patients (86%/male) who had reduced their dose of TNFI treatment were observed for 24 months. 47 (81%) were REM and 11 (19%) were REV. Mean disease duration prior to biologic therapy was 22.6 years for remainers and 18.6 years for reverters. Mean dose reduction was 38% and 41%, respectively. These 47 REM (95%/male) were of mean age 53.6 (range 36 to 71) years, compared with the 11 REV (63.6%/male) whose mean age was 51.9 (range 39 to 71) years. Mean BASDAI, BASFI and BASMI scores and CRP levels at the designated time points are shown in table 1.

Mean BASDAI scores reduced from 1.9 to 1.4 (28%) from dose reduction to 24 months whereas REV mean BASDAI scores increased from 1.8 to 2.4 (34%) from dose reduction to dose reversion. REM mean BASFI scores reduced from 2.5 to 1.4 (43%) from dose reduction to 24 months whereas REV mean BASFI scores increased from 2.8 to 3.3 (19%) from dose reduction to dose reversion. REM mean CRP scores decreased from 4.1 to 0.7mg/dl (83%) from dose reduction to 24 months and REV mean CRP scores also decreased from 4.7 to 3.5mg/dl (25%) from dose reduction to dose reversion.

Conclusion: Amongst these selected patients with axSpA 85% continued to respond to TNFI treatment in spite of 38% dose reduction. Reverters were more likely to be female and to have relatively low CRP levels at the initiation of TNFI treatment; reversion was preceded by modest rises in BASDAI, BASFI and BASMI but by continued fall in CRP levels.

Ixekizumab Significantly Improves Self-Reported Overall Health in Patients with Active Ankylosing Spondylitis/Radiographic Axial Spondyloarthritis: SF-36 Results of Two Phase 3 Trials

Jessica A. Walsh, Uta Kitz, James Cheng-Chung Wee, Filip van den Bosch, Theresa Hunter, Yan Dong, Li Xiaoqi, David Sandoval, Luis Leon, Vibeke Strand, University of Utah, Salt Lake City, United States of America; 1Vestergaards Medical Center, Salt Lake City, United States of America; 3Rheumazentrum Ruhrgebiet, Heme, Germany; 2Ruhr-Universiteit Bochum, Bochum, Germany; 5Chung Shan Medical University Hospital, Taichung City, Taiwan, Republic of China; 6Ghent University Hospital, Ghent, Belgium; 7El Lily and Company, Indianapolis, United States of America; 8Biphasical Consultant, Porto Valley, United States of America

Background: Using the Short Form-36 (SF-36) questionnaire, previous studies have determined that anklyosing spondylitis/radiographic axial spondyloarthritis (AS/axSpA) significantly impacts patients’ health-related quality of life (HRQoL). Ixekizumab (IXE), a humanized anti-interleukin-21A monoclonal antibody, improves disease signs and symptoms in patients with AS/axSpA. 1,2,3 Week 16 SF-36 results from two clinical trials with IXE are presented here (NCT02696785 and NCT02696798).

Objectives: To evaluate the efficacy of IXE versus placebo (PBO) in improving HRQoL assessed by the SF-36 questionnaire in patients with active AS/axSpA who were either naïve to biologic therapy or have failed or been intolerant of one or two TNF inhibitors (TNFI).

Methods: COAST-V and -W are randomized, double-blind, placebo-controlled clinical trials. Enrolled patients were adults with active AS/axSpA classified by ASAS criteria who fulfilled mHbY of sacroiliitis (central reading), with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and back pain ≥4. In COAST-V, patients naïve to biologic agents were randomized 1:1:1:1 to receive 80 mg IXE every 4 weeks (Q4W), 80 mg IXE every 2 weeks (Q2W), adalimumab 40 mg Q2W (ADA), or PBO. In COAST-W, patients who had failed on or were intolerant of one or two TNFI were randomized 1:1:1 to 80 mg IXE Q4W, 80 mg IXE Q2W, or PBO. In both studies, patients in the IXE arms were randomized to receive either 80 mg or 160 mg IXE as the starting dose. Comparisons of change from baseline to Week 16 in norm-based SF-36 scores between active groups and PBO were performed using mixed model for repeated measures.
Results: Biologic naïve and TNFi-experienced patients treated with IXE reported significantly greater improvement than PBO patients in SF-36 Physical Component Summary and the physical functioning, bodily pain, general health, and vitality domains. No changes between treatments were reported in Mental Component Summary scores. The greatest numerical improvements with IXE were observed in the bodily pain and patient global pain domain. Similar improvements were reported in the IXE Q4W, IXE Q2W, and ADO groups.

Conclusion: IXE improved self-reported HRQoL, as measured by the SF-36 questionnaire, at Week 16 in patients with active AS/r-axSpA who were naïve or experienced with biologic treatments.

Of the 136 subjects, 128 had adverse events (AEs) with 63 (92.6%) and 65 (95.6%) AEs occurring in the HS016 and China-licensed adalimumab, respectively. Among these AEs, 172 from 50 subjects (73.5%) in HS016 group and 148 from 55 subject (80.9%) in China-licensed adalimumab were treatment emergent adverse event. The proportion of confirmed anti-drug antibody responses in the 2 study arms were, 25.0% (17 cases) and 22.1% (15 cases) at day 14, 50.0% (34 cases) and 42.6% (29 cases) at day 42, for the HS016 and China-licensed adalimumab arms, respectively. Neutralizing antibodies were all negative at day 14 for both groups, except 2 cases (3.7%) and 1 case (1.6%) at day 42, for the HS016 and China-licensed adalimumab arms, respectively.

Conclusion: It is concluded that HS016 have shown a similar PK to China-licensed adalimumab in healthy male subjects, and no meaningful differences in safety of immunogenicity were observed.

Psoriatic arthritis

FR0423

NAIL ULTRASONOGRAPHY FINDINGS IN GRAYSCALE AND POWER DOPPLER TO DIFFERENTIATE PSORIATIC ARTHRITIS, PSORIASIS AND CONTROL INDIVIDUALS

Samanta DE Rossili,2, José Alexandre Mendonça2, Penelope Palominos1, Charles Kohen1, Tania Cestari2, Rafael Chac1, 1Hospital de Cânceres do Porto Alegre – Universidade Federal do Rio Grande do Sul, Rheumatology, Porto Alegre, Brazil; 2Hospital de Cânceres do Porto Alegre – Universidade Federal do Rio Grande do Sul, Dermatology, Porto Alegre, Brazil.

Background: The early diagnosis of psoriatic arthritis (PsA) on patients with psoriasis (PsO) is challenging, but may prevent functional impairment. Patients with nail psoriasis have an odds ratio of nearly 3.0 of developing psoriatic arthritis. Ultrasoundography is a replicable, radiation-free method that could be used to identify nail changes before clinical manifestations.

Objectives: To verify if nail changes identified via ultrasoundography can differentiate between PsA and PsO patients as well as between PsA/PsO patients and a control group.
Methods: Single-center, cross-sectional study. PsA patients were consecutively enrolled, PsO and controls were matched by age and gender with the PsA group. PsO patients must have had the diagnosis of psoriasis of any subtype. PsA patients had to fulfill the CASPAR criteria. Exclusion criteria, for all groups included: other joint inflammatory disease; dermatological or systemic disease that could modify the nail structure. Ultrasound examination was performed using a MyLab 50 system (Esaote Biomedeca, Genova, Italy), equipped with a linear probe of 18 MHz in greyscale (GS) and 8.0 MHz in power doppler (PD). The exams were performed in a room with temperature between 22°C and 26°C, after a 10 minutes rest period. Patients were seated, with hands and fingers in a neutral position over the table. The nails were scanned on a longitudinal plane. The 2nd and 3rd fingernails of both hands were examined. Through GS, the following characteristics were assessed: 1) the trilaminar appearance of the nail plate (NP), that was classified according to Wortsman characterization of changes on psoriatic nails (I – IV), 2) the nail plate thickness (NPT), 3) the nail bed thickness (NBT), and 4) the nail matrix thickness (NMT). The signal of PD in the nail matrix and in the nail bed were evaluated together and classified according to Guitierrez et al.’s score (1-3). Comparisons between independent means were analyzed using ANOVA or Kruskal-Wallis test. The association between categorical variables was calculated by chi-squared test or Fisher’s exact test.

Results: In the trilaminar structure (TS) evaluation, 137(99.3%) of the nails from control group had no change in the TS; for PsO group, 32 of the analyzed nails presented TS alterations, as follows: 9 type I, 5 type II, 7 type III and 11 type IV. For PsA group, there were also 32 of the analyzed nails that presented TS changes; 4 type I, 15 type II, 9 type III and 4 type IV. The mean NPTs SD (mm) was higher on both PsA and PsO groups when compared to the control group: 0.73 ±0.14 and 0.72 ±0.15 vs.0.67±0.10 (p=0.001), respectively. NBT and NMT means did not differ among groups. There was also no statistical difference between groups regarding the degree of nail PD, as well as no difference in the grayscale and PD evaluated parameters between PsA/PsO nails both with or without clinical involvement.

Conclusion: Alterations of the trilaminar structure of the NP and the NPT showed differentiation between psoriatic nails and the control group, but no differentiation between PsO and PsA nails. PD, NMT and NBT means also had no differences between groups. Studies with larger sample sizes are necessary to clarify the utility of these parameters in the evaluation of psoriatic patients.

FR10424 DIFFERENCES AND SIMILARITIES ACCORDING TO GENDER IN PATIENTS WITH PSORIATIC ARTHRITIS INITIATING BIOLOGICAL THERAPY

Diego Benavent, Chamsida Plasencia, Victoria Navarro-Compán, Laura Nuño, Irene Morio, Carolina Tomiero, Patricia Bogas, Juan Molina Collada, Alejandro Balsa. Hospital Universitario La Paz, Madrid, Spain

Background: The evolution of the disease is heterogeneous among patients with psoriatic arthritis (PsA). Specifically, the influence of gender on the disease outcomes (and the need of a more intensive treatment) has been pointed. However, data regarding this are scarce.

Objectives: to analyse the disease profile in male and female patients with PsA starting biological treatment.

Methods: Data from an observational prospective cohort including all patients with PsA initiating biological therapy from 2002-2018 in a university hospital was conducted. Demographic information, laboratory tests, disease presentation (axial presentation, including oligoarticular affection, and poviarticular presentation), disease activity indexes (ASDAS and DAPSA for axial and peripheral-only presentations, respectively) and concomitant treatment were collected before starting biological drug. Patients were stratified by gender to compare the characteristics of the populations. Chi-squared for categorical and t-student tests for continuous variables were used to analyse the differences between groups.

Results: Out of 109 included patients, 55 (51%) were males and 54 (49%) females. Baseline gender-stratified characteristics are shown in Table 1. Including the whole population of the study, mean age at diagnosis was 57 ± 14.6 years, mean PsA duration was 17.7 ± 9.2 years, and mean Body Mass Index (BMI) was 27.2 ± 4.9. Axial or oligoarticular presentation was shown in 57 patients (52%), whereas 52 patients (48%) had poviarticular manifestations. Mean baseline ASDAS was 3.2 ± 1.0 and mean baseline DAPSA was 25.4 ± 13.6. Biological therapies initiated included etanercept in 42% of the cases, infliximab in 25%, adalimumab in 19%, golimumab in 7% and secukinumab in 6%. No significant differences were observed between genders for most of the characteristics including age at starting biological, disease duration, BMI, smoking habit, positive HLA B27 and rheumatoid factor, baseline activity, baseline ESR, baseline CRP, baseline sulsalazine (SSZ), baseline prednisone (PRD), baseline patient global assessment and biological drug use. However, there were substantial differences between gender in some other characteristics. While males had more frequently a predominant axial disease (p<0.01), females more frequently presented a poviarticular disease (p=0.02) and received methotrexate more frequently (p<0.02). These differences in methotrexate use might be explained by the predominance of peripheral presentation in female patients.

Conclusion: In clinical practice, biological therapy (TNFi and IL-17i) is prescribed in a similar frequency in male and female patients with PsA. Nevertheless, the predominant articular manifestation behind the prescription of the biological therapy is different among genders: while men have predominant axial disease, women have predominant peripheral manifestations. These differences in clinical presentation in both genders may contribute to differences in therapeutic management, such as increased use of methotrexate in women with PsA who initiate biological therapy.

Table 1. Gender-stratified characteristics at the visit starting the biological therapy. Results are shown as mean (standard deviation) or absolute number (percentage).

LITERATURE REVIEW OF PATIENT PERSPECTIVES ON THE MANAGEMENT AND TREATMENT OF PSORIATIC ARTHRITIS

Annelies Boonen1, Neil Betteridge2, Andreas Pinter3, Colleen McHorney4, Catherine Reed5, Maastricht University, Maastricht, Netherlands; 2Ned Betteridge Associates, London, London, United Kingdom; 3University Hospital Frankfurt, Frankfurt, Germany; 4Eli Lilly, Windlesham, United Kingdom; 5Evidera, London, United Kingdom; 6Evidera, Bethesda, United States of America

Background: A patient-centred approach to the management and drug treatment of psoriatic arthritis (PsA) has been advocated by a multidisciplinary group of experts to improve skin and joint symptoms and health-related quality of life (HRQoL).

Objectives: To examine perspectives of patients with PsA on: (1) disease management and treatment goals, (2) disease management and treatment satisfaction, and (3) treatment adherence, including reasons for discontinuation. Areas of interest were those related to medication, symptom resolution, everyday living and overall HRQoL.

Methods: A targeted literature review was conducted to identify peer-reviewed literature on patient experience with PsA management and drug treatment. English-language articles published between 1 January 2010–6 October 2018 reporting qualitative or quantitative evidence from cross-sectional or longitudinal observational studies were identified from searches conducted using MEDLINE (via PubMed) and Embase. Selection criteria included adult patients with PsA (self-reported or clinician-diagnosed); drug-treatment studies could consider only regulatory-approved treatments for PsA and other studies had to provide evidence of patient perspectives on disease management and treatment goals, experiences and/or satisfaction. Studies involving paediatric/adolescent populations were excluded, as were results for PsA not distinguishable from other diseases.

Results: The literature search identified 266 titles, of which 48 duplicates were removed. The remaining 218 abstracts were screened: 58 full-text articles were assessed for eligibility and 16 articles were selected for full-text review. Of these 16 articles, 9 were primarily related to patient perspective on disease management, 6 to patient satisfaction and 1 to treatment adherence; some articles covered more than one of these objectives. None of the articles studied whether explicit consideration of treatment goals from the patient perspective would influence management or outcome of care. Symptom resolution, reduced fatigue, improved sexual relations, improved HRQoL and ability to participate in daily activities were consistently identified by patients as important aspects for disease management and daily living with PsA. Articles on patient satisfaction focused largely on general satisfaction with medication rather than satisfaction specifically with holistic PsA management. Notwithstanding, symptom resolution was clearly linked to greater patient satisfaction with medication. Patient dissatisfaction with PsA treatment was influenced by their attitude towards treatment, concerns about PsA medication, the physician-patient relationship and lack of patient involvement in decision-making. Treatment adherence has not been widely explored but mainly relates to perceptions about, and experiences with, medications, including efficacy and adverse events.

Conclusion: This literature review identified a lack of research on patient perspectives of PsA management and treatment goals. It also highlighted the lack of patient involvement in determining management and/or setting personal goals, which may ultimately affect satisfaction. There remains a lack of clarity on PsA symptoms and other disease- or patient-related parameters that impact patient satisfaction/dissatisfaction and patient-centred reasons for treatment discontinuation. The findings of this review will be used to develop a PsA patient survey to further explore patient perspectives to improve care in PsA.

IXEKIZUMAB MAKES REMISSION AND LOW DISEASE ACTIVITY POSSIBLE IN PATIENTS WITH PSORIATIC ARTHRITIS: TWO-YEAR RESULTS IN TNF INADEQUATE RESPONDERS OR BIOLOGIC-NAIVE PATIENTS

Laura C. Coste1, Alexis Ogdie2, Prashanth Sunkureddy3, Lisa Kerr4, Matthew Hulford5, Philip Hettwell6, 7University of Oxford, Oxford, United Kingdom; 2Penn Medicine, Philadelphia, United States of America; 3Clear Lake Rheumatology, League City, United States of America; 4Eli Lilly and Company, Indianapolis, United States of America; 5Univ of Leeds, School of Medicine, Leeds, United Kingdom

Background: Psoriatic arthritis (PsA) is a heterogeneous inflammatory disease that can involve peripheral and axial joints, skin, and entheses. A number of validated composite indices have been developed, not only to measure overall disease activity for PsA, but also to provide thresholds for treat-to-target goals. These include MDA (Minimal Disease Activity), DAPSA (Disease Activity in PsA), and PASDAS (PsA Disease Activity Score). We have previously demonstrated that higher proportions of PsA patients treated with ixekizumab (IXE), a monoclonal antibody that selectively targets interleukin-17A, achieved therapeutic thresholds defined by MDA, DAPSA, and PASDAS versus placebo (PBO) up to Week 24.

Objectives: To explore the extent to which IXE can help biologic-naive or tumor necrosis factor inhibitor (TNFi) inadequate responder patients achieve treat-to-target goals, as defined by composite indices incorporating multiple disease domains, through 108 weeks of treatment.

Methods: Data were analyzed from all patients initially randomized to 80 mg IXE every 4 weeks after a 160-mg starting dose in 2 double-blind, PBO-controlled phase III trials investigating the efficacy and safety of IXE. For SPIRIT-P1 (NCT01695239), patients (N=107) were bDMARD naïve. For SPIRIT-P2 (NCT02349295), patients (N=122) had an inadequate response or were intolerant to TNFis. The following composite measures and definitions were used: MDA and Very Low Disease Activity (VLDIA) (see Figure); DAPSA Low Disease Activity (LDA) (<14 and >4) and remission (<4); PASDAS LDA/VLDA (<3.2≤c≤1.9); and GRACE (GRAppa Composite score) LDA (≤2.3), Modified nonresponder imputation (mNRI; missing data treated as nonresponse for patients discontinued due to lack of efficacy or adverse events; multiple imputation for all other missing data) was used for all analyses.

Results: Therapeutic threshold results at Week 108 are summarized in the Figure. Whether measured using MDA, DAPSA, PASDAS, or GRACE, the proportions of IXE-treated patients achieving designated therapeutic thresholds were sustained through 2 years of treatment. Efficacy was similar between SPIRIT-P1 and SPIRIT-P2.

Conclusion: High proportions of IXE-treated patients, whether biologic naïve or TNFi inadequate responders, achieved treat-to-target goals, as defined by composite indices incorporating multiple disease domains, through 2 years of treatment.

Gemelli IRCCS, Department of Psychology, Rome, Italy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Department of Rheumatology, Rome, Italy

Background: Depression is one of the most common comorbidities in patients with Psoriatic Arthritis (PsA) but risk factors for mood disorders in these patients are still largely unrecognized. Pre-inflammatory cytokines involved in the pathogenesis of PsA have been also associated with depressive symptoms in patients without systemic autoimmune diseases.

Objectives: The aim of this study is to determine risk factors for depressive symptoms and compare serum cytokines concentrations in subjects with and without depressive symptoms in a court of PsA patients.

Methods: Eighty consecutive patients with PsA were screened for depressive symptoms with depression subscale of the Hospital Anxiety and Depression Scale (HADS-D). A validated cut-off of 8 was used to define patients with significant depressive mood. Patients with and without depressive symptoms were compared for the prevalence of general risk factors for depression, comorbidity, psoriatic disease age of onset, duration, activity and domains affected, treatment and serum levels of IL-6, TNF-α and IL-17A.

Results: Mean disease duration of skin disease and articular disease was 18.8 ± 15.3 years and 9.0 ± 11.1 years, respectively. All patients had a history of peripheral arthritis, 41.3% had dactylitis, 38.8% had enthesitis, 21.3% had spondylitis 82.5% had a psoriatic skin disease and 51.2% had psoriatic nail disease. According to DAPSA index, 20.0% were in remission, 50.0% in Low Disease Activity, 20.0% in Moderate Disease Activity and 10.0% in High Disease Activity. Thirty-five (43.8%) were in Minimal Disease Activity. Thirty-three patients (41.3%) had depressive symptoms according to HADS. Patients with and without depressive symptoms did not differ in terms of age, gender, comorbidity, general risk factors of depression, psoriatic disease age of onset, duration, domains affected, DAPSA activity, MDA achievement, PASI, HAQ, VAS pain, the intensity of treatment, serum TNF-α, IL-17A and IL-23. Serum levels of IL-6 were higher in patients with depressive symptoms. A cut-off of 2.27 pg/ml of serum IL-6 had the best ability to predict a HADS-D score using the higher Youden Index of the ROC curve (AUC = 0.682; p = 0.006). Multivariate logistic regression analysis revealed that serum IL-6 > 2.27 pg/ml was a predictor of depressive symptoms even when adjusted for DAPSA, HAQ and PASI (OR = 3.06; CI 1.14-8.20; p = 0.026).

Conclusion: Higher serum IL-6 is associated with depressive symptoms independently from articular and cutaneous disease activity and degree of disability. This association suggest a direct role of systemic inflammation in the modulation of mood in PsA patients.

Disclosure of Interests: Enrico De Lorenzi: None declared, Gerlando Natalello: None declared, Darío Bruno: None declared, Giacomo Tanti: None declared, Giovanni Battista Canestrari: None declared, Maria Rosaria Magurano: None declared, Clara Di Mario: None declared, Barbara Toluso: None declared, Glisy Peluso: None declared, Elisia Gremese Consultant for: AbbVie, BMS, Celgene, Janssen, Lilly, MSD, Novartis, Sanofi, Los Santos Ramirez, Pfizer, Speakers bureau: BMS, Speakers bureau: Roche, Speakers bureau: AbbVie, BMS, Celgene, Janssen, Lilly, MSD, Novartis, Sanofi, UCB, Roche, and Pfizer

Background: Psoriatic disease (PsD) refers to a systemic condition, probably driven by chronic and complex inflammatory mechanisms. PsD patients experience a fickle mixture of cutaneous (nail dystrophy, psoriatic lesions, seborrheic and musculoskeletal (MSK: arthritis, enthesitis, dactylitis, spondylitis)) inflammatory features, variously associated with other co-morbidities (ocular or bowel inflammatory disease, increased cardiovascular risk and metabolic syndrome). Current evidence is limited in respect of the management of early, treatment-naïve PsD.

Objectives: To assess the literature with a focus on pharmacological interventions in early, treatment-naïve PsD.

Methods: Seven research questions were formulated according to the PICO approach: are interventions effective in obtaining control of overall PsD activity? Are interventions effective on peripheral arthritis? Are interventions effective on dactylitis? On enthesis? On skin and nails? Criteria for including records were: adult human participants; participants with cutaneous features of PsD; participants with MSK features of PsD; double blind, single blind and non-blinded RCTs, well-designed prospective studies/surveys. The search protocol was registered on PROSPERO [1], the search was performed between June 2018 and January 2019.

Results: Resources available were widely explored (4 databases, 5 trial registers, 5 conference archives; see figure). The search retrieved 156,348 references (publication range 1946–2019) of which 308 (0.2%) qualified for full-text-assessment (FTA, figure); 7 (0.004%) fulfilled the selection criteria and only 4 underwent data extraction.

Meta-analysis was impossible due to data heterogeneity (disease classification criteria, outcome measures and intervention durations). Although no clinical study adopted comprehensive composite indexes as primary outcome measures, 40% of FTA references described more than one component of PsD (i.e.: cutaneous and MSK) at least within the baseline characteristics. A substantial proportion of FTA references did describe, among participants recruited, many who were early untreated PsD at baseline. Unfortunately, separate analyses were not possible due to unavailability of the original dataset. A subset (10%) of the FTA references did describe, among participants recruited, many who were early untreated PsD at baseline. Unfortunately, separate analyses were not possible due to unavailability of the original dataset. A substantial proportion of FTA references did describe, among participants recruited, many who were early untreated PsD at baseline. Unfortunately, separate analyses were not possible due to unavailability of the original dataset. A substantial proportion of FTA references did describe, among participants recruited, many who were early untreated PsD at baseline. Unfortunately, separate analyses were not possible due to unavailability of the original dataset.

Conclusion: Few studies addressed early, treatment naïve PsD. The underrepresentation of such data may be related to trial-enrolment criteria. More studies are needed to investigate this identified unmet need.

EFFECT OF PHOSPHODIESTERASE 4 INHIBITION WITH APREMILAST ON BODY WEIGHT AND VASCULAR FUNCTION IN PSORIATIC ARTHRITIS – INITIAL RESULTS FROM THE IMMUNE METABOLIC ASSOCIATIONS IN PSORIATIC ARTHRITIS (IMAPA) STUDY

Lyn D. Ferguson1, Paul Welsh1, Naveed Sattar1, Iain McInnes2, Stefan Siebert2.
1University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; 2University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom

Background: Psoriatic arthritis (PsA) is associated with obesity and increased cardiometabolic risk. Weight loss is associated with improved disease activity and has been noted with the phosphodiesterase 4 (PDE4) inhibitor apremilast.

Objectives: To investigate the effects of PDE4 inhibition with apremilast on body weight, vascular function and disease activity in psoriatic disease.

Methods: The Immune Metabolic Associations in Psoriatic Arthritis (IMAPA) study is a prospective, open label study of adults receiving apremilast 30mg BD as part of routine care for psoriasis and/or PsA. Cardiometabolic, anthropometric, and disease activity assessments were performed at baseline, months 1, 3, and 6. A subgroup underwent endothelial function assessment by Endo-PAT at baseline and month 3. Repeated measures mixed models were used to compare changes in body weight, waist circumference, systolic & diastolic BP, reactive hyperaemia index (RHI), and disease activity markers with apremilast.

Results: 53 participants were recruited; mean age (SD) 52 (13) years, 72% female. 10% (5/53) lost ≥5% body weight. Statistically significant improvements in 66/68 joint count, DAS28-ESR, PtGA, PGA, pain-VAS, LEI, and ESR were seen at month 6. There was no statistically significant change in RHI, SBP, or DBP (table 1). Weight change showed no statistically significant correlation with change in joint or skin disease activity markers.

Conclusion: Apremilast was associated with modest weight loss and reduced disease activity over 6 months. There did not appear to be any significant alteration in endothelial function, however this was assessed in relatively small numbers and many patients had baseline results within normal range. Improvements in disease activity with apremilast appear largely independent of weight change in this cohort.

Background: Evaluating psoriatic arthritis (PsA)-related enthesis is diagnostically and therapeutically essential, but may be very complex due to the wide range of signs and symptoms that partly overlap or coexist with the clinical features of fibromyalgia (FM) [1,2].

Objectives: The primary aim was to compute the prevalence of clinical and ultrasonographic signs of enthesitis in patients with PsA, FM or both. The secondary aim was to assess the impact of FM on disease activity and clinical scores.

Methods: This single-centre, observational cross-sectional study involved 103 consenting patients: 39 with PsA (CASPAR criteria), 23 with FM (2016 criteria), and 41 with both. Standard PsA and FM clinical, laboratory and, and clinical data were recorded. Disease activity in PsA and PsA-FM patients was assessed using BASDAI and ASDAS. The entheses were assessed using LEI and MASES score. All of the patients under- went B-mode (grey scale) ultrasonography, the US findings were scored using the GUESS.

Results: The mean age of the patients was 53.6 years, SD ± 9.47. Females accounted for 64.1% of the PsA patients (disease duration 9.13 years, SD ± 6.9), 95.6% of FM patients (disease duration 5.09 years, SD ± 3.6), and 92.3% of the patients with PsA-FM (disease duration 7.9 years, SD ± 5.5). There were no-between group differences in the patients’ BMI. None of the FM subjects reported any personal or family history of psoriasis. The mean BASDAI was 3.6 ± 3.1 in the PsA group, and 1.2 ± 4.45 in the PsA-FM group. The median BASDAI was significantly higher in PsA-FM than in PsA patients (p=0.001), with no statistically significant difference between FM and PsA-FM groups (6 [IQR 2] vs 7 [IQR 3]; p=0.737). The median LEI was significantly higher in FM or PsA-FM patients (p<0.001), with no statistically significant difference between these two groups (6 [IQR 2] vs 7 [IQR 3]; p=0.658). The median GUESS was significantly higher in PsA vs FM group (9 [IQR 7.5] vs 3 [IQR 2]; p<0.001), and in PsA-FM vs FM group (8 [IQR 4.5] vs 3 [IQR 2]; p<0.001). No statistically significant difference was found between PsA and PsA-FM group (9 [IQR 7.5] vs 8 [IQR 4.5]; p=0.12). No statistically significant Spearman correlation coefficient (rho) was found between GUESS and BASDAI/LEI in any of the groups. There was a correlation between GUESS scores and disease duration in PsA (rho=-0.37; p=0.019, 95% CI 0.10-0.61) or PsA-FM (rho=0.38; p=0.016, 95% CI 0.19-0.61), but not in the FM group, and GUESS scores correlated with BMI (rho=0.2; p=0.05, 95% CI 0.00-0.37) and dyslipidemia (rho=0.34; p=0.006, 95% CI 0.11-0.58) in all groups.

Conclusion: The use of a clinical examination and ultrasonic scores alone may overestimate active enthesitis in FM patients. As US was more frequently positive in patients with PsA and PsA-FM than in those with FM, it may be useful in differentiating pain due to enthesitis from enthesial pain due to FM.

10). SEC was used by 18% (n=19), and MTX by 42% (n=43, 25% sc, 13% oral, 4% unknown), respectively. Eighty percent had a combination therapy of MTX and SEC. Twenty-seven percent used GC and/or other biologics/conventional disease modifying antirheumatic drugs (DMARDs). Mean glucocorticoid cumulative dose (GCCD) was 12 ± 22.0 g. Patients with SEC showed a significantly longer disease duration (median: 24 years vs. 13 years) compared to MTX, but showed no other differences in baseline-characteristics or risk factors. T-Scores of both femora were significantly lower in the MTX versus the SEC group. We could not find significant differences between these groups with regard to physical activity, back pain, movement restriction, fracture rates or GCCD. Twenty-five percent of the MTX users and 27% of the patients in the SEC group additionally had GC while; in contrast to no patient in the combination group.

Conclusion: The prevalence of osteoporosis in patients with PSO or PSEA was found to be as high as in the normal population. However, there was a high frequency of peripheral fragility, but not vertebral fractures. Patients with PSO or PSEA patients treated with SEC had a longer disease duration and lower hip BMD, but showed no differences in back pain, physical activity or movement restrictions compared to MTX users.

THE RELATIONSHIP BETWEEN SYMPTOMS OF AUTONOMIC DYSFUNCTION AND CARDIOVASCULAR DISEASE IN PATIENTS WITH PLAQUE PSORIASIS

Halise Hande Gezer, Didem Erdem, Mehmet Tuncay Duruöz. Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Rheumatology Division, Istanbul, Turkey

Background: The incidence of cardiovascular disease (CVD), diabetes mellitus, metabolic syndrome and subclinical atherosclerosis is markedly increased in patients with psoriatic arthritis (PsA). The autonomic nervous system is the visceral nervous system of the body consisting of two parts; sympathetic and parasympathetic. Patients with PsA have predominantly parasympathetic involvement autonomic nervous system.

Objectives: The aim of this study was to evaluate the symptoms of autonomic dysfunction and their relationship with cardiovascular involvement and other clinic parameters in patients with PsA.

Methods: The study included patients diagnosed with PsA according to the CASPAP criteria. For evaluation of cardiovascular involvement, body mass index (BMI), abdominal obesity, hypertension (HT), diabetes mellitus (DM), hyperlipidemia (HL), metabolic syndrome, fasting glucose levels, lipid levels, systolic and diastolic blood pressures (SBP-DBP) were assessed. DAPSA (Disease Activity in Psoriatic Arthritis), BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), Leeds enthesis index, Psoriasis Area Severity Index (PASI), Psoriatic Arthritis Quality of Life (PsAQoL) and Health Assessment Questionnaire (HAQ) were used to assess patients clinical situations. The Composite Autonomic Symptom Score (COMPASS-31) (range:0-100) consisting of 6 subdivisions including orthostatic, vasomotor, secretomotor, gastrointestinal (GIS), bladder and pupilomotor was used for the symptomatics of autonomic dysfunction. The Mann-Whitney U-test, student’s t-test and Spearman’s correlation coefficient were used for statistical analysis. P<0.05 was considered statistically significant.

Results: A total of 64 subjects (43 female, 21 male) with a mean of age 49 years (SD:12.3) and disease duration of 59 months (SD:71.3) were recruited into the study. The patients had HT (23.4%), DM (17.2%), abdominal obesity (62.5%), metabolic syndrome (45.3%) and dyslipidemia (42.2%). The mean total COMPASS-31 score was 19.7 (SD:8.3). There was no significant difference in COMPASS-31 scores in patients with or without HT, DM, dyslipidemia. Bladder scores were significantly higher in patients with abdominal obesity and metabolic syndrome (p<0.05). GIS and pupilomotor scores were significantly higher in patients with enthesis (p<0.05). Significant correlations were found between: LDL and bladder (r=0.392), cumulative doses and GIS (r=0.300), pupilomotor (r=0.365) scores; DAPSA and total COMPASS-31 (r=0.310), secretomotor (r=0.359) scores; BASDAI and total COMPASS-31 (r=0.483), GIS (r=0.327), secretomotor (r=0.309), pupilomotor (r=0.302) scores; fatigue and total COMPASS-31 (r=0.503), GIS (r=0.577), pupilomotor (r=0.302) scores; HAQ and total COMPASS-31 (r=0.476), orthostatic (r=0.388), bladder (r=0.371) scores; PsAQoL and total COMPASS-31 (r=0.601), orthostatic (r=0.549), secretomotor (r=0.414), pupillo (r=0.380) scores.

Conclusion: The total score of COMPASS-31 and its subdivisions were high in PsA patients as compared with literature data on healthy subjects. The symptoms of autonomic dysfunction were increased in PsA patients. Disease activity, functional impairment, fatigue, LDL and quality of life are associated with autonomic dysfunction. Autonomic symptoms improve with disease control.

THE INFLUENCE OF BASELINE DEMOGRAPHICS AND DISEASE CHARACTERISTICS ON Efficacy of AN ORAL, SELECTIVE TYK2 INHIBITOR, BMS-986165, IN PATIENTS WITH PLAQUE Psoriasis in a Phase 2 TRIAL

Kenneth Gordon1, Kim Papp2, Melinda Gooderham2, Diamant Thaçi2, Peter Fidey2, Alcimich Morita3, Sudweep Kunda3, Renata Kilia3, Andrew Napoli3, Subhashis Banerjee1, Medical College of Wisconsin, Milwaukee, United States of America; K Papa Clinical Research and Proby Medical Research, Waterboro, Canada, SKIN Centre for Dermatology, Queen’s University and Proby Medical Research, Peterborough, Canada; University of Lübeck, Lübeck, Germany, The University of Melbourne, St Vincent’s Hospital Melbourne and Proby Medical Research, Skin and Cancer Foundation Inc, Melbourne, Australia, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; Bristol-Myers Squibb, Princeton, United States of America

Background: BMS-986165 is an oral, selective inhibitor of tyrosine kinase activity of Tyk2 (pseudokinase), an enzyme that acts as a transcription (STAT)-dependent cytokine signalling pathways involved in the pathophysiology of psoriasis (PsO). In a 12-week, Phase 2 trial of BMS-986165 in patients with moderate to severe plaque PsO, including those with baseline (BL) musculoskeletal symptoms, Psoriasis Area and Severity Index (PASI) 75 responses (primary endpoint) were highest at doses ≥3 mg twice daily (BID; 67–75%) vs placebo (7%; P<0.001), with a favourable safety profile.

Objectives: To evaluate the influence of BL demographics (weight, body mass index, age) and disease characteristics (age of onset, presence of musculoskeletal symptoms, disease duration, previous biologic use, PASI score, static Physician Global Assessment [sPGA] score, Dermatology Life Quality Index [DLQI] score) on Week 12 efficacy for the 3 most effective doses of BMS-986165 (3 mg BID, 6 mg BID, and 12 mg once daily [QD]) in the trial.

Methods: Adults with moderate to severe plaque PsO (body surface area [BSA] ≥10%; PASI score ≥12, sPGA score ≥3) were randomised equally to 1 of 5 oral doses of BMS-986165 (3 mg every other day, 3 mg QD, 4 mg BID, 6 mg BID, 12 mg QD) or placebo for 12 weeks.

Results: A total of 267 patients were treated; subgroup analyses based on BL characteristics are reported for patients treated with the most effective doses of BMS-986165 (≥3 mg BID; n=134). BMS- 986165 showed no meaningful differences in efficacy among almost all of the 3 subgroups, including age of onset, presence of muscu- loskeletal symptoms, and disease duration (Table), with some varia- bility across subgroups. Small patient numbers may underlie observed fluctuations in results. Similar consistency in responses was seen regardless of BL age (18–45 years, n=66; ≥45 years, n=68), weight

Background: The link between reaching a state of remission or LDA and patient-reported outcomes in PsA has been little explored in an observational setting.

Objectives: This analysis investigates the potential effect of reaching remission or LDA according to cDAPSA and achievement of VLDA/MDA on patient-reported outcomes such as HRQoL, functioning and pain in an observational cohort of PsA patients.

Methods: PsABoI (NCT026027278) is an ongoing real-world observational study in 8 European countries where PsA patients receive 1st-, 2nd- or 3rd-line biologics (starting either ustekinumab [UST] or a TNFi). Of 563 UST- or TNFi-treated patients enrolled Dec 2015 – Aug 2017, 303 had data available from their 6-month follow-up. Disease states were defined using cDAPSA ≤4 for remission and ≥13 for LDA (data available for 250 patients) and VLDA 7/7 and MDA 5/7 criteria (data available for 206 and 260 patients, respectively). HRQoL was assessed by the generic instrument EQ5D and the PsA specific tool PsAID-12. Physical functioning was measured by the HAQ-DI and pain with a Pain VAS (0–100).

Results: For the 303 patients, mean age was 49.7 (standard deviation [SD] 12.8) years, mean disease duration was 7.2 (SD, 8.2) years, and 50.5% were women. Figure 1 shows data at 6 months for cDAPSA remission, cDAPSA LDA, VLDA, and MDA in UST- and TNFi-treated patients. Start of treatment with either UST or TNFi did not significantly influence the rates of these outcomes at 6 months. cDAPSA remission/LDA and VLDA/MDA achievement (yes vs no) was associated with better general and disease-specific HRQoL assessments, (EQ5D VAS, PsAID-12) physical function (HAQ-DI) and Pain (VAS) shown by non-overlapping confidence intervals in Figure 2.

Conclusion: In real-life, treatment with either UST or a TNFi leads to considerable and comparable numbers of patients reaching LDA or remission. Reaching such LDA is associated with clinically important improvements exceeding minimal clinically important differences for QoL, functioning and pain experience. Our data therefore strongly support a treat-to-target strategy in routine care for PsA.

Background: In psoriatic arthritis (PsA), disease fluctuations lead to periods of flares which impact patients’ lives and treatment retention, these flares have been little studied.

Disclosure of Interests: This study was sponsored by Janssen

Acknowledgement: This study was sponsored by Janssen

Results: For the 303 patients, mean age was 49.7 (standard deviation [SD] 12.8) years, mean disease duration was 7.2 (SD, 8.2) years, and 50.5% were women. Reaching such LDA is associated with clinically important improvements exceeding minimal clinically important differences for QoL, functioning and pain experience. Our data therefore strongly support a treat-to-target strategy in routine care for PsA.
Objectives: To explore the frequency of flares in patients with PsA, and to assess the validity of patient-defined flares against PsA disease activity.

Methods: ReFlap (NCT03119805, ref) was a longitudinal study in 14 countries of consecutive adult patients with definite PsA, aged more than 2 years of disease duration. Patients were seen twice in the context of usual care, around 4 months apart. The proportion of flares was computed at the second visit according to a patient-reported question: “At this time, are you having a flare of your psoriatic arthritis, if this means the symptoms are worse than usual?” and a symmetrical physician question. These definitions were compared with a change in disease activity defined as transition to a more active disease category based on the Disease Activity in Psoriatic Arthritis (DAPSA) categories. Agreement was calculated using prevalence-adjusted kappas. Validity of patient-reported flares was assessed by comparing patients who flared with patients who did not flare at the second visit using clinical and patient-reported variables. Finally, for patients flaring, effect sizes corresponding to a patient transition to flare state were calculated by standardized response means (SRMs) for continuous outcomes, with p values based on McNemar test or rank signed test. There was no imputation of missing data.

Results: Overall, 222 patients were analysed: 127 (58.8%) were male, mean age was 53 ± 12.3 years, mean disease duration was 10.8 ± 8.3 years of disease duration. Patients were seen twice in the context of usual care, around 4 months apart. The proportion of flares was computed at the second visit according to a patient-reported question: “At this time, are you having a flare of your psoriatic arthritis, if this means the symptoms are worse than usual?” and a symmetrical physician question. PERCEIVED INFLUENCE OF HEALTH STATUS ON SEXUAL ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS IS ASSOCIATED WITH MUSCULOSKELETAL MANIFESTATIONS BUT NOT WITH PSORIASIS SKIN MANIFESTATIONS

Glenn Haugeberg1, Brigitte Michelsen1, Arthur Kavanaugh2, 3

Background: Psoriatic arthritis (PsA) is a heterogeneous disease involving multiple domains including the musculoskeletal system and the skin. The disease may have a significant impact on various aspects of quality of life including sexuality.

Objectives: To explore the prevalence of self-reported problems with sexual activity in patients with PsA, and any associations with demographic and disease related variables as well as treatment.

Methods: PsA patients were consecutively recruited from a Norwegian rheumatology outpatient clinic. Data collection included information on demographics, measures of PsA disease activity (both skin and musculoskeletal manifestations), patient reported outcome measures and treatment. The perceived effect of health status on sexual activity was assessed using question 15 in the Health Related Quality of Life (HRQoL) instrument 15D. The question reads: My state of health: 1. Has no adverse effect on my sexual activity. 2. Has a slight effect on my sexual activity. 3. Has a considerable effect on my sexual activity. 4. Makes sexual activity almost impossible. 5. Makes sexual activity impossible. For analytical purposes the answers were dichotomized into “no/little negative effect (answers 1 and 2)” and “large negative effect (answers 3-5). For group comparisons we used Chi-square test for categorical variables and student t-test for continuous variables. Adjusted logistic regression models were also applied.

Results: Among the 135 PsA patients assessed mean (SD) age was 52.1 (10.2) years and 51.1% were men. The majority of patients (111 patients, 82.2%) reported their state of health to have no/little effect on sexual activity, this also when adjusting for age and sex.

Conclusion: Approximately 20% of the PsA patients reported their health status to have a large negative effect on their sexual activity. Only disease duration and measures reflecting musculoskeletal disease were found to have a negative effect on sexual activity among PsA patients; skin psoriasis did not have an impact.

Disclosure of Interests: Daha D. Gladman1, Philip Heilemann2, Atul Deodhar3, Alice B. Gottlieb4, Dafna D. Gladman1, Henning Boehncke5, Xie L. Xu6, Stephen Xu7, Elizabeth C. Hsia6,7, 8.

Background: Psoriatic Arthritis Disease Activity Score (PASDAS), GRAppa Composite score (GRADE) index, modified Composite Psoriatic Disease Activity Index (mCPDAI), and Disease Activity Index for Psoriatic Arthritis (DAPSA) are composite indices recently developed to assess disease activity in psoriatic arthritis (PsA).

Objectives: The effect of guselkumab (GUS) on these indices was evaluated in a phase 2 study in patients with active psoriatic arthritis.

Methods: Patients with ≥3 tender and ≥3 swollen joints, C-reactive protein ≥3 mg/L, and ≥3% body surface area (BSA) of plaque psoriasis despite treatment were randomized 2:1 to receive GUS 100 mg subcutaneously (N=100) or placebo (PBO, N=49) at Weeks 0, 4, and every 8 weeks thereafter through Week44. At Week16, patients with <5% improvement in both swollen and tender joint counts were eligible for early escape (EE) to open-label ustekinumab. All remaining PBO patients crossed-over to receive GUS 100 mg at Weeks 24, 28, 36, and 44 (PBO→GUS). The PsA composite indices through Week24 were analyzed using last-observation-carried-forward for missing data and data post EE. After Week24, observed data were used. Missing baseline data were excluded in the analyses.

Results: Baseline PASDAS, GRACE, mCPDAI, and DAPSA showed moderate to high disease activity (mean (SD): 6.53 (1.079), 6.08 (1.208), 7.6 (2.15), and 46.65 (20.391), respectively), and were generally comparable between PBO and GUS. At Week24, GUS significantly decreased PASDAS, GRACE, mCPDAI, and DAPSA scores (mean (SD) change from baseline: -2.50 (1.59), -2.73 (1.76), -3.8 (2.72),
-23.08 (20.21), respectively) vs PBO (mean (SD) change from baseline: -0.49 (1.33), -0.35 (1.39), -0.8 (2.16), -4.97 (20.11), respectively, all p<0.001). Significantly more GUS-treated patients achieved a low or very low disease activity state defined by PASDAS, GRACE, and mCPDAI (35.0%, 29.6%, and 45.9%, respectively) vs PBO (41.1%, 21.1%, and 10.4%, respectively, all p<0.001). In addition, 12% of GUS- vs 0% of PBO-treated patients achieved DAPSA remission (p<0.01). Post Week24, improvements in PASDAS, GRACE, mCPDAI, and DAPSA were also observed in PBO–GUS patients (39.9%, 39.3%, 71.4%, and 50.0% achieved disease activity states of low, very low, or remission at Week 44), and were maintained through Week44 in GUS patients (45.8%, 42.2%, 62.7%, and 51.1% achieved disease activity states of low, very low, or remission, respectively).

Conclusion: GUS demonstrated consistent improvements based on all PsA composite indices evaluated, and efficacy was maintained through Week44.

FR0441 EFFECTIVENESS OF YTTRIUM KNEE SYNOVECTOMY IN PSORIATIC OR SERONEGATIVE ARTHRITIS WHO HAVE FAILED CONVENTIONAL THERAPY

Mark Hoey, Victoria Mc Dowell, Adrian Pendleton. Musgrave Park Hospital, Rheumatology, Belfast, United Kingdom

Background: Radiation synovectomy with Yttrium 90Y is indicated for refractory arthritis of various aetiologies e.g. inflammatory joint diseases such as rheumatoid arthritis, seronegative arthritids such as psoriatic arthritis and reactive arthritis, Haemophilic arthritis, Calcium pyrophosphate dihydrate (CPPD) arthritis and pigmented villonodular synovitis (PVNS). 1 Treatment of inflammatory arthritis has improved due to more effective therapy and earlier treatment therefore Yttrium therapy is less commonly used.

Objectives: To assess the response to Yttrium 90Y synovectomy in patients with Psoriatic arthritis or seronegative arthritis with synovitis affecting the knee joint in a cohort of patients who had failed conventional DMARDs, biological DMARDs or intra-articular steroid injections. To identify any possible predictors of good or poor response. To develop a standard operating procedure to improve consistency and also allow service to be potentially expanded.

Methods: Retrospective chart and electronic care record review of all patients receiving Yttrium therapy in Northern Ireland from March 2016 to April 2018. Patient demographics, MRI findings, conventional and biological DMARD use, previous intra-articular steroid use were recorded. Patients were reviewed approximately six months following treatment. The medical notes were reviewed to decide whether there had been a good or poor response to treatment and data analyzed to look for factors that may predict response. The process was evaluated and we developed a standard operating procedure to improve consistency and safety going forward.

Results: 17 patients in total received Yttrium therapy, 9 males. Age range was 18-75 with a mean 41. 10 patients were diagnosed with seronegative arthritis and 7 with psoriatic arthritis. All patients had an MRI of the affected joint(s) which confirmed synovitis in all cases. 9 MRIs showed no significant degenerative changes, 5 showed mild degenerative changes and 3 moderate/severe. All patients had previously received intra-articular steroid injection. 12 patients also were receiving or had failed treatment with a conventional or biological DMARD.

Long disease duration (OR 1.005, p<0.01), but not age, predicted NAFLD. In particular, those with disease duration of 10 years or more were of higher risk (OR 2.79, p<0.001). Cardiovascular risk factors including hypertension, diabetes mellitus, dyslipidaemia, and established cardiovascular diseases were not found to be predictors of NAFLD among PsA. None of the treatment agents including steroid, conventional synthetic or biological disease modifying anti-rheumatic drugs (DMARDs) was found to be risk factor for NAFLD.

Conclusion: NAFLD was common among patients with PsA, though it seldom led to significant hepatic impairment or interruption of treatment of PsA. Patients with longer duration of psoriatic arthritis were at risk of developing fatty liver. Traditional cardiovascular risk factors, established cardiovascular diseases or use of any particular treatment agent were not found to be predicting factor of development of NAFLD in PsA.

REFERENCES:

Disclosure of Interests: None declared
not appear to predict response in this group. There were no adverse events reported.

Conclusion: Yttrium therapy is not widely used with only one unit in Northern Ireland performing the procedure. The use of effective DMARDs and biological therapy has improved management of psoriatic and rheumatoid arthritis. In spite of this some patients still have refractory disease. We have shown in this observational study that in patients with knee synovitis despite treatment with DMARDs, biologics and intra-articular steroids, Yttrium synovectomy showed good efficacy, is a relatively low cost and generally safe treatment option for these patients.

Going forward this study and our standard operating procedure will allow us to develop criteria to help select patients for Yttrium therapy and standardize our treatment.

FRIS0443 IMPACT OF APREMILAST ON PSAID CORE COMPONENTS IN PATIENTS WITH A LIMITED NUMBER OF ACTIVE JOINTS: RESULTS FROM THE REAL-WORLD, PROSPECTIVE, MULTICENTRE REWARD STUDY

Tim Jansen1, Eric-Jan Kroot2, Arrie van Vliet3, Jan Pander3, Marijn Vis4.

Background: Recent data suggest that patients with moderately active psoriatic arthritis (PsA) and a limited number of active joints have a high likelihood of achieving treatment goals with apremilast treatment.1,2 Real-world evidence on the effect of apremilast on patients’ perception of the impact of their disease is limited.

Objectives: To describe the effects of apremilast on the impact of disease in the real world as measured by the Psoriatic Arthritis Impact of Disease (PsAID) questionnaire in PsA patients with SJC ≤4 at baseline.

Methods: The prospective, multicentre, observational REWARD study (The Netherlands) is investigating apremilast treatment in real-world patients with PsA. Descriptive statistics were assessed for disease measures, including swollen joint count (SJC; 0–66) and tender joint count (TJC; 0–68), PsAID (0–10) and patient perception of pain based on the visual analog scale (VAS; 0–100 mm) among patients with limited number of swollen joints (SJC ≤4) at baseline. We report the effects of apremilast on these disease measures at treatment initiation and at the first 6 months of treatment with a data cutoff of December 2018.

Results: A total of 48 patients from 9 clinics who were receiving apremilast were included in this interim analysis. Among these patients, 31 (65%) had SJC ≤4 and 17 (35%) had SJC >4 at baseline. Of patients with SJC ≤4 at baseline, 18 and 8 had at least 3 and 6 months of follow-up, respectively, at the time of data cutoff. Results are reported for patients with available data at each time point. Baseline characteristics for patients with SJC ≤4 included a mean age of 54 years, mean BMI of 29.1 and mean years since PsA diagnosis of 7.0 years; 58% of patients were female, 90% had prior csDMARD use and 29% had prior biologic use. For patients with SJC ≤4, disease measures were reported as follows: the mean SJC at baseline, 3 and 6 months were 1.1, 0.6 and 0.1 and the mean TJC at baseline, 3 and 6 months were 4.5, 3.6 and 1.5. The mean PsAID scores at baseline, 3 and 6 months were 4.2, 3.4 and 2.6. Individual PsAID domain scores by time points are shown (Figure). Patients with a limited number of swollen joints showed gradual improvements in all domains of the PsAID. Mean Pain VAS scores at baseline, 2 weeks, 6 weeks, 3 months and 6 months were 47, 48, 39, 29 and 26 in these patients.

Conclusion: Results from the real-world, prospective, multicenter, observational REWARD study suggest that PsA patients with a limited number of active swollen joints may benefit from apremilast treatment. Apremilast was associated with improvements in the perceived impact of disease, as observed by reductions in the PsAID and its core components.

**FR10445** IDENTIFICATION OF PSORIATIC ARTHRITIS USING AN ADMINISTRATIVE CLAIMS-BASED ALGORITHM

Hemin Lee1, Julia Ford2, Yinzhu Jin1, J. Adriano, Santiago Ortiz1, Angela Y. Tong1, SeoYoung Kim2,3; Brigham and Women’s Hospital, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Boston, United States of America; Brigham and Women’s Hospital, Division of Rheumatology, Immunology, and Allergy, Boston, United States of America

**Background:** Accurately identifying psoriatic arthritis (PsA) in large electronic healthcare database is critical for epidemiological studies.

**Objectives:** To develop and validate a claims-based algorithm to identify patients with PsA.

**Methods:** We conducted a retrospective chart review of the Partners Healthcare electronic medical record linked to Medicare claims from year 2012 to 2014. 7 claims-based algorithms were developed to identify PsA: 1) ≥2 International Classification of Diseases, Ninth Revision (ICD-9) codes for PsA (696.0) and at least one diagnosis of psoriasis (696.1) by any physician; 2) ≥2 diagnosis of PsA with at least 1 diagnosis by rheumatologist; 3) ≥2 PsA diagnosis with at least 1 diagnosis by rheumatologist and ≥1 diagnosis of rheumatoid arthritis (714.0); 4) ≥2 diagnosis of PsA and at least 1 diagnosis of psoriasis by dermatologist; 5) ≥1 diagnosis of PsA by rheumatologist and ≥1 diagnosis of psoriasis by dermatologist; 6) ≥2 diagnosis of PsA by any physician and ≥1 claims for PsA medication; 7) ≥2 diagnosis of PsA with at least 1 diagnosis by rheumatologist and ≥1 claims for PsA medication. The ICD-9 codes were separated by ≥7 days but <365 days. Medical record by the treating physician was considered as the gold standard, and two independent physicians confirmed the presence of PsA. Positive predictive value (PPV) and 95% confidence intervals (CI) of the algorithms were calculated.

**Results:** The 7 algorithms identified 357, 399, 315, 223, 215, 372, and 276 records, respectively. Approximately 45% of the identified records with adequate data were reviewed. The PPV of the algorithms ranged from 75.2% to 88.6% (Table 1). Mean age of identified PsA patients ranged from 72.6 to 73.5 years old. Presence of psoriasis 1 year prior to index date of PsA ranged from 54.2% to 89.2%. Algorithm 6 which captured ≥2 diagnosis of PsA and ≥1 claims for PsA-related medications identified second highest number of patients (n=372) yet still yielded high PPV of 82.4% (95% CI 76.5, 88.3).

**Conclusion:** All seven claims-based algorithms had a high PPV of 75-89% in identifying PsA. A claims-based algorithm utilizing two or more diagnosis codes of PsA by any physician with a claim for PsA medication can be a useful and efficient tool to identify the PsA population in large claims databases.

**FR10446** ATTAINMENT OF MINIMAL DISEASE ACTIVITY (MDA) IN PSORIATIC ARTHRITIS (PSA) PATIENTS (PTS) DEPENDING ON THE TIME OF SYNTHETIC (S) DMARD INITIATION IN CLINICAL PRACTICE: RUSSIAN PSA REGISTRY (RU-PSART) DATA

Elena Loginova1, Tatiana Kortaveva1, Anastasia Koltakova1, Elena Guban1, Yulia Korsakova1, Maria Sedunova1, Igor Pristavsky2, Irina Unnova2, Irina Bordareva, Snejana Kudishina2, Alexander Lila2, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 1St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg, Russian Federation; 2Omsk Regional Hospital, Omsk, Russian Federation; 3Kemerovo Regional Hospital, Kemerovo, Russian Federation; 4Vladivostok Clinical Hospital No.2, Vladivostok, Russian Federation

**Background:** According to the EULAR recommendations and treat to target strategy sDMARD are the first line of PsA therapy. But there are contradictory data about the efficacy of sDMARDs in PsA pts. Data was collected from 25 rheumatology clinics of the Russian Federation.

**Objectives:** To investigate the cumulative frequency and the time of MDA attainment in early and long-term PsA after starting sDMARDs in clinical practice.

**Methods:** 253 (MF-93/160) PsA pts according to CASPAR criteria were included in the RU-PSART, after signing consent participation forms; median age 65 (Min–Max 20 – Max 82) years. All patients were divided into two groups according to disease duration at time of sDMARDs initiation: early PsA ≤2 yrs. (165pts) and long-term PsA≥2 yrs (88pts). All pts underwent standard clinical examinations of PsA and psoriasis activity. All pts were treated with the following sDMARDs: Oral Methotrexate (MTX) (10/3pts), intramuscular MTX (30pts), Subcutaneous MTX (78pts), Leflunomide (7pts), Sulfasalazine (24pts), Apremilast (10pts), Tolctafilit (1pts). MDA was defined as ≥5 of the following criteria: tender joint count ≤1, swollen joint count ≤1, PASI≤1 or BSA≤3, patient pain global assessment VAS≤15, patient’s global disease activity VAS≤20, HAQ≤0.5, enthesis count ≤1. The cumulative frequency and the time of MDA attainment were calculated in both groups. Kaplan-Meier cumulative analysis, Me [Min-Max], ORs with 95% CI, Breslow, Tarone-Ware, Log Rank tests were performed. All CI-1, p<0.05, were considered to indicate statistical significance.

**Results:** MDA has been achieved by the use of sDMARDs treatment in 39 out of 165 (24%) pts with early PsA and in 4 out of 88 (5%) pts with long-term PsA. Early PsA pts have more chance to achieve MDA in comparison to long-term PsA pts: OR=4.65 [CI 95%: 2.2-16.9]. Comparative analysis has shown that cumulative frequency of MDA achievement after sDMARDs initiation was significantly higher (42% vs 5%) and faster (21 months vs 11 yrs.) in early PsA than in long-term PsA (p≤0.05 for Bre-slow, Tarone-Ware and Log Rank tests) (Fig. 1). The cumulative frequency and the time of MDA achievement were calculated by Kaplan-Meier analysis in both groups.

**Conclusion:** Our study suggests that sDMARDs initiation (mostly MTX-monotherapy) at an early stage of PsA allows to achieve MDA significantly faster and more often than in long-term PsA.

Background: Early started therapy of psoriatic arthritis with the goal to achieve minimal disease activity can slow the joint damage progression. Data concerning the persistence of psoriatic arthritis (PsA) patients on biologics in real clinical practice are insufficient.

Objectives: to analyze the survival of biological treatment of PsA and detect possible predictors of persistence on biologics.

Methods: PsA patients from Moscow Unified Arthritis Registry (MUAR) treated with biologics were included in study. Unadjusted survival analysis was performed by the Kaplan-Meier method. The search for independent risk predictors of the therapy discontinuation was carried out by the multivariate Cox regression.

Results: We recruited 236 treatment episodes in 141 PsA patients enrolled in MUAR, 61 men (43%); mean age was 50.1 ± 11.5 years. We used the following biologics: etanercept (71 patients), infliximab (51), adalimumab (50), ustekinumab (35), golimumab (11), certolizumab pegol (7). In unadjusted analysis mean treatment survival was longer with etanercept, adalimumab and infliximab. As significant independent predictors of withdrawal risk (potential confounders) low education, mutilating or polyarticular form of PsA, heel pain, shoulder joints swelling and absence of neck pain at the disease onset were detected. After the adjusting data for confounders there was no significant difference in risk of withdrawal between different biologics. Neither the year of onset of the case of treatment nor the number of previous biDMARDs show a significant relation with the risk of drug withdrawal (Picture 1). This data show the difference between the patterns of treatment survival of rheumatoid arthritis and psoriatic arthritis.

Conclusion: our analysis of PsA treatment persistence in real clinical practice detected several factors associated with withdrawal risk. These data can provide specialists with a tool for personalized treatment.

**REAL-WORLD EXPERIENCE OF SECUKINUMAB FOR PSORIATIC ARTHRITIS**

Background: Secukinumab, an inhibitor of IL-17, is a new option for the treatment of Psoriatic Arthritis (PsA) which has shown efficacy in clinical trials. However, real-world data of its use is still scarce.

Objectives: This study aims to analyze the experience of using secukinumab for PsA in four tertiary hospitals.

Methods: Multicentric observational, longitudinal, retrospective study conducted in 4 tertiary hospitals of the Madrid region. Patients with clinical diagnosis of PsA and having received at least one dose of secukinumab were included. Medical records were reviewed to collect demographic and clinical data (body mass index, BMI, risk factors cardiovascular disease, cancer, HBV/HCV infection), features of PsA (extra-articular involvement, radiological damage), previous therapies, assessment of the disease and response data at 6 months of secukinumab (joint counts, CRP, DAPSA, reasons for discontinuation, adverse events). Descriptive statistic analysis using mean and standard deviation was performed.

Results: 177 patients, of which 115 female (65%) were included. Mean age was 53 y.o.(SD 15) and average duration of the disease was 9 years (SD 7), 169 patients (95%) had peripheral disease (34% joint erosions), 84 (47%) had axial disease (68 with radiological damage), 148 (84%) had psoriasis, 61 (34%) showed dactylitis and 111 (63%) had enthesis. Average BMI was 28.4 (SD 6), with an obesity rate of 37% (52 pt). Observed comorbidities were hypertension (22 pt, 12%), diabetes mellitus (22 pt, 12%), dyslipidemia (58 pt, 33%), active smoking (55 pt, 31%) and others: 20 patients had HBV infection, 5 had HCV infection and 12 had malignancy.

Regarding previous treatments, 90% had received cDMARDs, particularly methotrexate (77%) and 119 (67%) had been exposed to at least one bDMARD (32% to one, 25% to two, 20% to three and 21% to four or more). 69% were on 150 mg dose and 31% on 300 mg dose. At baseline, average tender joint count was 7 (SD 8), swollen joint count was 4 (SD 4), CRP 7 mg/l and DAPSA 26. At 6 months of secukinumab therapy, tender joint count had decreased to 5 (SD 8), swollen joint count 2 (SD 3), CRP 5 mg/l and DAPSA 17. Thirty-eight (47%) of the patients with the data available (80) had DAPSA ≤14 (low activity) and 9 DAPSA >14 (remission). In naïve to biologic patients, DAPSA varied from 27 in the baseline visit to 16 at 6 months, and in the other group of patients with biologic experience, DAPSA varied from 24 to 17 at 6 months (if they had been exposed to 3 or more biologics, DAPSA from 18 to 10 at 6 months).

Average drug survival time was 20 months (1-34). 79 patients (44.6%) withdrew therapy, due to primary ineffectiveness (40), secondary ineffectiveness (28), adverse events (9) and other reasons (3). Adverse events do not differ from those reported in clinical trials.

Conclusion: Secukinumab in real-world setting had been indicated in a population of PsA with a high percentage of axial involvement (47%), with an important previous exposure to biologics, and with higher comorbidity than that reported in clinical trials. Response data were favorable, 47% of patients achieved remission or low activity by DAPSA, and similar profile of adverse events to the one reported in the clinical trials was observed.

**EFFECTIVENESS OF BIOLOGIC DRUGS WITH DIFFERENT MECHANISM OF ACTION IN PSORIATIC ARTHRITIS. AN APPRAISAL FROM THE APULIAN REGISTRY BIOPURE**

Nicola Marutti1, Giorgio Carlini2, Leonardo Santo2, Laura Quarta3, Romano Bucco2, Carmelo Zuccaro2, Angelo Semeraro2, Antonio Marsico2, Daniela Mazzotta2, Paola Chiara Francesca Falalopene2, Florenzo Iannone2, 1Rheumatology Clinic, University of Foggia, Foggia, Italy; 2Rheumatology Service, ASL LE – DSS Casarano-Gallipoli (LE), Gallipoli, Italy; 3Unità Operativa di Reumatologia ASLT, Barletta, Italy; 4”U.O. di Rheeumatologia, “V.Fazzì” Hospital, Lecce, Lecce, Italy; 5”Rheumatology Hospital Unit, A.O.U. Foggia, Foggia, Italy; 6Ambulatorio di Reumatologia Ospedaliero di Brindisi, Brindisi, Italy; 7Unità Operativa di Reumatologia ASLT Taranto, Taranto, Italy; 8DETO – Rheumatology Unit, University of Bari, Bari, Italy

Background: In the last decade, the number of drugs available for patients affected with psoriatic arthritis (PsA) is increased and rheumatologists have multiple choices to manage PsA refractory to conventional disease-modifying anti-rheumatic drugs (cDMARDs). However, the possibility
of identifying disease’s or patient’s related characteristics to drive the optimal choice is still under investigation.

Objectives: We aimed at evaluating the effectiveness and drug survival of the biological drugs (bDMARDs) and apremilast indicated for the treatment of PsA patients with inadequate response to cDMARDs. To this purpose, PsA patients on treatment with bDMARDs or Apremilast recorded into the Apulian BIOPURE registry have been retrospectively analyzed.

Methods: We retrospectively assessed PsA patients, fulfilling CASPAR criteria, starting a biologic drug or apremilast from June 2016 through December 2017. At baseline and at last observation within the time frame of the study, DAPSA, PASI, ASDAS-CRP, the presence of enthesis and dactylitis were collected. Rate of patients achieving DAPSA based remission was assessed at last observation. The persistence on the first treatment was evaluated by Kaplan-Meier survival curves. Estimated hazard ratios (HRs) of discontinuing therapy or achieving remission were assessed by multivariate stepwise backward Cox regression models, adjusting for patient demographics (gender, age) and disease characteristics (disease duration, number of prior bDMARDs, baseline DAPSA, PASI, presence of enthesis and dactylitis, type of current drug).

Results: We recruited 450 PsA patients (268, 60% female) with mean age 53 (±11) years, disease duration 19 (±13) months, 337 (75%) naïve to bDMARDs. At baseline, 404 had peripheral joint involvement and 46 axial disease, DAPSA was 18 (±10), PASI 1.6 (±3), ASDAS-CRP 2.5 (±1), 48/355 (13.5) had dactylitis and 78/231 (33%) showed enthesitis. Table 1 shows the type of drugs. At last observation, the rate of patients who achieved the DAPSA remission was significantly higher in naïve patients (25%) than in those bDMARDs experienced (14%, p=0.02). The rate of drug survival was not significantly different among drugs (Figure 1). Cox-regression multivariate models showed that independent baseline factors negatively associated to drug persistence were prior bDMARD treatment (HR 0.70, 0.50-0.97 (95% CI), p=0.03) and the absence of axial disease (HR 0.56, 0.35-0.91 (95% CI), p=0.02). Negative predictors of DAPSA remission were prior bDMARD treatment (HR 0.40, 0.19-0.83 (95% CI), p=0.01), gender female (HR 0.51, 0.29-0.91 (95% CI), p=0.02), and the absence of dactylitis/(HR 0.36, 0.19-0.68 (95% CI), p=0.002).

Conclusion: A good rate of DAPSA remission is achievable with all the current available drugs in PsA in settings of real life. Predictors of remission and persistence on treatment were being male and naïve to prior bDMARDs. No difference among drugs was detected.

1 Secukinumab 150 and 75 mg arms include 60 and 121 pts, respectively, who were dose escalated to 150 and/or 300 mg at wk 156 or later
2Pts with psoriasis affecting ≤3% body surface area at baseline (150 mg: N = 89; 75 mg: N = 82)
3Pts (N = 99 [150 mg] and 91 [75 mg]) with enthesitis at baseline
4Pts (N = 83 [150 mg] and 77 [75 mg]) with dactylitis at baseline, number of evaluable pts: n, total number of randomised pts: n, number of responders
TOFACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSIS OF DERMATOLOGIC ENDPOINTS FROM 2 PHASE 3 STUDIES

Joseph F. Merola1, Kim Papp2, Peter Nash3, Jordi Gratacos-Masmitja4, Wolf-Henning Boehncke5, Diamant Thaçi6, Daniela Graham7, Ming-Ann Hsu7, Cunshun Wang8, Joseph Wu9, Pamela Young9, Michael Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States of America; 5Probity Medical Research and K Papp Clinical Research Inc, Waterloo, ON, Canada; 4University of Queensland, Brisbane, Australia; 2Servicio de Reumatología, Hospital Universitario Parc Taulí Sabadell, Barcelona, Spain; 3Geneva University Hospital, University of Geneva, Geneva, Switzerland; 8Institute and Comprehensive Center for Inflammation Medicine, University of Lübeck, Lübeck, Germany; 9Pfizer Inc, Groton, CT, United States of America; 10Pfizer Inc, Collegeville, PA, United States of America

Background: Psoriatic arthritis (PsA) is a chronic, systemic inflammatory disease; the onset of dermatologic symptoms often precedes rheumatic manifestations. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. It has been shown that tofacitinib can improve dermatologic symptoms in patients (pts) with PsA.2,3

Objectives: To investigate the efficacy of tofacitinib in improving additional dermatologic endpoints in adult pts with active PsA.

Methods: This analysis included data from 2 placebo (PBO)-controlled, double-blind, Phase 3 studies in pts with active PsA and an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD) who were tumour necrosis factor inhibitor (TNFi)-naïve (OPAL Broaden [12 months; NCT01877668]; N=422) or had an IR to ≥1 TNFi (OPAL Beyond [6 months; NCT01882439]; N=394).2,3 Pts must have had active plaque psoriasis at screening only and were required to receive a stable dose of 1 csDMARD. Pts were randomised to tofacitinib 5 mg twice daily (BID), 10 mg BID, adalimumab 40 mg subcutaneous (SC) injection every 2 weeks (OPAL Broaden only) or PBO (advanced to tofacitinib 5 or 10 mg BID at Month [M]3). Percentage (% change from baseline (BL) (Δ) in Psoriasis Area and Severity Index (PASI) total score, % of pts achieving >75% PASI improvement from BL (PASI75) stratified by BL PASI severity (≥0 to <3, ≥3 to <10, ≥10) and Pts’ Global Joint and Skin Assessment-Visual Analogue Scale Psoriasis severity question (PGJS–VAS Psoriasis) were measured at M1, 3, 6, and at M9 and 12 (OPAL Broaden only); % ΔPASI total score and PASI75 were measured only in pts with BL affected body surface area (BSA) ≥3% and PASI >0. Safety endpoints were also analysed.

Results: BL demographics were similar between treatment groups and endpoints were also analysed. Serious adverse events (AEs) were similar across treatment groups up to M6 in OPAL Broaden and M12 in OPAL Beyond (Table). Similar effects across these endpoints. Serious adverse events (AEs) and discontinuations due to AEs were similar across treatment groups up to M6 in OPAL Beyond and M12 in OPAL Broaden.

Conclusion: In pts with PsA (TNFi-naïve or TNFi-IR), tofacitinib improved dermatologic endpoints, and responses were maintained to the end of each study. Tofacitinib may provide a treatment option for pts with active PsA, including the dermatologic symptoms of PsA.

Does Discordance Between Baseline Patient’s and Evaluator’s Global Assessment of Disease Activity Impact Retention and Remission Rates of TNF Inhibitors in Patients with Psoriatic Arthritis? Data from the EUROSPA Research Collaboration

Brigitte Michelsen, Lykke Ørnbjerg, Helman Mann, Joseph Sexton, Michael Nissen, Maria Jose Santos, Dan Nordström, Lennart T. H. Jacobsson, Ziga Rotar, Björn Gudbjørnsson, Sillemyen Serdar Koca, Catalin Codreanu, Manuel Pombo-Suarez, Irene van der Horst-Bruinsma, Anna Gilte Lof, Karel Paveška, Eirk Kristianslund, Burkhard Moeller, Elsa Vieira-Sousa, Anna-Mari Hokkanen, Ulf Lindström, Matija Tomsic, Thorvardur Jon Love, Berna Goker, Ruxandra Ionescu, Carlos Sánchez-Piedra, Marleen van de Sande, Mikkel Østergaard, Merete L. Hetland, EuroSPA Research Collaboration, on behalf of DANBIO (Denmark), ARTIS (Sweden), NOR-DMARD (Norway), ATTRA (Czech Republic), Reuma.pt (Portugal), BIOBADASER (Spain), ROB-FIN (Finland), biorx.si (Slovenia), ICEBIO (Iceland), TURKBIO (Turkey), RRBR (Romania), ARC (Netherlands), BSRB-AS (UK), GISEA (Italy), Denmark

Background: Discordance between baseline patient’s and evaluator’s global assessment of disease activity is common and may reduce the likelihood of remission following tumor necrosis factor inhibitor (TNFi) treatment in patients with psoriatic arthritis (PsA).

Objectives: To explore the impact of discordance, defined as patient minus evaluator’s global assessment (ΔPEG), on retention rates and remission rates (DAS28(3)/CRP) in PsA patients ini-

Results: A total of 5422 PsA patients were included. Mean (SD) age for women (n=2968/men=(n=2487) was 49.3(12.5)/47.4(11.7) years, disease duration 6.6(7.3)/6.7(7.2) years, median (25-75 percentiles) baseline ΔPEG 17(0-38)/10(0-30) mm. Retention rates and DAS28(4)/CRP but not DAS28(3)/CRP remission rates were lower for higher quartiles of baseline ΔPEG (table, figure).

Conclusion: High baseline discordance (ΔPEG) was associated with lower TNFi retention rates and with DAS28(4)/CRP but not DAS28(3)/CRP remission rates after 6, 12 and 24 months’ follow-up in both male and female PsA patients. The choice of remission criteria in the follow-up of PsA patients may affect important treatment decisions, and may be of particular impact in patients with high baseline ΔPEG.

Apolipoprotein B, HbA1c, CRP, ESR, ultrasensitive CRP, Apolipoprotein were collected. Other variables were collected from patients with peripheral joint involvement were included. Demographic (sex, age), clinical [duration of the disease, DAS28, current treatment, body mass index (BMI), CVRF, vascular events] and analytical variables (atherogenic index, glomerular filtration (GF-MDRD), fibrinogen, glycosylated hemoglobin (HbA1c), CRP, ESR, ultrasensitive CRP, Apolipoprotein A1, apolipoprotein B) were collected. Other variables were collected from the clinical history retrospectively. Basal vascular risk was estimated through SCORE tool. Extracranial carotid artery was explored with an Esote MyLab70XVG ultrasound with linear probe (7-12mHz) and an

Evolution of Subclinical Atherosclerosis in Patients with Psoriatic Arthropathy

I Montolio-Chiva1, M Robustillo-Villanovia2, A Sendra-García1,2, Marta Aguilar-Zamora1, C Vengara-Dangond6, Ana V Orenes Vera1,1, I Vázquez-Gómez3,4, A Martínez-Ferell5, Ella Valls-Pascual5, O Ybáñez-García5, V Náñez-Monje5,7,1, I Torner-Hernández1,2, Juanjo A. Jurek-Sanchez1,2,1, Universitary Peset Doctor Hospital, Valencia, Spain, 2La Plana Hospital, Villarreal, Spain, 3Foundation for the promotion of sanitary and biomedical research in the Valencian Community (FISABIO), Valencia, Spain, 4NIM Hospital, Madrid, Spain.

Background: Patients with psoriatic arthritis (PsA) have a higher prevalence of classical vascular risk factors (CVRF) and early atherosclerosis determined by chronic inflammation.

Objectives: To study the evolution over time of different vascular damage evaluation measures in patients with PsA and investigate the factors related to these changes.

Methods: Pre-post longitudinal study with analytical components. PsA patients with peripheral joint involvement were included. Demographic (sex, age), clinical [duration of the disease, DAS28, current treatment, body mass index (BMI), CVRF, vascular events] and analytical variables (atherogenic index, glomerular filtration (GF-MDRD), fibrinogen, glycosylated hemoglobin (HbA1c), CRP, ESR, ultrasensitive CRP, Apolipoprotein A1, apolipoprotein B) were collected. Other variables were collected from the clinical history retrospectively. Basal vascular risk was estimated through SCORE tool. Extracranial carotid artery was explored with an Esote MyLab70XVG ultrasound with linear probe (7-12mHz) and an
automatic program that measures intima media thickness (IMT) by radio-
frequency (‘Quality intima media thickness in real-time’), and the presence
of ateroma plaques was evaluated following Mannheim consensus. Pulse
wave velocity (PWV) was measured through Mobil o graph® disposable.
We retrospectively studied 3 years later, IMT: 900 μ and PWV: 100 μ
were considered as pathological values. Statistical analyses were per-
formed using SPSS 22.0 program.

