Methods: Population study based on the analysis of a national administrative database that includes a Minimum Basic Data Set (MBDS) of the income of patients with RA (ICD 9 714). Period: January 1, 1999 to December 31, 2015. The following entities were included as OI: tuberculosis (tb), nontuberculous mycobacteria, cytomegalovirus (CMV), Epstein-Barr virus (EBV), Herpes zoster (HZ), Candidiasis, Toxoplasmosis, Pneumocystis, Cryptococcus, Listeria, Nocardiosis, Aspergillosis, Coccidioidomycosis, Histoplasmosis, Blastomycosis, Strongyloides, Leishmaniosis, Cryptporidium, Trypanosoma cruzi, JVC and other prion viruses. These diagnoses were identified by the presence in primary and secondary diagnosis of their ICD9 codes. The population at risk was estimated
through the population census of the National Institute of Statistics, with an estimated prevalence of RA of 0.5% in both sexes (0.2% in men and 0.7% in women). Crude and adjusted rates were calculated at the national level. The trend was analyzed by Generalized Linear Models (GLM) using the year variable as the analysis variable. Clinical-demographic factors associated with these infections were analyzed, using uni- and multivariate logistic regression.

**Results:** Of the total of 338,343 hospital admissions in patients with RA during the 17 years of the study period, there were 17,497 (5.2%) admissions with opportunistic infection, 1591 (38.8%) in men and 2506 (61.2%) in women (p < 0.001). The infections found in order of frequency were: Pneumocystis (29.9%), Tbc 1227 (29.9%), Aspergillus 357 (8.7%), systemic candidiasis 342 (8.3%), CMV 270 (6.5%), EBV 133 (3.2%), Pneumocystosis 122 (2.9%), Leishmaniosis 100 (2.4%), Listeriosis 98 (2.1%), Mycobacterium tuberculosis 85 (2%), Nocardiosis 86 (2.1%), Trypanosoma Cruzi 19 (<1%), JVC 19 (<1%), Cryptococcosis 15 (<1%), Toxoplasmosis 14 (<1%), Strongyloides 11 (<1%), Cryptosporidium 6 (<1%), Histoplasmosis 1 (<1%), blastomycosis 1 (<1%). Between 20-40 years the most frequent infections were: Tbc, EBV, CMV; Between 40-60 years: Tbc, HZ, CMV; Over 60 years old: HZ, tbc, aspergillus. The mean age was 65.54 (SD16.6). 445 (10.9%) died during admission; 217 (13.6%) in men and 228 (9.1%) in women (p < 0.001). The mean of the Charlson index was 1.96 (1.49), 2.21 (SD1.6) in men and 1.81 (SD1.3) in women (p < 0.001). The Relative Risk male: female was 2.77. The infections with the highest male/female RR were: Leishmaniosis (4.77), Listeriosis (4.1) and Aspergillus (3.8). The infections with the highest lethality were: Pneumocystosis (9.4%), Candidiasis (29.8%), and Aspergillus (27.7%). The age-adjusted rate for all OI was 146.21/100,000 inh*year, 297.05 in men and 107.37 in women. Adjusted IO rates increased from 85.47 in 1997, to 193.48 in 2015. It is estimated that this increase is of 4.96% per year. In the multivariate analysis, the factors associated with OI were: male, COPD and liver disease.

**Conclusion:** In Spain, during the period 1997 to 2015, there has been an increase in the incidence rate of OI in patients with RA. We estimate an annual increase of 4.9%. Being male and having COPD or liver disease are associated with OI.

**POOR COMPLIANCE BY RHEUMATOLOGISTS AND ORTHOPAEViS WITH GUIDELINES FOR THE PERIOIOPERATIVE MANAGEMENT OF RHEUMATOID ARTHiRiTS PATIENTS UNDERGOING ARTHROPLASTY**

Kieran Murray1, Tristan Cassidy2, Abuelmagd Abdalla1, Timothy Murray3, Anna O’Rourke1, Douglas Veale1. 1Saint Vincent’s University Hospital, Dublin 4, Ireland; 2Cappagh Hospital, County Dublin, Ireland; 3Beaumont Hospital, Dublin, Ireland

**Background:** Appropriate management can reduce the increased perioperative infection risk in RA patients[1]. In 2017, American College of Rheumatology (ACR) and the American Association of Hip and Knee Surgeons released Guidelines for the Perioperative Management of Anti-rheumatic Medication in Patients with Rheumatic Diseases Undergoing Elective Total Hip or Total Knee Arthroplasty[1]. Atlanto-axial subluxation at induction of general anaesthetic (GA) is another concern. Preoperative C-spine X-rays with flexion-extension views are recommended[2].

**Objectives:** Assess compliance with medication guidelines and C-spine imaging practices for RA patients undergoing arthroplasty under GA.

**Methods:** An anonymous 24 question paper-based survey was distributed at Irish Society of Rheumatology Meeting (September 2017) and Irish Institute of Trauma and Orthopaedic Surgery Curriculum Day (January 2018) examining clinician demographics, imaging and prescribing practices.

**Results:** 33 orthopaedists and 23 rheumatologists responded. The majority (n=66) were trainees and <40 years old (n=43). Most rheumatologists were female and orthopaedists male.

The guideline advocates cDMARD continuation perioperatively[1]. Rheumatologists are more likely than orthopaedists to continue cDMARDs preoperatively. Responses varied by agent, 2 to 4 rheumatologists never stop bDMARDs preoperatively. Depending on the agent, 2 to 4 rheumatologists never stop bDMARDs preoperatively, 6 orthopaedists always increase steroids (13 sometimes, 9 never, 5 unsure), 7 never stop (13 sometimes, 6 always, 5 sure), 12 rheumatologists sometimes increased steroids (8 always, 1 never, 1 sure, 1 answer). 14 never stop steroids (8 sometimes, one not sure).

In RA patients undergoing GA, 22 orthopaedists always perform C spine imaging prior (10 sometimes, 1 never), 11 rheumatologists always do C spine imaging prior (11 sometimes, 1 never). Orthopaedists are more likely than rheumatologists to always perform spinal imaging preoperatively (P value=0.002, Fisher’s exact test).

**Conclusion:** There is poor compliance with guidelines and variability and uncertainty in prescribing. Orthopaedists often discontinue sDMARDS preoperatively despite guidelines to the contrary. Orthopaedists are more likely than rheumatologists to perform preoperative C spine imaging as per recommendations.

**FACTORS CONTRIBUTING TO DISCREPANT ESTIMATED GLOMERULAR FILTRATION VALUES MEASURED BY CREATININE AND CYSTATIN C IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)**

Akiakatu Nakashima1, Shigeto Horita1, Takahiro Matsunaga1, Ryo Inoue2, Ichiro Mizushima3, Mitsuhiro Kawanoo4, Hideki Nomura5, Ichikawa Prefectural Central Hospital, Division of Nephrology and Rheumatology, Kanazawa, Japan; 2Ishikawa-ken Saiseikai Kanazawa Hospital, Division of Internal Medicine and Rheumatology, Kanazawa, Japan; 3Graduate School of Medical Science, Kanazawa University, Department of Rheumatology, Kanazawa, Japan; 4Kanazawa University Hospital, Department of General Medicine, Kanazawa, Japan

**Background:** In rheumatoid arthritis (RA) patients, it is important to evaluate renal function, because it may deteriorate due to RA itself or drug use requiring drug dose adjustment. Recently, Cystatin C (CysC) has been used as a more accurate marker of renal function than Creatinine (Cr), because it is not affected by muscle mass. Renal function of some RA patients is overestimated by Cr, and shows a discrepancy in the estimated glomerular filtration between Cr and CysC. However, what
Comparisons of Serum Levels of GDF-15 in Patients with Rheumatoid Arthritis with or Without Disease Activity

Guadalupe Mendoza-Vázquez1,2, Francisco Espinoza-Gómez1, María Zavala1, Sandra Guzmán-Silahua1,2, Carlos Reuling-Nava1, Arnulfo Hernán Nava-Especialidades (HE) Centro Médico Nacional de Occidente (CMNO), Guadalajara, Jalisco, México, 1Programa de Doctorado en Ciencias Médicas, Facultad de Medicina, Universidad de Colima, Colima, México, 2Unidad de Investigación Biomédica 02, Instituto Mexicano del Seguro Social (IMSS) Hospital de Especialidades (HE) Centro Médico Nacional de Occidente (CMNO), Guadalajara, Jalisco, México, 3Programa Internacional, Facultad de Medicina, Universidad Autónoma de Guadalajara, Zapopan, Jalisco, México., 4Programa de Doctorado en Farmacología, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Jalisco, México, 5Unidad de Investigación en Epidemiología Clínica, Universidad de Médica de La Plata, Centro Médico Nacional IMSS, Ciudad de México, México, 6Hospital General de Occidente, Secretaría de Salud Jalisco, Servicio de Immunología y Reumatología/Programa Internacional de Medicina, Universidad Autónoma de Guadalajara, Guadalajara, Jalisco, México.

Background: The increase in morbidity and mortality in Rheumatoid arthritis (RA) is due to 50% by cardiovascular risk factors associated with chronic-inflammatory processes, among these factors, GDF-15 has been associated with chronic-inflammatory processes such as RA; in addition to being related to the state of the disease of several pathologies with similar mechanisms. GDF-15 could be involved in the pathogenesis of RA and thus, show an association with the activity of a disease in RA. The most common clinimetric tool to evaluate disease activity in RA is Disease Activity Score on 28 joints (DAS28).

Objectives: To compare the serum levels of GDF-15 in patients with RA with or without disease activity.

Methods: Cross-sectional study, including 162 patients with RA, aged ≥18 years old who fulfilled the 1987 ACR classification criteria. RA disease activity was assessed using DAS28-PCR. Sera samples were obtained from venous blood by centrifugation at 3500 rpm for 15 min at room temperature. Serum GDF-15 was measured using an ELISA kit (Biovendor, Germany). Descriptive statistics (mean and standard deviation (SD)) were used for assessing the demographics and clinical parameters. Differences between patients with and without disease activity were assessed using T-student and Chi2 tests. P-values <0.05 were considered statistically significant.

Results: The mean age was 57.2 ± 11.5 years and mean BMI was 27.5 ± 4.7 kg/m². The mean disease duration was 13.60 ± 9.50 years. The GDF-15 (mg/L) was 13.60 ± 31.04 mg/L. For number of swollen and tender joints, the score was 1.50 ± 3.52 and 2.81 ± 4.59 respectively. VAS-pain was 3.00 ± 27.77. DAS28-PCR score was 3.15 ± 1.18. When applying the cut-off value for disease activity (DAS28 score ≥2.6) or remission (DAS28 score <2.6) we obtained 65 (40.1%) and 97 (59.9%) respectively. Comparison of GDF-15 serum levels between active (455.09 ± 333.47) and remission (406.36 ± 272.94) showed no significant associations (p=0.32). When performing Pearson’s correlation among GDF-15 serum levels and PCR values (n=0.142, p=0.07) or DAS28-PCR values (n=0.081, p=0.30) no relevant correlations were obtained.

Conclusion: RA activity is not associated with values of serum levels of GDF-15. Prospective studies are necessary to explain changes in GDF-15 levels throughout RA.

Per Nived1,2, Göran Jönsson3, Bo Settergren4, Jon Einansson5, Tor Olsson1, Johan K Wallman1, Charlotte Svarke Jorgensen2, Melina C Kapetanovic2. 1Lund University, Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden, 2Central Hospital Kristianstad, Section of Infectious Diseases, Kristianstad, Sweden, 3Lund University, Department of Clinical Sciences Lund, Section of Infectious Diseases, Lund, Sweden, 4Statens Seruminstitut, Department of Microbiological Diagnostics and Virology, København, Denmark

Background: A vaccination using a combination of a dose of 13-valent pneumococcal conjugate vaccine (PCV13) followed by a dose of 23-valent polysaccharide vaccine (PPV23) after at least 8 weeks is currently recommended for the immunosuppressed patients with rheumatic diseases.

Objectives: To explore if the prime-booster vaccination strategy using the combination of PCV13 and PPV23 improves antibody response compared to PCV alone in immunosuppressed patients with inflammatory rheumatic diseases, and to compare with the prime-booster response in patients not treated with disease modifying anti-rheumatic drugs (DMARDs) and controls.

Methods: In total, 45 patients treated with rituximab (rheumatoid arthritis (RA), arthritis=35 and vasculitis=10), 20 RA patients on abatacept; 27 patients on methotrexate/azathioprine/mycophenolate moffetil (MTX/AA/MMF; RA=14 and vasculitis=13); 17 patients without DMARDs (RA/arthritis=12 and vasculitis=5) and 25 healthy controls participated. Only patients on an unchanged dose of DMARDs for at least 4 weeks before vaccination were eligible for the study. All participants were vaccinated with a dose PCV followed by a dose PPV23 after at least 8 weeks. A sub-group of rituximab treated patients had been vaccinated earlier with either 7-valent pneumococcal conjugate vaccine (PCV7) or PCV13. Blood samples were taken immediately before and 4-6 weeks after each vaccine dose. Pneumococcal serotype-specific antibodies to the 12 serotypes
Background: Joint destruction in rheumatoid arthritis (RA) includes both bone and cartilage lesions. Since joint space narrowing (JSN) is not a damage by semi-quantitative US score is valid and useful for patients with RA.

THU0150 FINGER JOINT CARTILAGE EVALUATED BY ULTRASOUND IN PATIENTS WITH RHEUMATOID ARTHRITIS AND HEALTHY SUBJECTS
Takehisa Ogura, Ayako Hirata, Norhide Hayashi, Hideki Ito, Sayaka Takenaka, Yuki Inoue, Takaharu Kagtagiri, Chihiro Imaizumi, Yuto Takakura, Hideto Kameda. Toho University, Division of Rheumatology, Department of Internal medicine, Tokyo, Japan

Background: Joint destruction in rheumatoid arthritis (RA) includes both bone and cartilage lesions. Since joint space narrowing (JSN) is not a direct evaluation of cartilage using X-ray, we aimed to examine the validity of ultrasound (US) cartilage evaluation in patients with RA.

Objectives: Methods: The cartilage thickness of bilateral metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints of the 2nd to 5th fingers were visualized from a dorsal view with joints in approximately 90 degrees flexion and measured at the middle portion. Furthermore, one US examiner performed the semi-quantitative scoring of the recorded cartilage images in a blinded manner on a scale of 0–2. In addition, the JSN of the corresponding joints was scored using the van der Heijde-modified Sharp method with a hand X-ray. Continuous variables were analysed using the Mann–Whitney U test. The relationships among the total measurement of cartilage thickness, its semi-quantitative score, and the JSN score were assessed using Spearman’s rank correlation coefficients.

Results: One hundred and three patients with RA and 45 healthy subjects were enrolled in this study. The total cartilage thickness was significantly thinner in patients with RA compared to healthy subjects for both the MCP and PIP joints (both p<0.001). The semi-quantitative sum of 16 joints ranged from 2 to 26 (median 8) in patients with RA, which was significantly greater than the 0 to 11 (median 4) seen in healthy subjects (p<0.001). In patients with RA, the semi-quantitative score showed a significant negative correlation with cartilage thickness (rho=−0.84; p<0.001) as well as a significant positive correlation with JSN score (rho=0.66; p<0.001). In addition, in healthy subjects, semi-quantitative score, but not cartilage thickness was significantly correlated with age (rho=−0.49; p<0.001 and rho=−0.25; p=0.118, respectively). On the other hand, in RA, these scores showed a significant correlation with RA disease duration but not correlated with age.

Conclusion: A simplified and direct evaluation of finger joint cartilage damage by semi-quantitative US score is valid and useful for patients with RA.

Conclusion: RRA was observed in a 20-30% of RA patients, slightly higher compared to previous evidence [1,2]. Characteristics of patients fulfilling different RRA definitions are diverse. Particularly, disease severity (disease activity and structural damage) was not associated with RRA if the definition considers only the exposure to bDMARDs. Given the large time span of the study period, RRA patients were more frequently those who started bDMARDs in earlier years.

THU0153
SARCOPENIA IS ASSOCIATED WITH PERSISTENT DISEASE ACTIVITY DURING FOLLOW-UP OF RHEUMATOID ARTHRITIS
Dong-Jin Park1, J-Hyoun Kang, Haimi Xu, Kyung-Eun Lee, Shin-Seok Lee. Cheonnam National University Hospital, Gwangju, Korea. Rep. of (South Korea)

Objectives: This study investigated the prevalence and impact of sarcopenia on clinical outcomes during follow-up in patients with rheumatoid arthritis (RA).

Methods: We enrolled 294 RA patients from a single tertiary center. Data were collected at the time of enrollment and annually thereafter for 3 consecutive years. Sarcopenia was assessed by bioelectrical impedance analysis and defined as a relative skeletal mass index (RSMI) < 5.14 kg/m² in women and < 7.40 kg/m² in men. Univariate and multivariate analyses were performed to identify the association between sarcopenia and clinical outcome.

Results: Of the 294 RA patients, 8.2% had sarcopenia at the time of enrollment. Patients with sarcopenia were more likely to be older (P=0.001), male (P=0.001), and smokers (P=0.001), and to have a higher body fat mass (P=0.034) and body fat percentage (P=0.039), and a lower basal metabolic rate (P=0.013), than non-sarcopenic patients. Biological agents were more commonly prescribed to sarcopenic patients than to non-sarcopenic patients (P=0.048). The sarcopenic patients had higher Physician Global Assessment (PGA) (P=0.015), higher mean and delta tender joints (P=0.007), higher mean and delta swollen joints (P=0.007), and higher mean DAS28-ESR (P=0.014) and DAS28-CRP (P=0.020) scores than the non-sarcopenic patients. In the multivariate analysis, sarcopenia was significantly associated with male gender (OR = 0.112, 95% CI: 0.041–0.304, P <0.001), mean PGA score (OR = 1.680, 95% CI: 1.067–2.645, P=0.025), and mean DAS28-ESR score (OR = 4.477, 95% CI: 1.661–12.067, P<0.003).

Conclusion: Sarcopenia at baseline was an independent predictor of disease activity during follow-up in Korean patients with RA. Our results provide a rationale for lifestyle interventions designed to maintain normal weight in RA patients and thus help control disease activity.

THU0153
PATTERNS OF SUSTAINED REMISSION AND SUBSEQUENT DMARD TAPERING IN EARLY RHEUMATOID ARTHRITIS: DATA FROM THE CANADIAN EARLY ARTHRITIS COHORT
Maria Powers1, Vivian Bykerk2,3, Orit Schier1, Janet Pope1, Susan J. Bartlett6,7, Louis Penafort4, Caroline Boire5, Carol Hitchon5, Edward Keystone5, Alex Cape4, Alice Thorne5, Marie-France Valois3, Glen Hazlewood1. 1University of Calgary, Calgary, Canada; 2Hospital for Special Surgery, New York, United States of America; 3Weill Cornell Medical College, New York, United States of America; 4University of Toronto Dalla Lana School of Public Health, Toronto, Canada; 5Western University, London, Canada; 6McGill University, Montreal, Canada; 7Johns Hopkins Medicine, Baltimore, United States of America; 8Université de Laval, Quebec, Canada; 9Université De Sherbrooke, Sherbrooke, Canada; 10The University of Manitoba, Winnipeg, Canada; 11University of Toronto, Toronto, Canada; 12Southlake Regional Health Center, Newmarket, Canada

Background: Rheumatoid arthritis (RA) treatment emphasizes aggressive titration of disease-modifying antirheumatic drugs (DMARDs) with the goal of achieving disease remission. This often includes the use of multiple DMARDs in combination, which can have a significant impact on patients’ lives and add costs to the healthcare system.

Objectives: To describe the patterns of sustained remission and subsequent treatment reduction in usual clinical practice for patients with early RA.

Methods: Patients (age >18) enrolled in the Canadian early Arthritis Cohort (CATCH) between January 2007 to March 2017 were analyzed. CATCH is a prospective, observational study of patients with early inflammatory arthritis (symptoms < 1 year) treated in rheumatology clinics across Canada. The analysis cohort included patients with a diagnosis of RA according to the 1987 or 2010 ACR/EULAR classification criteria, active disease at enrolment (DAS28=2.6) and those treated with at least one DMARD or biologic agent within the first three months of study enrolment. We defined sustained remission as achieving a DAS28 < 2.6 at two consecutive follow-up visits at least six months apart. Reduction of therapy was defined as a minimum of a 25% dose reduction of conventional, targeted or biologic DMARDs. Descriptive statistics were used to summarize the time to remission and reductions in DMARD therapy.

Results: Eight hundred and thirty-seven (40%) of the 2,097 eligible patients achieved sustained remission during the study period. Of these, 60% did so within the first 18 months and 92% within the first four years (Figure 1). The mean (SD) baseline DAS28 was 5.1 (1.3), and HAQ-DI was 1.0 (0.7). At the time of remission, 80% were prescribed methotrexate (55% subcutaneously), 71% were prescribed combination therapy with other conventional synthetic DMARDs, and 13% were prescribed a biologic agent. In the year after attaining sustained remission, 327 (39%) patients reduced treatment in the following pattern (patients may have had more than one change): 250 patients (30%) reduced or stopped methotrexate, 196 patients (23%) reduced or stopped non-methotrexate DMARDs, and 34 patients (4%) reduced or stopped biologic agents. Of those that reduced or stopped a biologic, only one was due to side effects. For the 250 patients who reduced or stopped methotrexate, 25 were for a side effect.

Conclusion: Achieving sustained remission occurred in 40% of early RA patients in usual clinical practice. Treatment reductions following sustained remission occurred in over a third of patients over the next 12 months, and consisted mainly of adjustment in non-biologic DMARDs.
High-resolution computed tomography (HRCT) of the lung in patients with rheumatoid arthritis: prevalence of interstitial lung disease involvement and determinants of abnormalities

Fausto Salaffi1, Marina Carotti2, Marco Di Carlo2, Marka Tardella3, Andrea Giovagnoni2.

1Dipartimento di Scienze Cliniche e Molecolari - Università Politecnica delle Marche, Jesi (AN), Italy; 2Radiology Department - Università Politecnica delle Marche, Ancona, Italy; 3Rheumatological Clinic, Dipartimento di Scienze Cliniche e Molecolari - Università Politecnica delle Marche, Jesi (AN), Italy

Background: Interstitial lung disease (ILD) causes significant morbidity and mortality in patients with rheumatoid arthritis (RA). An international consensus about the identification of a subgroup of RA-patients with an high risk to develop ILD is still lacking.

Objectives: To assess: (a) the prevalence of ILD involvement in RA on high resolution computed tomography (HRCT) scan; (b) the relationships between pulmonary function tests (PFTs), patient-centred measures and ILD, (c) the potential risk factors that contribute to ILD in RA-patients.

Methods: We retrospectively evaluated the data of RA patients afferent to an Italian rheumatological center from 1/1/2014 to 30/6/2018. We extrapolated clinical data (e.g., gender, age at onset the RA), laboratoryistic factor (RF) and anti-citrullinated protein antibodies (ACPA), respiratory functional data (forced vital capacity (FVC) and single-breath diffusing capacity for carbon monoxide (DLco)), patient-centred measures of dyspnea (PCMD) (modified Borg Dyspnea Index and VAS for breathing), health assessment questionnaire-disability index (HAQ-DI), and HRCT. HRCT abnormalities were scored using a conventional visual reader-based score (CoVR)

The relationships among the two HRCT scores, PFTs and PCMD were calculated using Pearson's correlation. The AUC-ROC curve was calculated to determinate the discriminative performance of measures between patients with and without ILD. Multivariate regression model was used to assess the strength of association between ILD and RA features.

Results: 151 patients with RA were included (45 males and 106 females, mean age of 53.4 ± 7.6 years). We identified ILD in 29 of 151 patients (19.2%). Usual interstitial pneumonia was the most common pattern on HRCT. Patients with ILD were older (p<0.01), their age at RA-onset and HAQ-DI were higher (respectively with p<0.01 and p<0.05) than patients without RA-ILD. RF positivity and titer were similar in the two groups, whereas ACPA positivity and titer were higher in ILD group (p=0.02).

Extent and severity of ILD, total CoVR and CaM score correlated closely with DLco and PCMD (both with p<0.0001). A reduced DLco was the most sensitive test to predict the presence of ILD on HRCT (AUC-ROC, 0.811±0.037). Multivariate analysis showed that older age (p<0.0001), age at RA onset, (p=0.025), APCA titers (p=0.004) and smoking habit (p=0.008) were independent explanatory variables of HRCT damage.

Conclusion: ILD is a frequent feature of RA. RA-ILD is associated with age, age at RA-onset, smoking habit, and ACPA titer. DLco seems the most sensitive measure to predict ILD on HRCT scan, followed by PCMD.

assessments, including disease activity (RADAi), function (MDHAQ), pain (PROMIS), fatigue (PROMIS), sleep (PROMIS), and depression (PROMIS). The current set of analyses focused on adherence to RAapp, overall, by scale, and over the 6 months of the trial. We examined adherence to RAapp over the duration of the study and examined factors related to adherence using mixed regression models. Factors tested included patient age, sex, educational attainment, and baseline CDAI.

**Results:** 75 patients received RAapp and have data included in these analyses (6 patients are in the last month of follow-up). 60 (80%) were female; age breakdown was 24% < 45 years, 49% 45-64 years, and 27% 65 years and over; and educational attainment was 19% high school, 59% college, and 23% beyond college. Baseline CDAI demonstrated 20% in remission, 45% low, 24% moderate, and 11% high disease activity. During the 6-month study, median adherence to the RAapp daily questionnaires was 81.6% (interquartile range 48.4% to 92.3%). Broken down by the type of questionnaire, median adherence was: disease activity 79.8%; pain 80.8%; mood 76.2%; function 79.3%; fatigue 77.0%; and sleep 77.8%. Adherence to the daily questionnaires was highest in the first month but decreased a small amount each of the following months (see Figure, p for trend < 0.001). The only significant predictor of higher adherence was age 65 or over (p = 0.04). High baseline CDAI was associated with a lower adherence but was not statistically significant (p = 0.07).

**Conclusion:** We developed and tested an ePRO app for RA (RAapp). Among a large group of patients, adherence to the app was good but declined slightly over time. There was no substantial variation in adherence with different ePRO scales. Older age was the only significant predictor of adherence.

**THU0157 REASONS FOR NON-PARTICIPATION IN A RANDOMIZED CONTROLLED TRIAL COMPARING TWO SEASONAL INFLUENZA VACCINES IN RHEUMATOID ARTHRITIS PATIENTS**

**Marina Iusche1, Jonathan Starr2, Katherine Rodriguez3, Agnihotram Ramakumar3, Marie Hudson2, Brian Ward1, Ines Colmegna1. 1The Research Institute of the MUHC, Montreal, Canada; 2Lady Davis Institute, Montreal, Canada.**

**Background:** Low recruitment rates (12%) into influenza vaccine studies are reported among healthy older adults. Fear of side effects, lack of insight into personal risk status, and doubts about vaccine efficacy are the most commonly reported reasons for non-participation. Rheumatoid arthritis (RA) patients are also at high risk for influenza and benefit from yearly immunization. A number of influenza vaccines are currently available; however, it is unknown which vaccine(s) provides optimal protection to RA patients. Estimating participation rates is key for designing studies to address that issue.

**Objectives:** To define the rate of non-participation and reported reasons for refusing entry into a randomized clinical trial (RCT) comparing two influenza vaccines (NCT02936180 - ClinicalTrials.gov).

**Methods:** Seropositive RA patients from McGill University Health Centre, on stable treatment prior to recruitment (<3 months), were invited by their treating rheumatologists to participate in the study. A vaccine nurse contacted participants from Year 1 (Y1) and those from Year 2 (Y2) encountered a recruiter immediately after their rheumatologist’s appointment. Patients invited to participate signed the consent form and were later contacted by a vaccine nurse to schedule their appointment. Reasons for non-participation were documented.

**Results:** Over two influenza seasons, 692 RA patients were invited to participate in the study. The non-participation rate was 59.5% (Y1=64.6%, Y2=53.1%, p=0.1). Non-participants and participants did not differ in age or sex (age mean±SD: 61.7±14.7 vs 60.9±12.9, p=0.5; female sex: 76.8% vs 79.9, p=0.33). Inclusion and exclusion criteria resulted in the loss of 17 (4.1%) and 19 (4.6%) subjects, respectively. The three most commonly reported reasons for non-participation were vaccine misconceptions (n=49, 20.4%), reluctance to participate in a clinical trial (n=35, 14.6%), and lack of available time (n=29, 12.1%). Thirty-one patients reported more than one reason for non-participation. Reasons for non-participation were similar according to sex and patient age (> or < 65 years).