Results: 108 patients were included. Twelve patients excluded due to
high vascular risk [previous event and/or diabetes type II or type I with
target organ injury]. Repeated VOP measurement was only available in
49 patients. 62.5% of patients were women and the mean age was 54.2
(SD 1.3) years. Mean disease duration was 93.1 (SD 12.7) months and
mean DAS28 was 1.7 (SD 0.1). 22.4% of patients received glucocorti-
coids, 47.8% NSAIDs, 83.6% DMARDs and 37.3% biological drugs. Mean
BMI was 26.5 (SD 0.5) kg/m², 38.8%, 28.4% and 43.3% of patients were
smokers, hypertensive (11.9% on ARA2, 3% on IECA, 1.5% on cal-
inus, 13.4% and 20.4% had a pathological IMT or PWV, respectively.
Mean SCORE was 1.06 (SD 0.1). Baseline, 23.9% of patients had atherosomatous plaques,
and 13.4% and 20.4% had a pathological IMT or PWV, respectively.
Three years later, we detected new and/or atherosomatous plaques rises
in 19.4% of patients and PWV and IMT worsening in 10.2% and 1.5%
of patients, respectively. As per logistic regression analysis, high baseline
SCORE (16.9%), high systolic blood pressure (8.6%), GF-MDRD (8.2%),
fibrogen (6.9%) and the presence of diabetes and/or dyslipidemia were the factors
that most contributed to the progression of vascular damage, with independ-
ence of the therapeutic objective used for their treatment.

Conclusion: Progression of vascular damage is mainly related to CVRF
in patients with PsA, therefore it is essential to intervene on CVRF early.

USE OF SECUKINUMAB IN PSORIATIC ARTHRITIS AND
ANKYLOSING SPONDYLITIS…REAL WORLD DATA

Ozgul Muftullar, Hilary Mcike, Antirn Area Hospital, Rheumatology, Antirn, United Kingdom

Background: Secukinumab was the IL-17 inhibitor licensed for use in
Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS). The aim of this
study was to evaluate the effectiveness and safety of Secukinumab in our
cohort of patients.

Objectives: In order to assess the effectiveness and safety of Secukinu-
hab, a retrospective analysis of patients treated with this drug in the
Netherlands Health and Social Care Trust was undertaken.

Methods: Retrospective data was collected from the Local Biologic data-
base. All patients who were on Secukinumab were selected. They were
divided into two arms, Psoriatic Arthritis and Ankylosing Spondylitis. From
this baseline, it was divided into five groups and patient cohort data was
collected. Patients were seen routinely at three monthly intervals and outcomes were collected up to a 12 month period.
From patient notes drug response and adverse effects were recorded.

Results: 41 patients with psoriatic arthritis were treated with
Secukinumab over the 12-month period studied. Twenty-six patients were
female and fifteen were male, with ages ranging from 26 to 70. Only 12
of the patients were on concomitant methotrexate, all met the NICE start
criteria with required DAS 76 scores. Seven of the patients were biologic
naive (17%) at commencement of drug.

Of all the patients who responded, most had some response by 3
months, and all had further response by six months. Sixteen patients (39%)
discontinued treatment due to no response, one
due to increasing shortness of breath, wheeze and rash, and one patient
developed colitis.

Other side effects were noted, which did not cause the drug to be dis-
continued. Five patients had rash and urticaria, three reported headaches.
Infections were fairly common, five patients had chest infections, four
had sinusitis and three had urinary tract infections. Four patients reported
thrust, one oral thrush and three vaginal.
A total of 18 patients with Ankylosing Spondylitis were commenced on
Secukinumab 11 males and 7 females. A third (6/16) were biologic
naive. Ages ranged from 27 to 65.
In the first three months of commencement there was a reduction in
BADSAl scores of all patients. This remained at six months. Inflammatory
markers CRP and ESR were also reduced.

Seven patients discontinued Secukinumab after six months due to side
effects or lack or perceived response by the patient (seen in 1 patient).

Two patients had a loss of efficacy. The remaining four patients noted
cutaneous skin infections, sinus symptoms or headaches as noted in the
PsA arm of the audit.

Conclusion: Patients in the Northern Trust starting Secukinumab generally
have severe disease and most have had prior treatment with biologics.
There was a high incidence of non responders in this group, however in
those patients who responded there was a good response rate at 3
months, and these patients were still on treatment at 12 months. Side
effects were as expected, with infections being the most commonly
reported side effects.

secukinumab for psoriatic arthritis and axial spondyloarthritis. Rheumatol-

Acknowledgement: Department of Rheumatology Antirn Area Hospital

Disclosure of Interests: None declared

Conclusion: This study showed that the burden of disease in axial PsA has a significantly different between genders. Female patients with PsA who have axial involvement have higher disease activity, physical disability, functional limitation and higher depression and anxiety risk than male patients. Therefore, we suggest that new strategies should be developed for more effective treatment of axial PsA in female patients.

OBJECTIVE MEASURES OF PSORIASIS SEVERITY AND THE RISK FOR PsA: RESULTS FROM THE INCIDENT HEALTH OUTCOMES AND PSORIASIS EVENTS PROSPECTIVE COHORT STUDY

Alexis Ogdie1, Daniel Shin2, Hyon Choi2, Christopher T. Ritchlin3, Joseph F. Merola4, Jose Scher5, Thordurard Jon Love5, Joel Gelfand6, 1University of Pennsylvania, Philadelphia, PA, United States of America; 2Massachusetts General Hospital; Harvard Medical School, Boston, MA, United States of America; 3University of Rochester, Rochester, NY, United States of America; 4University of Rochester, Rochester, NY, United States of America; 5Brigham and Women’s Hospital; Harvard Medical School, Boston, MA, United States of America; 6University of Iceland, Reykjavik, Iceland

Background: Psoriasis severity is a presumed risk factor for development of psoriatic arthritis (PsA) but most studies have examined this question retrospectively. Additionally, it remains unclear whether obesity and body surface area of psoriasis (BSA) are independent risk factors for PsA.

Objectives: We examined the association of psoriasis severity, obesity and other potential risk factors for the development of PsA in patients with psoriasis.

Methods: Between 2008-2011, patients with at least one code for psoriasis aged 25-60 years in The Health Improvement Network were randomly selected and questionnaires were sent to their general practitioners. The mean age was 46 and 53% were female. BSA was provided for 8,881 patients of which 52% had mild psoriasis, 36% moderate psoriasis, and 12% severe psoriasis. Mean follow up time was 4.2 years (SD 2.1); the incidence of PsA based on categories commonly used for epidemiological studies. Data through 2015 were used in the current analysis. After excluding patients with PsA at baseline, the incidence of PsA among patients with psoriasis was calculated. Cox proportional hazard ratios were used to examine the risk of developing PsA among patients with mild (<3%), moderate (3-10%) and severe (>10%) psoriasis. We also examined other covariates including obesity, depression, recent infections, smoking, and comorbidities in univariable models. Factors significant at the univariable level were included in multivariable models. We additionally tested an interaction between BSA and obesity.

Results: Among 10,474 questionnaires sent, 9,987 (95%) were returned and, of those, 9,069 (91%) had confirmed psoriasis. The mean age was 46 and 53% were female. BSA was provided for 8,881 patients of which 52% had mild psoriasis, 36% moderate psoriasis, and 12% severe psoriasis. Mean follow up time was 4.2 years (SD 2.1): the incidence of PsA was 5.4 cases per 1,000 person years. In univariable models, age and sex were not associated with PsA but obesity, BMA (continuous), BSA (continuous and category) and depression were significantly associated with development of PsA. The final multivariable model included BSA category (ref mild, moderate: HR 1.44, 95%CI: 1.02-2.03, severe HR 1.99, 1.28-3.11), history of depression (1.69, 1.22-2.34), obesity (1.64, 1.19, 2.25), age (HR 0.99, 0.98-1.00) and female sex (HR 0.72, 0.52-0.99). There was not a statistically significant interaction between BSA and obesity although patients that were obese and had >10% BSA had the highest risk (HR 3.90, 2.22-6.85).

Conclusion: In this large prospective cohort study, we found that body surface area is a strong predictor of developing psoriasis over the next 4-7 years and obesity is an additive risk factor.

PREVALENCE OF DISEASE DOMAIN PRESENTATIONS AMONG PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM THE CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS (PSA/SPA) REGISTRY

Alexis Ogdie1, Peter Hur2, Mei Lu3, Sabrina Rebello4, Robert Mclean4, Blessing Dube5, Meghan Glynn5, Philip J. Mease6, 1Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States of America; 2Novartis Pharmaceuticals Corporation, East Hanover, United States of America; 3Corrona, LLC, Waltham, United States of America; 4Swedish Medical Center/Pondiron St. Joseph Health and University of Washington, Seattle, United States of America

Background: Psoriatic arthritis (PsA) is a heterogeneous, chronic inflammatory disease of the skin and musculoskeletal system. Six key domains of PsA have been identified to help guide treatment: peripheral arthritis, axial disease, enthesitis, dactylitis, and psoriatic skin and nail disease. The most common mutu-

Objective: To describe the prevalence of disease domain presentations among patients with PsA in the Corrona PsA/SpA Registry.

Methods: This study included adult patients with PsA enrolled in the Corrona PsA/SpA Registry between March 2013 and August 2018. PsA cases were evaluated for the presence of 6 disease domains at enrollment: enthesitis (Spondyloarthritis Research Consortium of Canada enthesitis count > 0), dactylitis (dactylitis count > 0), peripheral arthritis (PA); tender and/or swollen joint count > 0), nail psoriasis (global nail psoriasis visual analog scale > 0), axial disease (physician-reported presence of spinal involvement, based on clinical judgment and/or radiographs or MRI showing sacroiliitis), and skin disease (BSA > 0%). The most common mutually exclusive disease presentations were summarized among all patients.
with PsA and those who initiated biologics using frequency counts and percentages.

**Results:** Of 2617 patients with PsA enrolled in the Corrona PsA/SpA Registry, 1698 patients (64.9%) had multidomain disease presentations, 617 (23.6%) had single-domain presentations, and 302 (11.5%) had no presentations. Overall, 1814 (69.3%) patients presented with skin disease, 1523 (68.2%) with PA, 1042 (39.8%) with nail psoriasis, 539 (20.6%) with enthesitis, 319 (12.2%) with axial disease, and 235 (9.0%) with dactylitis at enrollment. Among all patients with PsA, the most common disease presentations were skin disease (2.7%), PA + skin disease (11.7%), and PA + nail psoriasis + skin disease (10.3%) (Figure 1). A total of 354 patients initiated biologics at enrollment. Of these, 289 patients (81.6%) had multidomain disease presentations, 45 (12.7%) had single-domain presentations, and 20 (5.6%) had no presentations; 273 patients (77.1%) presented with PA, 267 (75.4%) with skin disease, 159 (44.9%) with nail psoriasis, 115 (32.5%) with enthesitis, 70 (19.8%) with dactylitis, and 64 (18.1%) with axial disease at enrollment. The most common disease presentations were PA + nail psoriasis + skin disease (11.6%), PA + skin disease (11.3%), and enthesitis + PA + nail psoriasis + skin disease (8.8%), and enthesitis + PA + skin disease (5.9%) (Figure 2).

**Conclusion:** The majority of patients with PsA presented with multiple disease domains. Biologic initiators generally had a higher prevalence of all disease features. These results may increase the physician awareness of the heterogeneity of disease presentations among patients with PsA, which can be important for the development of an effective management plan.

FR0461 GENETIC ANALYSIS OF THE NF-KB PATHWAY CAN BE USEFUL TO DISTINGUISH PATIENTS AT RISK OF PSORIATIC ARTHRITIS WITHIN THE SPECTRUM OF PSORIATIC DISEASE

Ruben Quiro Sika1, Pablo Coto-Seguras, Leire González-Lara2, Belen Alonso2, Juan Gómez3, Eliis Cuesta-Llavona, Eliise Coto2, 1Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain, 2Hospital Alvarez Buylla, Dermatology, Mieres, Spain, 3Hospital Universitario Central de Asturias, Genética Molecular, Oviedo, Spain

Background: Psoriasis and psoriatic arthritis (PsA) are the main manifestations of what is now known as psoriatic disease. Both entities share common genetic pathways, but they also differ. The NF-KB pathway has been implicated in the genesis of psoriatic disease, but the differential contribution of this genetic pathway to the risk of psoriasis and PsA is not fully understood.

Objectives: Our aim was to study the association of common polymorphisms at genes of the NF-KB pathway in patients with psoriasis and psoriatic arthritis.

Methods: The study involved a total of 690 psoriatic disease patients (187 of them with PsA) and 550 controls. We genotyped three common polymorphisms in NFKB1 (rs3217713 indel), NFKB1 (rs7152376), and NFKBIZ in 690 psoriatic disease patients (397 of them with PsA) and 550 controls.

Results: The rare NFKB1 rs7152376 C was significantly more frequent in the PsA group vs. controls (0.42 vs. 0.36; p=0.04, OR=1.29, 95% CI=1.01-1.63). Compared to PsA patients, PsA controls showed a significantly higher frequency of the rs7152376 C (0.42 vs. 0.31; p=0.001). In reference to the genotypes, carriers of rs7152376 C (CC+CT) were significantly more frequent in PsA as compared to controls (0.66 vs. 0.58; p=0.06). However, the frequency of these carriers was significantly higher in PsA vs. skin psoriasis (p=0.004). Thus, our data showed significant association between the rare NFKB1 rs7152376 C allele and PsA, and a trend toward the opposite effect for skin psoriasis. Neither NFKB1 rs230526 nor NFKBIZ rs3217713 indel were associated with the risk of developing psoriasis or PsA.

Conclusion: We found a significant association between NFKB1 variants and PsA. Our study shows that alterations in the same genetic pathway may have differential effects on different manifestations of psoriatic disease. Additional studies from larger cohorts and different populations are necessary to validate these results.

FR0462 UNDERSTANDING MEDIATORS OF PAIN REDUCTION IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH TOFACITINIB: ROLE OF INFLAMMATION

Background: Pain is a priority for patients (pts) with psoriatic arthritis (PsA) and physicians. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. As pain is a multidimensional phenomenon, there is growing interest in understanding mechanisms of pain relief during treatment with tofacitinib.

Objectives: To examine the potential role of inflammation in the effect of tofacitinib on pain in pts with PsA, using mediation modelling.

Methods: Data were from the Phase 3 OPAL Broaden (NCT01877668) and OPAL Beyond (NCT01882439) studies of pts with active PsA treated with tofacitinib on pain in pts with PsA, using mediation modelling.

Disclosure of Interests: None declared

with tofacitinib 5 mg twice daily (BID) or placebo; pts were tumour necrosis factor inhibitor (TNFi)-naïve or had previous inadequate response (IR) to ≥1 TNFi. All pts continued on a stable dose of a single conventional synthetic DMARD. Analyses used pooled and individual trial data (mean scores from Months 1, 2 and 3). Mediation modelling seeks to explain mechanisms underlying an observed relationship between independent and dependent variables via other explanatory variables (mediators). In this model, pain (100 mm visual analogue scale) was the designated dependent variable, treatment (tofacitinib 5 mg BID vs placebo) the independent variable and inflammation, measured by swollen joint count (SJC) and C-reactive protein (CRP), was a mediator. The primary model designated treatment effect on pain mediated via CRP/SJC as an indirect effect and treatment effect not attributable to CRP/SJC as a direct effect. Models were re-specified based on final results; model invariance by population (TNFi-naïve vs TNFi-IR pts) was assessed.

Results: In the pooled analysis (N=469), 25.9% (p<0.01) of the tofacitinib treatment effect on pain was mediated by CRP/SJC (indirect effect), of which changes via CRP and SJC were 17.8% (p<0.01) and 8.1% (p<0.05), respectively. The treatment effect on pain not attributable to CRP/SJC (direct effect) was 74.1% (p<0.0001). In TNFi-naïve and TNFi-IR pts, indirect effects via SJC were not statistically significant. In the re-specified model with CRP as sole mediator, the indirect effect was 21.3% (p<0.01) and 36.1% (p<0.05) and 16.7% (p<0.05) for TNFi-naïve and TNFi-IR pts, respectively (Figures B, C); the 19.4% difference between TNFi-naïve vs TNFi-IR pts was not statistically significant.

Conclusion: While inflammation, as assessed by CRP/SJC, was a significant mediator of the overall treatment effect on pain in tofacitinib-treated pts with PsA, the majority of the treatment effect was not attributable to CRP/SJC changes. When mediators were assessed individually, only CRP was a significant mediator in the pooled analysis. In the re-specified model, CRP-mediated effects differed in TNFi-naïve vs TNFi-IR pts, but this was not statistically significant. These results suggest that CRP/SJC-associated inflammation only partially explains pain in PsA; other potential mediators need to be identified to better understand the treatment effect of tofacitinib on pain.

PREDICTION OF INCIDENT FRAGILITY FRACTURES THROUGH RADIOFREQUENCY ECHOCOGRAPHIC MULTI SPECTROMETRY (REMS)

**Giovanni Adami**1, Giovanni Arioli2, Gerolamo Bianchi2, Maria Luisa Brandi4, Carla Caffarelli5, Sergio CASCiaro6, Loredana Cavalli4, Luisella Cianferotti6, Davide Gatti11.

**Background:** Radiofrequency Echographic Multi Spectrometry (REMS) is an innovative non-ionizing technique used for diagnosing osteoporosis at lumbar spine and femoral neck sites. In accordance with the results of a multicentre clinical study, REMS T-score values were highly correlated with Dual-energy X-ray absorptiometry (DXA) T-scores [1].

**Objectives:** To determine the predictive value in terms of fragility fracture risk reduction of the REMS T-score compared to DXA T-score in a representative female population.

**Methods:** We enrolled 1370 women (30-90 y, BMI ≤ 35 kg/m²) from 2013 to 2017. We performed in all patients both DXA and REMS lumbar scans. All analyses were performed under the strictest adherence to the corresponding guidelines. All patients underwent a follow-up lasting up to 5 years to assess the incidence of fragility fractures. Patients were stratified in two groups: patients who suffered a fragility fracture during the follow-up period (Group X) and those who did not (Group Y). Through an iterative process, the two groups were then age-matched with an enrolment proportion of 1:2. The finally obtained groups were identified as Group A (with incident fractures) and Group B (without fractures). The performance of REMS T-score in discriminating between Group A and Group B was quantitatively assessed and compared with DXA.

**Results:** Fragility fractures incidence was 14.0% (192 out of 1370 patients, mean follow-up 3.6 ± 0.8 years). Group A included 180 patients (mean age 67.2 ± 7.2 years) and Group B included 360 patients (mean age 67.3 ± 3.5 y). Group A and Group B did not show significant differences with respect to height (p=0.41), weight (p=0.68) and BMI (p=0.32). As expected we found significant differences in REMS T-score (-2.68 ± 1.28 in Group A vs -2.03 ± 1.23 in Group B, p<0.001) and DXA T-score (-2.52 ± 1.20 in Group A vs -2.08 ± 1.17 in Group B, p<0.001). REMS T-score ≤ -2.5 identified Group A patients with sensitivity = 65% and specificity = 58% (OR=2.6). DXA T-score identified Group A patients with sensitivity = 57% and specificity = 57% (OR=1.7).

**Conclusion:** REMS T-score resulted an effective predictor for the risk of incident fragility fractures in a representative population-based sample of female subjects. Reported OR values showed also that REMS had a better performance than DXA in the considered population, showing higher values for both sensitivity and specificity in the identification of fragile patients.

**FRI0466**

RISK FACTORS ASSOCIATED WITH THE DEVELOPMENT OF FRACTURES IN GLUCOCORTICOID TREATED PATIENTS. THE ROLE OF HYPOGONADISM

**Helena Florez1**, José Hernández-Rodríguez2, Afra Muxu2, Josep Lluís Carrasco2, Sergio Prieto-González2, Silvia Ruiz-Gaspá1, María C. Cid1, Ana Monegal2, Núria Guaralbés1, Pilar Peris1, Hospital Clinic, University of Barcelona, Metabolic Bone Diseases Unit, Department of Rheumatology, Barcelona, Spain; Hospital Clinic, University of Barcelona, Department of Nuclear Medicine, Barcelona, Spain; University of Barcelona, Biostatistics, Department of Basic Clinical Practice, Barcelona, Spain

**Background:** Glucocorticoid-induced osteoporosis (GIOP) is a common form of secondary osteoporosis (OP). Fractures in GIOP frequently occur with higher bone mineral density (BMD) than expected and typically at treatment initiation, complicating the identification of patients at risk of fracture.

**Objectives:** Identify risk factors associated with fragility fracture development in GC-treated patients.

**Disclosure of Interests:** None declared
Methods: 127 patients (aged 62±18 years, 63% women, 46% postmenopausal) on GC treatment (prednisone ≥5mg/day, >3 months) were included. Clinical data collected included: risk factors for OP and fractures, dose and GC-treatment duration, previous fractures and disease activity, anthropometric data, bone metabolism parameters (including gonadal axis study), BMD analysis (DXA: OP: T-score ≥-2.5, TBS (degraded microarchitecture [DMA]<1.230), dorsolumbar X-ray (assessing vertebral fractures [VF]) and FRAX risk (GC-adjusted).1

Results: Most patients received GC treatment for vasculitis or polyarthritis rheumatica during 47±69 months (mean daily dose: 14.5mg). 17% had VF, 28% had fragility fracture (VF + non-VF), 29% OP and 71% DMA. Patients with VF received more GC-boluses (57.1% vs. 29.5%, p=0.003), were older (68±13 vs. 60±19 years, p=0.02), postmenopausal (100% vs. 67%, p=0.015) and/or men with testosterone <250ng/dL (67% vs. 11%, p=0.017) and had higher TBS values (1.100 vs. 1.220, p=0.001) and higher FRAX risk (17 vs. 9, p=0.003); patients with fragility fractures showed higher accumulated GC-doses (6.1±13 vs. 6±18g, p=0.046). On multivariate analysis, hypogonadism (OR 14.3; IC95% 2.2-100, p=0.01) and having received GC-boluses (OR 3.40; IC95% 1.1-11.8, p=0.01) were the principal factors associated with VF. Hypogonadism (OR 7.1; IC95% 1.5-38.7, p=0.01) and having a FRAX >20 (OR 6.97; IC95% 1.3-51.7, p=0.02) were factors related to the presence of fragility fractures. Men with testosterone <250ng/dL had higher BMI (29.4 vs. 26.3, p=0.005) and disease activity (ESR 23 vs. 12, p=0.005) and lower TBS (1.050 vs. 1.210, p=0.001); age, daily and cumulated GC doses were similar to subjects with normal testosterone levels.

Conclusion: Hypogonadism is a major risk factor for developing fractures in GC-treated men and women, whereas receiving GC-boluses is related to VF, indicating the importance of evaluating the gonadal axis in these patients.

EFFECTS OF DIFFERENT VITAMIN D SUPPLEMENTATION SCHEMES IN POSTMENOPAUSAL WOMEN

Stefano Benard, Addolorata Corrado, Angiola Mele, Cinzia Rotondo, Antonello Trotta, Natalia Mansuetto, Francesco Paolo Cantatore. Rheumatology Clinic, Department of Medical and Surgical University, University of Foggia, Foggia, Italy

Background: Vitamin D exerts different extra-skeletal effects, including a positive effect on muscle function. Circulating levels of the 25 hydroxy-activated Vitamin D (25(OH)D) reflect the body Vitamin D reserve; to reach the optimal serum 25(OH)D threshold, Vitamin D supplementation is often requested. The commonest Vitamin D supplementation is represented by cholecalciferol (D3), but the hydroxylated Vitamin D metabolite 25(OH)D represents a therapeutic alternative.

Objectives: The aim of the study was to evaluate the efficacy of the calcifediol supplementation compared to various cholecalciferol administration schedules in increasing the 25(OH)D vitamin D serum levels and the effects on muscular function in post-menopausal women.

Methods: 60 post-menopausal women aged ≤ 65 years with low serum 25(OH)D levels (8-24 ng/mL) were included in the study. Recruited patients were randomly assigned to receive oral Vitamin D 1000 UI/day according to different regimens. 1) cholecalciferol (D3) 300.000 UI; single oral dose; 2) monthly cholecalciferol 100.000 UI for three consecutive months; 3) weekly cholecalciferol 7000 UI; 4) weekly HyD 7000 UI. At baseline and every three months, for 12 months, the following parameters were evaluated: serum levels of 25(OH)D; PTH, calcium, phosphates; at baseline and every 15 days muscular function was evaluated using the Timed Up and Go (TUG) and the Sit to Stand test.

Results: Weekly administration of HyD induced a significantly faster and greater increase of 25(OH)D levels, compared to the other treatment groups (at 12 months: +384% vs +145%, + 220%, + 246% in groups 1, 2, 3, respectively); the increase appeared after 1 month from baseline. D3 300.000 UI single dose induces a slower increase of 25(OH)D compared with weekly administration and weekly supplementation. An increase of muscular strength was observed after 12 months in all supplementation groups, starting from 1 month from baseline, with a greater effect in subjects treated with weekly HyD compared to D3 treated subjects (TUG 6 sec- ond vs 7.3, 7.7, 7.9 in groups 1, 2, 3, respectively, Sit to Stand 16.2 vs 15.4, 15.3, 15.7 in groups 1, 2, 3 respectively). Overall, the effects on 25(OH)D levels and on muscular function were greater in subject treated with weekly D3 compared to subject treated with monthly or single dose D3. No differences in PTH, calcium and phosphate serum levels were found between supplementation groups.

Conclusion: Supplementation with calcifediol is more effective and faster compared to cholecalciferol in increasing 25(OH)D serum levels; further, weekly cholecalciferol is more effective and faster compared to single dose or monthly administration. Increase in circulating levels of 25(OH)D is associated to an improvement of muscular strength.

Background: Denosumab, a monoclonal antibody against RANKL, is approved for the treatment of glucocorticoid (GC) induced osteoporosis (GIO). In postmenopausal women with osteoporosis, denosumab discontinuation leads to a transient increase in bone turnover above baseline, peaking at 12 months from the last dose, and a corresponding decline in bone mineral density (BMD). To better understand the effects of denosumab discontinuation in GC-treated patients, we analyzed a subgroup receiving GCs at baseline from a phase 2 study of denosumab in subjects with rheumatoid arthritis (RA), followed for 12 months after discontinuing denosumab discontinuation.

Objectives: To evaluate changes in bone turnover and BMD in subjects with RA on GCs treated with denosumab, after discontinuing denosumab for 12 months.

Methods: This double-blind, placebo-controlled study enrolled subjects with RA who were randomized to receive denosumab 60 mg, denosumab 180 mg, or placebo subcutaneously for 12 months, and followed for progression of structural damage. Subjects were followed for an additional 12 months after denosumab discontinuation. Outcome measures in this subgroup analysis of subjects treated with GCs at study baseline included percent change from baseline in serum C-terminal telopeptide of type I collagen (CTX) and lumbar spine (LS) and total hip (TH) BMD on- and off-treatment. Baseline mean (SD) prednisone equivalent dose (mg/day) was 6.1 (2.4), 5.2 (2.1), and 6.1 (3.2) in the placebo, denosumab 60 mg, and denosumab 180 mg groups, respectively. Data on CTX are reported as median and interquartile range. Percent changes in LS and TH BMD at each time point were assessed based on a repeated-measures model adjusting for treatment, baseline use of steroids, previous use of biologics, and baseline BMD value.

Results: Among 218 subjects in the phase 2 study, 82 (26 placebo, 27 denosumab 60 mg, 29 denosumab 180 mg) were included in this analysis. After 12 months of denosumab treatment, CTX decreased from baseline in both groups (Figure); in the off-treatment period, CTX returned to baseline by 18 months and was overall similar to placebo at 24 months. BMD increased at the LS and TH at 12 months with denosumab treatment (Figure) and returned to baseline levels after 12 months of discontinuation.

Conclusion: Like all non-bisphosphonate medications for osteoporosis, denosumab is reversible with discontinuation. In this small subgroup of GC-treated subjects with RA, BMD gains achieved with denosumab were lost upon discontinuation, consistent with observations in postmenopausal women receiving denosumab for osteoporosis. In this analysis of short-term denosumab use in subjects with RA receiving GCs, bone turnover was reduced with denosumab and gradually returned to baseline upon discontinuation, without a clear increase to above-baseline levels in the off-treatment period.

FRI0471 | BONE QUALITY ASSESSMENT IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

Nassima Hanouchine1, Salah Ouhadj1, Chafia Dahou-Makhlouf2, CHU Tizi Ouzou, Tizi Ouzou, Algeria; 2EPH DELLYS, BOUMERDES, Algeria; 3CHU BABELOUC, ALGIERS, Algeria

Background: Type 2 diabetes mellitus (T2DM) is a risk factor for osteoporotic fractures although bone mineral density is normal or even increased. Thus, diabetes may be associated with a reduction of bone strength that is not reflected in the measurement of bone mineral density (BMD)

Objectives: The aim of this study was to compare BMD with a non-invasive assessment of trabecular microarchitecture, (Trabecular bone score) TBS, in patients with T2DM

Methods: In a prospective cross-sectional study, trabecular microarchitectural analysis was examined in patients with T2DM and non diabetic control subjects. The exclusion criteria were diseases (hyperthyroidism, Cushing’s syndrome, primary hyperparathyroidism, renal failure, malabsorption), rheumatic diseases and/or medications that might affect bone and mineral metabolism, post menopausal women. Lumbar spine BMD was measured by dual-emission x-ray absorptiometry (DXA), and TBS was calculated by examining pixel variations within the DXA images using TBS Insight

Results: 205 patients (108 male, 97 female), aged 25 to 60 years with T2DM and 205 non diabetic control subjects ((105 male, 100 female) Mean TBS was lower in T2DM (1.256±0.103 vs. 1.291±0.101, p=0.001). Mean BMD was higher in T2DM Z score (0.516±1.346 vs. -0.815±1.53, p= 0.016).

Conclusion: In T2DM,TBS is lower than control subjects. Abnormal trabecular microarchitecture may help explain the paradox of increased fractures at a higher BMD in T2DM

ASSESSING THE CLINICAL RELEVANCE OF BONE DENSITOMETRY SCREENING IN PATIENTS UNDER 40 YEARS OF AGE: INDICATIONS AND RESULTS

Laura Chadwick, Deepal Challa, Sankalp Tripathi, Kiran Kumar Puthuchayya, Mid Cheshire Hospitals NHS Trust, Crewe, United Kingdom

Background: Guidelines for the diagnosis and treatment of osteoporosis in patients under the age of 40 years are lacking. The International Osteoporosis Foundation (IOF) working group has recommended dual-energy X-ray absorption (DXA) screening should only be performed in this age group if patients have an associated chronic disease such as inflammatory bowel disease (IBD) in conjunction with a vertebral fracture or multiple fractures elsewhere. For these patients, a T-score of < -2.5 can be used to diagnosis low BMD but the term osteoporosis may not be appropriate and there is minimal evidence supporting the use of bisphosphonates (BPs).

Objectives: In patients under 40 years of age undergoing DXA screening, to determine (1) the indication and (2) the DXA results (age adjusted Z score and standard T score), in order to conclude whether DXA screening in this group was appropriate and relevant for making meaningful treatment decisions.

Methods: Clinical details for all DXA scans requested for patients less than 40 years of age were obtained from the Mid Cheshire Hospital NHS Trust radiology department for a 6 month period from July to December 2018 inclusive. Descriptive data was produced regarding basic patient demographics, DXA indication and DXA results in the form of Z- and T-scores at the neck of femur (NOF) and spine.

Results: In total, 35 patients under the age of 40 years underwent DXA screening in the defined time period. The mean age of patients was 30.5 years (s.d. 6.0) and 24 patients (69%) were female. The youngest patients were 19 years. Regarding indications, only two patients (6%) were appropriate for DXA screening according to the IOF suggested guidelines, both of whom had vertebral fractures. Twenty seven patients (77%) had an established diagnosis of a disease known to cause OP but no history of fracture. Regarding results, at the NOF and spine respectively mean Z-scores were -0.88 (s.d. 1.19) and -0.945 (0.93). Only three patients (9%) had Z- or T-score of < -2.5: two patients who had a history of thoracic vertebral fracture, and a patient with high steroid use for IBD but no fracture history.

Conclusion: The majority of patients aged less than 40 years referred for DXA screening are being referred due to associated diagnoses with no history of fracture, not in keeping with IOF recommendations. Of the 33 patients with no history of fracture, only one patient (3%) had a T-score consistent with low BMD. There is little evidence to support bisphosphonate use in this group. We therefore conclude that DXA screening in patients less than 40 years should be reserved for those with a history of fracture.

Disclosure of Interests: None declared
Background: Bariatric surgery is increasingly common due to the obesity epidemic. However, there is controversial evidence about the association between bariatric surgery and fracture risk. This may be due to the fundamental differences between patients undergoing bariatric surgery with patients who do not, raising the question: within patients who fracture, are they an increased risk of fracture after surgery? And if so, who is at risk of fracture?

Objectives: 1. To investigate the association between bariatric surgery and risk of three fracture locations using a within person study design comparing a) the year incidence post surgery to the 5 years pre surgery, b) splitting the 5 year post surgery risk into two windows 0-2 and 2.01 – 5 years. 2. To predict who is at risk of fracture following bariatric surgery.

Methods: A self-controlled case series analysis (SCCS) and Stepwise logistic regression (LR) were conducted. Patients undergoing bariatric surgery were identified in the clinical practice research datalink (CPRD) GOLD dataset and linked to hospital episode statistics (HES) data. Prior outcome was any fracture (any skeletal sites except skull and digits). Secondary outcomes were major (hip, spine, forearm and humerus) and peripheral fractures (forearm and lower leg). For the SCCS, Poisson models in those who fractured were fit to calculate Incidence Rate Ratios (IRR) for the aforementioned time windows. Potential predictors were selected with an exit p-value of 0.157 and their predictive performance was reported using a C-statistic.

Results: Of 5,492 patients undergoing bariatric surgery, 252 patients had 272 any fractures, 75 (60) major fractures and 126 (135) peripheral fractures. Average BMI was 43.9. Major fracture risk increased nearly three-fold following surgery: IRR (95% CI) 2.70 (1.31, 5.57). Conversely, the incidence of any and peripheral fractures did not change: IRRs 1.17 (0.86, 1.60) and 0.92 (0.60, 1.42) respectively. Any and major fracture risk increased in the 3rd to 5th year post-surgery: IRRs of 1.73 (1.08, 2.77), 4.98 (1.94, 12.78) respectively. 7 variables were identified which may predict major fracture with a high c-statistics of 0.77 (0.71, 0.88).

Conclusion: Few patients had fractures (252/5492). The incidence of major osteoporotic fracture is increased after bariatric surgery by nearly 3 fold. To then increase to 5 fold in the 2-5 year window. Multiple factors were identified for patients at risk of major fracture post-operatively. External validation is needed. Further research is needed on post-bariatric surgery care to minimise fracture risk.

ISCHEMIA MODIFIED ALBUMIN IN OSTEOPOROSIS

Background: Osteoporosis is a common bone metabolism disease, characterized by low bone mass and pathological fractures. This disease is caused by loss of balance in bone resorption and formation. It is thought that this imbalance is associated with increasing in reactive oxygen species (ROS) and/or insufficiency of antioxidant defense (1). ROS adversely affect the formation and life cycle of osteoclasts, osteoblasts and osteocytes (2). Albumin has many functions such as the transport of molecules, the oncotic pressure of plasma and antioxidation. The damage of the ROS to the N-terminal of the albumin reduces the carrying capacity of the albumin and thus the antioxidant capacity. This damage is evaluated by decreasing the cobalt binding capacity of albumin called ischemia modified albumin (IMA), and IMA shows oxidative damage (3).

Objectives: The aim of this study was to determine IMA levels of patient with osteoporosis.

Methods: OP was diagnosed by T score of bone mineral density (BMD), IMA, albumin levels and IMA/Albumin ratio (IMAR) were studied from the sera of patients with osteoporosis (OP) and healthy volunteers (control) (4). Patients who had any chronic disease such as diabetes mellitus, hypertension, and etc. and any acute disease such as infection were excluded from study. Results were shown as mean ± standard deviation or median (IQR) according to the distribution of variables. p<0.05 was considered significant.

Results: The study included 28 female patients in OP group and 26 female volunteer in control groups. The mean age was 65.5 ± 5.4 and 66.4 ± 7.4 for OP and control groups, respectively (p=0.616). Median (IQR) lumbar T scores of BMD of OP group were -3.1 (-3.32; -2.85). The albumin values of OP and control groups were 4.38 ± 0.13 and 4.40 ± 0.11, respectively; and no significant difference was found between the groups (p = 0.441). The IMA and IMAR results of the OP group were 0.65 (0.61; 0.74) and 0.15 (0.14; 0.17), respectively; and 0.46 (0.40, 0.55), and 11 (0.09; 0.13) in the control group, respectively. (Figure 1). Both IMA and IMAR results were significantly lower in the OP group than in the control group (high ABSU) (p <0.001; for all).

Conclusions: The cobalt binding capacity of albumin decreased in patients with osteoporosis. To the best of our knowledge, this study is the first determining IMA levels in osteoporosis. It is known that the cobalt binding capacity of albumin decreased after oxidative damage. It is shown that IMA is increased in some diseases associated with oxidative stress. Similarly, it was showed that thiol-disulfide balance was shifted to disulfide side in postmenopausal osteoporosis and it was an indicator of oxidative stress (1, 2). In the light of these results, oxidative stress is thought to play role in the pathophysiology of osteoporosis. As a result, antioxidant replacement such as N-acetyl cysteine, lipoic acid, vitamin C, etc. may be recommended to the patients with osteoporosis.

STUDY OF CORTICAL AND TRABECULAR COMPARTMENTS THROUGH 3D-SHAPER IN LUNG TRANSPLANTED PATIENTS

Mireia Barceló-Bru1, Alba Erra1, Carina Espinell2, Hospital Universitari Vall d’Hebron, Rheumatology, Barcelona, Spain; 2Hospital Universitari Vall d’Hebron, Nuclear Medicine, Barcelona, Spain

Background: Osteoporosis in lung transplant (LT) patients is a frequent complication. Glucocorticoid treatment (GC) is a prominent risk factor (RF) that alters both bone mass and architecture. Studying the volumetric BMD using 3D-SHAPER software would help the study of architecture.

Objectives: To study the change in cortical surface density, volumetric trabecular density and integral volumetric density measured by 3D-SHAPER before and after LT as well as changes in bone mineral density (BMD) measured by densitometry (DXA).

Methods: LT patients assessed in Rheumatology are included. The demographic characteristics, diagnosis of lung disease and RF of low bone mass prior to LT are collected. Patients were grouped into 3 groups according to the type of disease, these being: Chronic Obstructive Pulmonary Disease (COPD), Interstitial Lung Diseases (ILD) and OTHER pathologies. Bone mass was evaluated by DXA (GE-LUNAR) before and after 6 months after LT and 3D-SHAPER software (v2.7, Galgo Medical) was applied in all DXAs.

Results: 49 LT patients were included (46.9% women), with an average age of 56.9 ± 8.7 years. In the ILD group, a higher proportion of patients with a low calcium intake (p = 0.027) and with high doses of GC (p = 0.001) was observed. COPD group presented the highest proportion of smokers (p = 0.027). Prevalence of osteoporosis prior to LT was 24.5%, higher in COPD (p=0.007). Values of BMD and 3D-SHAPER as well as the percentage of post-transplant variation are shown in Table 1. Of the 47 patients, 19 (39.8%) started osteoactive treatment before LT, with a higher percentage of patients treated in the COPD group (p = 0.007). Of 42 patients, we have DXA at 6 months post-transplant, with a prevalence of osteoporosis of 23.8%. 27/42 patients underwent post-transplant osteoactive treatment, with an average treatment time until DXA was 19.2 ± 26.1 months, with no differences between groups.

Conclusion:

- Prevalence of low bone mass is high both before and after the transplant.
- Prevalence of some osteoporosis RFs was different between the lung disease groups.
- COPD group presented a worse bone mass before LT. Subsequently, they experienced a significant improvement in BMD and volumetric measurements with respect to the other two groups, which showed losses of these parameters. COPD was the group most treated for osteoporosis and with a lower proportion of patients with GC at high doses.
- Trabecular BMDv was the most altered measure of 3D-SHAPER, with greater decrease in patients with GC at high doses and lower in those with osteoactive treatment.

**SPINAL MOBILITY AND BONE MINERAL DENSITY IN SPONDYLOARTHROSIS**

Laura Bautista1, Asunción Salmoral1, Inmaculada Gómez Gracia1, Ladhesa Pineda Lourdes1, Pérez Sánchez Laura1, Gómez García Ignacio1, Inmaculada Concepción Aranda-Valera2,3, María del Carmen Abalos-Aguilera2, Gamido Castro Juan Luis2,3, Font Ugalde Pilar2,3, María del Carmen Castro Villegas1,2,3, Alejandro Escudero Conteras1,2,3, Eduardo Collantes Estevez2,3, Reina Sofia University Hospital; Rheumatology, Cordoba, Spain; 2University of Cordoba, Cordoba, Spain; 3IMIBIC, Cordoba, Spain

**Background:** Osteoporosis is the most frequent comorbidity in axial spondyloarthritis (axSpA). The change in spinal mobility (traditional measures) in patients with axSpA has been associated with low bone mineral density (BMD) although the data are variable (DIM, lateral flexion, BASMI).

**Objectives:** The aim of our study is to understand the relationship between spinal mobility, BMD and fragility fractures.

**Methods:** Analytical, observational, longitudinal, and retrospective study of a cohort of patients with axSpA (ASAS criteria). Perimenaopausal or menopausal women, diseases and/or osteoporosis treatments, biological drugs, immunosuppressive drugs (at least one year before), and treatment with drugs that interfere in the bone metabolism were excluded; bisphosphonates, ranelate of strontium, selective modulators of the estrogen receptor, calcitonin, hormone therapy, denosumab and teriparatide, among others.

**Results:** 74 patients were studied, 67 were classified as axSpA and 7 as peripheral SpA. Bivariate analysis showed that the group of patients with osteoporosis (14,86%) had a worse DIM (p = 0,001), fragus to wall distance (p = 0,001) and lateral flexion (p = 0,045) than patients who did not have osteoporosis. The multiple regression analysis indicated that lumbar spine T-score was independently associated with BASMI index (B 0,895, p=0,028), and with lower levels of 25 OH vitamin D (B 0,895, p=0,028).

**Conclusion:** UCOAOSMI is a validated metrological index with three-dimensional measurements of human spinal mobility that shows higher levels of objectivity and precision than traditional measures. Subsequent studies will compare mobility parameters (UCOAOSMI) and BMD of patients with axSpA. Clarifying the relationship between spinal mobility, BMD and fragility fractures would help us to better understand the course of the disease in axSpA.

**CHANGES IN CIRCULATING SCLTA-4 FOLLOWING ZOLEDRONIC ACID INFUSION**

Gerardino Bianchi1, Daniere Saverino2, Dario Carmellino1,2, Andrea Giusti1, Erika Iervasi3, Giuseppe Girasole3, Socrates Papapoulos1,3,1. *LOCAL HEALTH TRUST 3, DIVISION OF RHEUMATOLOGY, MUSCULOSKELETAL SYSTEM DEPARTMENT, Arezzo, Italy; 2UNIVERSITY OF GENOA, AUTOIMMUNOLOGY LABORATORY, DEPARTMENT OF INTERNAL MEDICINE, Genoa, Italy; 3LEIDEN UNIVERSITY MEDICAL CENTER, CENTER FOR BONE QUALITY, Leiden, Netherlands

**Background:** Acute phase response (APR) is a transient, flu-like reaction to first exposure to intravenous nitrogen-containing bisphosphonate (NBP). APR is characterised by a strong inflammatory response, associated with increases in circulating levels of IL-6 and TNF-, that is thought to be due to activation and increased proliferation of γδ T cells related to the molecular mechanism of action of NBP. Cytoytic T-Lymphocyte Antigen-4 (CTLA-4), in both its soluble (s) and membrane-bound forms, is involved in the downregulation of T cell proliferation, cell cycle progression and cytokine production. High levels of serum sCTLA-4 have been reported in several autoimmune diseases, and its role as both inhibitor and enhancer of the immune response has been proposed.

**Objectives:** To evaluate the potential relationship between sCTLA-4 and the development of APR in patients treated with zoledronic acid (ZOL).

**Conclusion:** The trend for increasing low trauma distal forearm fractures in women age 40-59 yrs may reflect the decreased use of hormone replacement therapy, which would likely have particularly impacted this age group. The decrease in fractures in men age ≥ 80 yrs may reflect greater recognition, in recent years, of osteoporosis in older men and initiation of treatment. Whether changes in practice patterns are actually contributing to these observed trends warrants further review.

**FRI0479**

**TRENDS IN LOW TRAUMA DISTAL FOREARM FRACTURE INCIDENCE IN WOMEN AND MEN OVER 1995-2015 IN OLMSTED COUNTY, MINNESOTA, USA**

Delamo Beloje, Elizabeth Atkinson, Shreyasee Amin. Mayo Clinic, Rochester, United States of America

**Background:** It is unclear how recent practice changes of decreased use of hormone replacement therapy and drug holidays from bisphosphonate therapy have impacted incidence of fragility fractures. Fragility (low trauma) fractures at the distal forearm in women may be more likely to be impacted by these changes as compared with men.

**Objectives:** We examined the trends in distal forearm fracture incidence over 1995-2015, in both women and men, from Olmsted County, Minnesota, USA.

**Methods:** Using the Rochester Epidemiology Project, a unique medical records linkage system that allows access to all (inpatient and outpatient) community medical records for Olmsted County residents, we identified all incident distal forearm fractures among residents age ≥18 years between 1995-2015. Available medical records were reviewed by trained nurse abstractors to validate distal forearm fractures identified and to determine their antecedent cause (pathological process [e.g., malignancy], severe trauma [e.g., motor vehicle accidents, sports/other recreational activities] and low trauma [by convention, equivalent to a fall from standing height or less]). Overall incidence rates were summarized separately for women and men, as well as by 5 year strata for different age groups (ages 18-39, 40-59, 60-79 and ≥ 80 yrs). Rates for women and men were each directly age-adjusted to the population distribution of US whites in 2010.

**Results:** Between 1995-2015, we identified 2727 distal forearm fractures in women (70%, median age 62 yrs; 1915 due to low trauma) and 1193 distal forearm fractures in men (30%, median age 48 yrs; 450 due to low trauma), 92.3% of which were in whites. The overall age-adjusted annual incidence of first distal forearm fracture over 1995-2015 was 233 per 100,000 person-years (p-y) for women and 113 per 100,000 p-y for men. When considering only fractures due to low trauma, the overall age-adjusted annual incidence of first distal forearm fracture over 1995-2015 was 169 per 100,000 p-y for women and 49 per 100,000 p-y for men. Rates of low trauma distal forearm fracture appear to be stable in younger (18-39 yrs) women, but since 2005, seem to be increasing in women age 40-59 yrs (Table). In contrast, rates in older women appear to be decreasing or are stable since 2005. In men, the rates of low trauma distal forearm fracture appear to have relatively unchanged over the past 20 years, except in men age ≥ 80 yrs where the rates have generally been lower since 2005 (Table).

**Conclusion:** The trend for increasing low trauma distal forearm fractures in women age 40-59 yrs may reflect the decreased use of hormone replacement therapy, which would likely have particularly impacted this age group. The decrease in fractures in men age ≥ 80 yrs may reflect greater recognition, in recent years, of osteoporosis in older men and initiation of treatment. Whether changes in practice patterns are actually contributing to these observed trends warrants further review.

**DOI:** 10.1136/annrheumdis-2019-eular.7101
Methods: Included in the study were patients treated with a single intra-
venous ZOL infusion 5 mg. Exclusion criteria were previous treatment with 
ZOL, treatments interfering with CTLA-4, and estimated glomerular fil-
tration rate <35 ml/min. APR was defined as a rise in axillary tempera-
ture of 1°C or more at any time during the first 48 hours and an increase in 
musculoskeletal pain by more than 10 mm in a visual analogue scale 
(VAS, from 0 to 100 mm). Clinical and laboratory parameters were 
assessed at baseline, before ZOL, and at 24, 48 and 72 hours after the 
infusion.

Results: Ten female patients (mean age 73-10 years) were included (2 
avertbral fractures and the remaining had osteoporosis), 5 of whom 
experienced APR (APR+) associated with the expected increases in 
s serum CRP and IL-6. Baseline levels of sCTLA-4 did not differ between 
APR+ and APR- patients and decreased significantly in all from 32.9 ng/ 
ml to 24-9 ng/ml (p=0.007) at 24 hr, 16-8 ng/ml (p=0.004) at 48 hr and 
7-6 ng/ml (p=0.001) at 72 hr. Absolute value of sCTLA-4 and mean% 
change of sCTLA-4 after ZOL were not statistically different between 
APR+ and APR- patients. At 72 hr, sCTLA-4 decreased by 77% (-23%) 
in APR+ and by 81% (-20%) in APR- (p=0.786). There were no statisti-
cally significant correlations between serum sCTLA-4 levels with any cli-
nical or biochemical parameter of APR.

Conclusion: Our study is in accordance with our hypothesis, sCTLA-4 was not related to the 
ocurrence of the APR after ZOL. The significance of the substantial 
decrease of circulating levels of sCTLA-4 after ZOL in all studied patients 
warrants further investigation.

FRIO481 MEDIATORS OF BONE METABOLISM (DKK1, OPG 
SCLEROSTIN AND RANKL) IN A COHORT OF PATIENTS 
WITH ELDERLY-ONSET ARTHRITIS

Asavy Brandy-Gama1, Melanie Martinez-Morillo1, Roxana Cora2, Lourdes 
Mato Soria1, Susana Holgado Perez2, Maria Aparicio Espinar1, Angélica Prier-
Español1, Anne Riveros1, Clara Sanguesa1, Jordi Camins-Fàbregas1,
1Department of Rheumatology, Hospital Universitario Germans Trias i Pujol, University of Lleida, Spain; 
2University of California, Department of Medicine, School of Medicine, San 
Diego, United States of America

Background: Patients with elderly-onset arthritis have greater comorbidity 
than young patients, with a higher incidence of osteoporosis (OP), prob-
ably mediated by increased bone resorption. However, there are few data 
on bone metabolism mediators in this population.

Objectives: To analyze bone remodeling mediators (DKK1, sclerostin, 
osteoprotegerin [OPG], and RANKL) in patients with elderly-onset arthritis 
and its relationship with bone mineral density.

Methods: Longitudinal observational study that included patients with elde-
ry-onset arthritis (> 65 years) without diagnosis of OP or on antioste-
oporotic treatment. Phospho-calcium metabolism, quantification of bone 
remodeling mediators (ELISA, R&D systems) and bone densitometry, 
determined in all patients at diagnosis and at 12 months. The results 
were compared with a control group of the same age and sex 
(n=14). The statistical study was performed using SPSS.

Results: We included 73 patients (37F: 36M), with a mean age of 75±7 
years. Most were diagnosed with rheumatoid arthritis (RA) (n=43), fol-
lowed by polyarthritis rheumatica (n=16) and others (n=14). Fifteen 
patients were rheumatoid factor (RF) positive and 23 were ACA positive. 
Five patients had erosions at the diagnosis. 88.64% of patients with RA 
noticed an increase in musculoskeletal pain by more than 10 mm in a visual 
analogue scale (VAS, from 0 to 100 mm). Clinical and laboratory parameters were 
assessed at baseline, before ZOL, and at 24, 48 and 72 hours after the 
infusion.

At diagnosis, patients with elderly-onset arthritis had higher levels of 
DKK1 and CTX than the control group, with no statistically significant dif-
fences in sclerostin, OPG, and RANKL values (table 1). In addition, 
DKK1 values were negatively correlated with sclerostin (r=-0.286, 
p=0.016) and OPG (r=-0.276, p=0.020), 31.9% had densitometric OP. We 
found no significant differences in bone remodeling mediators between 
patients with/monthly basophil OCP.

At 12 months, DAS28- VSG was <2.6 in 38.1%. The mean corticosteroid 
dose was 5.5 mg/day with a cumulative dose of 1630±426 mg. 45.8% 
received antiresorptive treatment (28 patients’ bisphosphonates and 5 
denosumab). The prevalence of OP at 12 months was 31.3% and 4 
patients had new fractures during (4 vertebra and 1 femur fractures). We 
observed a marked decrease in the values of DKK1 (-18.89%, p<0.001) 
and sclerostin (-46.76%, p<0.001) and an increase in OPG (11.97%, 
p=0.018).

We didn’t found relationship between bone metabolism mediators and 
cumulative corticosteroid dose. There were no differences in terms of 
diagnosis (RA or PRM), ACPA positivity, activity scores or treatment with 
bisphosphonates.

Conclusion: Patients with elderly-onset arthritis have higher DKK1 values 
than the control group, and this correlate negatively with sclerostin and 
OPG. The marked decrease in Dkk-1 and sclerostin at 12 months, and 
the increase in OPG, suggests a role for these mediators in the bone 
metabolism of this population. It is important to note the high prevalence 
of OP in this group of patients.

Table 1. We excluded patients treated with denosumab. 1 p<0.005 with respect to the 
control group. 2 p<0.05 with respect to baseline

FRIO482 RISK FACTORS FOR FRAILITY FrACtURE IN 
PATIENTS WHO SMOKE: AN OBSERVATIONAL STUDY

Dominic Beith1, Manwan Bukhari1, 2Lancaster University, Lancaster Medical 
School, Lancaster, United Kingdom; 3Royal Lancaster Infirmary, Rheumatology, 
Lancaster, United Kingdom

Background: Smoking is a risk factor for osteoporosis and increases the 
likelihood of a fragility fracture. It is included in the FRAX™ tool, which 
is used as an aid for bone mineral density (BMD) referral and as a risk 
stratification for the propensity of developing a fragility fracture. The addi-
tive effect of other risk factors including demographics increasing the risk 
of fracture has not been explored in a large cohort.

Objectives: To investigate the additive predictors of fracture in patients 
who have smoking as their only risk for fracture, referred for BMD 
estimation.

Methods: Patients who were referred for bone mineral density (BMD) esti-
mation in a scanner in the North West of England between June 2004 
and October 2015 were included in the analysis. Patients with only 
smoking as a FRAX™ risk factor were then analysed. All patients have 
their other risk factors for fracture and demographics recorded at time of 
scan. All patients with other FRAX™ indications for scanning were 
excluded including Rheumatoid Arthritis, Excess Alcohol, Steroids, family 
history of fracture and Secondary Osteoporosis. Patients in the smoking 
group were divided into those that had experienced a fracture and those 
that had not before comparing with Chi-squared test for categorical varia-
tbles and T-test for continuous variables. Univariate and multivariate logis-
tic models were then fitted to examine predictors of fracture in this group.

Results: 35,759 patients were referred for scanning during the period. 
4096 (11.45%) were referred with smoking as their only indication for 
scanning. Mean age at scan was 64.43 (SD 12.38) and 3244 (79%) of 
the report were females. 1663 (40.6%) had a fracture. Fractures were 
more prevalent in males with 383 (44.9%) compared to 1280 (39.46%) 
in females (p<0.05).

Univariate predictors shown in the Table 1 below.
In the multivariate model, the only variables associated with increased fracture risk was increasing age at scan decreased BMD total left and increased percentage body fat. All other factors did not significantly increase fracture risk in this cohort.

Conclusion: Our study suggests that many risk factors are associated with fragility fractures in those with smoking as their only risk factor; the best predictor was age at scan, BMD and gender. The percentage body fat association with increased fracture risk is quite surprising and would need further study. Percentage body fat is not currently included in the FRAX™ tool.

FRD0483 INTEREST OF A SYSTEMATIC SCREENING OF OSTEOPOROSIS IN HEART TRANSPLANT PATIENTS

Coralie Romain1, Constance Verdore2, Sébastien Ottaviani1, Julia Goossens1, Lucie Demaria1, Elisabeth Palazzo1, Richard Doreen1, Philippe Dieude1, Marine Forlenic1, Hédiplat Bichat, Rheumatology, Paris, France; Hédiplat Bichat, Cardiology, Paris, France

Background: Osteoporosis is common among patients with end-stage heart disease. A rapid decrease of bone mineral density (BMD) is usually observed after heart transplantation. Bone loss is probably linked to gluconocorticoids and calcineurin inhibitors use and vitamin D deficiency. The prevalence of osteoporosis seems to be favored by a low BMI, which is common during CD in relation to the associated malabsorption. Thus, screening for osteoporosis should be advocated early in the course of CD.

Objectives: The aim of this study was to evaluate the interest of a systemic screening of osteoporosis in heart transplant patients.

Methods: We performed a prospective monocentric study including patients, who had heart transplantation in our hospital, from December 2016 to January 2019. The following parameters were systematically assessed: history of cardiac disease, immunosuppressive therapies, glucocorticoids, previous history of low trauma fracture, known risk factors of osteoporosis, treatment received for bone disease management (calcium, vitamin D and bisphosphonates). Blood tests with creatinine clearance, calcium and vitamin D levels, were assessed. Bone densitometry and spine radiographs (to search asymptomatic vertebral fractures) were assessed in all patients. Osteoporosis was defined respectively for patients ≥50 years and <50 years as a T-score ≤−2.5 SD and Z-score ≤−2 SD either at lumbar spine (L2-L4), femoral neck or hip.

Results: A total of 42 patients were included (76.7% male), mean age was 58.1±10.6 years, mean duration after transplantation was 2.6±3.1 years. Past or active smoking statuses were observed in 26 patients (mean 23.9 pack-years). Calcium, vitamin D and bisphosphonates were administered in 13 (30.9%), 10 (23.8%) and one patients, respectively. All patients received prednisone (mean dose: 10.75±4.9 mg per day). Mean lumbar spine BMD was 1.03±0.25 g/cm2 and left femoral neck BMD 0.85±0.15 g/cm2. Osteoporosis was observed in 18 (45%) patients. Only one hip fracture was known before heart transplantation. Incidental low trauma fractures after transplantation were diagnosed in 14 patients (33.3%). 11 patients with vertebral fractures (mean 2 vertebral fractures per patient) including 4 patients with asymptomatic vertebral fractures. Others low trauma fractures were hip fracture, proximal humerus and fibula for one patient each. Mean duration between transplantation and the first low trauma fracture was 7.5±3.7 months. Low level of calcemia was found in 20 patients (47.6%) and low level of vitamin D (≤30ng/ml) in 32 patients (76.2%) associated with secondary hyperparathyroidism in 21 patients (51.2%), mean creatinine clearance was 51.7±19.9 ml/min. After evaluation, specific treatment of osteoporosis was started for 33 patients (78.6%): zoledronic acid (n=20), denosumab (n=8), alendronate (n=4) and teriparatide (n=1).

Conclusion: Systematic screening of osteoporosis seems to be useful in heart transplant patients. Osteoporosis was observed in half of these patients with a high frequency of low trauma fracture after heart transplantation, particularly in the first year.

FRD0485 RESULTS OF BONE MINERAL DENSITY DURING CELIAC DISEASE: ABOUT 83 CASES

Cyrine Daldoul1, Nejla El Amri1, Khadija Baccouch1, Hela Zeglaoui2, Elyes Bouajina2.

Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

Background: The prevalence of osteopenia during celiac disease (CD) can range from 38% to 72%. In fact, it is a pathology that causes bone loss and is associated with a higher fracture risk compared to the general population.

Objectives: The aim of this work is to determine the frequency and factors associated with the decline in bone mineral density in adult subjects with CD.

Methods: This is a retrospective study, over a period of 4 years (from January 2016 to December 2019) and including patients followed up for MC who had a measurement of bone mineral density (BMD) by DXA. Clinical, anthropometric and densitometric data (BMD at the femoral and vertebral site) were recorded.

The WHO criteria for the definition of osteoporosis and osteopenia have been used.

Results: 83 patients were collected among them 12 were men (sex ratio = 0.16). The average age was 38.2 years old. The average body mass index (BMI) was 21.64 kg/m² [13.05-31.9 kg/m²]. Undernutrition (BMI <19 kg/m²) was found in 21 cases. It was associated with hyperthyroidism in 5 cases, autoimmune hepatitis in 1 case and primary amenorrhoea in 2 cases. 2 patients had a history of fragility fracture, and 5 patients had a history of fragility fracture in a first-degree relative.

Osteodensitometry showed low bone mass in 36 cases: osteoporosis in 23 patients (27.7%) and osteopenia in 13 cases. Osteoporosis was found in 21 patients: 1 man and 20 women. Mean femoral BMD was 0.887 g/cm³ and vertebral BMD was 0.999 g/cm³. The mean T-score at the femoral site and the vertebral site were -1.28 SD and -1.26 SD, respectively. No correlation was found between age and BMD and bone status. Comparing patients with a BMI <19 kg/m² to those with a BMI ≥ 19 kg/m², BMD at the vertebral site was significantly lower in malnourished subjects (p = 0.01), a significant correlation was found between BMI and vertebral BMD (p=0.000).

Conclusion: The decline in BMD was observed in third of our patients. It seems to be favored by a low BMI, which is common during CD in relation to the associated malabsorption. Thus, screening for osteoporosis should be advocated early in the course of CD.

Disclosure of Interests: None declared

including the TUG test. TUG performance was considered low if it took, 15 seconds or longer. A vertebral fracture assessment (VFA) image was obtained which was subsequently scored for the presence of significant vertebral deformities. VF grade 1 were excluded.

Results: Eighty-four patients were included. The mean age of our patients was 62.29±8.27 years with an average body mass index (BMI) of 31.45±6.21 kg/m² [18.18-44.38]. According to the WHO classification 42 patients (50%) had osteoporosis. Among 84 women, 47 had a low TUG performance, subjects with low TUG performance had an older age (57.94 vs 65.71 years) (p<0.001), and had a significantly lower BMD at femoral neck (0.825 g/cm² vs 0.752 g/cm²) (p<0.001). There was no significant difference between the two groups regarding duration of meno-

Disclosure of Interests: None declared

sensitivity, specificity and positive and negative predictive values (PPV, NPV) were evaluated to determine the diagnostic accuracy of the two methods.

Results: Most of the patients were receiving GC treatment for vasculitis or polyarthritis rheumatica over a mean period of 47.7±69 months at a mean daily dose of 14.5mg. 17% had VF, 28% any type of fragile fracture (VF + no-VF), 29% OP and 71% DMA. In patients with VF, low TBS (DMA) was more common than densitometric OP (76%, p<0.03 vs. 36%, p<0.05). Similar results were observed when analysing patients with any fragile fracture (69%, p=0.02 vs. 36%, p<0.05). The diagnostic accuracy of TBS was greater than BMD on evaluating VF, with a sensitivity, specificity, PPV and NPV of 0.76, 0.53, 0.25 and 0.92 for TBS and 0.38, 0.72, 0.22, and 0.85 for BMD, respectively. Specificity increased to 0.89 for VF and 0.99 for any fragile fracture on combining both assessments (OP+DMA).

Conclusion: TBS has greater discriminative power than BMD measurement and could be useful as a complementary tool for fracture risk assessment in OIFP.

FRIO488 ROLE OF DUAL-PHOTON X-RAY ABSORPTIOMETRY (DXA) IN PREDICTION OF FRACATURE AND MORTALITY

Sara Ganhão1, Miguel Guerra1, Francisco Aguilã1, Raquel Ferreira1, Teresa Martins-Rocha2, Ana Filipa Agueda3, Georgina Terroso1, Eva Mariz1, Carlos Vaz1,4, Lúcia Costa1,4,1 Centro Hospitalar e Universitário de São João, Department of Rheumatology, Oporto, Portugal, 2Centro Hospitalar de Vila Nova de Gaia/Espinho, Department of Rheumatology, Vila Nova de Gaia, Portugal, 3Centro Hospitalar do Baixo Vouga, Department of Rheumatology, Aveiro, Portugal, 4Faculty of Medicine of Oporto University, Oporto, Portugal

Background: The presence of a fragile fracture leads to a high risk for a subsequent fracture and mortality. Although bone mineral density (BMD) does not reflect the real fracture risk in many conditions, it is a well-established predictor of fracture risk and for many years, dual-photon X-ray absorptiometry (DXA) has been the reference standard for measuring BMD.

Objectives: To evaluate the predictive significance of femur BMD and T-score obtained by DXA in the outcomes fracture and mortality of elderly patients with a previous fragility hip fracture.

Methods: Longitudinal retrospective study of patients referred to the Rheumatology department’s Fracture Liaison Service (FLS) from March 2015 until March 2017 aged ≥65 years old. Demographic and clinical data were collected including DXA results. Statistical analysis was performed with STATA. Hazard ratios (HR) were calculated through cox regression, adjusted to age and degree of dependence.

Results: From a total of 522 patients, 214 performed DXA (77.6% with STATA. Hazard ratios (HR) were calculated through cox regression, were collected including DXA results. Statistical analysis was performed with STATA. Hazard ratios (HR) were calculated through cox regression, adjusted to age and degree of dependence.

Results: From a total of 522 patients, 214 performed DXA (77.6% with STATA. Hazard ratios (HR) were calculated through cox regression, adjusted to age and degree of dependence.

Results: From a total of 522 patients, 214 performed DXA (77.6% with STATA. Hazard ratios (HR) were calculated through cox regression, adjusted to age and degree of dependence.

Results: From a total of 522 patients, 214 performed DXA (77.6% with STATA. Hazard ratios (HR) were calculated through cox regression, adjusted to age and degree of dependence.

RESULTS:

FRIO489 THE ASSOCIATION BETWEEN CT-MEASURED BONE ATTENUATION AND PREVALENT VERTEBRAL FRACTURES IN THE THORACIC SPINE DIFFERS ACCORDING TO VERTEBRAL FRACTURE LOCATIONS

Mayke J van Dort1, Annemarie Driessen2, Joop van den Bergh1, Emiel Fm Wouters1, Elisabeth AM Romme1, Frank Wijn Smeenk2, Bert van Rietbergen3, Piet Geusens4, Maartje University, Maasricht, Netherlands; 4Maartje University, Maastricht, Netherlands; Universiteit, Maastricht, Netherlands; Catharina Hospital, Eindhoven, Netherlands; T+U Eindhoven, Eindhoven, Netherlands

Background: Subjects with prevalent vertebral fractures (VF) have lower bone mineral density (BMD) in the lumbar spine and hip than subjects without prevalent VF. However, VFs are not equally distributed across the thoracic spine. They occur preferentially at T7-T8 and T11-T12, which are the highest loaded vertebral regions during daily activities. (1).

Objectives: We evaluated the association of BMD with prevalent VFs at non-preferential locations (nprVFs: T4-T6 and T9-T10) and at preferential locations (pVFs: T7-T8 and T11-T12).

METHODS: Baseline CT images of T4-T12 in smokers with and without COPD were analysed for the presence of VFs according to Genant. Bone attenuation (BA), expressed in Hounsfield units (HU), was measured in all non-fractured vertebrae. Linear regression was used to compare mean BA and logistic regression was used to estimate the association between BA and prevalent VFs. All analyses were adjusted for age and sex.

Results: Prevalent VFs were most frequently located at T7-T8 (in >6% of vertebrae) and T11-T12 (in >4% of vertebrae).

At subject level and compared to subjects without prevalent VFs, mean BA of all non-fractured vertebrae was significantly lower in subjects with any prevalent VFs (-21%, p<0.0001). There was a significant progressive trend (p<0.0001) in decrease in mean BA of all non-fractured vertebrae between subjects with only prVFs (-15%), with only nprVFs (-25%, p<0.05 vs prVFs) and with both nprVFs and prVFs combined (-32%, p<0.0001 vs prVFs) (all p<0.0001 compared to subjects without VF). At each individual non-fractured vertebral level, each BA decrease of 5% was associated with a 2.0-2.5 increased odds of any prevalent VF, a 1.5-1.9 increased odds of only prVF, a 2.2-3.4 increased odds of only nprVF and a 3.8-4.6 increased odds of prVF and prVFs combined.

Conclusion: In addition to BA, other factors such as vertebral load during daily activities may determine the location of a VF. The location of a VF may be a potential in vivo marker of the load/strength ratio of bone.

GOAL-DIRECTED TREATMENT OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING DENOSUMAB FOR THREE YEARS

Yui Hirano1, Yasuhide Kanayama2, KyoSuKe Hattori2, Daisuke Kihira1, Naoki Ishiguro3, Toshihisa Kojima1, Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan; 2Toyota Kosei Hospital, Orthopaedic Surgery and Rheumatology, Toyota, Japan; 3Nagoya University School of Medicine, Orthopaedic Surgery and Rheumatology, Nagoya, Japan

Background: Osteoporosis (OP) is frequently concomitant with rheumatoid arthritis (RA). Effective treatment has to be performed in OP in RA (RAOP). Denosumab (DMB) is one of the promising drugs for the treatment of RAOP. We reported results of 12-month DMB treatment for RAOP. Denosumab (DMB) is one of the promising drugs for the treatment of RAOP. Longer duration or earlier initiation of DMB treatment for RAOP is not possible in LS-BMD and in TH-BMD when 3-year DMB treatment was used as treatment for RAOP. This study suggested that achievement of treatment goal within 3 to 5 years of starting therapy was achieved treatment goal in 19.2% at 1 year, 28.8% at 2 years and 44.4% at 3 years (Fig1A). The achiever had significant lower baseline T-score of TH-BMD (-2.6 vs. -3.3: p<0.01) than the non-achiever did. The achiever had significant lower baseline T-score of TH-BMD (-2.6 vs. -3.3: p<0.01) than the non-achiever did. The aim of this retrospective study is to evaluate whether 3-year DMB treatment can achieve treatment goal of OP reported recently from TBCR-BONE.

Methods: This study used 78 female RAOP patients who completed 3-year DMB treatment for RAOP. 36 patients in whom baseline T-score of LS-BMD were -2.5 or less were included in LS-BMD analysis. 52 patients in whom baseline T-score of TH-BMD were -2.5 or less were included in TH-BMD analysis in the same way. As was in clinical setting in Japan, 60mg DMB was administered every 6 months with vitamin D3 agent. Patients’ characteristics, time course of T-score and baseline characteristics related to achievement of treatment goal (T-score>2.5) were investigated.

Results: Baseline characteristics of 78 patients: Mean age was 71 years. RA duration was 17 years. Prednisolone user was 32%, LS-BMD analysis (n=35) T-score was significantly increased (-3.5 at baseline, -3.0 at 1 year, -2.9 at 2 years, -2.6 at 3 years). The rates of patients who achieved treatment goal were 30.6% at 1 year, 38.9% at 2 years and 44.4% at 3 years (Fig1A). The achiever had significant lower baseline fracture risk by FRAX (20.1% vs. 33.9%; p=0.013), significant lower baseline mHAQ (0.45 vs. 1.05; p=0.03) and significant lower baseline T-score of LS-BMD (3.0 vs. -3.9; p=0.01) than the non-achiever did. TH-BMD analysis (n=52) T-score was significantly increased (3.2 at baseline, -3.0 at 1 year, -2.9 at 2 years, -2.9 at 3 years). The rates of patients who achieved treatment goal were 19.2% at 1 year, 28.8% at 2 years and 25.0% at 3 years (Fig1B). The achiever had significant lower baseline bone turnover marker (PINP and TRACP-5b) and significant lower baseline T-score of TH-BMD (-2.6 vs. -3.3; p<0.01) than the non-achiever did. Cut-off values at baseline for achievement of treatment goal calculated using receiver operating characteristic analysis was -3.4 in LS-BMD and -2.7 in THBMD.

Conclusion: This study suggested that achievement of treatment goal in RAOP is possible in LS-BMD and in TH-BMD when 3-year DMB treatment was used as treatment for RAOP. Longer duration or earlier initiation of DMB treatment is necessary to achieve the goal. Although response in LS-BMD was related to fracture risk and physical function, response in TH-BMD was related to bone turnover. We will report 5-year results in the future.

MANAGEMENT OF SECONDARY OSTEOPOROSIS FRACTURES IN FRACTURE LIAISON SERVICE OF REIMS HOSPITAL IN FRANCE: STUDY AT 25 MONTHS OF FOLLOW-UP

HITTINGER Ambre1, Jean-Hugues Salmon2, Jean Paul Eschard2, Isabelle Charlal-Lambrecht1, 1Reims University Hospital, Rheumatology, Reims, France; 2Reims University Hospital, Rheumatology, Reims, France

Background: Osteoporosis is a major public health issue, progressing with the aging of the population and responsible for nearly 400,000 fractures/year in France. Fracture Liaison Services (FLS) are systems of detection and secondary prevention of osteoporotic fractures. These systems are recognized as effective by international scientific societies.

Objectives: The aim of this study was to evaluate the efficiency of Reims Hospital FLS protocol after 25 months of implementation.

Methods: We performed an ambispective monocentric observational study at the Reims Hospital between April 2016 and May 2018. We included patients over 50 years who were hospitalized in the orthopedic department for osteoporotic fractures. These patients were evaluated clinically, biologically and radiographically during a one-day hospitalization in the rheumatology unit. Therapeutic compliance and fracture recurrence were assessed in consultation at 3-month and 1-year telephone interviews.

Results: Sixty-four/242 patients (26.4%) identified in orthopedic service were included. The average age was 72 years old with a sex ratio of 1:1.0. The most common fracture was the proximal end of the femur for 25 patients (35%). Fifty-five patients (85.9%) had an indication for osteoporosis treatment, the most prescribed was zoledronic acid for 45 patients (81.9%). Twenty-four/55 patients (43.6%) started their treatment and 22/24 (91.7%) were still treated at one year. One patient (1.63%) died within the follow-up period. Twelve/55 patients (21.8%) presented a new fall and 7/55 patients (12.7%) experienced a new fracture.

Comparative analysis of observant versus non-observant population groups at 1 year showed that non-observant patients had significantly more recurrent falls (93.54% versus 68.18%, p = 0.024) and received treatment of zoledronic acid (93.56% versus 63.64%, p = 0.010).

Further analysis showed that our low rate of initiation treatment was due to difficulties in implementing bisphosphonates, mainly because of the dental care needed. However, we observed a high rate of treatment adhesion at 1 year, once the treatment is started. During this study, we identified 2 areas of improvement: therapeutic education to improve patient adherence and fall risk factors to decrease recurrent fall rate.

Conclusion: There is a real benefit to the establishment of this FLS with a high rate of therapeutic compliance at 1 year follow-up. However there are opportunities for improvements in treatment initiation through patient therapeutic education.

CALCULATING FRAX SCORE IN CLINICAL PRACTICE: PITFALLS AND PROBLEMS

Navneet Kaur1, Barbara Mendez2, Avneet Vig3, Beverly Johnson1, Tony Francis4, 1Albert Einstein College of Medicine/Jacobi Medical Center, Rheumatology, Bronx, United States of America; 2Cleveland Clinic Martin Health, Rheumatology, Port St. Lucie, United States of America; 3Christiana Hospital, Nuclear Medicine, Newark, United States of America

Background: Osteoporosis related fractures cause significant morbidity and mortality. FRAX score uses clinical risk factors and country-specific data in addition to Bone Mineral Density (BMD) to assess patients with high 10-year risk of hip (>3%) or major osteoporotic (>20%) fracture. We noticed discrepancies between radiologist reported and physician calculated FRAX scores at our hospital. We hypothesized that providers are calculating FRAX score differently as BMD in the FRAX calculator is an optional input variable.

Objectives: This study was initiated to see the differences in results when FRAX score is calculated using T-score, BMD and no BMD and how this difference can influence treatment.

Methods: Retrospective chart review of 1200 DEXA reports from 2013 to 2015 was done. Patients between ages of 40-90 years with T-score ranging from ≤ -1 to >2.5 at femoral neck were included in the study. Patients already on osteoporosis therapy and/or with T-score when FRAX score is calculated using T-score, BMD and no BMD value and radiology reported scores by radiologist in the chart was also reviewed. Subsequently, FRAX scores obtained using T-score, no BMD value and radiology reported scores were compared against FRAX score calculated using femoral neck BMD (gold standard)

Results:

When FRAX score calculated using BMD was compared with FRAX score calculated without BMD, number of patients with high 10-year fracture probability decreased from 49 to 11 patients, which was a statistically significant decrease of 77.6% (p<0.001). When data was stratified according to age, there was significant overestimation of risk in patients >65 years (p<0.0001) when FRAX was calculated without BMD.

Conclusion: FRAX score calculation without BMD leads to both statistically and clinically significant overdiagnosis especially in elderly.