**Conclusion:** Only half of eligible RA patients accepted to be enrolled in this influenza vaccine study. Enhancing patient literacy on vaccines and the relevance of conducting clinical trials is essential to optimize both recruitment to such trials and immunization rates.

**THU0158 IMPAIRED OLFACTORY FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**Joens Wendel1, Khang Tran2, Martin Aringer3, Florian Schuch1, Stefan Kleiner1, Antje Haehner3, Thomas Hummel3, 1Rheumatologische Schwerpunktpraxis, Erlangen, Germany; 2TU, Otorhinolaryngology, Dresden, Germany; 3TU, Rheumatology, Dresden, Germany.**

**Background:** Recent studies indicated that rheumatic disorder can be associated with olfactory loss.

**Objectives:** To specifically investigate chemosensory function in patients with rheumatoid arthritis (RA) by valid and reliable psychophysical tests and compare them to healthy controls.

**Methods:** We investigated 212 RA patients (43 men, 169 women; mean age 59 years) and compared their results to 30 healthy controls (10 men, 20 women; mean age 40 years). All participants underwent standardized olfactory (odor thresholds, odor discrimination and identification for suprathreshold testing) and gustatory tests (taste sprays – suprathreshold taste function; taste strips – quasi-threshold gustatory test). In addition, blood chemistry was also assessed (e.g., for CRP, RA factors, and anti-CCP).

**Results:** RA patients rated their senses of smell and taste to be as good as that of controls. However, in RA patients 4% were found to be anosmic, and 36% to be hyposmic. These numbers were 0 and 20%, respectively, in controls. RA patients exhibited significantly lower scores in odor identification and discrimination. Gustatory test scores were also decreased in RA patients. No such differences were found for odor thresholds. Interestingly, the changes in olfactory and gustatory function neither correlated with disease activity nor with treatment with MTX, or other RA activity or severity like C-reactive protein, rheumatoid factors, anti-CCP antibodies orDAS28-Score. Moreover, there was no correlation between olfactory dysfunction and treatment with DMARDs, e.g. amount of MTX, or Tumor necrosis factor α inhibitors.

**Conclusion:** These results indicate that olfactory and gustatory function is significantly decreased in patients with RA. This decrease in function seems to be unnoticed by most patients which may be due to the fact that RA patients have no complete loss of function (anosmia), but still function in the range of hyposmia or even normosmia. Importantly, the changes in olfactory function are not observed at the level of odor thresholds but only for suprathreshold tasks, which may suggest that the decrease in function is due to higher-order central-nervous processing of olfactory information. In addition, the lack of correlations between disease parameters and chemosensory dysfunction indicates that the decrease in chemosensory function may be a trait characteristic of RA patients.

**THU0159 RISK FACTORS FOR DEVELOPING SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS AT 2 YEARS: FROM THE CHIKARA STUDY**

**Yutaro Yamada1, Masahiro Tada2, Koji Manda1, Noriaki Hidaka3, Kentaro Inui1, Hiroaki Nakamura1, Osaka City University Graduate School of medicine, Osaka city, Japan; 2Osaka City General Hospital, Osaka city, Japan.**

**Background:** Patients with rheumatoid arthritis (RA) are at higher risk of sarcopenia due to joint dysfunction and chronic inflammation. The prospective observational CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease activity in rheumatoid arthritis; registration number UMIN000023744) was started in 2016 to clarify the correlation between RA disease activity and sarcopenia. We reported that glucocorticoid use and low body fat were independent risk factors for developing sarcopenia at 1 year in RA patients last year.

**Objectives:** Risk factors for sarcopenia were investigated over a 2-year period this time.

**Methods:** 100 patients (78 female, average age 68 years) enrolled in the prospective CHIKARA study underwent examinations of body composition (body weight, muscle mass, fat mass, predicted bone mass, etc.; measured by a body composition analyzer (MC-780A; TANITA, Tokyo, Japan)), laboratory data, disease activity, Health Assessment Questionnaire (HAQ), and treatment condition at baseline and at 2 years. Sarcopenia was diagnosed using the criteria of the Asia Working Group on Sarcopenia. Of 64 patients without sarcopenia at baseline, those who developed sarcopenia at 2 years were identified, and risk factors were investigated by univariate and multivariate analyses.

**Results:** Six patients (9.4%) developed sarcopenia during the 2-year follow-up. Glucocorticoid use >5 mg/day was significantly higher (p=0.009) and MMP3 (p=0.018) and HAQ (p=0.045) were significantly increased in the patients who developed sarcopenia during the 2-year follow-up. Sarcopenia development was significantly associated with male sex (r=0.28, p=0.03), age (r=-0.27, p=0.03), glucocorticoid use >5 mg/day (r=0.33, p=0.02).
p<0.01), CRP (r=0.33, p<0.01) at baseline, ΔMMP3 (r=0.30, p=0.02), and ΔHAQ (r=0.25, p=0.04) on univariate analysis. Multivariate analysis identified no independent factors (Table 1).

### Discussion

The most widely used DMARD is methotrexate (MTX) mainly because of its favorable efficacy-toxicity ratio. However, there is a lot of variability using MTX when it comes to dosage and route of administration; and little research on the overall response of patients to the different strategies used. The most widely used DMARD is methotrexate (MTX) mainly because of its favorable efficacy-toxicity ratio. The most widely used DMARD is methotrexate (MTX) mainly because of its favorable efficacy-toxicity ratio. However, there is a lot of variability using MTX when it comes to dosage and route of administration; and little research on the overall response of patients to the different strategies used.
In the PO MTX group, 8 (32%) patients required a change to SC MTX; in 87.5% of cases due to treatment inefficacy and 7 (87.5%) of these patients kept the SC route until the end of the study.

Abstract THU0161 – Figure 2

Out of the patients that began with SC MTX, the one that changed route to PO maintained a good response. All the patients with biologic DMARDs kept the SC MTX as adjuvant therapy. On the other hand, the 3 (12%) patients of the PO that used a biologic DMARD had suspended MTX several months before.

Abstract THU0161 – Figure 3

Both groups had a good response to MTX. There was a significant reduction in corticoid requirements during the first year of treatment/P

Abstract THU0161 – Figure 4

At the end of the study, 21 (41%) patients received SC MTX and the number goes up to 25 (49%) if we include those who also had biologic DMARDs.

Of those who suspended MTX, 85% were due to adverse effects, similar in both groups.

Conclusion:

• Our study suggests that patients that start with PO MTX require route administration changes more frequently than the SC group during the first year of follow-up.
• SC MTX was the route used by almost half the patients by the end of the study.
• We can also see that the inflammatory response to MTX was acceptable regardless of administration route and that corticoids could be reduced significantly in both groups.

THU0162 WHICH PERSISTENCE OF METHOTREXATE AFTER INITIATION OF THE 1ST BDMARD IN RHEUMATOID ARTHRITIS? THE RETRO-RIC2 STUDY

Guy Baudens1, Tonione Adrien2, Jean-Hugues Salmon3, Jean-Guillaume Letarouilly4, Elena Zinovieva4, Hélène Herman-Demars4, Elisabeth Gervais5, Rene-Marc Filipo5 1Private Practice, Valenciennes, France; 2University Hospital Lille, Lille, France; 3University Hospital Reims, Reims, France; 4NordicPharma, Paris, France; 5University Hospital Poitiers, Poitiers, France

Background: ACR and EULAR guidelines recommend to prescribe bDMARDs and particularly TNFi in combination with methotrexate (MTX). However, the MTX observence in RA is poor, mainly due to side effect and some bDMARDs (IL6 receptor antagonist) are almost as effective in monotherapy.

Objectives: to evaluate MTX use (dosage, route of administration…) in RA after initiation of the first bDMARD.

Methods: RETRO-RIC2 is a multicentric retrospective study. Were included all patients with RA under MTX therapy at the initiation of the 1st bDMARD from October 2008 to September 2016. The main criteria is the persistence of MTX after 1 and 2 years.

Results: 409 patients were included: mean-age = 58.9 years, female 69%, RF positive 76% and ACPA positive 83%, mean RA duration = 13.1y and mean DAS28-ES=4.48. The mean duration of previous MTX therapy = 32 months (mean dose = 16.2mg/w). At the inclusion MTX was administrated by oral route in 52% and subcutaneous in 48%. At the inclusion, 1.2% of the patients switch from oral route MTX for subcutaneous; inversely in only 0.2% the SC route was switched for oral administration.

The results are presented in table 1 and Figure 1.

Abstract THU0162 – Figure 1

Conclusion: In almost all patients MTX dose and route of administration are unchanged at the initiation of the first bDMARD in RA. With a 2 years follow up 49.9% of MTX dose were reduced and MTX was stopped in 2.9%. At 2 years MTX route of administration is oral for 64% of the patients and s/c for 36%.

A DESCRIPTIVE ANALYSIS OF LONGITUDINAL CHANGES IN RELATIVE MARKET SHARE PROPORTIONS OF BIOLOGIC AND TARGETED SYNTHETIC DISEASE-MODIFYING ANTI-RAHUMATIC DRUGS FOR TREATMENT OF RHEUMATOID ARTHRITIS: DATA FROM THE OBRI DATABASE

Elliott Hepworth, Mohammad Movahedi, Emomunnal Rampakakis, Reza Mirza

Elliott Hepworth, Mohammad Movahedi, Emomunnal Rampakakis, Reza Mirza, Claire Bombardier, Janet Poole, Claire Bombardier, Janet Poole, Claire Bombardier, Janet Poole

McMaster University, Internal Medicine, Hamilton, Ontario, Canada; Toronto General Hospital Research Institute, University Health Network, Ontario Best Practices Research Initiative, Toronto, Canada; JSS Medical Research, St-Laurent-OQ, Canada; McMaster University, Rheumatology, Hamilton, Ontario, Canada; Western University, Divisions of Rheumatology, Epidemiology and Biostatistics, Department of Medicine, London, Ontario, Canada; University of Toronto, Mount Sinai Hospital, Rheumatology, Toronto, Canada

Background: For patients with Rheumatoid Arthritis (RA) who do not achieve adequate clinical response with combined conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) or targeted synthetic DMARDs (tsDMARDs), bDMARDs include tumour-necrosis factor inhibitors (TNFi) or non-TNFi classes. Since inception of Ontario Best Practice Research Initiative (OBRI), new treatment options have become available.

Objectives: We aimed to describe the evolution of relative use of non-TNFi vs. TNFi in Ontario-based practices from 2008-2017.

Methods: Adult patients with RA enrolled in the OBRI who started therapy with bDMARDs or tsDMARDs anytime during, or up to 30 days before, enrollment were included. Using descriptive analysis of data from each year between 2008 and 2017, the relative proportion of the population treated with TNFi and non-TNFi therapy was measured for (i) all patients and (ii) those initiating their first bDMARD/tsDMARD. TNFi included: Etanercept, Adalimumab, Certolizumab, Golimumab, and Infliximab. Non-TNFi included: Abatacept, Rituximab, Tocilizumab, and Tofacitinib.

Results: A total of 1,057 patients were included of whom 653 were bDMARD/tsDMARD naïve. In 2008, the relative non-TNFi use was 3/56 (5.4%) in all patients and 0/31 (0%) in treatment-naïve patients. By 2013 the proportion non-TNFi use increased to 135/562 (24%) in all patients and 11/92 (12.0%) in treatment-naïve patients. This increasing trend in relative non-TNFi utilization continued in both groups until 2016 when relative use was 224/679 (33.0%) in all patients and 17/56 (30.4%) in treatment-naïve patients. This increasing trend in the proportion non-TNFi use increased to 135/562 (24%) in all patients and 11/92 (12.0%) in treatment-naïve patients until 2017. In 2017, the proportion non-TNFi use was 216/679 (31.9%) in all patients and 14/56 (25.0%) in treatment-naïve patients.

Conclusion: This descriptive analysis of data from the OBRI cohort shows an increase in the use of non-TNFis. The overall trend towards greater use of non-TNFi therapies as first line agents after combined csDMARDs may be partially explained by the presence of guideline lines that allow clinicians to select any of the above options as first line therapies. For patients with RA, the increase in the use of non-TNFi can be partially explained by the presence of guideline lines that allow clinicians to select any of the above options as first line therapies.}

THE DSAS BASED ON THE ERYTHROCYTE SEDIMENTATION RATE MAY OVERESTIMATE DISEASE ACTIVITY IN EARLY, TREATMENT-NAÏVE PATIENTS WITH RHEUMATOID ARTHRITIS WITH HIGH LEVELS OF RHEUMATOID FACTOR

Emanuele Bozzalla Cassione, Serena Bugatti, Francesca Benaglio, Garfalia Saekellariou, Antonio Manzo, Roberto Caporali, Carlomaurizio Montecucco, Division of Rheumatology, IRCCS Pollicino San Matteo Foundation, University of Pavia, pavia, Italy

Background: Disease activity in rheumatoid arthritis (RA) is commonly measured with the DSAS-ESR. However, ESR levels may be affected by factors not related to inflammation leading to possible disparities with the DSAS-CRP. A particular, increased levels of gammaglobulins may cause increase in ESR. In RA levels of autoantibodies such as rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) may be particularly high; however, their effect on the assessment of disease activity has not been investigated.

Objectives: To evaluate whether positivity and levels of RF and ACPA determine discordance between the DSAS-ESR and the DSAS-CRP, impacting on disease activity stratification in RA.

Methods: 578 early treatment-naïve RA patients (symptoms’ duration <12 months) consecutively recruited at our Early Arthritis Clinic between 2005 and 2014 were studied. Paired DSAS-ESR and DSAS-CRP were obtained at baseline and after 6 months of therapy with conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs). RF and ACPA were determined centrally on baseline sera and, and levels were considered high when >3 times the upper limit of normal (ULN). Agreement between the disease activity scores was compared using Bland-Altman statistics before and after stratification for autoantibody-positive and levels.

Results: Female/male ratio was 2.5:1, with mean (SD) age of 59.7 (14.8) years and median (IQR) symptoms’ duration at inclusion of 15.6 (9.4 to 27.8) weeks. Mean DSAS-ESR values at baseline were 0.39 points higher compared to DSAS-CRP in the whole cohort, with more pronounced differences in females and subjects aged >65 years (Table 1). Collectively RF-positive patients had significantly higher discrepancies compared to –negative subjects (mean [SD] difference 0.45 [0.46] vs 0.35 [0.47], p=0.03), particularly in females irrespective of age. The highest disagreement was recognized in patients with high autoantibody levels; females with RF >3 ULN had DSAS-ESR scores 0.56 points higher. Disparities in these patients impacted on disease activity stratification, as more RF-high females were in DSAS-ESR high disease activity compared with DSAS-CRP (43.1% vs 23%, p<0.001). In contrast, ACPA-positivity did not affect the agreement between the two disease activity indices (Table 1). After 6 months of treatment with csDMARDs discrepancies between the DSAS-ESR and DSAS-CRP in RF-positive patients was reduced but still significant in association with levels >3 ULN (mean difference [95% CI] 0.44 [0.33-0.55]).

Conclusion: In patients with early treatment-naïve RA, the DSAS-ESR and DSAS-CRP are not inter-changeable. In particular, the DSAS-CRP may overestimate disease activity when levels of RF are high. These findings suggest that disease assessment for treatment-to-target approaches should take into account additional factors such as autoantibody-positivity.

A COMPARATIVE ANALYSIS OF UPADACITINIB MONOTHERAPY AND UPADACITINIB COMBINATION THERAPY FOR THE TREATMENT OF RHEUMATOID ARTHRITIS FROM TWO PHASE 3 TRIALS

Maya Buch1, Alvin F. Wells2, Andrea Rubbert-Roth3, Manish Jain4, Casey Schlacher5, Heidi Camp5, Yihan Li5, Yanna Song5, Peter Nash6.

1University of Leeds & NIHR Biomedical Research Centre, Leeds, United Kingdom; 2Rheumatology and Immunotherapy Center, Franklin, United States of America; 3Kantonsprital St Gallen, St Gallen, Switzerland; 4Rheumatology, Great Lakes Clinical Trials, Chicago, United States of America; 5AbbVie Inc., North Chicago, United States of America; 6University of Queensland, Brisbane, Australia

Background: Upadacitinib (UPA), a selective JAK1 inhibitor, has demonstrated efficacy and safety in patients with rheumatoid arthritis (RA) as monotherapy and in combination with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) such as methotrexate (MTX).1,2 However, UPA monotherapy has not been compared directly with UPA combination therapy in the Phase 3 program.

Objectives: To compare the efficacy of UPA monotherapy and UPA in combination with MTX using data from two Phase 3 trials of RA patients with an inadequate response (IR) to prior MTX therapy.

Methods: In SELECT-MONOTHERAPY, 648 MTX-IR patients were randomized to receive UPA 15 mg or 30 mg monotherapy once daily (QD), or continue with MTX monotherapy (cMTX; given as a blinded study drug), for 14 weeks. In SELECT-NEXT, 661 csDMARD-IR patients were randomized to receive UPA 15 mg or 30 mg QD or placebo (PBO) for 12 weeks on a background of csDMARDs. Only patients receiving concomitant MTX (with or without additional csDMARDs) at baseline in SELECT-NEXT were included in this analysis. The primary endpoints of both studies were the proportion of patients achieving ACR20 and DAS28(CRP) <2.6, CDAI remission (≤2.8), CDAI low disease activity (LDA; ≤10), and change from baseline in HAQ-DI. Logistic regression or ordinary least squares analyses were used to compare outcomes with monotherapy versus combination therapy, adjusting for demographics and baseline disease characteristics.

Results: A total of 1114 patients were included in the analysis, of whom 67% received monotherapy in SELECT-MONOTHERAPY and combination therapy in SELECT-NEXT. Of the patients receiving combination therapy, 338 (72.5%) were receiving MTX background therapy only and 128 (27.5%) were receiving MTX plus other csDMARDs. Baseline characteristics were generally similar between the study cohorts; the majority of patients in both studies were female and of white ethnicity, with a mean age of approximately 55 years and a mean MTX dose of approximately 17 mg/week. Consistent with previously reported results from SELECT-MONOTHERAPY1 and SELECT-NEXT,2 both UPA monotherapy and UPA combination therapy led to significant improvements in efficacy outcomes versus cMTX/PBO+MTX (Table). No significant differences were observed between UPA monotherapy and UPA combination therapy across a range of clinical endpoints, including ACR20/50/70 responses and measures of LDA and remission. In addition, improvements in quality of life as measured by HAQ-DI were similar with UPA monotherapy and combination therapy. Efficacy was comparable between the two UPA doses in the combination therapy group, whereas in the monotherapy group numerically higher responses were observed with UPA 30 mg versus UPA 15 mg.

Conclusion: In MTX-IR patients with RA, the efficacy of UPA appears comparable when administered as monotherapy or when given in combination with MTX.

TREATMENT WITH UPADACITINIB IS ASSOCIATED WITH IMPROVEMENTS IN REVERSE CHOLESTEROL TRANSPORT IN PATIENTS WITH RHEUMATOID ARTHRITIS: CORRELATION WITH CHANGES IN INFLAMMATION AND HDL LEVELS

Christina Charles-Schoeman1, Thierry Sommase2, Jeremy Sokolove2. 1University of California Los Angeles, Los Angeles, United States of America; 2AbbVie Immunology Clinical Development, Redwood City, United States of America

Background: Rheumatoid arthritis (RA) is a systemic inflammatory condition associated with increased rates of atherosclerotic morbidity and mortality. One mechanism by which inflammation may increase atherosclerotic progression is via pathogenic remodeling of high-density lipoprotein (HDL)-associated proteins with resultant reduction in HDL function.1 Upadacitinib (UPA), a selective JAK1 inhibitor, has demonstrated efficacy in patients with moderate-to-severe RA.

Objectives: To assess the effect of UPA treatment on cholesterol efflux capacity (CEC) and evaluate the association of CEC with changes in inflammation and serum lipids.

Methods: A subset of patients from the Phase 2 BALANCE II study2 and the Phase 3 SELECT-NEXT study3 were selected from the pool of patients with serum samples available at baseline and Week 12. Patients were matched for age and sex, and selected based on level of response to UPA therapy (BALANCE II, UPA 6 mg BID: 39 responders [mean change in DAS28-CRP at Week 12 -3.22] and 30 non-responders [mean change in DAS28-CRP - 0.33]); SELECT-NEXT, UPA 15 mg QD: 20 responders [mean change in DAS28-CRP -3.78] and 20 non-responders [mean change in DAS28-CRP - 0.67]). A demographically similar placebo (PBO) group without selection based on degree of response was also included (20 patients from each study). J774 macrophages labeled with [3H]-cholesterol (treated with cAMP to expose cholesterol efflux capacity or CEC) were exposed to patient serum and HDL. The difference between cholesterol efflux from serum-exposed and unexposed cells provided a measurement of CEC. Results were compared between the responder, non-responder, and PBO groups using Tukey’s mean comparison method; correlations were calculated using the Pearson method; and all statistical analyses were performed in JMP 13.10 (SAS Institute).

Results: In both studies, changes in global and ABCA1-dependent CEC, and to a lesser extent non-ABCA1-dependent CEC, were significantly higher in the UPA-treated group compared with the PBO group (Figure). In the BALANCE II study, there was a significant increase in CEC among UPA responders relative to PBO and a numerically apparent difference observed between UPA non-responders and PBO. Notably, in the SELECT-NEXT study, a similar and highly significant improvement in CEC was observed for both UPA-treated groups relative to PBO (without a significant difference between the responder and non-responder groups). Despite the lack of a consistent association between change in CEC and change in clinical disease activity, observed increases in CEC correlated significantly with reduction in CRP levels in all groups across all active treatment groups. Additionally, increases in CEC at Week 12 correlated well with changes in total blood cholesterol and HDL levels, but weakly with changes in blood low-density lipoprotein (LDL) levels.

Conclusion: UPA treatment is associated with significant improvement in CEC. This effect was observed even among those demonstrating minimal clinical response (but not significant response) to UPA treatment. CEC seems to be primarily driven by ABCA1-dependent cholesterol efflux and is strongly correlated with a rise in HDL cholesterol as well as reduction in systemic inflammation as measured by change in CRP.

THU0166
SAFETY PROFILE OF UPADACITINIB IN RHEUMATOID ARTHRITIS: INTEGRATED ANALYSIS FROM THE SELECT PHASE 3 CLINICAL PROGRAM

Stanley B. Cohen1, Ronald van Vollenhoven2, Kevin Winthrop3, Cristiano Zerbini4, Yoshiya Tanaka5, Louis Bessette6, LI Yihan7, Nasser Khan7, Barbara Hendrickson1, Gerd Rödiger Burmester,1 1Metropolis Clinical Research Center, Dallas, United States of America; 2Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, United States of America; 3Oregon Health and Science University, Portland, United States of America; 4Centro Paulista de Investigação Clínica, São Paulo, Brazil; 5Univ of Occupational and Environmental Health, Kitayushu, Japan; 6Laval University, Quebec, Canada; 7AbbVie, Inc., North Chicago, United States of America; 8Charité University Medicine, Berlin, Germany

Background: Upadacitinib (UPA), a JAK1-selective inhibitor, significantly improved clinical signs and symptoms of rheumatoid arthritis (RA) in patients (pts) naïve to methotrexate (MTX) and with an inadequate response to conventional synthetic DMARDs (csDMARD-JR) or biologic DMARDs (bDMARD-JR).1-3

Objectives: Assess the safety of UPA as monotherapy (mono) and as combination therapy with background csDMARDs in pts with moderately to severely active RA from the safety database of the Phase 3 clinical program.

Methods: Treatment-emergent adverse events (TEAEs) from 5 pivotal, randomized, double-blind, controlled Phase 3 trials of UPA 15 mg (included in all 5 trials) or 30 mg QD (included in 4 trials) in RA pts randomized, double-blind, controlled; n [%], individual studies with long-term [LT] active comparator (UPA mono vs MTX; UPA 15 mg with background MTX vs originator adalimumab, ADA, events/100 patient-years [E100PY]), and integrated LT (all Phase 3 exposure; E100PY) analyses sets.

Results: Across the Phase 3 trials, 3384 pts received ≥1 dose of UPA 15 mg (n=2630) or 30 mg QD (n=1204) ~402.01 PY of UPA exposure with no option to switch doses. The ST frequencies of overall SAEs and AEs leading to discontinuation were low, but higher on both UPA doses vs PBO. LT event rates were similar on UPA 15 mg vs ADA and slightly higher on UPA vs MTX mono. Deaths occurred in all treatment groups. Serious infection (SIEs) frequencies were higher on both UPA doses vs PBO. SIE rates on both UPA doses were higher vs MTX, but similar on UPA 15 mg vs ADA. Herpes zoster (HZ) frequencies and rates were higher on both UPA doses vs PBO, and vs MTX, ADA, respectively. The rates of SIE and HZ were higher on UPA 30 vs 15 mg. Adjudicated MACE were reported in all treatment groups including PBO. LT MACE rates were similar on UPA 15 mg and ADA and on UPA 15 mg and MTX mono, but higher on UPA 30 mg mono (low number of events, 2-4 per set). Adjudicated VTEs occurred at comparable frequencies on UPA vs PBO and at comparable rates on UPA vs active comparators. Malignancy (excluding non-melanoma skin cancer [NMSC]) rates were similar on UPA vs MTX, UPA 15 mg vs ADA, and 15 vs 30 mg. The NMSC rates on UPA 15 mg and ADA were similar; the rate on 30 mg was higher than 15 mg, but both UPA NMSC rates were in the range reported for RA patients treated with DMARDs.4 The standardized incidence ratio (95% CI) for malignancy (15 mg: 0.98 [0.61, 1.49], 30 mg: 1.49 [0.85, 2.42]) was not elevated vs the general population.

Conclusion: Treatment with UPA increased the risk of SIE and HZ, but not those of VTE, MACE, and malignancy vs comparators. These data support that UPA has an acceptable safety profile in the treatment of moderately to severely active RA.

A MATCHING-ADJUSTED INDIRECT COMPARISON (MAIC) OF UPADACITINIB VERSUS TOFACITINIB IN CDMSARD-IR PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS (RA)

Christopher Edwards1, Ruta Sawant2, Ella Du3, Jordan Cammarota3, Patrick Tang3, Vishvas Garg2, Alan Friedman2, Keith Betts3.

Background: Upadacitinib (UPA), a JAK1 selective inhibitor, is being investigated as monotherapy and combination therapy with DMARDs for the treatment of moderate-to-severe RA. To date, no head-to-head trials have compared the effectiveness of UPA with tofacitinib (TOFA).

Objectives: To compare the efficacy of UPA 15 mg monotherapy and combination therapy with TOFA 5 mg combination therapy using MAICs.

Methods: Two MAICs were conducted. MAIC is an indirect comparison technique that utilizes individual patient data (IPD) for one treatment and aggregate data for the other treatment to provide comparative evidence after balancing differences in patient characteristics. The first MAIC used IPD from the SELECT-MONOTHERAPY trial of UPA monotherapy vs. methotrexate (MTX) and published data from the Oral Standard trial of TOFA+MTX vs. MTX. The second used IPD from the SELECT-COMPARE trial of UPA+MTX vs. adalimumab (ADA)+MTX and published data from the ORAL Strategy trial of TOFA+MTX vs. ADA+MTX. UPA monotherapy was not compared to TOFA monotherapy based on feasibility analysis and trial selection criteria. Patients in the UPA trials were reweighted based on age, gender, race, swollen joint count 66/28, tender joint count 66/28, and C-reactive protein (CRP), and patient’s global assessment, to match the baseline characteristics in each comparator trial. After matching, ACR20/50/70 and clinical remission (SDAI/CDAI) were compared for UPA monotherapy vs. TOFA+MTX relative to MTX at month 3 and UPA+MTX vs. TOFA+MTX relative to ADA+MTX at month 3 and 6 using a Wald test.

Results: After matching, baseline characteristics were balanced across the trial populations. At month 3, UPA monotherapy patients experienced significantly greater improvement in ACR70 compared to TOFA+MTX with a mean difference in difference (DD) of 9.9% (p<0.05) (Figure 1a) while UPA+MTX was associated with a higher ACR50 compared to TOFA+MTX with a DD of 12.9% (p<0.05). At month 6, UPA+MTX patients experienced significantly larger improvement in SDAI/CDAI/CRP-ESR clinical remission compared to TOFA+MTX with DDs of 9.1% (p<0.05), 7.5% (p<0.05), and 11.3% (p<0.01), respectively (Figure 1b).

Conclusion: The results from MAICs indicate that treatment with UPA 15 mg when used as monotherapy or in combination with MTX appears to produce improved outcomes at 3/6 months as compared to TOFA 5 mg +MTX (mono: ACR70 and combination: ACR50, SDAI, CDAI and DAS28-ESR remission).