Interchanging T score and BMD to calculate FRAX score leads to same treatment decision.

Further education of providers regarding FRAX score is needed.

FRIO493 CLINICAL EFFICACY OF DENOSUMAB IN PATIENTS WITH OSTEOPOROSIS BETWEEN RHEUMATOID ARTHRITIS AND PRIMARY OSTEOPOROSIS; 24 MONTHS OF FOLLOW-UP

Yasuhide Kanayama1, Taichi Tsujii2, Nashisa Futamura2, Naoki Osada2, Hiroto Tachi2, Kazuonri TODOROKI2, Ryusuke Sugimoto2, 1Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan; 2Toyota Kosei Hospital, Orthopedic Surgery, Toyota, Japan

Background: Denosumab (DMB) is a fully human monoclonal antibody to the receptor activator of nuclear factor-kappaB ligand (RANKL) that blocks its binding RANK, inhibiting the development and activity of osteoclasts, decreasing bone resorption, increasing bone density and reducing fracture risk. Also DMB is a useful therapeutic agent for both rheumatoid arthritis (RA-OP) and primary osteoporosis (P-OP). However there is still few comparative study of clinical efficacy of DMB between RA-OP and P-OP.

Objectives: To compare the clinical efficacy of DMB in patients with osteoporosis between rheumatoid arthritis and primary osteoporosis for 24 months.

Methods: RA patients diagnosed according to the 2010 ACR/EULAR criteria, RA-OP and P-OP patients met at least one of the following criteria were eligible: a bone mineral density T score of -2.5 or less at the lumbar spine or total hip and either one or more moderate or severe vertebral fractures or two or more mild vertebral fractures. All patients were initiated DMB from between October, 2013 and August, 2016. The final study cohort of 61 RA-OP and 50 P-OP patients received continuous DMB therapy more than 24 months. The DMB dose was 60mg at once every 6 months. In all cases native or activated vitamin D has been used. We reviewed the results for 24 months about the increase and decrease of bone mineral density(BMD) of lumbar spine(LS) and total hip (TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen(PINP) and tartrate-resistant acid phosphatase form 5b (TRACP-5b).

Results: In the patients of RA-OP (n=61) and P-OP (n=50), the number of female was each 56(92%) and 45(90%) cases (p=0.741). The mean age was 72.7 ± 7.5 and 76.8 ± 7.8 years old (p=0.006); disease duration of RA-OP patients was 12.6 ± 12.9 years; the body mass index was 20.4 ± 2.7 and 20.3 ± 3.0 (p=0.687) and the FRAX was 27.2 ± 15.7 and 24.6 ± 11.1 (p=0.745). Clinical findings related to RA-OP at baseline were as follows; CRP 0.8 ± 1.1; DAS-CRP 3.28 ± 1.36; HAQ 1.16 ± 1.04 in RA-OP patients and in the patients of RA-OP and P-OP, bone turnover markers and bone mineral density at baseline were as follows; PINP 57.7 ± 32.2 and 64.0 ± 32.7 μg/l (p=0.151); TRACP-5b 563

Disclosure of Interests: Navneet Kaur: None declared, Barbara Mendez: None declared, Avneet Vig: None declared, Beverly Johnson: Employee of ownership of Johnson and Johnson stock over 10,000 USD, Consultant for: I am a consultant for the rheumatology education group, Employee of: I have been paid indirectly by pharma as a consultant for the rheumatology education group, Tony Francis: None declared

CORRELATION OF METACARPAL BONE MASS MEASURED EITHER BY DUAL X-RAY DENSITOMETRY OR DIGITAL X-RAY RADIOGRAMMETRY WITH SEVERITY OUTCOMES IN PATIENTS WITH EARLY ARTHRITIS

Irene Llorente, Saturnino González, Eugenio Escolano, Ana María Ortiz, Alberto García-Vadillo, Isidoro González-Álvaro, Santos Castañeda. University Hospital La Princesa, Rheumatology Department, Madrid, Spain; University Hospital La Princesa, Radiology department, Madrid, Spain

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disorder that predominantly affects small joints of the hands and feet. X-ray digital radiogrammetry (DXR) is a validated technique for the evaluation of bone mineral density (BMD) in the diaphysis of metacarpals (MC) that has demonstrated that low bone mass at this location correlates with worse radiographic progression (1). However, this technique is not available in our environment. Dual X-ray densitometry (DXA) is a simple, accessible, and widely validated technique for the study of osteoporosis. Our group has previously validated the reproducibility of MCP measurements by DXA (2).

Objectives: To study the relationship between baseline MC BMD measured by DXA or DXR and disease severity in patients with early arthritis at 2 years follow-up.

Methods: 202 patients belonging to PEARL (Princess Early Arthritis registral longitudinal) study were included. Demographic, laboratory, radiographic and therapeutic data were recorded by protocol. Most patients (87%) were women, 59% fulfilled 2010 ACR criteria and 41% were classified as undifferentiated arthritis. More than 60% were seropositive (60% RF; 58% anti-CCP). Median disease duration at first visit was 4.6 months, median DAS28 4.2 and HAQ 0.875. The BMD of 2nd to 4th MC was measured by DXR at the standardized software by Sectra (Linköping, Sweden) applied on graphs of hands submitted in digital format (GE® DX Definium 8000). Baseline non-dominant hand DXA was performed using a densitometer Hologic® QDR4500. To arrive to 4th MC BMD, we created 3 regions of interest (ROI) similar to that generated in the DXR measurements; briefly, the ROIs cover the mid-third of each MC diaphysis, avoiding overlapping of ROIs. The statistical study was performed with Stata 12 for Windows, including linear correlation between MC-BMD and various variables of disease severity such as disease activity (DAS28), disability (HAQ) or cumulative DMARD treatment after 2 years of follow-up were included in order to determine whether there was an association with MC-BMD.

Results: The MCP-BMD measured by DXA and DXR at baseline showed a good correlation (r = 0.87, p < 0.001). As expected, being female (β coefficient -0.0381, p = 0.0001) and age > 65 years (β coefficient -0.076, p = 0.0001) were associated with lower BMD, whereas high body mass index (β coefficient 0.002 x kg/m², p = 0.004) was associated with higher BMD.

Conclusion: Despite of the good correlation between DXR and DXA, our data obtained either with DXA or DXR do not confirm the association of low MC-BMD measured with DXR and more aggressive disease in patients with early arthritis.

FRIO497 OSTEOPOROSIS IN PRIMARY CARE – ARE WE MISSING A TRICK?
Sultana Parvin1, Mannaj Barhey2, Talib Abubacker3, Muhammad Khurram Nisar4
1Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom; 2Woodland Avenue Practice, Primary care, Luton, United Kingdom; 3Bed House Medical Centre, Primary care, Luton, United Kingdom

Background: Globally various incentive schemes have been employed in primary care to improve early diagnosis and management of several rheumatic conditions. In the UK, the Primary Care Quality and Outcomes Framework (QOF) rewards general practices for the provision of ‘quality care’ and helps to fund further improvements in the delivery of clinical care. Currently, there is one quality indicator in place for secondary prevention of osteoporosis. In order to help establish an integrated care pathway encompassing the whole patient journey between primary and secondary care, we undertook a detailed survey of two GP practices.

Objectives: The aims of the exercise were to identify the utility of quality indicator and any gaps in the model of care for the high-risk osteoporosis patients.

Methods: An independent service evaluation tool was employed to interrogate the IT system used in the GP surgeries. All patients over the age of 65 were extracted from the database and FRAX analysis was undertaken. Those with medium to high FRAX score (i.e. ten-year risk of >20% for major osteoporotic fracture and/or >5% for hip fracture) were captured to explore whether they were offered further evaluation and bone-sparing therapy as necessary.

Results: Of 18,248 patients registered in the multi-cultural urban practices, 6796 were >65 years old. 793 had pre-defined moderate-high FRAX score. 300 (37%) had a confirmed diagnosis of osteoporosis. Median age was 78 (range 65-103 years). 249 (83%) were women. 88.5% were White and remaining of other ethnicities.

Conclusion: This study highlights the inadequacy of quality indicators in the overall management of osteoporosis burden in primary care. It relies heavily on active identification process for high-risk individuals and correct coding of fragility fracture. However the vast majority of patients with moderate-high risk, based on case finding strategy advised by international bodies e.g. FRAX, remain hidden. Less than 10% of patients with confirmed osteoporosis fulfil the quality outcome in this survey. The QOF hence fails to reflect the nature of disease burden in the primary care thereby risking the management strategies skewed towards too small a cohort and missing the big picture. It is clear that quality indicators for osteoporosis need to be aligned to risk stratification model. This will allow better identification of at-risk individuals and improved care pathway for patients requiring bone active therapies.

FRIO497 TRABECULAR BONE SCORE AND MALNUTRITION IN A COHORT OF SYSTEMIC SCLEROSIS PATIENTS
Sabrina Pezzi1, Massimo Patane1, Veronica Tomatis1, Andrea Casabella1, Carmen Pizzoniti1, Carlotta Schiorene1, Luca Carmisciano1, Alessio Signori1, Maurizio Cutillo1, 1IRCCS San Martino Polyclinic Hospital, Genoa, Italy, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, genoa, italy; 2IRCCS San Martino Polyclinic Hospital, Genoa, italy, 3Biostatistics Unit, Department of Health Sciences, University of Genova, Genoa, italy, genoa, italy

Background: Systemic sclerosis (SSc) is a connective tissue disease characterized by initial microvascular damage, immune system activation and progressive fibrosis of the skin and internal organs. Gastrointestinal (GI) involvement induce malnutrition due to gastrointestinal symptoms, GI dismotility and malabsorption that are related to fibrosis of bowel wall and bacterial overgrowth(1). Therefore the disease is associated with secondary osteoporosis with a few studies evaluating the bone microarchitecture(2).

Objectives: To evaluate a relationship between malnutrition and bone microarchitecture detected by trabecular bone score (TBS) in SSc patients.

Methods: 38 patients(6 male and 32 female) fulfilling ACR 2013 criteria for SSc underwent DXA to detect quantitative lumbar spine bone mineral density and TBS. DXA also assess body composition with a software that provides the physical quantitative parameters, including free fat mass index (FFMI), that identifies the patient with malnutrition/values <15 kg/m2 in women and 17 kg/m2 in men, according to the ESPEN criteria (2). Bone mass index was calculated for all SSc patients and every patient completed a diary reporting GI symptoms possibly related to intestinal disbiosis. Fastig blood samples were obtained in order to analyse some biochemical parameters of malnutrition (total proteins(g/L), albumin(g/L), serum total cholesterol(mg/dl) and blood lymphocyte count (N/mm3). Continue variables were summarized as mean and standard deviation(SD) or median and inter quartile range (IQR), discrete variables were summarized with count and percentage. Correlation was tested with Pearson or Spearman method. T-test was used to compare TBS between dichotomic groups Uni and multivariate linear regression models were used as well the Multiple R-squared variation was applied. The multivariate linear regression was performed with a stepwise approach to select the best model using highest AIC criteria.

Results: The mean age of patients was 64±13.3 years with mean disease duration 19.2±7.6 years. 36.8% of patients was found malnourished. The univariate analysis showed that only higher age of patients correlated to lower TBS(p<0.001). The R-squared of multivariate linear regression showed that about 45% of the TBS variations(TBSv) can be explained by the variation of the following variables(age, disease duration, lymphocyte count). Age explains about 25% of the TBSv. Older patients had lower TBS, with approximately 0.05 points of TBS loss every decade(= 0.05). The presence of symptoms possibly related to intestinal disbiosis, added to the model, might explains about 12% more of TBSv. Patients with symptom related to bacterial overgrowth had lower TBS respect to patients without(0.08), regardless of other variables(p=0.002). Disease duration, added to the model, further explains about 4% more of TBSv and suggest a trend between highest disease duration (regardless of other variables) and higher TBS(p = 0.103). Lymphocyte count added to

Results:

Participants was 63.2 years and mean of SUA was 4.4 mg/dL. The effect of SUA on osteoporosis in postmenopausal women was not statistically significant according to univariable logistic regression (OR 0.977, 95% CI 0.855-1.116, p = 0.729). However, SUA was negatively associated with incidence of osteoporosis in postmenopausal women with statistical significance after adjusting for age, obesity, amount of drink, smoking, intake of calcium, rheumatoid arthritis, thyroid diseases, and loss of activity (OR 0.867, 95% CI 0.752-0.999, p = 0.048).

Conclusion: Our data demonstrated that high SUA is associated with lower incidence of osteoporosis in postmenopausal women. This result suggests a protective role of SUA in metabolic bone diseases.

INCIDENCE OF CLINICAL FRACTURES IN ADULTS WITH KIDNEY TRANSPLANT

Pablo Rodriguez-Merlos1, Yarietti Hernández2, Gerardo Napky1, Lina Leon2, VictoriaNavarro-Compán3, Maria Lopez2, Alejandro Balsa1, Carlos Jimenez2, Pilar Aguado1. 1La Paz University Hospital, Rheumatology, Madrid, Spain; 2La Paz University Hospital, Nephrology, Madrid, Spain

Background: Chronic kidney disease is associated with an increased risk of fractures. However, the existing evidence investigating the incidence of fractures after kidney transplant is scarce.

Objectives: To evaluate the incidence of clinical fractures in patients with kidney transplant and analyze the possible factors that may influence its occurrence.

Methods: A retrospective observational study of patients who underwent kidney transplant between 2005 and 2015 in a tertiary hospital was conducted. A minimum follow-up period of 6 months after transplant was required. Sociodemographic and anthropometric data, clinical risk factors for bone fractures, drugs use (steroids, immunosuppressive drugs, vitamin D analogues, calcium and vitamin D supplements and calcimetics), as well as biochemical and densitometric data to assess bone metabolism were retrieved from medical records. The occurrence of new clinical fractures after the transplant and throughout the follow-up period was recorded. The statistical analysis included univariable analysis using chi-square and Fisher’s exact tests for the qualitative variables and T-Student and Mann-Whitney U for the quantitative variables. Subsequently, logistic regression multivariable analysis was carried out to investigate which factors were associated with fractures occurrence.

Results: A total of 163 patients were included, 63 (38%) females, with a mean age of 51 ± 14.6 years. The etiology of kidney disease was polycystic kidney disease (24.2%), glomerulonephritis (23.6%), diabetes mellitus (5.5%), vasculopathy (5.5%), connective tissue disorders (2.4%) and miscellany (38.7%). The daily average dose of steroids one year after transplant was 5.8 ± 4.4 mg. Bone densitometry was performed before transplant in 27 patients (19.6%), ten of whom (37%) presented osteopenia and 7 (26%) osteoporosis. The ten-year probability of bone fracture risk (FRAX) before transplant was 2.6 ± 2.6. Mean follow-up after transplant was 8.7 ± 3.5 years. During this period, 23 (13.9%) patients suffered a clinical fracture, with an average time of appearance after transplant of 5.5 ± 3.3 years. These were located in hip (6 - 26.1%), vertebrae (2 - 8.7%), extremities (9 - 39.1%) and hands and feet (6 - 26%). One year after transplant, 65.6% had vitamin D deficiency (<30 ng/dl serum calcium levels) and 12.2% had levels compatible with osteomalacic range (<10ng/dl).

The data of the descriptive study stratified by the fracture occurrence are shown in Table 1. Compared with the subgroup patients without (Fx -), the patients with (Fx +) post-transplant fractures showed to be more frequently female (60.9% vs 34.5%, p=0.01), older (50.1 ± 14.6 vs 56.3 ± 14.1, p=0.03), had more pre-transplant major clinical FRAX (2.4 ± 1.9 vs 4 ± 4.7, p=0.03), and higher levels of PTH (98.2 ± 75.7 vs 140.1 ± 86.9, p=0.02) and serum alkaline phosphatase [ALP] (90.2 ± 37 vs 117.6 ± 60.4, p=0.02) after one year of transplant. Also, a trend to present a higher prevalence of pre-transplant clinical fractures was observed in the second group (5.6% vs 17.4%, p=0.06). No difference in the use of immunosuppressants were detected. The multivari- able analysis showed a significant association between post-transplant fractures and female gender (OR of 3.8, p=0.01) and higher levels of ALP (OR of 1.01, p=0.03).

Conclusion: In patients with kidney transplant, an incidence of clinical fracture of 13.9% is observed after a mean follow-up of 8.7 years. The female population seems especially susceptible to present fractures. The persistence of a possible pre-transplant autonomous secondary hyperparathyroidism one year after kidney transplant seems to influence the risk of fractures.

EVALUATION OF BONE QUALITY BY TRABECULAR BONE SCORE (TBS) IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Andrea Casabella1, Sabrina Paolino1, Elisa Alessandri1, Vanessa Smith2, Barbara Russo1, Carmen Pizzorni2, Alberto Sulli3, Maurizio Cutolo1. 1Research Laboratory and Academic Division of Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; 3Department of Internal Medicine, Ghent University, Ghent, Belgium

Background: Systemic lupus erythematosus (SLE) patients shown an increased risk of low bone mass as a result of multifactorial events: osteopenia, persistent inflammation, low vitamin D levels (photosen- sitivity) and glucocorticoid treatment. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) that provides an indirect measurement of bone axial microarchitecture and allows to get information about bone quality in several rheumatic diseases (1-4).

Objectives: The aims of this study were to examine the prevalence and risk factors for low bone mineral density (BMD) (osteoporosis or osteopenia) in female patients affected by SLE and to compare with matched healthy subjects (CNT). Methods: 40 female patients (mean age 47±14 years) affected by SLE and 40 age- matched CNT (mean age 49±8 years) were enrolled. Bone Mineral Density (BMD, g/cm²) of the lumbar spine (L1-L4) was analyzed using a DXA scan (GE, Lunar Prodigy) Lumbar spine TBS was derived for each spine DXA examination using the TBS index (TBS Insight Medimaps).

Results: The mean BMD±SD was 0.85±0.22 g/cm² at the lumbar spine and 0.64 ± 0.32 g/cm² at the hip in SLE patients. The prevalence of osteopenia was 39.0%, and 16.4% of osteoporosis in SLE patients. Most of SLE patients (70%) presented a bone loss that was significantly lower when compared with control group (p<0.001). Likewise, lumbar spine TBS
score was found significantly lower in SLE patients compared with CNT (0.868±0.227 vs 1.482±0.113; p<0.001, respectively). An history of high-dose oral glucocorticoids (> 10 mg/day) was associated with the preservation of BMD at the lumbar spine but not in spinal trabecular bone as obtained by TBX analysis.

Conclusion: SLE is associated with significant trabecular bone loss, which could not be caused by glucocorticoid therapy. This study confirms the role of TBS as new and safe diagnostic tool for the quantification of the bone quality in chronic and systemic inflammatory rheumatic diseases, such as SLE.

CORRELATION OF THE DAILY DIETARY INTAKE OF CALCIUM WITH THE LEVEL OF BONE MINERAL DENSITY IN PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS INFECTION

Walter Alberto Silvério-Girão1, Maria Llop Vilalet1, Cristina Macia-Vila1, Pilar Vizcarr2, Marta Monsalvo2, Monica Vázquez Diaz1, José Luis Casado1.

Hospital Ramón YCajal, Rheumatology, Madrid, Spain; Hospital Ramón YCajal, Infectious Diseases, Madrid, Spain

Background: There are few studies in which the relationship between daily calcium intake and bone mineral density (BMD) in patients with human immunodeficiency virus (HIV) infection has been evaluated, as well as its correlation with other factors of risk for the development of fragility fractures in this population.

Objectives: To determine the correlation of daily calcium intake with the most predictive risk factors for fragility fracture in patients with HIV infection, as well as BMD values in a cohort of patients followed in a Tertiary Madrid hospital.

Methods: Cross-sectional evaluation of a prospective study carried out in a specialized unit in HIV/AIDS of a tertiary Madrid hospital. We included asymptomatic consecutive patients with HIV infection, older than 50 years, followed regularly between January 2014 and December 2016.

Results: A total of 128 patients were included (35 women, 27%), with a mean age of 57 years (range: 50-83) and body mass index of 23.8 kg/m² (range: 15.6-33.5). The mean time of HIV infection was 256 months (range: 202-306) and of antiretroviral therapy (ART) 219.7 months (range: 156-247). The average calcium intake obtained by dietary calculation (without supplementation) was 563.8 g/day (462-2772). Among the risk factors for fragility fracture (included in the FRAX): 44 (34%) reported smoking, 11 (9%) family history of fracture, 54 (42%) previous history of osteoporosis/osteopenia. Although a lower calcium intake was found in patients with vertebral fractures, this was not significant (486 (236) vs 583 (317), p = 0.09).

Conclusion: Although recent meta-analyses show that calcium intake in non-HIV population is not related to the development of fragility fractures, in our cohort (with the limitations of a cross-sectional study) a probable association of daily calcium intake with a low BMD is evidenced. These findings should be confirmed in the longitudinal analysis of the data of the cohort.

USING BONE MINERAL DENSITY VERSUS THE RATIO OF BODY MASS INDEX TO BONE MINERAL DENSITY TO PREDICT FRACTURE RISK IN HYPERTHYROIDISM

Khojasta Talash1, Maria Bhat2, Royal Lancashire Infirmary, Lancaster, United Kingdom

Background: Euthyroidism is important in the development of a normal skeletal system, with thyroid hormones acting as important regulators of bone homeostasis in adults. Hyperthyroidism, whether current or previous, increases the risk of developing osteoporotic fractures by stimulating osteoclastic bone resorption and hence bone remodelling, which overall results in decreased bone mineral density (BMD). Generally, BMD is used as a predictor of fracture risk; however there has been recent research that suggests using the ratio of BMD to Body Mass Index (BMI) is a better marker of predicting fracture risk in obese patients than BMI alone.

Objectives: Our research set out to find whether BMI alone or the ratio of BMI to BMD is a better predictor of fracture risk in patients with current or previous hyperthyroidism.

Methods: Data were used from a cohort of patients with current or previous hyperthyroidism, referred for DXA scan to a District General Hospital between June 2004 and October 2010. The following were recorded: age, sex, whether a fracture was sustained, whether they had had steroid therapy at any point, BMI, BMD at L1-L4, BMD at femoral neck (left and right) and BMI at hip (left and right). Logistic regression models were fitted using fracture as the dependent variable. The independent variables for the first set of logistic regression models were BMI and for the second set BMI:BMD ratio at the same levels. Data were adjusted for sex and age and scan. The fit of logistic models were compared using area under the ROC curves (AUC).

Results: 720 patients were used in the study, of whom 643 (89.3%) were female. Mean age was 63.6 years (SD 11.6) with age range of 28.4 to 89.6 years. 120 (16.7%) were recorded to have had steroid therapy at any point. BMI, BMD at L1-L4, BMD at femoral neck (left and right) and BMI at hip (left and right). Logistic regression models were fitted using fracture as the dependent variable. The independent variables for the first set of logistic regression models were BMI at each level and for the second set BMI:BMD ratio at the same levels. Data were adjusted for sex and age at scan. The fit of logistic models were compared using area under the ROC curves (AUC).

Conclusion: This study identifies that the BMI:BMD ratio does not provide a better indication of fracture risk than BMI alone in our cohort of patients with current or previous hyperthyroidism. We have previously shown that the same is true for patients with rheumatoid arthritis. A limitation of this study is not stratifying by presence of other diseases or steroid use.
Further work will be done to study the role of the ratio in predicting fracture risk in patients with other conditions.

**TOCILIZUMAB CONTROLS BONE TURNOVER IN EARLY POLYMIALGIA RHEUMATICA**

1Hospital La Cavale Blanche, Rheumatology, BREST, France; 2Hôpital Monav ChRU de Brest, Immunologie, BREST, France; 3CHRU Cavale Blanche, Rheumatology CERANO, Brest, France; 4Hôpital Monav, Immunology, Brest, France

**Background:** Tocilizumab has been proved to be an alternative to corticosteroids in treating polymyalgia rheumatica. Considering the action on interleukin-6 on bone turnover an effect of tocilizumab is supposed. Few data are available about bone turnover in rheumatoid arthritis patients treated with tocilizumab but no data are available in polymyalgia rheumatica patients.

**Objectives:** This study explores changes in the bone homeostasis by testing the N-terminal collagen type I extension propeptide (PINP) marker for osteo-formation and the carboxy-terminal region of collagen type I (CTX-I) marker for osteo-resorption in patients taking tocilizumab for poly-myalgia rheumatica (PMR).

**Methods:** Twenty patients were included in the prospective open-label TENOR study (Clinicaltrials.gov NCT01713842) and received three monthly tocilizumab infusions, followed by corticosteroids starting at week (W)12. PINP and CTX-I were tested at inclusion (W0), after tocilizumab but before steroid initiation (W12), at the end of the protocol (W24) and were compared to healthy controls. Information regarding disease activity, inflammatory parameters and interleukin-6 levels were collected during the follow-up of the patients.

**Results:** Polymyalgia rheumatica patients were characterized by higher levels of CTX-I relative to healthy controls matched in age and sex at baseline. PINP levels increased at W12 (p=0.008, versus W0) following tocilizumab introduction and CTX-I levels decreased at W24 and after steroid initiation (p=0.001, versus W0) (figure 1). Such modifications explain the altered correlation observed between PINP and CTX-I at W0 (r=0.255 at W0 versus r=0.641 in healthy controls) and its correction after treatment (r=0.760 at W12 and r=0.767 at W24). Finally, greater changes in PINP were observed in patients whose circulating IL-6 levels decreased after tocilizumab therapy.

**Conclusion:** Control of bone turnover, in part through the inhibition of the IL-6 axis, is observed during tocilizumab and subsequent steroid treatment of polymyalgia rheumatica.

**FR00505**

**CORRELATIONS BETWEEN CARTILAGE MOLECULAR COMPOSITION DETERMINED BY RAMAN SPECTROSCOPY AND MANKIN SCORE: IMPACT OF INTER AND INTRA-VARIABILITY**

Paula Casal-Berro1, Varela Balboa-Barreiro2, Noa Goyanes1, Purificación Figuera-Fernández1,2, Pio González1, Sorina Pertega1, Francisco J. Blanco1, Joana Magalhães1,2, Instituto de Investigación Biomédica de A Coruña (INIBIC), CHUAC, SERGAS, Grupo de Investigación en Reumatología (GIR), A Coruña, Spain; 3Instituto de Investigación Biomédica de A Coruña (INIBIC), CHUAC, SERGAS, Unidad de Epidemiología Clínica e Investigación Biosestadística, A Coruña, Spain; 4Centro de Investigación Biomédica en Red (CIBER), Madrid, Spain; 5Universidade de Vigo (UVigo), Grupo Nuevos Materiales, Vigo, Spain

**Background:** Osteoarthritis (OA) is an incurable disease and methods for its early diagnosis are still an unmet clinical need. Raman spectroscopy (RS) presents potential as a diagnosis technique based on the detection of peaks that can be assigned to cartilage components and molecular rearrangements during disease progression. 5Mankin score (MS) is the main validated method to evaluate severity of cartilage degradation considering structure, cell distribution, Saffrin- O staining and tidemark integrity.

**Objectives:** To evaluate the correlations between OA cartilage RS assigned peaks and MS, considering the inter- and intra-variability of different observers.

**Methods:** RS analysis (Subscore-I, structure: 0-6; -II, cellularity: 0-3; and -III, safranin-O staining: 0-4; Total Score: 0-13) of human OA cartilage explants from 22 donors (age range: 32-92), obtained from lesion (n=22) and/or adjacent tissues (n=14), was performed by 3 blinded observers (O1, 2 and 3). Moreover, one of the observers performed the scoring in triplicate, with at least one month between observations. Inter- and intra-observer variability was determined by kappa and intraclass correlation (ICC) coefficients. Raman spectra were obtained with a FT-Raman Bruker RFS100 (λ=1064nm) and main peaks assigned (6 ratios related to proteoglycans, collagen, lipid index or calcium phosphate). Spearman’s non-parametric correlation coefficient rho was used to compare MS and RS assigned peaks.

**Results:** Inte-observers variability indicated good (ICC>0.74) or moderate agreement (ICC<0.5) for all scores in lesions, whilst only a good agreement (ICC>0.70) was found for subscore-I, in adjacent tissues, and no agreement for the remaining parameters (subscores -II, -III, and total scoring). However, when performing analysis using kappa coefficients, a simultaneous agreement between the 3 observers was not observed. Intra-observer variability revealed good concordance (ICC>0.6) for all subscores and total scoring in cartilage for both sites, except for subscore -III, in adjacent tissues. In this case, ICC results were confirmed by kappa coefficients. Spearman’s correlation coefficient between cartilage main peaks assigned by RS and MS indicated significant differences between observers(Fig.1). Correlations were found for a greater number of MS subscores in O1 (6) regarding O2 (4) or O3 (3) which could be related to the observers’ experience (being O1>O2>O3). These correlations were mostly found in lesions (5, 3 and 1 for O1, 2 and 3, respectively) in comparison to adjacent tissues (2, 1 and 2 for O1, 2 and 3, respectively).

**Conclusion:** Evenhough inter-observation correlations for MS were in the moderate-good range, when analyzing kappa coefficients (categorial variables) these were not maintained. In addion, inter- and intra-observer variability results for adjacent tissues revealed possible limitations when characterizing early to mild OA. In view of MS-RS correlations, a reader dependency is underlined, indicating MS subjectivity and further limitations in the validation of RS using MS.

**FR0506 ROLE OF MITOCHONDRIA FROM PATIENTS WITH OA IN CELLULAR SENESCENCE**

**Andrea Dalmao-Fernandez**, Tamara Hermida Gómez, Maria Eugenia Vazquez Mosquera, Sara Relañó-Fernández, Ignacio Rego-Perez, Francisco J. Blanco, Mercedes Fernandez-Moreno.

**Background:** Chondrosenescence, chondropathy and autophagy contribute to cell death and tissue damage in OA. The mitochondria are related with these three processes implicated in the cartilage degeneration. Mitochondrial dysfunction is well documented in OA and has the capacity to promote abnormalities in chondrocyte viability contributing to cartilage degeneration. Cybrids are optimal cellular models to study the mitochondrial function, since they carry different mitochondrial variants with the same nuclear background, therefore, excluding the variations because of nuclear genome.

**Objectives:** The aim of this work is to study the role of human OA mitochondria in the cellular senescence, apoptosis and autophagy. **Methods:** Cybrids were developed using 143B.TK Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy (N) and knee OA donors. Senescence level was measured by real-time PCR method. The percentage of mitochondrial depolarization was evaluated incubating cells with DiC1(5) in presence of FCCP 1μM using Flow Cytometer. The percentage of apoptotic cells was measured by Flow Cytometry using Annexin-V. Autophagy was evaluated through the developed of Microtubule-associated protein 1A/1B-light chain 3 (LC3) WB. Appropriate statistical analyses were performed with GraphPad Prism v6. **Results:** The gene expression corresponding to senescence marker proteins (p53/30) showed higher levels in OA cybrids than in N (4.35±1.63; 1.21±0.42 respectively, p<0.0005). Similarly, OA cybrids showed higher increment depolarized mitochondria under negative stimuli in comparison with basal condition than N (2.57±1.20; p<0.0005; 1.76±0.99; p<0.05 respectively). The analysis of apoptotic levels, when the cells were submitted for a positive stimuli with staurosporine (2 μM) and an inflammatory environment with IL-1β (10 ng/ml), OA cybrids reflected a statistically significant increase in positive cells for Anexine-V in comparison with N cybrids in both conditions (staurosporine 15.65±3.39; 6.41±0.88 respectively, p<0.05; IL-1β 0.92±0.10; 1.47±0.24 respectively, p<0.05). Autophagy was analyzed studying LC3 a marker for autophagosome formation and the results showed that LC3 activation was reduced in OA cybrids (1.19±0.24; 1.41±0.21 respectively, p=0.05).

**Conclusion:** Mitochondria from OA patients is involved in cellular senescence, apoptosis and autophagy (three relevant processes involved in OA).

Study the effect of human umbilical cord mesenchymal stem cells derived exosomes(hUCMSC-exos) on bone destruction in Collagen Induced arthritis (CIA) rats.

Jinfang Gao, Ke Xu, Gailian Zhang, Jian Han, Yang Liu, Liyun Zhang, Shanxi Dayi Hospital, Rheumatology, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a highly disabling autoimmune disease, characterized by destruction of the cartilage and bone, which is difficult to reverse. Mesenchymal stem cells-derived exosomes (Mesenchymal stem cells-derived Exos) is a kind of extracellular vesicles, produced by MSCs in resting or stress state, which can simulate the tissue repair effect of its maternal cells and may be a new breakthrough point in the treatment of RA bone destruction.

Objectives: Study the effect of human umbilical cord mesenchymal stem cells derived exosomes(hUCMSC-exos) on bone destruction in Collagen induced arthritis CIA rats.

Methods: 1. After isolated by differential centrifugation, hUCMSCs was cultured in which was identified by morphology and surface markers. 2. Grouping: The CIA rats were randomly divided into CIA group, MTX group, hUCMSCs group, hUCMSC-exos low concentration group, hUCMSC-exos medium concentration group, hUCMSC-exos high concentration group, and a healthy control group. 3. Efficacy evaluation: the efficacy of hUCMSC-exos on CIA rats was evaluated by measuring joint swelling, arthritis index, micro-ct scanning and pathological score. The expression levels of RANKL and OPG in the serum of rats in each group were detected by ELISA. The levels of the above factors in the synovial fluid of rats in each group were detected by RT-PCR, and the mRNA levels were detected by quantitative RT-PCR for superoxide dismutase (SOD), interleukin-15 (IL-15), matrix metalloproteinase-1 (MMP-1) and vascular endothelial growth factor (VEGF).

Results: All the ratios LA:ALA of caused a remarkable reduction in MMP-1(P<0.001). Marginal reduction in VEGF was noted with 1:1, 4:1 and 8:1 ratios (P<0.05). IL-15 was noted with 1:1, 2:1 and 4:1 while a marked up-regulation was noted for 8:1 and 16:1 (P<0.01). Lastly, a significant MMP-1 reduction was caused by all the ratios of DGLA:DPA, except 4:1. The selected ratios were efficient against VEGF (P<0.001). A consistent high SOD was revealed by all the ratios excluding 4:1. The selected ratios were efficient against VEGF (P<0.001).

Conclusion: Consequence of synovial inflammation in typical and atypical forms results in cartilage-loss, osteophytes and pain. RA ratios when used in equivalent, was found highly effective against IL-15, MMP-1 and VEGF, whereas inflammation increases with increase in their proportions. Low SOD indicated lower oxidative-stress while it was up-regulated in response to high stress. FAs work in two distinct ways, membrane incorporation and metabolic modulation. Unsaturated fatty acid increases membrane fluidity and thus improves cell signaling. Analysis of treated and untreated cells showed incorporation of FAs in cell membrane, which improves membrane fluidity and status of signal transduction.

RETRO-INVERSO TAT-BECLIN-1 INDUCES SYNOVIAL FIBROBIS AND DOES NOT PROTECT CARTILAGE FROM DEGENERATION IN A MOUSE MODEL OF OA

Jason Rockel, Brian Wu, Sayaka Nakamura, Evgeny Rossumochka, Mohi Kapoor, University Health Network, Toronto, Canada

Background: Beclin-1 is a component of the autophagy pathway necessary for formation of autophagosomes, contributing to autophagy-mediated cellular homeostasis. Enhancing autophagy through inhibition of mTOR activity, either via genetic deletion in chondrocytes or intra-articular injection of rapamycin, attenuates progression of surgically-induced models of osteoarthritis (OA). Retro-inverso TAT-Beclin-1 is a cell-permeable peptide which competes for binding to the endogenous Beclin-1 inhibitor GAFR-1, thus promoting autophagy. It is unknown whether activation of Beclin-1 is sufficient to protect joints from osteoarthritis progression.

Objectives: For this study, we sought to determine if retro-inverso TAT-Beclin-1 could attenuate OA progression in a surgically-induced mouse model.

Methods: Eight-week old C57BL/6 mice underwent destabilization of the medial meniscus (DMM) surgery to induce OA, or sham surgery as a control. Mice were injected intra-articularly with retro-inverso TAT-Beclin-1 (2 mg/kg in 5 μl) twice weekly for 2 or 9 weeks. Mice were sacrificed at 10-weeks post-surgery. Knee joints were stained with Safranin-O/Fast green to evaluate cartilage degeneration and Masson’s trichrome to determine degree of synovitis using OARSI scoring for mice. Sections were stained for α-SMA (myofibroblast) and CD45 (hematopoietic-origin cell) to evaluate changes in markers of fibrosis and inflammation, respectively.

Results: As opposed to the effects of mTOR deletion in cartilage or rapamycin treatment in joints, injection of retro-inverso TAT-Beclin-1 for 2 into knee joints of mice with DMM-induced OA had no effect on the degree of articular cartilage degeneration in the tibia or femur as compared to PBS-injected controls. However, in both sham and DMM mice, retro-inverso TAT-Beclin-1 for 2 or 9 weeks of treatment induced a pronounced thickening of the synovium with increased cell numbers and collagen deposition compared to PBS-treated mice. The increased number of synovial cells in 9-week treated mice did not show substantial expression of α-SMA- or CD45+ cells, suggesting the increased number of cells and matrix in the synovium was independent of myofibroblast differentiation or inflammatory influx.

Conclusion: Contrary to our expected results, retro-inverso TAT-Beclin-1 did not attenuate cartilage degeneration. Rather, it promoted substantial synovial thickening that likely involved cell proliferation and collagen deposition. This severe fibroblastic phenotype appears independent of myofibroblast differentiation or inflammation, normally associated with typical fibroblastic responses. To evaluate the potential for dose responses with retro-inverso TAT-Beclin-1 in synovial joints, we are currently modifying our dosing strategy in an effort to determine possible disease-modifying effects of this novel Beclin-1 activator.

HISTONE-ACETYLTRANSFERASES CBP AND P300 REGULATE AUTOPHAGY AND PROTEASOMAL DEGRADATION IN SYNOVIAL FIBROBLASTS

Monika Kresel1,2, Marcel Gabathuler1, Christoph Kolling1, Matija Tomisic2, Oliver Distler3, Caroline Ospelt4, Kerstin Klein5, 1Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2Medical University Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 3Schultz-Clinic, Zurich, Switzerland

Background: Proteosomal degradation and autophagy are the major catabolic pathways that maintain the homeostasis of cells and are associated with cell survival. The histone acetyltransferases CARM response element binding protein binding protein (CBP) and p300 are close homologues and widely accepted as redundant proteins.

Objectives: To analyse individual functions of CBP and p300 in catabolic pathways in rheumatoid arthritis (RA) synovial fibroblasts (SF).

Methods: SF were isolated from knee, shoulder and hand joints of RA patients undergoing joint replacement surgery. The expression of CBP and p300 was silenced by transfection of antisense LNA gapmeRs (12.5 nM). 24h after transfection cells were stimulated with TNF-α (10 ng/ml, 24h). Transcriptions were determined by RNA-seq (Illumina NovaSeq 6000, n=6). Pathway enrichment analysis of RNA-seq data (fold change >1.5, FDR <0.05) was performed using DAVID bioinformatic resources. Autophagy was assessed by Western blotting using LC3B conversion and p62 as autophagy substrate (n=4) in presence and absence of bafilomycin A1 (100 nM, 4h), a lysosomal inhibitor. Cell death was analysed using the CytoTox-Glo cytotoxicity assay.

Results: The top pathway identified after silencing of p300 in SF in presence (p=1.33x10^-10) and absence of TNF-α (p=1.76x10^-10) was ‘proteasome’, with an enrichment of genes contributing to ‘proteasome assembly’ and ‘proteasome regulation’. The expression of several genes encoding proteasome subunits was increased after p300 silencing but unaffected by silencing of CBP. Genes contributing to the biological processes ‘autophagy’ (p=0.05) and ‘regulation of autophagy’ (p=0.05) were enriched after silencing of CBP and p300, whereas ‘autophagy assembly’ was only affected by CBP silencing. In RNA-seq data, the expression of MAP1LC3B, encoding the autophagy marker LC3B, and the autophagy substrate p62, was increased by p300 silencing but slightly decreased by CBP silencing. In line with the RNA expression, silencing of CBP reduced the conversion of LC3B and the protein expression of p62 in presence and absence of TNF-α. Results were similar in presence of bafilomycin A1, indicating a decrease in autophagy seen in synovial fibroblast cultures. In contrast, the conversion of LC3B and p62 expression were increased after silencing of p300 in unstimulated SF, indicating increased autophagy. This effect was lost for LC3B after treatment with TNF-α, and LC3B conversion was even delayed in presence of bafilomycin A1. This indicates a blockage of autophagy after silencing of p300 in TNF-α-stimulated SF. In line with this, silencing of p300 in SF (n=6, p<0.05) increased cell death only in presence of TNF-α. Viability of SF was not affected by silencing of CBP.

Conclusion: Here we identified p300 as a major regulator of the proteasome in SF and provide first evidence for individual functions of CBP and p300 in regulating autophagy in SF.

FRID514
NEW DIAGNOSTIC BIOMARKER OF BONE TISSUE METABOLISM DISORDERS IN RHEUMATOID ARTHRITIS

I. Sevodyova1, J. Poljakova2, B. Zavodovska1,2, Eugenie Papicheny1, Akhverdyan Yury1, 1Treatment and Prevention of Joint Disease Laboratory/ Federal State Budgetary Institution «Zborovsky Research Institute of Clinical and Experimental Rheumatology», Volgograd, Russian Federation; 2Volgograd State Medical University, Volgograd, Russian Federation

Background: Bone mineral density and proteins/peptides determination in blood and urine as markers of bone resorption and formation are currently used to diagnose osteoporosis (OP) and metabolic bone diseases. However, these methods have some disadvantages for bone turnover evaluation. Recent evidence suggests that in RA changes in the secretion of hormones of white adipose tissue can be revealed [1,2,3,4]. One of them is Adiponectin possessing anti-inflammatory, anti-diabetic and anti-atherogenic properties. Changes in Adiponectin levels may reflect influence of immune inflammation on bone turnover.

Objectives: To study the clinical and diagnostic value of serum Adiponecin determination in RA patients complicated by OP.

Methods: We examined 86 women with documented diagnosis of RA and mean disease duration of 6.5±0.88 years. We used EULAR/ARA 2010 criteria to diagnose the patients. Female patients with II degree of disease activity (DAS28), Steinbrocker stage II (erosive), rheumatoid factor- and anti-cyclic-citrullinated peptide antibody-positive were prevalent. We excluded patients who had surgery or developed an infection within the last 8 weeks, pregnant and breast-feeding women, patients with heart, liver or kidney disease, immune deficiency, leukopenia or chronic infection. A control group of 45 healthy females aged of 25 and 59 years were included in the study. There were no reported findings of
joint pain and RA symptoms in the group. The groups were adjusted for age (p<0.05) and showed no statistically significant differences.

We measured serum Adiponectin levels (µg/ml) using Human Adiponectin ELISA commercial test systems (BioVendor, Czech Republic, cat # R01902020100). We used spectrophotometer with wavelength of 450 nm to detect the test results ([MultiSkan- immunoenzyme analyzer, Finland]). We plotted a curve using computer software. We diagnosed OP using dual-energy X-ray absorptiometry with LUNAR DPX PRO (GE, USA).

Results: Serum adiponectin levels in the control group were 12.5±2.9 µg/ml. Adiponectin levels in healthy subjects measured as M ± 25% ranged between 0.44 and 24.56 µg/ml. Patients with OP and RA had significantly higher levels of serum Adiponectin (p<0.001). Mean serum Adiponectin levels in RA patients who had normal bone density and had no OP were 35.21±0.6 µg/ml. Mean serum Adiponectin levels in OA patients with low bone mineral density were 52.4±2.69 µg/ml. Adiponectin levels of 44 µg/ml and higher were associated with osteoporosis. Adiponectin levels of 43.9 µg/ml and lower were associated with normal bone density.

Conclusion: Thus, we revealed that Adiponectin levels depend on osteoporosis presence in RA patients. We suppose that Adiponectin determination may be useful laboratory marker for OP diagnosis. The test may be used to reduce the risk of low-energy fractures and to improve the quality of life in RA.

HSP90AA1, A CHAPERONE-MEDIATED AUTOPHAGY, IS A CHROMOSOME-ASSOCIATED WITH DEFECTIVE AUTOPHAGY IN OSTEOARTHRITIS

Irene Lorenzo1, Jose Antonio Pinto Tasende2, Natividad Oreiro2, Francisco J. Blanco1,2, Beatriz Carames1.
1Instituto de Investigación Biomédica de A Coruña (INIBIC), Grupo de Investigación en Reumatología, A Coruña, Spain; 2Complejo Hospitalario A Coruña, Servicio de Reumatología, A Coruña, Spain

Background: In osteoarthritis (OA), defects in cellular homeostasis, such as autophagy, are evident and precede joint damage (1). We have shown that there is a defect in autophagy in OA human chondrocytes and cartilage (2). Indeed, pharmacological activation of autophagy protects against joint damage (3). Our working hypothesis is that joint damage in OA could be due to a failure of autophagy that can be detected in the blood and tissue of patients.

Objectives: The objective of this study is to identify biomarkers associated with autophagy defects that could facilitate the development of personalized therapeutic strategies to prevent OA progression.

Methods: A comparative analysis of 35 autophagy genes was performed in blood from a Prospective OA Cohort of A Coruña (PROCOAC) of Non-OA and knee OA patients. Non-OA patients (Age: 61.4± 1.16 years; BMI: 25.25 ± 0.52; Females, n=18) and Knee OA patients (Age: 65.50 ± 1.05 years; BMI: 29.55 ± 0.67; Females, n=18, OA grade II-IV) were profiled using PrimePCR autophagy human panel array (Bio-Rad). Confirmatory studies of the candidate genes were performed in blood from Non-OA patients (Age: 60.13 ± 1.12 years; BMI: 24.85 ± 0.59; Females; n=30) and Knee-OA patients (Age: 68.4 ± 1.11 years; BMI: 29.65 ± 0.55; Females; n=30, OA grade III-IV) by Taqman Technology. A quantitative proteomic analysis of defective autophagy genes regulated upon deletion of Atg5 in human OA chondrocytes was performed by iTRAQ analysis. Moreover, the candidate gene was evaluated as a potential biomarker in human cartilage from Normal (n=19) and Knee-OA (n=20) patients in both spontaneous aging (6, 12, 18, and 30 months old, n=3) and surgically-induced OA (10 weeks after surgery, n=4) in mice by immunohistochemistry. Remarkably, the consequences of candidate gene silencing on autophagy, FOXO signaling, inflammation, senescence and cell death by apoptosis was investigated by gene expression and flow cytometry.

Results: 15 autophagy-related genes were downregulated in blood from knee OA patients compared to non-OA patients (p<0.05). Importantly, key autophagy-related genes, including ATG16L2, ATG12, ATG4B and MAP1LC3B, involved in relevant process including initiating autophagy, phagophore extension and autophagosome formation, were significant downregulated in knee OA patients (p<0.05). Interestingly, HSP90AA1 and HSPA8, chaperone-mediated autophagy genes involved in stress response and protein folding, were significant downregulated (p<0.001). In addition, several regulators of autophagy and apoptosis, such as Bnip3, Bcl-2 and Bcl2L1 were downregulated (p<0.01). Confirmatory studies for MAP1LC3B and HSP90AA1 showed a significant downregulation (p<0.001) in blood from knee OA patients. Remarkably, total proteome screening of human OA chondrocytes with defective autophagy, showed a significant reduction of HSP90AA1 (p<0.05). Remarkably, HSP90AA1 expression was reduced in OA cartilage (p < 0.01) and in spontaneous aging and surgically-induced OA in mice (p < 0.05). Interestingly, HSP90AA1 silencing increased LC3 and FOXO1 expression (p > 0.01), might be as a protective response, and increased Nfkb and p16 expression (p < 0.05) at 48 hours. In addition, genetic deletion of HSP90AA1 increased cell death by apoptosis (p < 0.05). These data indicate that HSP90 might be a potential biomarker associated with defective autophagy in OA.

Conclusion: We identified biomarkers of defective autophagy as a mechanism of central homeostasis, which gives us a general vision of the disease mechanisms linked to OA clinical reality.

CHONDROGENIC EFFECT OF KARTOGENIN ON AN IMMORTALIZED CELL LINE DERIVED FROM MESENCHYMAL STROMAL CELLS ISOLATED FROM HUMAN BONE MARROW

Carolina Guilance-Varela1,2, Cristina Rodríguez-Pereira1,2, Elena Fernandez-Burguera1,2, Tamara Hermida Gómez1, Noa Goyanes1, Francisco J. Blanco1,3, joana magalhães1,3.
1Instituto de Investigación Biomédica de A Coruña (INIBIC), Grupo de Investigación en Reumatología, A Coruña, Spain; 2Complejo Hospitalario A Coruña, Servicio de Reumatología, A Coruña, Spain; 3Centro de Investigaciones Científicas Avanzadas (CICA) Universidad de A Coruña (UDC), A Coruña, Spain; 3Centro de Investigación Biomédica en Red (CIBER), Madrid, Spain

Background: Mesenchymal stromal cells (MSCs) currently tested in regenerative medicine approaches for osteoarthritis (OA) present limitations in obtaining stable hyaline-like cartilage phenotype. Kartogenin (KGN) has been recently described to promote both reparative and protective effects hampering the hypertrophic effects of chondrogenesis.1

Objectives: The aim of this study is to evaluate the chondrogenic effect of kartogenin on an immortalized cell line (3a6), using a conventional cell pellet model and gold-standard chondroinductor transforming growth factor 3 (TGF-β3), as positive reference.

Methods: 3a6 cells, originally obtained from a 61-year old Asian woman bone marrow, was cultured under pellet culture system with basal (DMEM, low glucose) or commercial chondrogenic medium, supplemented with 10 ng/ml TGF-β3 or 100nM KGN for 3, 7, 14 and 21 days. Total RNA was isolated and real-time quantitative reverse transcription-polymerase chain reaction (RT-qPCR) was performed, using custom-made primers for run-related transcription factor 1 (RUNX1), proteoglycan 4 (PRG4), cartilage intermediate layer protein (CILP), collagen type-II (COL2A1), X (COL10A1) and -I (COL1A1), using RPL13A as housekeeping. Proteoglycans and zonal markers protein synthesis was evaluated by safranin-O (SO) staining and lubrican/PRG4 and CILP immunohistochemical analysis (both 1:50), respectively. The experiment was performed in triplicate and differences judged using one-way ANOVA with Bonferroni’s corrections, considering p<0.05 significantly different.
Results: The molecular analysis of KGN- and TGF-β3-chondrogenic induced 3α6 pellets is depicted in figure 1A. For zonal markers expression, both conditions showed a significant downregulation in PRG4 with time, concomitant with an upregulation of CILP, for TGF-β3 but not for KGN-induced cells. However, PRG4 and CILP were found on the protein level (Figure 1B) for both conditions. The studied zonal markers were found heterogeneously distributed for KGN-induced pellets (Figure 1C). This difference is also supported by proteoglycans SO staining, with an earlier formation of a more mature tissue for KGN- than TGF-β3-induced pellets. No expression was found for the main hyaline-like cartilage collagen (COL1A1). RUNX1 was practically unaltered in both conditions. For hypertrophic markers, RUNX2 was upregulated at 14 days in TGF-β3-, whilst in KGN-induced cells its expression seems to be delayed, although no significant differences were found. In both conditions, COL10A1 was very low, until 21 days. COL1A1 presented a significant upregulation at 14 days for TGF-β3- whilst in KGN-induced cells expression was non-significant.

Conclusion: This is the first study to report the chondrogenic effect of kartogenin on 3α6 immortalized human bone marrow MSCs line. On the molecular level, no significant differences were found between KGN- and TGF-β3-chondrogenic induction, although transition into a hypertrophic phenotype seems to be delayed. On the protein level, zonal markers and proteoglycan synthesis were found improved by kartogenin after 14 days.

Disclosure of Interests: carolina guanche-varela: None declared, cristiano rodríguez-perere: None declared, elena fernandez-burguera: None declared, tamara hernida gómez: None declared, noa oyanes: None declared, francisco j. blanco consultant for: AbbVie, bionera, bms, gsk, grünenthal, janssen, Lilly, pfizer, regeneron, roche, sanofi, trb chemedica, and ucb, joana magalhães: None declared

Results: Participants had a mean age 47±9 yrs and 6 out 7 (86%) were female. All had KL grade ≥2 with substantial knee pain at baseline. Enough SF (>500 uI) could be obtained from n=7 at baseline, n=4 at midpoint, and n=3 at endpoint of distraction. For the first time in this same group, we show how MSC number initially decline upon KJD (figure 1A-B) as seen previously in our animal study [4]. Also, MSCs present in the SF showed changes in their gene expression profile upon KJD, most clearly observed during the treatment (3 weeks; figure 1C). GFDF5 and Grem1 present with a statistically significant increased expression (p<0.05) during treatment while FAB4 expression was decreased. ACAN, PTHR1, and DDR expression had the tendency to increase over time. ADAMTS4, Sox9 and PTHLH expression showed a trend to decrease over time.

Conclusion: This explorative study provides the first-time data on changes in SF MSC number and their gene expression profiles upon knee joint distraction. As such, first clues are provided for the involvement of MSCs in the regenerative process induced by joint distraction for knee joint distraction. As such, first clues are provided for the involvement of MSCs in the regenerative process induced by joint distraction for end-stage knee OA. The fall in SF MSC number during distraction suggests adhesion to the arthritic surfaces in the KJD environment as found in our previous work in canine KJD [4]. Further studies are necessary to unravel the processes involved.

Acknowledgement: Funded by FOREUM and Dutch Arthritis Society.
Background: Ankylosing spondylitis (AS) is associated with enthesis inflammation and new bone formation. Resident populations of lymphocytes have been identified at the enthesis that on stimulation with IL-23 produce pro-inflammatory cytokines including IL-17A and IL-22 (1) which drive inflammation and may also influence osteogenesis. Surprisingly, enthesis resident mesenchymal stem cells (MSCs) have not been phenotypically or functionally characterised.

Objectives: To determine if human enthesis including entheseal soft tissue and peri-entheseal bone harbours a population of MSCs. Furthermore, to investigate the effect of spondyloarthritides associated pro-inflammatory cytokines on MSC osteogenesis.

Methods: Samples from healthy the spinoous process and interspinous ligament (male = 5, female = 10, median age = 19) were divided into entheseal soft tissue (EST) and peri-entheseal bone (PEB) and enzymatically digested (1). MSCs content was assessed using a CFU-F assay. Flow cytometry was used to examine expression of MSCs specific markers in plastic adherent cultures. Following osteogenic, chondrogenic and adipogenic inductions, osteogenesis was qualitatively by alkaline phosphatase and alizarin red staining and quantitatively by measurement of calcium accumulation. Chondrogenesis and adipogenesis were assessed using glycosaminoglycan assay and oil red o staining respectively. Osteogenic cultures were also supplemented with IL-17A (50ng/ml), IL-22 (10ng/ml) or TNF-α (1ng/ml).

Results: As a proportion of total cellularity EST developed approximately 5 fold more colonies than matched PEB (p<0.001). Cultured cells were overwhelmingly positive for expression of MSC markers CD73, CD90, CD105 (PEB median 98.66% range: 95.17-98.96%, EST median 98.42% range: 98.12-98.89%) however some CD34 expression was noted particularly in EST cultures (PEB median 0.34% range: 0-2.91%, EST median 1.1% range: 0-2.53%) and osteogenesis was qualitatively by alkaline phosphatase and alizarin red staining and quantitatively by measurement of calcium accumulation. Chondrogenesis and adipogenesis were assessed using glycosaminoglycan assay and oil red o staining respectively. Osteogenic cultures were also supplemented with IL-17A (50ng/ml), IL-22 (10ng/ml) or TNF-α (1ng/ml).

Conclusion: Both the EST and PEB contain cells that meet the ISCT criteria defining MSCs. However, MSCs from these sources are functionally distinct in terms of their differentiation potential and response to inflammatory cytokines. The cytokines tested had a negative influence on osteogenesis in the conditions tested.

MITOCHONDRIAL BACKGROUND IMPACT ON THE JOINT DEGENERATION PROCESS DURING AGING AND FORCED EXERCISE: A CONPLASTIC MOUSE MODEL

Morena Scotece1, Ignacio Rego-Perez2, Ana Victoria Lechuga Vieco2, Purificación Figueira-Fernández2, Jose Antonio Enriquez2, Francisco J. Blanco1
1Servicio de Reumatología. Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CUHAC), Sergas, Universidade da Coruña (UDC), A Coruña, Spain; 2Grupo de Genética funcional del sistema de fosforilación oxidativa. Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, España, Madrid, Spain

Background: Several studies indicated that osteoarthritis has a strong genetic component with a prevalent role of mitochondria and mtDNA variation. Conplastic mice (BL/6 NZB) strain was developed with the NZB/OlaHsd nuclear genome and the NZB/OlaHsd mtDNA to compare with the original C57BL/6J nuclear genome (BL/6). The results were found in various OA animal models and patients. Despite the severity of OA, the initial triggers of this disease are mostly unknown. Recent studies suggest that, metabolism is important for maintaining cartilage function, and aberrant metabolic activities in chondrocytes have been shown in various OA animal models and patients. In the present study, we aimed to investigate the influence of the mtDNA variation in the joint deterioration using mice with the same nuclear genome but different mtDNA variants (named conplastic mice) during aging and forced exercise.

Methods: Conplastic mice (BL/6NZB) strain was developed with the C57BL/6J/OlaHsd nuclear genome and the NZB/OlaHsd mtDNA to compare with the original C57BL/6J/OlaHsd strain (BL/6). Knee joints from BL/6NZB mice as well as from BL/6NZB mice were processed and cut into coronal sections. The mice were sacrificed at 25, 75 and 90 weeks of age and knee joints were collected for histological analysis. All sections were stained with Hematoxylin-Eosine and Safranin O-fast green and graded using a Rankin scoring system. Another group of mice from both BL/6 and BL/6NZB strains were subjected to exercise by running in a treadmill 400m/day three times a week. After 75 and 90 weeks of age, mice were sacrificed and knee joints were processed for histological analysis. Cartilage expression of markers of autophagy like LC3 and metalloproteases like MMP-13 were also analysed by immunohistochemistry in both strains. The results are given as mean ± SEM and statistical analysis was performed using non parametric unpaired t-test (Graph Pad Prism v 6.0).

Results: In response to aging, conplastic mice BL/6NZB presented reduced cartilage Rankin score at 25 (p=0.0079), 75 (p=0.0087) and 90 (p=0.064) weeks when compared with mice of the original strain BL/6 at the same age. Specifically, we showed a reduced score in both femoral condyle (FC) and tibial plateau (TP) of BL/6NZB mice that reached the statistical significance at 25 (FC: p=0.0317; TP: p=0.0079), 75 (FC: p=0.0411; TP: p=0.0238) and borderline the statistical significance at 90 (FC: p=0.0649; TP: p=0.0628) weeks of age. These results were accompanied with more expression of LC3 in cartilage from BL/6NZB mice at 75 weeks when compared with cartilage from BL/6 at the same age (p=0.0152). We also reported a significant decrease of LC3 expression in cartilage from mice at 75 weeks when compared with mice at 25 weeks in both strains confirming the decrease of autophagy with aging. Difference in MMP13 cartilage expression between the two mice strains were also found. In the mice subjected to exercise, BL/6NZB presented an increased cartilage score in the medial compartment (p=0.0286) and lateral compartment (p=0.057) of the joint at 90 weeks when compared with BL/6NZB mice at the same age.

Conclusion: This study demonstrated that aging and forced exercise in conplastic mice BL/6NZB are associated with a reduced joint deterioration compared with the original strain BL/6. Moreover, we showed that mtDNA variants can improve the aging process at joint level through the modulation of autophagy. These results support the hypothesis that mtDNA background has a role in the process of joint damage, suggesting that mtDNA has potential as novel therapeutic target in OA associated to aging.

TLR-1/2 SIGNALING IMPAIRS MITOCHONDRIAL OXIDATIVE PHOSPHORYLATION IN CHONDROCYTES VIA THE INDUCTION OF NITRIC OXIDE

Ping Shen1, Michael Fuchs2, Marie Reisener3, Clemens Gwinner3, Peihua Wu1, Tobias Jung1, Matthias Pumberger1, Carsten Perka1, Max Löhn1
1Deutsches Rheuma-Forschungszenrum, Pilzler Laboratory of Osteoarthritis Research, Berlin, Germany; 2RKU university hospital Ulm, Orthopedic surgery, Ulm, Germany; 3Chanté – Universitätsmedizin Berlin, Centrum für Muskuloskeletale Chirurgie (CMSC), Berlin, Germany

Background: Osteoarthritis (OA) is a degenerative disease that causes progressive loss of joint function, representing a severe health problem plaguing this ageing world. Cartilage matrix degradation and cartilaginous matrix production are closely associated with OA clinical symptoms. Recent studies suggest that, metabolism is important for maintaining cartilage function, and aberrant metabolic activities in chondrocytes have been shown in various OA animal models and patients. Despite the severity of OA, the initial triggers of this disease are mostly unknown. Small molecules generated during physiological catabolic reactions often function as damage-associated molecular patterns (DAMP) to activate innate immunity through receptors such as Toll-like receptors (TLR), resulting in enhanced expression of matrix metalloproteinases (MMP) and cartilage factors. Here we studied the effect of various TLR signaling on chondrocyte protein production and mitochondrial oxidative phosphorylation (OXPHOS).

Methods: Chondrocytes were obtained from the femoral condyles of C57BL/6JOlaHsd nuclear genome and the NZB/OlaHsd mtDNA to compare with the original C57BL/6J nuclear genome (BL/6). The results were found in various OA animal models and patients. This project is designed to investigate the roles of TLR signaling in the development of OA and the involved molecular mechanisms.

Results: TLR-1/2 and TLR-2/6 stimulation drastically impaired the cartilage matrix production, as they imposed the lowest pellet growth, lowest expression of matrix proteins COL2 and AGC1, but highest expression of matrix degrading enzymes MMP3, ADAMTSS, and the catabolic factor NO. Remarkably, this phenomenon is associated with drastically diminished OXPHOS activity, as shown by the reduction of both basal and maximal respiratory capacity. Moreover, blockade of NO production reversed the adverse effect imposed by TLR-1/2 stimulation, namely restored their OXPHOS activities and COL2 and AGC1 production in a dose-dependent manner.

Conclusion: Among the whole spectrum of TLR signaling, stimulation of TLR-1/2 and -2/6 impose the strongest inhibition on chondrocyte pellet growth by suppressing matrix protein synthesis and facilitating matrix degradation. TLR-1/2 stimulation causes the reduction of OXPHOS capacity, which is mediated by the induction of NO. Thus, TLR-1/2 stimulation, via inducing NO production, impairs the mitochondrial respiration in chondrocytes and thus possibly promotes the development of OA.

HUMAN MONOCLONAL ACPAS INDUCE MOBILITY OF PRIMED SYNOVIAL FIBROBLAST IN A PAD-DEPENDENT PATHWAY
Meng Sun, Aklan Krishnamurthy, Alexandra Circiumaru, Marianne Engrström, Johanna Steen, Philip Tilcombe, Vivianne Malmström, Heidi Wählimaa, Lars Klareskog, Borce Réthi, Anca Cătărina, Karolinska Institute and University Hospital, Rheumatology Unit, Department of Medicine, Stockholm, Sweden

Background: Anti-citrullinated protein antibodies (ACPA) play an important role in rheumatoid arthritis (RA) pathogenesis. They recognize a wide number of citrullinated targets and show limited cross-reactivity to acetylated ones.1

Objectives: We aimed to investigate the effect of monoclonal ACPAs with different binding patterns on RA synovial tissue derived fibroblasts (SF). Methods: Synovial fibroblasts were isolated from synovial tissue of RA patients by enzymatic digestion. ACPA and control monoclonal antibodies (mAbs) were derived from single B cells isolated from RA patients. Two monoclonal ACPA (1325:01B09 and 1325:05C06) showed cross-reactivity to acetylated-targets while four of them (1325:04C03, 1325:07E07, 14CFCT2D09, 14CFCT2H12) did not(1). mAbs were tested in synovial fibroblast migration (Tirucaly live time image analysis) and osteostet formation (TRAP) assays. The role of mAbs cross-reactivity was tested in fibroblast migration assays using inhibitors of peptidylarginine deiminases (Cl-amidine), histone acetyltransferase (anacardic acid) and histone deace-tylase (trichostatin A). Binding patterns of monoclonal ACPAs were tested in synovial biopsies obtained from both healthy donors and RA patients.

Results: One acetylation cross-reactive ACPA (1325:01B09) and two with no cross reactivity (14CFCT2D09 14CFCT2H12) significantly enhanced fibroblast migration (mean±SD fold increase of 1.9±0.4, 1.7±0.4 and 1.8±0.6, respectively) compared to control mAbs 1362:01E02 (p<0.05), while having no effect on osteostet formation. In contrast, one acetylation non-cross-reactive ACPA (1325:04C03) promoted osteostetogenesis (mean±SD fold increase of 1.6±0.05) compared to control mAbs 1362:01E02 (p<0.05), while having no effect on fibroblast migration. Cl-amidine completely abolished the effect of 1325:01B09, while neither anacardic acid nor trichostatin A had any effect. Moreover, the fibroblast-promoting ACPA (1325:01B09) but not the osteostetic ACPA1325:04C03 co-localize with CD55-positive SF in the inflamed rheumatoid synovium. No detectable signals were found in healthy synovium.

Conclusion: Monoclonal ACPAs have distinct cellular effects on synovial fibroblasts and osteostets that are not related to cross reactivity towards acetylated targets.

VISAFTIN-MEDIATED OSTEODESTRUCTIVE EFFECTS ARE REDUCED

DURING ADIPOGENIC DIFFERENTIATION OF MSC ON MINERALIZED BONE FRAGMENTS
Lali Tsiklauri1, Janina Werner2, Klaus Frommer2, Stefan Rehart2, Sabine Wensisch2, Ulf Müller-Ladner2, Elena Neumann1. Justus-Liebig-University Giessen, Department of Internal Medicine and Rheumatology, Kerckhoff-Klinik, Bad Nauheim, Germany, Bad Nauheim, Germany; Institute of Veterinary-Anatomy, -Histology and -Embryology, Clinic of Small Animals, JLU Giessen, Germany, Giessen, Germany; Markus Hospital, Frankfurt, Germany, Department of Orthopedics and Trauma Surgery, Frankfurt, Germany

Background: Osteoporosis (OP), as an age-related disease, is characterized by bone loss, increased fracture risk and poor regeneration. During aging and OP bone marrow adiposity is increased due to a shift of osteogenic towards adipogenic differentiation of bone marrow mesenchy-mal stem cells (MSC). The differentiation of MSC into adipocytes or osteoblasts is an important determinant of bone structural integrity. It is known, that fatty tissue not simply functions as energy storage but is metabolically highly active. Therefore, adipocyte-derived factors such as adipokines might influence MSC differentiation.

Objectives: The role of interactions between adipocyte-derived factors and MSC in the pathogenesis of OP is not fully elucidated. Thus, we ana-lyzed the presence of the adipokine visfatin in bone tissue and its effects on MSC differentiation in standard culture vs. spongioza.

Methods: The spongioza of femoral heads of patients with osteoarthritis (OA) after hip replacement surgery, or after osteoporotic femoral neck fracture were used for RNA- and MSC-isolation. Adipogenic MSC differen-tiation was performed with/without visfatin and its inhibitor Apo866 as well as SB203580 p38-MAPK inhibitor. For the transfer and differentiation of MSC on cancellous bone, bone fragments were purified and sterilized. Gene expression was measured by Realtime PCR. Protein production was evaluated by ELISA.

Results: Elevated visfatin-level were observed in OP compared to non-osteoporotic OA bone. Visfatin-induced secretion of proinflammatory factors was lower during adipogenesis on cancellous bone then in standard cell culture (e.g. 14d IL6, x-fold: standard culture 151±110, spong. 40±30, n=7). Significantly elevated MMP13 mRNA as well as protein expression production could be stimulated during adipogenesis on spongiosa as well as in standard cell-culture. However visfatin-mediated MMP13 expression was markedly reduced in the presence of cancellous bone (e.g. 21d, x-fold: standard culture 81±89, spong. 13±21, n=7). Inhibition of visfatin by Apo866 decreased the visfatin-induced cytokine release but not for the p38-MAPK inhibitor, p38-MAPK inhibitor did not influence cytokine release but reduced MMP13 expression in a time dependent manner.

Conclusion: Visfatin level was elevated in osteoporotic vs OA bone. Therefore, visfatin-mediated increase of MMPs and proinflammatory cyto-kines during adipogenic differentiation might influence bone turnover at the adipose tissue/bone interface. Our results support the idea that the extracellular matrix attenuates visfatin-mediated detrimental effects during adipogenesis. The observed visfatin-mediated effects most likely depend on different signaling pathways.

IL37 AMELIORATES EXPERIMENTAL MURINE OSTEOARTHRITIS

Arjan van Caam1, Ellen van Gellen, Joyce Aarts, Elly Vitters, Esmee Balsma Davidson, Peter van der Kraan. Radboud university medical center, Experimental Rheumatology, Nijmegen, Netherlands

Background: Osteoarthritis (OA) is the world’s most common degenerative joint disorder and leads to pain and disability. Currently, no disease-modi-fying drugs are available, resulting in a large unmet clinical need. Recently, we have shown that the anti-inflammatory cytokine IL37 lowers pro-inflammatory cytokine production, MMP3 activity and sulfated glyco-saminoglycan loss from ex vivo cultured chondrocytes and human cartilage explants. In this study, we further explored the ability of IL37 to amelio-rate OA pathology by studying its effects both in vitro on synovial fibro-blasts and in vivo in collagenase-induced OA.

Objectives: To establish if IL37 can ameliorate experimental OA pathology

Methods: Primary synovial fibroblasts were obtained from synovial biop-sies of 10 patients undergoing total joint replacement surgery. IL37 was overexpressed in these cells using an adenovirus and subsequently cells were challenged with IL1β or OA-synovium conditioned medium. Collage-nase-induced OA (GIOA) was induced by injecting 10 weeks old female C57BL6J with a single intra-articular injection of 3 units of collagenase type VIII. Four days after collagenase injection, Ad-IL37 or Ad-Luc (+ control) was intra-articular injected in the right knee joint of mice. Two weeks later this injection was repeated. Mice were sacrificed on day 7, 28 and 42 after collagenase-injection. Synovial thickening, cartilage damage and osteophyte formation were measured histologically. IL37, MMP3 and VDIPEN expression were investigated by immunohistochemistry.
Results: In primary synovial fibroblasts, IL37 overexpression significantly reduced IL11r- and OAS-CM-induced expression of MMP1, MMP3, IL1B and IL6 by more than 50%. In naïve knee joints, IL37 overexpression did not induce synovial thickening, cartilage damage or osteophyte formation and no overt immune response was detected after 28 days. Strikingly, in CIOA, at day 7, IL37 overexpression significantly reduced synovial thickening and the presence of the metalloproteinase-generated aggrecan-degradation neopeptide VDIPEN in cartilage. At day 28 of CIOA, cartilage degradation was significantly reduced by IL37 treatment at the lateral and medial femur by respectively 46% and 41%, and osteophyte size at the medial femur was reduced by 70%. At day 42 of CIOA, IL37 overexpression could no longer be detected. Osteophyte size formation at the medial femur was still significantly reduced by 46% at this time point, but only a trend (p = 0.06) towards reduced cartilage damage was observed on both femur and tibia.

Conclusion: Our results show that IL37 inhibits the production of catabolic mediators in synovial fibroblasts, similar to our previously obtained results in cartilage. Furthermore, IL37 clearly lowered synovial thickening and ameliorated cartilage damage and osteophyte formation in murine experimental OA. These results indicate that IL37 acts on multiple tissues and OA-related processes, which supports IL37 as a potential therapeutic agent for OA.

**Isorhamnetin inhibited the production of NO and PGE2, and the expression of iNOS and COX-2. The production of COMP and CTX-II were also inhibited in MIA-induced OA rats.**

**Conclusion:** Isorhamnetin may modulate the inflammatory progression of OA in MIA-induced OA rats. The prevention of cartilage damage was found in OA after adequate isorhamnetin treatment. Isorhamnetin may serve as a potential agent for the management of OA.

**SONIC HEDGEHOG PROMOTES PROLIFERATION, MIGRATION AND INVASION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS VIA P38-MAPK SIGNALING**

Shangling Zhu, Yiming Shi, Yuanmei Ye, Xiaoxue Feng, Jianlin Huang. The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

**Background:** Abnormal activation of Sonic hedgehog (Shh) signaling has been found in synovium from patients with rheumatoid arthritis and inhibition of Shh signaling pathway suppresses the proliferation and migration of fibroblast-like synoviocytes in rheumatoid arthritis (RA-FLS). However, the mechanism how Shh signaling promotes tumor-like behavior of RA-FLS is not well elucidated.

**Objectives:** In this study, we aimed to investigate the effect of Shh on p38 MAPK kinase signaling and hypothesized that Shh promotes proliferation, migration and invasion of RA-FLS via p38-MAPK signaling.

**Methods:** Cultured RA-FLSs were treated with Smoothened agonist (SAG) or IL-1beta combined with Smoothened antagonist (Cyclopamine). The levels of phosphorylation of p38, its upstream kinases including TGFbeta activated kinase 1 (TAK1), MKK3, MKK6 and downstream target MAPKAPK2 (MK2) were determined by western blot. The functional state of p38 was determined using in vitro kinase assay. Cell proliferation was evaluated by Cell Counting Kit-8 assay. Cell migration and invasion were performed by Transwell assay. The expression of matrix metalloproteinase proteins (MMPs), IL-6 and IL-8 was examined by real-time PCR.

**Results:** SAG rapidly increased phosphorylation of p38, TAK1, MKK3, MKK6 and MK2 in RA-FLS and combination of SAG and p38 inhibitor significantly decreased the phosphorylation of these kinases (P<0.01). Inhibition of Shh significantly decreased the levels of phosphorylation of p38, TAK1, MKK3, MKK6 and MK2 in IL-1beta stimulated RA-FLS (P<0.05). In vitro kinase assay showed that stimulation of SAG significantly increased the kinase activity, and the kinase activity was inhibited by p38 inhibitor. Furthermore, SAG increased cell proliferation, migration, invasion and production of MMP1, MMP3, MMP13, IL-6 and IL-8. However, these enhanced activities of RA-FLS were inhibited in the presence of p38 inhibitor.

**Conclusion:** The study indicates that Shh is associated with activation of p38 MAPK signaling in RA-FLS and Shh may promote the tumor-like behavior of RA-FLS via p38 signaling.

**ETHNICITY AND NEONATAL LUPUS RISK IN A LARGE MULTI-ETHNIC COHORT**

Talia Diaz1, Daniela Dominguez1, Lawrence Ng1, Franklin Silverio1, Andrea Knight1, Earl Silverman1, Linda Hiraki2, 3, *The Hospital for Sick Children, Rheumatology, Toronto, Canada; 4Child Health Evaluative Sciences, The Hospital for Sick Children, Toronto, Canada*

**Background:** Neonatal Lupus (NL) is an acquired autoimmune disorder of newborns secondary to the transplacental passage of maternal anti-Ro and/or anti-La. Approximately 2% of children exposed to these antibodies develop NL. Prior studies have suggested that babies of non-European ancestry have a higher proportion of cardiac NL when compared to babies of European ancestry. This finding has not been consistently replicated.

**Objectives:** To examine the association between ethnicity and clinical manifestations of NL in our multi-ethnic population.

**Methods:** We conducted a cohort study of our large, multi-ethnic NL clinic population. The Neonatal Lupus clinic at the Hospital for Sick Children, Toronto, Canada was established in 1986. Children born to anti-Ro and/or anti-La antibody positive mothers are referred to the NL clinic. Antenatal testing is completed due to maternal rheumatologic diagnosis, a prior child born with NL and/or a history of symptoms that prompted physician testing for these antibodies. Beginning in 2011, families routinely reported ethnicity (Canadian census categories). We divided our NL patient cohort in European and non-European groups; the non-European group includes patients of African, Latin American, Eastern Asian, South Asian and Mixed non-European ancestry (i.e. combination of two or more of non-European ethnicities). We included children assessed in the NL clinic ≤ 1 year of age between January 2011 to April 2018. There were 59 children censored for this analysis (7 missing ethnicity and 52 Mixed European-Non European ancestry). We analyzed prospectively collected data from our NL database, on specific NL manifestations: cardiac (heart block, myocarditis, endocardial fibroelastosis), dermatologic (typical rash of NL), hematologic (cytopneas), hepatic (transaminits) and neurologic (macer- rophyelitis). The frequency of NL clinical manifestations was compared among ethnicity groups (Fishers’ exact test). We tested the association between ethnicity and NL clinical manifestations in logistic models.

**Results:** Our study included 301 children, 149 (50%) female and 162 (55%) with NL (Table 1). The median follow-up period was 12.2 months (IQR 8.9, 28.8 months). Ethnicity data was available for 294 (98%) of the children. The non-European group (40%) was comprised of East Asian (14%), South Asian (13%), African (10%), Latin American (2%) and Mixed Non-European ancestry (17%). We did not observe a difference between European and Non-European babies in the proportion with NL, nor any difference in the frequency of specific NL manifestations (p-values > 0.3).

**Conclusion:** In our multi-ethnic NL cohort of children born to mothers with positive anti-Ro and/or anti-La antibodies, there was no association between ethnicity and NL, nor specific NL manifestations. Future analyses will examine the effect of maternal ethnicity and rheumatic disease status on the risk of NL and specific NL manifestations.

Objectives: We sought to quantify rates of newly treated diabetes mellitus, hypertension, and venous thromboembolism (VTE) associated with oral glucocorticoid exposure in children. We hypothesized that oral glucocorticoids were associated with each complication in a dose-dependent manner, most strongly with current or recent glucocorticoid exposure.

Methods: Using Medicaid claims data (2000-2010), we identified children ages 1-18 diagnosed with immune-mediated diseases (inflammatory bowel disease, juvenile idiopathic arthritis, or psoriasis) or a non-immune comparator condition (attention-deficit/hyperactivity disorder) based on diagnostic codes ± pharmacy claims. We studied time-varying oral glucocorticoid exposures using pharmacy claims after a ≥6-month glucocorticoid-free baseline period, categorizing dose as low (<0.25 mg/kg/day), medium (0.25-0.99 mg/kg/day), or high (≥1 mg/kg/day) based on prescribed prednisone-equivalent dosage and age/sex-imputed weights. Primary outcomes were incident treatment of diabetes (type 1 or 2), hypertension, and VTE. We used Cox regression and weighted cumulative exposure models to estimate adjusted hazard ratios (aHRs) and number needed to harm (NNH) for varying patterns of glucocorticoid exposure.

Results: We followed 932,517 children (21.3% glucocorticoid-exposed) for 1.6 million person-years. Glucocorticoid usage varied by disease (Table). After adjusting for age, sex, race/ethnicity, calendar year, inclusion diagnosis, comorbidities, other medications, and healthcare usage, we found strong dose- and time-dependent relationships between glucocorticoid exposure and rates of newly treated diabetes, hypertension, and VTE (Figure 1). These effects increased with longer durations of exposure and declined within 6 months after stopping (Figure 2). Sustained low-dose exposures (e.g., 0.1 mg/kg/day) appeared relatively safe (aHR<1.2), but risks increased even with brief high-dose exposures (2 mg/kg/day x7 days) (aHR 1.7-2.2). Risk differences were highest for hypertension (number needed to harm (NNH): 2 mg/kg/day x7 days, 6,206-17,894; 2 mg/kg/day x30 days, 233-671) and lowest for VTE (NNH: 2 mg/kg/day x7 days, 54,886-612,350; 2 mg/kg/day x30 days, 1,977-22,045). Absolute risks were higher for children with immune-mediated diseases (e.g., diabetes, 2 mg/kg/day x30 days, NNH: 424-691) than for those with ADHD (NNH: 959).

Units: duration, days; dose, mg/kg/day.

Diabetes mellitus (aHR 95% CI)
- Dose >1600 mg/day: 1.60 (1.45, 1.77)
- Dose 1-1600 mg/day: 1.83 (1.63, 2.04)
- Current low dose: 2.89 (1.79, 4.67)
- Current medium dose: 4.73 (3.55, 6.99)
- Current high dose: 5.93 (3.94, 8.91)

Hypertension (aHR 95% CI)
- Dose >1600 mg/day: 1.58 (1.44, 1.72)
- Dose 1-1600 mg/day: 1.87 (1.63, 2.07)
- Current low dose: 2.74 (1.93, 3.90)
- Current medium dose: 7.59 (5.59, 11.18)
- Current high dose: 19.13 (13.43, 23.73)

Venous thromboembolism (aHR 95% CI)
- Dose >1600 mg/day: 1.10 (0.80, 1.53)
- Dose 1-1600 mg/day: 2.20 (1.51, 3.21)
- Current low dose: 6.09 (3.43, 10.79)
- Current medium dose: 7.71 (4.82, 12.98)
- Current high dose: 10.16 (6.94, 20.22)

Conclusion: In children with various chronic conditions, current oral glucocorticoid use is strongly associated with newly treated diabetes, hypertension, and VTE in a dose- and duration-dependent fashion. Hypertension is a more common glucocorticoid-related complication than diabetes or VTE, but in absolute terms, all of these complications are uncommon in children.

OBJECTIVES: Our study aimed to compare the accuracy of serum bioarkers for the diagnosis of MAS complicating s-JIA and to investigate the clinical significance of serum neopterin levels as an indicator of disease activity and diagnosis of MAS complicating s-JIA.

Methods: Serum cytokine levels (neopterin, IL-18, and CXCL9) and soluble tumor necrosis factor receptor type I (sTNFR-I) and II were determined by enzyme-linked immunosorbent assay in 78 patients with s-JIA, including 21 with MAS. The accuracy of these levels for the diagnosis of MAS was compared. Next, serum neopterin levels, in total 125 patients with s-JIA, including 30 with MAS, 15 with Epstein-Barr virus-induced hemophagocytic lymphohistiocytosis (EBV-HLH), and 15 with Kawasaki disease (KD), as well as 28 healthy controls (HCs) were analysed. Results were compared with the clinical features of MAS.

Results: Receiver operating characteristic curve analysis revealed area under the curve values and cut off values of neopterin, IL-18, CXCL9, sTNFR-I/II ratio and ferritin were 0.94/55/4/3/2, 0.52/95/84/5/2, 0.93/5/4/3/2, and 0.88/7/8/6/5, respectively. Serum neopterin levels were significantly elevated in patients with MAS and EBV-HLH compared with those in patients with acute-phase s-JIA and KD. Serum neopterin levels profoundly and rapidly increased as MAS developed and were effectively used and discontinued in 72% of patients. No patients on anti-TNF inhibitors were the most frequently used (47 patients), with the highest efficacy rate (>90% complete response), while Etanercept was less effective and discontinued in 72% of patients. No patients on anti-IL1 drugs were the best maintenance treatment in patients with FMF.

Conclusion: Serum neopterin levels may be used as a promising indicator of disease activity in s-JIA and for evaluating it. It may also be a useful marker to diagnose the transition to MAS from active phase s-JIA.

FRI0536 FAMILIAL MEDITERRANEAN FEVER (FMF): A SINGLE CENTER EXPERIENCE FROM TURKEY

Ayge Tanjatir, Şerife Gül Karadag, Hatife Emine Sommez, Mustafa Çağan, Nuray Akbay Ayaz. University of Health Science, Karuni Sultan Süleyman Research and Training Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Familial Mediterranean fever (FMF) is the most common monogenic autoinflammatory disease mainly affecting ethnic groups living at Mediterranean region. Since the discovery of the Mediterranean Fever (MEVF) gene, molecular genetic testing has been used as a diagnostic adjunct especially in atypical cases (1, 2). Although substantial progress has been achieved about the etiopathogenesis of FMF during the past 20 years, the diagnosis is still based on clinical criteria.

Objectives: To define the demographic, clinical and laboratory characteristics of children with FMF and then to compare the identification capacity of 3 validated FMF diagnostic criteria (Tel-Hashomer, Livneh and Pediatric) at our cohort (3-5).

Methods: The medical records of 1685 children diagnosed and followed up as FMF were reviewed retrospectively. All patients were evaluated for three diagnostic criteria.

Results: A total of 1685 children (839 girls, 846 boys) were involved in the study. Family history of FMF was positive in 46.1%. The mean ± standard deviation of current age, age at symptom onset, onset at disease was 13±5.4, 5±4±15, 7±8±4±1 years, respectively. Median (min-max) follow-up period was 3 (0.5-18) years. Among 1685 patients, 82.8% had fever, 78.2% had abdominal pain, 36.1% had arthritis, 22.6% had chest pain and 16.6% had erysipelas-like erythema. Three patients had biopsy proven amyloidosis. Concomitant disease was present in 140 (8.3%) patients. Most of them (40.7%) were diagnosed with juvenile idiopathic arthriti and FMF. Henoch-Schönlein vasculitis was observed in 35 (25%) patients. Median (min-max) PRAS score was 7 (3-13). Forty-four patients (2.6%) were unresponsive to adequate doses of colchicine. Among them, 16 (36.4%) were treated with anakinra and 28 (63.6%) received canakinumab. Children homozygous for M694V were found to have more severe course of disease and higher PRAS scores (p<0.001). Furthermore, 34 (77.3%) of colchicine resistant patients carried at least one M694V variant. When we applied the diagnostic criteria to our cohort, 99.5% met the Livneh criteria, 91.6% fulfilled the pediatric criteria and 82.9% satisfied the Tel-Hashomer criteria.

Conclusion: This is the largest pediatric cohort studied and presented since now. We believe that the large numbers of our cohort is convincing at the point of discussing phenotype-genotype relations. We confirmed that carrying M694V mutation is associated with increased disease severity. On the other hand, we compared two adult and one pediatric validated diagnostic criteria at a largest group of children with FMF.

FR0537 LONG-TERM OUTCOMES AND TREATMENT EFFICACY IN PATIENTS WITH TNF RECEPTOR-ASSOCIATED AUTOINFLAMMATORY SYNDROME (TRAPS): A SERIES OF 290 CASES FROM THE EUROFEVER/EUROTARPS INTERNATIONAL REGISTRY

Riccardo Papa1, Thiruosa Lane2, Taryn Youngstein2, Tanner Reiz3, Charalampia Papadopoulos1, Nicolaio Ruperto1, Paul Brogan1, Philip N. Hawkins2, Patricia W2, Marco Gattorno1, Helen J. Lachmann2, Patricio Ruperto1, Maria Giannini3, Clinica Pediatra e Reumatologia, Genova, Italy; 1Division of Medicine, Royal Free Campus, University College London, National Amyloidosis Centre, LONDON, United Kingdom; 2UCL Great Ormond Street Institute of Child Health, Department of Infection, Inflammation and Rheumatology, LONDON, United Kingdom

Background: Tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is one of the best known monogenic auto-inflammatory syndrome resulting from an autosomal dominant variation in the TNF super family receptor 1A (TNFRSF1A) gene.

Objectives: To define best treatment approach in patients with TRAPS and effect on long-term outcomes.

Methods: We reviewed all data on patients with TNFRSF1A variants enrolled in the Eurofever/EUROTARPS international registry.

Results: Data on 290 patients were available. Patients with R92Q, P46L or intronic variants (49%) displayed milder disease than 147 patients with mutations affecting other coding regions, with less frequent abdominal pain and skin rashes (P<0.01), higher efficacy rate of colchicine as maintenance treatment, and none developed AA amyloidosis. Almost 90% of patients with exon mutations required maintenance therapy. Anti-interleukin (IL) 1(1) drugs were the most frequently used (47 patients), with the highest efficacy rate (>90% complete response), while Etanercept was less effectively used and discontinued in 72% of patients. No patients on anti-IL1 drugs treatment developed polyarthritis and 10 patients with amyloidosis have been successfully treated with anti IL-1 agents with preservation of native renal function in 7 and excellent long-term transplanta function in 2. Nine women had a history of failure to conceive and seven had successful pregnancies without fertility treatment following complete disease control with anti-IL1 drugs. Long term safety profiles for anti IL-1 agents were excellent even in the presence of comorbidity.

Conclusion: Anti-IL1 drugs are the best maintenance treatment in TRAPS with potential to reverse the most serious disease complications of AA amyloidosis and infertility. The diagnosis of TRAPS should be considered very carefully in patients carrying R92Q, P46L or intronic TNFRSF1A variants.

MAY SOME OF THE MEFV GENE VARIANTS CAUSE PFAPA SYNDROME LIKE SYMPTOMS?

YILDIZ Mehmet, Amra Adrovic, Ipek Ulkeroy, Neslihan Gucuyener, Oya Koker, Sezgin Sahin, Kenan Barut, Ozgur Kasapcopur. Cerrahpasa Medical School, Istanbul University Cerrahpasa, Department of Pediatric Rheumatology, Istanbul, Turkey

Background: PFAPA syndrome is characterized by periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis. As diagnosis usually depends on clinical diagnostic criteria, sometimes it can be difficult to distinguish this clinical entity from the other periodic fever syndromes, especially in regions endemic for FMF.

Objectives: The objective of the study is to evaluate the PFAPA patients’ MEFV gene variation frequencies (if it was performed) and relations between detected variants and clinical manifestations in pediatric PFAPA patients.

Methods: Nine hundred and thirty-seven patients that were recorded to our database as PFAPA syndrome were evaluated. Patients were reached by phone and asked about characteristics of their fever episodes, presence of acute phase reactant elevation, pharyngitis, aphthous stomatitis/aphthous tonsillitis, cervical lymphadenopathy, arthralgia, arthritis, abdominal pain, headache, nausea or vomiting, chest pain, diarrhea, skin changes, myalgia and conjunctivitis in the course of fever attack, if they had tonsillectomy, if they were attack-free after tonsillectomy and if they had clinical response to steroid or colchicine.

Results: There were 937 PFAPA patients in our database. MEFV gene analysis was performed in 407 (43%) of PFAPA patients and 305 of them had at least one mutation. Most common MEFV mutations of patients were: R202Q heterozygotes (25.9%), M694V heterozygotes (24.2%), E148Q heterozygotes (13.4%), P369S heterozygotes (9.8%), and V726A heterozygotes (8.6%), respectively. 54.5% of detected mutations were located in exon 2, 40.3% of them were located in exon 10 and 5.3% of them were located in exon 3 of the MEFV gene. Patients were divided into five groups according to their mutations’ localization and groups were compared according to clinical features. There were significant differences between groups according to presence of pharyngitis, arthralgia, abdominal pain, myalgia and tonsillectomy history (Table 1).

Conclusion: In this study, we reported increased frequency of MEFV mutations in a large PFAPA patients cohort. Frequency differences of clinical features between groups suggest that some of the MEFV gene mutations may modify phenotype of PFAPA syndrome. Furthermore, underlying MEFV gene mutations possibly lead to PFAPA like clinical presentation in FMF patients. Another remarkable finding of this study is the relatively high P369S mutation rates in patients with PFAPA syndrome.

WNT6 MUTATION CAUSES AN EARLY ONSET GRANULOMATOUS INTESTINAL DISEASE WITH RECURRENT HEMOHOGYCIC LYMPHOMIHOSTIOSITIC SYNDROME (HLH)

Claudia Brancarini,1,1, Daniela Kraipez,2, Fiannmeta Bracci,1, Antonella Insalaco1, Giulia Marucci1,1, Manuela Pardeo,1 Giusi Princlpe1, Ivan Cairelli,2, Antonia Pascarella1, Marcello Niceta,2 Francesca Pantaleoni,2 Andrea Ciolfi1, Bronislava Papadato1, Marco Tartaglia,1 Giuliano Torre1, Fabrizio De Benedetti1,1IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy; 2IRCCS Ospedale Pediatrico Bambino Gesù, Haplogenetics, Gastroenterology and Nutrition Unit, Rome, Italy; 3IRCCS Ospedale Pediatrico Bambino Gesù, Genetics and Rare Diseases Research Division, Rome, Italy

Background: Use of NGS in patients with unclassifiable disease lies a possible approach to the identification of novel disease causing genes.

Objectives: We report a patient with an early onset inflammatory bowel disease with granulomatous lesions and recurrent HLH episodes carrying a missense mutation in the WNT6 gene.

Methods: A trio based Whole Exome Sequencing (WES) approach was used. Cytokine levels were measured by multiplex assay and by specific ELISAs.

Results: Ten years old Caucasian boy affected by early onset pan-collitis from 9 months of age. Since the disease onset the patient is on glucocorticoid treatment with amino acidic enteral nutrition and oligo antigenic diet. Because of recurrent disease relapses at any attempt of glucocorticoid withdrawal, azathioprine and cyclosporine treatments were also added. At 2 years of age he received total colectomy with ileostomy.
Because of insufficient disease control, treatment with a TNF-inhibitor (infliximab) was started with apparent improvement of intestinal symptoms. However, persistent granulomatous inflammatory disease of the distal portion of the ileo-caecal anastomosis persisted. Moreover, the patient presented recurrent HLH episodes that required high dose of glucocorticoid and cyclosporine-A treatment. Except one HLH episode related to a varicella zoster infection, the other HLH events were most likely triggered by his underlying inflammatory condition. During the HLH episodes levels of IL-18 were moderately elevated (10.880 pg/ml), the IFN-gamma induced chemokine CXCL9 was markedly high (21.871 pg/ml) and remained markedly elevated also during clinical and laboratory HLH remission (3.121 pg/ml and 9.929 pg/ml respectively). Considering the early disease onset, primary immunodeficiency and early intestinal bowel disease onset were genetically ruled out as well as chronic granulomatous diseases through extensive NGS panels. WES revealed carriage of a private (MAF: 1/125568, TOPMED), predicted pathogenic (CADD: 31), homozygous variant of WNT6 (c.793G>C; p.(Asp265His); NM_006522.3). The patient is now partially controlled on low dose of oral glucocorticoid (0.1 mg/kg), cyclosporine-A (5mg/kg) and antimicrobial treatment.

Conclusion: WNT signalling has been primarily described as a regulatory pathway in ontogeny and homeostatic processes. Schaele at al. demonstrated that WNT6 is expressed in: 1) granulomas lesions in human lung of Mycobacterium tuberculosis-infected mice. Moreover, they found that the transcription factor c-Myc is significantly induced in murine macrophages by WNT6. This identifies WNT6 as a novel factor driving macrophage polarization toward an M2-like phenotype, suggesting a role for WNT6 in macrophage differentiation. Our case suggests defective function of WNT6 might be involved in the development of a granulomatous disease, WNT6 role in macrophage differentiation and polarization might also be important in the activation of the IFN-gamma pathway and in recurrent HLH episodes.

Background: Despite continuous advances in the identification of novel causative genes, several patients with a clinical autoinflammatory pheno-type remain unclassifiable

Objectives: to describe a novel hematological and autoinflammatory disorder in three unrelated patients caused by a de novo missense mutation of CDC42

Methods: Whole exome sequencing was used to identify the novel variant. The functional impact of the novel CDC42 function on hematopoiesis and inflammation was assessed through patient peripheral blood and bone marrow analyses, protein behavior and immune and non-immune cell functioning through in vitro biochemical and functional assays and in vivo C elegans modeling.

Results: Patients shared the same de novo missense mutation of CDC42 (NM_001791, Chr1:22417990, c.556C>T, p.R186C). Disease features included neonatal-onset cytopenia with dyshematopoiesis, autoinflammation, rash, and hemophagocytosis (collectively termed NOCARH syndrome) (Table). An altered hematopoietic compartment (prevalence of early differentiation elements and substantially decreased clonogenic progenitors) was demonstrated. Complementary assays documented the unique consequences of this mutation on CDC42 localization and function, and its disruptive effect on cell behavior and developmental processes, possibly linked to actin dysregulation. Increased secretion of IL-1β, and particularly of IL-18, was observed via ex vivo spontaneous release from unstimulated bone marrow mononuclear cells and by high levels in bone marrow supernatants and plasma. IFNγ was also increased and correlated to WNT6 levels which were strictly related to ferritin levels. Treatment with anakinra and emapalumab, a monoclonal antibody to IFNγ, was identified as critical in the survival of one patient, who underwent successful hematopoietic stem cell transplantation.

Conclusion: The p.R186C amino acid substitution in CDC42 underlies a novel, unique syndrome where CDC42 functional dysregulation has pleiotropic effects, causing hematopoietic disturbance, hyperinflammation, and immune impairment. Early recognition and control of HLH, through neutralization of IFNγ, followed by hematopoietic stem cell transplantation, appear to be crucial to survival.

HIGHLY ELEVATED FERRITIN LEVELS ARE ASSOCIATED WITH HAEMOPHAGOCYTIC LYMPHOPHILOPATHY - MACROPHAGE ACTIVATION SYNDROME WHEN CONSIDERED AS A SUGGESTING TREATABLE DIAGNOSIS? A RETROSPECTIVE SERVICE EVALUATION OF DIAGNOSIS IN PATIENTS WITH FERRITIN >10,000 MICROGRAM/L

BACKGROUND: Haemophagocytic lymphohistiocytosis (HLH)/macrophage activation syndrome (MAS) is a hyperinflammatory syndrome potentially leading to critical illness. Early recognition reduces mortality but diagnosis requires a high index of suspicion. Highly elevated ferritin levels (HEF) >10,000 µg/L are highly specific for HLH/MAS [1] and should prompt consideration of hyperinflammation. Diagnostic guidelines for HLH, requiring the presence of ≥5/8 criteria [2], and classification criteria for MAS complicating systemic juvenile idiopathic arthritides (sJIA) have been published [3].

OBJECTIVES: To assess recognition of HLH/MAS in a paediatric population with HEF.

METHODS: This retrospective study was conducted at 11 centres under local service evaluation permissions. Biochemistry databases identified patients ≤16 years with serum ferritin >10,000 µg/L during a 3-year period. Each case was assessed against the 2004 HLH criteria and, for patients with sJIA, the 2016 MAS criteria. Due to limited access to some of the laboratory tests, previously-published modified HLH criteria using a threshold of ≥45 (excluding tissue haemophagocytosis, decreased natural killer cell function, increased soluble interleukin-2 receptor) were also applied to all patients [4].

RESULTS: 153 patients (55.6% male) were identified. Patient diagnoses included: infections (29.4%), rheumatological (17.0%) and malignancies (17.0%). A diagnosis of HLH/MAS was made by the treating clinical team in 39.9% and considered in a further 16.3%. Using all available data, 30/153 (19.6%) met ≥5/8 criteria and 93.3% of these patients were diagnosed with HLH/MAS by the treating team. 56 (36.6%) met ≥45 criteria and 33 (59.9%) of these were diagnosed with HLH/MAS by clinicians. HLH/MAS was not documented as being considered in the differential in 23.2%. Of 23 patients with sJIA, 62.6% met MAS classification criteria and 89.5% of these were diagnosed with MAS by the treating clinicians. Overall mortality was 32.7% (50/153) and was 27.9% (17/61) in patients diagnosed with HLH/MAS during their admission.

CONCLUSION: Although HEF is highly specific for HLH/MAS, the diagnosis was only made or considered in just over half of paediatric patients with this laboratory result. Increased awareness of this potentially-lethal condition is likely to lead to earlier treatment and reduced mortality.

CLINICAL PRESENTATION, GENETIC ANALYSIS AND IFN-Score in Patients with Undefined Interferonopathies

Silvia Federici, Gian Marco Moneta, Chiara Passarelli, Claudia Bracaglia, Carmela Gerarda Luana Raffaele, Fabrizio De Benedetti, Antonella Insalaco. IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy

Background: In the last years, an expanding group of complex genetic disorders characterized by disturbance of the homeostatic control of IFN-mediated immune responses, have been identified, so called type I interferonopathies. An increased expression of type I IFN regulated genes, IFN signature (IS), is described in these conditions. IS represent a useful tool in clinical practice to classify patients with suspected interferonopathies.

OBJECTIVES: To evaluate the correlation between clinical presentation, genetic analysis and IFN-score in 10 patients with undefined interferonopathies.

METHODS: Patients with suspected interferonopathy based on the presence of typical clinical manifestations (neuropsychiatric, mucocutaneous symptoms), laboratory parameters (complement deficiency, low platelet count, presence of autoimmunity), instrumental abnormalities (cerebral calcification), were screened for the IFN-score. Defined IFN-mediated diseases were excluded. Patients presenting with a high IFN-score value (above a fixed cut-off of 10) underwent genetic screening by running a panel of 24 genes known to be involved in interferonopathies.

RESULTS: 10 patients with suspected interferonopathy followed in a single pediatric rheumatology center were included. 7/10 presented with recurrent episodes of fever (table). Patient 2, 3 and 7 displayed neurological manifestation resembling inflammatory bowel diseases were described while patients 5, 7 and 10 suffered from recurrent abdominal pain, diarrhoea and patient 10 from hypertransaminasemia. Half of the patients complained arthromyalgia; arthritis developed in patient 2. Cutaneous involvement presented in 3 patients (1,3,6) respectively with a widespread panniculitis of trunk and limbs, aspecific vasculitis and Schönlein Henoch purpura. Other cutaneous manifestation were urticarial rash (pt 2) and an erythematous, desquamative confluent eczema (pt 4). Autoimmun-ity was confirmed in 2/10 patients. Two patients (4, 6) had an immunological defect with recurrent infections. The genetic analysis resulted negative in patients 1 and 7 and is still ongoing in patients 5, 6 and 8. Patients 2,3,4,9 and 10 carried one mutation in at least one IFN correlated gene not confirming the diagnosis. All patients presented an increased IS ranging from 14,2 to 172,5.

CONCLUSION: An elevated IFN-score represent a useful instrument in the clinical practice to classify patients with suspected interferonopathy. It may represent an important tool to select those patients to be genetically screened with a defined panel of interferonopathies correlated genes. In those patients in which the genetic analysis result negative, the presence of IFN signature might suggest a type I interferonopathy.
of a positive IFN-score, confirming an activation of this inflammatory path- way, may guide the clinicians in the management of these patients and may support therapeutic decisions.

FRID543 EFFICACY AND SAFETY OF INTRAVENOUS GOLIMUMAB IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: RESULTS FROM A PHASE 3 OPEN-LABEL STUDY

Nicole Ruperto1, Alberto Spindler2, César Francisco Pacheco Tena3, Ingrid Louw4, Gabriel Vega Cornejo5, Daniel Kingsbury6, Michael Clark7, Karen Bensley, Li Xiao7, Hermine Brunner8, Investigators of the PRSCGS and PRINTO networks. 1Università Giannini Gaslini, Pediatrica II, Genova, Italy. 2Centro Médico Privado de Reumatología, San Miguel de Tucuman, Argentina. 3Universidad Autónoma de Chihuahua, Chihuahua, Mexico. 4Panorama Medical Centre, Cape Town, South Africa. 5Hospital México Americano, Guadalajara, Mexico. 6Randall Children’s Hospital at Legacy Emanuel, Portland, United States of America. 7Janssen Research and Development, LLC, Spring House, United States of America.

Background: Canakinumab is approved for the treatment of systemic juvenile idiopathic arthritis (sJIA) and also has demonstrated efficacy in the treatment of polyarticular juvenile idiopathic arthritis despite methotrexate therapy through 28 weeks of treatment. Methods: A multicenter, Phase 3, single arm, open-label trial was con- ducted using intravenous golimumab at a dose of 80mg/m2 given at weeks 0 & 4, then every 8 weeks thereafter, in pediatric patients ages 2-17 years old with active polyarticular juvenile idiopathic arthritis despite methotrexate therapy. Patients received commercial MTX weekly at same BSA-based dose as at time of study entry. All the results below are based on full analysis set which includes all patients who received at least 1 dose of study agent. Results: 180 patients were screened (130 enrolled, 127 treated) with the first patient screened on 22Dec2014; last patient first treated 26Dec2017, & last patient’s Wk28 visit was 09Jul2018. Proportion of JIA ACR 30,50,70, & 90 responders at Wk28 was 83.5%,79.5%,70.1%, & 46.3%, respectively. 29.1% of patients met criteria for inactive disease at Wk28. Median change from baseline for JADAS 10, 27, & 71 was -14.20, -16.60, & -20.32, respectively at Wk28. JADAS 10, 27, & 71 minimal disease activity was met by 15% of patients at Wk28. Proportion of patients experiencing at least 1 treatment-emergent AE through Wk28 was 77.2%. MedDRA system organ class with highest inci- dence of AEs was Infections & infestations (57.5%); most commonly reported AE upper respiratory tract infection (17.3%); then nasopharyngitis (15.5%). Six patients experienced serious AEs through Wk28: Herpes zos- ter disseminated, Infective exacerbation of bronchiectasis, Sepsi, Var- cella, Mycosis fungoides, & Suicidal ideation. These events resulted in permanent discontinuation of intravenous golimumab, except for Varicella. Conclusion: Intravenous golimumab delivered at a dose of 80mg/m2 at weeks 0 & 4 then every 8 weeks thereafter and appears to be effective in these patients with a safety profile similar to other TNF inhibitor therapies.

Disclosure of Interests: Niccolò Ruperto Grant/research support from: The Gaslini Hospital, where NR works as full-time public employee, has received contributions (> 10,000 USD each) from the following industries in the last 3 years: BMS, Eli-Lilly, GlaxoSmithKline, F Hoffmann-La Roche, Janssen, Novartis, Pfizer, Sanofi. FRID544 EFFICACY AND SAFETY OF CANAKINUMAB IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS—EXPERIENCE USING DATA OF THE BIKER REGISTRY

Gerdt Hornell1, Egbert Lillenthal1, Ralf Trauzeddell2, Toni Hospach1, Tilmann Kalinch1, Frank Dressler2, Michaela Sailler-Hohek3, Gerd Ganser4, Frank-Weiter-Heinemann1, Georg Pala1, Christoph Rietschel1, Markus Huhnagel1, Wolfgang Emminger1, Ariane Klein1, 1BIKER-Registry, Sankt Augustin, Germany. 2Asklepios Clinic Sankt Augustin, General Paediatrics, Sankt Augustin, Germany.

Background: Canakinumab is approved for the treatment of systemic juvenile idiopathic arthritis (sJIA) older than 2 years. Objectives: The aim of the German Biokinetics Registry (BiKeR) is the surveil- lance of JIA patients exposed to biologics. Methods: Baseline demographics and disease activity parameters were documented. Efficacy was determined using the JADAS and the proposed criteria for inactive disease on medication. Safety assessments were based on reports of adverse events (AE). All reports have been coded according to MedDRA. Results: 48 sJIA patients with 82.5 patient-years (PY) of exposure to Canakinumab were recorded in the German BiKeR registry. The total observation time (from date of first dose until last follow-up, censored, if another biologic was started) was calculated with 109.9 PY. The cohort treated with Canakinumab had experienced long disease dura- tion of 2.9±3.8 years (mean ± SD), 21 (44%) were pre-treated with methotrexate, 10 (21%) with Etanercept, 3 (6%) with Adalimumab, 18 (38%) with Anakinra and 19 (40%) with Tocilizumab. Concomitantly, 9 (18.8%) received methotrexate, 22 (45.8%) NSAIDs and 23 (48%) sys- temic corticosteroids. At last follow-up upon treatment, 48.4%/44%/42%/38% of patients reached PsA.CRD30/50/70/90 improvement. 8 patients (16.7%) had inactive disease according to the Wallace criteria. The median (IQR1-IQR3) JADAS10 score decreased from 12.6 (6.2-15.8) at baseline to 5.0 (0.0-2.8). During ongoing treatment, approximately 82% of patients achieved a JADAS defined minimal disease activity; while 64% reached a JADAS defined remission at last follow-up. 125 adverse events (AE) were recorded (114 events/100PY [95% CI 96- 136]). Of these, 22 qualified as serious adverse events (SAE) (20/100PY [13-30]). 100 AEs were observed during exposure or up to 90 days follow- up after the last exposure to Canakinumab (121/100PY [99-147]). 19 qualified as SAE (23/100PY [15-36]). Adverse Events of Special Interest were serious and medically important infection (n=4), cytopenia (n=4), macrophage activation syndrome (n=3). There was no opportunistic infection, intestinal perforation, anaphylaxis or other hypersensitivity, thrombolic event, evolving autoimmune disease, car- diac or cerebral event, bleeding, malignancy, or death. A total of 38 patients (79%) discontinued treatment, 8 (17%) due to lack or efficacy, 16 (33%) due to remission and 2 (4%) because of intolerance. Conclusion: The current analysis adds to the established safety profile of Canakinumab and demonstrates that safety was comparable and consis- tent with the overall AE profile of Canakinumab in paediatric patients. MAS occurred in 3 sJIA patients and might be a JIA-associated fea- ture. Infections were the most frequent AE, but only two serious infec- tions were reported. No new safety signals specific to the paediatric population were identified for Canakinumab; the risk profile of Canakinumab remains positive for the approved paediatric indication sJIA.

HEMODYNAMIC MEASUREMENTS AND ARTERIAL TRAJECTORIES OF DISEASE ACTIVITY OVER THE FIRST THREE YEARS FOLLOWING JUVENILE IDIOPATHIC ARTHRITIS DIAGNOSIS

Stephanie Sloop-Worall, Kimme Hygg, Lucy Wedderburn, Wendy Thomson, Nophar Gelman. The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom; The University of Manchester, Arthritis Research UK Centre for Epidemiology, Manchester, United Kingdom; Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester, United Kingdom; Great Ormond Street Hospital NHS Foundation Trust, Paediatric Rheumatology, London, United Kingdom; NIHR Great Ormond Street Hospital Biomedical Research Centre, London, United Kingdom; The University of Manchester, Arthritis Research UK Centre for Genetics and Genomics, Manchester, United Kingdom; The University of Manchester, The Manchester Molecular Pathology Innovation Centre, Manchester, United Kingdom

Background: The advent of biological therapies and early aggressive treatment strategies have drastically changed prognoses for children and young people (CYP) with juvenile idiopathic arthritis (JIA). Clinical trials and observational research have demonstrated improvements in disease for the majority, but not all, CYP over time. It is not currently known what the patterns of disease activity are in CYP with JIA and how these cluster over time.

Friday, 14 June 2019 967

Results: 63 JIA subjects and 50 healthy controls were included, mean age 11.5 ± 2.8 vs 10.7 ± 3.2 years (p = 0.17) and 70% vs 54% females, respectively. Both groups were also similar (p > 0.05) for nutritional state, sedentary lifestyle, smoking habits and family history of cardiovascular risk. Table 1 show lipid profile of both groups. Subtypes of JIA were: RF positive polyarthritis (29%), RF negative polyarthritis (29%), oligoarthritis (19%), enthesitis-related arthritis (14%) and systemic arthritis (9%). Mean time of disease evolution was 4 ± 3 years. There were no significant differences between groups in the main hemodynamic parameters (table 2). When comparing inactive vs active disease and active disease vs controls there were no differences either, we found a discrete trend to less carotid distensibility and higher cfPWV in patients with active disease compared to controls [0.63 ± 0.17 mm vs 0.66 ± 0.15 mm (p = 0.94) and 6.12 ± 2.86 m/s vs 5.42 ± 0.75 m/s (p = 0.33), respectively]. 59% of subjects with JIA were inactive according to the ILAR classification (9%). Mean time of disease evolution was 4 ± 3 años. There were no differences either, we found a discrete trend to less carotid distensibility and higher cfPWV in patients with 0-4 years than in patients with >4 years of evolution (p = 0.01).

Conclusion: We found a tendency to increased cardiovascular risk when the disease has more than 4 years of evolution, specially in patients with persistent active disease. Traditional and non-traditional cardiovascular risk factors add up in this population. We need longterm follow-up studies.

Objectives: To explore latent patterns of clinical juvenile arthritis disease activity scores (cJADAS) following a diagnosis of JIA.

Methods: CYP with JIA were selected if enrolled in the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort, before January 2015. cJADAS10 scores were calculated based on components (active joint count up to 10, physician global, patient/parent global) collected at diagnosis, six months, one year and then annually to three years. CYP were excluded if no cJADAS10 scores were available within this time frame. Group-based trajectory models were constructed to model latent groups of cJADAS10 scores. Linear, quadratic and cubic polynomials were tested, with one to six trajectories tested within each polynomial group. An optimal model within each polynomial group was selected using Bayesian Information Criteria. The final model was then selected from this shortlist based on model parsimony and clinical plausibility.

Results: Of 1183 CYP selected, the majority were female (65%) and of white ethnicity (90%) with oligoarticular JIA the most common JIA category (45%). The optimal model identified five cJADAS10 quadratic trajectories (Figure 1): Low-low (59%, initial cJADAS10 median: 6.1), moderate-low (16%, initial cJADAS10 median: 11.5) and three groups with high disease activity at initial presentation (initial median cJADAS10: 17.7 to 19.1). A high-low group experienced the greatest improvement (15%, median improvement 17.2 (IQR 13.7 to 20.1)), and a high-moderate group lesser improvement (8%, median improvement 7.3 (IQR 0.8 to 9.0)). A final high-low-high group experienced improvement to one year followed by disease relapse (5%).

Conclusion: Disease activity in CYP with JIA does not improve in a uniform manner following initial presentation to paediatric rheumatology. Five latent trajectory groups have been identified, with three of these displaying different patterns following initial high disease activity at diagnosis. Identifying distinguishing characteristics for each group may aid the stratification of different treatment strategies to facilitate personalised medicine in JIA.

Figure 1. Latent trajectories of cJADAS10 scores in young people with JIA over the first three years following diagnosis

EFFICACY AND SAFETY OF TOCILIZUMAB IN SYSTEMIC AND POLYARTICULAR YOUNG IDIOPATHIC ARTHRITIS – DATA OF THE BIKER REGISTRY

Ariane Klein1, Gerd Ganser2, Ralf Trauzeddel2, Kisten Minden2, Christoph Rietschel3, Jasmin Kuenemerte-Deschner4, Gerd Hornett1. BIKER-Registery, Sankt Augustin, Germany. BIKER-Registry; Sankt Augustin, Germany

Background: Since 2011 Tocilizumab is approved for systemic juvenile idiopathic arthritis (JIA) and since 2013 for polyarticular JIA

Objectives: To describe efficacy and safety of Tocilizumab in clinical practice in polyarticular (pJIA) and systemic JIA (sJIA) patients using the German Biologics registry (BíkerR).

Methods: Baseline demographics and disease activity parameters have been documented. Efficacy was determined using the JADAS10 prospectively. Safety assessments were based on adverse events reports (AE) processed according to MedDRA

Results: Until October 1, 2018, 345 JIA patients treated with Tocilizumab were registered, representing 635 patient-years (PY) of observation. The cohort treated with Tocilizumab had experienced disease duration of 5.5 +/-4.3 years (mean+/-SD) for sJIA and 5.9+/-4.1 years for pJIA. sJIA/pJIA patients received pretreatment with MTX 72%/95%, Enanercept 30%/85%, Canakinumab 2%/0%. Concomitantly, sJIA/pJIA patients received NSAIDs 64%/57%, systemic steroids 72%/35%, MTX 55%/54%, other DMARDs 4%/8%. At last follow-up, 63%/80%/51%/43% of sJIA and 56%/49%/40%/30% of sJIA patients reached JADAS30/50/70/90 criteria. After 2 years of treatment JADAS remission was reached by 50%/43% and JADAS minimal disease activity by 67%/67%.

586 AE were reported during exposure plus 90 days of observation. The rate was significantly higher in sJIA (104/100PY [95% CI 92-119]) than in pJIA patients (79 [79-90]; RR 1.3; p=0.003). 75 qualified as serious AE (SAE) with a higher rate in sJIA (22[16-29]) vs. 8 [5-12]; RR 2.6; p=0.001). The most frequent AE in the sJIA/pJIA cohort were grouped in the MedDRA SOC infections and infestations (n=92/76). Compared to pJIA, rates were significantly higher in sJIA patients for blood and lymphatic (RR 2.4; p=0.019), immune system (RR 2.6; p=0.04), infections & infestations (RR 1.7; p=0.001) and nervous system disorder (RR 2.6; p=0.012) and lower for general and administration site (RR 0.4; p=0.023). 169 patients (49%) discontinued treatment, 17% due to remission, 22% due to lack of efficacy and 9% because of intolerance.

Conclusion: The analysis adds to the established safety profile of tocilizumab in paediatric patients with systemic & polyJIA. Differences were notable between pJIA and sJIA cohorts, the latter with higher rates of total number of adverse events, serious AE, infections and cytopenias, probably due to higher doses or shorter application intervals. No new safety signals specific to the paediatric population were identified in this large cohort of JIA patients.

SARILUMAB, A HUMAN MONOCLONAL ANTIBODY TO THE INTERLEUKIN-6 (IL-6) RECEPTOR, IN POLYARTICULAR-COURSE YOUNG IDIOPATHIC ARTHRITIS (PCJIA): A 12-WEEK MULTINATIONAL OPEN-LABEL DOSE-FINDING STUDY

Fabrizio De Benedetti1, Immaculada Calvo Padare2, Nadina E. Rubio Pérez2, Alexey Maschari3, Pierre Quartier4, Zbigniew Zubér5, Marina Stanislavv6, Raul Bantía7, Daniel Clemente Garuño8, Gabriel Vega Corujo9, Nancy Liu10, Christine Xu11, Angeliki Giannoulou12, Bolariye Akirade12, Lydie Baret-Cormel13, on behalf of DRI13925 investigators. 1Spedale Pediatrico Bambino Gesù, Rome, Italy, 2Instituto de Investigación Sanitaria La Fe, Valencia, Spain, 3University Hospital Dr. José Eleuterio González, Monterrey, Mexico, 4Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, 5Necker Hospital, Paris, France, 6Andrzej Frycz Modrzewski Krakow University, Krakow, Poland, 7IVA Nasonova Research Rheumatology Institute, Moscow, Russian Federation, 8Bioreuma, Concepción, Chile, 9Hospital Infantil Universitario Niño Jesús, Madrid, Spain, 10CREA de Guadalajara, Jalisco, Mexico, 11Sanofi, Bridgewater, NJ, United States of America, 12Regeneron, Tarrytown, NY, United States of America, 13Sanofi, Paris, France

Background: Sarilumab blocks IL-6 from binding to membrane and soluble IL-6 receptor-a. Sarilumab is approved for adults with rheumatoid arthritis (RA) and is being investigated in a Phase 2 trial (NCT02776735)
in 2–17-year-old patients (pts) with pcJIA, comprising rheumatoid-factor (RF)-positive and RF-negative polyarticular and extended oligoarticular JIA.

Objectives: Evaluation of pharmacokinetics (PK), pharmacodynamics (PD), safety, and efficacy of 3 subcutaneous (SC) sarilumab doses in pcJIA.

Methods: A 12-week dose-finding study was performed to identify an appropriate sarilumab dose for use in the pcJIA population. Pts were divided by body weight into 2 groups: A (30–60 kg) and B (10–30 kg), and received sequential ascending doses of sarilumab, Dose 1 (Group A/B): 2.0/2.5 mg/kg qw; Dose 2 (Group A/B): 3/4 mg/kg qw; and Dose 3 (Group A/B): 2.0/2.5 mg/kg qw. Pts were targeted to achieve similar exposure to adult RA doses (150 mg qw2, 200 mg qw2, and 150 mg qw).

Primary outcome was PK; secondary outcomes were safety, PD, and efficacy of sarilumab.

Results: 42 pts enrolled (20/22 in Groups A/B); mean age was 13.0±5.2 years. At baseline, mean pcJIA duration, number of active joints, and JADAS27-CRP were 4.6±1.7 years, 17.2±11.0, and 22.2±19.1, in Groups A/B, respectively. As in adult pts, sarilumab exhibited nonlinear PK with target-mediated drug disposition (TMDD). Following repeated SC administrations, exposure increased in a greater than dose-proportional manner and accumulated 1.9–4.5 fold over 12 weeks. Sarilumab exposure was similar in both weight groups for each dose (Figure), and comparable to corresponding adult doses. Treatment (AE) rates were: for A in Groups 1, 2, and 3, respectively: JADAS27-CRP mean % changes from baseline in Doses 1, 2, and 3 were -74.6%, -87.9%, and -87.9%, respectively.

Conclusion: Sarilumab exhibited nonlinear PK with TMDD. Doses tested in pcJIA yielded similar exposure in both weight groups and were comparable to equivalent doses in adults with RA. All dose regimens proved effective for decreasing disease activity. Safety profile was consistent with class effects; higher incidences of neutropenia were observed with Dose 1 (Group A/B): 2.0/2.5 mg/kg qw; Dose 2 (Group A/B): 3/4 mg/kg qw; and Dose 3 (Group A/B): 2.0/2.5 mg/kg qw. Pts were targeted to achieve similar exposure to adult RA doses (150 mg qw2, 200 mg qw2, and 150 mg qw). Primary outcome was PK; secondary outcomes were safety, PD, and efficacy of sarilumab.
BACKGROUND: Research on Juvenile Idiopathic Arthritis (JIA) should have the primary goal to ultimately improve the lives of the affected patients and help health professionals provide the best care for them. Therefore, these end users of research evidence – patients, carers (parents/caregivers) and clinicians – should be included in the process of identifying research priorities. Importantly, patients and carers can use their unique experiential knowledge from living with the disease to give vital input to researchers in designing a study. Combining this input with the goal of research priorities setting in different regions are needed in order to provide more relevant data on issues that matter most.

METHODS: The method for research priority setting developed by the James Lind Alliance (JLA) is used [3]. This method consists of several steps with the end goal of creating a top 10 list of research priorities agreed on by all parties. First, a steering group with equal representation of patients, parents and clinicians was assembled. We are now in the process of collecting research questions through an online survey. Focus groups are being held to ensure the inclusion of younger patients. Questions will be clustered and checked against the evidence. Next, the process of interim priority setting will follow, in which a shortlist of up to 30 questions will be assembled. During a final workshop in which all parties are equally represented, the top 10 research priorities will be established.

RESULTS: A total of 321 PFAPA, 118 FMF and 45 JIA patients with mean age of 7.23±2.9, 14.7±3.09, 13.5±4.8 years, respectively, were included in the study. A 45% (146/322) of PFAPA, 50% (59/118) of FMF and 58% (23/45) of JIA patients were female. We found quite high sensitivity (90%) of newly proposed PFAPA criteria: 289 out of 321 (90%) patients followed up as PFAPA syndrome fulfilled newly proposed PFAPA criteria, as well. When applied to patients diagnosed with FMF and JIA, 46 out of 118 (39%) FMF and 10 out of 45 (22%) JIA patients also fulfilled newly proposed PFAPA criteria. Specificity of recently proposed PFAPA criteria was found to be 61% and 77%, among FMF and JIA patients, respectively. Positive predictive value was 86% and 97%, negative predictive value was 69% and 50% for FMF and JIA patients, respectively.

CONCLUSION: Recently proposed PFAPA criteria have satisfactory high sensitivity. Specificity of recently proposed criteria is still under expectation in regions endemic for FMF. Multicentric studies with higher patients’ number in different regions are needed in order to provide more relevant data on performance of newly proposed PFAPA criteria.

CANAKINUMAB AS A FIRST-LINE AND SECOND-LINE BIOLOGIC FOR TREATMENT OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN CHILDREN UNDER 4 YEARS OF AGE

Ekaterina Alneyeva1, Tatiana Dvoryakovskyakaya1,2, Ksenia Isaeva1, Rina Denisova1, Margarita Soloshenko1, Anna Fetisova1, Anna Mamutova1, Maria Rudnitskaya1, Dariya Vankova1, Ivan Krulin1, Kristina Chibisova1, Alina Alshevskaya3, Andrey Moskalev3, Ekaterina Alexeeva1,2, Tatyana Dvoryakovskaya1,2, Ksenia Isaeva1

Background: Development of biologics and their launching into clinical practice has yielded significant progress in pediatric rheumatology. Nevertheless, treatment of severe disorders, and systemic JIA in particular, still remains a challenge. JIA often has the early-onset form. If its course is aggressive and persistent, patients exhibit poor response to treatment with first-line biologics. Effectiveness of the second-line and subsequent biologics, as well as the optimal sequence of prescribing drugs belonging to different classes to children younger than 4 years, remains an open question.

Objectives: To compare the efficacy of canakinumab (CAN) in children with sJIA younger than 4 years (in biologic-naïve patients and when prescribed as a second-line biologic).

Methods: The study was conducted as a subanalysis of the prospective cohort study to evaluate the efficacy of biologics in children with sJIA. Comparative analysis involved 17 patients who had initiated CAN treatment at the National Medical Research Center of Children’s Health (Moscow, Russia) when aged < 4 years (9 biologic-naïve patients (the naïve group) and 8 patients switched from tocilizumab therapy (the switched group)). Treatment efficacy was evaluated according to the dynamics of clinical and laboratory signs using the ACRPedri criteria. The Wallace criteria were used to evaluate whether or not remission had been achieved. Treatment safety was evaluated according to the data presented in the Adverse Event Reports.

Results: At baseline, patients had comparable duration and severity of the disease. The biologic proved efficacious already after 4 weeks of treatment. Five (55.6%) patients in the naïve group and 4 (50%) patients in the switched group achieved ACR90 (p=0.999) within one year of treatment. A state of inactive disease according to the Wallace criteria was achieved in one patient in each group, (12.5% and 11.1%, respectively (p=0.999). JADAS-71 decreased significantly from 12.8 (IQR 10.4-16.2) to 4.4 (IQR 2.6-8.0) in the naïve group (p=0.012) and from 11.6 (IQR 8.138) to 2.35 (IQR 1-3.03) in the switched group (p=0.017).

Conclusion: CAN was found to be highly efficacious and have a good safety profile in children younger than 4 years regardless of prior biologic treatment.

DNASE1L3 VARIANT IN HYPOCOMPLEMENTEMIC URTICARIAL VASCULITIS SYNDROME IDENTIFIES A DIFFERENT CLINICAL PHENOTYPE

Marco Ranalli1, Chiara Passarelli2, Virginia Messia2, Manuela Pardeo3, Emanuela Sacco2, Antonella Insalaco2, Marina Vivarello2, Fabrizio De Benedetti3, Claudia Brocaglia4, La Sapienza University of Rome, Pediatric Department, Rome, Italy; 1IRCCS Ospedale Pediatrico Bambino Gesù, Unit of Laboratory of Medical Genetics, Rome, Italy; 2IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy; 3IRCCS Ospedale Pediatrico Bambino Gesù, Division of Nephrology, Rome, Italy

Background: Hypocomplementemic urticarial vasculitis syndrome (HUVS) is a rare disease characterized by persistent urticarial lesions and hypocomplementemia associated with systemic features involving musculoskeletal, pulmonary, renal and gastrointestinal systems. Systemic lupus erythematosus (SLE) develops in >50% of patients with HUVS, although the pathogenesis is unknown.

Objectives: We describe 6 paediatric patients with HUVS, three of whom carry a homozygous variant of DNASE1L3 and present a peculiar clinical phenotype.

Methods: A Targeted Resequencing using a panel including genes known to already be mainly associated to Interferonopathies Lupus-like (DNASE1, DNASE2, DNASE1L3, TREX1) on the Illumina NextSeq® platform was performed. All variants identified were confirmed by Sanger sequencing and, when possible, family members were tested to study the segregation of identified variants. We applied in silico studies only to variants with an allele frequency ≤1%.

Results: All patients described are Caucasian and 3 of them are female. Two patients presented at onset with extended cutaneous manifestation, joint and abdominal involvement with cholecytitis. They did not develop renal or pulmonary involvement. In contrast, the other four patients presented a more severe disease. All of them developed renal involvement (from microhaematuria up to nephrotic syndrome) with renal biopsy showing mesangial glomerulonephritis in three patients and pauci-immune glomerulonephritis (ANCA negative) in one. Moreover, two of them developed also pulmonary vasculitis (Table 1). A homozygous DNASE1L3 variant (c.290_291delCA) was identified in three of these patients. All of them were treated with glucocorticoid and dapsone at onset. Cyclophosphamide, mycophenolate mofetil and azathioprine were used in patients with renal involvement. None of them developed SLE.

Conclusion: HUVS is very rare disease in childhood. Approximately 50% of HUVS patients develop SLE. Genetic susceptibility to SLE is recognized and DNASE1L3-related SLE have been reported. Özçakar et al. have described 5 children from two families with HUVS who carry the same variant on DNASE1L3 that we report here (1). Our patients confirm that variant in DNASE1L3 can cause HUVS and support the hypothesis that this variant is responsible of a more severe phenotype with major organ involvement (renal and pulmonary). Patients with HUVS need to be flagged very strictly for the risk to develop SLE. Presence of variant in DNASE1L3 can identify patients with more severe disease and high risk to develop major organ involvement. These patients need more aggressive and possibly life-long immunosuppressive treatment.

Influence of anti-Tumor Necrosis Factor (TNF) drug immunogenicity on the treatment effectiveness in juvenile idiopathic arthritis (JIA) using serum calprotectin as a disease activity marker. Multicenter study. ITACA study

Immaculada Calvo1,2, Consuelo Modesto3, María Montoro3, Begoña Laiz4, Estibaliz Iglesias5, Estefanía Quesada-Massachs5, B Lopez-Montesinos5, R Bou5, M.I. Gonzalez-Fernández2, J Fonnes1, A Rodriguez2, J.J. Sanchez2, J Calzada4, Tamara Rodriguez4, Mireia Lopez-Corbeto2, Susana Gómez3, Jordi Anton5, 1Hospital Universitario y Politécnico La Fe, Pediatric Rheumatology, Valencia, Spain; 2Hospital Vall d’Hebron, Pediatric Rheumatology, Barcelona, Spain; 3Pfizer, Medical, Alcobendas, Spain; 4Hospital Universitario y Politécnico de La Fe, Valencia, Spain; 5Hospital Sant Joan de Déu, Pediatric Rheumatology, Hospitalalet de Llobregat, Spain

Background: There is a lack of evidence about the loss of efficacy of anti-TNF agents in JIA and its possible relation to the immunogenicity generated. In the last years there has been interest in the role of serum calprotectin in children diseases, including JIA.

Objectives: To assess the immunogenicity and bioavailability of anti-TNF drugs, their relationship with disease activity and the clinical utility of serum calprotectin in monitoring JIA patients.

Methods: This is a 12-month prospective, multicenter, non-interventional, observational study. Patients from 2 to 18 years diagnosed with non-systemic JIA according to ILAR criteria and receiving treatment with IFX, ADA or ETN were included. The patients were evaluated using the CHAQ and the juvenile arthritis disease activity score (JADAS 71) and determination of anti-TNF drug, anti-drug antibody and calprotectin serum levels were performed.

Results: 222 patients were included. At month 12, 181 (81.5%) continued receiving treatment, and 205 (94.5%) had positive serum levels of anti-TNF drug (96.2% of ETN, 93.5% of ADA and 66.7% of IFX) at baseline and at 12 months serum levels were positive in 161 (95.3%) patients (97.5% ETN, 93.2% ADA and 100% IFX). In total, 16 (7.3%) patients presented anti-drug A (1 of 106 anti-ETN, 13 of 109 anti-ADA, 2 of 3 anti-IFX) at baseline and 4 patients (2.4%) (0 of 81 anti-ETN, 4 of 88 anti-ADA, 0 of 1 anti-IFX) at 12 months. Regarding the relationship between anti-TNF levels or anti-drug Abs, disease activity, and functional disability overall, statistically significant differences were not observed between the groups. Patients with high levels of serum calprotectin at the baseline visit (16 of 216) showed higher JADAS-71 score [1.23 (2.06 SD) vs. 2.01 (3.44 SD) and CHAQ [0.11 SD (0.28 SD)] vs. 0.17 (0.40 SD)] compared with normal calprotectin group, although no statistically significant differences were observed (p = 0.066 and p = 0.288) between the groups with a normal and high level of serum calprotectin and the number of patients was small.

Conclusion: The low prevalence of anti-drug Abs observed was in consonance with the high proportion of patients with a positive serum level of anti-TNF drug. These data suggest an appropriate management of the long-term treatment of Spanish JIA patients, who showed a maintained inactive disease/low disease activity state and a very low functional disability state as a consequence of a low immunogenicity and good bioavailability of anti-TNF drugs.

GENETIC SCREENING IN PATIENTS WITH UNDIFFERENTIATED PERIODIC FEVER SYNDROME

Farhat Demir1, Özlem Akgün Doğan2, Yasemin Kendirci2, Kubra Ermis Tekkus3, Sezgin Carbek1, Nuray Aktay Ayaş3, Levent Doğanşar4, Betül Sözeri1. 1University of Health Sciences, Istanbul, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 2University of Health Sciences, Istanbul, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 3University of Health Sciences, Istanbul, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Autoinflammatory diseases (AID) are a group of hereditary diseases characterised by inflammation periods accompanied with clinical findings such as fever, skin rash, lymphadenopathy, abdominal pain, musculoskeletal symptoms, and with sign of inflammation in the blood. Each disease has own typical clinical findings and they are associated with mutations in specific genes such as in MEFV gene in familial Mediterranean fever (FMF), MVK gene in hyperimmunglobulin D syndrome (HIDS), TNFRSF1A gene in tumor necrosis factor-alpha receptor associated periodic fever syndrome (TRAPS) and NLRP3 gene in cryopyrin associated periodic fever syndrome (CAPS) (1,2). Also in some patients with periodic fever syndrome (PFS), clinical signs of these diseases can be seen but no mutation can be detected in the related genes (3,4). There are also patients exhibit the incomplete phenotype of a disease or overlap signs of more than one AID. The diagnosis of these undifferentiated patients have difficult and may not be possible by a single target gene analysis (5). Screening of the periodic fever syndrome (PFS) panel including various AID genes may be beneficial to define the atypical cases. Molecular genetics has an important role for lead to diagnosis in these patients.

Objectives: The aim of this study was to investigate the genotypic diagnosis in patients with non-characteristic PFS findings for any AID.

Methods: This is a prospective study and conducted between June 2016 and December 2016. Next-generation sequencing (NGS) analysis was performed by using “Fever and Autoinflammatory Syndrome panel: Panel by Sophia Genetics” including 8 genes (MEVF, MVK, NLRP3, NLRP12, TNFRSF1A, TNFRSF11A, LTIP2 and PSTPIP1) in 30 patients with undifferentiated PFS. Clinical features and genetic results were evaluated together and final diagnoses were determined.

Results: Thirty patients included in the study did not have typical clinical features for any of the eight monogenic diseases in the PFS panel. In the result of the genetic screening; disease-causing mutation was found in MEFV gene in 12 patient, in NLRP3 gene in four patient, in NLRP12 gene in two patient and in MVK gene in one patient. Also, genetic variants of uncertain significance (VUS) in different genes were shown in five patient. No mutation was detected in remaining six patient. The final diagnosis was made by both phenotypic and genotypic data. 12 patients were diagnosed with FMF, four were FCAS, two were FCAS2, one was TRAPS and one was HIDS. Patients with negative genetic screening or had mutation as VUS, were followed as undifferentiated PFS.

Conclusion: Autoinflammatory diseases may not always be appear with typical clinical findings of related diseases. In such patients, target gene sequencing and detection of underlying disease can be challenging. Our study has shown that the NGS analysis may help to determined the diagnosis in patients with non-characteristic PFS findings for any AID.

NOVEL G-CSF RECEPTOR MUTATION CAUSING NEUTROPAENIA AND AUTO-IMMUNE DISEASE

Mark Friswell1, Sophie Hambleton2, Tina Biss3. 1Great North Children’s Hospital, Paediatric Rheumatology, Newcastle upon Tyne, United Kingdom; 2Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; 3Great North Children’s Hospital, Haematology and Oncology, Newcastle upon Tyne, United Kingdom

Background: Novel G-CSF receptor mutation causing neutropaenia and auto-immune disease:

We present 2 brothers, born to consanguineous (second cousin) parents, with persistent, moderate neutropaenia secondary to a previously undiagnosed mutation in the CSF3R gene.

Objectives: Both brothers had associated autoimmune phenomena – one with poly-arthicular arthritis and the other with kerato-conjunctivitis.

Methods: Patient A is a 13-year old boy who was referred with a history of recurrent knee swelling. His father described that, from an early age, whenever he had a viral illness he developed marked swelling of his knee which settled spontaneously over a few days. In between episodes he remained completely well and fully active. Growth was normal and there was no history of recurrent or unusual infections. U&S & MRI confirmed the presence of large effusions in the knees during these episodes.

On examination A had clinical evidence of synovitis in his right knee which settled spontaneously over 3 weeks. However a few months later his arthritis subsequently extended to involve his other knee, both hips, elbow and shoulder. He was treated with Etanercept with good clinical response.

Patient H is the younger brother of A. He was diagnosed with severe eczema at age 3 which needed treatment with topical steroids & tacrolimus, along with oral montelukast, to control. He subsequently developed vernal kerato-conjunctivitis which required high-dose cyclosporine & steroid eye-drops to control.

Initial Investigations: Both A and H had been noted from an early age to have neutropaenia. This was initially noted during admission for a viral illness but repeat samples over several years showed persistent neutropaenia (Patient A 0.27 – 0.94, patient H 0.9 - 1.1). Patient A also had markedly raised ESR (range 27 – 120mm/hr) noted during episodes of arthritus. All other investigations were reported as normal.

Results: Whole exome sequencing of patient A revealed a novel homozygous single nucleotide variant c.909C>A affecting exon 8 of the CSF3R gene on Chr. 1. This was confirmed by Sanger sequencing, and the same homozygous mutation was found in patient H.

Patient H was noted to have neutropaenia. This was initially noted during admission for a viral illness but repeat samples over several years showed persistent neutropaenia (Patient A 0.27 – 0.94, patient H 0.9 - 1.1). Patient A also had markedly raised ESR (range 27 – 120mm/hr) noted during episodes of arthritus. All other investigations were reported as normal.

Conclusion: G-CSF is a crucial cytokine that induces proliferation, differentiation, & survival of myeloid progenitors. This variant has not, to our knowledge, been previously described. It is compatible with low level neutrophil production, as in our patients, which may be boosted by GM-CSF, but not G-CSF.

Other recessive loss-of-function mutations in CSF3R have been found in patients with severe congenital neutropaenia. These patients are, unsurprisingly, refractory to rhG-CSF treatment.

It is not clear how this mutation is linked to autoimmunity in these 2 boys. Theoretically both G-CSF, which is likely to be circulating in high concentrations, and GM-CSF, which may be increased to stimulate neutrophil production, have been shown to have pro-inflammatory effects, and indeed are potential targets for future treatment modalities in autoimmune diseases.

PREVALENCE OF SUBCLINICAL SACRITISITIS IN YOUNG PATIENTS WITH INFLAMMATORY BOWEL DISEASE REVEALED BY ENTERO-MRI

Teresa Giani1,2, Viola Filistrucchi, Maximo Basile3, Anna Perrone4, Marco Di Maurizio2, Azzurra Bernardino, Sara Renzo5, Paolo Lionetti6, Rolando Cima7. 1Pediatric Rheumatology, Meyer Children’s University Hospital of Florence, Florence, Italy; 2Department of Medical Biotechnology University of Siena, Siena, Italy; 3Pediatric Rheumatology, Meyer Children’s University Hospital of Florence, Florence, Italy; 4Pediatric Radiology, Meyer Children’s University Hospital of Florence, Florence, Italy; 5Pediatric Cardiology, Meyer Children’s University Hospital of Florence, Florence, Italy; 6Pediatric Gastroenterology, Meyer Children’s University Hospital of Florence, Italy; 7Pediatric Gastroenterology, Meyer Children’s University Hospital of Florence, Italy

Background: Sacritisis is one of the extraintestinal manifestations associated with inflammatory bowel disease (IBD), and may be underdiagnosed especially in the pediatric age. MR-enterography (Enteror-MRI) is currently the gold standard imaging technique for the detection of sacritisis.
the imaging gold standard to assess intestinal disease activity and to detect complications in patients with IBD. Only few studies have been conducted on adult patients with IBD in order to define the role of this technique in assessing sacroiliitis, while no data are available on pediatric patients.

Objectives: To study the prevalence of inflammatory sacroiliitis on MRI performed for intestinal investigation in an IBD pediatric population.

Methods: This is a retrospective study conducted on patients suffering from IBD followed in our gastroenterology department between 2010 and 2018 whose enterocol-RM (1.5 or 3 Tesla, Philips depending from year of scanning) were blindly and independently scored by two readers experienced in pediatric musculoskeletal imaging. Each sacroiliac joint was divided into 4 quadrants. Signs of sacroiliitis were identified according to the ASAS criteria, with a particular attention to the presence of bone marrow edema (using T2 weighted sequences with fat suppression), diffusion restriction in DWI sequences (Diffusion Weighted Imaging) or DWIBS (Diffusion Weighted Imaging with Background Suppression) and post-contrastographic uptake in dynamic acquisitions. Demographics, IBD characteristics, clinical, radiological, and laboratory data were recorded and a dedicated Excel database was constructed. Results were elaborated using descriptive statistics.

Results: A total of 34 patients (10 F, 24 M, age at scanning range 5-20 yrs, median 15) were included in the study, for a total of 59 enterocol-MRI evaluated (some patients were subjected to more than one scan). Two out of 34 patients were affected by Ulcerative Colitis, 32 by Crohn disease. Joint examination resulted negative in all patients, and none complained of articular symptoms including back pain. In 5 IBD patients (4 CD, 1 UC) a monolateral slight degree of sacroiliitis (grade 1) was radiologically identified. They were all males, without clinical laboratory-radiologic inflammatory signs of intestinal activity, with the exception of a patient who presented signs of intestinal and sacroiliac inflammation at his first enterocol-MRI, while 18 months later, at his MRI control under pharmacological treatment, signs of sacroiliitis were still present in the absence of intestinal signs of inflammation.

Conclusion: Asymptomatic sacroiliac involvement therefore can be underdiagnosed in these patients. Enterocol-MRI with specific sequences could be a good tool to detect early signs of sacroiliac inflammation.

FRIO559 VALIDATION OF NORDIC JUVENILE IDIOPATHIC ARTHRITIS CLINICAL PREDICTION MODELS IN A CANADIAN COHORT

Andrew Herrey1, Veronika Rydpal2, Martin Rydpal2, Thomas Lough1, Ellen Nordal2, Jaime Guzman2, for the ReACCh-Out Investigators and the Nordic Study Group of Pediatric Rheumatology (NoSPeR). 1Simon Fraser University, Statistics and Actuarial Science, Burnaby, Canada, 2University Hospital of North Norway and The Arctic University of Norway, Department of Pediatrics and Department of Clinical Medicine, Tromso, Norway, 3University of Tromsø – The Arctic University of Norway, Norway, 4Department of mathematics and statistics, Tromsø, Norway, 5RC Children’s Hospital and University of British Columbia, Pediatrics, Vancouver, Canada

Background: Validation of clinical prediction tools for juvenile idiopathic arthritis (JIA) in populations different than those in which they were first developed is essential to understand their applicability across healthcare settings.

Objectives: To determine if clinical prediction tools to predict 1) non-achievement of remission off medication and 2) functional disability, developed in the Nordic cohort can be directly applied to JIA patients in the Canadian Research in Arthritis in Canadian Children emphasizing Outcomes (ReACCh-Out) cohort; and to assess performance of the prediction tools if model parameters are fine-tuned to the Canadian cohort.

Methods: Since the Nordic models were developed to predict outcomes 8 years after disease onset but the follow-up of the ReACCh-Out cohort was shorter, we chose to cross-validate the tools in a subpopulation of 513 subjects at the 3 years follow-up (3.75 years after onset). Attainment of remission off medications was determined by a panel of 3 pediatric rheumatologists as previously described and functional disability was defined as a Childhood Health Assessment Questionnaire Disability Index (CHAQ)=0. Missing data was handled with multiple imputation by chained equations and prediction ability was assessed with c-index and Receiver Operator Characteristic (ROC) curves. The Nordic models were first evaluated exactly as published on the entire Canadian cohort. Then we fine-tuned the model coefficients using repeated runs of cross-validation in the Canadian cohort. This way, fine-tuned models were tested in patients not included in the fine-tuning process while also minimizing the standard error of prediction.

Results: In total, 408 of 506 evaluable patients (81%) were not on remission and 137 of 361 evaluable patients (38%) had functional disability at the 3-year visit. The Nordic model for predicting non-achievement of remission had a c-index of 0.68 (95%CI 0.62-0.74) when directly applied, and a c-index of 0.74 (0.70-0.78) when it was fine-tuned for the Canadian population. The latter values are comparable to those reported in the Nordic cohort (median AUC 0.78, IQR 0.72-0.82). Table 1 shows fine-tuned coefficient values along-side the original values. The Nordic model for predicting functional disability had a c-index of 0.57 (0.50-0.63) when directly applied, and fine-tuning failed to improve its performance, a c-index of 0.53 (0.43-0.63). Figure 1 shows ROC curves for fine-tuned models in the multiple splits.

Conclusion: After fine-tuning of coefficients, the Nordic model for prediction of non-achievement of remission had similar prediction ability in Canadian patients with JIA. We could not confirm the validity of the Nordic model for prediction of functional disability in Canadian patients.

**FRIO560**

**EFFICACY AND SAFETY OF ANAKINRA IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS – DATA OF THE BIKER REGISTRY**

Ariane Klein, Veronika Ntam Atemkeng, Frank Dressler, Ivan fooldevari, Rolf Michael Küster, Tori Hospach, Gerd Ganser, Kirsten Minden, Dirk Foeßl, Frank Weller-Heinemann, Jasmin Kuenmerle-Deschner, Boris Huegel, Christoph Rietschel, Eggert Lillenthal, Gerd Homelf, BIKER-Registry, BIKER-Registry, Sankt Augustin, Germany

**Background:** Anakinra (ANA) is recommended for treatment of systemic juvenile idiopathic arthritis (sJIA) and has recently received EMA approval. Objectives: To describe safety and effectiveness of ANA in clinical practice in sJIA patients documented in the German Biologics registry (BiKeR).

**Methods:** Demographic and clinical parameters of the patients were recorded at BiKeR enrollment, ANA effectiveness was evaluated by half-yearly evaluation of disease activity using JADAS-10. Safety assessments were based on MedDRA-coded adverse events (AE) reports.

**Results:** Until December 1, 2018, 50 sJIA patients treated with ANA were registered, representing 113.4 patient-years (PY) of observation, with 10 patients (20%) receiving ANA for at least 4 years. The cohort treated with ANA had experienced a prior disease duration of 3.5±3.8 years (mean±SD). Most sJIA patients treated with ANA received pretreatment: 35 patients (70%) were pretreated with at least one other biologic, mostly etanercept (n=28), followed by tocilizumab (6) and canakinumab (1). Further pretreatments included methotrexate (MTX, n=35), ciclosporine A (n=13), azathioprine (n=8) and other DMARDs at lower frequency, 39 patients had received corticosteroids. Concomitant treatment consisted of NSAIDs (n=20), systemic steroids (n=35), MTX (n=29) and other DMARDs (n=8). At month 3, JADAS minimal disease activity (MDA)/JADAS remission and inactive disease according to Wallace [1] were observed in 42%/37% and 47%, respectively. After one year of treatment, the rates were 62%/45% and 56%, respectively (Figure 1).

**Conclusion:** The current analysis adds to the established safety profile of Anakinra and demonstrates that in ANA treated patients with sJIA the rate of SAEs was comparable and consistent with the overall AE profile of ANA in pediatric patients. Hospitalisation was the usual reason for classification as serious AE. New safety signals specific to the paediatric population were identified in this large cohort of JIA patients.

**FRIO561**

**COMPARISON OF INITIAL PRESENTATIONS BETWEEN JUVENILE IDIOPATHIC ARTHRITIS CHILDREN WITH SYSTEMIC ONSET WITH NON-BIOLOGIC MONOCYCLIC AND PERSISTENT COURSES**

Mikhail Kostil, Maria Rumiantseva, Eugenia Isupova, Irina Chikova, Margaretta Dubko, Vera Masalova, Ludmila Sniegireva, Tatiana Komishina, Tatiana Likacheva, Ekaterina Gaidar, Andrey Santinov, Olga Kalashnikova, Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation

**Background:** Juvenile idiopathic arthritis with systemic onset (soJIA) may have mononcylic, polycyclic or relapsed course [1]. There were not known soJIA course predictors.

**Objectives:** The aim of our study was to evaluate initial clinical or laboratory features of the patients with soJIA who had mononcylic course without biologics.

**Methods:** In the present study were included data about 130 soJIA patients. After selection we identified a subgroup of the soJIA patients (n=22) who successfully achieved remission without any biologic medication and were stable in the remission off-medication at least two years. The second group consisted of the patients with chronic persistent course (n=83). The remained 25 patients were excluded due to missing data or who did not meet the selection criteria. We evaluated routine clinical (fever, rash, hepatosplenomegaly, serositis, lymphadenopathy, MAS, joint involvement) and laboratory (WBC, PLT, Hb, ferritin, ALS, AST, LDH, GGT, ALP, albumin, Na, triglycerides, ESR, CRP, prothrombin, fibrinogen) soJIA features in the onset of the disease.

**Results:** Patient with mononcylic course have no any differences except the ferritin level: 275 (133; 698) ng/ml vs 950 (150; 3240) ng/ml, (p=0.04), time to achievement remission 17.7 (8.2; 38.0) months vs 60.2 (36.0; 90.0) months (p=0.00002) and rare elbow involvement 4.6% vs 30.9% (p=0.01). The parameters, associated with possible mononcylic course are in the table.

**Conclusion:** Patients with soJIA initially have quite similar clinical presentations independently the further clinical course. The prediction of possible course of soJIA is a difficult problem. Patients with soJIA with monocyclic course were younger and had less impressive laboratory activity. Further investigations required.

**FRIO562**

**CONCENTRATION OF SURVIVIN IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) – DIAGNOSTIC AND PROGNOSTIC VALUE**

Joanna Lipinska1, Joanna Swiadowska-Jaros1, Krystyna Wyka2, Elżbieta Smolewska1, Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Łódź, Poland, 1Medical University of Lodz, Department of Pediatrics, Oncology, Hematology and Diabetology, Łodź, Poland

**Background:** Survivin is an anti-apoptotic protein that has been suggested as a predictive marker of severe course of adult rheumatoid arthritis and could be used for preclinical recognition of rheumatoid process.

**Objectives:** The goal of the study was to evaluate the diagnostic and prognostic value of survivin in Juvenile Idiopathic Arthritis (JIA).

**Disclosures of Interests:** None declared
Methods: Sixty three children with newly diagnosed JIA (46 girls and 17 boys) aged 1.5-17 years and 32 healthy children as a control group appropriately matched in terms of sex and age, hospitalized in the Department of Pediatric Cardiology and Rheumatology, Medical University of Lodz due to functional disorders of the cardiovascular system were included into the study. Concentration of survivin was assessed by an ELISA test in blood and 18 matched synovial fluid samples collected from JIA patients and in sera of children from control group.

Results: Children with JIA were divided according to the subtype of the JIA. In 68.2% of patients oligoarthritis was diagnosed. The disease activity was established on the basis of JADAS-27 criteria, distinguishing three levels of rheumatoid process activity: low, medium and high. The largest group comprised children of low activity (56%). The concentration of survivin was significantly higher in JIA compared to the controls (p=0.00041). Higher concentration of survivin correlated positively with the presence of anti-CCP antibodies (p=0.004) and with higher disease activity (p=0.0014). The higher survivin concentration was found more often in polyarticular and systemic JIA onset. In all synovial fluid samples the concentration of survivin was higher than in matched blood (p=0.0002).

Conclusion: On the basis of the conducted study, it could be concluded that the higher concentration of survivin is being associated to more severe course of the JIA. Determination of survivin may be helpful in the diagnosis of JIA and may be used to identify a group of children with early arthritis and JIA with bad prognosis who should be treated more aggressively early from the disease onset.

FRIO563 A NATIONAL SURVEY ACROSS GENERAL PÆDIATRICIANS REGARDING IMMUNIZATION PRACTICES IN CHILDREN WITH RHEUMATIC DISEASES

Despoina Maritsi1,2, Irene Eleftheriou2, Katerina Markante2, Olga Vougiouka2, Maria Tsidia2, Athens Medical School, National and Kapodistrian University of Athens, Rheumatology Unit, Second Department of Paediatrics, Athens, Greece; 1Athens Medical School, National and Kapodistrian University of Athens, Rheumatology Unit, Second Department of Paediatrics, Athens, Greece

Background: Robust scientific evidence on the safety and efficacy of certain vaccines in patients with rheumatic diseases is available; therefore guidelines regarding immunizations in this vulnerable group of children are published via a variety of official health organizations/societies including the Greek Rheumatology Society. Nonetheless, the uptake of specific immunizations is suboptimal. In Greece, vaccinations are mainly delivered by primary care paediatricians.