THU0169 JANUS KINASE INHIBITORS DEMONSTRATE EFFECTIVENESS IN A REAL-WORLD MULTI-BIOLOGIC DMARD REFRACTORY RHEUMATOID ARTHRITIS POPULATION

John Fitton1,2, Andrew Melville1,2, Shouvik Dass1,2, Paul Emery1,2, Jacqueline Nani1,2, Maya Buch1,2. 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Chapel Allerton Hospital, Leeds, United Kingdom; 2NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: The Janus Kinase inhibitors (JAKi) Tofacitinib and Baricitinib are licensed for use in Rheumatoid arthritis (RA). Trials in refractory RA (inefficacy and/or toxicity) to date (1, 2) suggest targeting intracellular signalling molecules and interrupting downstream effects of multiple cytokines may confer benefit in the management of patients who have failed multiple targeted therapies.

Objectives: To evaluate safety and efficacy of JAKi in a real-world population, including response in multi-bDMARD refractory RA.

Methods: We evaluated RA patients who had failed at least 2 csDMARD +/- one or more bDMARD, who were commenced on a JAKi. Patients who commenced Tofacitinib on a compassionate use programme in 2014 (reflecting compassionate access scheme). Number of previous bDMARD was higher in the Tofacitinib group (457-468.). With rheumatoid arthritis (ORAL Strategy).

Results: Seventy seven RA patients (80% female; mean (SD) age 55.9 (12.52) years) have been treated with one (or more) JAKis; 38 have received Tofacitinib and 39 Baricitinib (5 both). Table 1 details treatment stage and clinical outcomes where available (majority pending assessments). Of the 38 patients who received Tofacitinib, 24 stopped treatment, 10 due to primary non-response, 2 secondary non-response and 12 due to

A MULTICENTER STUDY ASSESSING THE EFFICACY AND SAFETY OF REPOSITORY CORTICOTROPIN INJECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS: INTERIM DATA FROM THE OPEN-LABEL TREATMENT PERIOD

Roy Fleischmann1, Dan Furst2, Jingyu Liu3, Julie Zhu4, Erin Connolly-Strong5, Erin Connolly-Strong6

1University of Texas Southwestern Medical Center, Dallas, Texas, United States of America; 2David Geffen School of Medicine at UCLA, Los Angeles, California, United States of America; 3Mallinckrodt ARD, LLC, Bedminster Township, New Jersey, United States of America; 4Washington University School of Medicine, St. Louis, Missouri, United States of America

Background: Rheumatoid arthritis (RA) is an autoimmune disorder associated with chronic inflammation and is treated with disease-modifying anti-rheumatic drugs (DMARDs) and/or biologic disease-modifying anti-rheumatic drugs (bDMARDs). Both American College of Rheumatology (ACR) and EULAR recommend that short-term administration of corticosteroids (CSs) may be beneficial for its anti-inflammatory effects. Repository corticotropin injection (RCI) is a complex mixture containing purified porcine pituitary adrenocorticotropic hormone (ACTH)-analogue and an agonist for all 5 melanocortin receptors (MCRs). Activation of MCRs by ACTH has been shown to have direct and indirect anti-inflammatory and immunomodulatory effects. RCI is approved in the United States as adjunctive therapy for short-term administration in RA.

Objectives: To present interim data after 100% enrollment from the initial 12-week open-label phase of a multicenter, 2-part study evaluating the efficacy, safety, and appropriate duration of RCI therapy in patients with persistently active RA despite receiving 1 or 2 DMARDs and/or CsA.

Methods: In the open-label period (Part 1, Weeks 0–12), all enrolled patients received RCI 1 mL (80 U SC) twice weekly for 12 weeks. Patients who achieved low disease activity (LDA; DAS28-ESR score <3.2) at Week 12 continued in the double-blind, randomized maintenance phase of the trial (Part 2) for an additional 12 weeks. The primary endpoint was the proportion of patients who achieved LDA at Week 12. Secondary endpoints included assessment of the safety and tolerability of RCI. Disease activity was also assessed by the proportion of patients who achieved ACR 20%, 50%, and 70% (ACR20, 50, 70) responses and patient reported outcomes at Week 12. Bone turnover markers were assessed as an exploratory endpoint.

Results: 259 patients had enrolled, 235 had completed and 24 had discontinued the 12-week open-label period of the study; 88.9% were female and mean age was 51 years. RCI treatment resulted in 62.5% of patients achieving LDA at Week 12; results for this interim analysis are presented in the Table. Bone turnover markers were stable from baseline to Week 12, indicating no effect of RCI on bone metabolism. 98 (37.8%) patients reported adverse events (AEs) with 3 (1.2%) patients reporting serious AEs (ie, non-communicable cancer, myocardial infarction, and stroke). The most common AEs were urinary tract infection (n=10), headache (n=9), and pharyngitis (n=7).

Conclusion: In the 12-week open-label period of this study, RCI appeared to be generally safe and effective in patients with persistently active RA who were nonresponsive to DMARDs and CsA. This was demonstrated by improvement in multiple measures of disease activity. Further results will be evaluated in Part 2 of the study.

Background: Tofacitinib (TF) is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

Objectives: To evaluate the one-year effectiveness of tofacitinib as first-line therapy in RA conventional synthetic (cs) DMARDs non-responders. Methods: Data from 415 patients from Russian national register of patients with RA treated with TF were analyzed. 119 RA patients, who had complete clinical and laboratory data from 4 consecutive visits after baseline within an interval of 3 months between these visits and who used the TF as first-line therapy after failure of cs DMARDs, were included. Treatment with any biologics ever was an exclusion criteria.
Demographical (age, sex) and RA activity data (DAS28, SDAI, number of tender and swollen joints (NTJ, NSJ), erythrocytes sedimentation rate (ESR), C-reactive protein (CRP), and HAQ, EQ5D were collected, table 1. Statistical analysis performed in SPSS 2017. p-value <0.05 considered as significant.

**Results:** At baseline 12 (10%) were treated with NSAIDs, 15 (12.6) with 5-10 mg/day of prednisolone, 82 (68.9) – with methotrexate (10-25 mg/week), 8 (6.7%) – with sulfasalazine (2.0-3.0 g/day).

In patients (pts) with active rheumatoid arthritis (RA) and inadequate response or intolerance to bDMARDs, treatment with upadacitinib (UPA), a JAK1-selective inhibitor resulted in significant improvements over 24 weeks (wks).

**Objectives:** We assessed UPA safety and efficacy through Wk60 in an ongoing extension of the phase 3 SELECT-BEYOND study.

**Methods:** SELECT-BEYOND enrolled a population of patients with active RA who had failed at least one prior biologic therapy. Pts received UPA 15mg or 30mg once daily (QD) or placebo (PBO) on top of background csDMARD treatment for 12 wks. From Wk12, pts randomized to UPA at baseline (BL) continued their assigned doses while pts initially randomized to PBO received UPA 15mg or 30mg QD per pre-specified assignment at BL. Patients who completed Wk 24 entered the blinded long-term extension. Dose adjustments to UPA were not allowed. Adverse events (AE) per 100 pt years (PY) are summarized based on a cut-off date of 16 April 2018. Efficacy data up to the Wk60 visit are reported “As Observed”.

**Results:** 418/498 (84%) pts were randomized, completed 24 wks and entered the extension on study drug. By the safety data cut-off date, 19% pts discontinued study drug: 5% due to AE, 4% due to lack of efficacy, 3% withdrew consent, 2% were lost to follow-up, and 5% discontinued due to other reasons. Cumulative exposures to UPA15 and UPA30 were 301.7 and 290.7 PYs, respectively. Rates (Events/100PYs) of treatment-emergent AEs are reported (Table 1), and were numerically higher in the UPA30 vs UPA15 arm for serious AEs, AEs leading to discontinuation, serious infections, herpes zoster and hepatic disorders. Based on As Observed analysis, for pts completing Wk60 on UPA15 [172/216 (80%)] and UPA30 [168/202 (83%)], clinical and functional outcomes continued to improve compared to Baseline, or were maintained from Wk24 onwards in pts initially randomized to UPA15 or 30; Remission by CDAI≤2.8 at Wk60 was achieved by 20% and 32%, respectively, and DAS28-CRP<2.6 was achieved by 53% and 52%. Pts who were switched to UPA from PBO at Wk12 had comparable efficacy to pts initially randomized to UPA (Table 2).

**Conclusion:** The benefit: risk of upadacitinib treatment in this refractory population remains favorable. No new safety signals were identified. Some AEs were numerically higher for UPA30 vs 15; however the clinical significance of this, the assessment of rare safety events in this study, and the overall benefit: risk of upadacitinib 15mg and 30mg in the treatment of RA are best evaluated in an integrated analysis across the phase 3 program. UPA15mg and 30mg continued to be effective in treating RA signs and symptoms, and in improving physical function.

Filgotinib (FIL), an oral, selective Janus kinase 1 (JAK1) inhibitor, significantly improved the signs and symptoms of rheumatoid arthritis (RA) in the phase 3 FINCH2 study in bDMARD-IR patients with active RA.1

**Objectives:** To evaluate the efficacy and safety of FIL by geography and race in FINCH2.

**Methods:** FINCH2 enrolled 449 bDMARD-IR patients with active RA, who were randomized in a 1:1:1 manner to receive FIL 200 mg, FIL 100 mg, or placebo (PBO) on a background of csDMARDs for 24 weeks. In this prespecified subgroup analysis, patient and disease characteristics and treatments were analyzed by race and geographic region (Region 1: AU, BE, FR, DE, IS, IT, NL, KR, ES, CH, UK, US; Region 2: HU, CZ, PL; Region 3: AR, PR, MX; Region 4: JP).

**Results:** 449 patients received ≥1 dose of study drug; they were 80.4% female, with a mean [SD] age of 56 [12.2] years, and 23.4% had received ≥3 prior bDMARDs. Baseline characteristics were similar across regions and race. The primary endpoint and all key secondary endpoints were met in the primary analysis.1 Efficacy and safety parameters by region in FINCH2 are presented.

**Conclusion:** FIL demonstrated consistent safety and efficacy in bDMARD-IR patients with RA regardless of geography or race.

CHARACTERIZATION OF REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH UPADACITINIB OR COMPARATORS

Stephen Hall1, Tautomu Takeuchi2, Glen Thomson3, Paul Emery4, Bernard Comfort3, Andrea Everding5, Karel Pavelka8, Yanna Song2, Tim Shaw2, Alan Friedman6, In-Ho Song8, Eduardo Mysler9, Monash Univ, Cabrini Health and Emeritus Research, Malvern, Australia; 2Keio Univ School of Medicine, Tokyo, Japan; 3CIADS Research, Winnipeg, Canada; 4Leeds Inst of Rheumat and Musculoskeletal Medicine, Leeds NIHR BRC, Leeds, United Kingdom; 5CHU Montpellier, Univ Montpellier, Montpellier, France; 6HVF Hamburger Rheuma Forschungszentrum, Hamburg, Germany; 7Charles Univ, Prague, Czech Republic; 8AbbVie Inc, North Chicago, United States of America; 9Organización Medica de Investigación, Buenos Aires, Argentina

Background: Across all phase 3 studies, treatment with upadacitinib (UPA), a JAK1-selective inhibitor, was associated with significantly higher remission (REM) rates, compared to placebo (PBO) or active comparators, in RA patients (pts) who were methotrexate (MTX)-naive, had inadequate response to conventional synthetic (csDMARD-IR) or had inadequate response or intolerance to biologic DMARDs (bDMARD-IR).

Objectives: REM definitions are based on composite scores of various individual assessments of disease activity. To determine the response to UPA on REM and component assessments, we assessed the proportions of pts achieving REM using multiple REM definitions, and the improvement in their respective individual components, compared to PBO or active comparators, in 3 different RA pt populations spanning a range of RA pt populations.

Methods: Three phase 3 studies included pts who were RA-IR (MTX naive [SELECT EARLY, n=945]), MTX-IR (SELECT COMPAR, n=1629) and bDMARD-IR (SELECT BEYOND, n=498). The proportion of pts achieving REM at Week (Wk) 12 by 4 definitions (DAS28-4CRP≤2.6; CDAI≤28; SDAI≤33 and Boolean, defined as ≤1 for SJC, SJC, patient’s global assessment of disease activity [PGA], and CRP ≤1 mg/L) were determined. For each definition of REM, the mean change in each of the respective component scores was also assessed. Binary endpoints are based on Non-responder imputation (NRI), and continuous endpoints on mixed-effect model repeat measurement (MMRM). Comparisons were made between UPA-treated groups vs respective control arms (MTX, adalimumab [ADA] or PBO).

Results: Pt demographics and disease characteristics have been previously reported. 1–3 At week 12 in EARLY and COMPARE, a significantly greater proportion of pts receiving UPA 15 mg or 30 mg QD achieved REM by all 4 definitions vs MTX, PBO or ADA (Table). In BEYOND, (a refractory population many of whom had inadequate response to multiple bDMARDs), a significantly greater proportion of pts receiving UPA 30mg achieved all REM definitions vs PBO within the first 12 wks, with significantly greater proportions on UPA 15mg achieving DAS28-4CRP≤2.6 and Boolean REM (Table). Rates of REM in BEYOND further increased through Wk 24 for both dose groups. 3Compared to respective control groups, pts receiving UPA 15 or 30 mg QD had significantly greater improvements in each REM disease component (except for PhGA vs ADA in COMPARE). Significantly more pts receiving UPA also achieved the required cutoffs on the individual components of Boolean REM compared to respective control groups.

Conclusion: Significantly greater proportions of pts receiving UPA 15 or 30mg achieved REM by multiple definitions at 12 wks compared to PBO, MTX or ADA. All disease activity components of each REM definition were significantly improved in pts receiving UPA compared to MTX or PBO, and all Boolean components were significantly improved in pts receiving UPA 15mg compared to ADA.

THU0174 DOSE-DEPENDENT RISK OF METHOTREXATE FOR RENAL IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keigo Hayashi, Kenei Sada, Yosuke Asano, Sumire Hiramasu Asano, Yurko Yamamura, Keiji Ohashii, Michiko Morishita, Haruki Watanabe, Marko Narazaki, Yoshinori Matsumoto, Tomoko Kawabata, Jun Wada, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan

Background: Methotrexate (MTX) is a mainstay in the therapy of rheumatoid arthritis (RA). It is recommended that MTX should be rapidly
COMPARISON OF ADHERENCE TO MONOTHERAPY TREATMENT PATTERNS AMONG PATIENTS WITH RA

Objectives: The purpose of this study is to elucidate the association between MTX dosage and a one-year change of estimate glomerular filtration rate (eGFR) in RA patients.

Methods: Of outpatients with RA in Okayama university hospital between 2006 and 2017, 497 patients who had continued the administration of MTX for more than one year were enrolled. All patients fulfilled the ACR/EULAR 2010 Classification Criteria for RA. Patients who had nephrotic syndrome, unilateral kidney or other rheumatic disorders other than secondary Sjögren’s syndrome were excluded. The primary outcome was the change of eGFR during the most recent one year in each patient. The revised Japanese equation of Modification of Diet in Renal Disease was used to calculate eGFR. MTX dosage was defined as an average dosage of MTX during the observational period. We evaluated the association between MTX dosage and the primary outcome using univariate and multivariate analysis.

Results: Median (IQR) age was 64 (52 - 72) years, 78% were female, and median disease duration was 73 (31 - 160) months. The median dosage of MTX was 8 mg/week (6 - 10.1) and biological agents were used in 28% of the patients. The eGFR (mean ± SD) decreased by 1.2 ± 8.3 ml/min/1.73m² in one year and MTX dosage was associated with the change of eGFR significantly (p<0.0001). The eGFR in patients treated with MTX <8 mg/week (n=185), ≥8 and <10 (n=131), ≥10 and <12 (n=86), ≥12 (n=95) decreased 0.2 ± 0.6, 0.6 ± 0.7, 1.0 ± 0.9, and 4.6 ± 0.8 ml/min/1.73m²/year, respectively. After adjusting possible confounding factors such as sex, age, concomitant use of NSAIDs, hypertension, and C reactive protein (CRP) using multiple linear regression analysis, MTX dosage was still an independent risk factor for the decrease of eGFR (beta-coefficient: -0.4, 95% confidence interval -0.12 - -0.61, p=0.003).

Conclusion: Careful monitoring of renal function should be required in long-time treatment for RA patients with MTX.

THU0177
COMPARISON OF ADHERENCE TO MONOTHERAPY VERSUS COMBINED THERAPY IN RHEUMATOID ARTHRITIS

Iván de Jesús Hernández-Galarza, Dionicio Ángel Galarza-Delgado, Mariela Castro-González, Rita Pineda-Sic, Miguel Ángel Villarreal-Alarcón, Octavio Ilizaliturri Guerra, Rodolfo Allan Uriarte Botello. Hospital Universitario “Dr. José Eleuterio González”, UANL, Rheumatology, Monterrey, Mexico

Background: Treatment adherence in Rheumatoid Arthritis (RA) patients vary from 30 to 80% (1). It is important to identify the associated factors to a low adherence, so clinicians can make interventions to obtain better therapeutic results. Adherence to treatment has been described to be affected by several factors, such as access to healthcare facilities, education, socioeconomic status, quality of communication between physician and patient, among others (2). There are no previous studies that investi gate if the number of drugs received in RA patients affects this adherence. REPAIR is a program designed with the purpose of improve data collection and medical practice in our outpatient clinic.

Objectives: To compare the adherence to synthetic Disease-Modifying Antirheumatic Drugs (DMARDs) among RA patients prescribed with mono therapy and combined therapy.

Methods: Cross sectional, observational, comparative study. This study was conducted in the outpatient rheumatology clinic of University Hospital in Monterrey, Mexico. Consecutive patients with RA were approached during their normal routine rheumatology appointments, in the March 2018 to December 2018 period. They were asked how many days of the last month they forgot or took their DMARDs (self-report). We classified the adherence rate in 2 categories based on the days of the last month they took the indicated medication; adequate: 75%-100% (> 21 days), inadequate <75% (<21 days). When adherence was inadequate we interrogated about the cause. Data was obtained from REPAIR (internal electronic patient record). The Kolmogorov Smirnov test was used to determine if normal distribution. Categorical variables are expressed as total number and percentage (%), and numerical variables as median and the 25th-75th percentiles (q25-q75). Chi square and Mann Whitney U test were used to compare groups and considered significant if p<0.05. Data was analyzed with the statistical package SPSS version 24 (New York, USA).

Results: A total of 959 patients were included. When comparing adherence to treatment and gender between groups, no statistically significant difference was found. The main cause of inadequate adherence in the monotherapy group was the economic (30.3%) and own decision in the combined therapy group (29.1%).

Table 1:

<table>
<thead>
<tr>
<th>Monotherapy (n=346)</th>
<th>Combined therapy (n=613)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years), median (p25-p75)</td>
<td>54 (44-63)</td>
</tr>
<tr>
<td>Women, n (%)</td>
<td>317 (91.6)</td>
</tr>
<tr>
<td>Inadequate adherence to treatment, n (%)</td>
<td>52 (15)</td>
</tr>
<tr>
<td>Adequate adherence to treatment, n (%)</td>
<td>294 (85)</td>
</tr>
</tbody>
</table>

Conclusion: Patients with combined therapy had the same percentage of inadequate adherence as patients with monotherapy. These results may indicate that number of drugs prescribed not necessarily affects adherence to treatment. The principal causes for an inadequate adherence to treatment were: economic for monotherapy group and own decision for combined therapy group. However, long-term studies are needed to evaluate the persistence of treatment in these groups of patients.

THU0178
TREATMENT PATTERNS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH A BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUG OR JAK INHIBITOR: A NATION-WIDE STUDY IN KOREA

Min Jung Kim1, Anna Shin2, Seunghwan Shin2, You-Jung Ha2, Yun Jong Lee2, Eun Bong Lee1, Yeong Wook Song1, Eun Ha Kang2, Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)

Background: Limited data are available on whether patients with rheuma toid arthritis (RA) are treated with conventional, disease-modifying anti rheumatic drugs (cDMARDs) according to the current recommendations before they initiate biologic DMARDs (bDMARDs) or JAK inhibitors (JAKis).

Objectives: We examined the treatment patterns among Korean RA patients who received bDMARDs or JAKis in a real world setting, using the 2002-2016 Korean National Health Insurance Service database that covers the entire Korean population.

Methods: We identified RA patients who initiated bDMARDs (TNF inhibitor, abatacept, rituximab and tocilizumab) or JAKis (tofacitinib). Their treatment patterns during 1 year after RA diagnosis (defined as free of any RA diagnosis or any DMARD use for one year before the diagnosis) and prior to the initiation of index drugs (bDMARDs or JAKis) were examined regarding: initial cDMARD used, dose and parenteral use of methotrexate (MTX), use and time to combination therapy of cDMARDs, and steroid use.
Yuliya Kurochkina1, Tamara Tyrinova2, Olga Leplina2, Marina Tikhonova2, Elena Chernykh2.

Dendritic cells (DCs) are known to contribute to the pathogenesis of rheumatoid arthritis (RA) through the presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/cytotoxic T-lymphocytes, utilization of tolerogenic DCs seems to be a promising immunotherapeutic tool to treat RA.

Objectives: Objective of our study is to evaluate the safety and tolerability of a single intra-articular injection (into the knee joint) of autologous monocyte-derived dendritic cells generated in the presence of IFN-α/GM-CSF and tolerized with Dexamethasone in patients with RA.

Methods: DCs were generated by culturing blood monocytes for 5 days with GM-CSF and IFN-α and tolerized with Dexamethasone in RA patients. DCs were injected into the knee joint. 

Results: DCs injections were safe and well-tolerated. No one patients showed worsening of symptoms in targetting knee, fever, elevation of blood pressure or other AE within 7 days after injection. All patients, evaluated at 6 months follow-up showed a good EULAR response (improvement of DAS28-ESR >1.2). The median DAS28-ESR decreased from 5.10 (p=0.03). The median VAS score decreased from 52 (41-70) mm to 42 (15-55) mm; p=0.04. In addition, we detected median HAG improvement from (1.45 to1.0; p=0.04). The effect of treatment had been continued for 6 month and after that we indicated escape of effect. 

Conclusion: The data obtained suggest that single intra-articular injection of autologous tolerogenic dendritic cells is safe, well tolerated, and have a potential not long term efficiency and requires the repeating of procedure.

Disclosure of Interests: None declared

Piotr Ligocki1, Grzegorz Orlik2, Vishal Vekariya3.

Background: MTX is a well-established treatment with an anchor role in RA (1). Patients being treated for RA must pay attention to the specific dosage of drugs and the different routes of administration. Additionally, they suffer from the inconvenience related to the progression of the disease.

Objectives: We observed 125 RA patients diagnosed with RA, who were treated with subcutaneous (SC) MTX and possible risks associated with this therapy. The attention paid to the inconvenience for the patient associated with SC form of drug administration and the principles of MTX dosing with FA supplementation.

Methods: 32 rheumatologists were invited to non-interventional, post marketing observation. They collected information from 690 patients who already received a minimum of 1 dose of MTX SC. As part of a standard medical visit, the sociographic data of the patient and information obtained during the medical interview as well as subjective and objective examination were recorded in the prepared form. Data was collected on a weekly basis over a period of 8 weeks. The protocol was compliant with the regulatory and ethical requirements in the country.

Results: Out of 682 enrolled patients, 581 (85.2%) were siero-positive and 95 (14%) were siero-negative. The average level of anti-CCP antibodies before enrollment was 85.76 Units. The mean time from the diagnostic of the underlying disease was 28.7 months. The vast majority of patients confirmed that they had previously used FA supplementation (90.2%). Only 10 patients showed DAS28 at the remission level. During each visit no adverse events (AE) were reported in over 90% of patients. The most commonly reported AE are nausea or weakness. No severe, life threatening AE were recorded. 

Patients evaluated the pain of the injection on a scale of 1 to 10, where 1 is the minimum and 10 the maximum pain. Most patients assessed the pain of injections as the minimum (1) (56.5% - week 1 (W1), 52.9% - W2, 56.7% - W3, 61.5% - W4, 56.7% - W5, 53.8% - W6, 65.2% - W7, 61.8% - W8). The second most frequently mentioned pain assessment by respondents was 2 (34.6% - W1, 35.3% - W2, 34.3% - W3, 29.2% - W4, 34.3% - W5, 38.5% - W6, 26.1% - W7, 32.9% - W8). No patients reported values between 6 and 10. Patients also assessed how the pain at the site of injection on a scale of 1 to 10, where 1 is the minimum and 10 the maximum pain. Each week, more than half of the patients assessed pain at the injection site as 1 (55.9% - W1, 56.7% - W2, 56.7% - W3, 57.8% - W4, 50.8% - W5, 62.5% - W6, 60.3% - W7, 61.6% - W8). Patients did not report any value of 5-10. More than seven out of ten patients reported FA administration the day 2 of their therapy (76.5%, at W1). In remaining days FA supportive therapy reported 30.3-52.3% of patients (2).

Conclusion: Neither pain related with injection nor local AE was reported as a significant issue by patients. Adherence to FA administration recommendation is low. This should be evaluated in further studies, but there is a risk that inappropriate FA administration may reduce efficacy of MTX treatment.

REFERENCE:
Influence of Blue Mussel (Mytilus Edulis) Intake on Fatty Acid Composition in Erythrocytes and Plasma Phospholipids and Serum Metabolites in Women with Rheumatoid Arthritis

Helen Lindqvist1, Inger Gjertsson1, Philip Calder2, Linnea Barebring1. 1University of Gothenburg, Medicine, Gothenburg, Sweden; 2University of Southampton, Southampton, United Kingdom

Background: The positive effects of omega-3 on risk of cardiovascular disease, on inflammation and immune function are well established [1]. Unfortunately fish as a source of omega-3 is not economically or environmentally sustainable. In contrast, blue mussel farming is beneficial for the environment since excessive nitrogen is removed at harvest and eutrophication of the sea is reduced [2]. Blue mussels contain not only omega-3, but are rich in nutrients such as zinc, selenium, riboflavin and carotenoids. We have previously shown, in the randomized cross-over trial Mussels, Inflammation and RA (MIRA), that disease activity (DAS28-CRP), fatigue, pain and general health in RA is improved by a dietary intervention with blue mussels compared to control [3]. It is not clear what the mechanisms of the intervention were, and if the intake of omega-3 from the blue mussels plays a role.

Objectives: The aim of this study was to investigate if the intake of blue mussels in patients with RA lead to changes in fatty acid composition in plasma phospholipids and erythrocytes and/or in metabolites (detected by NMR-metabolomics), compared to a control diet, in an attempt to understand the health beneficial effects found in the MIRA study.

Methods: Twenty-three women completed the randomized 2 x 11-week cross-over dietary intervention, exchanging one cooked meal a day, five days a week, with a meal including 75 g blue mussels or 75 g meat. Fatty acid composition in erythrocytes and plasma and 1H-NMR metabolomics data were analysed and multivariate data analysis; Orthogonal Projections to Latent Structures (OPLS-DA) and OPLS with effect projections (OPLS-EP) were performed to compare the two diets.

Results: Intake of the blue mussels led to a different fatty acid profile in erythrocytes, compared to control, and all samples could be correctly classified with OPLS-DA (figure 1). The changes included significant increases in omega-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). The patterns for plasma phospholipids and 1H-NMR serum metabolites were not as specific for the diets and metabolites were strongly influenced by body mass index (BMI) (figure 2).

Conclusion: To conclude, the change in fatty acid pattern in erythrocytes could be related to reduction in disease activity in the MIRA-study, although it cannot be excluded that other factors than omega-3 fatty acids potentiate the effect. Multivariate modelling of fatty acids in erythrocytes increased the precision for compliance, compared to evaluating EPA and DHA content alone.

Treatment with Upadacitinib Results in the Normalization of Key Pathobiological Pathways in Patients with Rheumatoid Arthritis: Biomarker Results from the Phase 3 SELECT-NEXT and SELECT-BEYOND Studies

Thierry Somasse1, Jeremy Sokolove2, Lisa Meinnet3. 1AbbVie Immunology Clinical Development, Redwood City, United States of America; 2University of Glasgow, Glasgow, United Kingdom

Background: Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) with an inadequate response (IR) to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) or biologic DMARDs (bDMARDs) in the SELECT-NEXT1 and SELECT-BEYOND2 trials, respectively. The pivotal immune regulatory pathway targets served by JAK1 in patients with RA via a proteomic approach that evaluates a set of plasma proteins associated with inflammation.

Objectives: To investigate the mode of action (MoA) of UPA in patients with RA via a proteomic approach that evaluates a set of plasma proteins associated with inflammation.

Methods: Patients from the SELECT-NEXT and SELECT-BEYOND (PBO, n=167; UPA 15 mg QD, n=200) studies were randomly selected from the pool of patients with plasma samples available at baseline, Week 2, and Week 12. Samples from 24 age- and sex-matched healthy controls were included. The levels of 92 proteins were analyzed using the Olink® Inflammation Panel. Results from both studies were combined. Data were clustered using the Ward (unsupervised) method; correlations were calculated using the Pearson method; and multiple comparisons were corrected using the Benjamini–Hochberg method; all statistical analyses were performed in JMP 13.10 (SAS Institute). Pathway analysis was performed with Ingenuity® Pathway Analysis (Qiagen Inc.) version 43688156.
Results: At baseline, levels of IL-6, CXCL9, CXCL10, and CCL7 correlated significantly with baseline DAS28-ESR, consistent with effector roles for IL-6 and interferon (IFN) in intercurrent disease activity. Clustering of the differential protein fold change at Weeks 2 and 12 for UPA and PBO groups revealed four clusters enriched for proteins related to: 1) IL-6, IFN, leukocyte trafficking, and macrophage activation (1); 2) T helper cell differentiation (2); 3) T and B cell signaling (3); and 4) hematopoiesis and myeloid cell differentiation (4). Pathway analysis 2 based on the differential expression of 37 significantly modulated proteins suggests that treatment with UPA results in the normalization of key pathways associated with the pathobiology of RA including: 1) pathways associated with IL-1, IL-6, IL-12, IL-15, IL-18, IFNα, IFNβ, IFNγ, CSF2, and TNF; and 2) pathways associated with behaviors of leukocytes (lymphocytes, myeloid cells, and granulocytes), including leukocyte migration, T cell response, and inflammatory response. In keeping with these changes, in IL-6, CCL23, CCL7, MIPH, and S100A12 levels at Week 12 correlated significantly with the relative change in DAS28-ESR, suggesting a link between UPA MoA and macrophage activation.

Conclusion: In keeping with its selectivity for JAK1, UPA operates via inhibition of multiple JAK1-dependent upstream pathways that result in the normalization of key downstream effects associated with the pathobiology of RA, including T cell and myeloid cell-related pathways. Notably, non-JAK signaling pathways also normalize, suggesting functional integration of JAK1 with parallel pathogenic signaling in RA effector cells.

Abstract THU0182 – Table 1

THU0182

PHARMACOKINETICS AND SAFETY OF A SINGLE ORAL DOSE OF PEFICITINIB (ASP015K) IN SUBJECTS WITH NORMAL AND IMPAIRED RENAL FUNCTION

Daijuke Miyatake1, Tomohisa Shibata1, Masa Shibata1, Yuchi Kaneko1, Kazuo Oda2, Tomohisa Shibata1, Mai Shibata1, Yuichiro Kaneko1, Kazuo Oda2, Tomohisa Shibata1, Mai Shibata1, Yuichiro Kaneko1, Kazuo Oda2, Tomohisa Shibata1, Mai Shibata1, Yuichiro Kaneko1, Kazuo Oda2, Tomohisa Shibata1, Mai Shibata1, Yuichiro Kaneko1, Kazuo Oda2, Tomohisa Shibata1, Mai Shibata1, Yuichiro Kaneko

Objectives: To assess the pharmacokinetics (PK) and safety of a single, oral dose of peficitinib 150 mg in subjects with normal and impaired renal function.

Methods: This was an open-label, single-dose, parallel-group study conducted at two centres in Japan. All subjects were aged 20–75 years with a body mass index 17.6 to <30.0 kg/m2. Renal function was categorized according to estimated glomerular filtration rate (eGFR) using a GFR predictive equation for Japanese subjects: normal 90 mL/min/1.73 m2; moderate impairment 60 to <90 mL/min/1.73 m2; and severe impairment <60 mL/min/1.73 m2. Subjects with impaired renal function had unchanged renal impairment treatment (including diet) within 14 days prior to dosing. Subjects received a single oral dose of peficitinib 150 mg tablet under fasting conditions in a hospital setting. The selected dose was based on the peficitinib daily dose in the phase 3 RA studies. Blood samples for peficitinib plasma PK analysis were collected before administration and up to 72 h post dose. Safety was assessed throughout the study.

Results: A total of 31 subjects (87.1% male; Table 1) were enrolled and received study drug according to study protocol. Subjects comprised 8 with normal renal function, and 8 with mild, 8 with moderate and 7 with severe renal impairment. The peficitinib concentration–time profiles from dosing to 72 h (Fig 1), extrapolated to infinity (AUC∞) and maximum concentration (Cmax) were similar between those with normal and impaired renal function (Table 2). Two subjects had mild/grade 1 (CTCAE v4.0 JCOG) treatment-emergent adverse events (TEAEs): 1/8 (12.5%) with normal renal function had a headache (considered to be drug-related) and 1/8 (12.5%) with mild renal impairment had increased alanine aminotransferase (ALT) (not considered to be drug-related). There were no serious TEAEs or deaths during the study. There were no clinically significant mean changes from baseline in other clinical laboratory parameters or vital sign measurements, except for grade 1 increased ALT in a subject with mild renal impairment.

Abstract THU0182 – Figure 1

Conclusion: Exposure after a single 150 mg oral dose of peficitinib under fasting conditions was similar between subjects with and without renal impairment. The peficitinib dose was generally well tolerated, with no changes in TEAE incidence by renal function.

Upadacitinib Pharmacokinetics in Japanese Subjects with Rheumatoid Arthritis with the Extended-Release Formulation and Comparability to Non-Japanese Subjects

Mohamed-Eslam Mohamed, Ben Kluender, Sebastian Meerwein, Ahmed Othman, AbbVie, North Chicago, United States of America; AbbVie Deutschland GmbH and Co. KG, Ludwigshafen, Germany

Background: Upadacitinib (UPA), an oral selective JAK1 inhibitor, is being developed for treatment of patients with moderate to severely active rheumatoid arthritis (RA). UPA efficacy was demonstrated in subjects with moderate to severe RA in five global Phase 3 studies and a regional Phase 2b study in Japanese subjects.

Objectives: To characterize the pharmacokinetics of UPA after administration of the extended-release formulation in Japanese subjects with RA and to compare UPA plasma exposures between Japanese and non-Japanese subjects.

Methods: Population pharmacokinetic analyses were conducted using UPA data across Phase 1 to 3 studies including Japanese and non-Japanese subjects. The population pharmacokinetic model was used to estimate UPA plasma exposures from the extended-release formulation regimens in non-Japanese and Japanese subjects with RA in Phase 3 trials. Additionally, a total of 29 Japanese subjects with RA who were enrolled in SELECT-SUNRISE Phase 2b study participated in a pharmacokinetics substudy in which serial blood samples were collected from each subject over a 24 hour period after UPA dosing. UPA was administered in the study at doses of 7.5 mg, 15 mg, and 30 mg QD using the extended-release formulation. Pharmacokinetic parameters were calculated in the pharmacokinetic substudy using noncompartmental methods.

Results: UPA maximum plasma concentration was reached within 2 hours of dosing under fasting condition. UPA plasma exposures were approximately dose proportional over the evaluated dose range in Japanese subjects with RA. UPA model estimated plasma exposures (based on population pharmacokinetic analyses) were comparable (within 20%) between Japanese and non-Japanese subjects with RA (Table 1). Results from the pharmacokinetic substudy using noncompartmental methods were consistent with the population pharmacokinetic analyses.

Sirolimus Selectively Increases Circulating Treg Cell Numbers and Restores the Th17/Treg Balance in Rheumatoid Arthritis Patients with DAS28 £ 3.2 Who Previously Received Conventional DMARDs

Hong-Qing Niu, Li Zhao-Hua, Wen-Peng Zhao, Xiang-Cong Zhao, Chen Zhang, Jing Lu, Chong Gao, Caihong Wang, Li Xiao-Feng, The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; Bgham and Women's Hospital, Harvard Medical School, Department of Pathology, Boston, United States of America

Background: Many immunosuppressants used to treat rheumatoid arthritis (RA) were designed to broadly suppress T cell function, including that of regulatory T cells (Tregs). Patients with inactive RA also show a reduced frequency of peripheral Tregs [1]. Tregs are essential for maintaining effective immune tolerance and a homeostatic balance of Th17/Treg. Accordingly, there has been increasing interest in developing Treg-friendly regimens to minimize or eliminate the immunosuppression of conventional medications for RA. mTOR signaling negatively controls the development and function of Tregs. Rapamycin, an mTOR inhibitor, could expand Tregs (CD4+CD25+FoxP3+) in patients with active systemic lupus erythematosus [2] and active RA [3]; however, the response of Tregs to rapamycin in RA patients with DAS28 £ 3.2 is still unclear.

Objectives: To investigate the effects of rapamycin, under the generic name sirolimus, on Tregs in RA patients with DAS28 £ 3.2 who previously received conventional DMARDs.

Methods: Fifty-five RA patients and 60 healthy controls were enrolled in this study. All patients had previously received conventional DMARDs and had a low DAS28 score (≤ 3.2). Peripheral blood samples and clinical information were obtained at baseline and following 6 and 12 weeks of sirolimus treatment, or after 12 weeks of conventional treatment. The circulating levels of lymphocyte subpopulations were assessed by flow cytometry.

Results: Thirty-five patients received sirolimus and 20 patients continued treatment with conventional DMARDs. None of the baseline clinical characteristics differed significantly between the two groups. The absolute counts and proportions of CD4+CD25+FoxP3+ Tregs were significantly lower in all RA patients with DAS28 £ 3.2 as compared with those in healthy controls. By contrast, the difference in circulating Th17 cell numbers was not significant. Sirolimus administration resulted in significant elevations in circulating Treg cell numbers and significant reductions in the Th17/Treg cell ratio, whereas the circulating level of Tregs and the Th17/Treg cell ratio in patients under conventional treatment both showed a tendency of reduction (Figure 1). Furthermore, a greater proportion of patients under sirolimus treatment achieved DAS28-based remission at 12 weeks.

Conclusion: Sirolimus can favorably expand Tregs in RA patients with DAS28 £ 3.2, consequently restoring a healthy balance of Th17/Treg cells, which might improve the likelihood of long-term and sustained clinical remission and reduce the probability of disease flare-ups in RA. These findings provide valuable insights that might potentially lead to changes in clinical practice for the routine treatment of RA.

SAFETY, TOLERABILITY AND PHARMACOKINETICS OF MBS2320, A SELECTIVE MODULATOR OF IMMUNE METABOLISM, IN HEALTHY VOLUNTEERS AND PATIENTS WITH RHEUMATOID ARTHRITIS

Lisa Patel, Paul Marcus, Jim Bush, Andy Gray, Richard Fitzgeral, Sonya Abraham, Martyn Foster, Hiep Huatan, Laurence Skillern, Anna Daroszewska, Rob Van‘t Hof, Sam Williams, I tesso Ltd, London, United Kingdom; Covance Clinical Research Unit Ltd, Leeds, United Kingdom; The Royal Liverpool University Hospital, Liverpool, United Kingdom; Imperial College London, Faculty of Medicine, London, United Kingdom; University of Liverpool, Liverpool, United Kingdom

Background: Despite the availability of several treatment options some patients with Rheumatoid Arthritis (RA) fail to benefit and for those who do response rates are similar across therapeutic classes. Thus there remains a need for new therapies with novel mechanisms of action. MBS2320 is a selective modulator of immune metabolism that shows anatomically appropriate osteoid layering and a broader spectrum of osteoprotective efficacy compared to TNPx inhibition in preclinical models.

Objectives: To investigate the safety, tolerability and pharmacokinetics of MBS2320 in healthy volunteers and patients with Rheumatoid Arthritis (RA) receiving a stable dose of methotrexate (MTX).

Methods: Cohorts of healthy volunteers (randomised 6:2 drug:placebo) received single or multiple oral doses of MBS2320 for 14 days. Single Ascending Dose (SAD) cohorts comprised 2, 10, 25, 50, 75, 125, 250, 375 mg (PO) and Multiple Ascending Dose (MAD) cohorts. 75, 100, 150 mg/d. Patients with RA received 75 mg/d for 14 days in addition to their existing weekly MTX treatment. Safety and tolerability were assessed throughout. Plasma MBS2320 (SAD, MAD and patients with RA) and MTX (patients with RA only) were measured using LC-MS/MS. In patients with RA, C-reactive protein (CRP) and biomarkers of bone turnover were assessed on Day 14.

Results: A total of 96 healthy subjects and 9 patients with RA entered the Study and were randomised to the drug or matching placebo. MBS2320 was well tolerated by healthy subjects at single oral doses of 2 to 375 mg. There were no serious adverse events (SAEs). Nausea was the most commonly reported adverse event (AE) and occurred most frequently at the high doses but was mild and resolved without treatment. Daily doses of 75 to 160 mg QD MBS2320 for 14 days were generally well tolerated by healthy subjects. The most common drug-related treatment emergent adverse events (TEAEs) were gastrointestinal disorders.
EFFICIENCY OF TREATMENT SEQUENCES CONTAINING TOFACITINIB FOR RHEUMATOID ARTHRITIS IN SPAIN

Carmen Peral1, Alejandro Balba2, Federico Navarro3, José Luis Pablos4, José Manuel Martínez Sesmero5, Susana Gómez6, Monica Valderrama7, Itziar Oyagüez8, Miguel Angel Casado8, Fernando De Andres8, Maria Montoro8

1 Pfizer, Madrid, Spain
2 Hospital La Paz, Madrid, Spain
3 Hospital Universitario 12 de Octubre, Madrid, Spain
4 Hospital Universitario Clinico San Carlos, Madrid, Spain
5 PORIB, Madrid, Spain

Background: The availability of oral Janus kinase inhibitors, as tofacitinib, has extended the treatment pathways for management of patients with rheumatoid arthritis (RA).

Objectives: To assess the cost-effectiveness of tofacitinib as second-line treatment compared to treatment sequences containing standard biological therapies in patients with moderate to severe RA after failure to disease-modifying antirheumatic drugs (DMARDs) from the Spanish National Health System perspective.

Methods: A patient-level microsimulation model was used to compare the lifetime cost and quality-adjusted life-years (QALY) for treatment sequences initiating with tofacitinib (5mg BID) followed by biological therapies versus sequences of biological treatments excluding tofacitinib. The sequences were selected by a panel of experts based on clinical practice in Spain. Concomitant treatment with methotrexate (MTX) was considered along with all the therapies in the treatment sequences. Model parameters included age, weight, initial Health Assessment Questionnaire (HAQ) score and clinical response to short and long treatment. Efficacy was measured by means of HAQ score changes using mixed-treatment comparisons (for the first 6 months) and data from long-term extension trials (for later periods). Serious adverse event (SAE) information derived from literature. The estimation of total cost for sequences included: drugs acquisition (public ex-factory prices with mandatory deduction or reference prices) and parenteral administration, disease progression and SAE management.

Local unitary costs (€, 2018) were applied. Additional comparisons were explored testing other potential sequences.

Conclusions: The base case analysis showed that sequences initiating with tofacitinib provided greater outcomes than the correspondent sequences excluding tofacitinib. In scenario 1 tofacitinib+MTX—Rituximab+MTX—Etanercept+MTX—Ceritalzumab+MTX provided 13.92 QALYs versus 13.92 QALYs for adalimumab+MTX—Rituximab+MTX—sc Tocilizumab+MTX—Etanercept+MTX. In scenario 2 tofacitinib+MTX—Adalimumab+MTX—Rituximab+MTX—Etanercept+MTX—Ceritalzumab+MTX provided 13.75 QALYs versus 13.62 QALYs for Baricitinib+MTX—Adalimumab+MTX—Rituximab+MTX—sc Tocilizumab+MTX—Etanercept+MTX.

THU0187

EFFICIENCY OF TREATMENT SEQUENCES CONTAINING TOFACITINIB FOR RHEUMATOID ARTHRITIS IN SPAIN

THU0188

INHIBITION OF STRUCTURAL JOINT DAMAGE WITH UPADACITINIB AS MONOTHERAPY OR IN COMBINATION WITH METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS: 1 YEAR OUTCOMES FROM THE SELECT PHASE 3 PROGRAM

Charles Peterfy1, Mark C. Genovese2, In-Ho Song3, Alan Friedman3, Stephen Hall4, Eduardo Myers5, Patrick Durez6, Xenofon Baraliakos7, José Jeffrey Enesosa7, Tim Shaw7, Li Yihan7, Su Chen7, Vibeke Strand8, Siire Scines9, Inc., Kendtfield, United States of America; 1Stanford University, Palo Alto, United States of America; 2Monash University, Cabirib Health and Emeturus Research, Malvern, Australia; 3Organización Médica de Investigación, Buenos Aires, Argentina; 4Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium; 5Rheumazentrum Ruhrgebiet, Herne, Germany

Background: Long-term prevention of structural joint damage is a key treatment goal in the management of RA. Upadacitinib (UPA), a JAK1-selective inhibitor, inhibited the progression of structural joint damage at 6 months as monotherapy in methotrexate (MTX)–naive RA patients (pts)7 and in combination with MTX in pts with inadequate response (IR) to MTX.

Objectives: To evaluate the progression of structural joint damage (radiographic) through Week 48 in pts with moderately to severely active RA treated with UPA monotherapy or in combination with MTX.

Methods: Radiographic progression was assessed in 2 phase 3 randomized controlled trials (RCTs), as previously described2. MTX-naive pts were randomly assigned to UPA 15 or 30mg QD or MTX monotherapy (SELECT–EARLY, N=945), while MTX-IR pts were randomized to UPA 15mg QD or adalimumab (ADA) 40 mg eow or placebo (PBO), with continuous background MTX (SELECT–COMPARE, N=1629). Both RCTs specifically enrolled pts at high risk for progression of joint damage (high disease activity including elevated hsCRP, presence of baseline erosions and ACPO and/or RF positivity). The mean changes (Δ) from baseline
Conclusions: UPA both as monotherapy, and in combination with background MTX, was effective in inhibiting the progression of structural joint damage through Week 48 in MTX-naïve, and MTX-IR patients, respectively.

THU0189 A PROSPECTIVE STUDY OF TAPERING CONVENTIONAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (C-DMARDs) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IN STABLE REMISSION

SHAH ROMI, Canchi Balakrishnan. P. D. Hinduja Hospital and Medical Research Centre, Mumbai, India

Background: Remission in RA is being achieved more often nowadays with effective early aggressive therapy with DMARDS. Studies (1, 2 & 3) have shown that it is possible to taper and then stop DMARDS in patients with RA in stable remission. However there are no such studies or recommended protocols for c-DMARDS treated patients.

Objectives: To study the incidence and timing of flares in RA patients in sustained remission of at least 6 months duration on slow withdrawal of c-DMARDS and to identify predictors of flares.

Methods: Consenting adult(age >18 years) RA patients satisfying the ACR 2010 criteria attending our outpatient department with a disease duration of minimum 1 year and a stable remission (CDAI <2.8 on consecutive 2 visits at 3 months interval in last 6 months) on c-DMARDS were included. Patients receiving steroids or biologics were excluded.

Protocol for tapering:
On monotherapy: 50% dose reduction 3 weekly and stop eventually
On combination therapy: sequential dose reduction as monotherapy followed by stepdown of cDMARDs(in order from first to last: hydroxychloroquine, sulphasalazine, leflunomide, methotrexate)
Flare was defined as CDAI of >2.8. Number of RA flares and timing of flares were noted. Predictors of flare were analysed using univariate and multivariate regression.

Results: 66 patients satisfied inclusion criteria of which 5 did not consent, 5 committed protocol violation and 2 lost to follow up. Total 54 patients were included in the final analysis. 42 patients (77.78%) flared during the study period. Of these 42 patients, 29(69.05%) flared on the tapering protocol whereas, 13 (30.95%) flared after complete withdrawal of c-DMARDS. 20 patients (47.62%) flared within first 3 months of the tapering regimen and total 31 patients (73.8%) flared within first 6 months of tapering regimen. Baseline CDAI scores were significantly higher in patients who developed flare compared to those who remained in remission (0.82±0.82 vs 0.29 ±0.54, p<0.04).

RF positivity and age more than 60 years were predictors of flare in univariate regression analysis. With multivariate logistic regression, RF positivity was the only variable significantly associated with risk of flare (p=0.0098, SE =1.62 OR 66.31).

Conclusion: We found that on tapering of c DMARDs at 3 weekly intervals in RA patients with stable remission the incidence of flare was 78%. Most flared during tapering therapy itself and not after the drugs were stopped. Rheumatoid factor positivity seemed to predict flares. Although within the definition of remission, CDAI scores at baseline were significantly higher in patients who developed flare compared to those who remained in remission.CDAI has limitation in defining remission and inclusion of imaging in defining remission may lead to better remission on tapering cDMARDs.

BL in modified Total Sharp Score (mTSS), joint space narrowing (JSN), and erosion scores (ES) as well as the proportion of pts with no radiographic progression (ΔΔmTSS) (0) at Weeks 24/26 and 48 were determined in both RCTs. Data were analyzed by linear extrapolation (LE) for missing data imputation and treatment switching, and as observed (AO).

Results: BL demographics have been reported previously[2,3]. At Weeks 24/26, UPA as monotherapy and in combination with background MTX significantly inhibited radiographic progression measured by mean ΔΔmTSS and the proportion of pts with no radiographic progression vs MTX and PBO, respectively (LE and AO). Table. The significant inhibition of radiographic progression with UPA was maintained through Week 48 vs MTX (LE and AO) in EARLY and vs PBO (LE) in COMPARE. Following the observed for the overall mTSS scores but also its components the inhibition of radiographic progression vs comparators was not only CHANGES IN MEAN mTSS observed through Week 48 (AO, (LE and AO) in EARLY and vs PBO (LE) in COMPARE. Following the observed for the overall mTSS scores but also its components
THE SAFETY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF BMS-986166, A NOVEL, SELECTIVE, PARTIAL AGONIST OF THE SPHINGOSINE-1-PHOSPHATE (S1P) SUBTYPE 1 RECEPTOR IN HEALTHY PARTICIPANTS

Shalabh Singhal, Ihab Girgis, Jenny Xie, Santanu Dutta, Diane Shevell, John Throup. Bristol-Myers Squibb, Princeton, United States of America

Background: S1P mediates a number of immune processes including the egress of lymphocytes from lymphoid organs via stimulation of the S1P subtype 1 receptor (S1P1R). S1P1R inhibition has the potential to suppress abnormal immune responses and modulate autoimmune inflammatory diseases. BMS-986166, a novel, selective partial agonist of S1P1R, which is phosphorylated in vivo to its pharmacologically active form, BMT-212795, may have utility for the treatment of autoimmune and inflammatory diseases.

Objectives: To investigate safety, pharmacokinetics (PK), and pharmacodynamics (PD) of BMS-986166 in single- and multiple-ascending dose (SAD/MAD) placebo (PBO)-controlled studies in healthy participants.

Methods: SAD study (NCT02790125): BMS-986166 was administered as a single dose of 0.75, 2.0, or 5.0 mg (n=10/group; 4:1 ratio) of BMS-986166:PBO; a series of upwardly titrated single daily doses of 0.25, 0.5, 0.75, 1.0, and 1.5 mg over 14 days (n=16; 3:1 ratio); or as a single 2.0-mg dose in participants who were fed, fasted, or administered famotidine prior to dosing (n=8/group). MAD study (NCT03093871): BMS-986166 was administered as once-daily doses of 0.25 (n=12; 2:1 ratio), and 0.75 or 1.5 mg (n=10/dose; 4:1 ratio), for 28 days. Safety, PK, and PD (absolute lymphocyte count [ALC]) were assessed. Cardiac safety was assessed by continuous cardiac monitoring and at intervals by 12-lead electrocardiogram.

Results: 70 (80 BMS-986166, 10 PBO; mean [standard deviation (SD)] age: 32.8 [8.5] years) and 32 (24 BMS-986166, 8 PBO; mean [SD] age: 35.8 [8.6] years) participants were randomised to dosing in the SAD and MAD studies, respectively. Participants were predominantly male. Mean (SD) body mass index was 26.8 (2.9) and 27.2 (2.5) kg/m², respectively. Multiple oral doses of BMS-986166 up to 1.5 mg daily for 28 days were generally well tolerated, and all treatment-related adverse events were mild (Grade 1). In the MAD (Figure 1) and SAD studies, a clinically insignificant, dose-related decrease in mean hourly heart rate (HR) was observed following administration of BMS-986166 compared with PBO, based on a time-matched analysis of nominal hourly HR data from continuous cardiac monitoring over 72 hours post dose. Compared with participants receiving PBO, a mean decrease from baseline in hourly HR was apparent for participants in the 2 higher dose panels (2.0 mg, 5.0 mg) in the SAD study. In the SAD study, the largest decreases in PBO-corrected, time-matched, nadir hourly HR were –0.29, –6.38, and –8.37 bpm for the 0.75, 2.0, and 5.0 mg dose panels, respectively. Similarly, in the MAD study, these numbers were –0.83, –3.46, and –5.54 bpm at the 0.25, 0.75, and 1.5 mg dose levels, respectively. Increases in systemic plasma exposure (maximum concentration and area under the curve from time 0–24 hours) of BMS-986166 and its active metabolite BMT-212795 were approximately proportional to dose increases over the range of 0.25–1.5 mg with single doses, and of 0.25–1.5 mg on Days 1, 14, and 28 with multiple doses. Decreases in percent change from baseline in ALC with multiple doses of BMS-986166 vs PBO were dose-related over the 28-day treatment period. Between Day 0 and 35, median (range) nadir in lymphocyte reductions were 53.7% (31.7–55.9%), 75.9% (63.3–85.8%), and 81.9% (79.9–92.2%) at 0.25, 0.75, and 1.5 mg BMS-986166 dose levels, respectively. Recovery of ALC levels began 14, 14–21, and 7 days after the last dose of 0.25, 0.75, and 1.5 mg, respectively, on Day 28.

Conclusion: In healthy participants, multiple daily doses of BMS-986166 in the range of 0.25–1.5 mg were well tolerated, with no clinically relevant lowering of HR. PK were linear and decreases in ALC were dose related.

UPADACITINIB AS MONOTHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS AT 48 WEEKS FROM THE SELECT-MONOTHERAPY STUDY

Josef S. Smolen1, Paul Emery2, William Rigby3, Yoshia Tanaka4, Juan Ignacio Vargas5, Nemanja Dajcianov6, Manish Jain7, Yunxia Su8, Jeffrey Enesosa9, Aileen Pangan10, Heidi Camp8, Stanley B. Cohen9, 1Medical Univ of Vienna, Vienna, Austria; 2Leeds NIHR Biomedical Research Centre, Leeds Inst of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 3Dartmouth College, Hanover, NH, United States of America; 4Univ of Occupational and Environmental Health, Japan, Kitakyushu, Japan; 5Quantum Research, Puerto Varas, Chile; 6Univ of Belgrade, Belgrade, Serbia; 7Great Lakes Clinical Trials, Chicago, IL, United States of America; 8AbbVie, Inc., N Chicago, IL, United States of America; 9Metroplex Clinical Research Center, Dallas, TX, United States of America

Background: In the SELECT-MONOTHERAPY trial, upadacitinib (UPA), an oral JAK1-selective inhibitor, showed efficacy when used as monotherapy over 14 weeks (wks) in rheumatoid arthritis (RA) patients (pts) with an inadequate response to methotrexate (MTX).1

Objectives: Safety and efficacy of UPA monotherapy were assessed through 48 wks in an ongoing long-term extension period of SELECT-MONOTHERAPY.

Methods: At baseline (BL), pts on stable MTX were randomized to either continue MTX (cMTX, given as a blinded study drug) or switch to once-daily (OD) UPA at 15 (UPA15) or 30 mg (UPA30) monotherapy for 14 wks. From Wk14, the start of a long-term blinded extension, pts randomized to cMTX were switched to UPA15 or 30mg per pre-specified assignment at BL, pts randomized to UPA15 or 30 continued their initial treatment. No dose adjustments for UPA were allowed. Starting at Wk26 for pts who did not achieve CDAI ≤10, background csDMARDs could be initiated. Efficacy data up to the Wk48 visit are reported as “As Observed”. Adverse events (AE) per 100 pt yrs (PYs) are summarized up to May 25 2018.