Objectives: The purpose of this study was to describe the knowledge, attitude and current practice of General Paediatricians working in primary care regarding vaccination in children with rheumatic diseases on immunosuppressive medication across Greece and to identify barriers and facilitators that could be used to promote uptake.

Methods: This was a cross-sectional survey, conducted with an anonymous questionnaire of 25 items distributed to Paediatricians via an online platform. Data collected included demographics, questions on knowledge, perceptions and opinions as well as advice given to families. Additionally, questions addressed three specific categories: live-vaccines, non-live vaccines and annual influenza vaccine. This study was approved by the “P. & A. Kyriakou” Children’s Hospital Research and Ethics Committee.

Results: Out of 400 questionnaires sent out, 256 were returned. Mean age was 48 years age (±8.2) mean duration of working as a Paediatrician was 15 years (±6.7). 25% of the respondents worked in rural areas and the remaining in urban areas. 67% worked in the private sector. The majority (78%) of doctors felt that vaccination in children with rheumatic diseases is of pivotal importance. 50% gave specific advice on immunisations at initial diagnosis and 25% checked vaccination status at regular intervals. Responders were using a variety of guidelines in order to reach a clinical decision; still 45% were unaware of the existing national guidelines. 50% were hesitant to adhere to the national vaccination scheme without expert input. Reasons were: not convinced from current literature that the vaccine is safe (32%), afraid to cause disease flare (43%), unable to deal with parental concerns/refusal (54%). 12% of responders felt that the rheumatic disease may have been triggered by a vaccine. The majority (95%) were pro annual influenza vaccination, while a minority (15%) was against live vaccines administration even if the patient was not on immunosuppressive treatment. 75% of doctors were keener to administer booster doses rather than primary doses. While 75% of respondents would postpone vaccinations in all cases if disease was active.

Conclusion: Variation in opinion and clinical practice exists. Overall, although Greek Paediatricians are well informed regarding efficacy and side effects of immunizations, there are steps to be made from principle to practice. Further research will allow the development of clear guidelines to aid in the management of increasing numbers of children with rheumatic diseases.

FRIO564 PSTPIP1- ASSOCIATED MYELOID-RELATED PROTEINEMIA INFLAMMATORY SYNDROME/PAMI SYNDROME: CASE REPORT AND REVIEW OF THE LITERATURE

Manel Meibri, Katerina Theodoropoulou, Michael Hofer, Lausanne, Pediatric Rheumatology, Lausanne, Switzerland

Background: PAMI syndrome is a recently described condition, previously known as Hyperzincemia/Hypercalprotectinemia (Hz/Hc) syndrome. It is a very rare auto-inflammatory disorder characterized by a chronic systemic inflammation, cutaneous and osteo-articular manifestations, hepatosplenomegaly, anemia and neutropenia. Increased blood levels of MRP 8/14 (S100A8/A9 or calprotectin) and zinc distinguish this condition. Specific pathogenic mutations in PSTPIP1 gene (p.E250K and p.E257K) were identified as the genetic cause of this condition.

Objectives: Case presentation and review of literature

Case Presentation: We report a case of 13 months age female referred to our unit for recurrent episodes of osteoarthritis. Physical examination showed hepatosplenomegaly. Blood work revealed a systemic inflammation, a microcytic anemia and neutropenia. A complete workup for metabolic disorders, oncologic processes and uncommon infections was negative. Because of history of recurrent osteoarthritis, a whole-body MRI was performed and confirmed a multifocal osteomyelitis. Whole exome sequencing identified the missense p.E250K in the PSTPIP1 gene.

Methods: A literature search on PAMI syndrome was performed until the 15 October 2018. Pubmed was screened using a combination of the following terms: Hyperzinncemia, Hypercalprotectinemia, E250K mutation, PSTPIP1 mutation, PAPA with E250K mutation.

Results: We identified 20 cases of PAMI syndrome in the literature. PAMI syndrome is an early onset inflammatory disease with a median age of 2.4 years. Clinical manifestations include osteo-articular manifestations (80%), skin lesions (45%), hepatosplenicomegaly (68%), lymphadenopathy (42%), growth failure (58%) and hemorrhagic diathesis with recurrent epistaxis and/or haematoma tendency in 5 patients. All cases had relevant abnormalities in hematologic parameters: mild to severe neutropenia and anemia (100%). Thrombocytopenia (42%). Systemic inflammation was confirmed in 94% using the monitoring of CRP, ESR or SAA. Zinc and MRP 8/14 blood concentrations were markedly elevated in all tested patients. Genetic analyses of PSTPIP1 gene revealed the two specific identified mutations (p.E250K and p.E257K) in all patients. Response to the treatment was variable with no consistently effective therapy. Most common therapeutic options were AINS, Corticosteroids (n=9), Anakinra (n=9), Anti-TNF (n=6) and Cyclosporine A (n=4).

Conclusion: PAMI syndrome is a rare auto inflammatory condition which should be considered in patients with undefined systemic inflammation and neutropenia, even without skin or osteo-articular manifestations. Zinc and serum MRP 14/8 measurement may be helpful tools for the diagnostic orientation in these cases.

FRI0566 STUDY ON SERUM DNAASE1 ACTIVITY IN PEDIATRIC ONSET SYSTEMIC LUPUS ERYTHEMATOSUS FROM A TERTIARY CARE CENTRE IN NORTH WEST INDIA

Ramalingeshwara Noolu, Johnson Nameikampam, Deepit Suri, Amit Rawat, Surjil Singh. Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: DNAase is an apoptotic endonuclease responsible for degradation of chromatin released by inappropriately cleared dead cells. DNAase1 activity in systemic lupus erythematosus (SLE) patients is lower than that in inactive disease in studies conducted in adult SLE patients from developed country. There is a paucity of data on DNAase1 activity in paediatric SLE from India.

Objectives: To measure the serum level of DNAase1 in pediatric-onset SLE patients and to correlate the disease activity groups based on Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score and compared the serum DNAase1 level between the two groups.

Methods: A cross-sectional observational study was conducted over a period of 1 year. Thirty-three consecutive children with pediatric-onset SLE were enrolled and divided into active and inactive disease activity groups based on Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score and compared the serum DNAase1 level between the two groups.

Results: Out of 33 children enrolled, 13 (39.3%) had active disease (SLEDAI score ≥ 3) and 20 (60.6%) had inactive disease activity. Mean age at diagnosis was 8.5 years and 10.2 years in active and inactive disease activity groups respectively. There is female preponderance (66.7%) in the enrolled patients. Anti nuclear antibody (ANA) was positive in 90.9% of patients. The most common pattern of ANA was diffuse pattern (48.4%). There is female preponderance (66.7%) in the enrolled patients. Anti nuclear antibody (ANA) was positive in 90.9% of patients. The most common pattern of ANA was diffuse pattern (48.4%). There is female preponderance (66.7%) in the enrolled patients. Anti nuclear antibody (ANA) was positive in 90.9% of patients. The most common pattern of ANA was diffuse pattern (48.4%). There is female preponderance (66.7%) in the enrolled patients. Anti nuclear antibody (ANA) was positive in 90.9% of patients. The most common pattern of ANA was diffuse pattern (48.4%).
inactive group. Antiphospholipid antibody was present in 3 (23.1%) in active disease activity group and 5 (25%) in inactive disease activity group. The mean serum concentrations of DNAase1 were 15.394 ng/ml in active disease group and 15.205 ng/ml in inactive disease group. There was no statistically significant difference in the serum DNAase1 concentrations between the two groups (p=0.943). There was also no significant difference in the mean serum concentration of DNAase1 in patients with or without nephritis (p= 0.080).

Conclusion: The present study could not establish any correlation between serum DNAase1 levels and disease activity in pediatric-onset SLE. There was no association between serum DNAase1 levels and organ involvement such as nephritis in the enrolled patients

FRI0568
ABATACEPT THERAPY EXPERIENCE IN THE CASE SERIES OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED WITH OVERLAP SYNDROME AND/OR SJÖGREN’S SYNDROME
Irina Nikishina, Svetlana Arsenyeva, Olga Kostareva, Maria Kaleda. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation

Background: The choice of Biologics in patients with juvenile idiopathic arthritis (JIA) who have overlap syndrome with juvenile onset of systemic lupus erythematosus (JSLLE), juvenile dermatomyositis (JDM), juvenile systemic sclerosis (JSSc) and juvenile Sjögren’s syndrome (JSS) is difficult. TNF inhibitors are limited in this kind of disorders and abatacept (ABA) seems to be the favorable option for children, but there are not enough studies in pediatric overlap syndrome and JSS.

Objectives: The evaluation of the abatacept therapy in case series of patients with JIA associated with overlap syndrome and/or JSS.

Methods: Patients who fulfilled the criteria for JIA and the criteria of above mentioned rheumatic disorders and received abatacept therapy according to JIA indication in real clinical practice of our rheumatological clinic.

Results: 11 patients included in the retrospective study (6 girls, 3 boys). The average age of patients was 15.1 years (from 7 to 18 years). Mean duration of disease was 5.4 years. 9 patients were RF positive, 4 patients had ACCP. All of the patients had antinuclear antibody (from 1:320 to 1:2560), 3 patients had positive anti-Ro antibody. Sjögren’s syndrome was the most common concomitant autoimmune disorder (n = 1), JIA with psoriatic arthritis or other spondyloarthropathy (n = 2), JSSc (n = 2), JSLLE (n = 1). 7 patients were treated by a low dose of prednisolone (median 5.7 mg/day). All patients received methotrexate in dose 10-15 mg/m2/week. ABA was indicated as first line of biology therapy in 10 patients, in one patient after adalimumab withdrawal due to severe flare. Mean duration of abatacept treatment was 23.7 month (from 6 to 78). The most of the patients (82%) had excellent stable effect of ABA treatment, but two patients needed to be switched to rituximab due to secondary inefficacy. We observed wonderful result of treatment with full remission of arthritis, calcinosis regression and resolving of Sjögren’s syndrome in the boy with overlap syndrome treated by ABA for 78 months. The serconversion from initial levels of RF 32.9 IU/ml (>2N), anti-Ro antibody 1:840, anti-Ro antibody 200 U/ml (>9N) to negative results was registered. The ABA was good tolerated in all patients. In one case it was canceled due to pregnancy.

Conclusion: ABA is efficacy and safety option in patients with pediatric overlap syndrome and JSS. ABA is good alternative to anti-B cell therapy and preferable choice among Biologics in such category of patients.

FRI0568
THE USE OF NEXT GENERATION SEQUENCING PANEL IN UNDIFFERENTIATED AUTOINFLAMMATORY DISEASES IDENTIFY A SEPARATE SUBSET OF COLCHICINE-RESPONSER RECURRENT FEVERS DISTINCT FROM PFAPA SYNDROME
Riccardo Papa1, Marta Rusmini2, Stefano Volpi3, Roberta Caorsi1, Paolo Picc01, Alice Grossi4, Francesco Car0i5, Francesca Bovis2, Valeria Musso1, Laura Obici1, Cinzia Castanza6, Angelo Ravelli7, Marielle E van Gin7, Isabella Ceccherin8i, Marco Gattorno1,1, IRCCS Istituto Giannina Gaslini, Clinica Pediatrica Reumatologia, Genova, Italy; 2IRCCS Istituto Giannina Gaslini, Medical Genetics Unit, Genova, Italy; 3Università degli Studi di Genova, Department of Health Sciences (DIS Sal), Genova, Italy; 4IRCCS Fondazione Poloclinico San Matteo, Aymolidysis Research and Treatment Centre, Biotechnology Research Laboratories, Pavia, Italy; 5ARNAS Cicio Di Cristina Benfratelli, Pediatric Clinic, Pavia, Italy; 6University Medical Center Utrecht, Department of Medical Genetics, Utrecht, Netherlands

Background: The number of monogenic innate immune system disorders classified as systemic autoinflammatory diseases (SAID) has increased during the recent years. However, more than 70% of patients with clinical manifestations of SAID not achieved a molecular diagnosis, thus getting into the so-called undifferentiated or undefined SAID (uSAID).

Objectives: The aim of the present study is to characterize a subgroup of patients with recurrent fever episodes distinct to PFAPA that turned out to be negative to a large 41-gene NGS panel.

Methods: We designed an NGS panel including 41 genes clustered in seven subpanels.

Results: Fifty patients were enrolled in the study. 34 patients (72%) displayed recurrent fever and sixteen presented a chronic inflammatory disease course. A total of 100 gene variants were found (mean 2 per patient; range 0-6). Mutations with a sure or possible diagnostic impact were detected in five patients (10%). Differently from PFAPA syndrome (table), genetically negative patients with recurrent fever episodes presented episodes that lasted on average of six days (P<0.0001), Abdominal pain and limb pain were the most common symptoms. The classic PFAPA triad (pharyngotonsillitis, aphthosis and cervical lymphadenopathy) was less frequently reported (P<0.0001) while skin rash and arthritis were more frequent (P<0.0001). Eighteen patients were exclusively treated with steroid on demand with a high response rate (94%). In 18 patients, colchicine treatment was used with an overall complete or partial response of 78%.

Conclusion: Even with a low molecular diagnostics rate, an NGS-based approach is able to provide a final diagnosis in a proportion of uSAID patients. It also allows the identification of a subgroup of genetically negative patients with recurrent fever responding to steroid on demand and colchicine.

WHAT DOES IT MEAN TO BECOME PREGNANT WITH JUVENILE IDIOPATHIC ARTHRITIS? A MONOCENOTIC EXPERIENCE IN A TERTIARY CENTRE OF MILAN

Irene Pontikaki1, Maria Gerosa2, Lorenzo Maria Argolini3, Carolina Artusi4, Martina Cornalba5, Laura Trespidi6, Pier Luigi Meroni7, ASST Pini – CTO, Unit Of Pediatric Rheumatology-Department Of Rheumatology, Milan, Italy; 2University of Milan, Chair for Rheumatology, Milan, Italy; 3University of Milan, Chair for Rheumatology, Milan, Italy; 4Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Clinica Osteotica L. Mangiagalli, Milan, Italy; 5Istituto Auxologico Italiano, Milan, Italy

Background: During the last seventeen years, biological and non-biological therapies have been used in our center in an open prospective study for the treatment of refractory JIA not only in paediatric age but also in young adults. The availability of more effective drugs for JIA has dramatically increased the number of patients willing to become pregnant. Data regarding the effect of JIA on pregnancy outcome are scant.

Objectives: The study aims to evaluate the capability of JIA patients to become pregnant, the effects of drugs on pregnancy outcome and the impact of gestation on the disease course.

Methods: JIA patients regularly followed up in our Transition Clinic of the Division of Rheumatology, Gaetano Pini Institute of Milan, were enrolled in the study at the presence of pregnancy test. During the whole pregnancy patients underwent monthly clinical examination and obstetric ultrasound. Data regarding disease activity and pregnancy course (fetal morphometric parameters, fetal heart rate, fetal growth, Doppler velocimetry) were collected.

Gestational age, birth weight and APGAR score were also recorded.

Results: 29 pregnancies in 23 women affected by refractory JIA became pregnant during a 17 years follow up. All patients had a long lasting polyarticular disease (median duration of 23 years) not responsive to DMARDs and became pregnant during biologic therapy. Patients were treated with Etanercept (11 patients), Golimumab (4 patients), Rituximab (3 patients), Adalimumab and Certolizumab (2 patients respectively) as monotherapy, and in most of the cases after multiple switches. One woman was treated with Etanercept during the first pregnancy and Adalimumab during her second pregnancy. Three patients decided for an elective termination and 3 experienced an early miscarriage; among 23 pregnancies resulting in live born infants, only 3 had premature births and 1 cleft palate. A pregnancy was complicated by gestosis, two by placental detachment. All the babies were followed up during the 17 years of observation and did not experience any major late complication. Eight patients were subjected to intra-articular infiltrations during pregnancy to switch off the disease. 18 patients resumed therapy shortly after childbirth and only 7 patients decided to breastfeed.

Conclusion: Despite a large amount of studies demonstrating the safety of anti-TNF during pregnancy, data regarding the effects of biologics on pregnancy outcome in JIA are still lacking. The very low number of patients treated with traditional DMARDs achieving low disease activity underline the pivotal role of new biologic drugs in the management of aggressive long standing JIA, to improve the quality of life of these patients, including family planning. In our experience, no greater number of unexpected complications or side effects were observed in JIA patients during pregnancy compared to the other autoimmune diseases. Discontinuation of therapy has increased the risk of flare, requiring local therapy, confirming that EULAR recommendations for the use of biologics during pregnancy can be applied also in JIA.

MEASUREMENT PERFORMANCE OF REDUCED VERSIONS OF MUSCLE STRENGTH TOOLS IN JUVENILE DERMATOMYOSITIS

Silvia Rosina, Giulia Camilla Vanieri, Angela Pistorio, Alessandro Consolaci, Clarissa Pikkington, Susan Mallard, Adele Civo, Elena Taltsami, Jaime de Inocencio, Marija Jelusic, Jelena Vojinovic, Graciela Espada, Balahan Makay, Maria Katiska, Polixeni Pratsidou-Gertsis, Dragana Lazarevic, Anand Prakash Rao, Silvina Rosina

Objectives: To investigate whether reduced versions of the MMT8 and CMAS are equally reliable as the original tools.

Methods: The following 4 reduced instruments were devised: 1) MMT4 (score 0-40); 2) MMT6 (score 0-60), composed of the same items of MMT4 plus biceps brachii and quadriceps; 3) head lift time of CMAS (0-120 seconds or 0-5 points); 4) sum of CMAS head lift time in points and the 6 sit-ups maneuvers of CMAS (score 0-11).

Results: All reduced instruments revealed strong correlations (r > 0.7) with muscle activity VAS and total DAS, moderate correlations (r = 0.4-0.7) with physician’s global VAS, muscle DAS, skin activity VAS, pain VAS, parent’s overall wellbeing VAS, and CK. Correlations with skin DAS and fatigue VAS were low (r < 0.4). Cronbach’s alpha was excellent (0.92-0.95) for all reduced tools for which this property could be assessed. SRM was good-to-moderate (0.60-0.91) for all reduced instruments in patients judged as improved by the physician. All reduced tools discriminated strongly between patients classified in different disease activity states by the physician (p < 0.0001), and between patients whose parents were satisfied or not satisfied with their children’s disease status (p < 0.0001). Overall, the metrologic performance of the reduced instruments was comparable to that of MMT8 and CMAS.

Conclusion: We found that reduced versions of the MMT8 and CMAS have good psychometric properties and perform similarly to the original tools in a population of patients followed in standard clinical care. Our results suggest that these simplified and shortened instruments could serve as surrogate for the complete measures in routine practice, particularly in a busy clinical setting.

COGNITIVE IMPAIRMENT IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: EARLY DETECTION WITH MR SPECTROSCOPY AND ITS ASSOCIATION WITH MOG ANTIBODIES

Husayn Kilic1, Seran Sahin2, Meliya Filiz Toprak3, Gokce Hale Hatay4, Kubra Yilmaz2, Amra Atadzic2, Kenan Barut5, Esin Ozturk Isik6, Erdem Tuzun5, Osman Kizilkili5, Sema Saitli5, Ozgur Kasapcopur5, 1Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Neurology, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Rheumatology, Istanbul, Turkey; 3Bogazici University, Istanbul, Turkey; 4Istanbul University, Aziz Sancar Institute of Experimental Medicine, Neuroscience, Istanbul, Turkey; 5Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Neuroradiology, Istanbul, Turkey; 6Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Pediatric Neurology, Istanbul, Turkey

Background: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease characterized by the presence of various autoantibodies. Unnoticed and progressive cognitive impairment may develop in the course of disease even without overt neuropsychiatric (NP) features. Some authors attributed this mild impairment to the immune-mediated myelinopathy. Evidence exists that myelin oligodendrocyte glycoprotein (MOG) might act as a mediator of interactions between myelin and the immune system.

Objectives: To detect the role of MOG-Ab in neurologic manifestations of childhood-onset SLE (cSLE) and to better delineate the actual grade of cognitive dysfunction in non-NPSLE children.

Methods: MOG-Ab levels were studied in all healthy subjects (n=28) and in all patients with (NPSLE =9) and without (non-NPSLE=36) overt neuropsychiatric manifestations. All of the non-NPSLE group and healthy group underwent brain MR and MRS examination. However, only 20 subjects in each group met the MRS imaging standards for evaluation. In the non-NPSLE group, 29 cSLE patients were further evaluated by neurocognitive tests. Sixteen children with non-NPSLE were assessed by both MRS and neurocognitive tests.

Results: The mean age of the SLE patients at study time was 16.22±3.22 years. MOG-Ab was detected positive neither in cSLE nor in healthy group.

In children with non-NPSLE, verbal IQ ranged from 40 to 108 (mean: 79.06±17.66), performance IQ ranged from 42 to 111 (mean: 92.03±16.28), and full-scale IQ ranged from 40 to 106 (mean: 84.31±16.39). There were 15 patients (51%) in non-NPSLE group with a full-scale IQ under 85. There was no significant difference between the non-NPSLE group and healthy group in all patients with (NPSLE =9) and without (non-NPSLE=36) overt neurologic manifestations. All of the non-NPSLE group and healthy group underwent brain MR and MRS examination. However, only 20 subjects in each group met the MRS imaging standards for evaluation. In the non-NPSLE group, 29 cSLE patients were further evaluated by neurocognitive tests. Sixteen children with non-NPSLE were assessed by both MRS and neurocognitive tests.

Conclusion: More than a half of our patients in non-NPSLE group were found to have a full-scale IQ under 85. Cognitive impairment may develop insidiously in cSLE children even without any overt symptom or sign. There was no association of MOG-Ab with cSLE, whether neuropsychiatric manifestations present or not. A causal relationship between immune-mediated myelinopathy and neuropsychiatric involvement/cognitive impairment could not be suggested, since there has been no patient with positive MOG-Ab and there has been no difference in choline, creatine/creatinine levels in cSLE patients and healthy subjects. Decrease in the NAA/Creatine level of the left frontal white matter in MRS, which is a finding of neuronal loss, may be used as a first sign of cognitive impairment in patients with cSLE.

FR0574  CLINICAL RESPONSE TO HIGH-DOSE INTRAVENOUS METHYLПREDNISOLONE IN CHILDHOOD AUTOIMMUNE UVEITIS: A RETROSPECTIVE ANALYSIS

Anja Schnabel1, Elisabeth Unger1, Normi Bruck1, Annette Holt-Wieden2, Henner Morbach1, Reinhard Bemer1, Anna Leszcynska3, Christian Hedicr1, 
1Technical University of Dresden Carl Gustav Carus, Children's Hospital, Dresden, Germany, 
2University of Würzburg, Children's Hospital, Würzburg, Germany, 
3Technical University of Dresden Carl Gustav Carus, Department of Ophthalmology, Dresden, Germany, 
4Institute of Translational Medicine, University of Liverpool, Department of Women's and Children's Health, Liverpool, United Kingdom

Background: Intracocular inflammation accounts for up to 10-15% of total blindness cases [1]. The incidence of uveitis in children ranges among 4.9/100,000, and a significant number of patients develop chronic courses and irreparable complications [2]. An impressive 74% of children with juvenile idiopathic arthritis (JIA)-associated uveitis are legally blind at diagnosis [3]. This underscores the importance of timely diagnosis and effective anti-inflammatory treatment.

Objectives: To evaluate the clinical response to high-dose intravenous methylprednisolone (IVMP) in children and adolescents with autoimmune uveitis.

Methods: A retrospective chart review was conducted in two tertiary referral centers in Germany (TU Dresden and University of Würzburg) to investigate treatment responses to IVMP (10-30mg/kg/day on three successive days with a total of one to five IVMP at monthly intervals) in children and adolescents (<16 years) with autoimmune uveitis diagnosed between 2003 and 2016. Clinical features of uveitis, disease activity, outcomes, and concomitant anti-inflammatory treatment were documented at treatment initiation, after 3 and 6 months.

Results: Fifty-six patients (93 affected eyes) with a median age of 7.4 (range: 2.5-16.7) years were included. In 29% of patients uveitis was associated with JIA. Uveitis was predominately located in the anterior segment (43%), bilateral (66%) and recurrent (43%). Complications occurred in 77% of patients and included visual loss, synechiae, cataract, and/or retinal lesions. Patients with active uveitis received between 1 and 5 IVMP. Visual acuity improved significantly (0.52±0.33 to 0.69±0.30 at 3 months (p=0.001), 0.78±0.31 to 0.6 ± 0.31 (p=0.001)) independent of the number of IVMP. Furthermore, anterior chamber cells (45% to 18%, p=0.01), synechiae (47% to 32%, p=0.005), keratic precipitates (27% to 18%, p=0.01), papillary edema (30% to 13%, p=0.001) and/or macular edema (15% to 4%, p=0.01) improved 3 months after IVMP. Over all, children treated with 3 or more IVMP (n=27) (as compared to 1 IVMP (n=18)) experienced fewer relapses (Median 1 [0-6] vs 3 [0-13], p=0.186), developed fewer cataracts (7% vs 39%, p=0.02) and less frequently required treatment with biologics (19% vs 39%, p=0.174).

Conclusion: High-dose IVMP induces rapid improvement in children with autoimmune uveitis. Data suggest improved outcomes in children treated with three or more courses of IVMP when compared to one course (without reaching statistical significance). Prospective randomized trials in larger cohorts are required to confirm results.

FR0575  PREVALENCE OF OVERWEIGHT AND OBESITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Meriem Sellami, Alia Fazaaz, Saousen Miladi, Kmar Ouenniche, Leila Souabni, Selma Kassab, Selma Chekili, Leilh Zakraoui, Kawther Ben Adebghari, Ahmed Laatar. Mongi Sihlim Hospital, Rheumatology, Tunis, Tunisia

Background: Children with juvenile idiopathic arthritis (JIA) may have an increased risk for overweight and obesity, which could be an additional risk factor for inflammatory arthritides. The aim of the study was to determine the prevalence of overweight and obesity in children and adolescents with JIA, and to assess the association between overweight and disease parameters in this population.

Objectives: The aims of this study were to determine the prevalence of overweight and obesity in children and adolescents with JIA, and to assess the relationship between overweight and disease parameters in this population.

Methods: We assessed the weight (kg) and height (cm) according to the standard deviation score (SDS) in a cross-sectional study of JIA children. The diagnosis of JIA was based on the International League of Association of Rheumatology (ILAR) criteria. Overweight and obesity were defined by the Body Mass Index (BMI) (weight/height^2) matched on age and sex and in reference to the French curves. Children were classified as obese if their BMI was ≥ 95th percentile, overweight if their BMI was between the 85th and 94th percentile, and healthy weight if their BMI was between the 5th and 84th percentiles. Functional disability was determined by the Childhood Health Assessment Questionnaire (CHAQ).

Results: Fifty-five patients (38 boys and 17 girls) with JIA were enrolled in this study. The median age was 8.5 ± 4.12 years (range 6–14). Thirty-one patients (53%) had persistent oligoarticular JIA, 15 (27%) had polyarticular JIA, 5 patients (9%) had systemic JIA, and 4 (7%) had enthesitis-related arthritis. The median disease duration was 3.2 ± 2.8 years. Twelve patients had active disease at the time of the study with a mean CHAQ 27 of 6.9 ± 2.7. The mean CHAQ was 1.4 ± 0.5. Nine-teen children (52.7%) had received corticosteroids during an average period of 1.7 years [0.6-3] with a mean of 10mg/day of prednisone or equivalent. The mean BMI was 14.56 ± 2.1 kg/m^2. Twenty-two patients (40%) were overweight, 15 (27%) were obese and 18 (33%) have normal weight. Patients with normal weight, overweight and obese represented respectively 60%, 20% and 20% of systemic forms, 53%, 27% and 20% of polyarticular form, 39%, 32% and 29% of persistent oligoarticular forms, and 50%, 25% and 25% of enthesitis-related arthritis forms. Obesity was more frequent in older patients (p=0.021) with significant functional impairment (p=0.001) and with active disease (p=0.001). Only systemic JIA was more likely to be associated with overweight (p=0.031) and obesity (p=0.024). There was no relationship with other subtypes of JIA (p=0.428) or with corticosteroid treatment (p=0.636).

Conclusion: In our study, more than 60% of patients were overweight. Severely functional limitation, systemic JIA, and active disease were the most correlated parameters with obesity. Better management of the activity and functional status of the disease may reduce overweight in children with JIA.

Disclosure of Interests: None declared
Greece, between September 2015 and June 2018 and 42 healthy controls.

Results: Patients with FMF presented similar systolic Blood Pressure (sBP), central Systolic Pressure (cSP) and cf-PWV values to controls, but significantly higher Aix75 values (patients vs. controls, 19.76% and 9.36%), (p<0.05). Only one FMF patient had cf-PWV > 95th percentile. Statistical analysis in FMF patients showed that Aix75 adjusted for age and sex associated with complete response compared to partial response to treatment (B=-17.78 95% CI:31.17-(-4.40), P<0.05) and the presence of M694V.M680I genotype (B=-16.75 95% CI: -33.81-0.30, P<0.05). Cf-PWV presented an inverse relationship with colchicine treatment duration (B=-0.003, 95% CI: (-0.006)-0.00, P<0.05). Cf-PWV values adjusted for age and sBP associated with attacks frequency for <2 months vs. >2 months, B=0.48 95% CI: 0.01-0.96, P<0.05). Addition of colchicine treatment duration to the model, attenuated the association between cf-PWV and attack frequency, supporting the protective role of colchicine.

Conclusion: The normal values of cf-PWV in FMF patients may reflect the compliance to colchicine treatment, that seems to have a protective role against vessel inflammation. However, the increased values of Aix75 need further investigation.

FRIO577 ANTI-PHOSPHOLIPID SYNDROME SECONDARY TO PEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS. EXPERIENCE IN A THIRD-LEVEL HOSPITAL IN MEXICO CITY

Erika Silvientes, Alejandra Ramirez, M. A. Yamazaki-Nakashimada, F. Rivas-Larrauri. Instituto Nacional de Pediatría, Mexico City, Mexico

Background: Antiphospholipid syndrome (APS) is a multisystemic autoimmune disease that is characterized by thromboembolic events, pregnancy morbidity and other manifestations in the presence of elevated titers of antiphospholipid antibodies.(1)

APS can be either primary, occurring as an isolated clinical entity, or secondary to other diseases including infections, malignancy or autoimmunity, the latter associated in particular with systemic lupus erythematosus (SLE). (2)

Patients with SLE can produce a great variety of autoantibodies, including the so called antiphospholipid antibodies (aPLs), such as lupus anticoagulant (LA); anti-cardiolipin antibodies (aCL) or anti-beta2Glycoprotein-1 antibodies (anti-beta2GPI). (2) These aPLs have been described in 20-40% of SLE patients.

Objectives: To report frequency of patients with antiphospholipid syndrome secondary to pediatric systemic lupus erythematosus (pSLE) at National Institute of Pediatrics in Mexico City from 2005-2016. We then identified patients with positive antiphospholipid antibodies (aPLs) and/or clinical manifestation of antiphospholipid syndrome (APS).

Methods: Retrospective study that included all pediatric systemic lupus erythematosus (pSLE) patients diagnosed at National Institute of Pediatrics in Mexico City from 2005 to 2016. We then identified patients with positive antiphospholipid antibodies (aPLs) and/or clinical manifestation of antiphospholipid syndrome (APS). Demographic, clinical and laboratory features were extracted from their clinical records. Study approved by the local Ethics Committee.

Results: Over the 12-year study period, we collected 295 patients with a diagnosis of pediatric systemic lupus erythematosus (pSLE). Eighty patients (27.11%) had at least a positive antiphospholipid antibody (aPL) or a clinical manifestation of antiphospholipid syndrome (APS). Figure 1 shows our study population. Of these 80 patients, 75 (93.75%) had a positive aPL at moment of pSLE. With respect to the remaining 5 cases, 3 of them developed a positive aPL during follow-up, while the remaining 2 cases presented a clinical feature of APS simultaneously to pSLE diagnosis and their serology persisted negative during follow-up.

Twenty (25%) patients had a clinical manifestation associated to APS. Concerning these patients, 11 (55%) patients presented clinical features of APS at time of pSLE diagnosis, 6 (30%) patients developed it during follow-up and the remaining 3 (15%) patients had previous history of a clinical manifestation associated to APS prior to pSLE diagnosis. Nevertheless, 2 of these 20 patients never reported positive antiphospholipid antibodies.

Antiphospholipid antibodies (aPLs) were positive in 27% of cases with psLE. And more than 90% of cases had positive aPLs at moment of pSLE diagnosis, which is why we strongly agree with international recommendations of performing aPLs screening simultaneously to pSLE diagnosis.

LACC1 MUTATION IN THREE SIBLINGS WITH POLYARTHRITIS WITHOUT SYSTEMIC MANIFESTATIONS

Ankita Singh1, Deepali Sunil2, Prince Jacob2, Katta Mohan Girisha3, Ankur Jindal4, Surjit Singh2, 1Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatrics, Allergy Immunology Unit, Chandigarh, India; 2Kasturba Medical College, Manipal, Medical Genetics, Manipal, India; 3Post Graduate Institute of Medical Education and Research, Chandigarh, Advanced Pediatrics Centre, Chandigarh, India

Background: Juvenile idiopathic arthritis (JIA) is a complex group of disorders characterized by wide phenotypic diversity and genetic heterogeneity. It has multifactorial etiology varying among different subtypes. There are emerging reports on new gene loci being identified especially in familes with many affected members (1,2).

Objectives: To report 3 siblings with polyarthritides who were detected to have mutation in Laccase domain containing 1 (LACC1) gene.

Methods: We reviewed case records of 3 siblings with infantile onset polyarthritides and performed whole exome sequencing on their DNA samples for LACC1, MMP2 and WHISP genes.

Results: A non-consanguineous family from north-western part of India reported with 3 daughters having polyarticular joint disease. The chronology of symptoms was similar in all 3 children. Joint symptoms started in later half of infancy with swelling of knee and ankle. This disease was progressive and over the following 2 years there was involvement of spine, sacroiliac joints and in 3 patients (20%) in the “Standard therapy group”. However, the difference is not statistically significant (p = 0.598).

Conclusion: Our study shows that corticosteroid therapy is associated with a faster resolution of Sydenham’s Chorea’s symptoms compared to treatments considered of first line, such as: no therapy, valproate or pimozide.

Disclosure of Interests: Elena Favaretto: None declared, Giulia Gornati: None declared, Gabriele Simonini Grant/research support from: Abbvie, Speakers bureau: Abbvie, Speakers bureau: Abbvie, Serena Pastore: None declared, Rolando Cinaz: None declared, Alberto Tommasini: None declared, Andrea Taddio: None declared

PREDNISONE VERSUS STANDARD THERAPY IN SYDENHAM’S CHOREA: RESULTS FROM A RETROSPECTIVE STUDY

Elena Favaretto1, Giulia Gornati2, Gabriele Simonini3, Serena Pastore4, Rolando Cinaz2, Alberto Tommasini2, Andrea Taddio1-2. 1University of Trieste, Trieste, Italy; 2Mie University School of Medicine, Italy; 3Kasturba Medical College, Manipal, India

Background: Sydenham’s chorea is a major and delayed manifestation of acute rheumatic fever [1] and is considered to be a prototype of an autoimmune disorder triggered by an infectious agent. Aside from conventional symptomatic treatment (carbamazepine, valproate, neuroleptics), the use of steroids has also been advocated, mainly in severe, drug-resistant cases, or if clinically disabling effects develop with first line therapies. However the evidence of corticosteroids efficacy is weak.

Objectives: To describe the efficacy of corticosteroids therapy versus standard therapy in children affected by Sydenham’s Chorea in a cohort of Italian patients with acute rheumatic fever (ARF).

Methods: A retrospective observational study was conducted. The hospital records for all children diagnosed as having ARF between January 2007 and December 2017 in the Pediatric Rheumatology Division of the Meyer Children Hospital (Florence) and IRCCS Burlo Garofolo (Trieste) were reviewed. The diagnosis of ARF was made by pediatric rheumatologists and all the children discharged with a ICD 9 code consistent with ARF were included. For the purpose of the study only patients with Sydenham’s Chorea were enrolled. Files were analyzed for demographic data, clinical and laboratory findings on admission and during the hospital stay and patients with incomplete information were excluded. Time and resolution of choreic symptoms were evaluated in consideration of presence or absence of corticosteroid therapy.

Results: Thirty patients were enrolled; 23 out of 30 (76%) had generalized chorea, 15 (50%) were treated with prednisone (2 mg/kg/day in a single administration per day for 14 days before tapering), 11 (36.6%) were not treated with medications and 4 (13.3%) received pimozide or sodium valproate. We considered together patients who did not receive any specific therapy for chorea and patients who received only symptomatic anti-chorea drugs (pimozide in 3 cases and sodium valproate in 1 case). Therefore we obtained two groups of 15 participants each: “Prednisonone group” and “Standard therapy group”. The time required for clinical improvement in the two groups appeared statistically different (P = 0.002). In “Prednisonone group” the median time for improvement was 4.0 days (interquartile range: 3) whereas in “Standard therapy group” it was 16.0 days (interquartile range: 16). Furthermore, the “Prednisonone group” had a median remission time of 30.0 days (interquartile range: 34) whereas “Standard therapy group” presented a median remission time of 135.0 days (interquartile range: 309 (P < 0.001). At least one episode of relapse occurred in 1 (6.7%) out of 15 patients in the “Prednisonone group” and in 3 patients (20%) in the “Standard therapy group”. However, the difference is not statistically significant (p = 0.25).

Conclusion: Our study shows that corticosteroid therapy is associated with a faster resolution of Sydenham’s Chorea’s symptoms compared to treatments considered of first line, such as: no therapy, valproate or pimozide.

Disclosure of Interests: Elena Favaretto: None declared, Giulia Gornati: None declared, Gabriele Simonini Grant/research support from: Abbvie, Speakers bureau: Abbvie, Speakers bureau: Abbvie, Serena Pastore: None declared, Rolando Cinaz: None declared, Alberto Tommasini: None declared, Andrea Taddio: None declared

ULTRASONOGRAPHY SCORE CORRELATES WITH DISEASE ACTIVITY IN JUVENILE IDIOPATHIC ARTHRITIS – ENTHESIS RELATED ARTHRITIS – A CROSS SECTIONAL OBSERVATIONAL STUDY FROM INDIA

harkrishnanvelayuthanpillai*, Rasini Ranjan Sahoo, Saumya Ranjan Tripathy, Ummila Dhakad, Funeeet Kumar, Apnam Wahlu, Siddharth Kumar Das, King George’s Medical University, Lucknow, India

Background: Enthesis is a distinct clinical hallmark of spondyloarthritis in children and adults. Ultrasonography (US) is a powerful tool to detect enthesitis. There are only a few studies on US detected enthesitis in Juvenile Idiopathic Arthritis - Enthesitis Related Arthritis (JIA-EAR) from India.

Objectives: To assess the presence of clinical and US detected enthesitis in JIA- ERA and to correlate with disease activity.

Methods: 51 consecutive JIA-ERA patients fulfilling the ILAR classification criteria were evaluated clinically and sonographically from October 2016 to September 2017 in a tertiary care centre from Northern India. Enthesitis was clinically assessed using the MASES (Mastricht Ankylosing Spondylitis Enthesis Score). Additionally peripheral enthesal sites of lower limb (insertion of plantar fascia at calcaneal tuberosity, insertion of Achilles at superior pole of calcaneus, quadriceps tendon at superior pole of patella and patellar tendons proximally at inferior pole of patella and distally at anterior tibial tuberosity) were clinically and sonographically assessed for enthesitis. The clinical assessment included JADAS 27 and BASDAI for disease activity and BASFI for function. Ultrasound was performed with a multi-frequency linear-array transducer (8-13MHz) using B-mode settings of dynamic range (40-50dB); GS- frequency (11-13 MHz); GS gain (60 dB). Power Doppler (PD) mode settings used: pulsed repetition frequency (400-800 Hz); PD-gain (highest possible gain with minimum background noise). US parameters (hypo echogenicity, increased thickness of entheses, intratendinous calcification, enthesophyte and erosion(s)) were assessed according to OMERACT 2014 definitions of ultrasonography
findings of enthesitis (1). Each parameter at every site was scored as 1 if present and 0 if absent. Grading of Power Doppler signals was done as per definition by Kiris et al (2); Grade 0-no signal, Grade 1- separate dot signals or short linear signals, Grade 2- vascularity involving less than half of the enthesis, Grade 3-vascularity involving more than half of the enthesis. US enthesis score was calculated by adding 1 point for each positive finding and the grade of PD. PD score was calculated by adding the grade of PD. Presence of clinical and US detected enthesitis was correlated with parameters of disease activity by Spearman’s correlation coefficient.

**Results:** The mean age of patients was 14.3± 3.2 years with mean duration of disease 34.6±4.9 months. Male: Female ratio was 7.5:1. Clinical enthesitis was seen in 36 of the 51 patients (70.5%) while US detected enthesitis in all (p<0.001). The mean JADAS score, BASDAI and BASFI were 17.1±10.2, 4.1 ±2.4 and 37.2±27.2 respectively, indicating active disease. The US enthesis score correlated positively with JADAS (r = 0.3, P<0.03), BASDAI (r = 0.39, P=0.005) and BASFI (r = 0.38, P=0.006). PD score correlated positively with BASFI (r = 0.33, P= 0.02), but did not correlate with JADAS (r = 0.22, P=0.1), BASDAI (r= 0.24, P= 0.08).

**Conclusion:** Ultrasound is more sensitive in detecting enthesitis in JIA-ERA than clinical assessment. The US enthesis score correlated positively with disease activity which has implications for treatment.

**COMPARISON OF CLINICAL CHARACTERISTIC IN ADULTS AND CHILDREN WITH GOUT**

Shaoling Zheng1, Pui.Y Lee2, Shuyang Chen1, Yukai Huang1, Li Tian-Wang1.

1Guangdong Second provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2Boston Children’s Hospital, Division of Allergy, Immunology and Rheumatology, Boston, United States of America

**Background:** The incidence of gout in China is increasing in adults as well as children. The clinical manifestations of juvenile gout are not well described due to the limited number of cases in the past. Delineating the features of adult and juvenile gout may help pediatric providers recognize gout more effectively.

**Objectives:** We aim to describe and compare the clinical characteristic of adults and children with gout.

**Methods:** A total of 51 juvenile gout patients (age ≤ 18 years) and 337 adult gout patients in our hospital from Jan 2016 to Dec 2018 were enrolled in the study. Clinical parameters and laboratory data of the 2 groups were analyzed.

**Results:** The average age of onset in children with gout was 15.0±1.9 years and the youngest patient was 8 years old. Compared to the adult group, juvenile gout patients displayed lower BMI (23.0±3.8 vs. 25.6±3.5 kg/m², P<0.001) but higher serum uric acid levels (9.98±2.65 vs. 8.09 ±2.47 mg/dL, P<0.001). Interestingly, systemic inflammation was less prominent in children compared to adult as illustrated by lower C-reactive protein levels (7.1±13.5 vs. 23.7±40.7 mg/L, P<0.004) and lower erythrocyte sedimentation rate (12.7±12.9 vs. 33.1±34.2 mm/h, P<0.001). Renal function impairment was rare in children compared to adults (serum creatinine 98.73±11.04 vs 120.38±34.58 μmol/L, P<0.001). In terms joint manifestations, juvenile gout was associated with greater finger joint involvement (23.53% vs. 8.82%, P<0.001) and less knee involvement (11.76% vs. 41.84%, P<0.001) compared to adults. Ankle involvement was slightly more common in the pediatric group (49.02% vs. 30.56% in adults, P=0.009) while MTP was similarly affected (50.98% vs. 32.94%, P=0.012). In addition, tophi was found in four cases (7.8%) in the juvenile group compared to 113 cases in adults (33.5%), suggesting that although less common, advanced features of gout can also occur in children.

**Conclusion:** Juvenile gout is associated with higher serum uric acid levels and greater involvement of finger joints. Correlations with BMI and systemic inflammation were less prominent compared to gout in adults. These findings will help clinicians better recognize gout in children.

**NON-INFEKTIOUS UVEITIS AS A MANIFESTATION OF THE IMMUNE RECONSTITUTION INFLAMMATORY SYNDROME IN PATIENTS INFECTED BY HIV**

Ester Carreño, Andrea María Alvear Torres, Neltia Muñoz, Francisco Javier de la Hera Fernandez, Sheila Recuero Diaz, Fredeswinda Romero, Olga Sanchez Pernauta. Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

**Background:** Immune reconstitution inflammatory syndrome (IRIS) is a paradoxical clinical worsening of an already known condition or the new onset of an inflammatory manifestation that is presumably related with the immune reconstitution after starting highly active anti-retroviral therapy (HAART) in patients infected by the human immunodeficiency virus (HIV).

**Objectives:** The aim of this study is to describe the clinical characteristics, presentation and response to immunosuppressive treatment in patients with uveitis secondary to ocular IRIS in our cohort of patients infected by HIV.

**Methods:** Retrospective review of clinical charts of patients diagnosed with HIV and non-infectious uveitis. Data collected included: demographics, anatomic classification of the uveitis, phenotypic diagnosis of the uveitis, other systemic immune-mediated disorders (IMD), time from HIV diagnosis to uveitis, CD4 count, viral load, treatment and complications of treatment and time of follow-up.

**Results:** Nine-teen patients (17 males) were included in the study. The mean age at the time of HIV diagnosis was 35.4±9.6 years. The time lag between HIV diagnosis and the onset of uveitis was 9±8.9 years. Mean CD4 count was 649±292 cells/ml, while the viral load was undetectable in 13 out of 17 cases. In 2 patients, there were a worsening of a previous IMD and in 6 patients another IMD was diagnosed prior to or concurring with the uveitis diagnosis (3 cases of reactive arthritis). The most common anatomic classification of the uveitis was anterior (13 cases). The use of immunosuppressive therapies to control either the uveitis or the additional IMD was necessary in 6 patients (including biologics in 4 cases) during the follow-up. Only one patient had a complication of the immunosuppressive treatment. The mean follow-up was 43.8 months (range: 0.6 -115.7).

**Conclusion:** Non-infectious uveitis could be the first manifestation of immune-mediated systemic disease in patients with well-controlled HIV infection. Immunosuppression appeared to be a safe therapeutic option in our cohort of patients.

NEUROMYELITIS OPTICA OVERLAPS FREQUENTLY WITH SYSTEMIC RHEUMATIC DISEASES IN AFRICAN-AMERICANS: EXPERIENCE AT A LARGE US ACADEMIC MEDICAL CENTER

Michael Belsky1, Hassan Amer2, Sunita Dia2, Christopher Collins1, Konstantinos Loupasakis1,2, MedStar Washington Hospital Center, Department of Neurology, Washington, United States of America; 3Medstar Washington Hospital Center, Internal Medicine, Washington, United States of America

Background: Neuromyelitis optica (NMO) and neuromyelitis optica spectrum disorders (NMOSD) are immune-mediated demyelinating disorders of the central nervous system, primarily characterized by optic neuritis and longitudinal extensive transverse myelitis. Antibodies to aquaporin-4 (AQP4-IgG) are highly specific markers of NMOSD. The coexistence of NMOSD with systemic rheumatologic autoimmune disease has been well documented, especially systemic lupus erythematosus (SLE) and Sjögren syndrome (SS) [1]. Several recent studies have demonstrated that NMOSD may disproportionately affect black patients [2,3].

Objectives: Our objective was to characterize African-Americans diagnosed with NMO at our academic medical center, and identify any associate systemic rheumatologic autoimmune diseases.

Methods: We conducted a retrospective chart review of adult African-American patients diagnosed with NMO at a single academic medical center between 2011 and 2017. The charts reviewed were identified using ICD codes for NMO, transverse myelitis and optic neuritis. The diagnosis of NMO was then confirmed as per the 2015 International Consensus Diagnostic Criteria. The diagnosis of SLE and SS were also confirmed based on existing diagnostic criteria.

Results: Of the 60 charts reviewed, 25 patients (41.7%) met criteria for NMO, and of those, 21 patients (84%) were African-American. Of the 21 African-American NMO patients, 89.5% (n=19) were AQP4-IgG positive, 95.2% were women, and 38.1% had an associated systemic rheumatologic autoimmune disease. In 60% of the NMO patients with SLE, the diagnosis of NMO preceded the SLE diagnosis. Conversely, in 100% of the NMO patients with SS, the diagnosis of NMO either followed, or was made simultaneous to, the SS diagnosis. Notably, 80% of the NMO patients with SS had concurrent neuropsychiatric manifestations, and 78.6% of the African-American patients in whom ANA testing was performed (n=19), with anti-SSA (64.3%, n=14) and anti-SSB (50%, n=11) the next most prevalent autoantibodies. Mean age of NMO onset was 46.7 years (SD 13.6). Transverse myelitis was the most common presenting manifestation (71.4%), followed by optic neuritis (61.9%).

Conclusion: Our population had a higher mean age of onset (46.7 vs 33 years) compared with other cohorts of seropositive NMO African-Americans [2]. Additionally, African-Americans with NMO at our institution had a higher female:male distribution than has been documented[3]. Not surprisingly, SLE was the most common associated systemic rheumatic disease in our cohort, however the frequency of SLE and ANA positivity in our NMO cohort was higher than has been reported (23.8% and 78.6%, respectively) [4]. Additional larger studies are needed to further explore how NMOSD in African-Americans may differ from other populations.

EFFICACY AND SAFETY OF RITUXIMAB FOR INDUCTION OF REMISSION AND MAINTENANCE OF IGG4-RELATED DISEASE: EXPERIENCE FROM AN ITALIAN NATIONAL REFERRAL CENTRE

Corrado Campochiaro, Emanuel Della Torre, Marco Lanziolotta, Enrica Bozzolo, Elena Baldissera, Lorenzo Dagna. San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy

Background: IgG4-related disease (IgG4-RD) is a systemic fibro-inflammatory disease. Treatment is based on corticosteroids (CS) but up to 50% of patients may relapse. Rituximab (RTX) has emerged as an effective treatment option[1].

Objectives: To assess the free relapse rate (FRR) in patients receiving or not maintenance RTX therapy. Secondary outcomes: time to relapse, incidence of adverse events and differences in FRR between Group 2a and 2b patients.

Patient # | Age (years) | Sex | N° of Organs involved | IgG4-RD (% of patients) | PGA | ESR (mm/h) | CRP (mg/L) | lgG4 (mg/L) | Concomitant DMARD therapies | Previous DMARD therapies | Outcomes after RTX induction | Relapses (time to relapse) | N° of RTX infusions | RTX Adverse Events | Follow-up (months)

EFFICACY OF CANAKINUMAB AS FIRST-LINE THERAPY OF ADULT-ONSET STILL’S DISEASE

Giulio Cavalli, Alessandro Tomelleri, Giacomo De Luca, Lorenzo Dagna.

Methods: Data of IgG4-RD patients treated with RTX and followed-up for >18 months were reviewed. Patients were treated with two 1 g RTX doses 15 days apart (standard dose SD) and then divided into: patients receiving RTX in case of relapse (Group 1) and patients receiving maintenance AXT treatment 6 monthly (Group 2). Patients in Group 2 received a first maintenance treatment RTX SD and were then further divided into patients receiving RTX SD (Group 2a) or single 1 g RTX dose (Group 2b).

Results: 14 IgG4-RD patients were included. Median number of organs involved was 3 (IQR = 1–5). Baseline median physician global assessment (PGA) was 70 (50–90), IgG4-RD responder index (IGG4-RD RI) 12 (6–12), Median eosinophil count, CRP, ESR, and serum IgG4 level were 100 cells/μL (50–1,800), 19 mm/h (6–64), 3.7 mg/L (0.1–36) and 3.17 mg/L (470–21,800) respectively. Indications for RTX were: relapse in 10/14 (71%), partial response in 3/14 (21%) and first-line treatment in 1/7 (14%) patient. CR5 were stopped in 5 patients and reduced by month 3 in remaining patients (p < 0.001). Median eosinophil count, CRP and ESR levels did not change significantly. 8 (57.1%), 5 (35.7%) and 1 patient (7%) were on disease remission (DR), complete remission (CR), and partial remission (PR), respectively. Median number of RTX courses was 2 (2–3) in Group 1, 3 (3–7) in Group 2a, and 4 (3–5) in Group 2b. Organ involvement, PGA, IgG4-RD RI, ESR, CRP, and serum IgG4 levels were not significantly different between the 2 Groups at baseline. FRR at 18 months in Group 1 was significantly lower than that in Group 2 (29% vs 100%, p = 0.006). 5 (71%) patients in Group 1 relapsed on average 9 (7–12) months after RTX induction. 2 (14%) patients had hypersensitivity reactions during RTX induction. 6 (43%) patients, 3 in Group 1 and 3 in Group 2, experienced low-grade infections.

Conclusion: RTX is a safe and effective treatment in IgG4-RD. Both SD and single 1 g RTX dose seem effective in maintenance.

FR0586 THE EFFECT OF TOCILIZUMAB IN THE PREVENTION OF FAMILIAL MEDITERRANEAN FEVER ATTACKS

Seda Cokel, Erine Tekgoz, Muhammet Cinar, Sedat Yilmaz. University of Health Sciences, Gulhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

Background: Familial Mediterranean Fever (FMF) is the most frequent hereditary autoinflammatory disease in the worldwide. Colchicine is the mainstay of the treatment that is used for both preventing the attacks and developing amyloidosis. In case of colchicine resistance, which constitutes almost 5% of all patients, there are some alternatives such as anti-TNF agents, IL-6 and IL-1 antagonists. These agents have also been used in patients with established amyloidosis secondary to FMF. Tocilizumab (TCZ), an IL-6 receptor antagonist, although is effective in the treatment of amyloidosis, little known about its effectiveness in the preventing of febrile attacks.

Objectives: In this study, we aimed to find out whether TCZ therapy decrease the frequency of recurrent attacks of FMF or not.

Methods: This retrospective cross-sectional study designed in a tertiary rheumatology clinic between the years 2009 and 2019. A total of 15 patients were given intravenous TCZ at a dose of 8mg/kg/month, to improve amyloidosis associated with FMF. Data of demographic and clinical characteristics of patients were obtained retrospectively from patient files.

Results: Three female and 12 male patients received TCZ for amyloidosis treatment. The mean age of patients was 42.07±14.37 years and disease duration was 25.73±10.86 years. All of the patients had biopsy results providing amyloidosis. According to international severity scoring system for FMF, all of the patients had severe disease. Demographic and clinical data were shown in Table 1. The frequency of attacks was evaluated during TCZ treatment, and it was reported that 1 patient had no response, 6 patients had decreased attack frequency and 8 patients had no attacks. Serious adverse effects were seen in none of the patients.
MEFV: Mediterranea Fever, TCZ: Tocilizumab

Conclusion: Tocilizumab is found to be effective on improvement of amyloidosis. In the current analysis, we found that TCZ also decreases the frequency of recurrent attacks in patients with FMF. Besides, TCZ is well tolerated among the patients. Further and prospective studies with larger sample are needed to support these results.

FRI0588 THE SCALE OF ACTIVITY IN IDIOPATHIC LOBULAR PANNICULITIS
Olya Egorova, Boris Belov, Svetlana Glukhova. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Idiopathic lobular panniculitis (ILP) refers to chronic systemic connective tissue lesions (M 35.6). The disease develops with typical clinical symptoms and is characterized by alternating periods of stable condition (remission) and active manifestations (exacerbations). Assessment of the activity and identification of the disadvantageous predictors is the main task in monitoring patients with ILP; however, the “gold standard” has not been developed yet. Objectives: to create a rating scale for the inflammatory process activity in ILP on the basis of clinical and laboratory parameters

Methods: We examined 67 patients (9 men and 58 women) with the ILP diagnosis verified in the V.A. Nasonova Research Institute of Rheumatology in 2007-2017. The age of patients ranged from 20 to 76 years, the average duration of the disease was 78.91±48.50 months. At the time of treatment at the institute only 16 patients (23.88%) were diagnosed with ILP. All the patients underwent comprehensive clinical examination and laboratory and instrumental examination of biochemical and immunological parameters, radiography or computed tomography (CT) of the chest organs, as well as pathomorphological examination of skin and subcutaneous fat biopsies from the node area.

Results: Analysis of clinical manifestations allowed to identify four forms of ILP: nodular (30 patients), plaque (10), infiltrative (15) and mesenteric (12), which had specific clinical and laboratory features. Based on the obtained data we developed a scale of the ILP activity (SA), which includes a description of the state of the 7 organ systems. The maximum score for individual systems is from 1 to 3 points depending on the number of estimated parameters. The total maximum possible score is 42 points. The score includes all types of damage since the onset of the disease (caused directly by ILP or developed as a result of therapy), while taking into account only signs that persist for 6 months. Score <5 shows inactive disease, 5-10 - low disease activity, 11-20 - moderate activity and >20 - high activity of the disease. Thus, low disease activity is characterized by the predominance in the clinical picture of limited moderately painful indurations in the absence of any significant changes in laboratory tests. At the moderate disease activity, changes in various localization with a predominance of proliferative disorders (common painful compaction of the 1st and/or 3rd stage, moderate area of damage to the trunk and limbs, sublebile temperature, cognitive impairment, mesenteric disorders, etc.) are revealed against the background of less pronounced laboratory tests. ILP with high activity is characterized by the presence of fever and other common signs of the disease, the predominance of the 2nd stage with a pronounced VAS pain intensity of the indentation, the common nature of the defeat of the pancreas, involvement of the lungs, heart and gastrointestinal tract in the pathological process.

Conclusion: In fact, SA is an analysis of the organ damage, assessment of the symptoms severity, and it takes into account the development of exacerbations with the involvement of new organs in the process of the disease. The proposed ILP SA is of practical importance. Further
research and possibly search for new parameters of the ILP activity are needed.

FR0589
IS THERE AN OVERLAP OF ANTINEUTROPHIL CYTOPLASMATIC ANTIBODY-ASSOCIATED VASCULITIDES WITH IGG4-RELATED DISEASE OR NOT?

Abdulkareem Ertugrul, Erdinç Can Bölek, Gözde Kübra Yardımcı, Sule Apras Bilgen, Omer Karadag, Hacettepe University Vascularitis Centre, Ankara, Turkey

Background: Pseudotumor orbita, pachymeningitis, periaortitis could be seen in both ANCA-associated vasculitis and IgG4-RD. Sometimes it may be difficult to differentiate these two entities. The co-occurrence/concurrence of Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) and IgG4-related disease (IgG4-RD) was recently published by a collaborative EUVAS group [1].

Objectives: Firstly, we aimed to investigate ANCA positivity of our IGG4-RD cohort. Secondly, a literature review of co-occurrence/concurrence of AAV and IgG4-RD was done.

Methods: Data of totally 62 patients with IgG4-RD in Hacettepe Vascularitis Center Database was used. Patients were diagnosed with IgG4-RD according to comprehensive diagnostic criteria [2]. Dataset of patients including demographic data, clinical characteristics, and imaging and laboratory findings of IgG4-RD was re-evaluated in terms of AAV and ANCA test.

At next step, we performed a systematic literature review of the PUBMED database covering the time period until April 2018. Relevant publications were searched using the MeSH terms “IgG4-related disease” and “Eosinophilic Granulomatosis with Polyangiitis”, “IgG4-related disease and Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis” and “IgG4-related disease and Granulomatosis with Polyangiitis”.

Results: Totally 29 (46.7%) of our patients had ANCA results. Out of 29 patients 15 (51.7%) were considered as probable, 10 (34.5%) as definite and 4 as possible (13.8%) for IgG4-RD. Three (10.3%) of these patients had ANCA positivity. All of these ANCA titers were in low degree positivity (MPO-ANCA 1/100, MPO-ANCA 1/32 and PR3 ANCA 1/100). These three patients didn’t have any findings of vasculitis and didn’t have granuloma in their biopsy. When we evaluate these three patients with regards to meeting the Ig G4 -RD criteria, 1 was definite, 1 was probable and 1 was possible. In literature review, we found 17 cases that having both features of IgG4-RD and AAV (Table). These cases were re-evaluated according to the ‘Comprehensive Diagnostic Criteria for IgG4-RD’. Diagnoses of IgG4-RD were definite in 11 cases (64.7%), probable in 2 cases (11.8%) and possible in 4 cases (23.5%). ANCA were positive in 15 of 17 patients (88%). ANCA were directed against proteinase 3 (PR3-ANCA) in 6 patients and were directed against myeloperoxidase (MPO-ANCA) in 5 patients. Other four cases had both MPO-ANCA and PR3-ANCA. All PR3-ANCA positive cases have high titers of ANCA, whereas only one MPO-ANCA positive case has low titers of ANCA.

Conclusion: None of our IgG4-RD patients have any overlap with ANCA-associated vasculitis. Only in 3 patients (10.3%), ANCA positivity was detected without any histopathologic evidence. Just two patients of literature review, seemed to be full compatible with both diseases. Even though ANCA-associated vasculitis and IgG4-RD share clinical features, we think this might be as co-occurrence instead of a histopathologic link.

FR0590
UVEITIS SECONDARY TO CHECKPOINT INHIBITORS

JAVIER GARCIA, Eugenio Perez-Blazquez. HOSPITAL 12 DE OCTUBRE, MADRID, Spain

Background: The introduction of immunotherapy (immune checkpoint inhibitors, ICI) has led to a revolution in oncological treatments. The inhibitors of CTLA4 (ipilimumab), of PD1 (pembrolizumab, nivolumab) and of the ligand of PD1 (atezolizumab, avelumab, durvalumab) regulate T activation and its effector function, being effective for the treatment of various types of cancer1. However, this effect leads to a series of immune-mediated adverse events, among which uveitis of autoimmune mechanism have been described in about 1% of treatments2.

Objectives: Methods: descriptive study of retrospective review of the cases of a tertiary hospital with about 1000 treatments between the beginning of 2014 and the end of 2018.

Results: A series of 4 cases of uveitis of autoimmune origin associated with ICI is presented (see table). The series described has characteristics similar to the information previously reported in the literature2, with an incidence of around 0.4%, according to the previously described, with frequencies of ocular toxicity around 1%, being the uveitis is the most frequent form of presentation. The time of presentation of uveitis since the beginning of treatment has been in all cases in the first 6 months. The frequencies of ocular toxicity around 1%, being the uveitis is the most frequent form of presentation. The time of presentation of uveitis since the beginning of treatment has been in all cases in the first 6 months. The frequencies of ocular toxicity around 1%, being the uveitis is the most frequent form of presentation. The time of presentation of uveitis since the beginning of treatment has been in all cases in the first 6 months. The frequencies of ocular toxicity around 1%, being the uveitis is the most frequent form of presentation. The time of presentation of uveitis since the beginning of treatment has been in all cases in the first 6 months. The frequencies of ocular toxicity around 1%, being the uveitis is the most frequent form of presentation. Disclosure of Interests: None declared
Conclusion: Uveitis is an infrequent, although potentially serious, immune-mediated side effect of ICI. Early recognition, discarding other causes of uveitis, particularly the masquerade syndrome, and early intervention are key to a good prognosis. The collaboration between the oncology teams and the ocular inflammation units must be close to establish the correct diagnosis and treatment, as well as to decide individually on the reintroduction or not of the oncological treatment. The implementation of registries on the adverse effects of these drugs can help to dimension the problem more accurately.

FR0591 RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS ASSOCIATED WITH TREATMENT WITH IMMUNE CHECKPOINT INHIBITORS: A CASE SERIES FROM TWO REFERRAL CENTRES
Sebastian C. Rodriguez-García1, David Lobo2, Raul Castellanos-Moreira1, Ana Milena Milán Arciniegas2, Roberto Gumucio1, Ana Laiz2, Virginia Ruiz-Exiqued1, Berta Magallares1, Cesar Díaz-Torné2, Patricia Moya1, Ivan Castellví1, Hector Corominas3, Jose A. Gómez-Puerta1. 1Hospital Clínic de Barcelona, 2Hospital de la Santa Creu i Sant Pau, 3Hospital Clinic de Barcelona, Barcelona, Spain; 1Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain

Background: Immune checkpoint inhibitors (ICI) against CTLA-4 or PD-1/PD-L1 improve the survival of patients with advanced malignancies including melanoma, lung cancer among other tumours. Because of its mechanism of action, ICI are prone to produce different immune-related adverse events (irAEs), including musculo-skeletal manifestations.

Objectives: Our aim was to describe the experience with rheumatic irAEs in two tertiary centres.

Methods: All adult patients referred to the Rheumatology department from 2015 to 2018 because of the onset of musculo-skeletal symptoms following treatment with an ICI were included. Data collected comprised demographic features as well as ICI indication and type, history of rheumatic disease, disease manifestations at irAE onset, laboratory tests, ultrasound findings and treatment. Diagnostic and treatment approach was done according clinical judgment and in a daily clinical practice setting.

Results: 20 patients were included, 50% female, with a mean age of 61.5 years (range 32-83). The indication for ICI was melanoma in 10 cases, lung cancer in 5, urothelial neoplasia in 2 and squamous skin, breast and head and neck cancer in 1 case each. Pembrolizumab was the most used ICI accounting for 9 cases (1 combined with epacadostat), 8 patients were treated with Nivolumab (4 combined with Ipilimumab), 2 wit Atezolizumb (1 combined with Ibatuzumab) and 1 Ipilimumab in monotherapy.

A history of previous rheumatic disease was reported in 8 patients (1 seropositive RA, 1 Spondyloarthritis, 1 SLE, 1 gout, 1 chondrocalcinosis, 1 fibromyalgia, 1 De Quervain tendinitis, 1 hand osteoarthritis) and 1 had psoriasis.

The most frequent irAE presentation was arthritis with 8 cases (40%), arthralgia in 4 cases (20%), 1 case of myalgia, 2 presented PMR-like symptoms, 1 tenosynovitis and 2 paraesthesia (1 with associated dysesthesia).

After assessment, 7 patients were diagnosed as undifferentiated arthritis, 1 leucocytoclastic vasculitis, 1 small-vessel vasculitis, 2 psoriatic-like arthritis, 1 tenosynovitis, 2 PMR and 6 were classified as having non-inflammatory symptoms.

Antibody status was analyzed in 16 patients. Anticytotoxic peptide antibodies, rheumatoid factor and HLA B27 were negative in all cases (except for 1 patient with seropositive RA), ANAs were positive in 4 (including 1 patient with previous SLE) but without any specificities (i.e. ENAs) and ANCA were negative in one case with small-vessel vasculitis. Ultrasound assessment was performed in 6 patients, 3 presented synovial hypertrophy with positive power Doppler (1 with tenosynovitis associated), 1 peritendinous fluid collection, 1 elbow joint effusion and 1 bilateral supraspinatus calcified tendinopathy.

Most patients were treated with glucocorticoids 12 (60%) and NSAID 6 (30%) and only 3 patients had to discontinue ICI treatment due to irAEs.

Conclusion: Our results were in line with previous studies showing that musculo-skeletal irAEs associated to ICI may present as a flare of a previous known rheumatic disease or as a de novo symptom. Most patients presented with asymmetric mono or oligoarthritis having a good response to GC and NSAID without the need of adding DMARD or withdrawal of ICI therapy.

FR0592 CLINICAL CHARACTERISTICS OF OLDER AGE-ONSET BEHÇET SYNDROME PATIENTS
Gül Guzelant Ozkoo1, Yılmaz Ozyazgan2, Cem Mat1, Vedat Hamuryudan1, Hasan Yazıcı1, Emre Seyahi1, 1Istanbul University-Cerrahpasa, Medical Faculty of Cerrahpasa, Dermatology, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Medical Faculty of Cerrahpasa, Ophthalmology, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Medical Faculty of Cerrahpasa, Dermatology, Istanbul, Turkey

Background: The usual onset of Behçet syndrome (BS) is in the 3. decade. Older age-onset defined as fulfilling the ISG criteria after 40 years of age is rare. One study from our center had reported the severity of eye disease was not different between early onset (≤ 24 years) and late onset (> ≥ 25 years) group. (1). While there is ambiguity in the definition of older onset, a few case series (2,3) coming mostly from ophthalmology or dermatology settings describe a similar or less severe clinical picture among late onset patients (pts) compared to early onset.

Objectives: To evaluate clinical characteristics of older onset pts and to compare them with classic onset pts.
Methods: The charts of 3335 BS pts who were registered between 2000 and 2010 were reviewed retrospectively. Pts who fulfilled ISG criteria for BS after 40 years of age were defined as older onset, while those who fulfilled the criteria before 30 as classic onset. For each older onset chart, 2 consecutively registered early onset charts were selected. Only clinical manifestations at presentation were recorded. A clinical activity index (1) was modified and calculated.

Results: There were only 134(70 M/64 F) pts with older onset BS, which gave a prevalence of 4% in the whole cohort. Age of onset was 40-44 years of age in 54 pts, 45-49 years in 47 and 50+ in the remaining 32. As controls 268(163 M/105 F) classic onset pts were selected. Demographic and clinical characteristics among older and classic onset pts are described for males and females separately, in Table. The frequency of skin manifestations, arthritis and eye disease as well as the mean clinical activity scores were significantly higher among male classic onset pts compared to older onset male pts. Interestingly, the frequency of those with positive pathergy test, vascular involvement and severe eye involvement did not seem to be different among older and classic onset male pts. On the other hand, clinical characteristics and total activity scores were similar between older and classic onset groups among females (Table). The main limitation is that the information was based solely on patient's charts and outcome information was not available.

Conclusion: Compared to classic onset pts, males tend to be less frequent in older cohort. At presentation, older onset male pts had significantly less frequent skin, joint, eye disease, and significantly lower total activity scores compared with classic onset pts. There was no difference between the classic and older onset group, among females.

| Table. Clinical characteristics of older age-onset and classical-onset BS pts (Males/ Females) |
|---|---|---|---|---|---|
| Age at ISG criteria fulfilling, yrs | Oral ulcer, n (%) | Genital ulcer, n (%) | Papulo-pustular lesions, n (%) | Nodular lesions, n (%) | Arthritis, n (%) |
| Olders (n=163) | 47.0 ± 6.0 | 24.2 ± 4.5 | 46.6 ± 5.7 | 23.1 ± 4.4 |
| Classical (n=64) | 64 (100) | 60 (96) | 137 (84) | 5.60 ± 3.15 | 13 (21) | 6 (96) | 0.307 |
| P | 0.050 | 0.845 | 0.0001 | 0.006 |
| Olders (n=163) | 61 (99) | 63 (100) | 138 (86) | 51 (80) | 39 (61) | 29 (45) | 41 (64) | 0.710 |
| Classical (n=64) | 105 (100) | 105 (100) | 138 (100) | 90 (96) | 71 (68) | 60 (87) | 42 (65) | 0.142 |

</table>
The most commonly (68.5%) used imaging method for diagnosis was computed tomography (CT). All the patients used initial glucocorticoid treatment. 4 patients (7.5%) received only glucocorticoid, others were under- went the following treatments combined with glucocorticoid: azathioprine (AZA) (60.4%), methotrexate (MTX) (11.3%), rituximab (RTX) + AZA (9.4%), MTX + AZA (5.7%), RTX (3.8%) and infliximab (1.9%).

In the follow-up, a significant decrease in acute phase reactants was found in 62% of the patients at their last visits. While 27.3% of the patients had complete remission, 36.4% had partial remission, 20.5% had stable course, 13.6% had progression in the disease and 2.3% had recurrence. In 16 patients (64.3%) out of 28 patients who were in partial or complete remission, remission was achieved by using glucocorticoid and AZA combination treatment.

Conclusion: In conclusion, we have described a considerably large series of patients with IgG4-related disease from Turkey. The results of the study suggested that AZA and glucocorticoid combination treatment was commonly used in Turkish patients with IgG4-related disease and it might be a good treatment option to achieve remission.

AA AMYLOIDOSIS IN RECIPIENTS OF CADAVERIC DERIVED PITUITARY GROWTH HORMONE – POTENTIAL EFFECT OF AN AMYLOID ENHANCING FACTOR

Helen J. Lachmann1, Nora L. Rowerzeno, Janet A. Gilbertson, Islam Noor, Hadija Trojer, Julian D. Gillmore, Ashutosh D. Wechalekar, Philip N. Hawkins.

Division of Medicine and Royal Free Hospital London NHS Foundation Trust, National Amyloidosis Centre, London, United Kingdom

Background: The development of Creutzfeldt–Jakob disease (CJD) in individuals treated with human cadaveric pituitary-derived growth hormone (c-hGH) was reported in 1985 resulting in its immediate withdrawal(1). Amyloid-β protein (Aβ) deposits have been found at autopsy in individuals previously exposed to c-hGH and misfolded Aβ peptide was recently identified in archived vials of human c-hGH; this induced Aβ pathology in an experimental model(2). The suggestion that contaminants in c-hGH could seed protein misfolding is reminiscent of the concept of amyloid enhancing factor (AEF), in which administration of tiny amounts of amyloidotic material is associated with acceleration of experimentally induced murine AA amyloidosis(3). In humans AA amyloid is a rare complication of chronic inflammation in which the amyloid fibrils are derived from Serum Amyloid A protein (SAA), a circulating component of the acute phase response.

Objectives: To seek evidence of prior exposure to c-hGH in patients with AA amyloidosis.

Methods: A database of 782 patients with AA amyloidosis seen between 1990 & 2017 was searched using: pituitary, craniopharyngioma & growth hormone. Only patients exposed to c-hGH were included. 20 patients eventually required long-term FUP were 100% and 78% respectively. Additionally, juvenile arthritis disease activity score (JADAS)-10 ≤ 1 scores were reported for ANA or CAN, CAN, ETN and TCZ as 52%, 48%-91%, 20% and 36% at short-term FUP. The mean changes in JADAS-71 scores at short-term FUP for ANA and TCZ were 10% and 11% respectively while the corresponding scores at long-term FUP were 13% and 14% (p<0.001).

All interventions were generally well tolerated by SJIA patients; infections, injection site reactions and macrophage activation syndrome were reported for all biologics. Other complications included gastrointestinal disorders, pharyngitis, skin disorders, increase in liver enzymes etc.

Conclusion: The current interventions especially ANA, CAN, ETN and TCZ were found to be effective and generally well tolerated in SJIA. However, the lack of head-to-head studies limits a rigorous comparison.

FR06000 FIRST SINGLE-CENTERED COHORT OF CHINESE PATIENTS WITH PEDIATRIC SAPHO

Yuming Shao1, Chen Li2, Shuang Liu3, Wen Zhang4, 1Peking Union Medical College, Beijing, China; 2Peking Union Medical College Hospital, Traditional Chinese Medicine, Beijing, China; 3Peking Union Medical College, Beijing, China; 4Peking Union Medical College Hospital, Rheumatology, Beijing, China

Background: The SAPHO syndrome (Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis) is an disease entity with chronic inflammatory osteoarticular symptoms and typical dermatological lesions. Pediatric SAPHO is regarded as equivalent of Chronic Recurrent Multifocal Osteomyelitis (CRM0) or Chronic Non-bacterial Osteomyelitis (CNO). There have already been several pediatric SAPHO cohorts about Caucasian populations. No Chinese cohorts have been reported.

Objectives: The aim of this study was to evaluate clinical features and treatment for all pediatric SAPHO patients admitted to Peking Union Medical College Hospital from April 2014 to August 2018 [1].

Methods: We conducted a single-centered non-intervention retrospective study of 24 pediatric SAPHO patients who were diagnosed with Khan’s modified criteria in PUMCH from April 2014 to August 2018 [1]. The demographic (sex, age, onset age, follow-up years), clinical (bone and skin symptoms), laboratory (ESR, CRP, HLA-B27, ANA, IL-6, IL-8, TNF-α), imaging (CT, MRI, bone scintigraphy), histologic (lymphocytic, granulocytic) and treatment (medications and effect) data were collected.

Results: Detailed information of 15 male and 9 female was available. The mean ± SD age at onset of bone and skin symptoms was 11.7 ± 3.8 and 14.4 ± 2.7 years, respectively. The duration of follow-up was 19.2 ± 15.2 months. 17 (71%) patients had skin manifestations (46% Severe Acne, all male; 21% Palmpoplantar Pustulosis, all female; 4% psoriasis), Involvement of bone lesions varied (42% anterior chest wall, 29% mandible, 50% peripheral bones, 21% spinal bones), ESR, CRP, IL-6, IL-8, IL-10 was elevated in 88%, 96%, 50%, 71%, 70% patients, respectively. 11 did bone biopsy (6 dominantly lymphocytic, 3 granulocytic, 2 both). CT, MRI and bone scintigraphy were performed in 79%, 96% patients, respectively. A total of 6 patients have been treated with NSAIDs, 10 with bisphosphonate, 10 with TNF-α antagonist, 1 with Glucocorticoids, with a variable response. 70% patients showed complete remission after bisphosphonate or TNF-α antagonist therapy.
Conclusion: High serum IgG4 was very common in liver diseases without IgG4 related diseases especially in HBV hepatitis. Differential diagnoses should be made in patients with hepatitis accompanied with high serum IgG4.