Results: Of 648 pts randomized at BL, 598 (92%) completed 14 wks and continued on to the extension period. By May 25 2018, 16% discontinued study drug; 5% due to AE, 0.5% due to lack of efficacy, 4% withdrew consent, 1% were lost to follow-up, and 6% due to other reasons. Cumulative exposures to UPA15 and UPA30 were 336.0 PYs and 337.1
PYs, respectively. Starting from Wk26, background csDMARDs were initiated for approximately 18% of pts. Based on As Observed data, for pts on UPA from BL through Wk48 on UPA15 [250/300 (83%)] and UPA30 [251/298 (84%)], clinical and functional outcomes continued to improve, or were maintained (Table 1). For pts continuing UPA15 and 30, DAS28-CRP<2.6 was 55% and 68%, and CDAL≤2.8 was 28% and 42%, respectively. Pts who were switched from cMTX to UPA15 or 30 at Wk14 had similar responses at Wk 48. The most frequently reported treatment-emergent AEs were urinary tract infection, blood creatine phosphokinase increase, upper respiratory tract infection, nasopharyngitis, worsening of RA, herpes zoster (H2), alanine aminotransferase increase, and bronchitis. The most frequently reported serious AE was pneumonia (8 events). Events/100PYS were numerically higher in the UPA30 vs UPA15 arm for HZ, and hepatic disorders, and were comparable for serious infections and malignancies excluding non-melanoma skin cancer (Table 2). Adjudicated venous thromboembolic events (VTE) were observed only on UPA15 (2 pts with deep vein thrombosis and 2 pts with pulmonary embolism; all patients had at least one risk factor for VTE).

Conclusion: UPA 15 or 30 monotherapy resulted in similar improvements in signs and symptoms and physical function through 48 wks. The overall benefit-risk profile of both doses of UPA was favorable based on safety and efficacy data through Wk48 but will be confirmed through an integrated safety analysis across all the ph 3 trials.

Background: Monotherapy use of upadacitinib (UPA), a selective JAK1 inhibitor, demonstrated clinically meaningful improvement in the signs and symptoms of rheumatoid arthritis (RA) compared with methotrexate (MTX). To better understand the impact of UPA treatment in RA from the patient’s perspective, we examined the effect of UPA on patient-reported outcomes (PROs).

Objectives: To evaluate the effect of UPA monotherapy vs MTX at week 12 on PROs in SELECT-EARLY (NCT02706873), a randomised controlled trial in MTX-naive patients with moderate to severe RA.

Methods: Patients were randomised 1:1:1 to receive once daily UPA (15 mg or 30 mg) or weekly MTX (titrated by Week 8). PROs assessed included Patient Global Assessment of Disease Activity (PtGA) by visual analogue scale (VAS), patient global response, Health Assessment Questionnaire Disability Index (HAQ-DI), fatigue by Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), duration and severity of morning (AM) stiffness, HRQoL by Short Form 36 (SF-36), and Work Productivity and Activity Impairment (WPAI) measure. Least square mean (LSM) changes from baseline (BL) to Week 12 were based on analysis of covariance. Percentages of patients reporting changes in PRO scores from BL to Week 12 ≥ minimum clinically important differences (MCIDs) or scores ≥ normative values (age- and gender-matched for SF-36 only) were determined for UPA and MTX groups; comparisons used chi-square tests. For each PRO, the incremental number needed to treat (NNT) to achieve clinically meaningful improvement from BL was calculated.

Results: Data from 945 patients (MTX: 314; UPA 15 mg: 317; UPA 30 mg: 314) were analysed. Mean age was 53 years; 76% were female; 49% had RA for ≤6 months. Statistically significant LSM changes from BL to Week 12 were reported for both doses of UPA vs MTX for all PROs (Table).

To Week 12, both UPA doses had significantly higher proportions of patients reporting improvements ≥ MCID vs MTX in HAQ-DI duration and severity of AM stiffness, pain, and PtGA. Compared with MTX at Week 12, a significantly greater proportion of patients receiving UPA at either dose reported improvements ≥ MCID in all PROs. A significantly greater proportion of patients receiving UPA also reported scores ≥ normative values for all PROs except SF-36 Mental Health (UPA 15 mg and SF-36 General Health [both UPA doses] domains. For most PROs, NNTs with UPA ranged from 4 to 8 patients at Week 12.
Conclusion: Among MTX-naïve patients with active RA, treatment with UPA 15 mg or 30 mg daily for 12 weeks resulted in statistically significant and clinically meaningful improvements in physical function, pain, fatigue, AM stiffness, HRQoL, and work productivity compared with MTX. The NNTs to achieve these improvements were favourable.

Results: 241 pts had early RA (tofa mono: N=80; tofa+MTX: N=83; ADA+MTX: N=78; mean RA duration: 1.0–1.1 yrs); 905 pts had established RA (tofa mono: N=208; tofa+MTX: N=208; mean RA duration: 9.4–10.4 yrs). BL demographics and disease characteristics were generally comparable for early vs established RA pts, with some expected differences (the latter were slightly older, and a greater proportion had received prior bDMARDs); RF and anti-CCP+ rates were higher for early RA than established RA (p<0.05). ADA was not statistically different vs tofa+MTX in early RA (Figure). Trends were similar for all outcomes. AE rates were generally similar in early vs established RA. Rates for SAEs were less clear; rates were lowest for tofa+MTX in early RA and slightly higher for both tofacitinib arms vs ADA (Table 1). Conclusion: Efficacy was similar for tofa mono and tofa+MTX in early RA, and significantly higher for tofa+MTX in established RA. ADA+MTX was numerically but not always significantly more effective than tofacitinib in early RA. AE rates were generally similar regardless of BL RA duration. These findings, especially in established RA, are consistent with the conclusion of the primary analysis.2 Limitations to this post hoc analysis include low numbers of early RA pts.

SELECTIVE INHIBITION OF JANUS KINASE 1 (JAK1) BY FILOTINIB MODULATES THE DISEASE-ASSOCIATED WHOLE BLOOD TRANSCRIPTIONAL PROFILE OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

Peter C. Taylor1, Bryan Downie2, Luting Zhuo3, Rachael E. Hawtin4, Jinfeng Liu5, Amer M. Mirza6, 2Botnar Research Centre, University of Oxford, Oxford, United Kingdom; 3Gilead Sciences, Inc., Foster City, United States of America

Background: Filgotinib (FIL), an oral selective JAK1 inhibitor, was safe and efficacious in FINCH2, a randomized, double-blind, placebo-controlled, phase 3 study in patients with active rheumatoid arthritis (RA) who had an inadequate response to biologic disease-modifying anti-rheumatic drugs (bDMARDs).1 The whole blood transcriptional profile of patients was evaluated.

Objectives: Identify RA-associated gene transcripts and biological pathways that are altered in response to FIL treatment and interrogate FIL-modulated biomarkers correlated with disease activity.

Methods: RA patients enrolled in FINCH2 (n=449) were randomized 1:1:1 and received FIL (100 mg, 200 mg, or placebo (PBO)) once daily plus a stable background dose of methotrexate. Whole blood samples from enrolled patients were collected at baseline (BL) and weeks 4 and 12 for RNA sequencing. Spearman’s rank correlation of BL disease activity (DAS28CRP) was calculated to define disease-associated genes (DAGs) and pathways (DAPs). Differential expression of 5155 genes and FIL-specific changes were determined after subtracting gene expression changes in the PBO group. Biological pathways (910 total) were analyzed by Gene Set Enrichment Analysis (GSEA) or single-sample GSEA. A false-discovery rate of 5% was applied for all analyses.

Results: At weeks 4 and 12, more genes were significantly differentially expressed in the FIL 200 mg arm vs the 100 mg arm; and, consistent with increased clinical efficacy, the average magnitude of change in gene expression was larger. No single gene reached a threshold of significance for differential expression in PBO-treated patients. FIL treatment induced a stronger reversal of DAS expression (rho range: ~0.35 to ~0.59) compared to PBO (rho ~0.3) at weeks 4 and 12. DAGs most prominently reversed by FIL included FAM20A and METTL7B. Top-ranked pathways associated positively with disease activity at BL included inflammatory response, cell proliferation activity, and cell cycle. By week 12, pathways most significantly reduced following FIL treatment included IL-6/JAK/STAT, inflammatory, and interferon response, consistent with observed effects of FIL in preclinical models and phase 2 DARWIN studies. In contrast, IL-6/JAK/STAT signaling increased at weeks 4 and 12 with PBO. DAGs showed a similar reversal of gene expression (rho range: ~0.43 to ~0.58) with FIL at weeks 4 and 12 compared to PBO (rho range: ~0.007 to ~0.024) suggesting that FIL treatment may attenuate RA-mediated IL-6/JAK/STAT signaling, inflammation, and other RA-associated pathways correlated with clinical outcome measures.

Conclusion: The whole blood transcriptional profile of patients following FIL treatment showed a dose-dependent reduction in the expression of
JAK/STAT signaling and inflammation genes. No significant changes in the expression of DAGs were observed in PBO-treated patients. F I L also broadly reversed DAGs and DAPs, and ongoing research is exploring the relationship between changes in gene and pathway modulation across a range of clinical endpoints.

THU0195

ULTRASOUND EVALUATION FOR MONITORING RESPONSE TO BARICITINIB IN RHEUMATOID ARTHRITIS PATIENTS AT EARLY STAGE AFTER TREATMENT

Eiji Torikai1, Daisuke Suzuki2.1: Iwata city hospital, Iwata, Japan; 2: Hamamatsu university school of medicine, Hamamatsu, Japan

Background: Baricitinib (bari) is approved for treating moderate-severe RA in many countries including Japan. Bari, an oral Janus kinase (JAK1)/JAK2 selective inhibitor, has shown the efficacy in patients with rheumatoid arthritis (RA) and in adequate response to conventional synthetic DMARDs in some clinical trials. Thanks to technological improvement in Ultrasound (US) equipment and the use of internationally approved scanning techniques and definitions for normal findings and pathology, US monitoring are widely used to assess inflammatory and structural lesions in daily clinic.

Objectives: To monitor the short-term response to baricitinib therapy in bilateral wrist and finger joints of RA patients by US and to evaluate correlation between US findings and clinical assessments.

Methods: We included 23 Japanese patients with RA who have inadequate response to csDMARDs or bDMARDs (biologics-naive cases, and biologics-experience cases). Patients were scheduled to receive bari 4mg or 2mg once daily dose as monotherapy or in combination with other csDMARDs. They were allowed to be decreased prednisolone when their disease activity was improved. Clinical evaluation was performed blinded to the results of the US assessment that had been carried out on the same day. Swollen joint counts on 28 joints (SJC), tender joint counts on 28 joints (TJC) and Clinical Disease Activity index (CDAI) were registered for each patient. Each parameter was evaluated at baseline, after 1 month and 3 months. Four sonographers, experienced in musculoskeletal US, who were blinded to the clinical and laboratory data, performed the US examination. The US assessment and scanning technique included evaluation of synovial sites in 26 joints (wrist, radiocarpal, midcarpal, radiocarpal joints, 1 - 5 MCP joints and 1 - 5 PIP joints). Gray scale (GS) and power doppler (PD) were graded according to a 0 - 3 semi-quantitative score depending on their severity [1]. We calculated total scores for each patient in GS (GS score) and PD (PD score) differently. We compared the change of GS score and PD score. In addition, we evaluated the correlation between the changes in GS score or PD score and the variations in clinical evaluation items.

Results: Patient’s backgrounds were provided in Table 1. All clinical parameters were significantly improved at each follow-up periods after treatment. Mean SJC, TJC and CDAI decreased from 7.52 ± 3.89, 8.26 ± 3.82 and 26.89 ± 9.48 at baseline to 1.52 ± 1.75, 1.82 ± 1.89 and 6.40 ± 5.17 at 1month and to 1.27 ± 1.39, 1.27 ± 1.38 and 3.99 ± 3.49 at 3 months respectively (Table 2). GS and PD score at each follow-up periods after treatment were also significantly improved. Mean GS and PD decreased from 8.11 ± 3.41 and 12.42 ± 4.45 at baseline to 3.63 ± 2.45 and 7.73 ± 4.70 at 1 month and to 2.10 ± 1.49 and 4.21 ± 2.70 at 3 months respectively (Table 2). GS score significantly correlated with SJC (r= 0.586, p<0.01), TJC (r=0.602, p<0.01) and CDAI (r=0.656, p<0.01). PD score significantly correlated with SJC (r= 0.608, p<0.01), TJC (r=0.621, p<0.01) and CDAI (r=0.658, p<0.01).

Conclusion: Baricitinib therapy had significantly improved disease activity of RA patients at early stage after the treatment. GS and PD score were also significantly improved and correlated with clinical parameters.

These data confirm that the use of US evaluation is very useful method for evaluating the monitoring the response of treatment and feasible method complementary to clinical assessment for guiding the clinician in the appropriate therapeutic decision.

THU0196

EFFICACY AND SAFETY UP TO 24 WEEKS OF BARICITINIB FOR JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL WORLD MULTICENTER CLINICAL DATA

Eiji Torikai1, Daisuke Suzuki2.1: Hamamatsu university school of medicine, Hamamatsu, Japan; 2: Hamamatsu university school of medicine, Hamamatsu, Japan

Background: Baricitinib (bari) is approved for treating moderate-severe rheumatoid arthritis (RA) in many countries, including Japan. Bari is an oral Janus kinase (JAK1)/JAK2 selective inhibitor that has shown good efficacy in patients with RA and adequate response to conventional synthetic DMARDs in some clinical trials. However, there have been few reports about the efficacy and safety of bari in real-world clinical data.

Objectives: We evaluated the efficacy and safety of bari for Japanese RA patients who have an inadequate response to DMARDs in real-world multicenter clinical data.

Methods: We included 32 Japanese patients with RA who show an inadequate response to csDMARDs or biDMARDs (biologics-naive BN group): 19 cases, and biologics-experience (BE group): 13 cases). Patients were scheduled to receive bari 4 or 2 mg once daily dose as a monotherapy or in combination with other csDMARDs. If the disease activity was not improved within 3 months in patients treated with bari 2 mg, the bari dose was increased to 4 mg. Patients were allowed to decrease their prednisolone treatment if their disease activity improved. First, we evaluated changes in the number of swollen joints and tender joints, CRP (mg/dL), visual analog scale of pain (0–100 mm), patient’s global assessment (0–100 mm), Clinical Disease Activity Index, and HAQ-DI for 24 weeks. Second, we evaluated the proportion of patients with adverse events (AEs) and progress after these AEs.

Results: Patients’ backgrounds were provided Table 1. Many patients fell the early effect of bari. At 1 month after treatment, ACR20/50/70 were 84.2%/63.2%/21.1% in the BN group and 53.8%/23.1%/7.7% in the BE group, respectively. All measurement items of disease activity and patient-reported outcomes were significantly improved after treatment. This tendency continued until the final evaluation (Table 2). At 24 weeks, remission and low disease activity rates were 47.4% and 78.9% in the BN group and 15.4% and 61.5% in the BE group, respectively. One case in the BE group discontinued bari treatment due to no response. These data were better than clinical trial data (Japanese subpopulation data from RA-BEAM and RA-BUILD studies[1]). We determined that we could take an aggressive treatment course according to treat to target strategies in real-world clinics. Greater early improvements in HAQ-DI were seen. HAQ-DI was improved significantly at each evaluation time point after bari treatment (Table 2). We had two cases of mild pneumonia and one case of herpes zoster. These cases were improved after 1–2 weeks of antibiotic therapy or anti-viral drug therapy. One case discontinued bari. Although the other two cases withdrew from bari treatment, we could restart it. We think that the most important reason why they did not advance in severe because we were not able to diagnose and treat these cases earlier. No patient showed malignancies, cardiovascular events, or deep vein thrombosis. No patient discontinued bari treatment due to AEs. Also, increases in blood pressure and d-dimer were not observed during the follow-up period. Other mild AEs, including upper respiratory tract infection, nasopharyngitis, and laboratory data abnormalities occurred in 62.5% of patients (Table 3). A small increase in lymphocyte count and small decrease in neutrophil count...
were seen at 1 month after bari treatment. These either remained flat or improved 3 months after treatment. An increase from baseline in creatinine was also seen. These tendencies continued to the final observation. Moving forward, these items should be monitored for long-term evaluation.

#### THU0197

**MONOTHERAPY WITH UPADACITINIB IN MTX-NAÏVE PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS AT 48 WEEKS FROM THE SELECT-EARLY STUDY**

Ronald van Vollenhoven1, Tsutomu Takeuchi2, Aileen Pangan3, Alan Friedman3, Vibeke Strand4, 5, 6, 7, 8, 9, 10.

### Methods:

SELECT-EARLY had a 48-wk double-blind active comparator-controlled period. Pts were initially randomized to monotherapy (mono) with UPA 15 or 30 mg or MTX (titrated up to Wk8). Rescue therapy was offered if pts met the following: (1) From Wk 12-24, pts without ≥20% improvement from BL (±) in both TJC and SJC at 2 consecutive visits continued monotherapy study drug with optimized background RA medications. (2) At Wk26, pts with CDAI ≥28 continued their original study drug; in pts with CDAI >2.8 but ≤20% in TJC and SJC, for those on MTX, UPA15/30mg was added; for those on UPA15/30mg, MTX was added for 19 (6%) and 9 (3%) of pts on UPA15 and 30 respectively vs 17% on MTX; 28% and 33% vs 13% achieved Boolean REM. At Wk48, ∆mTSS were significantly less on UPA15 and UPA30 vs MTX. The safety profile of UPA15 and UPA30 was similar generally to MTX, except for total AEs and herpes zoster, which were higher with UPA15 and 30 vs MTX (Table 2). There were 11 deaths (including 3 treatment-emergent deaths) due to varied causes.

### Conclusion:

These data showed that bari has a favorable benefit-risk balance in a real-world clinic and thus may be considered as a good treatment option for Japanese RA patients who have an inadequate response to csDMARDs or bDMARDs.

**Conclusion:** UPA15 and 30 monotherapy continued to show significant improvements in RA signs and symptoms and inhibition of structural damage vs MTX through 48 wks. Only a small proportion of pts required MTX addition to UPA mono at Wk26 to achieve and maintain response. The safety profile based on all exposure remained consistent with ph 2 and 3 RCTs in RA, although an integrated safety analysis of UPA across the full ph 3 RA program will provide a more comprehensive understanding of the benefit:risk profile of UPA in RA.

EFFECTIVENESS OF REMISSION-INDUCTION STRATEGIES FOR EARLY RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

Maxime Verhoeven, Paco Welsing, Johannes Wij Bijlsma, Jacob M. van Laar, Floris Lalleber, Janneke Tekstra, Johannes W. G. Jacobs. University Medical Center Utrecht, Utrecht, Netherlands

Background: Several trials studied initiation of therapy in early RA patients with a more intensive strategy than the standard disease modifying anti-rheumatic drug (DMARD) strategy according to current guidelines, with the aim of rapidly inducing clinical remission (remission-induction strategies).

Objectives: To establish in early RA patients the effectiveness of remission-induction strategies compared to standard DMARD strategies with or without concomitant glucocorticoids (GCs), with delayed tapering (not ‘bridging therapy’) or starting ≥2 csDMARDs. Standard DMARD strategy was defined as starting mono-therapy with a csDMARD, with or without GCs as bridging therapy.

The outcome was remission according to a validated disease activity index or the Boolean definition. Numbers of patients were extracted from all studies and relative risks (RR) for achieving remission with 95% confidence intervals (95%CI) per study were calculated. Subgroup analyses were performed for different definitions of remission, the use of a b/tsDMARD as part of the induction therapy strategy (yes/no) and the use of concomitant GC bridging therapy (yes/no) in standard DMARD strategies.

Results: Included were 22 clinical studies, involving 4435 patients in induction strategies and 3314 in standard DMARD strategies. For remission, 17 studies applied the criterion of DAS28 <2.6, 12 the Boolean remission definition, 7 CDAI ≤≤20 and 10 studies SDAI ≤≤3.3. Remission had to be present during 6 to 12 months in all studies. Heterogeneity in study design prohibited providing an overall pooled effect estimate, but for subgroup pooled estimates were given for descriptive purposes.

In the figure we provide results for studies applying the DAS28 remission definition. Of those studies, 13/17 (76%) showed a statistically significant effect in favour of induction therapy. The pooled RR of achieving remission for strategies initiating bDMARDs was 1.73 [95%CI 1.59 to 1.88] versus the standard DMARD strategy without GC bridging, and it was 1.20 [95%CI 1.03 to 1.40] for induction strategies without bDMARD versus standard DMARD strategies without GC bridging. No superior effect of any induction strategy was found compared to that of standard DMARD strategies with GC bridging (pooled RR 1.06, 95%CI 0.83 to 1.35).

When using other remission definitions, all induction strategy studies with Boolean/CDAI/SDAI outcomes applied a b/tsDMARD, and 63%, 100% and 78%, respectively found a statistically significantly superior effect compared to standard DMARD strategies without GC bridging; however, compared to standard DMARD strategies with GC bridging, only trends in the same direction were found.

Conclusion: The PK of baricitinib in Chinese healthy subjects were characterized by rapid absorption and elimination following single and multiple oral doses of up to 10 mg. Systemic exposure to baricitinib increased in an approximately dose-proportional manner following single and multiple doses. Single and multiple oral doses of daily-administered baricitinib up to 10 mg were well tolerated by healthy Chinese subjects.

THU0200

DRUG UTILISATION IN PEOPLE WITH EARLY RHEUMATOID ARTHRITIS IN THE UNITED KINGDOM

Sarah Wood, Kimme Hyrich, Suzanne Verstappen, Douglas Steirke. The University of Manchester, Manchester, United Kingdom

Background: Despite a growing body of evidence in the pharmacological management of people with early rheumatoid arthritis (RA), there is still uncertainty concerning the most effective treatment regimen. Until 2018, guidance for England and Wales stated that everyone with early RA should receive combination therapy with 2 or more conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) in parallel. However, from epidemiological studies and anecdotal information, we know that this has not been the case in practice.

Objectives: (i) To determine the proportion of patients with new onset RA who start methotrexate (MTX) either alone or in combination with another csDMARD (ii) to describe which combinations are currently being prescribed and (iii) to describe the characteristics associated with the choice of initial RA treatment strategy.

Methods: Consecutive patients with RA participating in the Rheumatoid Arthritis Medication Study (RAMS), a large UK study recruiting patients starting MTX for the first time, were eligible. Data on demographics, disease activity, comorbidity and all RA treatments are captured at baseline, 6 and 12 months following start of MTX. Analysis was limited to patients starting MTX within the first 2 years of symptom onset as part of their first treatment regimen for RA. Prevalent users of alternative csDMARDs, defined as use > 6 weeks prior to MTX start, were excluded. Participants were categorised as either starting MTX monotherapy or MTX in combination with another csDMARD (defined as started +/- 6 weeks of MTX start date). Baseline characteristics were compared between monotherapy and combination therapy groups using descriptive statistics.

Results: 1,374 patients with a mean (SD) age of 58 (14) years were included in this study; 64% were female. At baseline, 996 (76%) started MTX monotherapy and 316 (24%) started MTX/csDMARD combination therapy (84% with hydroxychloroquine and 16% with sulphasalazine). Patients starting combination therapy were younger (p<0.005), with higher DAS28 scores (p<0.005), higher HAQ scores (p<0.05), lower MTX starting doses (p<0.005), and shorter symptom duration (p=0.05) compared with the monotherapy group.

Conclusion: These data show that despite national guidelines recommending combination csDMARD therapy in all patients diagnosed with RA, over three quarters of patients still started MTX monotherapy. People who were prescribed combination therapy had more severe disease suggesting that prescribers do consider prognosis in their treatment decisions. A majority of patients starting combination therapy did so with hydroxychloroquine, despite a lack of evidence for the benefits of this particular combination in clinical practice.

ANALYSIS OF GUT MICROBIOTA DIVERSITY IN PATIENTS WITH RHUMATOID ARTHRITIS AND BENEFICIAL EFFECTS OF PROBIOTICS ON INTESTINAL FLORA

Mina Yao1, Sheng-Xiao Zhang1, Chong Gao2, Xiao-Bin Zheng1, Lili Shang1, Xu-Fang Yin1, Zhang Mingxing1, Jia Wang1, Ting Cheng1, Nalin Lal1, Li Xiao-Feng1.

1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Brigham and Women’s Hospital, Harvard Medical School, Department of Pathology, Boston, United States of America

Background: Rheumatoid arthritis (RA) is a progressive, irreversible disease characterized by autoimmune imbalance. Recent studies have found that the number and type of intestinal flora in RA patients were changed (called disorders), which in turn leads to immune imbalance in RA patients. The breath test can indirectly assess the growth of bacteria in the intestine. This study aimed to investigate the intestinal flora imbalance in RA patients and the effect of probiotics on the intestinal flora of RA patients using methane and hydrogen breath test.

Objectives: To study the beneficial effects of probiotics on the intestinal flora of RA patients by detecting the concentrations of methane and hydrogen and the microbial populations in patients with rheumatoid arthritis (RA) before and after probiotic treatment.

Methods: The lactulose methane and hydrogen breath technique were used to detect and compare the concentration of methane and hydrogen in 36 patients with RA before and after probiotic treatment (mainly Bifidobacterium, Clostridium butyricum, Lactobacillus) for 3 weeks. At the same time, the 16SRNA V3 region in stool samples of 17 patients with RA was qualitatively analyzed by Roche/45 high-throughput sequencing platform and compared with 9 healthy adult stool samples.

Results: Compared with pre-intervention, after 3 weeks of probiotic treatment, the exhaled methane concentration was significantly increased in RA patients at 30 minutes, 60 minutes, and 90 minutes (P < 0.05). The sum of methane and hydrogen concentrations increased at 30 minutes (P < 0.05). There was no significant difference in hydrogen concentration before and after treatment (P > 0.05) (Table 1). Compared with healthy adults, the fecal diversity index (Shannon) of RA patients increased (P < 0.05) and the species uniformity index (flatness) also increased.

Conclusion: Patients with RA had a significant difference in the structure of intestinal flora compared with that of healthy controls, which may represent perturbations of microbial communities and contribute to the pathogenesis and condition of RA. Probiotics can restore the composition of the gut microbiome and introduce beneficial functions to gut microbial communities through diet, probiotics or fecal transplantation, providing a promising prospect for clinical treatment of RA.

SLE, Sjögren’s and APS – etiology, pathogenesis and animal models

INTERFERON STIMULATED GENE 15 PROTECTS REGULATORY T CELL OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS FROM INTERFERON ALPHA-MEDIATED DEPLETION

Francesca Romana Spinelli, Ilenia Pacella, Silvia Piconese, Fulvia Ceccerelli, Francesca Miranda, Cristiano Alessandri, Vincenzo Barnaba, Guido Valesini, Fabrizio Conti. Sapienza University of Rome, Rome, Italy

Background: Data on T regulatory (T reg) cells number and functions in patients with Systemic Lupus Erythematosus (SLE) are conflicting (1). Type I interferon (IFN) decreases Treg proliferation and induces Treg apoptosis (2). IFN stimulated gene 15 (ISG15) is an IFN-induced protein with a negative effect on IFN pathway.

Objectives: Aim of the study was to evaluate the effect of IFN alpha and ISG15 on Treg number and on STAT1 phosphorylation in patients with SLE.

Methods: We recruited patients with SLE classified according to 1997 ACR criteria. We collected demographic and clinical data including disease duration, disease activity scored according to Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) 2.0. Peripheral blood mononuclear cells (PBMC) were isolated from whole blood samples. Intras cellular phosphorylated STAT1 (pSTAT1) levels were evaluated in Treg (CD4+FOXp3+CD127 low cells) and conventional T cell (Tconv, CD4+FOXp3- cells) by multiparametric flow cytometry, ex vivo or after stimulation with recombinant IFN alpha. PBMC were cultured for 48 hours with anti-CD3 or anti-CD3 and IFN alpha; the frequency of Treg was analysed by multiparametric flow cytometry. ISG15 mRNA expression was evaluated by RT-PCR on PBMC from SLE patients. Data were expressed as mean ± standard deviation or median (interquartile range) according to the distribution; Mann-Whitney and Spearman tests were applied. P value <0.05 were considered statistically significant.

Results: We enrolled 21 SLE patients [F:M 20:1; mean age 45.2 ± 12.9 years; mean disease duration 157.5± 103 months; median SLEDAI 2(4)] Overall, median baseline ISG15 mRNA expression was 0.06 (IQR 0.16); patients were divided into ISG15-high (n=9) and ISG15-low (n=12), according to the mean mRNA expression. Ex vivo, after short-term treatment with IFN alpha (15 and 25 minutes), we observed a significant increase in STAT1 phosphorylation compared to baseline both in Treg and Tconv (p<0.00001), in ISG15-high and ISG15-low patients (Figure 1 A and B); however, high ISG15 levels protect both Treg and Tconv from STAT1 phosphorylation (Figure 1 C). After 48 of culture with IFN alpha, we observed a decrease in Treg and Tconv number, significantly greater in ISG15-low cells (Figure 1 D). Treg frequency and ISG15 expression in Treg were higher in active vs inactive SLE patients [SLEDAI > 4 vs SLEDAI ≤ 4] (p<0.05).