Conclusion: This is the first Chinese cohort of pediatric SAPHO patients. Their bone lesions could be divided into 4 types, anterior chest wall, mandible, peripheral bones and spinal bones. We also provide evidence that bisphosphonate and TNF-α antagonist are useful for pediatric SAPHO treatment.

FRI0602 SERUM IMMUNOGLOBULIN G4 LEVEL IN INHEPATITIS B WAS HIGHER THAN AUTOIMMUNE LIVER DISEASE IN A CHINESE POPULATION

Zetao Liao, Yanli Zhang. Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: High serum level of Immunoglobulin G4 (IgG4) was detected in autoimmune hepatitis (AIH), but little was known in other types of hepatitis such as hepatitis B, primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC).

Objectives: The aim of this study is to evaluate the level of serum IgG4 in hepatitis B and autoimmune liver disease.

Methods: Hepatitis B and autoimmune liver disease patients were enrolled between January 1st and August 30th 2018. Diagnosis of Hepatitis B, AIH, PBC and PSC was basing on corresponding classification criteria, and established IgG4 related diseases were excluded. The levels of serum IgG4 were determined by nephelometric assay. The cut-off value of serum IgG4 was 2.01 g/L. Serum IgG4 among different liver diseases were compared.

Results: 161 HBV hepatitis and 112 autoimmune liver diseases (52 AIH, 57 PBC, 3 PSC) were enrolled in this study. The HBV hepatitis patients were younger than patients with autoimmune liver disease (44.79±12.56 vs 52.52 ± 11.16 years old). In total, 61 patients (22.34%) had elevated serum IgG4 level. IgG4 level in HBV hepatitis was significantly higher than in AIH, PBC, respectively (1.64±1.80 vs 1.11±1.16, 1.64±1.80 vs 0.96±0.87 g/L, p<0.05).

Conclusion: High serum IgG4 was very common in liver diseases without IgG4 related diseases especially in HBV hepatitis. Differential diagnosis should be made in patients with hepatitis accompanied with high serum IgG4.

Sarcoidosis in a Tertiary Hospital Systemic Sarcoidosis. Study of 381 Patients

Neurological 4(7)

Increased levels of ACE were associated with clinical remission of the S remitted. In 54% of the patients the S had a chronic course and in 14%) or biological treatment (1 patient with Adalimumab and another with Infliximab). In 94% of the patients have been treated with oral glucocorticoids, 52% and biological agents (table 2).

Disclosure of Interests: None declared

FR10603 SARCOIDOSIS IN A TERTIARY HOSPITAL Isabel Madroñal García, Clara Aguilera Cros, Maria Dolores Arcila Duran, Lara Mendez, Maritza Gomez Vargas, Alberto Ruiz Roman, Ricardo Juan Gil Velez, Jose Antonio Rodriguez Portal, Noemí Patricia Garrido Puñal, Esteban Rubio Romero. Hospital Universitario Virgen del Rocio, Reumatología, Sevilla, Spain

Background: Sarcoidosis (S) is a systemic granulomatous disease of unknown etiology. The most frequent affection is pulmonary, ocular and cutaneous, although sarcoidosis can damage other organs, such as the musculoskeletal system.

Objectives: To describe the clinical characteristics and the radiological pattern, in a cohort with predominant pulmonary S, as well as to establish the relationship between the angiotensin converting enzyme (ACE) levels and the S course (chronification or remission).

Methods: This is a retrospective descriptive study of patients treated in our hospital, since 2008 to 2018, with diagnosis of S. The data was obtained through the review of medical records. The delay in the diagnosis of S was defined as the difference in months between the initial diagnostic suspicion and the final diagnosis of S. We use Chi-square tests to study the association between ACE levels and the course of the disease.

Results: Fifty-five patients (31 women) were included, with a mean age of 52 ± 12 years. The first diagnosis was: 85% S, 10% lymphoma and 4% tuberculosis. The median of months for the definitive diagnosis of S was 5.5 months. Extrapulmonary clinical manifestations in table 1. The ACE is increased in 38 patients (70%). Simple x-ray and high resolution tomography of chest were done in all patients. Pulmonary stage 2 was the most frequent (51%), followed by stage 3 (16%), stage 0 (14%) and stage 4 (9%). In 90% of the patients, histological confirmation was obtained by transbronchial (47%), cutaneous (11%) or lymph node biopsy (29%). 94% of the patients have been treated with oral glucocorticoids, 52% associate immunosuppressive therapy (Methotrexate 27% and Azathioprine 14%) or biological treatment (1 patient with Adalimumab and another with Infliximab). In 54% of the patients the S had a chronic course and in 43% S remitted. Increased levels of ACE were associated with clinical remission of the disease and normal levels with chronically (p: 0.013).

Extrathoracic Clinical Manifestations

Conclusion: The results of our study resembles, in general, what has been published in the literature. In our study, elevated ACE is associated with remission of the disease, contrary to the published, in which increased levels of ACE in symptomatic patients may reflect disease activity.

Disclosure of Interests: None declared

FR10604 SYSTEMIC SARCOIDOSIS. STUDY OF 381 PATIENTS FROM A TERTIARY UNIVERSITY HOSPITAL IN THE NORTH OF SPAIN José Luis Martín-Vartaras1, Lara Sánchez Bilbao1, Iñigo González-Mazón1, Raul Fernandez Ramón1, D. Prieto-Peña1, David Martínez-Lopez1, Eva Pería Saiz-Pardo1, Belén Alenaz-Mateo1, Monica Caldentén-Goecke1, Rosalía Demetrio-Pablo1, Vanesa Calvo-Rio1, Miguel A. González-Gay1, Ricardo Blanco1. 1H.U.M. Valdecilla, Rheumatology, Santander, Spain; 2H.U.M. Valdecilla, Ophthalmology, Santander, Spain; 3H.U.M. Valdecilla, Paediatrics, Santander, Spain

Background: Sarcoidosis is a systemic granulomatous disease characterized by the presence of non-necrotizing granulomas in different parenchyma.

Objectives: To describe demographic, clinical and analytical features in a cohort of patients with Sarcoidosis diagnosis from northern Spain during the last twenty years.

Methods: Descriptive study of 381 patients diagnosed with sarcoidosis during the period 01/01/1999 to 01/01/2019. Biopsy and/or clinical and compatible imaging tests were required for the diagnosis of sarcoidosis. Demographic parameters, clinical manifestations, complementary tests and treatment were registered. Results are expressed as mean±SD or as median and interquartile range (IQR) as appropriate.

Results: 381 patients (192 female/191 male, ratio 1:1), with a mean age of 45.5±15.4 years at disease onset, and with 94.8% of Spanish nationality. 33% were smokers at diagnosis and 6.3% had tuberculosis (Table 1). The sarcoidosis incidence rate in our population was 3.3 cases/100000 p/year, similar to other national series. Most frequent clinical manifestations were as follow: pulmonary symptoms (72.3%), general symptoms (37.3%), skin involvement (31%), joint manifestations (27.9%), ophthalmological manifestations (13.0%), digestive disorders (9.3%), neurological symptoms (6.5%), nephrological (4.7%) and cardiological involvement (1.6%) (Table 1). In addition, 11.5% of the patients had a Löfgren syndrome, 0.5% a Heerford syndrome and up to 11.5% had mediastinal adenopathy as an incidental finding in simple chest radiography. A simple chest radiograph was performed in all patients. 83.7% presented abnormal patterns: stage I (41.4%), stage II (32%), stage III (7.6%) and stage IV (3.8%). In addition, 29.9% and 10.5% of patients presented pathological scintigraphy and PET respectively. Biopsy was performed in 81.9%, with a mediastinal approach in 43.3% (Table 2).

After a median follow-up of 11.0 [6.0-17.0] years, we observed that up to 32% of patients never received treatment. In the remaining 68%, the main treatment was oral glucocorticoids with a mean dose of 43.4±19.1 mg/day. Other treatments used were conventional immunosuppressants and biological agents (Table 2).

Conclusions: Results obtained were similar to other national and international series, with the exception of non-predominance of female sex and the highest percentage of ocular involvement in our study. Currently, biological treatment (especially anti-TNF-alpha) is used more frequently.

García-Sánchez Bilbao: None declared, Iñigo González-Mazón: None declared.

Objectives: To describe off-label use, efficacy and tolerance of TCZ use in Internal Medicine Departments.

Methods: This is a retrospective, descriptive and multicenter study from 9 departments of Internal Medicine. Data were reported using a standardized case report file in January 2019.

Results: Fifty one patients were included (19 men, 32 women). Mean age was 55.6 ± 17 years (range 23 - 80). TCZ was used in:
- 12 connective tissue diseases (23.5%): relapsing polychondritis (n=6), systemic sclerosis (n=3), anti-synthetase syndrome (n=1), and unclassified connective tissue disease (n=3).
- 10 vasculitis (19%): Takayasu arteritis (n=7), Cogan disease (n=1), panarteritis nodosa (n=1), unclassified vasculitis (n=2).
- 10 ophthalmologic conditions (19%): non infectious posterior uveitis (n=8), sympathetic ophthalmitis (n=1), Basowd orbitopathy (n=1).
- 8 adult-onset Still’s diseases (16%).
- 5 cases of polyarticular rheumatism (10%).
- 3 miscellaneous diseases (6%): idiopathic AA amyloidosis, multicentric non HHV8 Castelmann disease, Erdheim Chester disease (1 case each).

Mean disease duration was 7.5 ± 6.4 years. In 44 cases (86%) TCZ was administered for refractory disease to corticosteroids and immunosuppressive drugs. Previous therapies included corticosteroids (83%), methotrexate (66%), TNF inhibitor drug (44%), azathioprine (20.8%), mycophenolate (12%), cyclophosphamide (8%), rituximab (10%), hydroxychloroquine (6%), anakinra in 2 patients and interferon, dapsone, etoposide, leflunomide, abatacept, salazopyrin or intra-venous immunoglobulin in 1 patient each.

TCZ was initiated as first-line therapy (15.5%), second-line therapy (17.5%), third-line therapy (31%), fourth-line therapy (19%), fifth-line therapy (14%), sixth-line therapy (12%) or as seventh line therapy in one case. TCZ was associated with methotrexate in 3 cases (6%). Treatment route was intravenous (96%).

At the end of the follow up, 41 patients (80%) were still using TCZ, with a mean follow up period of 22 ± 3 months (range 1-90). In these patients, daily corticosteroid use significantly decrease from 16.5 ± 18 mg to 5.7 ± 13.7 mg (p<0.005, using paired T test). Considering the 28 patients using TCZ since more than 6 months, short term efficacy was 93% (2 cases of loss of efficacy).

TCZ was interrupted in 10 patients (19%), because of treatment failure (n=2), loss of efficacy (n=2) or side effect (n=6). Side effects were infection (2 pneumonias, zonaria, sinus infection), puritus (n=1), urticaria (n=1), dyslipidemia (n=1), high blood pressure (n=2), infusion-related reaction (n=1), bullous dermatitis (n=1), acute renal failure (n=1), angioedema (n=1), mouth ulcers (n=1).

Conclusion: TCZ is used in various autoimmune diseases. TCZ allowed a significant corticosteroids reduction and short term efficacy was 93% in patients using TCZ for more than 6 months. Nevertheless TCZ was interrupted in 19% of the patients. TCZ use will probably be more common in the future to treat refractory autoimmune diseases.

Disclosure of Interests: None declared

variables were collected. Statistical analysis was performed with SPSS.25.

Results: We included 116 patients from which 55% were women, with a mean age at diagnosis of T1D 18.7 (± 12.2) SD years. Average age at autoimmune disease diagnosis was 39.8 (± 12.2) SD years. Average time of evolution between onset of T1D and autoimmune comorbidity was 10.1 (± 10.6) SD years, except one patient with autoimmune thyroiditis 10 years before T1D. Autoimmune manifestations were showed by 19/116 patients (16.4%); with the following diagnoses: autoimmune hypothyroidism: 10 patients (8.6%); autoimmune polyglandular syndrome: 3 patients (2.6%), RA in 2 patients (1.8%). As well, 1 patient with celiac disease, 1 with cutaneous lupus erythematosus (CLE), 1 with psoriasis and another one with IgG4-related orbital inflammatory disease, (0.9% respectively). Three patients developed ocular manifestations (2 rheumatoid polyarthritis and 1 with limited joint mobility or cheiroarthropathy). 4/19 patients (21%) showed cutaneous lesions (2 with vitiligo, 1 CLE and 1 with psoriasis). Hematological alterations type pemphigus amiliar in one patient. No visceral involvement was found. Antibodies were detected to be organ-specific: 7/17 antibodies to thyroid peroxidase (TPO) (+) and 3/17 antibodies to thyroglobulin (+) and one with anti-gludain IgA (+). ANA (+) was detected in four patients (two fine granular pattern, one nucleolar and one homogeneous) with negative specificities and 1 patient RF (+). No Anti-CCP antibodies were detected.

Conclusion: 1) 16% of patients with T1D presented autoimmune comorbidity at 10 years after the onset of endocrinopathy, 2) Autoimmune hypothyroidism was the most prevalent autoimmune manifestation (8.6%), followed by autoimmune polyglandular syndrome and RA, similar to other studies. 3) We highlight the unusual finding of IgG4-related orbital inflammation as comorbidity of T1D. 4) The cutaneous lesions (21%) were the most common clinical manifestation in patients with T1D and autoimmun- ity. We emphasize the absence of visceral involvement.

Background: The European Reference Network on Rare and Complex Connective Tissue and Musculoskeletal Diseases (ERN ReCONNET) is a virtual Network that aims to improve and standardize the quality of care offered to rCTDs patients in Europe, empower patients, share knowledge and expertise, enhance research, support efficient use of resources. ERN ReCONNET covers 10 rCTDs: APS, UCTD, Idiopathic Inflammatory myopathies, IgG4, MCTD, Systemic sclerosis, Relapsing Polychondritis, SLE, SJogren and EDS.

Objectives: Identification of unmet needs in diagnosis, monitoring and management of rCTDs after literature review of existing clinical practice guidelines (CPGs).

Methods: After the review of existing CPGs, the most relevant unmet needs, both for clinicians and patients, were identified by discussion among the members of the network.

Results: A considerable number of unmet needs were identified. In particular, the lack of shared classification criteria, of evidence-based CPGs, validated tools for the assessment of treatment response and disease activity/damage are the major unmet needs especially for the rarest rCTDs. Transversal topics for all rCTDs that need to be addressed are the scarcity of EU/international randomised controlled trials, the identification of patient-reported outcomes and non-adherence to treatment, quality of life indicators, the need to develop composite disease activity scores for all rCTDs and specific (inter)national web-based registries. Patients highlighted the need of a more holistic approach to rCTDs, demanding more attention to pain, fatigue and psychological aspects related to the diseases and the promotion of an early diagnosis.

Conclusion: The identification of rCTDs unmet needs provided a very useful picture on future actions to be undertaken in order to provide a better care to patients. Many activities are ongoing towards these goals in ERN ReCONNET. These will be possible as a result of a EU collaboration among rCTDs stakeholders, the main added value of ERN ReCONNET.

Acknowledgement: Thanks to all ERN ReCONNET Steering Committee, to the EUCORP EuroCare, providers, eFGs and Team for huge support.

ventricular arrhythmias and 1 was found to have incidental abnormal myocardial uptake on PET imaging. 8 of the 9 patients had abnormal myocardial uptake on PET imaging. All but 1 patient had been initially treated with oral steroids (1 refused) and 7 of the 9 patients had also been given oral DMARDs; methotrexate (n=6), azathioprine (n=2), hydroxychloroquine (n=2) and mycophenolate mofetil (n=1). Biologics used were adalimumab (n=5), infliximab (n=3) and rituximab (n=1). The most common indication for biologics was progression of disease despite optimal doses of standard therapy, followed by intolerance or contraindication to standard therapy. 75% of the patients were noted to have marked clinical improvement with the addition of a biologic. 4 out of 9 patients had decreased myocardial uptake on PET following treatment with a biologic. One patient had no change on PET and 4 have not had repeat imaging done yet. None of the patients had worsening of left ventricular systolic function with the addition of a TNF alpha antagonist. There were no reported major infections or significant adverse events that were attributable to the use of biologics.

Conclusion: Based on our small cohort, biologics (mainly TNF alpha antagonists) appear to be safe and efficacious as salvage therapy for cardiac sarcoidosis. However, there is a need for prospective studies to further validate these findings as well as to identify the subset of patients that would benefit from early initiation of these therapies.

FRIO610
CRYOPYRIN-ASSOCIATED PERIODIC SYNDROME: A SERIES OF CASES IN A ADULT PATIENTS’ COHORT WITH AUTOINFLAMMATORY SYNDROME IN A THIRD LEVEL HOSPITAL

Alberto Ruiz Román1, Salvador Garcia Morillo1, Marco Montes Cano2, Clara Aguilera Cres3, Esteban Rubio Romero1, Ricardo Gil Velez1, Hospital Virgen del Rocio, Rheumatology, Seville, Spain; Hospital Virgen del Rocio, Immunology, Seville, Spain

Background: The Cryopyrin-associated Periodic Syndrome (CAPS) or cryopyrinopathies are part of the spectrum of autoinflammatory diseases. The term cryopyrinopathy encompasses three clinical entities such as: CINCA/NOMID (chronic infantile neurologic, cutaneous and articular/neonatal onset multisystem inflammatory disease), Muckle-Wells disease and FCAS (familial cold-associated periodic syndrome). There are three different diseases that would be part of the same clinical spectrum, ranging from CINCA/NOMID (more serious) to FCAS (the less severe). It is more frequent in pediatric age although they can also be observed in adulthood. They are characterized by mutations in the NLRP3 gene and have an autosomal dominant inheritance pattern.

Objectives: To describe the clinical characteristics and genetic variants of a cohort of patients in adulthood diagnosed with cryopyrinopathy and with follow-up in a 3rd level hospital.

Methods: Retrospective descriptive study in adults patients with diagnosis of cryopyrinopathy since 2013 (year of introduction of genetic tests in the hospital laboratory) until now. The data was obtained from the review of medical records. All patients with mutations in NLRP3 gene and clinically compatible with this diagnosis were reviewed.

Results: Of a total of 44 patients in adulthood diagnosed with periodic fever syndromes (FMF, TRAPS, cryopyrinopathies, HIDS) and compatible genetic mutations, 7 patients (15.9%) were diagnosed with cryopyrinopathies, presenting 6 of them (13, 6%) mutations in NLRP3 gene. 1 patient was diagnosed with Muckle Wells based on clinical criteria without genetic test. 6 patients (13.6%) were women. 4 patients (9.1%) presented mutations in heterozygosis in exon 3 of NLRP3 gene (p.(V100M). 1 patient presented heterozygous mutation in exon 3 of NLRP3 gene (p.R260W) and another patient presented a mutation in heterozygosis in exon 3 of the NLRP3 gene (p.S726C). The mean age at diagnosis was 38 years (IQR 13-71 years). The total of patients diagnosed with cryopyrinopathy showed elevation of acute phase reactants. 6 patients (13.6%) presented fever, joint symptoms (arthritis and/or arthralgia) and myalgias. 4 patients (9.09%) showed cutaneous involvement in the form of urticarial rash. 4 patients (9.09%) showed neurosensory deafness since childhood. 3 patients (6.8%) presented ocular involvement in form of conjunctivitis and/or uveitis. In 3 cases (6.8%), anti-IL1 (anakinra) or anti-TNF were used.

Conclusion: Cryopyrinopathies are autoinflammatory diseases that occur mainly in the pediatric age, but there are also cases in adulthood. We must consider its diagnosis in those cases with periodic fever, arthralgia or arthritis, sensorineural deafness, APR elevation and urticarial rash. The genetic diagnosis will help us to confirm the diagnosis and avoid a delay in it. Disclosure of Interests: None declared

Conclusion: In hospitalised patients with new-onset or recurrent pericarditis (secondary or idiopathic) refractory or intolerant to CT, Anakinra is associated with improved symptom relief and decreased recurrence risk. Extended continuation of Anakinra after symptom relief does not reduce post-treatment relapse risk.

FRIO612 IMMUNE-RELATED ADVERSE EVENTS ASSOCIATED WITH IMMUNOTHERAPY. LONG-TERM FOLLOW-UP OF 102 PATIENTS FROM A REFERRAL SINGLE CENTER

Lara Sánchez Bilbao1, Íñigo González-Mazón1, José Luis Martín-Varillas1, Martina Delgado Ruiz1, Isabel Bernat Piña1, Belén Aiterza-Mateo1, D. Prieto-Peña1, Monica Calderón-Goercke1, Almudena García Castaño2, Ricardo Blanco1, Miguel A. González-Gay2,1 Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 2Marqués de Valdecilla University Hospital, Oncology, Santander, Spain

Background: Immune checkpoint blockade therapy (ICBT) has shown remarkable benefit in different cancer types. Blockade of intrinsic down-regulators of immunity increases the activity of the immune system, which can lead to different immune-related adverse events (irAEs). Our aim was to assess the immune-related adverse events in patients who received anti-cytotoxic T-lymphocyte antigen 4 (CTLA-4), anti-programmed cell death 1 (PD-1) or anti-programmed cell death ligand 1 (PD-L1).

Objectives: Our aim was to assess the incidence, treatment and evolution of irAEs due to ICBT.

Methods: We set up an observational study of patients treated with Nivolumab and Pembrolizumab (anti-PD1), Atezolizumab (anti-PD-L1) and Ipilimumab (antiCTLA-4) for solid organ tumors. All these patients were followed in a single reference University Hospital from March-2015 up to December-2018. The main outcome was to determine the incidence of irAEs.

Results: We studied 102 patients (63/39) with a mean age of 60.6 ±9.7 with lung (n=63), melanoma (21), kidney (11), gastric (3), bladder (1), and colon cancer (n=3). Only 7 patients had a previous diagnosis of an immunemediated disease: psoriasis (n=2), psoriatic arthritis (1), systemic lupus erythematosus (1), spondyloarthritis (1), rheumatoid arthritis (1) and skin lupus (1). ICBT was performed as follows: nivolumab (52), pembrolizumab (35), atezolizumab (10) and ipilimumab (5).

After a median of 5 [2.5-10.5] months since the ICBT onset, we observed 87 (85.3%) patients with different irAEs, summarized in TABLE. ICBT discontinuation was required in 39 patients. 36 patients received specific treatment (prednisone, antihistamine, levothyroxine and thiamazol), obtaining a good response in 31 cases (79.5%). ICBT was reintroduced in 28 patients (71.8%) after resolution of the adverse event, with an appropriate tolerance in all cases.

Gastrointestinal irAEs were the most frequent (n=39, 41.1%), with severe manifestations in 4.9% of the patients. Among these 39 patients, only 11 of them required specific treatment, with oral prednisone in all cases. The diagnosis of gastrointestinal irAEs was based on the clinical manifestations and the laboratory tests. The cutaneous most frequent irAE was rash (n=7, 6.8%), followed by vitiligo (n=2, 1.9%). 15 patients developed a rheumatological irAE (14 arthralgias/arthritis and 1 aortitis).

Patients who developed any type of irAE had a better answer to ICBT (70.1%) than those who did not (20%).

Conclusion: In our study, the majority of autoimmune side effects due to ICBT were gastrointestinal, thyroiditis and rheumatological. The develop of any irAE could be an indicator of good response to ICBT.

Disclosure of Interests: Lara Sánchez Bilbao: None declared, José Luis Martín-Varillas: None declared, Marina Delgado Ruı́z: None declared, Isabel Bernat Piña: None declared, Belén Aiterza-Mateo: None declared, Monica Calderón-Goercke: None declared, Almudena García Castaño: None declared, Ricardo Blanco: Consultant for: Abbvie, MSD, and Roche, Consultant for: Abbvie, Pfizer, Roche, Bristol-Myers, Janssen, Speakers bureau: Abbvie, Pfizer, Roche, Bristol-Myers, Janssen, Miguel A. González-Gay Grant/research support from: Prof. MA Gonzalez-Gay received grants/research support from: Abbvie, MSD, Janssen and Roche., Speakers bureau: Consultation fees/participation in company sponsored speaker’s bureau from Pfizer, Lilly, Sobi, Celgene, Novartis, Roche and Sanofi.

Background: Recently the term 'interstitial pneumonia with autoimmune features' (IPAF) has been proposed to identify patients with interstitial lung disease and autoimmune characteristics, not fulfilling the criteria for specific connective tissue diseases (CTD). Until now, only few data are available about the clinical and serological features of IPAF patients, their survival and the possible evolution in a CTD.

Objectives: Aim of the study was to investigate the therapeutic choices in IPAF patients, their efficacy and safety.

Methods: Fifty-two patients (mean age at diagnosis 65.5±11.0 years, female/male ratio 29/23) were consecutively enrolled and prospectively followed for 45±31.6 months.

Data about therapies, disease onset, serological, clinical and therapeutic features, pulmonary function tests and high-resolution computed tomography were periodically repeated. A worsening of lung function was defined as a reduction of 10% compared to baseline of forced vital capacity (FVC) and diffusion lung capacity of CO (DLCO).

Results: An immunosuppressive therapy was prescribed in 15 patients (namely cyclophosphamide in 4, mycophenolate mofetil in 6 and azathioprine in 6, respectively), while 6 patients were treated with anti-fibrotic therapies (pantoprozol or nintedanib). Thirty-three patients took corticosteroids, associated to other drugs in 18 patients, and alone in 15. Finally, no therapies were prescribed in 16 patients. At the end of follow-up FVC remained stable in 35% of patients, worsened in 50% and increased in 15%; DLCO remained stable in 25.8% of patients, worsened in 58.1% and increased in 16.1%.

Mean survival was 94±8.5 months, and no differences were recorded according to the kind of therapy, while survival was significantly associated to the lung function at baseline (FVC and DLCO were confirmed to be significantly associated to death at multivariate analysis).

The treatment was generally well tolerated. In 7/15 patients treated with immunosuppressive therapy was recorded at least an adverse event, responsible for the treatment discontinuation only in 3 patients.

Conclusion: The therapeutic strategy in IPAF patients reflects the ethiopathogenicity of the disease. Waiting for specific trials in this population, therapeutic strategies in IPAF patients need to be carefully tailored for each patient according to both clinical and laboratory features, pulmonary function tests and high-resolution computed tomography.

EVALUATION OF COMPLIANCE AND RELATED FACTORS IN COLCHICINE TREATMENT IN FAMILIAL MEDITERRANEAN FEVER PATIENTS

Errne Tekgoz1, Seda Colak3, Fatma Ilknur Cinar2, Sedat Yilmaz1, Muhammet Cinar1, 1University of Health Sciences, Gulhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2University of Health Sciences, Gulhane Faculty of Nursing, Department of Internal Medicine Nursing, Ankara, Turkey

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease requiring long-term treatment. Increasing the compatibility with colchicine treatment in patients with FMF is the first step for preventing amyloidosis. Patients' beliefs about medicines and treatment may affect treatment adherence and treatment success.

Objectives: The aim of this study was to determine adherence to colchicine treatment and related factors in FMF patients. In addition, patients' beliefs about colchicine, which are one of the important factors affecting the treatment adherence of patients, were evaluated.

Methods: Total of 179 patients with FMF was included in this study. The demographic and clinical features and MEFV gene mutations were recorded. The treatment adherence of the patients was assessed using a Compliance Questionnaire on Rheumatology (CQR). The Beliefs About Medicines Questionnaire (BMO-T) was used to assess patient's beliefs about colchicine. The relationship between compliance of treatment and clinical characteristics of patients were assessed.

Results: One hundred thirteen (63.1%) of the patients were male. The mean age of patients was 34.5 ± 12.7 years and mean delay in diagnosis was 6.7 ± 3.4 years. The mean dose of colchicine was 1.37 ± 0.43 mg/day and, the percentage of patients using colchicine regularly was 66.5%. Adherence to treatment was higher in patients with concomitant diseases than those without comorbidities (p = 0.028). In addition, treatment compliance was higher in married patients compared to single patients (p = 0.013). The colchicine dose used in compatible patients was higher than in non-compatible patients (p = 0.003) (Table 1). We also found that as the BMO-T Specific Necessity scores increased, compliance with treatment increased. On the other hand, as the BMO-T General Overuse and General Harm scores increased, non-compliance with treatment increased (Table 2).

Conclusion: In patients with FMF, it is important to evaluate the compliance with the treatment due to the importance of colchicine to prevent amyloidosis that may occur in patients without treatment. As this study shows it is also important to determine patients' beliefs about medicine in terms of their influence on patients' compliance with treatment.

Disclosure of Interests: None declared

ANAKINRA TREATMENT IN RECURRENT PERICARDITS: SINGLE CENTER EXPERIENCE

Zeynep Tokar Dincer, Osman Corball, Serdal Uğulu, Huri Ozdogan, University of Istanbul-Cerrahpaşa, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey

Background: Recurrent pericarditis (RP) is a well-known condition characterized by recurrent episodes of pericardial inflammation. Alternative treatments have been reported for recurrent pericarditis related to FMF as well as patients with idiopathic recurrent pericarditis (IRP) (1). Alternative treatments have been reported for cases with colchicine resistant RP.

Objectives: The aim is to present our data regarding anakinra treatment in recurrent pericarditis either related to FMF or idiopathic, who are resistant to colchicine.

Methods: Patients who had received anakinra with a diagnosis of recurrent pericarditis either idiopathic or secondary to FMF followed in our autoinflammatory disease center between 2014-2018 were evaluated retrospectively. Treatment decisions were based on patients' files, demographic and clinical features, response to other treatment approaches such as NSAI, colchicine, were evaluated. All patients have been genetically screened for monogenic autoinflammatory diseases (MEVF, NOD2, NLRP3, NOD2). Patients who had at least 3 attacks were administered anakinra 100 mg/day. Therapeutic efficacy, as well as side effect profile of anakinra is also assessed.

Results: There were 5 patients (3 male and 2 female) with the diagnosis of RP. 1 was related to FMF and 4 were idiopathic. The mean age of

the group was 28±8 (range 20–40). All patients diagnosed with IRP were negative for autoinflammatory genetic screening, while a MEFV variant (K695R het.) was detected in the FMF patient. Median duration of follow-up was 30 months (range 11–129). In table 1, demographic and clinical features are given. The median number of recurrence was 6 before anakinra treatment. No episode of pericarditis was observed in any of the patients after the initiation of anakinra. The response to anakinra persisted even after the dose was reduced to 100 mg/alternate day in 3 patients, and 2, recurrence of pericarditis was observed and anakinra was escalated to initial dose. It was possible to discontinue corticosteroid treatment in all patients. Currently all patients continue anakinra treatment. No side effect including injection site reaction, has been observed by now.

Conclusion: Anakinra seems to be a safe and effective treatment approach for colchicine resistant recurrent pericarditis. However recurrence may occur during dose tapering.

FR0617 APPLICATION OF AUTO-INFLAMMATORY DISEASE DAMAGE INDEX (ADDI) TO PATIENTS WITH FMF AND RELATED FACTORS WITH DAMAGE

Hakan Babaoglu¹, Berkan Armagan², Erdal Bodakci³, Timuçın Kapılıoglu⁴, Hasan Satış⁵, Nuhi Atas⁵, Alper Sarı⁶, Nazife Sulay Yasar Bilgi⁷, Gökize Köbra Yardımcı⁸, Reyhan Bilbi Salman⁹, Levent Kılıçⁱ⁰, Mehmet Akif Ozturk¹¹, Benna Goker¹², Seminir Haznedaroglu¹³, Umut Kalyoncu¹⁴, abdurrahman tufan¹⁵,¹⁶
¹Osman Gazi University Faculty of Medicine, Department of Internal Medicine-Rheumatology, Ankara, Turkey; ²Hacettepe University Faculty of Medicine, Department of Internal Medicine-Rheumatology, Ankara, Turkey; ³Eskisehir Osmangazi University Faculty of Medicine, Department of Internal Medicine-Rheumatology, Eskisehir, Turkey

Background: Familial Mediterranean Fever (FMF) is the most frequent auto-inflammatory disease caused by MEFV gene mutations. Available reports investigated only specific components of damage such as amyloidosis. All possible organ targets of damage have not been entirely evaluated before. Such as Disease severity index which is emerged especially for FMF do not cover entire damage domains related to FMF. Recently, a new scoring system (Auto-inflammatory disease damage index) was developed and validated for autoinflammatory diseases. Objectives: We aimed to investigate damage accrual caused by FMF and associated features with damage. Methods: All patients recruited from FMF in Central Anatolia (FICA) cohort, however in 2, recurrence and duplication disabled cross-sectional, multicenter accessible web-based cohort. This study is comprising 970 adult patients (mean age 35.3 ±12.1 years, 61.5% female). Demographic data, FMF disease characteristics, co-morbid conditions, disease complications were meticulously questioned and laboratory features and genotype data (if available) were recruited from patient files. FMF caused damage was assessed by auto-inflammatory disease damage index (ADDI) which is recently validated. Association between damage and demographic, disease and treatment characteristics were analyzed.

Results: Proportions of FMF manifestations were fever 83.1%, peritonitis 91.5%, pleuritis 47.9%, arthritis 43.3% and skin rash 26.2%. Dominant attack types were fever in 6.2%, serositis in 65.7%, musculoskeletal in 16.8% and all types of attacks were common in rest of patients. MEFV mutations were available in 814 subjects and 75.9% of these subjects were harboring M694V mutation (42.5% homozygous for M694V). Among all 63.1% patients were well responded to colchicine and 10.8% were non-responders. Median ADDI score was 1 (min 0-max 11). Most common FMF related damages were observed in musculoskeletal, reproductive and kidney domains. Chronic musculoskeletal pain was present in 49%, joint deformity in 2.9%, infertility in 8.6%, amenorrhea in 3.9%, proctitis in 6.9%, amyloidosis in 5.9% and renal failure in 3.7% of the patients. 411 (54.2%) of patients had no damage accrual. M694V homozygous mutation, male gender and colchicine nonresponse were found to be the independent predictors of damage. Conclusion: M694V homozygous mutation, colchicine non-response and male gender were predictors of damage and effective therapeutic interventions must be undertaken to prevent from damage in these patients.

INPATIENT BURDEN AND COMORBIDITIES OF SARCOIDOSIS: NATIONWIDE INPATIENT SAMPLE 2013–2014

Pattornpong Ungprasert1, Kam Wijarnpreecha2, Weit Cheungpasitporn2, Charal Thongrayanont2, Paul Kroner2, 1Faculty of Medicine Siriraj Hospital, Mahidol University, Clinical epidemiology unit, Bangkok, Thailand; 2Mayo Clinic Florida, Jacksonville, United States of America; 3University of Mississippi Medical Center, Jackson, United States of America; 4Mayo Clinic Rochester, Rochester, United States of America

Background: Little is known about the inpatient burden and healthcare utilization among patients with sarcoidosis. Previous studies have focused on trends of hospitalization rate of patients with sarcoidosis over time [1] but none has investigated their inpatient prevalence, mortality and expenditures.

Objectives: The current study was conducted with the aims to shed more light on those characteristics as well as to investigate the comorbidities of sarcoidosis using the data from a large national database.

Methods: Patients with sarcoidosis were identified within the Nationwide Inpatient Sample (NIS) database of the years 2013 and 2014 using the ICD-9 diagnostic code. NIS is the largest publicly available inpatient database in the US. Data for more than seven million individual hospitalization across all-payers in the United States (US) is recorded annually in the NIS database. This is itself a 20% stratified sample of over 4,000 non-federal acute care hospitals from more than 40 states of the US and is representative of 95% of hospital discharges nationwide. Data on patient and hospital characteristics, comorbidities, total hospital costs and total hospitalization charges was collected. A propensity-matched cohort of patients with sarcoidosis from the same database was created and used as comparators for the analysis of comorbidities. Inpatient prevalence of sarcoidosis was calculated using all admissions in the NIS database as denominator. Odds ratios (OR) comparing the prevalence of comorbidities between cases with sarcoidosis and propensity-matched controls without sarcoidosis were calculated.

Results: A cohort 78,055 patients with sarcoidosis was identified from the database, corresponding to an inpatient prevalence of 2.21 cases per 1,000 admissions. The most common reasons for admission among patients with sarcoidosis in this cohort were as follows: pneumonia (34.3%), respiratory failure (26.1%), cardiomyopathy (10.9%), coronary artery disease (9.2%), acute kidney injury (8.5%) and atrial fibrillation (5.5%). Analysis of comorbidities found that patients with sarcoidosis had significantly higher odds of atrial fibrillation, conduction abnormalities, aortic valvulopathy, congestive heart failure and cardiomyopathy compared to propensity-matched patients without sarcoidosis (Table 1).

After adjusting for confounders, patients with sarcoidosis displayed a mean additional $27,205 (p<0.01) for total hospitalization charges (the amount of money that each hospital billed for providing its service on each case) when compared to hospitalization of patients without sarcoidosis.

Conclusion: The inpatient prevalence of sarcoidosis was relatively high compared to its overall incidence. Hospitalization of patients with sarcoidosis was associated with a significantly higher total hospitalization charges (the amount of money that each hospital billed for providing its service on each case) when compared to hospitalization of patients without sarcoidosis.

Background: Symptomatic differences between male and female patients with IgG4-related disease (IgG4-D) have been reported [1]. Associations between IgG4-D and allergy and malignancy have also been reported, although they are controversial.

Objectives: We previously analyzed the treatment course of IgG4-D using a multi-center cohort [2]. In the present study, we investigated the associations between organ symptoms and gender, allergic diseases, and malignancies.

Methods: Data of 166 patients with a definitive diagnosis of IgG4-D were retrospectively analyzed.

Results: The cohort consisted of 108 men (65%) and 58 women (35%). Most frequently, the submandibular gland (52%), pancreas (46%), lachrymal gland (43%), and thyroid gland (43%) included the thyroid gland (43%), and lymph node (38%) were affected. Furthermore, we assessed the frequencies of female sex, allergy, and malignancy in patients with each affected organ (Table 1). The organs with high frequencies of women included the lachrymal gland (50%), lungs (44%), and submandibular gland (43%). Those with low frequencies of women included the thyroid gland (0%), retroperitoneum (17%), and para-aorta (19%). In addition, allergic diseases were found in 60 patients (36%) (Fig. 1A). The organs with high frequencies of allergy included the thyroid gland (50%), submandibular gland (47%), and lachrymal gland (40%). Those with low frequencies of allergy were the para-aorta (38%), prostate gland (30%), and retroperitoneum (31%). Malignancies were found in 23 (14%) patients (Fig. 1B). Organs with high frequencies of malignancy included the para-aorta (38%), prostate gland (30%), and retroperitoneum (21%). In comparison, those with low frequencies of malignancy included the thyroid gland (0%), lungs (8%), and kidney (8%).

Conclusion: Craniofacial organ involvement was associated with female sex and presence of allergic diseases, suggesting that allergy may contribute to onset of IgG4-D in some patients. Abdominal organ involvement was associated with male sex and presence of malignancies, suggesting that malignancy may in part contribute to IgG4-D.

**FRI0622** JOINT TENDERNESS AND ULTRASOUND INFLAMMATION IN EARLY RHEUMATOID ARTHRITIS PATIENTS INCLUDED IN THE ARCTIC TRIAL

nina sundsland1, Anna-Birgitle Aga1, Hilde Bemer Hammer2, Tii Iihii1, Tore K. Kvin1,2, Espen Haavardsholm1,2, Siri Lillegreven1. 1Dakhaunjome Hotel, Oslo, Norway; 2University of Oslo, Faculty of Medicine, Oslo, Norway

**Background:** A tender joint count is part of most disease activity scores and remission criteria in rheumatoid arthritis (RA). A recent study found that tender joint count might not reflect inflammatory activity, assessed by ultrasound, in established RA (1).

**Objectives:** To explore if tender non-swollen joints is associated with sub-clinical inflammation, assessed by ultrasound, in DMARD-naïve early RA patients.

**Methods:** DMARD-naïve RA patients with <2 years symptom duration from first swollen joint and indication for DMARD treatment were included in the ARCTIC trial (2). For the current analyses we used data from the baseline examination, including a tender joint count assessed by Ritchie Articular Index and a 44-swollen joint count. The Ritchie Articular Index treat certain joints as a single unit (as the MCP-joints), and scoring of tenderness in joints and joint groups is graded 0-3. All patients underwent an ultrasound examination of 34 joints, with a semi-quantitative 0-3 score for power Doppler in each joint. An ultrasound atlas was available for reference (3). We predefined the wrist and the MCP 1-5 joints as joint areas of interest since they are commonly involved in RA and were assessed both clinically and by ultrasound. We selected only joints that were clinically non-swollen, and assessed the association between joint tenderness and ultrasound power Doppler signal by mixed logistic regression models with patient-specific intercept to adjust for within-patient dependencies. The analyses were repeated using generalized estimating equations for robustness. The frequency and odds ratio (OR) of ultrasound power Doppler activity (yes/no) in tender non-swollen wrists compared to non-tender non-swollen wrists were calculated. Similar analyses were performed for the MCP joints.

**Results:** A total of 222 patients with complete baseline data were included. 63% were female, median [SD] age 53.6 [41.2, 62.3], symptom duration 5.8 [2.9, 10.4] months, swollen joint count 9 [4, 15], joint tenderness 7 [4, 13] and power Doppler score 7 [3, 14]. Of 444 wrists, 268 were not swollen. The frequency of power Doppler signal >0 in tender non-swollen wrists was 50% (18/36), compared to 23% (53/232) in non-tender non-swollen wrists. The frequency and odds ratio (OR) of ultrasound power Doppler activity (yes/no) in tender non-swollen wrists compared to non-tender non-swollen wrists was calculated. Similar analyses were performed for the MCP joints. Similar results were found for the non-swollen MCP-joints (Table).

**Table:** The frequency and odds ratio (OR) of ultrasound power Doppler (PD) activity in Ritchie positive versus Ritchie negative non-swollen wrists and MCP joints

</tr>
</tbody>
</table>

**Conclusion:** Ultrasound power Doppler activity was more frequent in non-swollen wrists and non-swollen MCP joints if the joints had been scored as tender or painful by Ritchie Articular Index. Our findings indicate that in early RA patients, tenderness might reflect inflammation which is not detectable clinically.

**FRI0623** MRI-DETECTED DIGITAL FLEXOR TENOSONVITIS IN BILATERAL PROXIMAL INTERPHALANGEAL JOINTS CONTRIBUTE TO JOINT TENDERNESS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Ying-Gian Ma1, Ze-Hong Yang2, Jun-Wei Wang1, Li-Gian Hui1, Xin-Yun Du1, Yan-Hui Xu1, Kui-Ming Yang1, Guang-Zi Sh1, Jun Shen2, Lie Dai1, 1Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China; 2Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Radiology, Guangzhou, China

**Background:** Independent predictive value of ultrasonography-detected digit flexor tenosynovitis has been reported for rheumatoid arthritis (RA) development in patients with early arthritis, and it also was reported as an independent risk factor of flare in remission RA. However, proximal interphalangeal joints (PIPJs) were scarcely evaluated by MRI, nor recommended by RAMRIS so far.

**Objectives:** To explore the characteristics of MRI-detected inflammation in bilateral PIPJs in early RA patients and its clinical significance.

**Methods:** Early RA patients who fulfilled 2010 ACR/EULAR classification criteria with disease duration ≤1 year and DAS28-CRP ≥2.6 were recruited. New methodology of 3.0T whole-body MRI with contrast-enhanced imaging was used to scan bilateral hands simultaneously. MRI tenosynovitis, synovitis and ostesitis were scored referring to the 2016 updated RAMRIS. Clinical data were collected.

**Results:** 1) Among 75 patients recruited, the median age was 49 years old (IQR: 38-59) with 71% female. The median disease duration was 7 months (IQR: 3-12) and the mean DAS28-CRP was 5.1 (IQR: 4.2-6.1). Forty-four patients (59%) were treatment-naive who had never taken any DMARDs or glucocorticoids before recruitment. Both joint tenderness and swelling were present the most frequently in PIPJ2 and PIPJ3 (48% 61% and 43% 56%, respectively, Figure 1A,2). MRI tenosynovitis, synovitis and ostesitis were detected in 84%, 100% and 83% of the patients; and respectively in 21% 44%, 43% 56% and 5% 11% of various PIPJs. There were 12% 30%, 28% 40%, and 2% 8% of PIPJs without tender or swollen showing MRI tenosynovitis, synovitis and ostesitis respectively. When non-dominant hands were used as self-control, the frequency of digit flexor tenosynovitis in dominant interphalangeal joint (IPJ) of thumb, PIPJ2 and PIPJ4 was 16% 18% higher than the non-dominant counterparts, indicating a potential impact of overuse on dominant tenosynovitis. 3) Tenosynovitis affects pericarticular digit flexor tendon compartment and 65% 87% of tenosynovitis in PIPJs occurred together with synovitis in joint cavity and/or ostesitis in subchondral bone. Among tender IPJ of thumb, 50% of them showed MRI synovitis together with digit flexor tenosynovitis, which was significantly more than those who showed MRI synovitis alone (21, Chi-square test, p<0.017). Similar trend was found in tender PIPJ2 (45% vs. 26%, p<0.01). Generalized Estimating Equations with multivariate logistic regression showed not only MRI synovitis but also digit flexor tenosynovitis in bilateral PIPJs independently had more than twice probability of joint tenderness (both p<0.01, Figure 1B).

**REFERENCES:**
Conclusion: This preliminary study showed MRI-detected digit flexor tenosynovitis in bilateralPIPJs contributed to joint tenderness in early RA patients independently of synovitis which should not be ignored in clinical practice.

FR10625 ASSESSING SYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS BY ULTRASOUND – AN AGREEMENT STUDY EXPLORING THE MOST ACTIVE SIDE

Lene Terslev1,2, Robin Christensen2,3, Anna-Bingitte Aga1, Joe Sexton1, Espen A. Haavardsholm1, Hilde Berner Hammer1,1, Rigshospitalet-Glostrup, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 2Frederiksberg Hospital, parker Institute, Copenhagen, Denmark; 3Odense University Hospital, Rheumatology, Odense, Denmark; 4Dakshinhjemmet hospital, Rheumatology, Oslo, Norway

Background: Though ultrasound examination of all RA patients - if offered a very tight clinical control – may not be necessary for obtaining clinical remission (1,2), there are still patients where ultrasound may have a role in monitoring disease activity. Scoring synovitis unilaterally will by far reduce the examination time, however, no consensus exists on how to choose the side to be examined and if one side per se is always the most inflamed side.

Objectives: To assess ultrasound (US) inflammation and sensitivity to change in hands, aiming to identify if the right hand, the dominant hand, or the hand with more clinically swollen joints (SwJ) is per se the most inflamed and more sensitive to change, and hence the preferred side for unilateral scoring of synovitis by US in rheumatoid arthritis (RA) patients.

Methods: This is an agreement study exploring the impact on US scoring methods in a longitudinal study of early RA (ARCTIC trial, n=230) and established RA (ULRABIT trial, n=212) patients initiating conventional and biological Disease Modifying Anti-Rheumatic Drugs, respectively. Tender and swollen joint count for 28 joints (TJC28 and SJC28) and C-reactive protein (CRP mg/L) were obtained. Using the hands as model, bilateral MCP 1-5,PIP 2-3 and wrists were evaluated by US using a 0–3 scoring system for grey-scale (GS) and power Doppler (PD) ultrasound using EULAR/OMERACT combined score (0-27). Targeted synovitis was defined to correspond to a 95% Confidence Interval around the observed paired mean difference: -2.99 to +2.99.

Conclusion: The U9 score gave the best correlation with disease activity parameters. It is simple and applicable and gives a high degree of flexibility to the sonographer according to the clinical picture.

DOI: 10.3109/14397595.2014.974305

Disclosure of Interests: None declared

Results: 437 RA patients were included in the current analysis; 71% women, 79% anti-CCP pos, 71% RF pos, median(IQR) age 54(42-62) years, CRP 7(3-16), SJJC28 5.3(2-6) and TJC28 6.2(28). The median (IQR) PD sum score was 3(0-7) for right hand and 2(0-5) for left hand, GS sum score was 5(2-9) for both hands, and GLOESS was 5(2-10) for right hand and 5(2-9) for left hand. The average ultrasound measured inflammation at baseline and 3 months follow-up are shown in the table. The hands with more vs fewer SwJ had more inflammation at baseline for all sum scores, all p<0.0011) and had a greater change for all sum scores at 3 months follow-up (all p<0.0005). No such differences were found between the dominant vs non-dominant or the right vs left hands at any time points – see table.

Conclusion: Based on this study, assessment of the dominant hand is not superior to the non-dominant hand in inflammatory activity evaluated by US. The hand with clinically more SwJ at baseline is likely to have more active inflammation according to GS, Doppler and GLOESS sum scores and exhibit a greater change, and is potentially the best choice for unilateral US scoring systems.

DIFFICULTIES WITH MAKING A FIST IN PATIENTS WITH CLINICALLY SUSPECT ARTHRAGLIA: AN EARLY PHENOMENON PREDICTIVE FOR RA THAT IS RELATED TO MRI-DETECTED TENOSYNOVITIS

Ferron Wouters1, Florus van der Giesen 1, Xanthe Matthijssen1, Ellis Nienantsverdriet1, Annette van der Helm - van Mil2, 1Erasmus Medical Centre, Rheumatology, Leiden, Netherlands; 2Erasmus University Medical Centre, Rheumatology, Rotterdam, Netherlands

Background: Difficulties with making a fist in patients presenting with recent-onset arthralgia of small joints, in whom there is no clinically detectable arthritis, is often considered a risk factor for the development of inflammatory arthritis. The fact that rheumatologists consider difficulties with making a fist a feature of imminent Rheumatoid Arthritis (RA) is also reflected by this sign being incorporated in the EULAR definition of arthritis suspicious for progression to RA. However, to date there is little comprehension of its predictive value and underlying cause in patients with recent-onset arthralgia.

Objectives: This study was performed to 1) determine if difficulties making a fist is indeed predictive for the development of clinical arthritis, and 2) evaluate if this sign is associated with subclinical joint inflammation, detected by magnetic resonance imaging (MRI).

Methods: 566 patients presenting with recent-onset (<1 year) arthralgia of small joints that were consecutively included in the Clinically Suspect Arthralgia (CSA) cohort were studied. At baseline the ability to completely close the fist (all fingertips touching the palm) was assessed at physical examination. Additionally, contrast-enhanced 1.5T MRI of wrist, 2nd-5th metacarpophalangeal (MCP) and 1st-5th metatarsophalangeal (MTP) joints was performed. MRI findings were scored for synovitis, bone marrow edema (BME) and tenosynovitis in line with the RAMRIS. MRI-detected subclinical inflammation was considered present if it was more than observed in symptom-free controls from the general population in the same age-category (n=193). Patients were followed on the development of clinically detectable inflammatory arthritis identified at joint examination (median follow-up 19 months); none of the patients received DMARDs before the development of clinical arthritis. χ2 tests, logistic and Cox proportional hazards regression were used as appropriate.

Results: At first presentation 12% of CSA-patients had difficulties making a fist, which only 13% of both hands, Having difficulties making a fist was predictive for development of clinical arthritis in univariable analysis (HR 2.47 (95% CI 1.46-4.19)) and in multivariable analysis (HR 2.16 (1.25-3.74) corrected for age, CRP, ACPA and MRI-detected subclinical inflammation). Patients with difficulties making a fist had significantly more often MCP tenosynovitis (flexor tenosynovitis and extensor periteninitis combined) than patients who did not experience these problems (42% versus 16%, p<0.001). The main difference was seen in MCP flexor tenosynovitis (39% versus 10%, p<0.001). MCP flexor tenosynovitis was significantly associated with difficulties making a fist in univariable (OR 5.6 (95% CI 3.2-9.9)), and multivariable regression (OR 5.7 (3.2-10.2)) corrected for extensor periteninitis, synovitis and BME in MCP joints). Extensor periteninitis, synovitis and BME in MCP joints were not associated with difficulties making a fist (multivariable OR 0.7 (0.2-2.1), 0.99 (0.5-2.1) and 1.6 (0.7-4.1), respectively).

Conclusion: Difficulties making a fist in patients with CSA is predictive for future inflammatory arthritis development. This sign is presumably caused by MCP flexor tenosynovitis in a significant proportion of patients.

Disclosure of Interests: : Fenne Wouters: None declared, Florus van der Giesen: None declared, Xanthe Matthijssen: None declared, Ellis Nienantsverdriet: None declared, Annette van der Helm - van Mil Grant/research support from: The research leading to this research received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (Starting grant, agreement No 714312) and from the Dutch Arthritis Foundation. DOES ADDING AN US EXAMINATION OF SHOULDERS, TO A ROUTINE DAS28 SCORE, IMPROVE THE ACCURACY OF DISEASE ACTIVITY SCORES AND DISEASE STATUS? RESULTS OF A SINGLE CENTRE PILOT STUDY

Gásim Arkan1, Lara Valtor2, Justina Jantá, Juan Carlos Nieto3, Letilda García1, Belen Serrano1, Teresa Pedrosa1, Francisco J. López-Longo4, Indalecio Monteagudo Sáez5, Esperanza Naredo5,1, The Penney Acute Hospitals Trust, Rheumatology, Manchester, United Kingdom; 2Gregorio Marañón, Madrid, Spain; 3Gregorio Marañón Hospital, Madrid, Spain; 4Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background: The DAS28 forms the mainstay of current RA and other chronic inflammatory arthritis (CIA) (i.e. peripheral spondyloarthritides [SpA]) management in clinical practice. DAS28 has certain limitations. Some joints especially the shoulders are difficult to evaluate correctly using this method. The shoulder is deep and highly affected by rotator cuff tendon lesions either due to degenerative or inflammatory arthritis This structural damage can produce pain and swelling. A swollen shoulder joint can be difficult to palpate by physical examination. Using a clinical approach can be inaccurate to ascertain whether shoulder involvement is actually due to true RA-derived inflammatory activity or other degenerative or structural causes.

Objectives: To investigate the added value of adding a US assessment of shoulders to DAS28 scores and on disease activity status, in patients with CIA (RA or peripheral SpA) in either disease remission or low disease states who had shoulder pain.

Methods: Patients were recruited prospectively over a 3-month period. Each patient had a standard DAS28 performed followed by a formal physical shoulder examination, of both shoulders, including testing active and passive range of movements. A complete US examination of both shoulders was carried out by a rheumatologist experienced in this technique. All patients were examined using the same real-time US machine (Esaote MyLab Twice) using a linear probe, 3-13 MHz frequency and a linear probe, 5-13 MHz frequency. All patients were examined by a rheumatologist experienced in this technique. All patients were examined using the same real-time US machine (Esaote MyLab Twice) using a linear probe, 3-13 MHz frequency and a linear probe, 5-13 MHz frequency.

Results: Thirty-eight patients [82% females; mean (± SD) age 60.3 (11.96) years] were included. In 33 out of 38 (87%) [C195%: 76-98%] patients the original DAS28 was greater than the US-modified DAS28. This percentage was significantly greater than 50% (p < 0.001). The mean ± SD reduction of DAS28 in those patients who showed DAS28 decrease was 0.73 ± 0.39 units. Twenty-five patients (65.8%) maintained the same disease activity status with original DAS28 and US-modified
DAS28. The remaining 13 (34.2%) patients changed their status: 11 (28.9%) patients moved from low activity to remission while 2 (5.3%) patients moved from low activity to moderate activity. Figure 1 and 2 demonstrate some of the ultrasound findings observed in our patient group.

Figure 1: Biceps tenosynovitis in a. transverse and b. longitudinal views.

![Figure 1](image)

Figure 2: Subacromial-subdeltoid (SASD) bursitis in a. transverse and b. longitudinal views.

Conclusion: This study showed that patients improved their disease activity scores and status after an US assessment of their shoulders. A low percentage increased their disease status after shoulder US which can provide valuable additional information in clinical practice. Rheumatology (Oxford) 2007; 46: 975-9.

Background: Valid assessment of disease activity leads to improvement of long-term outcomes in patients with rheumatoid arthritis (RA) (1). Clinical disease activity assessment tools such as the Disease Activity Score 28 (DAS28) are partially subjective and do not always depict the real inflammatory burden. Ultrasound (US) and Hand-MRI are important diagnostic modalities which can nevertheless be time consuming (US, MRI), expensive (MRI) or usually performed unilaterally (MRI). Thus, further diagnostic tools are needed. Optical spectral transmission (OST) is a new modality able to assess the blood-specific absorption of light transmitted through a tissue promising quantification of inflammation in the finger and wrist joints of RA patients (commercial device: HandScan - Hemics, The Netherlands)(2).

Objectives: To examine the diagnostic value of OST in detecting inflammation in patients with RA and to evaluate for the first time its relationship with disease activity markers and various anthropometric and epidemiologic patient characteristics.

Methods: OST-Measurements were performed in 168 RA-patients and 114 healthy controls. The difference between OST in the two groups was statistically examined and subsequently controlled for the effect of possible confounding factors. Moreover, association of OST with clinical, ultrasound and serological RA activity markers was evaluated. Finally, relationship of OST with radiographic joint pathology and various anthropometric and epidemiologic parameters (BMI, hand-size, gender, age) was examined.

Results: OST was significantly higher in the patients group in comparison to the control group, even after adjustment for the effects of various confounding factors (p<0.001). OST correlated in both groups significantly with gender, hand-size and Body Mass Index (all: p<0.001). In the patients group, OST correlated significantly with all examined disease activity markers (DAS28, ESR, counts of tender/swollen joints, VAS; all, p<0.001) and with age (p=0.001). OST showed significant correlations with a power Doppler ultrasound-Score (p=0.001) and with a combined power Doppler/grey scale ultrasound-Score (p<0.001). Finally, receiver operating characteristic showed the best OST performance at the level of metacarpophalangeal joints level (AUC=0.75; 95%CI=0.686-0.821).

Conclusion: OST correlated with serological and clinical disease activity markers as well as with different anthropometric and epidemiological parameters of RA-patients. OST could therefore prove to be a good non-interventional complementary tool to assess RA activity next to well established diagnostic methods such as the US or MRI.

APPLICATION OF AN ADVANCED NOISE REDUCTION ALGORITHM FOR IMAGING OF HANDS IN RHEUMATIC DISEASES – EVALUATION OF IMAGE QUALITY COMPARED TO STANDARD DOSE IMAGES

Katharina Ziegeler, Stefan Siepmann, Alexander Beck, Alexander Lembcke, Bernd Hamm, Kay Geert A. Hermann, Charité – Universitätsmedizin Berlin, Radiology, Berlin, Germany

Background: X-ray is the fundamental imaging technique in diagnosis and follow up of rheumatic diseases. As patients often require sequential X-rays, dose reduction is of great importance. New advanced noise reduction algorithms allow for a dose reduction of up to 50%.

Objectives: The aim of this study was to evaluate, whether the application of an advanced noise reduction algorithms is feasible in the context of imaging of rheumatic diseases.

Methods: A total of 268 patients were enrolled prospectively into three tiers: 80%, 64% and 50% dose reduction groups. All patients received imaging of one hand (laterality randomly assigned) with low-dose technique and of the contralateral side with standard protocol. All images were evaluated by two blinded independent readers who scored (on a scale of 1 to 5) the visualisation of bony cortex, trabeculae and joint spaces of fingers and wrist separately as well as soft tissue and overall contrast. Score values were analysed using T-tests for paired samples.

Results: Overall image quality (expressed by mean sum scores out of 40) of the 50% low-dose images was 31.52 (SD 1.94) vs. 31.66 (SD 1.82) for standard images (p=0.001). Bony contours as well as trabeculae was equally well visualized in both image sets. An image example is given in Fig. 1 (Left hand: 50%-dose image; right hand: standard-dose image). Soft tissue visualization was slightly lower for low-dose compared to standard images (mean score of 3.81 vs. 3.89; p=0.001).

Conclusion: Overall image quality of low dose images was not inferior to standard dose images. Therefore, application of low-dose technology based on advanced noise estimation algorithms in the context of imaging of rheumatic diseases is feasible.

DIAGNOSTIC UTILITY OF FLUORESCENCE OPTICAL IMAGING IN INDIVIDUALS WITH SUSPECTED ARTHRITIS – A PROBABILISTIC APPROACH

Yogan Kisten1, Adrian Levitsky1, Hamed Rezaei2, Aase Hensvold3, Erik Af Klint1, Ronald van Vollenhoven1,2, Anca Catrina1,2, Karolinska Institute, Department of Medicine, Division of Early Arthritis Clinic of the Karolinska University Hospital, Stockholm, Sweden; 2Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands

Background: In the arsenal of available techniques used for arthritis pre-diction and diagnosis1, fluorescence optical imaging (FOI) has been proven useful in detecting clinically manifest and silent synovitis of the hands and wrists of patients with various rheumatic diseases, particularly rheumatoid arthritis (RA)2.

Objectives: To assess the diagnostic utility of FOI in individuals with joint symptoms referred for further rheumatologic investigation, using a probabilistic approach.

Methods: Those with increased suspicion of inflammatory arthritis were referred to the rheumatology unit and clinic of Karolinska University Hospital. On acquiring informed consent and medical history, the standard clinical examination coupled with ultrasound findings of fingers, wrists and feet were assessed. Laboratory results included ESR, CRP, RF, and ACPA tests. Using the above information, a diagnostic probability assessment was completed by the responsible rheumatologist, where the probability of a) any inflammatory joint disease and b) rheumatoid/RA was given on a 5-point scale – ranging from unlikely (0-20%) to very likely (80-100%) probability. Subsequently, an FOI examination was performed. After reviewing the image reports in consensus, post-FOI diagnostic probabilities were again scored, using the same scale. If no score change in probability resulted, the rheumatologist was asked to mark whether FOI was still helpful in the diagnostic decision-making. Proportions of individuals with maximal and minimal diagnostic certainty pre- and post-test were compared using Fisher exact tests, and one-sample binomial tests for assessing the helpfulness of FOI in the absence of pre- and post-test probability score changes.

Results: Of 24 individuals screened, 21 without prior rheumatic diagnosis were included (66.7% female, 11 RF (+), 10 ACPA (+), with age average and symptom duration (SD) of 55.6 (±18.1) years and 13.9 (±15.3) months respectively). The final diagnoses were: early RA (n=17), other inflammatory joint disease (n=3), and non-inflammatory joint disease (n=1). Regarding diagnosis of any inflammatory arthritis, where the proportion of patients for whom diagnostic certainty was maximal – namely, combining <20% (lowest probability) or >80% (highest probability) of diagnostic likelihood – there was an increase from 52.4% (n=11/21) maximal certainty before FOI to 80.1% (17/21) maximal certainty after FOI (p=0.035). Regarding early RA, the maximal diagnostic certainty increased from 57.1% (12/21) to 71.4% (15/21) (p=0.002), respectively. In the event that diagnostic certainty scores didn’t change pre- vs. post-test (15/21 cases, any inflammatory joint disease; 13/21 cases, early RA), the diagnosing rheumatologist indicated that FOI was still helpful in setting a final diagnosis for most cases (86.7% (13/15) p=0.007; 84.6% (11/13), p=0.022, respectively).

Conclusion: FOI significantly increased the diagnostic certainty and confidence of rheumatologists in establishing the presence and absence of inflammation in individuals suspected of inflammatory arthritis. The changes from pre- to post-test quantify the diagnostic utility of FOI in probabilistic terms.

**FR10631 MUSCLE STIFFNESS AND WEAKNESS IN RHEUMATOID ARTHRITIS – A SHEAR WAVE ELASTOGRAPHY STUDY**

Abdulrahman M. Alfaera,1,2 Al Lyn Tan2,3, Philip O’Connor4, Paul Emery5,3, Richard Wakefield2,3,1. Prince Sattam Bin Abdulaziz University, Radiology and Medical Imaging, Khobar, Riyadh, Saudi Arabia; 2.University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 3. Leeds Teaching Hospitals NHS Trust, Leeds Biomedical Research Centre, Leeds, United Kingdom

**Background:** Myopathy is a recognised but less investigated symptom of rheumatoid arthritis (RA) compared to other extra-articular manifestations. To date, the documentation of myopathic features in RA is poorly detailed. No studies have yet utilised a non-invasive quantitative method to define and investigate these features. Shear wave elastography (SWE), a novel ultrasound technology, can measure muscle stiffness to provide insight into the biomechanical properties of skeletal muscle.

**Objectives:** 1- To investigate muscle stiffness (using SWE) and strength in three cohorts of RA patients compared to healthy controls.

2- To study the association between muscle strength and stiffness in RA.

**Methods:** Shear wave velocity (SWE), as a measure of muscle stiffness, was evaluated in the quadriceps, hamstrings and biceps brachii in 80 RA patients from three disease activity groups newly diagnosed treatment naïve RA [n=29; mean age 56.8 ± 10.6 years], persistent active RA for at least 1 year [n=18; 60.9 ± 15.9 years] and remission RA for at least 1 year [n=33; 65.9 ± 11.6 years]. The participants performed various muscle tests (handgrip strength, expanded timed get up and walk test (ETGUG), chair stand and isokinetic knee extension/flexion) to assess their strength and physical performance. One-way ANOVA was used to compare SWE and muscle assessment results, and Pearson’s correlation was used to evaluate the correlation between muscle stiffness and strength.

**Results:** Mean SWV was not significantly different amongst the RA groups or compared to the healthy controls (p>0.05). For example, the rectus femoris SWV was 1.68±0.15 m/s for healthy controls, 1.68±0.18 m/s for new RA, 1.70±0.16 m/s for active RA and 1.68±0.14 m/s for remission RA (p=0.96). The muscle assessment results are presented in table 1 and compared to healthy controls in figure 1. Overall, the active and new RA groups showed significant muscle weakness compared to healthy controls. The remission RA group did not show a significant difference except in the isokinetic knee strength (-21%; p=0.027). The correlations between SWE and the muscle assessment results were weak and insignificant (r<0.30; p>0.05).

**Conclusion:** Muscle stiffness, as determined using SWE, does not appear to be altered or associated with muscle weakness in RA patients. The remission RA group showed significantly better strength and physical performance compared to new untreated or persistently active RA groups. Future research should investigate the significant muscle weakness in RA in addition to developing prevention and therapeutic strategies.

**FR10632 ASSOCIATION BETWEEN ULTRASOUND DIAGNOSIS AND ANALYTICAL AND SEROLOGICAL DATA IN PATIENTS WITH SUSPECTED PRIMARY SJÖGREN SYNDROME**

Laura Barrio Nogal, Cristina Bóhórquez, Lucia Ruiz, Adrián Abbasi, Ana Pérez Gómez, Alisa Movasat, Ana Sánchez Atreo, Fernando Albarrán, Eduardo Cuende, Paula Pretel, Valentina Emperiale, Melchor Álvarez de Mon. Hospital Universitario Príncipe de Asturias, Madrid, Spain

**Background:** Pathophysiology of primary Sjögren syndrome (SSp) is characterized by oligoclonal B-cell proliferation and ectopic lymphoid tissue formation. The association between ultrasound glandular parenchyma heterogeneity and hyperproduction of autoantibodies, which in turn represents characteristic B-cell hyperactivity of SSp, is described.

**Objectives:** To study the association between major salivary gland ultrasonography (MSGUS) and their respective pathological grades with the analytical and serological data, and activity indexes obtained in patients with suspected SSp.

**Methods:** 72 patients were recruited consecutively with clinical and/or analytical suspicion of SSp from the Rheumatology outpatient consultations at the Príncipe de Asturias Hospital (2015-2018). Demographic, serological and validated activity indexes, ESSPRI and ESDAI, were collected. All of them underwent a MSGUS and their results were classified in three grades according to the-Conenc et al system: normal (grade 0 and 1), mild (grade 2) and moderate-severe (grades 3 and 4). The final SSp diagnosis was made using both 2002 AECG and 2016 ACR/EULAR classification criteria. Data were analyzed using the software STATA. Association between MSGUS and qualitative variables was described according to the number of cases and the percentage by grades of MSGUS; the significance of the associations was tested with the Chi square test. For the quantitative variables, the association was described with median and interquartile range (IQR) by grades of MSGUS and the significance of the association was verified with the non-parametric test of Kruskal-Wallis.

**Results:** From patients with pathological MSGUS: 51% had antiRo52, 51%, antiRo60 and anti-La positive; 62% hypergammaglobulinemia, 40% positive rheumatoid factor (RF), 6% and 13% C3 and C4 hypocomplementemia, respectively. Mean values were obtained: ESR 36, CRP 1.6, RF 12, ESSPRI 5.6 and ESDAI 2. Statistically significant differences (p<0.05) were only found in antiRo52 and hypergammaglobulinemia variables in patients with normal MSGUS exam compared to those with...

**FO0634** STANDARD REFERENCE VALUES OF METACARPAL HEAD CARATILAGE THICKNESSMEASUREMENT BY ULTRASOUND IN HEALTHY SUBJECTS

Eduardo Cicinella1, Emilio Filippucci, Andrea Di Matteo2, Jana Humakova, Marco Di Carlo1, Karel Pavelka3, Walter Grassl1, Polytechnic University of Marche, Rheumatology Clinic, “Carlo Urbani” Hospital, Jesi, Italy; 2Charles University, Institute of Rheumatology, Department of Rheumatology, First Faculty of Medicine, Prague, Czech Republic.

Background: The hyaline cartilage of metacarpal head (MH) is frequently involved in patients with chronic arthritis. Moreover, in a recent study a high correlation has been found between the anatomical and sonographic (US) measurements of hyaline cartilage2. However, only very few data are available on the prevalence of pathological findings and the standard reference values in healthy subjects (H).

Objectives: To determine the prevalence of the US abnormalities at metacarpal head (MH) in H, and to measure MH cartilage thickness (CT) in order to provide standard reference values. Methods: US examinations were performed on 944 metacarpophalangeal (MCP) joints of 118 consecutive H using a MyLab Two (Esaote Biomedica, Genoa, Italy), equipped with a high frequency probe (up to 22 MHz). H were recruited among the staff of Rheumatology Department of the “Carlo Urbani” Hospital (Jesi, Ancona, Italy), students in medicine and patients’ healthy relatives. Exclusion criteria were: hand pain (VAS score >1/10) or stiffness in the previous month or hard tissue enlargement of MCP, proximal and distal interphalangeal joints.

The MH hyaline cartilage from II to V digits of both hands was scanned with the MCP joints in maximum flexion in longitudinal and transverse dor- sal views, paying attention on maintaining an angle of 90° between the direction of the US beam and the cartilage surface2. CT was scored both semi-quantitatively (using a five-grade scoring system5) and quantita- tively (using the mean value of longitudinal and transverse measurements of the CT). Moreover, the presence of osteophytes and bone erosions was recorded.

The association between CT and demographic data was analyzed.

Results: The semi-quantitative score: Cartilage damage was found in 21 out of 118 H (17.8%) and in 59 out of 944 MHs (6.3%); grade 1 and grade 2 in 43 (4.6%) and in 16 (1.7%), respectively. No grades 3 and 4 were detected. Osteophytes and bone erosions were respectively found in 12 (10.1%) and in 8 (6.7%) out of 118 H and in 24 (2.5%) and in 12 (1.3%) out of 944 MHs. A slight correlation between semi-quantitative score and the presence of osteophytes was found (r=0.16, p=0.01). No association between bone erosion and cartilage thinning was found.
Quantitative assessment: A significantly thicker cartilage was found in males [0.71±0.10 mm (mean±SD)] than in females [0.68±0.12 mm, (mean ±SD)] (p<0.01). No significant difference was found between left and right side for each digit (p>0.05).

CT value of the II MH was significantly greater than the one of the other fingers (p<0.01). No difference was found between the CT values of III, IV and V MH (p>0.05).

There was a significant association between the CT value and gender (r=0.39; p<0.01), age (r=-0.33; p=0.01), height (r=-0.28; p<0.01) and grade of the semiquantitative scoring system (r=-0.19, p<0.01). No correlation was found between the CT value and weight (p=0.20).

Conclusion: This study confirms the presence and provides data on the prevalence of US abnormalities at MH level in healthy individuals. Moreover, overall values for US CT of MH were reported.

sensitive to joint space alterations (T1: SE 40%, SP 94%; SWI: SE 80%, SP 100%).

Conclusion: While T1 weighted MRI provides sufficient diagnostic accuracy for the detection of erosions, the CT-like images derived from SWI allow for a more accurate depiction of structural lesion of the SI-join. SWI provides additional information identifying sclerosis. However, it is not suited to replace T1-weighted imaging because fatty metaplasia of the bone marrow or inside an erosion cavity cannot be detected.

Figure 1. T2 measurements in myositis patients compared with healthy controls in the hamstrings

Figure 2. T2 measurements compared to semi-quantitative scores in myositis patients and healthy controls

MUSCLES IN MYOSITIS PATIENTS WITH NORMAL MRI APPEARANCE HAVE HIGHER QUANTITATIVE T2 COMPARED TO THOSE IN HEALTHY CONTROLS

Matt Farrow1,2, John Biglands2, Paul Emery2, Steven Tanner2, Andrew Grainger2, Andreas Ladas2, Philip O’connor2, Al Lyn Tan2.1 Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 2NIHR Leeds Biomedical Research Centre, Chapel Allerton Hospital, Leeds, United Kingdom

Background: Myositis is an autoimmune disease which can cause a decrease in quality of life and increased mortality. Clinical presentation includes muscle weakness, myositisositis, raised muscle enzymes and myalgia. Currently, diagnosis is reliant on subjective clinical examinations, blood tests, conventional MRI and invasive muscle biopsies. Quantitative T2 imaging offers a non-invasive measurement of muscle oedema which could help improve the understanding of muscle pathology and potentially inform diagnosis (1).

Objectives: To evaluate whether quantitative T2 MRI of muscles is sensitive enough to be able to detect differences in myositis patients compared to healthy controls, and how it compares with current radiologist scoring methods.

Methods: 19 active myositis patients (12 female, mean age 55 ± 18) diagnosed according to the Bohan and Peter myositis criteria (Mean CK 1511 ± 11291) and 19 age and gender matched healthy controls had an MRI scan of their dominant thigh. Imaging was performed using a fat-suppressed turbo-spin echo (TSE) sequence with 16 echo times, evenly spaced from 9.9ms to 153.4ms. Quantitative T2 measurements were obtained from regions of interest (ROI) drawn manually within the individual muscles that make up the quadriceps and hamstrings with no distinction made between affected and unaffected muscles. A mono-exponential fit was used to obtain an estimate of the T2 from each ROI. Two radiologists semi-quantitatively scored by consensus the muscles on a 4-point visual scale as either no oedema (0), mild oedema (1), moderate oedema (2) or severe oedema (3). In addition to MRI, all participants had knee extension and flexion measured as power and torque on an isokinetic dynamometer. Differences were assessed using independent T-tests.

Results: Quantitative T2 values were significantly higher (P<0.001) in myositis patients compared to healthy controls with mean measurements in the hamstrings (figure 1) of 47ms in patients and 40ms in healthy controls, and in the quadriceps 52ms in patients and 41ms in healthy controls, whilst muscle strength and power were significantly reduced (P<0.001). Interestingly, 8 myositis patients scored as having no oedema in the muscles by the radiologists (score = 0) still had significantly higher T2 values than 8 age and gender matched healthy controls (P=0.003 in hamstrings and P=0.001 in quadriceps) with mean T2 measurements in the hamstrings (figure 2) of 43ms in patients with no oedema and 37ms in healthy controls and in the quadriceps 43ms in patients with no oedema and 40ms in healthy controls. These results were consistent across both muscle groups and the individual muscles.

Conclusion: Quantitative T2 measurements can detect muscle differences between myositis patients and healthy control groups. They are also sensitive to differences between the muscles of myositis patients which are assessed to have no oedema by radiologist scoring, and healthy controls. This suggests that subtle systemic changes in muscle in myositis patients, which go undetected in semi-quantitative scoring, can be detected using quantitative T2 measurements. This shows the potential for T2 measurements to be a diagnostic measure in the diagnosis and management of myositis.

LUMBAR SPINE BONE MASS DENSITY AS A PREDICTOR OF FRACTURES IN PATIENTS WITH COELIAC DISEASE: AN OBSERVATIONAL STUDY

Mariam Gaddah1, Manwan Bukhari2, Lancaster University, Lancaster, United Kingdom; 3Royal Lancaster Infirmary, Lancaster, United Kingdom

Background: Previous studies have indicated that Lumbar spine Bone Mineral Density (BMD) could be used as an indicator to predict fractures in patients with coeliac disease (1). Patients with coeliac disease are at a higher risk of developing fragility fractures as a result of the underlying metabolic pathology. Despite previously highlighting the lumbar spine BMD usefulness in predicting fractures, score systems, like the FRAX score still has not acknowledged it. Additionally, recent data suggested that using a ratio of BMD mass index (BMI) to BMD could increase the predictive models for fracture.

Objectives: Through a large observational study, we set out to determine the various predictors of fractures in patients with coeliac disease. Age, gender and lumbar BMD were some of the factors that were considered in relation to fractures. This data was scrutinised to assess specifically the lumbar BMD’s ability to predict fractures with and without using the BMI ratio.

Methods: A sample of 788 patients with coeliac disease referred for bone density estimation to a scanner in the North west of England from 2004-2010 was used to assess various predictors of fractures. Data were initially analysed using simple statistical analyses (chi-squared for categorical variables and t-test for continuous variables) to compare patients who had sustained a fracture to those that had not sustained a fracture. The data was then subject to further analysis initially using univariate and then multivariate logistic regression models. Variables analysed included Lumbar spine L1-L4 BMD, BMI/BMD ratio, gender, age at scan, family history of fractures, alcohol, smoking and rheumatoid arthritis. In order to further assess the Lumbar spine BMD’s vs BMI/BMD in predicting fractures, the data was further adjusted for age and gender and models compared using areas under the receiver operating characteristic (ROC) curve.

Results: Out of the 788 patients referred in the analysis period, 159 (20.2%) sustained a fracture. The mean age at the time of the fracture was 55.4 (SD 14.4). A total of 576 (73.1%) were female and of those 127 (22%) had sustained a fracture. Female gender was significantly associated with fracture (p=0.003). Patients with fractures were older 59.2 years (SD 14) compared to 54 years (SD 14) (p=0.001). Using the multivariate model, it was evident that even after being adjusted for gender and age, the lumbar spine BMD was a good predictor of fractures (OR 0.98 95%CI 0.92-0.93). This performed better than the ratio of BMI/BMD. AUC 0.64 vs AUC 0.62.

Conclusion: The FRAX tool should consider using lumbar spine BMD as an indicator of fragility fractures in patients with coeliac disease. We have shown using both univariate and multivariate analyses that many factors are associated with fragility fractures, but the lumbar spine BMD was the best predictor. This study took the data another step further and adjusted the data for gender and age and added the ratio of BMI to BMD, but still reached a similar conclusion. Lumbar spine BMD should be taken into consideration with more care in this group of patients.

COMPARING DISEASE ACTIVITY IN THE WRIST BY REPEAT SYNOVIAL BIOPSY, RAMRIS MAGNETIC RESONANCE SCORE AND EULAR-OMERACT ULTRASOUND SCORE: A 6-MONTH PROSPECTIVE TRIAL IN EARLY AND LONGSTANDING RHEUMATOID ARTHRITIS

Seren Andreas Just1,2, Christian Nielsen2, Jens Wenrin1, Pia Veldt Larsen3, Camilla Schuit Karleby4, Henrik Daa Schroder5, Frances Hurnby1, Trine Torfing6, Hanne Merete Lindegaard7, 1Svendborg Hospital, Odense University Hospital, Department of Medicine, Svendborg, Denmark; 2Odense University Hospital, Department of Rheumatology, Odense, Denmark; 3Odense University Hospital, Department of Clinical Immunology, Odense, Denmark; 4Odense University Hospital, Department of Orthopedics, Odense, Denmark; 5Epidemiology and Biostatistics, Department of Public Health, Odense, Denmark; 6Odense University Hospital, Department of Pathology, Odense, Denmark; 7William Harvey Research Institute, Bart’s and The London School of Medicine and Dentistry Queen Mary University of London, London, London, University Kingdom; 8Odense University Hospital, Department of Radiology, Odense, Denmark.

Background: Standardized scoring systems for Rheumatoid Arthritis (RA) joint disease activity are validated in different imaging modalities and objectives: To determine the effect of retinal outer nuclear layer thinning on the progression of hydroxychloroquine retinopathy. Methods: We used a Heidelberg Spectralis(R) Spectral Domain Ocular Coherence Tomography (SD OCT) scanner to record the volume of the ONL in 194 eyes of 100 patients who have been on Hydroxychloroquine for 5 years or more. Volume data was analysed using the Statistical Package for Social Sciences (SPSS), we used logistic regression method to determine the probability of developing maculopathy based on the degree of reduction of the ONL volume. We correlated the loss of ONL to changes in visual fields.

Results: Mean age: 62.2 years, 20% males and 80% females. Diagnosis: 68% rheumatoid arthritis, 14% Sjogren’s syndrome, 16% Systemic Lupus and 2% others. Mean duration of use was 6.3 years. Logistic regression results show strong negative correlation between the ONL volume and probability of toxicity, a reduction of 0.5 mm3 of the ONL volume carries a 51% chance of developing maculopathy (P<0.001), the Hosmer-Lemeshow test indicates a high significance with a high P value of 0.61. Onset and progression of visual field defects strongly correlate to loss of ONL volume of 50% or more (P<0.000) and age above 35 years (P<0.0001).

Conclusion: Outer nuclear layer volume reduction provides an accurate and objective way of predicting the development of hydroxychloroquine retinopathy, this method also helps building a cooperative relationship between ophthalmologists and rheumatologists to establish an effective screening service.

include Larsen score for radiographs, RAMRIS for magnetic resonance imaging (MRI) and EULAR-OMERACT score for ultrasound (US). However, pairwise correlations between all three imaging modalities and their correlations with synovial histopathological assessment have not been performed.

Objectives: To investigate the relationship between histological synovitis and radiological synovitis, assessed by conventional X-ray, US and MR imaging at baseline and after 6 months. Imaging was conducted on the same hand as biopsied. MRI was performed at baseline for all, and also at 6 month for the ERA group, and scored with the RAMRIS system. Wrist X-ray was scored by Larsen score at baseline and after 6 month. Hand US examination at baseline, 3 and 6 months was scored by the EULAR-OMERACT US system. Synovial biopsy inflammation at baseline and 6 months was determined by the Larsen score, scores for CD20, CD3, CD138, CD68 staining, and classification of synovial pathotypes.

Results: In the ERA group at baseline, Krenn score was strongly correlated with both EULAR-OMERACT US combined score (r=0.77, p<0.001) and RAMRIS MRI synovitis score (r=0.85, p<0.001), while uncorrelated at 6 months (r=0.18, p=0.38 and r=0.14, p=0.65). In the LRA group at baseline, these scores correlated strongly (r=0.83, p<0.001) to moderately (r=0.61, p=0.002), and persisted at 6 months for US score (r=0.81, p<0.001). Larsen score was not correlated with Krenn score at any point in any group. For all RA patients, change in Krenn score between baseline and 6-month biopsy, was correlated with both change in EULAR-OMERACT US combined score (r=0.65, p<0.001) and change RAMRIS MRI synovitis score (r=0.50, p=0.03), but not to change in Larsen score. Patients with the lymphoid pathotype had higher US combined score, MRI synovitis score (r=0.50, p=0.03), but not to change in Larsen score. MRI synovitis score and Krenn-score at baseline compared to other pathotypes (all p<0.05).

Conclusion: The MRI RAMRIS synovitis score and EULAR-OMERACT US scoring system are sensitive measures of histological synovitis in LRA and ERA. After 6 months, this correlation persists in the established RA group despite effective treatment, but not in the ERA group. This suggests that ERA and LRA may have different responses to treatment and that ERA could potentially be used to estimate disease extent. We suggest the ‘slope’ sign be included in axillary artery ultrasound scan protocols for all patients with suspected GCA and also for monitoring disease activity in LVGCA.

FRI0642 THE ‘SLOPE SIGN’: A FEATURE OF LARGE VESSEL VASCULITIS?
Kate Smith1, Abdullah Khan2, Bhaskar Dasgupta2. 1NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 2Southend University Hospital, Rheumatology, Westcliff-on-Sea, United Kingdom

Background: Ultrasonography in large vessel vasculitis (LVV) has become popular as a non-invasive, radiation-free, point of care examination that allows assessment of entire temporal and axillary vessels. EULAR recommends ultrasound as first line imaging of giant cell arteritis (GCA) and LVV (1) and poly/ polymyalgia rheumatica (PMR). Cranial and large vessels GCA (LV GCA) are considered the two subtypes of the disease. Ultrasonography in cranial GCA is well established, with the non-compressible halo of temporal arteries considered the key diagnostic finding. In LV GCA, increased intra-medial thickness (cut off >1.0 mm), is the preferred method of diagnosis. There are other causes of thickening of arterial wall, such as atherosclerosis. Atherosclerotic US changes in US are localized and discrete, however, at times it may be challenging to differentiate vasculitic from atherosclerotic changes.

Objectives: We describe the ‘slope sign’ as a unique additional finding in US scan of axillary arteries in LV GCA. Ultrasound scan of the axillary arteries in patients with LVGCA, is a secondary confirmation alongside the abnormal IMT, of LV disease. Biologics therapy has reduced the utility of inflammatory markers in GCA and highlighted need for imaging in disease assessment (2). The ‘slope sign’ may not only differentiate increased IMT of LVV from atheroma but also the area under the ‘slope’ could potentially be used to estimate disease extent. We suggest the ‘slope’ sign be included in axillary artery ultrasound scan protocols for all patients with suspected GCA and also for monitoring disease activity in LVGCA.

FRI0641 USE OF MAGNETIC RESONANCE IMAGING FOR ASSESSMENT OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES – A SUBANALYSIS OF THE PROMETHEUS STUDY
Kateřina Kubínová1,2, Jit Vencovsky1,2. 1Institute of Rheumatology, 1st Faculty of Medicine, Charles university, Prague, Czech Republic; 2Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

Background: Prometheus study was a prospective, randomized, assessor-blind multicenter trial, conducted to evaluate the efficacy and safety of the combination therapy with methotrexate and glucocorticoids (GC) compared to GC treatment only in patients with polymyositis (PM) and dermatomyositis (DM). Muscle MRI has been used to assess disease activity and response to treatment.

Objectives: To assess MRI findings we developed new semi-quantitative scoring method and used it for activity assessment and evaluation of treatment effect after 3 months of therapy.

Methods: In a novel semi-quantitative assessment of edema, we used scoring 0, 1, 2, and 3 according to intensity of signal in each of the 16 thigh muscles. Muscle damage was evaluated in 3 basic thigh muscle compartments and pelvic muscles using Goutallier grading (0 – 5) based on extent of fatty replacement. Both sides were assessed, an average was made for each muscle, and values were summed up in the total score. Images were scored by 2 independent evaluators and the mean was used. Manual muscle test (MMT) and creatine kinase (CK) were measured and patient’s global assessment (PGA), physician’s GA (PGA) and muscle disease activity (MDA) were recorded on visual analogue scales.

Results: Seventeen patients had MRI images taken before the baseline visit. 8 had also the second MRI after 3 months of therapy. There was a significant reduction of total MRI edema score (MRI ES) after 3 months in patients with PM and DM (from the mean 17.4 points, SD 13.7 to 8.0 points, SD 12.3; p=0.025). No significant progression of fatty atrophy was observed (from 16.0 points, SD 8.8, to 19.4, SD 4.6; p=0.3). At baseline, a significant correlation between MRI ES and MMT was noted (r=0.27). There was also a borderline association of MRI ES with muscle strength evaluated by MMT (r=0.3). In a subset of 8 patients with longitudinally performed two MRI evaluations we found a good correlation between

Table: Mean maximum and normal IMT and length of ‘slope’ in LV GCA patients

<table>
<thead>
<tr>
<th>Maximum (Proximal) IMT</th>
<th>Normal (Distal) IMT</th>
<th>Slope Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean (SEM) mm</td>
<td>1.23 (0.04)</td>
<td>0.52 (0.03)</td>
</tr>
</tbody>
</table>

Conclusion: Presence of the ‘slope sign’ in the ultrasound scan of the axillary arteries in patients with LVGCA, is a secondary confirmation alongside the abnormal IMT, of LV disease. Biologics therapy has reduced the utility of inflammatory markers in GCA and highlighted need for imaging in disease assessment (2). The ‘slope sign’ may not only differentiate increased IMT of LVV from atheroma but also the area under the ‘slope’ could potentially be used to estimate disease extent. We suggest the ‘slope’ sign be included in axillary artery ultrasound scan protocols for all patients with suspected GCA and also for monitoring disease activity in LVGCA.
Conclusion: We proposed a new semi-quantitative scoring system for assessment of MRI images in patients with PM and DM. This system was applied to record degree of muscle edema and fatty replacement in a subpopulation of patients treated in the Prometheus study. A significant reduction of MRI ES and no relevant progression of muscle atrophy and fatty replacement after 3 months of therapy was demonstrated. Initial MRI edema score correlated with some clinical and laboratory parameters (PGA, CK) but was not predictive to a degree of improvement during treatment. The results are limited by a small sample size, particularly in the subset with longitudinal MRI.

FRI0644 ANALYSIS OF CARDIOVASCULAR RISK AND CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH PSORIASIS

José Alexandre Mendonça1, Elaine Cristina Faria Abrahão Machado2, Luciana B. Nuccí1, Ana Carolina Beliní Bazán Amudá1, 1Pontifical Catholic University of Campinas, Rheumatology, Campinas, Brazil; 2Pontifical Catholic University of Campinas, Campinas, Brazil

Background: Psoriasis (Ps) is associated with atherosclerosis and an increased risk of cardiovascular disease (CVD). Currently, a new automated ultrasound software, based on radio frequency, called QIMT (quantitative intima media thickness) technology, proved to be a useful method for assessing subclinical atherosclerosis with the measurement of the intima-media thickness (IMT) in carotid arteries.1-2

Objectives: To analyze the ultrasound results of the QIMT and Framingham score for psoriasis patients submitted to two types of treatments: methotrexate (MTX) and tumor necrosis factor inhibitor (TNF-α).

Methods: Fifty patients with psoriasis in plaques, were divided into two groups, using MTX and using TNF-α (infliximab and adalimumab). We
evaluated the measurement of abdominal circumference, blood pressure, body mass index (BMI) and presence of metabolic syndrome (SM). In addition, we evaluated cardiovascular risk with the Framingham score and IMT of the two common carotid arteries using automatic software (QIMT) and laboratory tests, including fasting glycemia and total cholesterol, fractions and triglycerides. Data were analyzed using the t-student, chi-square test and the Mann-Whitney test. For the evaluation of the CVR, univariate and multivariate logistic regression analyses were performed. The level of significance (α) adopted was 5%, being considered statistically significant values of p <0.05.

Results: Total of 50 patients in the study, 25 were on MTX (group 1) and 25 were on ad-TNFα (group 2). Mean age was 54.8 ± 12.5 with a slight male predominance (58%). Total cholesterol, HDL, LDL and triglycerides were lower in the group 1 (76%, 30% and 42% of patients, respectively). Overall, 84% of the patients had high waist circumference and 82% had a BMI above the ideal. There was a statistically significant difference (p <0.05) between the groups for metabolic syndrome results (68% vs. 32%); 44% of the patients in group 1 presented Framingham score intermediate to high and 28% of group 2, in relation to the QIMT. 56% of group 1 and 72% of group 2 showed higher than expected (p= 0.05). For the correlation between QIMT and Framingham Score, the Pearson (r) linear correlation coefficient found was 0.617 (p <0.001), indicating a moderate to strong positive association. The cross-sectional analysis does not provide information on causality and the protective or non-protective effect of the aforementioned therapies in relation to cardiovascular risk was not evaluated.

Conclusion: The results show that patients with Ps have high rates of metabolic syndrome and subclinical atherosclerosis. There was a positive association correlating the Framingham score values with the QIMT measurement, providing evidence for the use of ultrasound in clinical practice.

**FR00645** EVALUATION OF MARKETED KITS FOR MEASUREMENT OF ABP 501, THE FIRST APPROVED ADALIMUMAB BIOSIMILAR, DRUG CONCENTRATION AND ANTI-DUPLICATE ANTIBODY LEVELS IN PATIENT SERUM

Dan Mytych, Marta Starcevic Manning, Alexander Colbert, Sarah Hoofring, Jill Miller, Melissa Gessner, Vincent Chow, Gary Fanjiang. Amgen, Thousand Oaks, CA, United States of America

Background: Adalimumab and its biosimilars are anti-tumour necrosis factor (TNF)-monoclonal antibodies that are approved in Europe as treatment for various autoimmune-related indications, including Crohn’s disease and ulcerative colitis. Despite the clinical success of adalimumab, some patients show a diminished response after prolonged treatment. It is known that serum adalimumab trough levels are correlated with clinical response and the development of anti-adalimumab antibodies (AAA) may negatively impact trough levels. Currently, therapeutic drug monitoring (TDM) is used to measure adalimumab concentration and/or AAA allowing individualized optimization of treatment regimens. This then facilitates better clinical outcomes by avoiding delay in treatment decisions. Therefore, having a single assay that provides reliable TDM for both adalimumab and adalimumab biosimilars is important for physicians and patients. ABP 501, the first adalimumab biosimilar, is approved for the same indications as adalimumab (except those protected by regulatory exclusivity).

Objectives: The aim of this study was to evaluate the Promonitor® TDM kits for measurement of drug levels and AAA in serum samples from a selected representative subset of subjects, treated with ABP 501 or adalimumab reference product (RP) in the phase 3 study (NCT01970475).

Methods: A total of 30 subjects (15 ADA-positive; 15 ADA-negative) served as a representative subset in this evaluation. AAA positive control antibody and serum samples from subjects treated with either ABP 501 or adalimumab RP in the Phase 3 study were used to assess the suitability of the TDM (Promonitor®) kits for AAA (Promonitor® ANTI-ADL) and quantitative drug detection (Promonitor® ADL).

Results: The Promonitor®-ANTI-ADL TDM kit was able to detect a low level (10 ng/ml) of AAA positive control antibodies for ABP 501. In subjects whose serum was evaluated (18 treated with ABP 501 adalimumab biosimilar and 10 treated with adalimumab RP), the TDM kit produced 100% concordant positive or negative AAA results when compared to the assay that had been used in the phase 3 study. The quantitative drug assessment in subjects whose serum was evaluated (11 treated with ABP 501 and 9 treated with adalimumab RP) using the Promonitor® ADL TDM kit displayed a high degree of correlation (average Pearson’s r = 0.987) compared with results obtained in the phase 3 study.

Conclusion: This evaluation indicates that the Promonitor® kits are suitable for use in routine detection of AAA and in quantitating serum levels of the ABP 501 adalimumab biosimilar in patients.

**FR00646** EFFECT OF LONG-TERM MEDIUM-DOSE STEROID TREATMENT ON 18F-FDG PET/CT FINDINGS TO ASSESS VASCULAR AND MUSCULOSKELETAL INVOLVEMENT IN PATIENTS WITH POLYMYALGIA REUMATICA

R. Pinto-Peña, Monica Calderón-Guercio, Isabel Martínez-Rodríguez, Jose Ignacio Banzo, Miguel A. González-Gay, Ricardo Blanco. Marqués de Valdecilla University Hospital, Santander, Spain

Background: Fluorine-18-fluorodeoxyglucose (18F-FDG) PET/CT has been proposed as a promising tool for both musculoskeletal and vascular involvement in patients with polymyalgia rheumatica (PMR). Glucocorticoids (GC) may decrease the intensity of 18F-FDG uptake. Therefore, performance of PET/CT before steroid therapy is recommended. However, in many patients with PMR, large vessel vasculitis (LVV) is precisely suspected because of steroid resistance after a long-term treatment with GC 1.

Objectives: Our aim was to assess the influence of long-term medium-dose treatment on 18F-FDG uptake to discern if 18F-FDG PET/CT could be useful to evaluate musculoskeletal and vascular involvement in patients under treatment with GC.

Methods: Single-center study of 75 patients with PMR diagnosis based on 2012 EULAR/ACR criteria. All patients underwent a PET/CT scan due to LVV suspicion based on the presence of atypical symptoms and/or persistent symptoms despite steroid therapy. We considered two groups: a) Steroid-naïve PMR patients. b) Steroid-resistant PMR patients. Both musculoskeletal and vascular 18F-FDG uptake was assessed. The statistical analysis was performed with SPSS. Student’s t test or Mann-Whitney U test was used to compare continuous variables, and Chi-squared test or Fisher’s exact test for categorical variables as appropriate.

Results: We evaluated 75 patients, 27 men and 48 women (mean age ± SD: 68.2 ± 10.7 years). PET/CT was performed in 14 steroid-naïve PMR patients (18.7%) and 61 steroid-resistant PMR patients (81.3%). Patients under steroid treatment had received a median dose of Prednisone of 10.0 [5.0-15.0] mg/day during 9.0 [2.0-22.0] months. Vascular 18F-FDG uptake was more frequently detected in steroid-naïve patients. In regard to musculoskeletal 18F-FDG uptake, no statistically significant differences were seen between both groups (TABLE).
COST-EFFECTIVENESS OF RHEUMATOLOGY

FR00647
COST-EFFECTIVENESS OF RHEUMATOLOGY ULTRASOUND: RETROSPECTIVE AUDIT OF THE AINTREE ULTRASOUND CLINIC
Laura Ranieri1,2,3, Robert N. Thompson4, Jagdish R. Nair4, Cristina Estrach4,1
1Hospital General Alicante, Alicante, Spain; 2Fundación Valenciana de Reumatología, Valencia, Spain; 3Biomab, Bogotá, Colombia; 4Center for Rheumatoid Arthritis, Nursing Research, Bogotá, Colombia

Background: Ultrasound is useful to guide escalation of synthetic disease-modifying antirheumatic drugs (sDMARDs) and optimization of biological (bDMARDs) in inflammatory arthritis. However, there is limited published evidence of the cost effectiveness of the use of ultrasound in selecting patients for treatment tapering or escalation avoidance [1].

Objectives: To evaluate the usefulness of a Rheumatology-led Ultrasound Clinic.

Methods: Retrospective descriptive analysis of patients evaluated in the Aintree Ultrasound Clinic between January and September 2018. Our Ultrasound Clinic runs once a week and the scans are performed by expert rheumatologists (2 EFSUMB level 3, 1 advance EULAR level). Patients can be referred by specialist nurses or by other rheumatologists. Synovitis is assessed following EULAR/OMERACT guidelines.

Results: 113 patients were analysed and 10 patients were excluded (7 did not attend and 3 excluded due to not enough information available). The mean time from referral to ultrasound was 48.17 days (SD 20.21). Forty seven patients (42%) were referred by a doctor and 65 patients (58%) by a specialist nurse. Rheumatoid arthritis was the most frequent diagnosis with 74 patients (66%), other inflammatory arthritis in 23 patients (23%) and other non inflammatory conditions in 16 patients (14%). The indication for scan was to exclude subclinical inflammation in 91 patients (81%), to exclude inflammatory arthritis in 15 patients (13%) with not clear referral question in 7 patients (6%). The ultrasound was positive for inflammation (defined as >= power doppler OMERACT grade 2 in at least 1 joint)) in 37 patients (33%) all of whom had their treatment changed: sDMARD escalation (n=10), initiation bDMARD (n=4), change of bDMARD (n=2) and steroid therapy (intraarticular or intramuscular injection) the same day of the scan (n=28). Fifty eight patients were on sDMARD treatment: 14 patients had a change in treatment based on the scan (4 patients started biologic drugs, 10 patients had sDMARD escalation). There was no change of treatment in 44 patients, 7 of whom were being considered for bDMARDs before scan. Three of the 29 patients on bDMARD had a change of treatment based on the scan (2 changed to other biologic, in 1 patient another sDMARD was added). Steroidos were administrated the same day of the scan to 28 patients (intraarticular injection 10; intramuscular injection 18).

Conclusion: Ultrasound altered our management in most patients (n=108, 96%). Avoiding escalation to biologics in 7 patients who met clinical criteria saved an estimate of £35,000. We conclude that point of care ultrasound in patients with inflammatory arthritis is cost effective, not only in saving unnecessary escalation to high cost drugs but by prompt treatment of those with active disease.

FR10404
USEFULNESS OF THE ULTRASOUND IN THE DECISION-MAKING PROCESS ABOUT THE USE OF BIOLOGICALS IN PATIENTS WITH RHEUMATOID ARTHRITIS – EXPERIENCE OF REAL LIFE IN A MIDDLE INCOME COUNTRY
Edwin Castillo1, Michael Cabrella2, Diana Builrago-Garcia1, Pedro Santos-Moreno1, Eva Cardozo1, Ivania Ramirez2, Danny Gomez1, Sandra Barrieta1,1 Biomab – Center for rheumatoid arthritis, Rheumatology, Bogotá, Colombia; 2Biomab – Center for rheumatoid arthritis, EHR administration, Bogotá, Colombia

Background: Rheumatoid arthritis (RA) is an inflammatory autoimmune disease with a prevalence of 0.5 to 1% and the advances in pharmacological treatments offered to manage the disease have achieved many goals; however, the appearance of biologics has made the treatment of RA very costly, which has a great impact in the developing countries where accessibility to these therapies is lower. On the other hand, we now know that patients who are in clinical remission of disease activity by clinimetry in a significant percentage of cases may have the so-called subclinical activity that is found using ultrasound (US).

Objectives: To evaluate the usefulness of ultrasound within the component of evaluation of patients with moderate-severe activity of the disease before they are taken to a medical board making decision process about the initiation or switching of biologics.

Methods: Once a rheumatologist has identified a patient RA with clinical indication for biological therapy, patient is sent, among other things, to a medical board to take a collegiate decision about beginning or switching of biologics. Between 24 and 72 hours before the medical board decision, the patient undergoes an US (normally 12 joints are measured plus those clinically committed at that time), in order to determine if it presents disease activity by US which is considered negative for activity if the patient has synovitis ≤ 1 or has Power Doppler ≤ 1 in a single joint.

Results: During 12 months, 988 patients had clinical indication for using biologic based on moderate or high disease activity; they were evaluated by a multidisciplinary team to define the appropriateness of a therapy; mean DAS28 of patients was 4.81 ± 1.37. Once the patients were evaluated by US, the medical board of decisions did not in all cases decide to initiate or change a biological treatment; the choices made by the team were: 30% initiated or re-initiated biological therapy, in 29% of cases the team decided to wait and continuing observing the patient, 22% were switched to other biologic therapies, 12% did not have indication to start biological therapy because no activity by US and in 5% the medication dose was adjusted. Thus, in a total of 41% of the patients, biological therapy was not started or changed, which is important from the point of view not only clinical but also of the health payers.

REFERENCE:
Conclusion: Basically, this study shows that in patients with clinical indication of biological therapy by RA activity, a previous evaluation and a ultrasound are necessary in order to have a more accurate approach in making decisions; ultrasound is a practical, real-life, cost-low test to define activity in RA patients. Also we avoid high costs therapies for the management of rheumatoid arthritis, therefore we contribute not only to the health outcomes of patients but the health economic aspects in the management of RA.

FRI0649 PREVALENCE OF ANCA AND ANA IN PATIENTS WITH PULMONARY TUBERCULOSIS

SHARMA AMAN1, Yogesh Chander1,2, Marish Rath2, Garink Naidu1, Saket Jha1, Ranjana Mitti1, Sanjay Jain1, Digamber Behera1. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Internal Medicine, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Nephrology, Chandigarh, India; 3Post Graduate Institute of Medical Education and Research, Chandigarh, Immunopathology, Chandigarh, India; 4Post Graduate Institute of Medical Education and Research, Chandigarh, Pulmonary Medicine, Chandigarh, India

Background: Tuberculosis is known to have diverse clinical presentations, some of which may mimic systemic autoimmune diseases like ANCA associated vasculitis and systemic lupus erythematosus (SLE) 1. Considering the paucity of specific biomarkers in rheumatologic practices, caution needs to be applied while interpreting ANA and ANCA results, especially in TB endemic areas. Previous studies on prevalence of autoantibodies in tuberculosis have shown contrasting results 2-4. Objectives: To study the prevalence of ANCA subtypes and ANA in patients with bacteriologically confirmed pulmonary tuberculosis.

Methods: Patients with bacteriologically confirmed pulmonary tuberculosis were screened for recruitment. Anti-PR3, anti-MPO, anti-lactoferrin and anti-elastase ANCA subtypes were tested using enzyme-linked immunosorbent assay (ELISA). ANA was done by Indirect immunofluorescence (IIF) using Hep 2 cell lines. Patients who were positive for ANA were tested for presence for various extractable nuclear antigens using line immunoassay.

Results: Eighty nine patients were recruited in the study. Median age was 28 (range 20 – 46) years. The bacteriological confirmation was done via sputum examination in 81 (79 smear and 2 Gene Xpert) patients and bronchoalveolar lavage (BAL) fluid in 8 patients (5 smear and Gene Xpert). Out of 89, 62 patients were treatment naïve for pulmonary TB. The clinical features were fever (70%), Cough (99%), expectoration – (6.7%) patients had positive ANA (IIF). Line immunoassay in these patients detected anti-Schistosoma mansoni ANCA (5.5%) and ANA in 10.1%, ANA-IgM in 22.2%, and ANA-IgG in 11.1% patients respectively.

Conclusion: The NC findings were: morphological alterations (tortuous, bushy and/or ramified capillary) in 100% patients with pAPS, in 77% sAPS patients and in 88% aPL carriers; microhaemorragies in 56% pAPS patients, in 49% sAPS patients and 24% aPL carriers; enlarged hairpins in 23%, 41% and 18% subjects with pAPS, sAPS and aPL carriers respectively. In 6.3% sAPS patients, an early scleroderma pattern was detected. A NC semi-quantitative score 1 was found in 58.9% pAPS patients, in 57.4% sAPS patients and in 70.5% aPL carriers. Among those cases with abnormal NC findings, we found that a higher NC score (>2) was significantly more frequent in pAPS (21.7%) and sAPS (22.2%) patients respect to aPL carrier cases (8.3%) (p<0.005).

FRI0650 A NAILFOLD CAPILLAROSCOPY STUDY IN A COHORT OF PATIENTS WITH ANTI-PHOSPHOLIPID ANTIBODIES

Massimiliano Vasile1, Katia Stefanantoni1, Fulvia Cacciarelli2, Elena Marafioti1, Fabrizio Conti1, Valeria Riccieri1, Guido Valesini2. 1Sapienza Università di Roma, Medicina Interna e Specialità Mediche-Reumatologia, Roma, Italy; 2Sapienza Università di Roma, Medicina Interna e Specialità Mediche-Reumatologia, Roma, Italy

Background: Nailfold capillaroscopy (NC) is a simple and non-invasive diagnostic technique, able to investigate microvascular features. In subjects with anti-phospholipid autoantibodies (aPL) many different endothelial abnormalities have been described.

Objective: We aimed to investigate the role of NC in aPL positive (aPL +) subjects, highlighting the main microvascular alterations, detected by NC.

Methods: We enrolled 39 patients with primary anti-phospholipid syndrome (pAPS) (32 females, mean age 43 years, mean disease duration 7.8 years), 47 patients with secondary anti-phospholipid syndrome (sAPS) due to Systemic Lupus Erythematous (36 females, mean age 44 years, mean disease duration 15.5 years) and 17 aPL+ subjects without any autoimmune disease, defined as aPL carriers (16 females, mean age 42 years). All subjects underwent clinical and laboratory evaluations as well as NC with both characterization of morphological parameters and attribution of a semiquantitative score.

Results: The main NC findings were: morphological alterations (tortuous, bushy and/or ramified capillary) in 100% patients with pAPS, in 77% sAPS patients and in 88% aPL carriers; microhaemorragies in 56% pAPS patients, in 49% sAPS patients and 24% aPL carriers; enlarged hairpins in 23%, 41% and 18% subjects with pAPS, sAPS and aPL carriers respectively. In 6.3% sAPS patients, an early scleroderma pattern was detected.

Conclusion: Our findings show that some NC aspecific abnormalities are more frequently found in aPL positive subjects, mainly in pAPS and sAPS ones. Although not specific, such NC features seem to be associated with the presence of vascular risk factors. Thus NC could be regarded as a useful tool in order to evaluate microcirculation in aPL positive cases.

Background: Granulomatosis with polyangiitis (GPA) mainly involves the upper and lower respiratory tracts and kidneys and induces necrotising vasculitis and granuloma. Nasal biopsy has been recommended in GPA-suspected patients to not only completely rule out chronic rhinosinusitis, but also clearly discriminate its aetiology.

Objectives: We investigated whether the classification of GPA could be made without nasal biopsy in immunosuppressant drug-naïve 45 patients with chronic rhinosinusitis who had previously been classified as GPA.

Methods: We retrospectively reviewed the medical records of 45 patients with GPA. Twenty-six patients exhibited chronic rhinosinusitis, among which 16 patients underwent nasal biopsy (10 with granuloma and 6 without granuloma). We applied the 2007 European Medicines Agency algorithm for the classification of GPA, the 2012 Chapel Hill Consensus Conference Nomenclature of Vasculitis and the 2017 American College of Rheumatology/European League Against Rheumatism provisional classification criteria for GPA to them for reclassifying GPA. (Figure1)

Results: The mean age was 58.4 years and 17 patients were men. There were no differences in clinical and laboratory results between those with and without granuloma. Among 6 patients without granuloma on nasal biopsy, 3 patients with only ANCAs and chronic rhinosinusitis could be classified as GPA due to PR3-ANCA (or C-ANCA) positivity. Among 9 patients without nasal biopsy on granuloma, 3 patients with only chronic rhinosinusitis could be classified as GPA due to GPA-specific lung lesions. (Table 1) When we excluded an item of granuloma in 10 GPA patients with granuloma on nasal biopsy, 4 patients without ANCAs could be classified as GPA due to GPA-specific lung lesions and cartilaginous involvement. (Table 2)

Conclusion: Nasal biopsy is necessary and useful for classifying GPA. However, nasal biopsy could be replaced with PR3-ANCA (or C-ANCA) positivity, GPA-specific lung lesions and cartilaginous involvement in GPA suspected patients with chronic rhinosinusitis.

Implying and Validating the Predictive Accuracy of MRI Detected Subclinical Inflammation for Rheumatoid Arthritis Development in Clinically Suspect Arthralgia

Xanthe Matthijsen1, Fenne Wouters1, Debbie Boeters1, Aleid Boer1, Yousra Dakkak1, Ellis Niemantsverdriet1, Saskia Le Cessie1, Annette van der Helm1

Background: Presence of MRI-detected subclinical joint inflammation in clinically suspect arthralgia (CSA) is predictive for progression to Rheumatoid Arthritis. Despite high negative predictive values (84%), its positive predictive value (PPV) is moderate (31%).

Objectives: We studied if, in addition to the presence of inflammation, incorporating information on severity, number and combinations of MRI-inflammatory locations improves the predictive accuracy.

Methods: In the discovery cohort, 225 CSA-patients were followed on clinical arthritis development. Contrast-enhanced 1.5T MRIs were made of unilateral MCP(2-5), wrist and MTP(1-5)-joints at baseline and scored for synovitis, tenosynovitis and bone marrow edema. Severity, number and combination of locations (joint/tendon/bone) with subclinical inflammation were determined, with symptom-free controls of similar age category as reference. Cox regression was used for predictor selection. Predictive values were determined, with symptom-free controls of similar age category as reference.

Results: In both cohorts 15% developed arthritis <1-year. The number of locations HR 3.75 (1.49-9.48) and presence of MCP-extensor peritendinitis HR 2.54 (1.11-5.82); 1-2 locations HR 2.07 (1.05-4.05); ≥3 locations HR 3.81 (1.96-7.42) were independently predictive. Seventy and combinations of inflammatory lesions were not. Based on these variables, five risk categories were defined: no subclinical inflammation, 1-2≥3 locations, without MCP-extensor peritendinitis. PPVs ranged 5% (lowest category; NPV 98%) - 67% (highest category). Similar findings were obtained in the validation cohort; PPVs ranged 4% (lowest category; NPV 96%) - 63% (highest category).

Conclusion: Incorporation of the number of locations with subclinical inflammation and MCP-extensor peritendinitis in MRI-evaluation improved risk stratification, yielding PPVs up to 63-67%. This promotes optimal use of MRI-data in an evidence-based way.

DECREASING INCIDENCE OF CARDIOVASCULAR DISEASE IN PATIENTS WITH INCIDENT RHEUMATOID ARTHRITIS IN RECENT YEARS

Elena Myasoedova1, John Davis2, Veronique Roger2, Sara Achenbach3, Cynthia S. Crowson1, Mayo Clinic, Rheumatology, Rochester, MN, United States of America; Mayo Clinic, Cardiovascular Disease, Rochester, MN, United States of America; Mayo Clinic, Health Sciences Research, Rochester, MN, United States of America

Background: There is a recognized excess burden of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) as compared to the general population. Several studies suggested reduced CVD mortality in RA in recent decades [1-3]. Longitudinal studies on trends in occurrence of CVD events in RA patients over time, and studies comparing trends in CVD events in RA vs general population are lacking.

Methods: The study population comprised Olmsted County, Minnesota residents with incident RA (age ≥18 years, 1987 ACR criteria met in 1980-2009) and non-RA subjects from the same underlying population with similar age, sex and calendar year of index. All subjects were followed until death, migration, or 12/31/2016. Follow-up was truncated for comparability. Incident CVD events included myocardial infarction (MI), stroke (ischemic or hemorrhagic), coronary heart disease (CHD) death and first occurrence of any of these. Patients with CVD events prior to RA incidence/index date were excluded. Cox proportional hazards models were used to compare incident CVD events by decade, adjusting for age and sex. Cumulative incidence of CVD events adjusted for other causes was also computed.

Results: The study included 906 patients with RA (mean age 55.9 years; 69% female). There were 201, 299 and 406 patients with incident RA in 1980-89, 1990-99 and 2000-09, respectively. During median follow-up of 10.6, 10.4 and 10.2 years per decade, CVD events occurred in 31, 38,
and 31 patients. Patients with incident RA in 2000–09 had markedly lower cumulative incidence of any CVD events than patients diagnosed in 1990s and 1980s (Figure). Hazard ratios (HR) for any CVD events demonstrated significant reduction in CVD events among patients with incident RA in 2000s compared with incident RA in 1990s (HR: 0.52, 95% confidence interval (CI): 0.32–0.86) and a reduction approaching significance compared with incident RA in 1990s (HR: 0.65; 95% CI: 0.40–1.05). Patients with incident RA in 2000s were compared with 405 patients without RA in 2000s who experienced 30 CVD events during follow-up. Patients with incident RA in 2000s had no excess in CVD events over subjects without RA (HR: 0.88, 95% CI: 0.53–1.46). Results were similar for MI, stroke and CHD deaths when examined separately.

Conclusion: Our findings show a dramatic reduction in incidence of major CVD events in RA in recent decades. The gap in CVD occurrence between RA patients and the general population may be closing. These findings may reflect increased awareness, improved primary CVD prevention and more optimal RA disease management in recent years. More studies are needed to understand the reasons and implications of these trends.

FR0655 THE IMPACT OF PREGNANCY ON STRUCTURAL PROGRESSION IN PREMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

Deshire Alpizar-Rodriguez1, Frauke Förger2, Axel Finkoth1. On behalf of the physicians of the Swiss Clinical Quality Management Program for Rheumatoid Arthritis.1University of Geneva, Division of Rheumatology, Geneva, Switzerland, 2University Hospital and University of Bern, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland

Background: Disease activity often improves during pregnancy and worsens at the postpartum period [1]. The long-term effect of pregnancy on radiographic joint damage progression among premenopausal women with RA has been rarely studied.

Objectives: The aim of this study was to analyse the impact of pregnancy on radiographic progression in premenopausal women with RA.

Methods: This is an observational cohort study of RA patients included in the Swiss Clinical Quality Management in Rheumatoid Arthritis (SCQM-RA). Patients enrolled are followed-up yearly and have radiographic assessments at regular intervals. Information about female reproductive factors, such as pregnancies, breastfeeding and hormonal treatment were retrospectively retrieved using a questionnaire. For this analysis we included premenopausal women with at least two radiographic assessment and full information on reproductive factors. The primary outcome was the rate of radiographic progression (Ratingen erosion score). We analysed the radiographic progression between premenopausal women with at least one pregnancy and those with no pregnancies. Baseline time was the first radiographic assessment. We used a multilevel regression model for longitudinal data, adjusted for potential confounders, such as baseline age, disease duration, DAS-28 and treatment.

Results: Among 1966 women who were interviewed, 430 premenopausal women with sequential radiographic assessments during follow-up were analysed. Half of premenopausal women had at least one pregnancy. Women with at least one pregnancy were older than nulliparous (median of 41 vs 36 years, p=0.001) and had longer disease duration (median of 3.4 vs 2.6 years, p=0.04) (Figure 1). During follow-up, the rate of radiographic progression was lower in women with pregnancies than in nulliparous women [0.9% (95% CI: 0.0 to 1.9) vs 2.1% (95% CI: 0.9 to 3.1) over 10 years, respectively, p<0.04, Figure 1]. In a sub-analysis, the rate of radiographic progression appeared to be lower during the 13-year period after first pregnancy than after this period [0.2% (95% CI: -0.8 to 1.3) vs 2.6% (95% CI: 1.3 to 3.9) over 13 years, respectively, p=0.003]. We found no difference in the rate of radiographic progression between women with a single pregnancy and multiparous women.

Conclusion: In premenopausal women with RA, joint damage progressed more rapidly in nulliparous women than in women with at least one pregnancy. However, we cannot make any definite causal inference, since it is well possible that women renouncing getting pregnant might be patients with more severe disease. Radiographic progression appeared to increase the longer the time since pregnancy.

FR0656 ENVIRONMENTAL AND ATMOSPHERIC FACTORS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A REGRESSION ANALYSIS

George Stojan1, Frank Curriero2, Anton Klein2, Michelle A. Petri3,4. Johns Hopkins University Medical School, Baltimore, United States of America; 4Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America

Background: Understanding the role of environmental exposures in the development of SLE and their association with SLE activity may help identify modifiable risk factors and potential etiological mechanisms.

Objectives: We hypothesized that changes in fine particulate matter (PM2.5) concentration, ozone concentration, temperature, resultant wind, relative humidity, and barometric pressure are predictive of organ specific flares in lupus.

Methods: 1628 patients who fulfilled 4 of the 11 ACR or SLICC classification criteria for SLE were included in the analysis. The data ranged from 1999 to 2017. Maximum distance between visits was 110 days with 1-month time aggregation units. Disease activity was expressed as Physician Global Estimate (PGA), taken at
every patient visit. A flare was defined as a PGA score increase of 1 point or more compared to the previous visit. Environmental and atmospheric data was obtained from the EPA, including PM2.5 and ozone concentration, temperature, residual surface area, air pressure, and barometric pressure. The average values of each factor for 10 days prior to patient visit was calculated. Univariate and multivariate models were built in order to study the association of these variables with lupus disease activity. The models were adjusted for age, sex, income, racial distribution, and rural vs. urban patient residence. Multivariate logistic regression was used to identify significant determinants associated with lupus flares. Regression was performed for each organ flare outcome. Regression inference was based on generalized estimating equations (GEE) to account for the time repeated outcomes. Standard regression techniques on model building and evaluation were followed, including but not limited to performing both univariate and multivariate regressions, coefficient significance, collinearity, confounding, variable interactions and reductions in model AIC.

Results: Rash, serositis, hematologic, and joint flares were statistically significantly associated (p<0.05) with an increase in temperature in univariate and multivariate analysis. Renal flares were negatively associated with increases in temperature (p<0.05) in univariate and multivariate analysis. PM2.5 concentration was significantly associated (p<0.001) with rash, joint, serositis, neurologic, pulmonary, and hematologic flares in univariate and multivariate analysis. Ozone concentration, residual wind, and relative humidity were significantly associated with lupus flares in univariate analysis only, while barometric pressure had no associations.

Conclusion: There is a strong association between changes in PM2.5 concentration and temperature 10 days prior to patient visit and organ specific lupus activity at the visit. These data could add an important aspect to lupus trials, the outcomes of which may be affected by so far unrecognized environmental factors, and ultimately it could allow predictive modelling of lupus flares which would revolutionize the approach to treatment.

#### FRIO657

**METABOLIC SYNDROME PRECEDES THE ONSET OF HIP AND KNEE PAIN AND THE RISK IS NOT MODIFIED BY DIET OR CHANGES IN BMI**

Max Yates1,2, Jordan Tsigaris2, Shabina Hayat1, Robert Luben1, Jack Dainty1, Max Yates1,2, Jordan Tsigaris2, Shabina Hayat1, Robert Luben1, Jack Dainty1

**Objectives:** To examine longitudinal data from a large prospective population-based cohort to assess the association between metabolic syndrome components and the subsequent development of either knee or hip pain over 10 years of follow-up. Methods: Known risk factors data were obtained at enrolment to the EPIC-Norfolk cohort between 1993 and 1997. Data were available on anthropometric variables, smoking status and lipid metabolites. Knee and hip pain were self-reported at 18 months, 3 and 10 years when respondents reported significant pain in either knee or hip on most days in the preceding month. Metabolic syndrome components were defined in line with the Alberti formula. Logistic regression was used to investigate metabolic syndrome components: waist circumference (men >102 cm, women >88 cm), low HDL (men <1.0 mmol/L, women <1.3 mmol/L), high triglycerides (>1.7 mmol/L) and their association to incident pain and any effect-modification of dietary patterns and changes in BMI over time. Results: Amongst 20,517 respondents (age at enrolment 59.7 years (SD 9.2), 62% were female), there were 3,886 who reported knee pain and 2,619 who reported hip pain at 18 months. By the end of follow-up there were 2,619 who had developed incident knee pain and 1,752 who had developed incident hip pain. In a logistic model adjusted for age and sex, significant associations were seen for incident pain for ever-smoking (knee: odds ratio 1.22, 95% CI 1.11, 1.33 p<0.001), (hip: odds ratio 1.21, 95% CI 1.08, 1.35 p<0.001) and obesity (knee: OR = 1.70 95% CI 1.51, 1.91 p<0.001), (hip: OR = 1.68 95% CI 1.47, 1.92 p<0.001). Adjustment for obesity, components of the metabolic syndrome associated with pain included waist circumference (knee: OR = 1.17 95% CI 1.03, 1.33 p<0.019), (hip: OR = 1.37 95% CI 1.17, 1.59 p<0.001) and for triglycerides, low HDL (OR = 1.15 95% CI 1.05, 1.27 p<0.003) and high triglycerides (OR = 1.10 95% CI 1.00, 1.21 p=0.043). These associations were not modified by dietary patterns nor changes in weight over the follow-up interval. Conclusion: There is a strong association between metabolic syndrome and a predictor for the future onset of hip and knee pain over an interval of 10 years and the risk is not modified by diet or subsequent weight change. These data suggest that preventative strategies need to be targeted early in the disease course, and should include a range of measures including smoking cessation and those that prevent the onset of metabolic syndrome.

#### FRIO658

**INCIDENCE AND PREVALENCE OF VACCINE PREVENTABLE INFECTIONS IN ADULT PATIENTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES (AIIRD): A SYSTEMATIC LITERATURE REVIEW InformING THE 2019 UPDATE OF THE EUULAR RECOMMENDATIONS FOR VACCINATION IN ADULT PATIENTS WITH AIIRD**

Victoria Furer1, Christien Rondaans2, Marbes W. Heijstek1, Ulf Müller-Ladner1, Sander van Assen2, Jacob M. van Laar3, Marc Bijl1, On Efkyam1, Tel Aviv University, Tel-Aviv-Yafa, Israel, 1University of Groningen, Groningen, Netherlands; 2Utrecht University, Utrecht, Netherlands; 3University of Gessens, Giessen, Germany

**Background:** Despite the well-established fact of a high burden of infections among patients with autoimmune inflammatory rheumatic diseases (AIIRD), little evidence is available regarding the real incidence and prevalence of vaccine preventable infections (VPI) in this population. **Objectives:** To update the evidence on the incidence and prevalence rates of VPI in patients with AIIRD and compare the data to the general population when available. Methods: A systematic literature review was performed using Medline, Embase, and Cochrane library, from October 2009 to August 2018. Search terms were defined for AIIRD and VPI. Observational studies including cohort studies for incidence rates and cross-sectional studies for prevalence rates were included, as well as systematic reviews of cohort studies and meta-analyses. The primary outcome was the incidence or prevalence of VPI in the adult AIIRD population. Meta-analysis was performed when appropriate. Results: The search identified 2876 records, out of which 63 met the inclusion criteria. Data on the following VPI rates was retrieved and analyzed: influenza (incidence: n=4), pneumococcal disease (incidence: n=7), hepatitis B virus (HBV) (incidence and prevalence: n=10), herpes zoster (HZ) (incidence: n=29), human papilloma virus (HPV) (incidence and prevalence: n=13). For influenza, limited data pointed to an increased incidence (409.33 vs 306.12 cases per 100,000 patient-years in patients with rheumatoid arthritis (RA) vs controls, respectively) and influenza-related complications in patients with AIIRD. Data on pneumococcal disease, available mainly for patients with systemic lupus erythematosus (SLE), showed a substantially increased risk in all age groups compared to controls (incidence rate ratio (IRR) 4.7, 95% confidence interval (CI) 3.7-6.0). For HZ, an increased risk was observed across all patients with AIIRD in comparison to the general population: pooled incidence rate 2.4, 95% CI 2.05-2.76, with the highest incidence rates observed in inflammatory myositis (pooled IR 35.98, 95% CI 32.33-39.64), followed by SLE (pooled IR 18.87, 95% CI 8.7-29.64), and RA (pooled IR 11.64, 95% CI 9.37-13.91). Studies on HPV mainly investigated the SLE population in the Latin America and Asia: HPV pooled prevalence 26%, 95% CI 17%-36% and pooled prevalence ratio 1.58, 95% CI 0.74-3.36 in comparison with the general population. In RA, limited data showed a similar prevalence of HPV in patients and controls: pooled prevalence ratio 0.72, 95% CI 0.46-1.12. For hepatitis B virus, pooled prevalence of hepatitis B surface antigen in patients with AIIRD was similar to the general population. 3%, 95% CI 1%-5%.
Conclusion: Current evidence shows an increased risk of vaccine-preventable infections in patients with AIIRD, emphasizing that prevention of infections is essential in these patients.

Remission Persistence in Rheumatoid Arthritis, Psoriatic Arthritis and Axial Spondyloarthritis Under Biologic Treatment

Background: Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) under biologic treatment are increasingly achieving prolonged remission and tapering treatment is becoming standard practice. However, the optimal timing to start tapering remains unclear and predictors of loss of remission (LOR) are missing. Guidelines disagree on whether to wait for 6 or 12 months of sustained remission before tapering.

Objectives: To determine whether longer sustained remission (6 versus 12 months) influences subsequent LOR rates and to identify predictors of LOR.

Methods: We used the Rheumatic Diseases Portuguese Register (Reuma.pt), to identify RA, PsA and axSpA patients on stable biologic treatment in a single center and retrospectively analyze those who achieved sustained remission for at least 6 and 12 months. Survival analysis was used to characterize stability of remission and identify predictors of LOR. The Cox proportional hazards regression was stratified by diagnosis and adjusted for age, gender, smoking, baseline disease activity, type of biologic, previous switches and starting year of biologic treatment.

Results: 195 patients (100 RA, 51 PsA and 44 axSpA) of 1078 patients (785 RA, 116 PsA, 177 axSpA) registered in Reuma.pt at a single center and treated with biologics between 1999 and 2018, had at least one remission period with a minimal duration of 6 months. This corresponded to 310 individual remission periods longer than 6 months, 232 of which (74.8%) were longer than 12 months. Median remission time (since the start of remission period) was 78.6 weeks overall vs. 99.0 weeks for patients with a minimum 12 months remission (difference in median survival: 20.4 weeks). PsA patients showed significantly longer remission periods (p=0.0001), followed by axSpA and RA. We identified active smoking (HR 1.96, p=0.008 for the total population; HR 1.53, p=0.20; HR 7.42, p=0.01, HR 0.74, p=0.79 for RA, PsA and axSpA, respectively), and infliximab use (HR 2.23, p=0.005 for the total population; HR 4.07, p=0.001, HR 3.20, p=0.16, HR 0.62, p=0.62 for RA, PsA and axSpA, respectively; subcutaneous TNF inhibitors (TNFi) used as index category) to be significantly associated with LOR. A sensitivity analysis excluding infliximab patients further suggested female gender (HR 3.21, p<0.001) and duration of disease until first biologic (HR 1.05, p=0.031) as important co-variates.

Figure 1 – time to loss of remission considering a single flare (a) vs. persistent flare (b), all patients (minimum 150 days in remission). Number of failure events indicated in parenthesis.

Figure 2 – time to loss of remission considering a single flare (a) vs. persistent flare (b), only patients with minimum 320 days in remission. Number of failure events indicated in parenthesis.
Results: Before coronary angiography fasting blood samples were collected and plasma levels of interleukin-6 (IL-6), C-reactive protein (CRP) and serum amyloid A (SAA) were measured by immunonephelometry. IL-6 and SAA polymorphisms were genotyped.

Results: During a median observation time of 9.9 years 949 deaths (30.3%) occurred, of these 597 (19.2%) died from cardiovascular events. Plasma levels of IL-6, CRP and SAA were associated with unstable CAD as well as established risk factors including type 2 diabetes, smoking, lower eGFR, lower triglycerides and lower HDL-C. In addition, IL-6 correlated with age, use of lipid lowering therapy and hypertension, SAA correlated with female gender and hypertension, and CRP correlated with female gender, lipid-lowering therapy and BMI. After adjustment for established cardiovascular risk markers and the other two inflammatory markers, SAA was found an independent risk factor for cardiovascular mortality after a short-term follow-up (1 year) with a HR of 1.41 (1.03-1.93, p=0.030), whereas IL-6 was identified as an independent risk factor for long-term follow-up (3, 5-9.9 years) with HRs of 1.21 (1.02-1.43, p=0.006), 1.22 (1.06-1.40, p=0.006) and 1.18 (1.07-1.31, p=0.001), respectively. Although 6 SNPs in the SAA gene were significantly associated with SAA plasma concentrations (none of the IL-6 SNPs associated with IL-6 levels), the genetic risk score was not associated with mortality.

Conclusion: In our large, long-term LURIC cohort study we demonstrate for the first time prospectively that plasma levels of IL-6 and SAA are not only associated with cardiovascular risk factors and the prevalence of CAD but also independently predicted cardiovascular mortality. These findings underline the importance of low-grade systemic inflammation for the cardiovascular risk and the prognostic relevance of inflammatory biomarkers, independently predicting cardiovascular mortality. Although it was not within the focus of this study, our findings might suggest that even low-grade inflammation is unfavourable in chronic rheumatic disease.

Disclosure of Interests: None declared.

LONG- AND SHORT-TERM ASSOCIATION OF LOW- GRADE SYSTEMIC INFLAMMATION WITH CARDIOVASCULAR MORTALITY

Jan Leipe1, Anna-Isabelle Kaetsch2, Marcus Kleber3, Hubert Schamaggi4, Wolfgang Sattler5, Winfried Mäcz5, Ernst Malle5, Bernhard Kraemer6, University Medical Centre Mannheim, Division of Rheumatology, Mannheim, Germany; 2University Medical Centre Mannheim, Department of Medicine V, Mannheim, Germany; 3Medical University of Graz, Graz, Austria; 4Synlab Academy, Mannheim, Germany

Background: Evidence suggests a critical role for inflammation in the pathogenesis of coronary artery/heart disease (CAD/CHD), implicating inflammatory molecules as central mediators of chronic inflammatory processes within the vascular wall. In this regard, patients with chronic inflammatory disease such as RA and SLE are at increased risk, which was attributed to the high levels of inflammatory mediators. However, less is known about the association of low-grade systemic inflammation with the cardiovascular risk.

Objectives: The aim of the present study was therefore to evaluate biomarkers representing low-grade systemic inflammation and their association with mortality in a large cohort of patients.

Methods: The Ludwigshafen Risk and Cardiovascular Health (LURIC) study included 3316 consecutive patients undergoing coronary angiography between June 1997 and May 2001 with a median follow-up of 9.9 years. Before coronary angiography fasting blood samples were collected and plasma levels of interleukin-6 (IL-6), C-reactive protein (CRP) and serum amyloid A (SAA) were measured by immunonephelometry. IL-6 and SAA polymorphisms were genotyped.

Results: During a median observation time of 9.9 years 949 deaths (30.3%) occurred, of these 597 (19.2%) died from cardiovascular events. Plasma levels of IL-6, CRP and SAA were associated with unstable CAD as well as established risk factors including type 2 diabetes, smoking, lower eGFR, lower triglycerides and lower HDL-C. In addition, IL-6 correlated with age, use of lipid lowering therapy and hypertension, SAA correlated with female gender and hypertension, and CRP correlated with female gender, lipid-lowering therapy and BMI. After adjustment for established cardiovascular risk markers and the other two inflammatory markers, SAA was found an independent risk factor for cardiovascular mortality after a short-term follow-up (1 year) with a HR of 1.41 (1.03-1.93, p=0.030), whereas IL-6 was identified as an independent risk factor for long-term follow-up (3, 5-9.9 years) with HRs of 1.21 (1.02-1.43, p=0.006), 1.22 (1.06-1.40, p=0.006) and 1.18 (1.07-1.31, p=0.001), respectively. Although 6 SNPs in the SAA gene were significantly associated with SAA plasma concentrations (none of the IL-6 SNPs associated with IL-6 levels), the genetic risk score was not associated with mortality.

Conclusion: In our large, long-term LURIC cohort study we demonstrate for the first time prospectively that plasma levels of IL-6 and SAA are not only associated with cardiovascular risk factors and the prevalence of CAD but also independently predicted cardiovascular mortality. These findings underline the importance of low-grade systemic inflammation for the cardiovascular risk and the prognostic relevance of inflammatory biomarkers, independently predicting cardiovascular mortality. Although it was not within the focus of this study, our findings might suggest that even low-grade inflammation is unfavourable in chronic rheumatic disease.

ASSOCIATIONS OF CURRENT AND CHILDHOOD SOCIOECONOMIC STATUS WITH PATIENT-REPORTED HEALTH OUTCOMES AMONG PATIENTS WITH KNEE OR HIP OSTEOARTHRITIS IN A FAMILY PRACTICE SETTING IN MEXICO CITY

Julio Pisarty Alatorre, Maria Victoria Grycoches Rebollar, Instituto Mexicano del Seguro Social, HGZMF 5, Mexico, Mexico; 2Instituto Mexicano del Seguro Social, Unidad de Investigación en Epidemiología Clínica HGR1, Mexico, Mexico

Background: The life-course approach is a useful framework to understanding socioeconomic inequalities in the prevalence and outcomes of chronic disease, and in particular in osteoarthritis (OA). Previous studies have measured Socioeconomic Status (SES) in 2 points of the life-course (childhood and current) and found consistent relationships between them and both prevalence and presence of worse outcomes, but this relationship has been little explored in the Latin-American region where exposure to low SES throughout the life-course is higher than in developed countries.

Objectives: Our aim was to investigate the association of current and childhood SES with functional status, quality of life and disability among patients with knee or hip OA.

Methods: We recruited 146 patients with a mean age of 69.4 yr. 80% were female; 92%, 30% and 45% suffered from knee, hip and other joint OA, respectively. 60% had incomes in the upper 2 quintiles of the general Mexican population. We found current income to be the best predictor of WOMAC (Spearmans r=0.354, p=0.01), AMICAL (r=0.362, p=0.01) and HAQ-DI scores (r=0.335, p=0.01), and education to be correlated with all three scores as well. Occupation type was significantly associated with AMICAL and HAQ-DI but not WOMAC scores. Paternal and maternal education, and maternal occupation type, were significantly associated only with AMICAL scores.

Disclosure of Interests: None declared.

Conclusion: Among patients with knee or hip OA in our setting, current SES is a significant predictor of functional status, quality of life and disability, while childhood SES – best modeled by maternal education – is a significant predictor of quality of life. More research is needed to elucidate the relationship of SES throughout the life course with outcomes among patients with OA.

FR0662 ACTIVATION AND LEUKOCYTE ADHESION IS ASSOCIATED WITH VASCULAR DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

Marta Aguilar-Zarco1, L Montoliu-Chiva, Aña V Orenes Vera, 1Vázquez-Gómez, 1Isabel Andújar, 2Pérez, 2Patricia García-Martínez, 2A Martínez-Ferrer, 1Elia Vallés-Pascual, 1Ybáñez-García, 1A Sendra-García, 1, 2V Núñez-Monje, 1, 2I Torner-Hernández, 1V. Espugues, 1Juanjo J. Llarena-Sancho, 1Hospital Universitario D. Peset. Rheumatology, Valencia, Spain; 2Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunidad Valenciana-FISABIO., Valencia, Spain; 3Universitat de València, Pharmacology, Pharmacology, Valencia, Spain; 4Universidad Europea de Valencia, Biomedic Science, Valencia, Spain

Background: Patients with inflammatory rheumatic diseases, such as rheumatoid arthritis (RA) or psoriatic arthritis (PsA), have a higher cardiovascular risk than the general population. There are data in other pathologies about the role of leukocyte adhesion on endothelial damage.

Objectives: To evaluate the relationship between leukocyte adhesion and subclinical vascular damage in patients with RA and PsA.

Methods: Observational, cross-sectional exploratory study. Patients with RA and PsA who had at least one previous vascular study were recruited in a tertiary hospital during a period of 3 months. All of them donated a sample of fresh blood. Neutrophils were isolated and perfused on a monolayer of healthy endothelial cells of the umbilical cord vein to evaluate its degree of activation, determining the leukocyte adhesion parameter. The expression of different adhesion molecules was analyzed by flow cytometry. We also gathered demographic (sex, age, BMI), clinical (disease duration, classical CV risk factors) and analytical (CRP, ESR) variables. The previous vascular studies consisted of an exploration of the extracranial carotid tree with an Essato MyLab70XVG ultrasound scanner with a linear probe (7-12MHz) and an automated program for measuring the carotid intima-media thickness (CIMT) using (“Quality intima media thickness” or “real-time, QIMT”), the presence of atheroma plaques as per the Mannheim consensus and the measurement of pulse wave velocity (v’P) using the Mobi or graph device. We consider as pathologic the vascular study with the presence of abnormal plaque and/or IMT (>900µ) and/or v’P (>10ms). The statistical analysis was performed with the SPSS Statistics 22.0 program.

Results: We included 27 patients, 18 women and 9 men, with a mean age of 58.07 (SD 11.64). Eight patients were diagnosed with RA and 19 with PsA, with mean disease duration of 14 years (SD 7.14). Of these 27 patients, 15 were on biologics, 11 were treated only with DMARDs and one patient was naive for any immunomodulatory treatment. In addition, 14 (51.9%) were taking NSAIIDs and 7 (25.9%) glucocorticoids. Regarding cardiovascular risk factors, 51.9% were exposed to tobacco, 25.9% suffered hypertension, 37% were dyslipidemic, 11% were diabetic and 11% were obese, with an average of 1.41 classic cardiovascular risk factors (SD 1.36) per patient. The previous vascular study had been considered pathological in 44.4% of the patients.

A tendency to greater leukocyte adhesion was observed in these patients with pathological IMT values (>0.059) and in those patients who presented atheromatous plaque (p = 0.66). No significant associations were found in relation to the rest of the adhesion parameters analyzed, nor could subanalyses be performed due to the small sample size.

Conclusion: Our preliminary data suggest that an increase in leukocyte adhesion on the endothelium is involved in the mechanisms of subclinical atherosclerosis in patients with RA and PsA. Studies with a larger sample size will allow us to confirm these findings, as well as the factors implicated in their development.

FR0663 TREATMENT WITH BIOLOGIC DRUGS OF PREGNANT WOMEN WITH AUTOIMMUNE DISEASE, EXPERIENCE OF A REFERENCE CENTER IN HIGH RISK PREGNANCY WITH AUTOIMMUNE DISEASES

Jorge Álvarez Troncoso1, Edurne Hueso Zaldíve, Nuria Martínez Sánchez, Gemmán Daroca Bengoa, Luis Ramos Ruperto, Ángel Robles Marhuenda
1Hospital Universitario La Paz, Unidad de Enfermedades Autoinmunes Sistémicas, Servicio de Medicina Interna, Madrid, Spain; 2Hospital Universitario La Paz, Servicio de Ginecología y Obstetricia, Madrid, Spain

Background: Autoimmune diseases predominantly affect women of child-bearing age. These women must be without clinical activity before conception, which is usually achieved thanks to immunosuppressive drugs. Also, information on new drugs does not include their possible effects on pregnancy because pregnant women are usually excluded from clinical trials.

Objectives: The aim of the study is to evaluate the safety of biological drugs (BD) in pregnant patients with different autoimmune diseases (AD).

Methods: Patients were prospectively followed in a reference Spanish center for high-risk pregnancies and AD. Follow-up was performed by a multidisciplinary team with at least one obstetrician and one expert clinician in autoimmune diseases. Females exposed to BD during the periconceptional period or during pregnancy were included in the study. Obstetric and neonatal outcomes were assessed.

Results: Between 2015 and 2018 we identified 37 exposed pregnancies in 35 women affected by different AD. At the start of pregnancy, 18 patients were taking infliximab, 11 adalimumab, 3 natalizumab, 2 rituximab, 1 etanercept y 1 tocilizumab.

BD that required BD were Crohn’s disease (20 patients, 54.1%), ulcerative colitis (7, 18.9%), rheumatoid arthritis (4, 10.8%), ankylosing spondylitis (3, 8.1%) and multiple sclerosis (3, 8.1%). Regarding pregnancies, 5 (13.5%) had left the BD just before the pregnancy. Of these, 1 remained stable and 4 (80%) had a flare during pregnancy requiring restart of BD. Of the 32 pregnancies who took the BD during pregnancy, 8 (25%) abandoned the treatment after knowing the pregnancy, meaning that 2 of them flared; 10 (31.5%) continued with the treatment until the end of the second trimester (week 25-26) and 14 (43.7%) continued during the third trimester, 4 of them kept the drug during the entire gestation due to disease activity.

In our study there was a positive correlation between periconceptional abandonment of the BD and the risk of presenting a flare (p=0.003), especially in the first and second trimesters (p=0.004). However, no relationship was found between BD and infections in the newborn (p=0.05), nor between each of the BD with the risk of infections. Preconceptional treatment reduced the risk of flare (OR 0.545, 95%CI) and the risk of maternal complications (OR 0.5, 95%CI). Indeed, the presence of a flare during pregnancy increased the risk of maternal complications (OR 2.0, 95%CI).

Pregnancies under BD were compared to healthy controls adjusted by age finding no differences in the perinatal delivery rate (p=0.05), in the induction rate of delivery (p=0.05) nor in the cesarean section rate (p=0.05).

Conclusion: In our series, the use of preconceptional BD and/or during pregnancy is not associated with an increase of maternal or fetal complications. However, fewer flares were observed. This may imply that BD can be a good tool for the treatment of women of childbearing age since control of the disease resulted in better maternal-fetal outcomes. However, more studies are needed to determine the usefulness and safety of these treatments during pregnancy.

DISEASE ACTIVITY IS THE MAJOR DISCRIMINATOR WHEN DEFINING REFRACTORY RHEUMATOID ARTHRITIS

Marcel Becede, Josef S. Smolen, Daniel Aletaha, Division of Rheumatology, Department of Medicine 3, Vienna, Austria

Background: Rheumatoid arthritis (RA) is characterised by the presence of a progressively destructive joint inflammation. Even in times of modern therapeutics, a subgroup of patients continues to be refractory to numerous consecutive therapeutic interventions with regards to control of inflammation and joint damage. To date, there exists no definition for refractory RA.

Objectives: To explore different modifications of a definition for refractory RA.

Methods: Here we defined the base case of refractory RA as patients who had experienced ≥3 treatment courses (with at least one biological failure) over a minimum of 18 months since first treatment initiation (to avoid counting treatment courses that were given for a too short period), and the lack of reaching the treatment goal of low disease activity or remission (defined by a Clinical Disease Activity Index, CDAI, >10). We then modified our working definition based on these four variables (disease duration: 12/18/24 months; disease activity: moderate/high; number of treatment courses: ≥3;≥4; different biologic agents: ≥1/≥2).

Results: From our clinic’s ongoing longitudinal data set we identified 68 refractory patients out of 688 RA outpatients. There was virtually no difference based on modifying disease duration, so we kept our working definition of a minimum disease duration of at least 18 months (n=464; 12 months: n=466; 24 months: n=453). Changing the disease activity component of the definition had a great impact on the identified refractory RA population, by requiring high instead of moderate disease activity (MDA: CDAI >10, n=129 vs. HDA: CDAI >22, n=31). In both, the MDA and the HDA group of patients, we could observe ≥60% of patients, who already experienced at least three treatment courses (MDA, n=82/129; HDA, n=21/31). Above a half in each group qualified as refractory according to the criterion of an addition fourth failed treatment course (MDA, n=64/129; HDA, n=15/31). When further stratifying patients based on the number of failed different biologic DMARDs, we could observe that regardless of the level of disease activity and number of failed treatment courses, most patients experienced at least one or even a second biologic agent (table).

Conclusion: The level of disease activity is the major discriminator when defining a population of refractory RA. The duration of treatment does not significantly impact the identification of refractory RA. The number of failed treatment courses and insufficient responses to biologic DMARDs further helps characterizing patients with refractory RA. Considerations of the impact of these different characteristics of refractory disease may well inform future criteria for refractory RA.

THE ROLE OF CLINICAL JOINT INFLAMMATION AND ACUTE PHASE RESPONSE ON STRUCTURAL PROGRESSION OF PATIENTS WITH PSORIATIC ARTHRITIS

Carina Bord, Farideh Alasti, Daniel Aletaha, Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria

Background: Psoriatic arthritis (PsA) belongs to the group of the spondyloarthropathies. It is associated with psoriasis and typically seronegative for autoantibodies. PsA disease activity can be measured using the Disease Activity in Psoriatic Arthritis (DAPSA) score which is based on both clinical (e.g., swollen joint count, SJC) and systemic (e.g., C-reactive protein, CRP) markers of inflammation. [1] However, the impact of clinical and systemic inflammation on structural progression is unclear.

Objectives: To determine the contribution of clinical and systemic inflammation on structural progression of patients with PsA.

Methods: In a secondary data analysis, we analyzed patient data from the IMPACT 2 trial of infliximab (INF) vs. placebo (PLC) in patients with established PsA (disease duration in years: INF: 7.5±7.8, PLC: 8.4±7.2). Concomitant methotrexate treatment was allowed but not mandatory in both treatment arms. [2] We obtained modified Sharp-van-der-Heyde scores from X-rays performed at baseline and after one year to compute radiographic progression. We further extracted levels of SJC and CRP and calculated time-averaged SJC (tsSJC) and CRP (tsCRP) values to reflect the clinical and systemic inflammation, respectively. In a multivariable logistic regression model, we assessed the impact of tsSJC, tsCRP, and their interaction, on structural progression. Next, we divided patients into different subgroups depending on their tsSJC and tsCRP levels into active (+) or inactive (-). We tested whether radiographic progression was different in tsSJC+ vs. tsSJC– and tsCRP+ vs. tsCRP– using the Mann-Whitney U test.

Results: 200 patients were enrolled in the IMPACT 2 trial (100 INF, 100 PLC). 151 patients were included in the analyses (76 PLC, 75 INF). Due to drop out or missing data, the remaining 49 patients were not considered for further analyses. Patients in the INF arm showed no radiographic progression (−1.16±3.96), while patients in the PLC arm showed little progression (0.74±2.98). We therefore focused on the 76 PLC and 75 INF patients. Despite the small overall progression, tsSJC, tsCRP, and their interaction were associated with radiographic progression (OR for tsSJC: 1.24, CI 95%: 1.04–1.47, p=0.016; OR for tsCRP: 6.08, CI 95%: 1.12–33.03, p=0.036; interaction term: p=0.097). Radiographic progression was higher in tsSJC+ patients compared to tsSJC– patients (1.05±2.31 and 0.56±2.30, respectively; p=0.16), as well as numerically higher without statistical significance in tsCRP+ vs. tsCRP– patients (1.14±3.23 and 0.05±2.37, respectively; p=0.532). Also, despite the limited power of subgroup analyses, there was evidence that SJC activity plays a role in CRP patients (p=0.076), whereas CRP activity seems to be of less importance in SJC– patients (p=0.643).

Conclusion: In patients with PsA, both clinical and systemic inflammation have impact on structural progression; in patients without systemic inflammation, clinical joint activity may still be considered as a risk factor for progression.

RESULTS:
At 18/01/2019, information on 80 098 drug prescriptions in 13 614 patients was collected in the TARDIS-RA registry. Of these 80 098 drug prescriptions, 30 434 (38.0%) were csDMARDs and glucocorticoids, and 49 664 (62.0%) were bDMARD or tsDMARD prescriptions. This last category consisted of 30 380 (61.2%) tumour necrosis factor inhibitor (TNFi) bDMARDs, 17 104 (34.5%) non-TNFi bDMARDs and 2 170 (4.3%) tsDMARDs. Only 642 (2.3%) TNFi biosimilar prescriptions were registered. Fig 1 shows the yearly evolution of bDMARD and tsDMARD prescription in Belgium from 2015 to 2018. At first registered interaction with the rheumatologist, the 13 614 patients had a median (IQR) age of 59 (50-68) years with a median (IQR) disease duration of 9 (4-16) years; 9 666 (73.4%) were female. The clinical characteristics showed a median (IQR) DAS28CRP of 3.6 (2.1-4.8) and a median (IQR) HAQ of 1.1 (0.6-1.8). Of patients at first time registration, 36.7% could be validated as being bionaive and 62.5% as bioexperienced.

Conclusion: Approximately 70 000 individuals in Belgium are estimated to have a RA diagnosis. Depending on numbers of other western European countries, 20%-25% of them would be expected to receive ts/bDMARDs. This suggests that almost the entire Belgian RA population on biologic treatment is covered by TARDIS. The registration of initiation, prolongation and discontinuation of every ts/bDMARD since 2015 combined with the simultaneous collection of demographic and clinical data, will make the TARDIS-RA registry a useful and powerful tool for the long-term drug analyses in Belgian patients with RA.

HOW DO GOUT-RELATED COMORBIDITIES AND LIFESTYLE FACTORS CLUSTER IN A LARGE HEALTH SURVEY OF THE GENERAL POPULATION? – RESULTS FROM THE MALMÖ PREVENTIVE PROJECT COHORT IN SOUTHERN SWEDEN

Tahzeeb Fatima1, Peter Nilsson2, Carl Turesson2, Mats Dehlin3, Nicola Dalbeth3, Lennart T.H. Jacobsson1, Melita C. Kapetanovic2, 1University of Gothenburg, Dept of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2Lund University, Dept of Clinical Sciences, Malmö, Sweden; 3University of Auckland, Dept of Medicine, Auckland, New Zealand

Background: Several factors (comorbidities and lifestyle) have been shown to be associated or predict hyperuricemia or gout. Since these factors often are closely associated with each other, they may represent a few pathophysiological pathways rather than being individually important predictors. Identifying clusters of such factors may thus lead to a better understanding of the pathways involved in increased risk of gout. Two studies have previously indicated four to five phenotype clusters in prevalent cohorts of gout patients of European ancestry1,2. However, identification of clusters of gout-associated factors in the general population is lacking.

Objectives: To identify clusters of gout-related baseline comorbidities and lifestyle factors among participants in a population-based health survey.

Methods: The Malmö Preventive Project is a screening program for cardiovascular risk factors, alcohol abuse and breast cancer in Malmö, Sweden. Overall, 33,346 individuals (67% male, mean age 45.7 years at inclusion) participated. The study population was screened between 1974 and 1992. A subset of 22,057 individuals (screening period: 1975-1992) was eligible for the cluster analysis. Agglomerative hierarchical cluster analysis was performed to group similar variables and subgroup individuals with similar characteristics, using principal component and Ward’s minimum variance methods in Rv3.5.2, respectively. Variables selected to cluster were obesity (BMI>30 kg/m²), renal dysfunction (eGFR<60 mL/min/1.73m²), diabetes mellitus (DM), hypertension, prevalent cardiovascular disease (CVD), dyslipidemia (abnormal cholesterol or triglyceride values), pulmonary dysfunction (PD, FEV₁/FVC on spirometry<0.7), smoking and use of diuretics.