Conclusion: ISG15 protects T conventional cells from STAT1 phosphorylation and induces resistance to T regulatory cells depletion. The results of the study suggest that ISG15, a protein induced by IFN in the acute phase of the disease, exerts a negative feedback, allowing the recovery of T reg.
PROMOTER DNA METHYLATION AND HSA-424-5P ASSOCIATION OF LILRA3 GENE WITH mRNA levels together with a decrease in ATF6 levels found in LSG from SS-patients (p=0.02), which were inversely correlated with 3D-acini with IFN-γ treatment.

Results: LSG from SS-patients showed a significant decrease of ATF6 mRNA expression in LSG from SS-patients and controls. The effect of IFN-γ on both mechanisms was also evaluated in a 3D-acini model.

Methods: SG biopsies from SS-patients and controls were analyzed. In vitro assays 3D-acini incubated with 1 or 10 ng/mL IFN-γ for 24 h were employed. Specific DNA methylation of ATF6 gene promoter was evaluated by methylation-sensitive high-resolution melting PCR. For in vitro assays, 3D-acini were incubated with 1 or 10 ng/mL IFN-γ.

Conclusion: The results suggest that the ATF6 promoter overexpression is regulated by two complementary epigenetic mechanisms: the DNA hypermethylation of its promoter and the silencing of its mRNA by hsa-miR-424-5p in LSG from SS-patients. IFN-γ affects the expression of ATF6 by modulation of epigenetic mechanisms, regulating the abundance of epithelial cells to handle the chronic ER stress. Interestingly, these changes carry out under a global DNA hypomethylation condition.

Disclosure of Interests: None declared
Background: In SLE, all terminally differentiated blood cells demonstrate an aberrant phenotype. HSCs are the most primitive cell type of the hematopoietic lineage when exposed within the bone marrow (BM) to adjuvants and inflammatory mediators change their transcriptional landscape and this may persist in the HSCs circulating in the peripheral blood or those infiltrating peripheral tissues. Within peripheral tissues these reprogrammed HSCs differentiate into myeloid cells mounting enhanced protective or aberrant immune responses.

Objectives: To dissect whether aberrant phenotypes of blood cells in SLE could be traced back to HSCs and explore how the inflammatory environment of SLE shapes the HSC differentiation process.

Methods: We analyzed the transcriptional alterations (genetic or epigenetic) of CD34+ cells in the BM of SLE patients, compared it to healthy individuals and the NZB/W lupus mice at the onset of disease (6 months). CD34+ cells were isolated from BM aspirates and peripheral blood of SLE patients (n=8) and healthy subjects (n=2) with magnetic separation (Stem Cell Technologies). mRNA was extracted and libraries were prepared. Sequencing was performed in NextSeq Illumina Platform. Alignment in human genome v.38 was done by Star package and differential expression analysis was performed by edgeR algorithm. Genes with FC>1.5/-1.5, FDR <0.05 were considered statistically significantly up/down-regulated, respectively. Heatmaps were constructed in R, GO/Pathway Analysis and enrichment analysis were performed in ClueGo, RENA, GeneMania and GSEA, respectively.

Results: Overlaying the transcriptome of BM-derived CD34+ of SLE patients and healthy subjects, we identified in total 598 differentially expressed genes (DEGs) (82 up-514 down-regulated in SLE). DEGs participate in hematopoietic cell lineage fate, regulation of stem cell differentiation, cell adhesion and cell cycle regulation. We also found evidence for cell cycle checkpoints signature which drives HSCs to experience replication stress and activate ATR pathway. Comparison of CD34+ profile between severe-moderate SLE reveals a prominent neutrophilic signature in severe disease. Comparative transcriptomic analysis of human vs murine SLE revealed a panel of common genes again related to cell proliferation and differentiation and platelet activation.

Conclusion: HSCs in SLE patients and murine lupus reprogram their transcriptome in response to the inflammatory milieu within the BM, thus exiting from dormancy, differentiating to myeloid cells and mounting a DNA damage response to the replication stress. This activated phenotype renders HSCs both susceptible to cell exhaustion while at the same time priming them and their progenies towards enhanced immune responses.

HELPER AND CYTOTOXIC FOLLICULAR T-CELLS IN SJÖGREN’S SYNDROME

Filipe Barcelos1,2,3, Catarina Martins1, Ricardo Monteiro1, Carlos Geraldes1, Ana Luísa Papoila1, Joana Cardigos3, Nathalie Madeira1, Nuno Alves1, José Vaz-Pattou1, Jaime Branco1, Miguel Sítima1, Tiziano Prussiani1, Miguel Silhma1, José Vaz-Pattou1, Jaime Branco1,2,3, Luis Miguel Borrego1,2,3, Instituto Português de Reumatologia, Lisboa, Portugal; Hospital Cuf Descobertas, Lisboa, Portugal; 2Nova Medical School, CEDOC, Lisboa, Portugal; 3Nova Medical School, Lisboa, Portugal; Centro Hospitalar Lisboa Central, Lisboa, Portugal; Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

Background: Follicular T-cells, characterized by the expression of CXCR5, secrete interleukin 21 (IL-21) and help B-cell differentiation in lymphoid follicles. They are also found in circulation and may play a key role in Sjögren’s syndrome (pSS) chronic autoimmune epithelium.

Objectives: To study circulating follicular helper (Thf) and cytotoxic (Tc) T-cells in peripheral blood (PB) from pSS patients, Rheumatoid Arthritis (RA) patients and healthy controls (HC), and to investigate how they correlate with B-cell subsets. We also aimed to explore associations between the Thf and Tc cells and clinical and laboratory features of pSS.

Methods: PB from 57 pSS patients, 20 RA patients and 24 HC was analysed by flow cytometry to characterize T and B-cell subsets, with CXCR5 defining Thf and Tc within CD4 and CD8 T-cells, respectively. A stimulation assay was used to assess the production of IL-21 by CD4+ and CD8+ T-cells.

Results: Compared to HC, pSS and RA patients presented significantly lower lymphocyte absolute counts (1615 and 1935 cells/µL, respectively) compared to 2228 cells/µL in HC, p<0.001 for HC vs pSS, p=0.018 for HC vs RA), and percentages (29.9% in pSS, 24.0% in RA, and 35.4% in HC, p=0.02 for HC vs pSS, and p=0.001 for HC vs RA). B-cell and T-cell absolute counts were also lower in both groups of patients compared to HC (in HC vs pSS, p=0.011 for B-cells and p=0.001 for T-cells; in HC vs RA, p=0.001 for B-cells and p=0.018 for T-cells). B-cells absolute counts and percentages in pSS were higher than in RA (177 vs 132 cells/µL, p=0.013; 9.7 vs 6.4%, p<0.001). There were no differences in CD8 T-cells percentages between groups, but pSS had lower CD4+ T-cell percentages compared to HC (p=0.004).

pSS patients presented lower absolute counts of CXCR5+ Tfh compared to RA (134 vs 181 cells/µL, p=0.039) and HC (134 vs 241 cells/µL, p=0.001). No differences were found in Thf percentages. RA patients had lower percentages of CXCR5+ Tfh compared to pSS (2.1 vs 2.6%, p=0.113) and HC (2.1 vs 3.0%, p=0.046).

pSS patients exhibited higher percentages of IL21+CD4 and IL21+CD8 T-cells (IL21+CD4 T-cells: 12.4% in pSS vs 9.0% in RA, p=0.046; vs 9.7% in HC, p=0.028; IL21+CD8 T-cells: 4.1% in pSS vs 2.3% in RA, p=0.001; vs 2.8% in HC, p=0.030). In pSS patients, CXCR5+ Tfh correlated positively with the percentages of plasmablasts (r=0.262 for CD24+CD38+ cells, and r=0.282 for IgM−CD38++ cells). IL21+CD8 T-cells correlated positively with the Naïve/Memory B cells ratio (r=0.370; p=0.002) and negatively with Bm1 memory cells (r=-0.323; p=0.014) and with Bm1 memory B cells (r=0.370; p=0.003). IL21+CD4 T-cells behaved similarly, though without statistical significance.

Anti-SSA-positive patients (n=38) presented higher CD4+IL21+ (133 vs 8.5%, p=0.025) and CD8+IL21+ percentages (4.4 vs 4.0%, p=0.198) than SSA-negative patients (n=19). Although there were no differences between pSS patients with active (n=27) and inactive disease (n=30), a tendency for positive correlations was found between IL21+CD4 and IL21+CD8 T-cells and the ESSDAI score (r=0.229, p=0.086 for CD4-, r=0.223, p=0.096 for CD8). Moreover, ESSDAI correlated positively with the Thf1/Thf17 ratio.

Conclusion: pSS patients present a profile of circulating Thf and Tc distinct from RA and HC, both phenotypically and functionally. Moreover, our data suggest a crucial role for these cells in B cell development, as they correlate with B cells, in pSS patients, which are known to exhibit a typical circulating B cell compartment. Both Thf and Tc cells can be critical for disease pathophysiology and activity, as underlined by the correlations between these cells and ESSDAI scores.

4-PHENYL BUTYRIC ACID AMELIORATES LUPUS: RNA-SEQ REVEALS THE MECHANISM OF THALIDOMIDE IN LUPUS CUTANEOUS LESIONS

THU0209

4-PHENYL BUTYRIC ACID AMELIORATES LUPUS HEPATITIS AND NEPHRITIS THROUGH SUPPRESSION OF NF-κB ACTIVATION IN EXPERIMENTAL LUPUS MODEL

Yun-Jung Choi1, Ji-Hyun Jeong1, Eun-Kyeong Lee1, Chang-Hoon Lee2, Myeung-Su Lee3, Wan-Hee Yoo4, 1Chonbuk National University Hospital, Internal Medicine, Jeon-Ju, Korea, Rep. of (South Korea), 2Wonkwang University Hospital, Internal Medicine, Iksan, Korea, Rep. of (South Korea)

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease presenting diverse manifestation involving multiple organs, such as liver and kidney. Endoplasmic reticulum (ER) stress has been revealed as one of the contributing factors of lupus pathogenesis.

Objectives: The purpose of the present study was to investigate whether ER stress inhibition suppresses organ inflammation including liver and kidney in lupus murine model and the activation of mitogen activated protein kinases (MAPK) and NF-κB.

Methods: A murine lupus model was induced through a 4-week treatment with Resiquimod, a toll-like receptor agonist 7. From the 8th week, the mice were treated with phosphate buffered saline, 4-phenylbutyric acid (4-PBA), and dexamethasone for 4 weeks. The increment of body weight, liver weight, inflammation mediator level, and the pathology of hepatitis and nephritis were analyzed at 12 weeks of age. The level of phosphorylated MAPK expression and activation of NF-κB were also evaluated.

Results: 4-PBA-treated group showed lower level of body weight increment with liver to body weight ratio compared with vehicle-treated group. 4-PBA group showed decreased inflammatory cell infiltration and fibrosis in the histologic finding of liver and kidney and lower level of inflammatory mediators, including TNF-α and IL-6, compared to vehicle-group. GRP78 and CHOP expression was decreased in the spleen of 4-PBA treated mice compared to vehicle-treated mice and 4-PBA group showed the lower expression level of phosphorylated JNK, ERK, p38 and NF-κB of the spleen.

Conclusion: Our results suggest that 4-PBA attenuates the inflammation on liver and kidney of experimental lupus model through suppression of MAPK and NF-κB activation. Thus, inhibition of ER stress could be function as anti-inflammatory therapeutics for SLE.

THU0210

RNA-SEQ REVEALS THE MECHANISM OF THALIDOMIDE IN LUPUS CUTANEOUS LESIONS

Cristina Solé-Marcé1, Ana Maria Alvarez-Rios2, Teresa Moline3, Berta Ferrer2, Josep Ordí-Ros1, Josefina Cortés-Hernández1, 1Vall Hebron Institute Research, Barcelona, Spain; 2Hospital Vall Hebron, Barcelona, Spain

Background: Cutaneous Lupus Erythematosus (CLE) is common, largely heterogeneous and characterized by a chronic relapsing course. As many as 70 to 80% of patients with SLE will develop skin lesions at some point during the course of their disease, with a significant proportion being disfiguring and debilitating [1]. Conventional therapy consists of topical steroids and antimarial agents but 40% of patients will be refractory to this regimen [2]. Thalidomide has been the only one that has shown an effectiveness of 90% [3], however, its mechanism of action in the disease is not known at all. In addition, its use is limited due mainly to its side effects such as teratogenicity and the development of peripheral polyneuropathy.

Objectives: Identification of the possible mechanisms of thalidomide in cutaneous lupus erythematosus.

Methods: Skin biopsies before and during treatment has been performed on a cohort of CLE patients treated (N=20) and not treated with thalidomide (N=5). Through a differential study of gene expression with RNA-seq and its subsequent validation, the mechanism of thalidomide action has been identified. The cell population in the tissue and in the blood of the patients and their evolution due to the treatment has also been studied by flow cytometry. In vitro experiments using isolated lupus cutaneous lymphocyte and keratinocytes has been performed to see the specific biological effect of thalidomide (Figure 1).

Results: Flow cytometry of immune cells from blood obtained pre- and post-treatment revealed a significant activation of Thelper (p<0.001), a differentiation towards Th2 subpopulation and an increase of natural killer effectors such as perforin and granzyme B. Not significant difference were observed in macrophages and dendritic cell. In addition, after RNA-seq analysis two fundamental molecular pathways has been identified in responder thalidomide treatment patients: 1) via IRF4-NFκB pathway modulation. 2) via AMPK-mTOR pathway modulation. In vitro experiments using isolated primary cells from lupus cutaneous patients showed that thalidomide modulate IRF4 in lymphocytes to inhibit NFκB pathway; however, AMPK-mTOR pathway is inhibited in keratinocytes by thalidomide effect.

Conclusion: Taken together, we show that mechanism of thalidomide in CLE is dual. It might inhibited NFκB pathway by modulation of IRF4 in lymphocyte but, in the same time, might inhibited MTOR pathway by modulation of AMPK in keratinocytes.

THU0211

EVOLUTION OF KIDNEY ANTIBODY SECRETING CELLS MOLECULAR SIGNATURE IN LUPUS PATIENTS WITH ACTIVE NEPHRITIS UPON IMMUNOSUPPRESSIVE THERAPY

Étienne Criqui1,2, Farah Taminou1,4, Tessa Huscenot2, Nathalie Costedoat-Chalumeau1, Marion Rabant2, Alexandre Karras3, Alisa Robbins4, Tatiana Fadeev2, Véronique Le Guern2, Philippe Reym3, Aurelie Hummel1, Bertrand Godée2, Bernard Lauwereyns3,4, Jean-Claude Weill5, Claude-Agnès Reynaud1, Frédéric Houssiau1,2, Matthieu Mahévas3,4, Institut Necker Enfants Malades, INSERM U1151/CRNS UMS 8253, Paris, France; 2Hôpital Henri-Mondor (APHP), Department of Internal Medicine, Créteil, France; 3Cliniques Universitaires Saint-Luc, Service de Rhumatologie, Bruxelles, Belgium; 4Université de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Bruxelles, Belgium; 5Hôpital Lariboisière (APHP), Department of Nephrology, Paris, France; 6Cochin Hospital (APHP), Internal Medicine Department, Paris, France; 7Necker Hospital (APHP), Pathology Department, Paris, France; 8Hôpital Européen Georges-Pompidou (APHP), Department of Nephrology, Paris, France; 9Robert Debré Hospital, Department of Internal Medicine, Reims, France; 10Hôpital Henri-Mondor (APHP), Department of Nephrology, Créteil, France; 11Necker Hospital (APHP), Nephrology Department, Paris, France

Background: Pathogenic antibody secreting cells (ASC) have been identified in the kidney of SLE-prone mice, but are poorly characterized in human lupus nephritis (LN). We hypothesized that long-lived plasma cells may contribute to the failure of immunosuppressive therapy in refractory patients.

Objectives: To characterize and compare the single cell molecular signature of ASC in kidney and urine from patients with active LN, either untreated or after immunosuppressive therapy failure.

Methods: We included patients with biopsy proven active LN from 4 centers and meeting the ACR revised classification criteria for SLE. Renal biopsies were scored according to 2003 International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification, and stained with anti-CD138 to visualize ASC. ASC were single cell sorted as CD3-/CD14-/CD16-/CD27high/CD38high cells. Single-cell gene expression profiling was performed by multiplex RT-PCR using Fluidigm Dynamic Arrays. We used a set of genes derived from a previous transcriptomic analysis of human splenic and bone marrow ASC to distinguish the process of ASC maturation from plasmablast (PB) to long-lived PC. We also studied ASC transcriptional program from urine of untreated LN patients at diagnosis and after 3 and 6 months of a prospective follow up during induction therapy (Plasma-Lup study).

Results: Immunohistochemistry staining on kidneys biopsies from both untreated (N=15) and refractory patients (N=6) showed infiltrates of CD138+ ASC mainly located in the interstitium, particularly in untreated patients. Single cell molecular signature of kidney ASC from 3 untreated patients with class IV LN revealed that these cells were mostly PB expressing multiple genes linked with cell division, and PC without long-lived PC genes expression. This contrasted with ASC signature from 3 patients with active LN and mycophenolate mofetil (MMF) failure that expressed long-lived PC genes and no proliferative genes. Primary component analysis of 170 single-cells showed clustering of ASC from MMF treated patients with long-lived bone marrow PC from healthy donors that were distinct from PB/PC from untreated patients (Figure 1). A PB signature was observed in urine ASC at diagnosis, similar to their kidney counterpart. The concentration of ASC in urine in 22 untreated patients correlated with ISN/RPS classification, with higher concentration in class IV patients (p<0.01).

Conclusion: These results suggest that PB infiltrate kidney of untreated LN patients, and that kidney long-lived PC may contribute to the failure of immunosuppressive therapy.

THU0212

BARICITINIB-ASSOCIATED CHANGES IN GLOBAL GENE EXPRESSION DURING A 24-WEEK PHASE 2 CLINICAL SLE TRIAL DESCRIBE A MECHANISM OF ACTION THROUGH INHIBITION OF JAK/STAT AND IFN RESPONSIVE GENE EXPRESSION

Thomas Dömer1, Yoshiya Tanaka2, Michelle A Petri3, Josef S. Smolen1, Ernst Dow1, Richard E Higgs3, Guilherme Rocha4, Robert Benschop5, Maria Sik6, Steppenweber De Bon4, Robert Hofman6, 1Charite Universitätsmedizin Berlin and Deutsches Rheumaforshungszenrum (DRFZ), Berlin, Germany; 2University of Occupational and Environmental Health, Kitakyushu, Japan; 3Johns Hopkins Univ School of Medicine, Baltimore, United States of America; 4Medical Univ of Vienna, Vienna, Austria; 5Eli Lilly and Company, Indianapolis, United States of America

Background: Baricitinib (bari) is an oral selective Janus kinase (JAK)1 and JAK2 inhibitor. In the Phase 2 study, JAH2 (NCT02708095), treatment with bari resulted in significant improvements in patients (pts) with active systemic lupus erythematosus (SLE) receiving standard background therapy, compared with placebo (PBO).1

Objectives: To use global gene expression to characterize baseline (BL) gene expression among SLE pts in JAH2 and to describe the mechanism of action (MoA) of bari during treatment in active SLE.

Methods: A total of 314 pts were randomized 1:1:1 to PBO, bari 2-mg, or bari 4-mg once daily for 24 weeks (Wks) in JAH2. RNA isolated from whole blood at BL and Wks 2, 4, 12, and 24 was analyzed using HTA2.0 arrays, possessing over 925,000 specific individual probes. Data were summarized to transcript level and analyzed using a mixed effects model on a log2 transformed response with multiplicity correction.

Results: Baseline gene expression analysis comparing healthy controls to SLE pts revealed elevated expression of genes involved in innate and adaptive immune pathways and biologic processes thought to be key to SLE pathogenesis. Baseline findings from the ILLUMINATE trial of tabalumab (1760 SLE pts at BL)2 were independently replicated, including individual gene-specific changes in the SLE populations versus controls. Treatment-induced changes were predominantly observed in the bari 4-mg versus PBO group at early time points (Wks 2 and 4; bari 4-mg > 2-mg). Statistically significant changes were observed for type I and II IFN responsive genes, and in the JAK/signal transducer and activator of transcription (STAT) canonical and noncanonical signaling pathways, in the bari 4-mg versus PBO group comparisons. There were biologically notable and statistically significant bari-associated decreases in gene expression from BL, compared to PBO, for interleukin (IL)-3, -5, -6, -7, and granulocyte macrophage colony-stimulating factor pathways, attributable to inhibition of JAK/STAT signaling.

Conclusion: These results build upon previous studies of gene expression in ILLUMINATE, comparing SLE at BL with healthy controls; they advance our understanding of lupus pathogenesis, and further delineate the MoA of bari in SLE. These data independently confirm the marked elevations of specific type I and II IFN genes at BL in clinical trial pts on standard of care treatment. Changes in gene expression with bari impacted IFN responsive genes as well as JAK/STAT signaling pathways. Interpretation of results is limited by sample size and statistical power, and presence of concomitant medications. Importantly, gene expression may not translate directly to protein expression; however, ongoing proteomic studies (including specific assays for type I IFN, IFN-γ, IL-12, IL-17, and IL-23) will help extend these gene expression results and further describe the MoA of bari in SLE.

THU0214

THE PI3Kα SELECTIVE INHIBITOR INCB050465 ABROGATES KIDNEY PATHOLOGY IN A SPONTANEOUS MURINE MODEL OF SYSTEMIC LUPUS ERYTHEMATOSUS

Brittany Fay, Monika Scuron, Niu Shun, Yan-Ou Yang, Eddy Yue, Andrew Combis, Eduardo Huarte, Melissa Parker, Paul Smith. Incyte Corporation, Wilmington, United States of America

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that affects multiple organs, including the skin, joints and kidneys. Though SLE typically cycles through periods of flares and remission, patients often eventually succumb to end-stage kidney or cardiovascular disease. SLE is characterized by the presence of autoantibodies that form immune complexes resulting in kidney deposition that significantly contribute to lupus nephritis pathogenesis. Phosphatidylinositol 3-kinases (PI3Ks) are divided into three classes (Class I, II, and III) according to their structure, regulation and substrate specificity. The Class I PI3K delta isoform (PI3Kδ) has been implicated in autoimmune diseases associated with aberrant B cell and antibody responses. INCB050465 is an oral small molecule PI3Kδ selective inhibitor currently being evaluated in clinical trials for the inflammatory indications Sjögren’s syndrome and autoimmune hemolytic anemia (NCT03627065 & NCT03538041).

Objectives: To quantify the efficacious potential of INCB050465, a selective PI3Kδ inhibitor, in a preclinical model of systemic lupus erythematosus with kidney pathology.

Methods: The MRL/lpr mouse model spontaneously develops multiple inflammatory phenotypes that mimic human SLE pathologies, including kidney damage resulting in proteinuria, cutaneous skin lesions and anti-double stranded DNA (anti-dsDNA) antibodies. Kidney sections were stained with hematoxylin and eosin (H&E) and assigned a composite score based on glomerulus, crescents, protein casts, interstitial inflammation and vasculitis by a rater unaware of the treatment groups. Flow cytometry was performed on splenocytes to characterize B cell and T cell subsets. Anti-dsDNA antibodies were determined by commercial ELISA.

Results: In vitro enzymatic selectivity screening revealed INCB050465 potently inhibited the PI3Kδ kinase enzyme (IC50 = 1.1 ± 0.5 nM), with 20,000-fold selectivity for the other PI3K family member enzymes. Proteins identified spontaneous kidney damage in 85% of vehicle treated mice by 21 weeks of age, and kidney histology revealed gross tissue enlargement associated with structural abnormalities. In contrast, treatment of INCB050465 treated mice by 21 weeks of age, and kidney histology revealed gross tissue enlargement associated with structural abnormalities. In contrast, therapeutic INCB050465 treatment dose-dependently reduced spleen weight (p < 0.01) and lymph node weight (p < 0.01) weight. Cutaneous skin lesions were unaffected by INCB050465 treatment. Splenocyte flow cytometry revealed no reduction in absolute lymphocyte, CD19+ B cell, CD4+ or CD8+ T cell frequencies following INCB050465 treatment. However
INC050465 reduced the absolute counts of germinal center (CD19GL7) and marginal zone (CD19CD21) B cell subsets. Anti-dsDNA antibodies were abrogated by INC050465 therapy (p < 0.005).

Conclusion: INC050465, a selective PI3Kι inhibitor, was highly efficacious against immune-mediated mechanisms associated with lupus nephritis, but not cutaneous lupus disease manifestations in this preclinical model. Treatment-induced reduction of kidney tissue integrity corresponded to specific B cell subset modulation and autoantibody reduction. Selective PI3Kι inhibitor treatment did not induce lymphocyte depletion.

The maximal difference between cases and controls was shown for SLE patients than controls (p=0.02). IgG1 anti-PC levels were higher among SLE patients than controls (p=0.02). IgG1 anti-PC was negatively associated with atherosclerosis and SLE.

Results: The maximal difference between cases and controls was shown for MCTD: significantly lower IgM Anti-PC but not anti-MDA among patients (median 49.3±7μl vs 70.4 in healthy controls, p(t-test)=0.0037).

Low levels (below 25th percentile) of anti-PC but not anti-MDA were significantly more prevalent in MCTD, SLE, SjS and SSc. The IgM anti-PC variable region profiles were distinctly different and also more homologous in their content than anti-MDA. Anti-PC but not anti-MDA were significantly more prevalent with CV in the whole patient group. In contrast to IgM anti-PC, IgM anti-MDA did not promote polarization of Tregs.

Conclusion: Anti-PC could be a protection marker for MCTD and also for SLE, SjS and SSc while anti-MDA did not differ. anti-PC level is negatively correlated with CV in the patient group cohort. These findings could have both diagnostic and therapeutic implications, one possibility being active or passive immunization with PC.

Background: IgM antibodies against phosphorylcholine (anti-PC) may be protective in atherosclerosis, cardiovascular disease (CVD) and systemic lupus erythematosus (SLE). Less is known about other anti-PC isotypes and subclasses. In this study, we study the role of IgG1 and IgG2 anti-PC, with focus on atherosclerosis and SLE.

Methods: To study the role of IgG1 and IgG2 anti-PC, with focus on atherosclerosis and SLE, both in clinical setting and by experimental studies, where we use our in-house produced monoclonal IgG1 anti-PC. We determined IgG1 and IgG2 anti-PC in our SLE cohort study (SLEVIC), among 116 SLE-patients from Karolinska University Hospital Huddinge and 110 population controls matched for age and gender. The level of antibodies was measured by ELISA. For functional studies, we used three of our in-house generated, fully human monoclonal IgG1 anti-PC (A01, D05, E01). Primary human macrophages were derived from peripheral blood. Apoptosis was induced in Jurkat T-cells and pre-incubated with A01, D05, E01 or isotype control IgG1 and effect on phagocytosis by macrophages studied. Anti-PC peptide/protein characterization was determined in anti-PC clones compared to isotype control using a proteomics de novo sequencing approach.

Results: IgG1 but not IgG2 anti-PC levels were higher among SLE patients than controls (p=0.02). IgG1 anti-PC was negatively associated with prevalence of atherosclerotic plaques, below 10th percentile. (OR: 2.49, CI: 0.69-9.00). IgG1 Anti-PC was negatively associated with CVD, SLE and SLEDAI (OR: 4.74 CI: 1.29-17.39, OR: 4.74 CI: 1.29-17.39). Monoclonal D05 had maximum effect on macrophage effecrocytosis efficiency, followed by A01 and E01. This is because anti-PC IgG1 binds to phosphorylcholine exposed on apoptotic cells and facilitate the uptake by macrophage. The in-house produced monoclonal antibodies showed differential binding specitivity to PC and PC associated neo-epitopes. Peptide analysis showed difference in the CDR3 region of the three anti-PC IgG1 clones which are crucial for recognition of the phosphorylcholine on the apoptotic cell surface and other neo-epitopes.
SERUM THYMIC STROMAL LYMPHOPOIETIN (TSLP) AS A BIOMARKER OF B-CELL LYMPHOPROLIFERATION IN SJÖGREN’S SYNDROME

Saviana Gandolfo, Cinzia Fabro, Milena Buti, Elena Dorighi Breatta, Daniela Cesielli, Carla Di Loreto, Salvatore De Vita, \textit{Rheumatology Clinic, Udine, Italy; Institute of Anatomical Pathology, Udine Academic Hospital; S. Maria della Misericordia, Udine, Italy.}

Background: Thymic stromal lymphopoietin (TSLP) has been demonstrated to be expressed on salivary glands (SG) biopsies of patients with primary Sjögren’s syndrome (pSS), mainly in more advanced degrees of lymphoid tissue (MALT) involvement and lymphoproliferation, i.e. persistent parotid swelling and mixed cryoglobulinemia.

Objectives: To study serum TSLP in a larger number of pSS patients, to confirm its correlation with the already studied tissue expression, and then to investigate a possible role of TSLP not only as a tissue biomarker, but also as a peripheral blood biomarker.

Methods: Serum TSLP levels were assessed by ELISA in sera collected from ninety-one anti-SSA-positive pSS patients (females n=86, 94.5%; mean age 57.2 years, range 25-80), fulfilling the 2016 ACR-EULAR pSS classification criteria, 80 matched healthy blood donors (HBDs), and 21 patients with non-autoimmune sicca syndrome (nSS). pSS patients were then stratified according to the degree of lymphoproliferation (2), well previously defined by tissue studies in the same patients, as follows: pSS fully benign (fbSS), pSS with myoepithelial sialadenitis (MESA), and pSS B-cell MALT lymphoma (NHL); the difference in serum TSLP levels was studied between these three subgroups.

Results: Serum TSLP was significantly higher in pSS patients (mean 47.19 pg/mL, range 0-324.89) compared to nSS (mean 2.74 pg/mL, range 0-15.9), p<0.0001, and to HBDs (mean 0.59 pg/mL, range 0-324.89), p<0.0001. The significance was the same when including only patients with extreme disease activities (LA, n=40), p<0.0001, and to HBDs (mean 0.59 pg/mL, range 0-324.89), p<0.0001. The significance was the same when including only patients with extreme disease activities (LA, n=40), p<0.0001, and to HBDs (mean 0.59 pg/mL, range 0-324.89), p<0.0001.

Conclusion: Serum TSLP could represent a novel biomarker of pSS-related B-cell lymphoproliferation, characterized by a heavier MALT involvement. The validation of the present monoclonal results is currently ongoing within the EU HarmonicSS Project.

THE INVOLVEMENT OF MITOCHONDRIAL ACTIVATION VIA GLUTAMINOLYSIS IN HUMAN B CELL DIFFERENTIATION AND ITS RELEVANCE TO THE PATHOGENESIS OF SLE

Maiko Hajime1, Shigeru Iwata1, Mingzeng Zhang2, Hiroko Miyata1, Kitakyushu, Japan; 2Nagasaki University School of Medicine, Biomedical Research Support Center, Nagasaki, Japan

Background: B cells play a crucial role in Systemic Lupus Erythematosus (SLE). Recently, "Immunometabolism" attract much attention. Glucose and glutamine are important nutrition for energy production such as ATP in various cells. It has been reported that aerobic glycolysis, glutaminolysis and mitochondrial functions enhanced in cancer cells. However, the involvement of metabolic reprograming in plasmablast differentiation and its relevance to the pathogenesis of SLE remained elusive.

Objectives: We first investigated the abnormality of mitochondria in B cells from patients with SLE by flow cytometry. Next, B cells were isolated from healthy donors (HDs) and mitochondrial reprogramming were assessed in vitro.

Methods: First, peripheral blood mononuclear cells (PBMCs) were obtained from age-matched 31 HDs and 29 patients with SLE. The mitochondrial membrane potential was measured with DiOc6 by flow cytometry. In addition, CD19+ cells were isolated from HDs and stimulated with CpG (TLR9 ligand) and IFN-α. Change of aerobic glycolysis, glutaminolysis and mitochondrial functions were assessed in the absence of glucose or glutamine and in the addition of metformine, which is known as AMPK activator, in vitro.

Results: We first examined the abnormality of mitochondria in B cells from patients with SLE using DiOc6 as a marker of depolarization-active mitochondrial membrane. Baseline characteristics of SLE were males: females=1:2.8, age 40.2 years, disease duration 132.2 months, SLEDAI 6.4 and BILAG 6.2 at the timing of admission due to exacerbation of SLE. The percentage of IgGCD27 memory B cells were higher than those of HDs, while the percentage of IgM memory B cells were lower than that of HDs. The percentage of CD24+DiOc6+ cells in IgD-/CD27+ memory B cells from patients with SLE were higher than that of HDs. These results indicate that B cells from patients with SLE have the abnormality of differentiation and mitochondrial functions. Next, we assessed the change of aerobic glycolysis, mitochondrial functions and glutaminolysis in the process of plasmablast differentiation in vitro. Stimulation with CpG and IFN-α, 1) enhanced aerobic glycolysis, which was assessed with lactate production. 2) increased the area of cytoplasm including many expanded mitochondrial cristae with slightly wider and loosely organized intermembrane space in electric microscopy, accompanied with ROS production and DiOc6 up-regulation, 3) induced CD27+CD38+ plasmablasts differentiation and immunoglobulin production. Lactate production was decreased in the absence of both glucose or glutamine. ROS production and DiOc6 expression were decreased in the absence of glucose, leading to inhibition of plasmablasts differentiation and immunoglobulin production. On the other hand, this tendency was not shown in the absence of glucose. Next, we evaluated oxygen consumption rate (OCR). OCR was also suppressed in the absence of glutamine. Metformin, abrogated glutamine uptake, resulting in suppression of NOVDS production, decreased expression, plasmablast differentiation and immunoglobulin production.

Conclusion: These results suggest that mitochondrial activation via glutaminolysis may play an important role in the differentiation from IgG/CD27+ double negative B cells to plasmablasts and production of immunoglobulins in patients with SLE.

DRY EYE IN SJÖGREN’S SYNDROME: CHEMOKINE AND CYTOKINE TEAR SPECTRUM

Background: Previous studies have linked the participation of multiple chemokines and cytokines in the physiopathology of primary Sjögren’s syndrome (pSS), however data regarding their presence in tears is scarce.

Objectives: To evaluate a panel of chemokines/cytokines in the tears of patients with pSS and correlate them with ocular symptoms as well as objective ocular tests.

Methods: We included 21 patients with pSS (EULAR/ACR criteria). A single expert ophthalmologist in dry eye evaluated the patients and assessed the tear film break-up time. Schirmer-I test, tear meniscus height, the Van Bijsterveld staining score and the SIcCA Ocular Staining Score (OSS). We classified lacrimal dysfunction severity in two categories (1=mild, mild/moderate or moderate, and 2= moderate/severe and severe).

We scored the ESSPPIR, and ocular dryness VAS as well as the Ocular Surface Disease Index (OSDI), a 12-item scale for the assessment of symptoms related to dry eye disease and their effect on vision. Tear samples were collected using sterile tear flow strips, that were immediately frozen at -86°C until assayed. Once defrosted, the tears were extracted from the strips using a buffer containing 0.5 M NaCl and 0.5% Tween-20. We tested IFN-γ, IL-10, IL-12, IL-17A, IL-19, IL-2, IL-21, IL-23, IL-5, IL-6, IL-8, TNF-α, BAFF, CXCL10 and CCL2 by Luminometry. We also included 21 healthy controls without dry eye, to test chemokines/cytokines that after our initial screening were meaningful.

Results: Most patients were females (90.4%), mean age 59.3±13 years and median disease duration 7.9 years (0.5-27). All of them had ocular and oral symptoms. The median tear film break-up time was 6 seconds (2-9), median Schirmer-I test 6 mm (1-25), median Van Bijsterveld staining score 10 points (2-9), median OSS 7 points (2-11), median ESSPPIR score 6.7 points (2.9-9.2) and median ocular dryness VAS score 9 points (1-10).

We did not detect most of the evaluated chemokines/cytokines with the exception of IL-8, CXCL10, and CCL2. The former was similar in both, patients and controls. PSS patients had lower levels of CXCL10 (472.8±102.1 pg/ml vs 625.7±121.4 pg/ml, p=0.01) and CCL2 (3.03±0.53 pg/ml vs 9 pg/ml, p=0.02) than controls. Indeed, patients with worst lacrimal dysfunction severity had the lowest levels of CXCL10 (239.3±12 pg/ml vs 646.2±15 pg/ml, p=0.02). We found correlations among CXCL10 and CCL2 (r=0.30, p=0.02) and lacrimal meniscus height (r=0.55, p=0.005), as well as with CCL2 and lacrimal meniscus height (r=0.57, p=0.01). None of the other variables were correlated.

Conclusion: We identified CXCL10 and CCL2 as the main chemokines in tears of patients with pSS. CXCL10 seems to participate in the normal eye homeostasis.

PLASMACYTOID DCS FROM PATIENTS WITH SJÖGREN’S SYNDROME ARE TRANSCRIPTIONALLY PRIMED FOR ENHANCED PRO-INFLAMMATORY CYTOKINE PRODUCTION

Maarten Hillen1, Aridaman Pandit1, Sofie Blokland1, Auke Kruize2, Joel van Roon1, Timothy R. Radstake2.

1University Medical Centre Utrecht, Laboratory of Translational Immunology/Rheumatology and Clinical Immunology, Utrecht, Netherlands; 2University Medical Centre Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands

Background: Type-I IFN activity is associated with pathogenesis and increased disease activity in primary Sjögren’s syndrome (pSS). In addition, deficiency for the type-I IFN receptor in mice prevents experimental-Sjögren’s syndrome. Plasmacytoid dendritic cells (pDC) are the premier type-I IFN producing immune cells and aberrances in their functional properties may underlie pSS immunopathology. Assessing the molecular basis of this may provide a better understanding of pSS pathogenesis and new opportunities for therapeutic intervention.

Objectives: To delineate the dysregulation of pSS pDCs using RNA-sequencing and compare their transcriptional profile to pDCs obtained from patients with non-Sjögren’s sicca (nSS) and healthy controls (HC).

Methods: All pSS patients met the classification criteria. nSS patients presented with dryness complaints without a known cause, did not have any genetically relevant autoimmune disease including pSS as evaluated by an experienced rheumatologist, and did not fulfill the classification criteria. pSS (n=25), nSS (n=20), and HC (n=17) donors were included in two independent cohorts (n=31 each). Circulating BDCA-4 expressing pDCs were isolated and RNA-sequencing was performed, after which data-driven networks and modular analysis were used to identify signatures of consistently differentially-expressed genes. pSS and HC pDCs were cultured in the presence of endosomal TLR ligands, after which gene expression and secreted cytokine levels were measured.

Results: We identified signatures of consistently co-expressed and differentially expressed genes that indicated transcriptional activation in patient pDCs, which was remarkably reproducible in two independent cohorts. These included a type-I IFN-associated signature, a ribosomal protein signature, and a transcriptional machinery signature. Corroborating the transcriptomic profile, stimulated pSS pDCs produced higher levels of type-I interferon upon in vitro stimulation. nSS patients formed an intermediate group in which some patients were molecularly similar to pSS patients. Finally, we developed a discriminative classifier on the basis of the identified transcriptional profiles that discriminated pSS patients from HC with 100% sensitivity and 80% specificity, and identified a group of pSS-like patients within the nSS group.

Conclusion: Circulating pSS pDCs exhibit a transcriptional signature similar to activated pDCs and are primed for enhanced production of pro-inflammatory cytokines, including type-I IFN. Our data provide in-depth characterization of the aberrant regulation of pSS pDCs and substantiate their perceived role in the immunopathology of pSS and other type-I interferon-associated autoimmune diseases.

THU0223

CHRONIC ADRENERGIC STIMULATION OF MINOR SALIVARY GLANDS OF PATIENTS WITH PRIMARY SJÖGREN’S DRIVES ER STRESS AND ACTIVATION OF THE UNFOLDED PROTEIN RESPONSE

Kalliopi Moustakas1, Stereios Katsiogianis1, Roxane Tenta1, Sofia Havaki1, Pari Koutsoudaki1, Haralampos M. Moutsopoulos2, Fotini Skopoul1, 1Harokopio University, Nutrition and Clinical Dietetics, Kifissia, Greece, 2National and Kapodistrian University of Athens, Histology and Embryology, Athens, Greece, The Academy of Athens, Athens, Greece

Background: Sjögren’s syndrome (SS) is a common autoimmune disease in which the main targets of immune injury are specific secretory epithelia, such as salivary and lacrimal glands. Stress appears to play a significant role in the initiation and exacerbation of SS.

Objectives: The aim of the present study was to investigate whether chronic stress plays a role in triggering endoplasmic reticulum (ER) stress in salivary gland epithelial cells from SS patients.

Methods: Minor salivary gland biopsy specimens were obtained from six SS patients and six control patients with sicca symptoms not fulfilling AECG criteria [1]. The expression and cellular localization of β1-, β2- and α1-adrenoceptors and the levels of cAMP were measured by immunofluorescence. The morphology of the ER was evaluated in situ by Transmission Electron Microscopy (TEM). Primary salivary gland epithelial cell lines (SGEC) derived from minor salivary gland biopsies, were established by the explant out-growth technique [2] and were treated with epinephrine and norepinephrine. The protein levels of the ER stress markers GRP78/Bip and C/EBP homologous protein (CHOP) were determined by immunoblot analysis.

Results: In situ immunofluorescence staining revealed increased expression of β1-, β2- and α1-adrenoceptors as well as cAMP levels in tissues derived from SS patients compared to controls. TEM evaluation of salivary tissues from SS subjects revealed extensive dilation of the ER lumen compared to controls. Treatment of SGEC with epinephrine and norepinephrine did not influence cell survival (cell viability assay). To mimic chronic stress in vitro, epinephrine was applied for 10 days on SGEC. It was found that 20μM Epinephrine induced severe ER stress on SGEC, as attested by increased expression ofGRP78/Bip and CHOP, after 3 and 6 days of treatment. The expression of ER stress markers returned to basal levels after 10 days of treatment.

Disclosure of Interests: None declared
Conclusion: Our data revealed that adrenergic receptors are differentially expressed by salivary epithelium of SS patients compared to control tissues. This finding was further substantiated by the increased levels of cAMP, indicating a profound sympathetic stimulation of this secretory tissue. The dilated ER lumen of the salivary gland epithelial cells from SS patients confirmed the occurrence of ER stress. Moreover, the finding that catecholamines induce severe ER stress in vitro in SGEC under conditions resembling chronic stress suggests a causative relationship between sympathetic tone and ER stress. Deciphering the role of chronic stress in ER machinery will provide important insights that may lead to novel therapeutic targets for SS.

THE HEPATITIS VIRUS PRESI PROTEIN RETARDS THE ONSET OF LUPUS-LIKE GLOMERULONEPHRITIS IN NZB/W F1 MICE

Roberto Luissetto1, Anna Ghirardelloi, Gianmarco Villanoi, Anna Scannu2, Mariele Gatto3, Felipe Leite de Oliveira 3, Patrizia Pontisso2, Andrea Doria2.

Background: Infection can trigger autoimmunity but the nature of the pathogen could enhance or inhibit the onset of the disease. In this study we tested the tolerogenic effect of the surface Hepatitis B Virus capsid protein preS1 in a lupus mouse model.

Objectives: To evaluate the effect of administration of Hepatitis B virus preS1 subunit to NZB/WF1 mice

Methods: Mice (10 each group) were injected with a total volume of 200μl of 32.5 μg PreS1 in 200μl PBS (group 1), 200μl PBS (group 2), 3 times at 11th, 14th and 17th weeks of age. Urine samples were collected weekly to evaluate proteinuria by reactive strips. Blood samples were collected before every injection, at 22th and 26th weeks, and at death to evaluate levels of anti-C1q and anti-dsDNA by home-made ELISA tests. Tissues were harvested for histological analyses. Proteinuria free and survival rates were analyzed by Kaplan-Meier method using Mantel-Cox test for comparisons. Neurocognitive functions were evaluated with Staircase, Y-Maze and Forced Swim Test.

Results: Anti-dsDNA and Anti-C1q levels (ODxSD) were significantly higher in PBS than in preS1 treated mice (Figure 1). Mean proteinuria levels (mg/dl±SD) were higher in PBS than in preS1 treated mice. Proteinuria free survival rate (300 mg/dl) was lower in group 2 than group 1 (p=0.016; Figure 2). Also survival rate was significantly lower in PBS than in preS1 treated mice. Severe segmental and focal glomerulonephritis in both groups with large cellular infiltration in the glomeruli and extramedullary hematopoiesis in the spleen and liver. Notably, in salivary glands, severe acute inflammation was observed in group 1 and chronic inflammation in group 2.

Conclusion: HBV capsid protein preS1 causes a delay in the onset of lupus-like glomerulonephritis and ameliorates behavioral disorders in NZW/B1 F1 mice. This peptide seems to induce a tolerizing rather than a pathogenic effect in these autoimmune prone mice models.

THU0225

THE MOLECULAR PROFILING OF MONOCYTES FROM PATIENTS WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME IDENTIFIES SEVERAL NETWORKS RELATED TO THEIR ATHEROTHROMBOTIC STATUS.

Maria Luque-Tévar1, Pérez Sánchez Laura1, María A Aguirre1, Alejandra M. Patiño-Trives1, Núria Barbera Juto2, Ivan Arias de la Rosa1, María del Carmen Abasolo-Aguilera1, Pedro Seguí Apilguéita1, Jose M Villalba2, Eduardo Collantes Estévá3, Carlos Perez-Sánchez2, Chary Lopez-Piedra2. 1MIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; 2Departamento de Biología Celular, Fisiología e Inmunología, Universidad de Córdoba, Cordoba, Spain

Objectives: 1. To characterize the miRNAs and microRNAs transcriptomes of monocytes, key immune cells in the atherothrombotic pathology of Antiphospholipid Syndrome patients (APS). 2. To evaluate the role of antiphospholipid antibodies (aPL) in the regulation of these processes. 3. To identify and characterize circulating microRNAs secreted by activated monocytes.

Methods: Monocytes from peripheral blood of 40 APS patients and 40 healthy donors were purified by negative immunomagnetic selection. Gene expression microarray (Nanostring) were performed on purified RNA. Functional expression microarray (Agilent G4112F platform) and nCounter microRNA expression array (Nanostring) were performed on purified RNA. Functional categorization of altered genes and miRNAs was made using IPA software, and miRNA-mRNA interaction networks showing inverse correlation expression were identified. Genes and miRNAs integrating the networks were validated in the whole APS cohort by RT-PCR, as well as on a set of thrombotic non-autoimmune patients. Predicted miRNA-mRNA interactions were tested by microRNA transfection experiments. In parallel, a miRNA array in the plasma of those patients was performed, and common deregulated miRNAs between monocytes and plasma were identified. Monocytes isolated from HD were treated in vitro with purified aPLs and the altered gene/miRNA expression induced in monocytes was evaluated. Moreover, the effects of aPLs on the secretion of common deregulated microRNAs in the supernatant of cultured cells were evaluated. 390 Thursday, 13 June 2019

Results: Anti-dsDNA and Anti-C1q levels (ODxSD) were significantly higher in PBS than in preS1 treated mice (Figure 1). Mean proteinuria levels (mg/dl±SD) were higher in PBS than in preS1 treated mice. Proteinuria free survival rate (300 mg/dl) was lower in group 2 than group 1 (p=0.033). Memory deficits (p<0.01) and anxiety-like behavior was pronounced in PBS treated mice. Severe segmental and focal glomerulonephritis in both groups with large proliferation of mesangial and endothelial cells and Russell bodies were found by histological analysis. Mouse treated with preS1 had more chronic inflammation in the kidneys and extramedullary hematopoiesis in the spleen and liver. Notably, in salivary glands, severe acute inflammation was observed in group 1 and chronic inflammation in group 2.

Conclusion: HBV capsid protein preS1 causes a delay in the onset of lupus-like glomerulonephritis and ameliorates behavioral disorders in NZW/B1 F1 mice. This peptide seems to induce a tolerizing rather than a pathogenic effect in these autoimmune prone mice models.

Abstract THU0224 – Figure 2

Abstract THU0225 – Figure 1
occurrence and type of thrombotic events, obstetric complications and presence of atheroma plaques were demonstrated. Transfection studies further confirmed the relationship between specific miRNAs and their identified target genes. In vitro studies demonstrated the specific modulation of several genes/miRNAs by aPLs. Furthermore, those autoantibodies promoted the increase in several secreted miRNAs, found simultaneously altered in plasma and monocytes, and deeply involved in the development of inflammation and cardiovascular disease.

Conclusion: 1. Gene and microRNA expression profiles allowed the identification of relevant genes and pathways altered in monocytes and plasma of APS patients, associated with the pathogenesis of the disease and modulated, at least partially, by aPLs. 2. Specific microRNA-miRNA regulatory networks control the biological processes and factors related to the CV pathology in APS. 3. aPL antibodies induce the secretion by monocytes of specific microRNAs that might act as messengers in the bloodstream to propagate their deleterious effects.

THU0227

DOES THE PRESENCE OF CLASSIC AND NOVEL ANTIPHOSPHOLIPID ANTIBODIES INFLUENCE THE RISK OF THROMBOSIS DEVELOPMENT IN PATIENTS WITH UTERINE MALIGNANCIES?

Andrzej Majdan1, Magdalena Dryglewiska, Jan Kotarski, Maria Majdan2, Medical University of Lublin, Dept of Gynaecological Oncology and Gynecology, Lublin, Poland; 2Medical University of Lublin, Dept of Rheumatology and Connective Tissue Diseases, Lublin, Poland; 3Medical University of Lublin, Department of Rheumatology and Connective Tissue Dis, Lublin, Poland

Background: Patients with uterine malignancies (UM) are at a higher risk of venous thromboembolism (VTE) than the general population. The malignancy itself, the treatment modalities including medication, surgery and also increased levels of leukocytes, platelets, and tissue factor-positi-ve microvesicles contribute to the risk of developing VTE.

Objectives: Several authors have shown that the antiphospholipid antibodies (aPLs) can be detected in peripheral blood of patients (pts) with malignancies. However, whether or not the aPLs could induce thrombosis in pts with UM is not yet known. The aim of our study was to determine whether the presence of aPLs in patients with uterine malignancies is associated with higher VTE risk than in pts with non-cancer gynecological disorders (NCGD).

Methods: The study involved 151 female pts scheduled for gynecological surgery divided into two groups: Group I with UM (70 pts) confirmed by histopathological examination after surgery; group II with non-cancer gynecological disorders (NCGD) (81pts).

The presence of aPLs was detected in patients' serum before surgery using the commercially available test aPL-immunodot assay Anti-Phospholipid 10 Dot, for the qualitative detection of IgG or IgM antibodies. The statistical data analysis was performed using Statistica v13.0.

The following aPLs were assessed in the study groups: IgM and IgG of a- cardiolipin; a- phosphatidyl acid; a- phosphatidylcholine; a- phosphatidylethanolamine; a- phosphatidylglycerol; a- phosphatidylinositol; a- phosphatidylyserine; a- annexin V; a- 9 2-GP I and a-prothrombin.

Results: The VTE occurred significantly more frequently in pts with UM, compared to pts with NCGD. In UM group VTE was diagnosed before surgery in 9/70 (12.9%) pts; in NCGD group VTE was diagnosed in 3/81 (3.7%) pts, p=0.0001. We have obtained positive test results for classic and novel aPLs significantly more frequently in group I pts with UM (mainly a-9 2-GP I IgM and IgG; a-prothrombin IgM, a- annexin V IgM) than in group II NCGD pts. The positive test for classic or novel aPLs was detected in 17/70 pts with UM (24,3%) and in 6/81 pts with NCGD (7.4%). The differences were statistically significant (p=0.003). All pts with thrombosis in group I (9 pts UM) were positive for at least 3 aPLs (a-9 2-GP I IgM and IgG; a-prothrombin IgM, a- annexin V IgM).

Conclusion: The classic and novel aPLs are found more frequently in pts with uterine malignancies than in pts with non-cancer gynecological disorders. The higher risk of thrombosis is connected with malignancy and the presence of classic and novel aPLs.

The better understanding of the relationships between thrombosis in cancer patients and its immunological determinants (presence of aPLs) may lead to reducing the morbidity and mortality associated with thrombosis in cancer and non-cancer gynecological disorders. We suggest that aPLs could be a novel biomarker of thrombosis risk in gynecological malignancies.

BIOLOGICAL MONITORING OF REMISSION IN SYSTEMIC LUPUS ERYTHEMATOSUS: ABNORMAL SERUM INTERFERON-ALPHA LEVELS PREDICT RELAPSE

Suzanne Mories-Martin1, Alexis Mathian1, Hervé Devilliers2, Karim Dorgam3, Delphine Sterlin4, Fleur Cohen4, Julien Haroche4, Miguel Hel5, Marc Pinet6, de Chambon6, Makoto Miyara6, Micheline Pha7, Du Boutin-Le Thi Huong6, Flore Rozenberg6, Guy Gorochov6, Zahir Amoura1. 1Assistance Publique–Hôpitaux de Paris (APHP), Groupement Hospitalier Pitié-Salpêtrière, French National Referral Center for Systemic Lupus Erythematosus, Antiphospholipid Antibody Syndrome and Other Autoimmune Disorders, Service de Médecine Intéme 2, Institut E3M, Paris, France; 2Centre Hospitalier Universitaire de Dijon, Hôpital François-Mitterrand, Service de Médecine Intéme 2 et Centre d’Investigation Clinique, Inserm CIC 1432, Dijon, France; 3Sorbonne Université, Inserm UMR1135, Centre d’Immunologie et des Maladies Infectieuses (CIMI), Paris, France; 4Hôpital Cochin, Service de Virologie, Paris, France

Background: Remission and relapses prevention are the main objectives of the treatment of Systemic Lupus Erythematosus (SLE). Interferon alpha (IFNα) is a key cytokine in SLE, but its usefulness for the definition of remission and for the prediction of flare has not been validated in clinical practice.

Objectives: To study the association between serum IFNα level, remission and risk of relapse.

Methods: 502 SLE patients were assessed for serum IFNα level using a biological functional assay(1). Remission was defined by the absence of clinical manifestation of lupus activity (clinical SELENA-SLEDAI = 0) and a prednisone intake ≤ 5 mg/day(2). Patients in remission were subsequently followed for one year. The SELENA-SLEDAI Flare Index was used to identify SLE flare. Uni- and multivariable analyses were performed to define disease parameters associated with serum IFNα positivity in patients in remission at baseline. Survival curve analysis, log-rank tests and Hazard Ratios (HR) were calculated to evaluate the risk of flare depending on IFNα, dsDNA Abs and C3 levels at baseline.

Disclosure of Interests: None declared.
Results: 345 samples were obtained from patients in remission. 28.6% of the patients in clinical remission on treatment (requiring clinical SELENA-SLEDAI = 0, no positive anti-dsDNA antibodies nor C3 decrease and prednisone intake 1 – 5 mg/day) had an abnormal serum IFNα level, compared to 6.5% of the patients in complete remission on treatment (requiring clinical SELENA-SLEDAI = 0, no anti-dsDNA antibodies and/or C3 decrease and prednisone intake 1 – 5 mg/day). In patients in remission, high serum IFNα levels at baseline were associated in multivariable analysis with the positivity of anti-dsDNA Abs (HR 3.4 [95%CI 1.6-7.2]), p<0.0001) and anti-RNP Abs (HR 3.2 [95%CI 1.5-6.8], p<0.0002). In patients in remission, high serum IFNα level at baseline was a significant and independent risk factor of lupus flare (HR=4.8 [95%CI 2.3-9.7], p<0.0001). Low C3 was also associated with the risk of relapse with a HR=3.2 [95%CI 1.4-7.0], p=0.005, but positive anti-dsDNA Abs was not (HR=1.8 [95%CI 0.9-3.6], p=0.1).

Conclusion: A large number of SLE patients in remission display abnormal levels of serum IFNα. Abnormal levels of serum IFNα in patients in remission were significantly associated with positive anti-dsDNA and anti-RNP Abs and were an independent predictive biomarker of lupus flare in the following year. Adding serum IFNα to the routine laboratory assessments perform in patient in remission could help clinicians to identify a subgroup of SLE patient clinically in remission but serologically active and at higher risk of relapse.

EXPRESSON OF APOBEC FAMILY MEMBERS AS AMPLIREGULIN ATTENUATES LUPUS NEPHRITIS VIA SUPPRESSION OF PRO-INFLAMMATORY T-CELL FUNCTIONS IN AN ANIMAL MODEL OF SLE

Simon Melder1, Matthias Warkotten1, Julia Hagenstein1, Georg Hermstad1, Osa Tieg3, Oliver Steiermetz1,2, University Medical Center Hamburg-Eppendorf, III Department of Medicine, Hamburg, Germany, 2University Medical Center Hamburg-Eppendorf, Experimental Immunology and Hepatology, Hamburg, Germany

Background: Amhregulin (AREG) is a member of the epidermal growth factor (EGF) family and plays a role in development, tissue homeostasis and tumorigenesis. Recently, however, AREG has also emerged as novel player in immunity. Interestingly, AREG expression was shown to be one of the most highly upregulated transcripts in peripheral blood leukocytes of patients with systemic lupus erythematosus (SLE) [1]. The functional role of AREG in SLE, and inflammation in general, remains unclear to date and both, pro- and anti-inflammatory functions have been postulated [2, 3].