Results: Overall, 66% of the participants in the cluster analysis were males, mean age was 47 years and mean body mass index 24. Clustering of comorbidities and lifestyle factors indicated three pathways i.e. 1) mainly cardiovascular risk factors and disease, 2) variables associated with insulin resistance and 3) variables associated with PD (Fig A).

Fig Results of cluster analysis illustrating (A) variable and (B) observation clustering

Five different clusters (C1 to C5) were identified based on clustering of observations (Fig1; B), C1 (n=16,063), mean age=46 years, characterized low rate of hypertension (14%) and PD (15%); none had obesity, kidney dysfunction, DM, CVD or dyslipidemia. C2 (n=750; mean age 51 years) had the highest proportions with gout (7.1%) and kidney dysfunction (100%), with no record of DM, CVD or use of diuretics. C3 (n=528; mean age=48 years) had the highest rates of CVD (100%) PD (22%), smoking (74%) and alcohol risk behaviour (41%). C4 (n=3673; mean age=47 years) had the highest percentage of males (75%), the highest BMI (25.91) and the greatest proportions with obesity (34%) and dyslipidemia (74%), regular smoking (65%) and alcohol risk behaviour (36%). C5 (n=1043; mean age=48 years) had by far the highest occurrence of DM (51%), frequent use of diuretics (52%), hypertension (54%) and the highest percentage of abnormal liver enzyme values (16%).

Conclusion: Definition of clusters of comorbidities and lifestyle factors closely associated with gout, identified five separate “pathways” in this large health survey of the general population. “Pathways” relates to lifestyle, metabolism and specific comorbidity patterns. Further analyses will be performed to elucidate how these clusters predicted diagnosed gout in this population.

SURVEY OF POTENTIAL TOXIC EXPOSURE IN PATIENTS WITH SYSTEMIC SCLEROSIS IN RESCLE REGISTRY. A PRELIMINARY STUDY

Mayra Freire1, Bernardo Sopeña1, Arturo González-Quintela1, Alfredo Guillén del Castillo1, Carles Tolosa1, Jose Antonio Vargas-Hitos1, Xabier Pla Salas2, Cristina González-Echávarri3, Antonio-J Chamarro3, Vicent Fordosola Pila2, Carmen Pilar Simén-Aznar3, On Behalf of Rescle Investigators, Autoimmune Diseases Study Group (Geas)3, 1Hospital Clínico Universitario de Santiago, Internal Medicine, Santiago de Compostela, A Coruña, Spain; 2Hospital Universitario Valt d’Hebron, Unit of Autoimmune Diseases, Department of Internal Medicine, Barcelona, Spain; 3Corporación Sanitaria Universitaria Parc Taulí, Department of Internal Medicine, Sabadell, Barcelona, Spain; 3Hospital Universitario Virgen de las Nieves, Department of Internal Medicine, Granada, Spain; 3Consorcio Hospitalario de Vic, Unit of Systemic Autoimmune Diseases, Department of Internal Medicine, Vic, Barcelona, Spain; 3Hospital Universitario de Cruces, Autoimmune Diseases Research Unit, Department of Internal Medicine, Barakaldo, Spain; 3Complejo Asistencial Universitario de Salamanca, Internal Medicine, Salamanca, Spain, 3GEAS, Madrid, Spain

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease with extremely heterogeneous clinical features and unknown etiology, although numerous studies suggest a relationship with environmental and occupational factors. So far there is little information on whether toxic substances can play a relevant role in its phenotypic expression (1).

Objectives: To analyze in a cohort of patients with SSc the proportion of patients exposed to toxic and their correlation with epidemiologic, clinical and serological data.

Methods: A survey was conducted aimed at the knowledge of the working life of patients from six centers belonging to the Spanish Scleroderma Registry (RESCLE), categorizing them in six groups: no potential exposure to toxic substances, potential exposure to silica, to hydrocarbons, to organic solvents, to mixed toxics (silica and/or hydrocarbons and/or organic solvents) and to another toxics. In all patients 87 epidemiological, clinical and analytical variables included in the registry were analyzed, carrying out a comparative study between groups.

Results: 225 SSc patients were selected. Of these, 81 patients (36%) had worked in professions with potential risk of toxic exposure, 64 women out of the 227 included (28%) and 17 men out of the 28 included (60%). The toxic agent most frequently involved was silica in 28 patients (35.8%), followed by hydrocarbons in 21 (25.9%), mixture of toxic...
INCIDENCE OF GIANT CELL ARTERITIS IN 6 DISTRICTS OF PARIS, FRANCE (2015–2017)

GONZALEZ-CHIAPPE Solange1, Sarah Lechtman2, Carla Maldini3, Arsene Mekinian4, Thomas Papo5, Thomas Sené6,7, Alfred Mahr3,8.

1Saint-Louis Hospital, Internal medicine, Paris, France; 2Lariboisière Hospital, Internal medicine, Paris, France; 3Saint-Louis Hospital, Internal medicine, Paris, France; 4Bichat hospital, Internal medicine, Paris, France; 5Rothschild Ophthalmologic Fondation, Internal medicine, Paris, France; 6Diaconesses Croix Saint-Simon Hospital, Internal medicine, Paris, France; 7Gentofte Hospital, Hellerup, Denmark; 8Sorbonne Paris Cité Research Center UMR 1153, Inserm, ECSTRA Team, Epidemiology and Biostatistics, Paris, France

Background: Little is known about the current incidence of giant cell arteritis (GCA) in France.

Objectives: We conducted a prospective, population-based survey over 3 years to estimate the incidence of GCA in inhabitants of Paris, France.

Methods: From January 2015 to December 2017, new GCA diagnoses in 6 districts of northeastern Paris (257,888 inhabitants ≥ 50 years old) were prospectively identified by 1) biannual postal mails to 1,134 general practitioners and other specialists practicing in the study area; 2) quarterly e-mail surveys among 28 hospital departments located in or close to the study area; and 3) new records in the National Health Insurance System database with code M31 (other necrotizing vasculopathies) in the International Classification of Diseases, 10th revision. Clinical data of notified cases were retrieved from medical records. Retained cases lived in the study area at the time of diagnosis, fulfilled the 1990 American College of Rheumatology classification criteria and/or were ≥ 50 years old, with imaging or histology evidence of large-vessel inflammation and increased levels of inflammatory biomarkers. Clinical presentations with no cranial symptoms were classified as large-vessel GCA and otherwise as cranial GCA.

Annual incidence rates were calculated by dividing the number of incident cases by the size of the study population and the study period (in years); 95% confidence intervals (CIs) were calculated by using the Poisson distribution. Completeness of case ascertainment was assessed by a three-source capture-recapture analysis.

Results: Among 61 retained cases (69% females; mean age: 77 [SD: 9.0] years), 57 (93%) were cranial GCA and 4 (7%) large-vessel GCA. GCA diagnoses were supported by temporal artery biopsy findings, imaging of the aorta and its main branches, temporal artery ultrasonography and/or aortic tissue histology in 35 (57%), 18 (30%), 7 (11%), and 1 (2%) cases, respectively. GCA incidence rate (per 100,000 inhabitants/C21 years), 57 (93%) were cranial GCA and 4 (7%) large-vessel GCA. GCA diagnoses were supported by temporal artery biopsy findings, imaging of the aorta and its main branches, temporal artery ultrasonography and/or aortic tissue histology in 35 (57%), 18 (30%), 7 (11%), and 1 (2%) cases, respectively. GCA incidence rate (per 100,000 inhabitants ≥ 50 years old) was estimated at 7.9 cases (95% CI: 6.0–10.1). Completeness of case ascertainment was estimated at 66% (95% CI: 52–90%).

Conclusion: Our annual incidence estimate of GCA is close to the sole published estimate for another French population established 4 decades ago [1] and adds further support to the lower incidence of GCA in non-Scandinavian versus Scandinavian populations. Large-vessel GCA cases seem a rare form of GCA as compared with cranial GCA.

The association between joint erosions plus autoantibody positivity at initiation of methotrexate or biologic therapy for rheumatoid arthritis and disease activity and disability over one year

James Gwinnutt1, Kimme Hyrich1,2, Mark Lunt3, Darren Plant4, Nisha Nair5, Anne Barton6,7, Suzanne Verstappen6,8, RAGGS co-investigators.

1Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom; 2NHRI Manchester Biomedical Research Centre, Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; 3Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom

Background: Joint erosions and autoantibody positivity (rheumatoid factor [RF], anti-cyclic citrullinated peptide antibody [anti-CCP]) predict poor outcomes in patients with rheumatoid arthritis (RA). There are limited data on the combination of these factors and clinical and patient reported outcomes over time.

Objectives: To compare the disease activity and disability over 1 year of those with poor prognostic factors at treatment initiation (methotrexate [MTX] or biologics) to those without.

Methods: Patients were recruited to 1 of 2 UK-based multi-centre prospective cohort studies: MTX-starters: Rheumatoid Arthritis Medication Study (RAMS); biologic-starters: Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS). Anti-CCP (Axis-Shield Anti-CCP test; U/ml; anti-CCP titre >5 U/ml = anti-CCP+) RF (Beckman Coulter AU4000, RF latex assay; U/ml; RF titre >14 U/ml = RF+) status were determined from baseline (BL) blood samples at the co-ordinating centre; erosions (yes/no) were recorded from medical notes. Missing data resulting from anti-CCP assay failure were imputed using multiple imputation. Patients who were anti-CCP+ and/or RF+ and had erosions were classified as having poor prognosis (PP); all other patients were classified as not having poor prognosis (NPP). Patients completed the Health Assessment Questionnaire (HAQ) and the Disease Activity Score (DAS28) was calculated at BL, 6 months and 12 months. The DAS28 and HAQ scores of the prognostic groups were compared at each assessment using linear regression, adjusted for age, gender and disease duration.

Results: In total, 1179 (PP = 182 [15.4%]) MTX-starters and 1152 (PP = 467 [40.5%]) biologic-starters were included (BL characteristics in Table). For MTX-starters, PP and NPP patients had similar DAS28, whereas for biologic-starters, PP patients had lower DAS28 compared to NPP patients after baseline (adjusted mean difference [95% CI]: MTX-starters BL = 0.1 [-0.1, 0.3]; 6 months = -0.1 [-0.2, 0.0]; 12 months = -0.1 [-0.4, 0.2]; biologic-starters BL = -0.1 [-0.2, 0.0]; 6 months = -0.2 [-0.4, 0.0]; 12 months = -0.4 [-0.6, 0.1]). HAQ scores were similar between PP and NPP patients in both cohorts (adjusted mean difference [95% CI]: MTX-starters BL = 0.08 [-0.04, 0.20]; 6 months = -0.02 [-0.11, 0.15]; 12 months = -0.03 [-0.17, 0.10]; biologic-starters BL = 0.00 [-0.09, 0.08]; 6 months = 0.00 [-0.12, 0.13]; 12 months = 0.01 [-0.14, 0.16]).

Conclusion: PP and NPP MTX-starters had similar outcomes. For biologic-starters, PP patients had lower disease activity after baseline; knowledge of these prognostic factors may have prompted more intensive assessment of PP patients after starting treatment. Patients in both cohorts (adjusted mean difference [95% CI]: MTX-starters BL = 0.1 [-0.1, 0.3]; 6 months = -0.1 [-0.2, 0.0]; 12 months = -0.1 [-0.4, 0.2]; biologic-starters BL = -0.1 [-0.2, 0.0]; 6 months = -0.2 [-0.4, 0.0]; 12 months = -0.4 [-0.6, 0.1]). HAQ scores were similar between PP and NPP patients in both cohorts (adjusted mean difference [95% CI]: MTX-starters BL = 0.08 [-0.04, 0.20]; 6 months = -0.02 [-0.11, 0.15]; 12 months = -0.03 [-0.17, 0.10]; biologic-starters BL = 0.00 [-0.09, 0.08]; 6 months = 0.00 [-0.12, 0.13]; 12 months = 0.01 [-0.14, 0.16]).

Conclusion: PP and NPP MTX-starters had similar outcomes. For biologic-starters, PP patients had lower disease activity after baseline; knowledge of these prognostic factors may have prompted more intensive assessment of PP patients after starting treatment. Patients in both cohorts (adjusted mean difference [95% CI]: MTX-starters BL = 0.1 [-0.1, 0.3]; 6 months = -0.1 [-0.2, 0.0]; 12 months = -0.1 [-0.4, 0.2]; biologic-starters BL = -0.1 [-0.2, 0.0]; 6 months = -0.2 [-0.4, 0.0]; 12 months = -0.4 [-0.6, 0.1]). HAQ scores were similar between PP and NPP patients in both cohorts (adjusted mean difference [95% CI]: MTX-starters BL = 0.08 [-0.04, 0.20]; 6 months = -0.02 [-0.11, 0.15]; 12 months = -0.03 [-0.17, 0.10]; biologic-starters BL = 0.00 [-0.09, 0.08]; 6 months = 0.00 [-0.12, 0.13]; 12 months = 0.01 [-0.14, 0.16]).

rates according to treatment. Comparisons of survival rates between treat-ments were performed using log-rank tests. A p level of <0.05 was con-sidered significant. Statistical analyses were performed using SPSS 24.0

Results: A total of 109 patients (155 eyes; 79.8% female; mean age 53.9 ±12.5 (63 to 81) years) were included. The frequency of the associ-ation between PUK and an autoimmune systemic disease, was 86.3% (94). The leading etiology was RA (52.3%; n=57); VAA (30.3%; n=33), being GPA the foremost recognized in this group (84.8%; 28/33). Other were SLE, PSS, JIA, and ReA.

When PUK started, RA was already diagnosed in 87.7% (50/57); 18.2 (633) of AAV. Mean disease evolution in RA was 15 ± 8.2 years; AAV had 3.9 ± 5.6 years (p<0.05). 29% (n=17) of RA untreated; only 4 (12.2%) AAV were immunosuppressed by the time PUK settled.

Systemic autoimmune activity, was found in 31.5% (18/57) of RA and 90.9 (30/33) of AAV. Antrilagia was foremost referred by RA (94.4%;17/18); ear–nose–throat symptoms were in AAV (86.6%; 20/30). In the latter, some degree of renal dysfunction was found in 33.3% (10/30).

PUK characteristics in RA and AAV. Moderate (34.2%) and mild (383%) PUK were more frequently seen in RA; whereas moderate (36.3%) and severe (33.3%) in AAV (p<0.016). RA associated PUK commonly involved the inferior corneal quadrant (54.3%), as AAV the superior one (73.8%; p < 0.001). Corneal perforation was more frequent in RA than AAV (54.5% vs 22.7%; p=0.481); although the risk of perforation associated to RA didn’t show statistical significance [OR 1.14 [IC 95% 0.8 - 1.63]]. Necrot-izing scleritis was more commonly seen in AAV (RA n=1 vs AAV n=10). The more frequent initiated treatment in RA was oral prednisone combined with oral DMARDs (31.6%; 18/57). More aggressive therapy (MPS, CYC or Rituximab) was designated in 22.8% (n=13). On the other hand.

78.7% (26/33) of AAV were managed with the MPS-pred scheme merged with CYC (38.4%; n=12) or Methotrexate (42.4%; n=14).

Conclusion: RA and AAV are the more frequent autoimmune diseases that can manifest with PUK. In RA, the lack of arthritis could be mis-taken as quiescent, and wrongly undertreated, allowing it to progress to a vasculitic stage. It may impact their life quality if complicated with cor-neal perforation. In AAV the PUK can be the initial symptom of the dis-ease and is associated with a more severe ocular presentation. Routine ophthalmologic examinations might help the rheumatologist to assess RA and AAV activity and treatment.

PREVALENCE AND UVEITIS CHARACTERISTICS OF A COHORT OF PATIENTS WITH SPONDILIOARTROPATHY

Sycille Jeria1, Patricia Moya2, Ana Laiz2, Jose Vela2, Hye-sang Park2, Ana Milena Millán Arciniegas2, Josep Versil1, Ivan Castellví2, Josep Maria Libbét2, Hector Coromina2, Josep Maria Libbét2, Hector Coromina2, Josep Maria Libbét2, Hector Coromina2, Josep Maria Libbét2, Hector Coromina2
HOSPITAL DE LA SANTA CREU Y SANT PAU, RHEUMATOLOGY, BARCELONA, Spain;
HOSPITAL DE LA SANTA CREU Y SANT PAU, Ophthalmology, BARCELONA, Spain

Background: Uveitis can be a clinical manifestation of different systemic processes, known is the association of anterior uveits with patients with spondiloarthritis (SpA)

Objectives: To describe the prevalence, characteristics and course of ocular inflammatory pathology from a cohort of patients with SpA

Methods: Retrospective descriptive study made in a cohort of 451 SpA patients according to the ASAS classification criteria in a tertiary university hospital from Barcelona. Were selected patients who presented or had presented uveitis (defined according to the SUN1 classification crite-ria) Demographic, clinical, radiological and serological data of the joint disease and characteristics of the ocular affection were collected, as well as the treatment of both

Results: Of the 451 patients reviewed. 43 (9.53%) patients with a history of uveitis were included in the study. From the cohort, the average age at diagnosis of SpA was 37 (± 27) years and 38 (88.4%) had positive HLAB27. The most prevalent subtypes of SpA were Ankylosing Spondylitis (AS): 27 (60.8%) and Psoriatic Arthritis (APSO): 8 (18.6%). The char-ac teristics of the sample are summarized in Table 1.

The average age at the first uveitis outbreak was 45 ± 23 years. The anterior location was more prevalent (n: 39, 90.7%), unilateral (n: 35, 81.4%) and acute onset (n: 42, 97.6%)

Two of patients with anterior uveitis had other associated complications, one had macular edema and other retinal vasculitis. The treatment of uveitis was topical corticosteroids in 39 (90.6%) patients, 2 (4.6%) treatment with oral sulfasalazine. Despite the treatment, 22 (51.2%) patients presented a recurrent course. Table 2 shows the ocular clinical features

IMPACT OF COMORBIDITY ON THE USE OF BIOLOGICAL AND TARGETED THERAPY IN RHEUMATIC DISEASES IN THE CLINICAL PRACTICE

Dmitry Karateev, Hava Hamhoeva, Helen Luchihina, Aminat Tangieva. Moscow Regional Research and Clinical Institute ("MONIKI"), Rheumatology department, Moscow, Russian Federation

Background: Comorbid conditions often accompany rheumatic diseases and can influence the prescription of immunosuppressive therapy. Comorbidity seems to be a factor that is still underestimated in actual practice.

Objectives: To study the influence of comorbidity on the prescription of biological and targeted therapies in patients with rheumatic diseases (RD) in clinical practice.

Methods: We perform a retrospective analysis of comorbidity and prescription of biological and targeted immunosuppressors in a group of inpatients with systemic autoimmune RD in rheumatology department. From January 2018 to January 2019, 218 patients with inflammatory RD hospitalized - 146 (67.5%) women, mean age 50.6±14.6 years. Diagnoses: rheumatoid arthritis - 83 patients, spondyloarthritides - 80, systemic lupus erythematosus - 19, systemic scleroderma - 16, ANCA-associated vasculitides - 10, other conditions - 10 patients. Biologics were used in 117 (53.7%) of patients (anti-TNFs – 64 patients, rituximab – 18, tocilizumab – 16, abatacept – 8, secukinumab – 4, uestekinumab – 4, tofacitinib – 3 patients). We examined patients for comorbidities through careful examination of the history, medical records, and general therapeutic laboratory and instrumental screening. The Charlson comorbidity index calculated for every patient.

Results: 174 (79.8%) patients had at least 1 comorbid condition. The most frequent comorbidities were type 2 diabetes (19.5% patients), chronic kidney disease (12.6%), cerebrovascular accident (11.5%), ischaemic heart disease and chronic heart failure (11%), chronic liver disease (7.5%). Mean Charlson index was 2.1±2.05 in total group; it was significantly lower in patients who were treated with biological and targeted therapy (1.84±1.8) than in patients who did not received this therapy (2.76±2.1), p=0.01. Biologics were prescribed in 81.8% of patients without comorbidities, in comparison with 55.3% of patients with Charlson comorbidity index 1 or 2, and 36.3% of patients with Charlson index 3 or more.

Conclusion: Comorbidity has a direct impact on the use of biological and targeted therapy in patients with rheumatic diseases in real clinical practice, limiting the ability to control the activity of the disease. It is necessary to develop a general therapeutic strategy for treating comorbid conditions in patients with rheumatic diseases.

PREVALENCE, PATIENT CHARACTERISTICS, AND TREATMENT OF GOUT AND ASYMPTOMATIC HYPERURICEMIA IN JAPAN: CROSS-SECTIONAL STUDY OF A HEALTH INSURANCE CLAIMS DATABASE

Ruriko Koto1, Akhiro Nakajima2, Hideki Horuchi2, Hisashi Yamanaka3, 1Teijin Pharma Limited, Medical Science Department, Tokyo, Japan; 2Teijin Pharma Limited, Pharmaceutical Development Administration Department, Tokyo, Japan; 3Tokyo Women’s Medical University, Institute of Rheumatology, Tokyo, Japan

Background: The prevalence of gout is increasing worldwide [1,2], but evidence suggests that current treatment practices do not effectively reduce serum uric acid (sUA) levels in many gout patients [3]. In Japan, urate lowering therapy (ULT) is provided to patients diagnosed with asymptomatic hyperuricemia as well as to those with gout. However, the actual treatment situation for asymptomatic hyperuricemia has not been well-documented.

Objectives: To assess the prevalence and characteristics of gout and asymptomatic hyperuricemia and the current treatment practices for these conditions in Japan.

Methods: This retrospective cross-sectional study assessed disease prevalence, patient characteristics, prescriptions, proportion of patients achieving target sUA, and incidence of gouty arthritis among 2,531,383 individuals in a database, using data from Japanese health insurance claims and medical check-ups from April 2016 to March 2017.

Results: Gout was diagnosed in 1.1% (men 1.9%, women <0.1%) of the study population and asymptomatic hyperuricemia in 2.6% (men 4.1%, women 0.4%). Hyperuricemia (sUA >7.0 mg/dL) was identified in 13.4% (men 19.6%, women 1.0%) of cases in which sUA level was measured at check-up. ULT adherence was satisfactory (median medication possession ratio [MPR] of 69.0% for febuxostat and 78.1% for allopurinol in gout, and 79.5% and 88.5%, respectively, in asymptomatic hyperuricemia), but most patients were receiving low-dose ULT. The sUA target (≤6.0 mg/dL) was achieved by less than half of patients treated with either febuxostat or allopurinol (Table). In gout patients, the incidence proportion of gouty arthritis was 47.8% and the incidence rate was 0.74 flares/person-year.

Conclusion: The prevalence of gout in our study population was low. Japanese physicians often treat gout and asymptomatic hyperuricemia with low-dose ULT, and many patients fail to reach their target sUA, suggesting gout management is suboptimal in Japan.

biological therapies has not been investigated in detail, and little is known about the predictive value of sociodemographic and lifestyle factors.

Objectives: To investigate the predictive value of a panel of potential predictors of death in a cohort of patients with RA followed for up to 12 years during the era of biological treatments.

Methods: Outpatients with RA were recruited consecutively between July 2006 and July 2007 and followed in routine care with prospective registrations in the DANBIO registry until death or August 20th, 2018, whichever occurred first. Baseline variables considered to be potential predictors were: disease activity, disease duration, IgM-rheumatoid factor (IgM-RF), radiographic status (erosive disease yes/no) and medical therapy as well as patient-reported marital status, educational level, comorbidity conditions, smoking, exercise, body mass index (BMI) and health assessment questionnaire (HAQ). Vital status and date of death were extracted from the Danish National Register. A Cox proportional hazards model was used to estimate the hazard ratio for death for each of the potential predictors.

Table: Age-adjusted Cox proportional hazards model with death as outcome.

Results: 3693 patients were recruited at baseline, 75% women, 77% IgM-rheumatoid factor positive, 65% with erosive disease, median (IQR) age 62 years (52-71), disease duration 7 years (3-15), DAS28 3.0 (2.2-3.9), HAQ 0.63 (0.25-1.25). 20% received a biological disease modifying anti-rheumatic drug (DMARD), 71% received a synthetic DMARD and 9% received no DMARD. The median (IQR) duration of follow-up was 11 years (9-11); 1041 patients (28%) died during follow-up. 640 patients received no DMARD. The median (IQR) duration of follow-up was 11 years (9-11); 1041 patients (28%) died during follow-up. 640 patients received no DMARD. The median (IQR) duration of follow-up was 11 years (9-11).

Conclusions: In a large cohort of RA patients followed for a decade in the era of biological treatments, we identified strong clinical (high HAQ, comorbidity), treatment related (glucocorticoid last month), sociodemographic and lifestyle related (male sex, living alone, smoking, physical inactivity, low BMI) risk factors for death. In the effort to prevent a poor long term outcome in patients with RA, this study provides new insight into potentially modifiable baseline variables.

3. Central Statistics Office Ireland
Background: Body composition, physical activity and physical performance with knee cartilage thickness and subchondral bone area in young adults were unknown.

Objectives: To describe associations of body composition, physical activity and physical performance with knee cartilage thickness and subchondral bone area in young adults.

Methods: Body composition, physical activity and physical performance were measured 4-5 years prior to knee magnetic resonance imaging (MRI). Cartilage thickness and subchondral bone area of patella and lateral/medial femoral compartment were measured quantitatively from MRI. Total knee cartilage thickness was calculated as the weighted-average according to bone area of each compartment; total knee bone area was calculated as the sum of each compartment. Associations were assessed using linear regression analysis. Age, gender, height (if fat mass or lean mass was predictor) and BMI (if physical activity or physical performance measures were predictors) were examined as potential confounders and were included in the regressions. Mediator was identified using mediation analysis (Stata’s medeff command).

Results: Participants were aged 31-40 years, 48% were female (n = 186). Greater lean mass, but not fat mass, was positively associated with total knee cartilage thickness (β = 0.50 μm/kg, 95% confidence interval (CI): 0.86 to 12.13) and subchondral bone area (β = 13.66 mm²/kg, 95% CI: 5.73 to 21.59). Physical performance measures were positively associated with knee cartilage thickness (long jump: β = 2.36 μm/cm, 95% CI 0.68 to 4.04; hand grip strength: 7.65 mmHg, 1.53 to 13.77; physical work capacity: 1.04 μWatt, 0.27 to 1.81) and subchondral bone area (long jump: β = 4.25 mm²/cm, 95% CI 1.01 to 7.50; hand grip strength: 19.89 mmHg/cm, 8.23 to 31.55; leg strength: 3.32 mmHg/cm, 1.25 to 5.40; physical work capacity: 3.00 μWatt, 1.54 to 4.45). Mediation analysis suggested these associations were mediated by lean mass (effect mediated: 29-95%). Questionnaire based activity measures (including walking, moderate activity, vigorous activity and total activity) were not associated with total knee cartilage thickness or subchondral bone area.

Conclusion: Greater lean mass and better physical performance measures were associated with greater knee cartilage thickness and subchondral bone area in young adults, and the associations of physical performance were largely mediated by lean mass. These findings suggest lean mass may play an important role in maintaining knee joint health in young adults.
DEFINING THE GUT MICROBIOME IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

catherine najem1,2, Jung-Jin Lee2, Ceylan Tanes2, Antoine Sreih2, Rennie Rhee2, Abdallah Gearsa2, LI Hongzhe2, Kyle Bittinger2, James Lewis2, Peter Merkel2, 1Temple University Hospital, Rheumatology, Philadelphia, United States of America; 2University of Pennsylvania, Philadelphia, United States of America

**Background:** Although a link between gut microbiome and autoimmune diseases has been suggested, there is a gap in the understanding of the gut microbiome in ANCA-associated vasculitis (AAV).

**Objectives:** This study evaluated the gut microbiome in AAV (granulomatosis with polyangiitis (GPA), microscopic polyangiitis, and eosinophilic granulomatosis with polyangiitis) compared to healthy controls.

**Methods:** Using cross-sectional and longitudinal designs, the gut microbiome was compared among patients with i) newly-diagnosed AAV (active and remission); ii) chronic AAV (active and remission), and iii) healthy controls. Fecal samples were collected using standardized methods and sequenced the bacterial 16S rRNA gene (V1-V2 region). Disease severity was analyzed by sequencing the bacterial 16S rRNA gene (V1-V2 region).

**Results:** 63 fecal samples were studied: 29 active AAV (15 new diagnosis/14 chronic), 20 in remission, and 14 healthy controls. Compared to healthy controls, patients with active AAV had a different microbial composition (p<0.01) (Figure 1A). The relative abundance of the taxa Dialister and Prevotella were different between active and remission AAV. The relative abundance of the genera Faecalibacterium and Sutterella were different between active and remission AAV. Taxa with mean abundance >1% were compared using Wilcoxon rank sum test, correcting for multiple comparisons. Disease severity was assessed with the Birmingham Vasculitis Activity Score for Wegener’s Granulomatosis (BVAS/WG). Effects of medications were studied using mixed effects models.

**Conclusion:** Active AAV is associated with an altered gut microbial composition. Patients in clinical remission have microbial composition similar to healthy controls. Immunosuppressive agents, glucocorticoids, and antibiotics use. Immunosuppressive agents was similar to controls (p=0.54), whereas the gut microbiome of patients with GPA on immunosuppressive agents was similar to controls (p=0.04), whereas the gut microbiome of patients with GPA not on these therapies was significantly different from controls; similar results were found with glucocorticoids and antibiotics use.

**Disclosure of Interests:** None declared

NOVEL MAPPING FUNCTION ILLUSTRATES NONLINEARITY BETWEEN TRIAL ACR RESPONSE, DAS28 CHANGE AND EULAR RESPONSE CRITERIA

Nuria Navarro Coy1, Kimme Hyrich2, Sue Pavill2, Robert West4, Maya Buch1,5, 1Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), Leeds, United Kingdom; 2Institute of Inflammation and Repair, Manchester, United Kingdom; 3School of Dentistry, Leeds, United Kingdom; 4Leeds Institute of Health Sciences, Leeds, United Kingdom; 5NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, United Kingdom

**Background:** The American College of Rheumatology (ACR) definition of improvement is a standardised, widely used outcome measure for clinical trials in rheumatoid arthritis. In routine clinical practice (and registries),
improvement is assessed by the DAS28 (Disease Activity Score 28), particularly in the UK, where it is the basis of current NICE guidance.

**Objectives:** To develop a mapping function that charts ACR20/50/70 and ACRn to ∆DAS28 and EULAR response, and determine the relationship between response measures.

**Methods:** Individual patient-level data from the 428 participants randomized to the ATTRACT trial were used. The proportion of participants with ACRn (ACR10-ACR90) response and the change in DAS28 (∆DAS28) at 30 weeks from baseline were calculated and analysed in participants with complete data. The cut points in ∆DAS28 that provided the equivalent proportion of participants achieving ACR10 to ACR90 at 30 weeks overall and per individual arm were searched for through tabulation. Regression models were conducted and misclassification rates calculated to test the accuracy of the mapping function. The minimum and maximum ACRn achieved per EULAR response category were also determined to establish the correlation of these two response criteria. A version 3.4.3 (2017-11-30) was used for all statistical analyses.

**Results:** 53%/27%/12% of all trial participants achieved ACR-ESR 20/50/70 responses, respectively. The mapping function shows that at 30 weeks a 20% improvement in ACR is equivalent to a lower improvement in the DAS28, at 55.8% for ESR and 59.3% for CRP. Similar results were obtained when analysing the individual arms (Table 1 & Figure 1). Baseline DAS28 for all analysed groups was > 6.0. Moderate or good EULAR responses correspond to 80% and 90% improvement in ACR, respectively, whereas the no response EULAR category showed a maximum improvement in ACR-ESR/CRP of 30%-50%, respectively (Figure 2).

**Conclusion:** This novel mapping function enables the comparison of trials through tabulation. Regression models were conducted and misclassification rates calculated to test the accuracy of the mapping function. The minimum and maximum ACRn achieved per EULAR response category were also determined to establish the correlation of these two response criteria. A version 3.4.3 (2017-11-30) was used for all statistical analyses.

RELATIONSHIP BETWEEN VITAMIN D NEUROMYELITIS SPECTRUM DISORDERS

Muir 2011
RCT Medicine, Almería, Spain
Monica Solana-Tramunt4, M Guerra-Balic4. Maria Betina Nishishinya1, 6 to 12 months. ranged from 121 to 5615. Patients mean age oscillated between 58-88 years improves muscle mass, strength and performance in older patients.

Background: Sarcopenia is the loss of skeletal muscle mass, strength and function that occurs as a consequence of aging. This condition result in physical disability, which limits the capacity to walk, increases the risk of falls and osteoporotic fractures. Several studies suggested an inverse relation between 25OHD serum levels, muscular strength and physical performance in the eldest.

Objectives: To evaluate if vitamin D supplementation in patients > 50 years improves muscle mass, strength and performance in older patients.

Methods: We performed a systematic review through Medline, Cochrane Library, and EMBASE. Inclusion criteria: 1) patients > 50 years old, 2) objective measurements 4) systematic reviews (SR) 5) randomized clinical trials (RCT) 6) Papers written in English or Spanish.

Results: Five studies were included (4 SR and 1 RCT), n patients ranged from 121 to 5615. Patients mean age oscillated between 58-88 years. receiving variable vitamin D dose. Follow-up period fluctuated from 6 to 12 months.

Conclusion: Vitamin D supplementation in patients > 65 years with inadequate 25OHD serum levels, improve muscular strength.

**PREICTORS OF EROSION AND JOINT SPACE NARROWING PROGRESSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

*Emil Rydel*1,2, Kristina Forslind*1,4, Jan-Åke Nilsson*1,2, Lennart T.H. Jacobsson*1,3, Carl Turesson*1,2, *Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden; 2Department of Rheumatology, Skåne University Hospital, Malmö, Sweden; 3Rheumatology, Department of Clinical Sciences, Helsingborg, Lund University, Helsingborg, Sweden; 4Research and Education, Helsingborg Hospital, Helsingborg, Sweden; *Rheumatology and Inflammation Research, Sahlgrenska Academy at Gothenburg University, Göteborg, Sweden

**Background:** Joint damage in rheumatoid arthritis (RA) includes erosions and joint space narrowing (JSN). Predictors of these processes, and the underlying mechanisms, require further study.

**Objectives:** To investigate the relation between patient characteristics at RA diagnosis and progression of erosions and JSN, over 5 years.

**Methods:** Consecutive early RA patients (symptom duration <12 months), recruited 1995-2005 from a defined area, managed according to usual care with no pre-specified treatment protocol, were followed through 5 years. Radiographs of hands and feet were scored in chronological order by a trained reader according to the modified Sharp-van der Heijde score (SHS), including separate erosion- and JSN scores. The relations between baseline variables and progression of erosion- and JSN scores over 5 years (log transformed), were assessed using linear regression.

**Results:** 233 early RA patients where included. Radiographs at baseline and 5 years were available for 162 patients. Results on predictors of rapid radiographic progression of the total SHS have been reported previously2. The median (interquartile) progression of erosion and JSN scores were 4 (0-8) and 8 (1-16), respectively. RF and anti-CCP predicted progression of erosions and JSN over 5 years, with stronger associations for erosions (Table 1). Baseline erosion- and JSN scores each predicted progression of JSN, while baseline JSN did not predict progression of erosions. In crude analyses, higher disease activity, CRP and ESR were associated with disease activity and GH.

**NA, not applicable; vs, versus; †** Overweight or obese >25 kg/m2; normal 18.5 – 24.99 kg/m2.

Conclusion: RF, anti-CCP and markers of inflammation and disease activity predicted progression of erosions and JSN, in particular erosions. Development of erosions may predate cartilage damage leading to JSN. Smoking and high baseline levels of COMP predicted progression of erosions, but not JSN. Overweight and obesity may be associated with mechanisms that protect from JSN.

**EFFECT OF AIR POLLUTION EXPOSURE ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS**

Tommaso Schioppo1, Isabella Scotti1, Simonia Iodicic1, Mirjam Hoxta1, Orazio De Lucia1, Antonella Murgio1, Valentina Bollati1, Francesca Ingegnoli1, 2, 3, 4, *LAMST Pini-CITO*, Division of Clinical Rheumatology, Milano, Italy; 5University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy

**Background:** Environmental exposure (e.g. tobacco smoking, pollution) has been accepted to contribute in autoimmune diseases. Air pollution has been described to be a risk factor for developing rheumatoid arthritis (RA). Currently, RA disease remission is considered an achievable target in a significant proportion of patients. Nevertheless, diseases flares, that significantly contributes to damage progression and disability, remains unpredictable. Thus, factors able to potentially interfere on disease activity should be considered and assessed.

**Objectives:** The aim of our study is to evaluate the influence of particulate matter (PM) on disease activity and general health (GH) in patients with RA.

**Methods:** Consecutive patients with RA (ACR/EULAR Criteria 2010) resident in Lombardy (Italy) were enrolled. In each patient Disease Activity Score on 28 joints (DAS28), Simple Disease Activity Index (SDAI) and patients’ GH were assessed. Daily PM concentrations, estimated by Regional Environmental Protection Agency at municipality resolution, were used to assign short-term exposure from day of visit back to 14 days. Continuous variables are expressed as mean±SD. Categorical variables are presented as absolute numbers and frequencies. Multivariable linear regression models were performed to identify the day of PM10 and PM2.5 independently associated with DAS28, GH and SDAI indices, adjusting for the variables significant at the univariate analysis. GH was log transformed to achieve normality of residuals. β coefficients were reported for 10 μg/m3 increments of PM concentrations. All statistical analyses were performed using SAS 9.4.

**Results:** 258 patients (age at visit 57.4±13.5 years, disease duration 16.2±12.1, female 80.2%, rheumatoid factor and/anti-citrullinated peptide antibodies positivity 60.5%, smokers 15.5%, radiographic damage 41.5%) were enrolled in the study. Multivariable linear regression models were adjusted for radiographic damage, disease duration and age. Increases of PM2.5 and PM10 exposure (9 day before the visit) were significantly associated with worsening of DAS28, SDAI and GH (table below). PM concentrations in days other than 9 days before were significantly associated with disease activity and GH.

<table>
<thead>
<tr>

<td>0.03</td>
</tr>
<tr>
<td>PM10 Day 9</td>
<td>0.14</td>
<td>0.05</td>
<td>0.06</td>
</tr>
</tbody>
</table>

Conclusion: In our cohort, PM10 and PM2.5 exposure seems to influence RA disease activity with a lag period that can last until 9 days before the visit. Nevertheless, the association between day-to-day PM changes and disease activity do not confirm causation. Further studied are required to evaluate the influence of air pollution on RA activity.

WOMEN WITH RHEUMATOID ARTHRITIS HAVE HIGHER LIFETIME PROFESSIONAL AND NON-PROFESSIONAL EXPOSURE TO SILICA DUST COMPARED TO FRENCH GENERAL POPULATION

Johanna Sigaux1,2, Catherine Cavaill3,4,5, Odile Macchi6, Salima Challal2, Sarah El Rharras6, Mylene Petit2, Marie-Christophe Boissier1,2, Paul-André Rosental4,6,7, Luca Semerano1,2, 1INSERM UMR 1125, Université Paris 13, 93000 Bobigny, France, Bobigny, France; 2Assistance Publique-Hôpitaux de Paris, Hôpital Avicenne Service de Rhumatologie, 93000 Bobigny, France, Bobigny, France; 3IRISSO – UMR CNRS-INRA 7170-1427 Université Paris-Dauphine, Paris, France; 4SILICOSIS project, ERC Advanced Grant, Centre for European Studies, Sciences Po, Paris, France, Paris, France; 5Laboratory for Interdisciplinary Evaluation of Public Policies (LIEPP, Sciences Po, Paris), Paris, France; 6Centre for Historical Research, CNRS-EHESS, Paris, Paris, France; 7National Institute for Demographic Studies (INED), Paris, France

Background: Occupational exposure to silica dust is associated with increased risk of developing ACPA positive Rheumatoid arthritis (RA). Little is known about non-occupational exposure, as there are no available tools to assess it in clinical practice.

The Dust Exposure Life-Course Questionnaire (DELCQ), developed within the SILICOSIS project, a European Research Council Advanced Grant, provides clinical research with a tool derived from social sciences. The DELCQ allows to quantify both occupational and non-occupational (e.g. body care; hobbies such as DIY, woodworking, stone cutting, etc.) exposure to silica and some other inorganic particles during the whole lifetime.

In the DELCQ, the identification of sources of exposure is grounded on an extensive list of products and activities summed up by the International Agency on Research on Cancer and on a wide overview of the literature addressing silica exposure and silica-related (or suspected-to-be-related) diseases.

Objectives: To explore occupational and non-occupational silica exposure in a series of consecutive RA patients and the association of quantified silica dust exposure with major disease features (ACPA positivity) or outcomes (erosive disease).

Methods: The DELCQ was administered to 97 consecutive RA patients (77F, 20M, mean age 59.1±13.3 yrs., 75 ACPA positives, 66 with erosive disease) attending the rheumatology department of Avicenne Hospital (Bobigny, FRANCE). The DELCQ scores of patients were compared to those of 388 controls, matched for sex, age and smoking status, from a 2739-subject national cohort, representative of the general French population (ELIPSSilice). Within RA subjects, the association of the scores with ACPA positivity and with erosive disease was assessed after adjustment for tobacco use.

Results: RA patients had higher median scores of occupational (10 [0, 17] vs. 0 [0, 4]) exposure vs. controls (p<0.0001). Median occupational exposure was higher in both men and women compared to controls matched by age, sex and tobacco use (23.5 [18, 34.5] vs. 2.5 [0, 12] for men and 7 [3, 14] vs. 0 [0, 5] for women, p<0.0001 for both). Non-occupational median exposure was significantly higher only in women with RA (15 [9, 21] vs. 12 [5, 21], p< 0.05). Male vs. female RA patients had higher median occupational scores of exposure (p<0.001), while non-occupational exposure was not significantly different. After adjusting for smoking (smokers>5 pack/y vs. nonsmokers or smokers <5 pack/y), neither professional of non-professional scores were associated with erosive disease, despite a strong negative interaction with tobacco use.

Conclusion: Women with RA have higher professional and non-professional lifetime exposure to silica dust compared to age, and sex-matched subjects from the French general population. In this series, constituted mainly of non-smoking women, exposure to silica may be a relevant environmental factor for the development of RA. Higher occupational exposure in RA is confirmed in men with RA. Neither occupational nor non-occupational exposure was associated with ACPA positivity or erosive disease, likely due to the high prevalence these features in the patient series.

DISCREPANCY BETWEEN THE EFFICACY OF BIOLOGICAL DMARDS BASED ON RANDOMIZED CONTROLLED TRIALS AND THE EFFICACY OF BIOLOGICAL DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A STUDY USING THE IORRA COHORT

Eri Sugano1, Eiichi Tanaka1, Eisuke Inoue1, Mai Abe1, Mika Kawano1, Kumiko Saka1, Naohiro Sugitani1, Katsunori Ikari1, Ayako Nakajima1, Eisuke Inoue1, Mai Abe1, Mika Kawano1, Kumiko Saka1, Naohiro Sugitani1, Katsunori Ikari1, Ayako Nakajima1, Eisuke Inoue1, Mai Abe1, Mika Kawano1, Kumiko Saka1, Naohiro Sugitani1, Katsunori Ikari1, Ayako Nakajima1, Eisuke Inoue1, Mai Abe1, Mika Kawano1, Kumiko Saka1, Naohiro Sugitani1, Katsunori Ikari1, Ayako Nakajima1, Eisuke Inoue

Background: Randomized controlled trials (RCTs), which are currently considered to provide the highest level of evidence, include patients with high disease activity and exclude those with comorbidities often seen in the real world. With the increasing recognition of the importance of real-world evidence, attention is being paid to discrepancies between RCT-based evidence and the patient population in routine clinical practice; however, few reports assessing these gaps in the context of rheumatoid arthritis (RA) are available.

Objectives: We investigated the discrepancy between the efficacy of biological DMARDs (bDMARDs) in RCTs and the effectiveness of bDMARDs in routine clinical practice in patients with RA based on the IORRA cohort.

Methods: The effectiveness of bDMARDs (etanercept [ETN; n=33], golimumab [GLM; n=29], certolizumab [CZP; n=17], abatacept [ABT; n=19]) and tocilizumab [TCZ; n=24]) in RA patients who newly initiated bDMARD therapy in our hospital in 2016 was compared with the efficacy reported in phase 2 or 3 trials (8 total RCTs: ETN: 1; GLM: 2; CZP: 2; ABT: 1; TCZ: 2) during the RCT’s observational periods. Effectiveness was evaluated by percentages of patients achieving ACR20, ACR50, and ACR70 and clinical remission based on DAS28 remission criteria using the IORRA cohort database. We also compared treatment responses between IORRA eligible and non-eligible patients in the MATSURI study, a phase 2 trial that evaluated TCZ-sc efficacy and safety and had relatively lenient inclusion criteria, since some RA patients in the IORRA cohort belonged to both the eligible and non-eligible groups.

Results: In 7 RCTs (excluding the MATSURI study), very few patients fulfilled the IORRA inclusion criteria (Table). The ACR achievement rates were higher among patients in RCTs, while remission rates were higher among IORRA patients (Table). The average DAS28 at baseline in the RCTs’ group was significantly higher than that in the IORRA group (Table). In the MATSURI study, 13 of 24 patients who newly initiated TCZ-sc met the inclusion criteria in the IORRA. Although the percentages of patients achieving ACR20, ACR50, and ACR70 and clinical remission among eligible patients were similar to those of patients in the MATSURI study, those of non-eligible patients were lower than those of MATSURI patients (Table). This indicates better effectiveness in eligible patients than in non-eligible patients.

Conclusion: Although RA patients in RCTs experienced a better ACR achievement rate than those in routine practice, clinical remission was difficult to achieve. This might be due to the difference in disease activity at the time of bDMARD introduction, suggesting that it is necessary to interpret the efficacy of RCTs based on differences in patient background.

RESILIENCE TRAITS IN A LARGE COHORT OF PATIENTS WITH ANKYLOSING Spondylitis (AS), RHEUMATOID ARTHRITIS (RA) AND FIBROMYALGIA (FM)

FRI0693 RESEARCHER GROUPS IDENTITY AND RESILIENCE IN PATIENTS WITH ANKYLOSING Spondylitis (AS), RHEUMATOID ARTHRITIS (RA) AND FIBROMYALGIA (FM)

Background: The study of resilient traits (RT) including self-compassion, self-forgiveness, forgiveness of others, and gratitude has garnered attention for its potential to inform health and healthcare research. Little is known about how RT differ in different patient groups. The purpose of the current study is to compare RT among patients with AS, RA and FM.

Objectives: To examine patient group differences in levels and mental and physical health correlates of self-compassion, self-forgiveness, forgiveness of others, and gratitude.

Methods: We conducted an online survey with patients attending the Gastein Healing Galleries in Bad Gastein, Austria. In this health facility, approximately 12,000 patients suffering from different diseases are treated annually. Of those, 6,465 patients were invited by email to participate anonymously. Socio-demographics and health-related variables including depression, pain, and current health status were measured in all respondents. Also measures of self-compassion, self-forgiveness, forgiveness of others, and gratitude were administered in a subset of participants.

Results: In total 2,017 patients responded (31%) of which a subset of 562 patients with AS (44%), FM (38%), and RA (18%) completed measures of RT. Sex ratio (male/female) was 52%/48%, mean age 57 (SD=11) and level of education was: Elementary School 28%, Junior High School 22%, High School 20%, College 13%, and University 17%. Across patient groups, no differences emerged in levels of self-forgiveness, forgiveness of others, or gratitude (p>0.30), although FM patients reported lower levels of self-compassion compared to patients with AS and RA (p<0.05). Self-compassion, self-forgiveness, forgiveness of others, and gratitude were related to depression in all three patient groups, but gratitude was the only RT that was related to depression, pain, and health across all three patient groups.

Conclusion: We found that only self-compassion varied across patient groups, with FM patients reporting lower levels. All RT were consistently related to depression across the three patient groups, but gratitude was also related consistently across groups to both pain and health. RT may well vary according to patient diagnoses with some traits offering more support and resilience-building to the patient than other traits. An important key for treatment support and management may be to identify which traits are most useful to encourage the development of resilience and health in specific patient groups.

FRI0694 SELF-REPORTED SLEEPING PROBLEMS AND FATIGUE IN LARGE COHORT OF PATIENTS WITH ANKYLOSING SPONDYLITIS (AS), RHEUMATOID ARTHRITIS (RA) AND FIBROMYALGIA (FM)

Background: Sleep problems and fatigue are very common in rheumatic diseases and painful conditions. There is mounting evidence that sleep problems and fatigue have reciprocal influences on musculoskeletal pain, mood, and overall well-being of patients with rheumatic disorders. In addition, sleeping problems are a risk factor for developing chronic widespread pain.

Objectives: To assess and compare self-reported sleep problems and fatigue in a large cohort of patients with AS, RA and FM.

Methods: We conducted an online survey with patients regularly attending the Gastein Healing Galleries in Bad Gastein, Austria. In this health facility approx. 12,000 patients with a variety of disease are being treated annually. Of those, 6,465 patients were invited by email to participate in the survey anonymously. Sociodemographics and disease-related variables including depression, pain, and current health status were measured in all respondents. Also measures of self-compassion, self-forgiveness, forgiveness of others, and gratitude were administered in a subset of participants. In total 2,017 patients responded (31%) of which a subset of 562 patients with AS (44%), FM (38%), and RA (18%) completed measures of RT. Sex ratio (male/female) was 52%/48%, mean age 57 (SD=11) and level of education was: Elementary School 28%, Junior High School 22%, High School 20%, College 13%, and University 17%

Results: In total 2,017 patients responded (31%) of which a subset of 562 patients with AS (44%), FM (38%), and RA (18%) completed measures of RT. Sex ratio (male/female) was 52%/48%, mean age 57 (SD=11) and level of education was: Elementary School 28%, Junior High School 22%, High School 20%, College 13%, and University 17 %. Across patient groups, no differences emerged in levels of self-forgiveness, forgiveness of others, or gratitude (p>0.30), although FM patients reported lower levels of self-compassion compared to patients with AS and RA (p<0.05). Self-compassion, self-forgiveness, forgiveness of others, and gratitude were related to depression in all three patient groups, but gratitude was the only RT that was related to depression, pain, and health across all three patient groups.

Conclusion: We found that only self-compassion varied across patient groups, with FM patients reporting lower levels. All RT were consistently related to depression across the three patient groups, but gratitude was also related consistently across groups to both pain and health. RT may well vary according to patient diagnoses with some traits offering more support and resilience-building to the patient than other traits. An important key for treatment support and management may be to identify which traits are most useful to encourage the development of resilience and health in specific patient groups.

FRI0695 NEURAL MANUAL MOBILIZATION VS ROBOTIC ASSISTED MOBILIZATION TO REDUCE PAIN HYPERSENSITIVITY IN HANDOSTEOARTHRITIS: A RANDOMISED CONTROLLED PILOT TRIAL

Background: Recent studies suggest that osteoarthritis (OA) is a mixed pain state and that in some patients' central nervous system factors can play an important role.
Objectives: In this study, we showed some preliminary data on the effectiveness of a manual mobilization vs robotic assisted mobilization, on reduce pain sensitivity in subjects with dominant hand OA.

Methods: A pilot randomized controlled trial was conducted. 50 patients (50 to 90 years old) with a diagnosis of dominant hand OA were randomized into two groups of 25 participants. The experimental group received an intervention of neurodynamic mobilization of median, radial and ulnar nerves plus exercise, the control group received a robotic assisted passive mobilization treatment (Grohes Workstation, Grohes et al., Brescia, Italy) plus exercise. Both groups received 12 treatment sessions over 4 weeks. Pressure pain thresholds (PPTs) were assessed bilaterally over the Radial, Median and Ulnar nerves, first Carpometacarpal (CMC) joint, Hamate bone and in the C5-C6 sympathetic joint. Intensity of pain (Visual analogue scale, VAS), QuickDASH scale, grip and pinch strength were also measured bilaterally. Patients were assessed at beginning, at the end of therapy and after a period of 1 and 3 months.

Results: In comparison with pre-treatment values, the experimental treatment increased the PPTs in the first CMC joint, radial and median nerves (P < 0.05) and this effect was maintained until the 2nd Follow up session in the dominant hand. No significant changes in PPT at the hamate bone and ulnar nerve during treatment were found. No significant interaction for pain intensity (VAS) of hand while executing a grip strength, over the last 24 hours and over the last week also was found. Similarly, grip and pinch of the dominant hand did not increase after treatment.

Conclusion: Neurodynamic mobilization by sliding technique decreases pain in the hand joints in patients with hand OA, suggesting alternative therapies to surgery or to the use of analgesic. This research suggests that these patients can benefit from this approach.

products and the development of RA was observed: HR for the fully adjusted model=1.12 (95% CI: 0.78-1.59) (Table 1). Also when evaluating milk and cheese consumption separately, no association with the risk of RA was observed: HR for the highest milk consumption=1.10 (95% CI: 0.82-1.44) and highest cheese consumption HR=1.20 (95% CI: 0.81-1.79), compared with low consumption (fully adjusted models, table 1). Conclusion: In this large population-based cohort study, consumption of dairy products was not associated with risk to develop RA.

Methods: In this randomised controlled single-blinded study patients with a history of lateral upper arm pain with MRI confirmation of rotator cuff pathology or positive testing on a cluster of clinical rotator cuff tests were included. Patients with a recent history of shoulder surgery or a shoulder fracture were excluded. Participants were randomly assigned to complete either 6 weeks (short group) or 12 weeks (long group) of the exercise programme. Both groups performed the same specific set of loaded exercises daily at home and attended 6 clinic-based group exercise sessions2. Participants were assessed at 6 weeks, 3 and 6 months. Shoulder function was assessed using the Constant-Murley (CM) score. Disability was assessed using the QuickDash and the Shoulder Pain and Disability Index (SPADI). Pain was assessed using a visual analogue scale. Group comparisons were made using univariate generalised linear models.

Results: 85 patients were included in this study as per Table 1.

Within each group shoulder function, self-reported disability and pain improved significantly at 3 months (p < .05). Comparisons at 3 months showed the long group had significantly lower pain scores (p = .02). At 3 months there was no significant difference between the two groups in the CM score (p = .415), SPADI score (p = .053) and QuickDash score (p = .245). However, at 6 months, the long group had significantly greater changes in both the CM score (p = .007) and the SPADI score (p = .002).

Conclusion: In the management of patients with rotator cuff related shoulder pain the findings of this study indicate that a 12 week exercise programme results in better outcomes for pain at 3 months and self-disability and shoulder function at 6 months.

HPR Interventions (educational, physical, social and psychological)

FRI0698-HPR A RANDOMISED CONTROLLED CLINICAL TRIAL COMPARING THE EFFECTIVENESS OF 6 AND 12 WEEKS OF A SHOULDER SPECIFIC EXERCISE PROGRAMME FOR PATIENTS WITH ROTATOR CUFF RELATED SHOULDER PAIN

Sandra Keyes1, Noreen Walsh1, Mark Phelan2, 1South Infirmary Victoria University Hospital, Physiotherapy, Cork, Ireland, 2South Infirmary Victoria University Hospital, Rheumatology, Cork, Ireland

Background: Research has shown loaded exercise to be beneficial for patients with rotator cuff related shoulder pain in terms of improving shoulder function, self-reported disability and pain 2. The optimal duration for which these patients should complete a loaded exercise programme to achieve beneficial effects remains unclear.

Objectives: The purpose of this study is to determine if 6 weeks of a supervised shoulder specific exercise programme is as effective as 12 weeks of the same programme, for improving shoulder function, self-reported disability and pain, in patients with rotator cuff related shoulder pain.

Methods: A randomised controlled single-blinded study patients with a history of lateral upper arm pain with MRI confirmation of rotator cuff pathology or positive testing on a cluster of clinical rotator cuff tests were included. Patients with a recent history of shoulder surgery or a shoulder fracture were excluded. Participants were randomly assigned to complete either 6 weeks (short group) or 12 weeks (long group) of the exercise programme. Both groups performed the same specific set of loaded exercises daily at home and attended 6 clinic-based group exercise sessions2. Participants were assessed at 6 weeks, 3 and 6 months. Shoulder function was assessed using the Constant-Murley (CM) score. Disability was assessed using the QuickDash and the Shoulder Pain and Disability Index (SPADI). Pain was assessed using a visual analogue scale. Group comparisons were made using univariate generalised linear models.

Results: 85 patients were included in this study as per Table 1.

Within each group shoulder function, self-reported disability and pain improved significantly at 3 months (p < .05). Comparisons at 3 months showed the long group had significantly lower pain scores (p = .02). At 3 months there was no significant difference between the two groups in the CM score (p = .415), SPADI score (p = .053) and QuickDash score (p = .245). However, at 6 months, the long group had significantly greater changes in both the CM score (p = .007) and the SPADI score (p = .002).

Conclusion: In the management of patients with rotator cuff related shoulder pain the findings of this study indicate that a 12 week exercise programme results in better outcomes for pain at 3 months and self-disability and shoulder function at 6 months.

FRI0698-HPR DEVELOPMENT OF DELPHI-BASED RECOMMENDATIONS FOR THE MANAGEMENT OF CARDIOVASCULAR COMORBIDITIES IN PATIENTS WITH PSORIATIC ARTHRITIS AND MODERATE-TO-SEVERE PSORIASIS: STUDY PROTOCOL

ALMODOVAR RAQUEL1, Jose Luis Lópezz Estebanbarzu2, Eva De Higés Martínez3, María Jesús López Navas4, Carlos Guijarro Herraiz2, Juan José Gorgojo Martínez5, David Palacios2, José Carlos Peñé Alvarez3, Diana Ruiz Génao4, Ana Pérez Carbonell9, Susana Gómez10, Erica Falkelbach10, Francisco Rebollo10, Pedro Zarco Montejo1, 1Hospital Universitario Fundación Alcorcón (HUFA), Rheumatology Unit, Alcorcón, Spain; 2Hospital Universitario Fundación Alcorcón (HUFA), Dermatology Service, Alcorcón, Spain; 3Hospital Universitario Fundación Alcorcón (HUFA), Rehabilitation Unit, Alcorcón, Spain; 4Hospital Universitario Fundación Alcorcón (HUFA), Internal Medicine Department, Alcorcón, Spain; 5Hospital Universitario Fundación Alcorcón (HUFA), Endocrinology and Nutrition Service, Alcorcón, Spain; 6National coordinator for dermatology at SEMERGEN, Madrid, Spain; 7Hospital Universitario Fundación Alcorcón (HUFA), Psychiatric Service, Alcorcón, Spain; 8Medical Statistics Consulting, Valencia, Spain; 9PZer Rubí, Medical Department, Madrid, Spain

Background: Psoriasis (PsO) and Psoriatic Arthritis, (PsA) particularly moderate to severe disease (MS-PSO), are inflammatory systemic
conditions that are associated with a high risk of cardiovascular (CV) complications further beyond the increased prevalence of classical risk factors in this population. Consequently, the early identification of patients with MS-Pso and PsA who may benefit from primary CV prevention is essential. However, medical providers do not routinely screen or counsel their patients for CV risk factors or comorbidities. In addition, paucity of robust clinical data complicates the implementation of management protocols for primary CV prevention in MS-Pso and PsA.

Objectives: To generate expert-based recommendations on the management of CV comorbidities in patients with MS-Pso and PsA through the application of the Delphi technique.

Methods: The development of Delphi-based recommendations included four steps: (1) systematic literature review to explore current information and clinical recommendations on management of CV comorbidities in patients with PsOs and PsA; (2) two subsequent meetings with project coordinators (n = 3) and scientific advisors (n = 7) from different medical specialties (rheumatology, dermatology, endocrinology, internal medicine, pneumology, rehabilitation, psychiatry, and primary care) to examine the results of the review and decide which statements should be included in the final version of the questionnaire; (3) a two-round Delphi questionnaire aimed at specialists in rheumatology and dermatology to assess the degree of consensus on the different points raised; (4) finally, a face-to-face meeting with the project coordinators and scientific advisors to discuss and ratify the results of the Delphi process.

Results: As a result of the literature review and the assessment and approval of scientific advisors, the final version of the Delphi survey contains 52 statements grouped into 35 questions. The questionnaire is divided into 3 topic sections: (1) identification, diagnosis and referral of MS-Pso and/or PsA patients with CV comorbidities (n = 12 statements); (2) management and treatment of CV comorbidities associated with MS-Pso and/or PsA (n = 36); (3) influence of MS-Pso and/or PsA treatments on CV comorbidities and vice versa (n = 4).

Conclusion: This Delphi-based study may fill an important gap in the evidence by providing relevant information on the management of CV comorbidities in patients with MS-Pso and/or PsA.

Systematic review: Objective: To evaluate the quality of the current evidence from SRs on the effects of non-pharmacological interventions for the management of FM.

Methods: A systematic search of seven databases (1990-2018) was completed to identify SRs reporting the effects of non-pharmacological interventions on the primary outcomes of pain, function and quality of life (QoL). Data was extracted according to the PICO framework in addition to intervention prescription where appropriate. Methodological quality was assessed using the Assessing the Methodological Quality of Systematic Reviews (AMSTAR-2) instrument (Shea et al 2017). Reviews were classified into 6 categories (1) land-based exercise; (2) water-based exercise; (3) mind-body; (4) electrotherapy; (5) manual therapy and (6) complementary and alternative medicine (CAM). Quality of the included SRs were variable with many interventions scoring low to critically low. High quality evidence was found to support the use of land-based exercise and mind-body therapies for the improvement of pain, function and QoL (Table). In particular aerobic exercise with or without strength training and mind-body therapies demonstrated the best outcome.

Conclusion: With the exception of land-based exercise and mind-body exercise, the quality of evidence for the non-pharmacological management of FM is mostly poor, with more than half of the included reviews scoring low or critically low on the AMSTAR-2 instrument. Improved reporting of outcome data and stricter methodological quality will allow stronger recommendations in the future.

After the demographic characteristics and disease related data of the individuals were recorded; for the functional status, the Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Metrology Index (BASM1) were used. Six-minute walk test (6MWT) was used for the assessment of aerobic capacity. Group I was attended 40 min aerobic exercises sessions (5-min warm up, 30-min treadmill, 5-min cool down), plus supervised spinal mobility exercises and Group II was attended only supervised spinal mobility exercises per day, 3 times a week, for 12 weeks. Data were analysed Wilcoxon and Mann Whitney U Test.

Results: After training aerobic exercise group, BASMI (p = 0.021), BASDAI (p = 0.002) and 6MWT (p = 0.036) results were statistically significant, while the difference was not significant in BASFI (p = 0.66). It was observed that there was no significant difference in the after training period in the supervised exercises group. BASDAI, in group aerobic exercise group had improved more significantly when compared to supervised exercises group.

Conclusion: As a result of the study, it was noted that when aerobic exercise training applied together with the supervised exercises in ankylosing spondylitis patients, effectiveness on mainly disease activity, spinal mobility and aerobic capacity was increased. Key words: Ankylosing spondylitis, aerobic exercise training, supervised exercise.

FR0704-HPR
THE EFFECTS OF CLINICAL PILATES TRAINING IN PATIENTS WITH FIBROMYALGIA: A RANDOMIZED CONTROLLED TRIAL
CAGLAYAN Benna Cagla1, Aylin Keskin1, Elif Gur Kabali1, Bilge Basakci Calik1, Ummuhan Bas Astd1, Ugur Karasu2, Pamukkale University, Physical Therapy and Rehabilitation, DENIZLI, Turkey; Pamukkale University, Department of Rheumatology, DENIZLI, Turkey

Background: Fibromyalgia (FM) is a chronic condition characterized by widespread pain, sleep disorders, fatigue and reduced quality of life. Exercise is commonly recommended in the approach of people with FM. Researches support some forms of exercises reduce fibromyalgia symptoms and improve quality of life. Pilates recently has become popular form of exercise which focused core strengthening, posture and coordination of breathing with movement. Studies showed that clinical pilates can be used to provide improvements in patients with FM. However there is no study which compared clinical pilates-based supervised exercises and group exercises on FM patients in literature.

Objectives: The first aim of the study was to investigate the effects of clinical pilates training, secondly to compare the effects of supervised exercises and group exercises training on disease activity, functional status, anxiety, quality of life and biopsychosocial status in individuals with FM.

Methods: 42 voluntary women diagnosed with FM according to 2010 American College of Rheumatology Criteria in the age range of 35-65, who applied to Pamukkale University Department of Internal Medicine, Department of Rheumatology were included in the study. Individuals were randomly divided into two groups, as there would be supervised exercises (Group I, n = 16, mean age 55.38±8,03) and group exercises (Group II, n=26, mean age 47.80±5,87). All participants attended 60 min exercises sessions (10-min warm up, 40-min clinical pilates exercises, 10-min cool down) per day, 2 times a week, for 6 weeks. The training was applied by same physiotherapist who received clinical pilates certificate by an experienced Pilates instructor and physiotherapist. After the demographic characteristics and disease related data of the individuals were recorded; disease activity were assessed with the Fibromyalgia Impact Questionnaire (FIQ), functional status with Health Assessment Questionnaire (HAQ), anxiety with Beck Anxiety Inventory (BAI), quality of life with Short Form 36 (SF-36) scale and biopsychosocial status with the Cognitive Exercise Therapy Approach Scale (BETY). All outcomes were assessed just before and 6 weeks after training. The data were statistically evaluated by the Wilcoxon test and Mann-Whitney Test.

Results: There were no significant differences in baseline demographics between the Group I and Group II (p>0,05). After 6 weeks, for both groups a statistically significant improvement in FIQ, SF-36 (physical and mental component) and BETY also Group II showed a statistically significant improvement in HAQ and BAI (p<0,05). When both group were compared, a significant difference was observed in FIQ (p<0,05) in Group II, whereas no statistical differences were found in other outcomes (p>0,05).

Conclusion: This study showed that clinical pilates training which were applied 6 weeks, resulted in improvement on disease activity, functional status, anxiety, quality of life and biopsychosocial status in individuals with FM. Besides group exercises training provides social interaction so we suggest clinical pilates as an effective and safe method for people with FM.

**FRI0706-HPR** COMPARISON OF IMPACT OF VERUM AND PLACEBO THUMB BASE ORTHOSES ON SKIN SURFACE TEMPERATURE AND PRESSURE: A PROOF OF CONCEPT STUDY

Louis Davis1, Marcus Loyte2, Peter Worsley2, Jo Adams2. 1University of Southampton, Health Sciences, Southampton, United Kingdom; 2University of Southampton, Health Sciences, Southampton, United Kingdom

Background: Basal thumb osteoarthritis (OA) can cause significant pain and cause a decline in hand function (Litwic et al 2013). Guidelines for treatment of symptomatic basal thumb OA supports a conservative approach, including splinting to support the carpometacarpal joint (CMCj) and reduce the painful movements of the thumb joint during functional tasks (Zhang et al 2000). Lack of legitimate placebo thumb splint has been a barrier to research to distinguish the specific mechanism of the perceived therapeutic effect of wearing thumb splints. Despite this, splinting of the basal thumb joint remains a common intervention for pain. This research contributed to a national CRN portfolio adopted study examining the clinical effectiveness and efficacy of basal thumb splints for people with basal thumb OA.

Objectives: In the present study, the efficacy of two novel placebo splint designs are examined in comparison to widely used verum thumb splint and no splint for the effect at skin surface interface whilst performing a functional task

Methods: This proof of concept study used a single blind, cross-over design that assessed the effect of wearing different splint conditions on the skin surface interface during a functional hand task. 17 healthy participants (male n=8; female n=9) who met the inclusion criteria were recruited to take part in the study. Skin surface temperature ('°C) and pressure exerted at the skin surface interface was recorded during performance of a standardised hand function task, the nine-hole peg test (9HPT) for four splint conditions i) verum splint (Promedics NC79562), ii) placebo lycra splint (P1); iii) placebo lycra splint ‘lite’ (P2) and iv) no splint. Data were recorded and analysed by one rater using Matlab and SPSS software. Results: It was observed from the mean rank that the verum splint condition caused the greatest pressures compared to all other splint conditions. Post hoc analysis revealed there was no difference in pressure exerted over the CMCj between the no splint condition and P1 (Z=1.577, p=0.115) and P2 (Z= -0.365, p=0.715). The verum splint caused a significant increase in pressure over the CMCj in comparison to all other test conditions (Z= -3.516, p<0.0005). ANOVA showed a significant effect of splint design on temp (F(3,16)=22.96, p=0.005). Post hoc analysis revealed that the verum splint produced a significantly higher skin surface temperature (32.67°C ±1.10°C) than P1 (31.75°C ±1.10°C, p<0.0005), P2 (31.85°C ±1.11°C, p<0.001) and no splint (31.06°C ±1.24°C, p<0.0005) conditions. No differences in skin temperature were shown between placebo designs (p=1.00).

Conclusion: This study is the first to characterise the effect of different thumb splint designs on the skin surface temperature and the mechanical loading force local to the CMCj. This study further informs the specific effect of thumb splints at the joint interface. Identifying that new placebo splint designs do not provide additional support to the thumb joint is a novel supplement to research surrounding thumb splinting intervention and can support the use of these devices as placebo splint conditions in future trials.

FRIO708-HPR PROGNOSTIC FACTORS ASSOCIATED WITH AN EARLY RESPONSE TO PHYSIOTHERAPY TREATMENT IN PATIENTS WITH CHRONIC NONSPECIFIC NECK PAIN: AN EXPLORATORY PROGNOSTIC MODEL
Lucia Domingues1,2, Eduardo B. Cruz2, Fernando Pimentel Dos Santos1,4, Jaime Branco1,4, CEDOC-Chronic Diseases Research Center – Nova Medical School/Faculdade de Ciências Médicas, Rheumatic Diseases, Lisbon, Portugal, 2Centro de Medicina e Reabilitação de Alcântara, Lisbon, Portugal, 3Escola Superior de Saúde – Instituto Politécnico de Setúbal, Physiotherapy Department, Setúbal, Portugal, 4CHLO/Hospital Egas Moniz, Rheumatology Department, Lisbon, Portugal

Background: Chronic nonspecific neck pain (CNP) is a common health problem worldwide. Previous studies identified sociodemographic and clinical factors associated with successful outcomes in patients at discharge of physiotherapy treatment. However, the prognostic factors associated with an early response to physiotherapy treatment in patients with CNP are unclear. This knowledge may allow to identify a profile of patients with higher odds of improvement at the beginning of treatment, supporting clinical decision-making considering benefits versus non-benefits at short-term.

Objectives: This study aimed to identify prognostic factors associated with an early successful response to Physiotherapy treatment in patients with CNP. The successful response was defined as a reduction on disability of ≥30% after 3-weeks of physiotherapy treatment.

Methods: A prospective cohort study was conducted on 52 patients with CNP lasting ≥3 months, undergoing a physiotherapy treatment programme of mobilisation and exercise (coordination, strength, endurance). Patients were assessed at baseline, and then 3-weeks later. Participants were categorised as having a successful outcome if they scored a difference in their disability above the Minimal Clinical Important Difference (MCID) of the Neck Disability Index (NDI). Logistic regression analysis (backward stepwise conditional method) was used to identify the associations between baseline prognostic factors and outcome. Socio-demographic and clinical characteristics of CNP were included as potential prognostic factors.

Results: A total of 51 participants completed the intervention. At 3-weeks post-treatment, 75% (38/51) of the participants achieved a successful response to physiotherapy treatment. In the final multivariate model (Omnibus Tests p<0.001), an early successful response to Physiotherapy treatment was significantly associated with the disability score (OR 1.16 – CI 95% 1.02-1.32), and pain intensity (OR 1.81 – CI 95% 1.03-3.20) at the baseline. This model improves the classification ability from 74.5 to 81.7%.

Conclusion: This study confirms that patients with medium to high levels of disability and high levels of pain at the baseline, treated with a physiotherapy programme of mobilisation and exercise, are more likely to have increased odds of achieving an early response to treatment in the presence of both variables (+LR=1.71 95% CI: 0.84-3.50) or one variable (+LR=1.45 95% CI: 0.69-3.04).

FRIO709-HPR EFFECTS OF LAND- AND WATER-BASED EXERCISE INTERVENTIONS ON PAIN IN PEOPLE WITH FIBROMYALGIA: A PRELIMINARY REPORT FROM THE AL-ANDALUS RANDOMISED CONTROLLED TRIAL
Fernando Estévez-Lopez1,2, Inmaculada C. Alvarez-Gallardo3, Victor Segura-Jiménez1,2, Milikana Borges Cosic1, Pedro Acosta-Manzano1, Blanca Gavilán Carrera1, Ana Carboneil-Baeza2, Manuel Delgado-Fernández1,2, Virginia A. Aparicio1,2, University of Granada, Granada, Spain; 3Uster University, Belfast, United Kingdom; 4University of Cádiz, Cádiz, Spain

Background: Non-pharmacological approaches are the mainstay of treatment in fibromyalgia. The current recommendations of the European League Against Rheumatism (EULAR) for the management of fibromyalgia highlight that exercise is the only therapy with a ‘strong’ evidence [1]. Exercise has been typically implemented on either land- or water-based settings. However, it is unclear whether to perform exercise in different settings has different effects on pain; this knowledge might help to maximise the beneficial effects that exercise has in fibromyalgia [2].

Objectives: To compare the effects of two exercise interventions (land- and water-based training) on pain in people with fibromyalgia.

Methods: From 272 initially randomized, a total of 151 participants (50.6 ±7.6 years old, 98% women) completed all the assessments and attended to at least 70% of the programme; 48, 42 and 61 participants pertained to the land-based exercise, water-based exercise, and usual care (control) groups, respectively. The intervention groups trained 3 non-consecutive days/week (45-60 minutes per session) for 24 weeks. Each session included aerobic exercises, muscular strengthening and stretching for all the major muscle groups. Pain was measured by the 0-100 mm visual analogue scale (VAS) from the Fibromyalgia Impact Questionnaire (FIQ), Catastrophizing and self-efficacy pain-related cognitions were assessed by the Pain Catastrophizing Scale (PCS total score) and pain management subscale (PSE) of the Chronic Pain Self-efficacy Scale (CPSS), respectively. We calculated an algometer score based on the sum of pain thresholds (kg/cm2) of the 18 tender pints according to the 1990 American College of Rheumatology fibromyalgia diagnostic criteria.

The groups were comparable in sociodemographic and clinical characteristics; they only differ on age, which was included as a covariate along with baseline levels of pain.

Results: Adjusting for Bonferroni, most of the between-group comparisons of pain changes over time were not significant. As exceptions, in comparison to the control group, participants in the land-based exercise group lowered catastrophizing and improved algometer score at the post-tests; mean difference (95% interval confidence) [MD(95% CI)] = -4.0 (-7.5 to -0.5) and 6.2 (2.0 to 10.5), respectively. These differences became non-significant at the re-test.

Conclusion: These preliminary results suggest that a 24-week land-based exercise intervention had beneficial effects by reducing pain catastrophizing and increasing algometer score in people with fibromyalgia. However, these benefits were unsustained after the detraining period. In comparison to the control group, a water-based exercise intervention did not show any effect on pain. Although our finding suggest that a land-based exercise intervention may have short-term beneficial effects on pain, these findings must be considered as preliminary until more robust analyses are performed.

EFFECTIVENESS OF EXERCISE IN THE MANAGEMENT OF FATIGUE AND SLEEP QUALITY IN FIBROMYALGIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Fernando Estevez-Lopez1,2, Cristina Maestre Cascales3, Deborah Russell1, Immaculada C. Alvarez-Gallardo1, Maria Rodriguez-Ayllon2, Ciara Hughes1, Gareth W. Davison1, Borja Sañudo1, Joseph Mowfeld1, Ulster University, Belfast, United Kingdom; 1University of Granada, Granada, Spain; 2Universidad Politécnica de Madrid, Madrid, Spain; 3University of Cadiz, Cadiz, Spain; 4University of Seville, Seville, Spain; 5University College Cork, Cork, Ireland

Background: Non-pharmacological interventions are the mainstay of treatment for fibromyalgia, however, current evidence-based guidelines report that the only therapy supported by ‘strong for’ evidence is exercise intervention for pain in fibromyalgia [1]. While increased fatigue and poor sleep quality are among the most burdensome symptoms in fibromyalgia, there remains limited evidence for the effectiveness of exercise in the management of these symptoms [2,3].

Objectives: To determine the effectiveness of exercise in the management of fatigue and sleep quality in fibromyalgia.