Objectives: Our aim was to investigate the role of AREG in the mouse model of pristane induced lupus (PIL) with particular focus on lupus nephritis (LN). We further wanted to identify target cells and mechanisms by which AREG exerts its immunomodulatory effects.

Methods: PIL was induced in AREG knock-out (KO) mice and wild type controls. Animals were sacrificed at pre-specified time points. Renal histology, immune complex deposition, leukocyte influx and mRNA expression levels were analyzed. Furthermore, broad in vivo and in vitro analyses of renal pro- and anti-inflammatory cytokine productions were carried out.

Results: Renal AREG mRNA expression significantly increased during development of LN, indicating functional relevance. Indeed, lupus nephritis was significantly aggravated in AREG-KO mice both at early (9 months) and later (12 months) stages after PIL induction. In line with this, we noted increased mRNA expression of immune- and renal-cytokines of pro-inflammatory leukocytes (CD3+ T-cells, macrophages and neutrophils). In addition, we found the CD4+ T-cells of AREG-KO mice to have a more pro-inflammatory phenotype with significantly increased production of pro-inflammatory cytokines (IFNγ and IL-17A) both in ex-vivo culture, as well as FACS-analyses of nephritic kidneys. Mechanistically, we found that AREG treatment of spleen cell cultures potently suppressed cytokine production. More detailed mRNA expression by further in vitro studies indicated, that AREG can directly suppress cytokine production by effecting CD4+ T-cells as well as enhance the suppressive capacity of Foxp3+ regulatory T-cells (Treg).

Conclusion: These data show that AREG has a protective role on development of LN induced by pristane, which might be therapeutically exploited. Our results further suggest, that direct effects on CD4+ Teffector cells, as well as indirect effects via Tregs, are two mechanisms by which AREG exerts its protective role.

TNF-ALPHA PROMOTER POLYMORPHISMS (G-308A AND G-238A) ARE ASSOCIATED WITH SUSCEPTIBILITY TO SLE: A HOSPITAL-BASED CASE-CONTROL INVESTIGATION

MOHAPATRA DEBASHISH1, Rina Tripathy2, Aditya Kumar Pandya3, Manoj Kumar Parida1, Saumya Ranjan Tripathy4, Bidyut Kumar Das5. 1.S.C.B. MEDICAL COLLEGE, Cuttack, Medicine, Cuttack, India; 2.S.C.B. Medical College, Biochemistry, Cuttack, India; 3.Khaltikote University, Life Sciences, Brahmapur, India; 4.S.C.B. Medical college, Cuttack, Rheumatology, Cuttack, India; 5.S.C.B. Medical college, Cuttack, India

Background: Tumour necrosis factor-α (TNF-α) is a proinflammatory cytokine associated with various autoimmune disorders.1 High levels of TNF-α has been reported in systemic lupus erythematosus (SLE)2. Two functional common polymorphisms (G-238A and G-308A) at promoter region of TNF-α gene have been linked to SLE susceptibility in different populations.3,4

Objectives: To investigate association of TNF-α (G-238A and G-308A) polymorphisms with susceptibility/resistance to SLE.

Methods: A total of 102 female SLE patients and 112 age and sex matched healthy controls were enrolled in the study. Patients were examined in detail, physical findings recorded and SLEDAI 2K calculated to assess disease severity. TNF-α polymorphisms (G-238A & G-308A) were typed by polymerase chain reaction and restriction length polymorphism (PCR-RFLP), Plasma level of TNF-α was quantified by ELISA. Statistical analysis was carried using GRAPH PAD PRISM 7.01.

Results: Mean age of SLE patients and healthy controls was 27.84±8.83 and 29.56±5.48 years, respectively. At the time of enrolment, mean disease duration of patients was 2.07±1.13 years. The mean SLEDAI 2K of patients was 16.07±7.56. The prevalence of heterozygous mutant and minor allele of TNF-α (G-238A) polymorphisms were significantly higher in SLE patients compared to healthy controls (GA: P=0.04, OR=2.16; A: P=0.02, OR: 2.09). Furthermore, heterozygous (GA) and minor allele (A) of TNF-α (G-238A) polymorphism were associated with susceptibility to lupus nephritis (GA: P=0.02, OR=2.89; A: P=0.001, OR: 2.92). SLE patients displayed higher levels of plasma TNF-α compared to healthy controls. Although the prevalence of heterozygous mutant and minor allele of TNF-α (G-308A) polymorphism was higher in SLE patients, it was not statistically significant. TNF-α (G-238A and G-308A) variants were associated with higher plasma TNF-α in both SLE patients and healthy control. However, no significant association was observed on distribution of TNF-α polymorphisms (G-238A and G-308A) with severity of disease activity of SLE patients.

Conclusion: The results of the present study demonstrate that TNF-α (G-238A) variant is associated with higher plasma TNF-α level and increased susceptibility to development of SLE and lupus nephritis.

THU0232 GELSEolin a New Biomarker of Disease Activity in SLE Patients Associated With HDL-C

Sandra Pare1,2, Mercedes de Las Heras3, Pol Herrero4, Nuria Amigó5, Esperanza García6, Josepa Giróna7, Xavier Coreu7, Nuria Canela8, Antoni Castro9,10,11. 1,2Sant Joan University Hospital, Internal medicine department. Autoimmune diseases unit, Reus, Spain; 3Institut Investigacions Sanitàries Pere i Virgili, Reus, Spain; 4Universidad Rovira i Virgili, Unitat de Recerca de Lípidos i Arteriosclerosis (URLA), Reus, Spain; 5Universitat Rovira i Virgili, Centre for Omic Science, Joint Unit, Reus, Spain; 6Universitat Rovira i Virgili, Department of Electronic Engineering, Reus, Spain

Background: Recent proteomics techniques have demonstrated that high-density lipoprotein (HDL) associated proteins are involved in functions related to systemic inflammatory and immune responses in several pathological conditions, including autoimmune diseases. HDL undergoes structural and functional modifications in systemic lupus erythematosus (SLE) patients.

Objectives: To identify potential biomarkers of disease activity analyzing the proteome of HDL particles from SLE patients in clinical remission and when they develop a flare compared to a healthy control group.

Methods: Quantitative proteomic analyses of purified HDL were performed using Tandem Mass Tag (TMT) isobaric tag-labeling and nanoLC-Orbitrap (nLC-MS/MS) from 9 SLE patients in clinical remission when they developed a flare and from 9 healthy controls (9-9-9). We verified the identified proteins by Western blot and ELISA in a cohort of 104 SLE women patients, 46 healthy women and 14 SLE patients when developed a flare.

Results: A total of 83 proteins associated with HDL were identified. We found 17 proteins with a significant fold-change (>1.1) compared with their levels in control patients. In lupus patients experiencing a flare compared with those in remission, we identified 4 proteins with a significant fold-change (C4, Indian Hedgehog protein, S100A8 and gelsolin). Plasma gelsolin (pGSN) levels were decreased in the 104 SLE patients (176.02 (74.9) mcg/l) compared with the control group (217.13(86.7)mcg/l); p <0.005 and when they developed a clinical flare (104.84(41.7)mcg/l); p = 0002). pGSN levels were associated with HDL-c levels (r =−0.316, p<0.001). Antimalarial treated patients showed significant higher levels of pGSN (214.56(88.94)mcg/l respect 170.39(66.38) mcg/l); p = 0.017.

Conclusion: The proteome cargo from HDL differentiates SLE patients from healthy controls. HDL from SLE patients carries proteins that are involved in the activation of the immune system. Decreased pGSN are associated with clinical disease activity in SLE patients. Antimalarial treatment and HDL-c are associated with higher levels of pGSN in SLE patients. pGSN is a potential biomarker of disease activity in SLE patients.

THU0233 DIFFERENTIAL METHYLATION OF IL8 AND TISSUE FACTOR PROMOTER IN ANTIIPHOSPHOLIPID SYNDROME

Markos Patsouras1,2, Karagianni Panagiota3, Paraskevi Kogionou4, Panayiotis Vlachoyiannopoulos5, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Background: Antiphospholipid syndrome (APS) is an autoimmune thrombophilia characterized by recurrent thromboembolism and/or pregnancy morbidity in the presence of Antiphospholipid antibodies mainly anti-β2glycoprotein 1 (anti-β2GPI), which lead to monocyte and endothelial cell activation and subsequent tissue factor and proinflammatory cytokine expression such us IL-6 and IL-8 (1). Epigenetics describes changes in gene expression without alterations in the genomic sequence. Methylation of DNA at CpG islands by adding a methyl group to the nucleotide cytosine, is one of main epigenetic mechanisms. Internal medicine department.

Objectives: To explore the possible differential methylation of IL8 and Tissue Factor (F3)gene promoters, which are critical for the pathophysiology of APS.

Methods: Whole blood and serum were isolated from 27 APS patients and 25 healthy donors (nDs). Human umbilical vein endothelial cells (HUVECs) and peripheral blood monocytes were isolated from 3 HDs. Anti-β2GPI IgG was isolated and pooled from 8 APS patients.HUVECs and monocytes were stimulated with a mixture of IgG, β2GPI and CXCL4. Then mRNA was isolated and qPCR was performed for the assessment of IL8 and tissue factor (F3)gene expression. Whole blood DNA from APS patients and HDS and DNA from the in vitro experiments was isolated and bisulfite treated. The methylation of Cpg in the
The association between demyelinating diseases and autoimmune rheumatic disease (SARD) was investigated. The objective was to characterize the clinical profile of patients with SARD and to describe the frequency of antiphospholipid and antinuclear antibodies.

**Background:**
- Multiple sclerosis (MS) and neuromyelitis optica (NMO) are demyelinating processes of the central nervous system (CNS) that can mimic multiple sclerosis (MS).
- The presence of inflammatory arthralgias, Raynaud phenomenon, and neurological symptoms is common in patients with SARD.

**Methods:**
1. The study was a retrospective observational study of patients referred to the Demyelinating Diseases Unit of the Rheumatology Department of the Universitary of Canarias, Neurology, San Cristobal de la Laguna, Spain.
2. Patients were assessed jointly by the Demyelinating Diseases Unit and the rheumatology service.
3. The study included patients with demyelinating processes of the CNS.

**Results:**
- A total of 561 patients were evaluated.
- Of these, 32 patients had MS, 4 had NMO, and 32 had other SARD.
- The most common neurological symptoms were hyperintense injuries in T2, in brain and/or the spinal cord.
- These patients were characterized by a high frequency of reumatic antibody positivity in MS.

**Conclusion:**
- The study highlights the importance of considering SARD in the differential diagnosis of MS.
- Further research is needed to understand the pathophysiological mechanisms underlying the association between demyelinating diseases and SARD.

**Disclosure of Interests:**
- None declared.

**ASSOCIATION BETWEEN DEMYELINATING DISEASE AND AUTOIMMUNE RHEUMATIC DISEASE: A MULTIDISCIPLINARY EVALUATION**

Sonia Peña Montelongo, González Plata Montserrat, Alicia García Dorta, Hernández Díaz Marta, Sagramo Bustabad, Rodríguez Lozano Beatriz, Hospital Universitario de Canarias, San Cristobal de la Laguna, Spain; Hospital Universitario de Canarias, Neurology, San Cristobal de la Laguna, Spain

**Background:**
- The association between demyelinating diseases and autoimmune rheumatic disease (SARD) is not well understood.
- The aim of this study was to evaluate the association between demyelinating diseases and SARD.

**Methods:**
- A retrospective observational study of patients with demyelinating diseases and SARD was conducted.
- Patients were classified into three groups: MS, NMO, and other SARD.

**Results:**
- A total of 561 patients were evaluated.
- The most common neurological symptoms were hyperintense injuries in T2, in brain and/or the spinal cord.
- These patients were characterized by a high frequency of reumatic antibody positivity in MS.

**Conclusion:**
- The study highlights the importance of considering SARD in the differential diagnosis of MS.
- Further research is needed to understand the pathophysiological mechanisms underlying the association between demyelinating diseases and SARD.

**Disclosure of Interests:**
- None declared.

Results: The density of Ikaros and Aiolos positive cells was significantly higher in the SGs of ELS positive SS patients compared to NSCs. As shown in Table 1, the density of Ikaros and Aiolos positive cells in the SGs of SS patients significantly correlated with B and T cell semiquantitative scores and the number of lymphocytic foci. Ikaros positive cell density also correlated with IgG levels and disease activity measured by ESSDAI. Accordingly, SS patients with high expression of Ikaros (>10 Ikaros+ cells/mm², n=11/23) had significantly higher ESSDAI (p=0.023) and higher prevalence of ANA positivity (p=0.019). In vitro experiments confirmed that Ikaros+ cells synthesize more B and T cell mediators and that Ikaros overexpression in vitro stimulates cell growth and proliferation as marker to discriminate active LN [4]. To the best of our knowledge, this is the first screening of miRNAs in urinary exosomes from LN patients to study their role as predictors of response to therapy. 

Methods: Urinary exosomes were isolated and characterized from lupus patients (N=14) during flare and post-treatment time. Patients were divided between responder and non-responder and urinary exosomal miRNA screening analysis was performed according their clinical response. To validate initial results, a new cohort of LN patients were used (N=44).

Results: In the screening, 25 miRNAs were significantly different in comparative group analysis. High levels of miR-31, miR-107 and miR-135b-5p were confirmed to be related with responder patients. We found that miR-135b has the best profile to distinguish the two groups (AUC=0.783 (95% confidence interval [CI], 0.640 - 0.926), cut-off <0.0884 with 77.8% sensitivity and 71.4% specificity). Renal tissue samples from responder patients showed miR-31, miR-107 and miR-135b-5p to be highly expressed compared with non-responders. All miRNAs were predominantly localized in the tubular cells. Stimulated tubular renal cells displayed the higher expression levels of exosome-derived miR-miRNA screening and their delivery cell target (Figure 1).

Background: We previously revealed a role for EZH2 in inducing pro-inflammatory genetic changes in lupus CD4+ T cells.

Inhibitory effect of EZH2 on lupus-like disease in MRL/lpr mice

Dallas Rohraff1, Ye He1,2, Evan Farkash3, Mark Schonfeld1, Eliza Tsou1, Amr Sawalha1,2, University of Michigan, Ann Arbor, United States of America; 2The University of Michigan, School of Medicine, Department of Pathology, Ann Arbor, United States of America

Objectives: To determine if inhibiting EZH2 ameliorates lupus-like disease in MRL/lpr mice.

Methods: EZH2 expression levels in multiple cell types in lupus patients were evaluated using flow cytometry and mRNA expression data. Inhibition of EZH2 in MRL/lpr mice was achieved by DZNep intraperitoneal administration using a preventative and a therapeutic treatment model. Effects of DZNep on animal survival, anti-dsDNA antibody production, proteinuria, renal histopathology, cytokine production, and T and B cell numbers and percentages were assessed.

Results: EZH2 expression levels were increased in whole blood, neutrophils, monocytes, B cells, and CD4+ T cells in lupus patients. In MRL/lpr mice, inhibiting EZH2 with DZNep treatment before or after disease onset improved survival and significantly reduced anti-dsDNA antibody production. DZNep-treated mice displayed a significant reduction in renal involvement, splenomegaly, and lymphadenopathy. Lymphoproliferation and numbers of double-negative T cells were significantly reduced in DZNep treated mice. Concentrations of circulating cytokines and chemokines, including TNF, IFN-γ, CCL2, RANTES/CCL5, IL-10, KC/CXCL1, IL-12, IL-1p40 and MIP-1β/CCL4 were decreased in DZNep treated mice.

Conclusion: Inhibition of EZH2 ameliorates lupus-like disease in MRL/lpr mice, suggesting that EZH2 inhibitors may be repurposed as a novel therapeutic option in lupus patients.

Disclosure of Interests: None declared

URINARY EXOSOMAL MIR-31, MIR-107 AND MIR-135B-5P FROM TUBULAR RENAL CELLS AS RESPONDER BIOMARKER IN LUPUS NEPHRITIS

Cristina Solé-Marcé1, Eloi Garcia-Vives1, Irene Agraz2, Josep Ordí-Ros3, Josefina Cortés-Hernández1, Vall Hebron Institute Research, Internal Medicine – Lupus Unit, Barcelona, Spain; 2Hospital Vall Hebron, Department of Renal Pathology, Barcelona, Spain

Background: Lupus nephritis (LN), occurring in 40–75% of patients with systemic lupus erythematosus (SLE), continues to be one of the most severe forms of lupus with an unpredictable course. Conventional clinical parameters are not sensitive or specific enough for detecting ongoing disease activity, early relapse, disease progression or response to therapy [1]. Exosomal-derived urinary miRNAs can accurately reflect renal dysfunction and structural damage making them good biomarkers for diagnosis and prognosis [2]. In LN, urinary exosomal miR-29c expression levels have been identified as predictor of early fibrosis [3] and miR-146a upregulation as marker to discriminate active LN [4]. To the best of our knowledge, this is the first screening of miRNAs in urinary exosomes from LN patients to study their role as predictors of response to therapy.

Methods: Urinary exosomes were isolated and characterized from lupus patients (N=14) during flare and post-treatment time. Patients were divided between responder and non-responder and urinary exosomal miRNA screening analysis was performed according their clinical response. To validate initial results, a new cohort of LN patients were used (N=44).

Results: In the screening, 25 miRNAs were significantly different in comparative group analysis. High levels of miR-31, miR-107 and miR-135b-5p were confirmed to be related with responder patients. We found that miR-135b has the best profile to distinguish the two groups (AUC=0.783 (95% confidence interval [CI], 0.640 - 0.926), cut-off <0.0884 with 77.8% sensitivity and 71.4% specificity). Renal tissue samples from responder patients showed miR-31, miR-107 and miR-135b-5p to be highly expressed compared with non-responders. All miRNAs were predominantly localized in the tubular cells. Stimulated tubular renal cells displayed the higher expression levels of exosome-derived miR-31, miR-107 and miR-135b-5p when compared with endothelial or mesangial cells (p<0.0001). Nevertheless, urinary exosomes from non-responder patient’s internalization was only 50% by mesangial cells compared to 90% from responders.

Conclusion: These results indicated that levels of urinary exosomal miRNAs produced by tubular cells might have a renal recovery role in mesangial cells and be used as new biomarkers of lupus nephritis outcome.

MUSCLE ARCHITECTURE IN PATIENTS WITH SJÖGREN’S SYNDROME

Duygu Tecer1, Dilek Büyüksüreçoğlu2, Jale Meray2, Feride Nur Göğüş3, 1Mehmet Akif İnan Education and Research Hospital, Rheumatology, Sanurfa, Turkey; 2Gazi University Faculty of Medicine, Physical Medicine and Rehabilitation, Ankara, Turkey; 3Gazi University Faculty of Medicine, Physical Medicine and Rehabilitation/Rheumatology, Ankara, Turkey

Background: Although fatigue and skeletal muscle involvement is not rare in Sjögren’s Syndrome (SS) patients, there is not much data about the macroscopic structure of the skeletal muscle.

Objectives: 1) To investigate if ultrasonographic muscle architecture and muscle strength differed in SS patients 2) To investigate if these changes correlated with disease activity, fatigue, anxiety and depression.

Methods: Assuming 2.4 mm mean difference and 2.5 mm SD of thickness at vastus lateralis muscle with 80% power and 5% significance 19 SS patients and 19 healthy controls (HCs) were recruited (1). Disease activity was measured by EULAR Sjögren Disease Activity Index (ESSDAI), anxiety and depression were assessed with the Hospital Anxiety and Depression Scale (HADS), fatigue with Multidimensional Assessment Questionnaire (HAQ). A single rheumatologist, blind to the participants’ group assignment, performed the ultrasonographic evaluation using a multi-frequency linear probe. Thickness of bilateral quadriceps femoris, gastrocnemius and soleus muscles, pennation angle and fascicle length were measured. Isokinetic knee and ankle muscle strength tests were performed at 60-180°/s and 30-120°/s respectively by a calibrated isokinetic testing machine.

Results: Patients with SS scored higher than HCs for depression, anxiety, quality of life and fatigue (p<0.0001). At dominant leg, pennation angle of vastus medialis muscle was significantly lower in SS group than HCs (10.26±3.63 SD deg vs 14.15±3.63 SD deg, p=0.049). At non-dominant leg, pennation angle of gastrocnemius medialis muscle was significantly higher in SS group than HCs (22.89±4.82 SD vs 19.15±4.68 SD deg, p=0.006). In addition, fascicle length of gastrocnemius medialis muscle was significantly shorter in SS group than HCs (42.26±10.33 SD mm vs 49.25±8.27 SD mm, p=0.036). Peak torque/body weight of knee and ankle muscles in SS group did not differ from that of HCs. However, in SS group, at dominant leg, ESSDAI was negatively correlated with knee extension strength at velocities 60°/s (r=-0.492, p=0.033), ankle plantar flexion strength at 30°/s velocity (r=-0.730, p=0.001). Similarly at non-dominant leg, ESSDAI was negatively correlated with knee extension strength at velocities 60°/s and 180°/s (r=-0.572, p=0.010, r=-0.617, p=0.05 respectively), knee flexion strength at 60°/s velocity (r=-0.492, p=0.033), ankle plantar flexion strength at 30°/s (r=0.508, p=0.026 respectively) and ankle plantar flexion strength at 30°/s velocity (r=0.506, p=0.027). Fatigue was negatively correlated with ankle plantar flexion strength at 120°/s velocity (r=-0.484, p=0.036) at dominant leg, knee extension strength at 180°/s (r=-0.521, p=0.022) knee flexion at 60°/s velocity (r=0.585, p=0.011) at non-dominant leg. There was no correlation between anxiety, depression and muscle strength.

Conclusion: Patients with SS have some minor structural changes on ultrasonographic evaluation. Although there was no difference in isokinetic muscle strength measurements between groups, knee strength and endurance had a moderate negative correlation with disease activity in SS patients.

THU0238 CLINICAL Efficacy of Leflunomide/Hydroxychloroquine Combination Therapy in Primary Sjögren’s Syndrome IS Predicted by Serum Proteome Biomarkers – Results from Repurpss-I

Joel van Roon, Eefje van der Heijden, Solie Bliekland, Ana Lopes, Frederique Moret, Paco Welsing, Nard Janssen, Toine Rosenberg, Aridaman Pandit, Wei Yang Tao, Maarten Hillen, Aike A. Kruize, Timothy R. Radstake. University Medical Center Utrecht, Utrecht, Netherlands

Background: Despite major efforts to treat primary Sjögren’s syndrome (pSS) advances in pSS treatment remain disappointing. Treatment strategies effective in other immunological conditions lack an effect in pSS. Hence, there is a huge unmet need in finding an effective treatment, let alone to have the ability to predict who responds to what treatment.

Methods: Clinically active (European SS disease activity index ESSDAI score ≥5) pSS patients (n=29) were randomized to receive LEF 20 mg daily and HCQ 200 mg twice daily or placebo/placebo (2 verum:1 placebo) for 24 weeks. Clinical and safety outcomes were assessed at baseline, 8, 16 and 24 weeks. Clinical response was defined by a decrease in ESSDAI of ≥3 points at 24 weeks. In addition, at baseline 386 proteins involved in inflammation, immune response, metabolism and cardio-metabolism were measured in serum of all patients using the Olink platform (for panels, see Olink website).

Results: Overall, LEF/HCQ was safe and well-tolerated and significantly reduced ESSDAI scores, the primary endpoint (p<0.0001). Furthermore, LEF/HCQ treatment was associated with improvement of oral dryness, ESSPRI, Physician’s and Patient’s Global Assessment, serum IgG, IgM rheumatoid factor, C3 and C4 levels (all at least p<0.05), which was not observed in the placebo group. Clinical response was observed in 11 out of 21 patients receiving treatment, providing a unique opportunity to examine biomarkers to predict response. However, except for C3 levels, clinical markers at baseline were not significantly different between responders and non-responders, underscoring the challenges in prediction of therapy response. Olink proteomic analysis revealed 43 significantly differentially expressed proteins between responders and non-responders. Unsupervised hierarchical clustering using the most differentially-expressed analytes (p-value based) demonstrated distinct serum proteomes in responders vs. non-responders. Using multidimensional scaling, based on all measured analytes, a high degree of dissimilarity of responders and non-responders was observed. Next a random forest machine-learning model was established to identify the proteins that best predict response to treatment using the baseline serum proteome. The results were validated using 500 leave-7-out iterations. The highest mean accuracy (84%) was achieved using a set of 16 differentially expressed analytes, indicating a 96% chance to robustly predict responders and a 74% chance to correctly identify non-responders.

Conclusion: We demonstrated a clinical response in pSS patients treated with the combination of leflunomide and hydroxychloroquine. Strikingly, a set of 16 circulating proteins predicts response to therapy with clinically meaningful accuracy. Given the exciting but preliminary nature of these observations a follow-up RCT aimed at replication of these results is warranted.

IDENTIFICATION OF BIOMARKERS AND IMMUNE PATHWAYS FOR PERSONALIZED DRUG TARGETING IN PATIENTS WITH NEWLY DIAGNOSED PRIMARY SJÖGREN’S SYNDROME

Gwenny M. Verstappen1, Lu Gao2, Sarah A. Pringle1, Janneke H. Terpstra2, Silvia C. Lefers3, Jolien F. van Nijmegen4, Arjan Visink3, Vishal Patel4, Aiqing He5, Amy Truong2, Sarah Hu2, Ashok Dongre6, Arathi Krishnakumar2, Stefan Kroiv6, Julie Carman8, Hendrika Bootsm9, Frans G.M. Kroese1, 1University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Bristol-Myers Squibb, New Jersey, United States of America; 3University of Groningen, University Medical Center Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands

Background: Patients with primary Sjögren’s syndrome (pSS) present with heterogeneous clinical symptoms and immune dysregulation. How immune dysregulation in SS arises is poorly understood, which hampers development of effective therapies. Identification of key immune pathways contributing to pSS pathogenesis is essential for successful drug development.

Objectives: To identify early systemic biomarkers and dysregulated immune pathways in newly diagnosed pSS patients by multidimensional immuno-profiling.

Methods: We included 40 newly diagnosed pSS patients (39 female; mean age 51±14 years) and 20 age- and sex-matched non-SS sicca patients (19 female; mean age 50±13 years). All pSS patients fulfilled ACR-EULAR criteria. Serum and peripheral blood mononuclear cells (PBMC) were collected and cryopreserved. PBMCs were thawed for immunophenotyping by flow cytometry and RNA isolation. RNA sequencing was performed using TruSeq Stranded Total RNA Library Prep Gold (Illumina), following manufacturer’s recommendations, and RNAseq libraries were sequenced on a HiSeq2500 system. Additionally, serum proteomics and immunosequencing were performed for pro-inflammatory cytokines in serum were performed.

Results: Interferon (IFN) type I signaling pathways were at the top of enriched pathways in PBMCs from pSS patients, compared with non-SS sicca controls (adjusted p<0.05). Additionally, the gene signature of IgD+CD27-CD16+CD5- (double negative 2; DN2) B cells was significantly upregulated in pSS patients (adj. p<0.05). Immunophenotyping analysis showed increased frequencies of CD4+ pDCs (p=0.004), intermediate monocytes (p<0.008), ICOs+ memory CD4+ T cells (p<0.001), cTfh cells (p<0.001), and cTfr cells (p<0.001) in pSS patients. Memory B cells were significantly decreased in pSS patients (p<0.001). Serum proteomics showed that the top proteins up-regulated in pSS patients were immunoglobulin subunits. The top of up-regulated pathways involved IFN signaling (adj. p<0.05), similar to RNAseq data. Consistently, immunosequencing showed increased levels of CXCL10 in serum and MxA in whole blood of pSS patients, compared with non-SS sicca controls (p<0.009 and p=0.001, respectively). Blood MxA protein levels correlated significantly with the IFN signature score in PBMCs (R=0.8; p<0.0001). The top cell-related biomarkers described above, the frequency of memory B cells, and MxA levels correlated significantly with EULAR Sjögren’s disease activity index (ESSDAI) scores, whereas the frequency of CD4+ pDCs, intermediate monocytes, and serum CXCL10 levels did not correlate with these scores. When a correction for multiple testing was applied, only cTfr cells correlated significantly with ESSDAI scores (R=0.6; p=0.002).

Conclusion: Newly diagnosed patients with pSS show co-activation of the IFN type I and B cell activation pathways, compared to non-SS sicca controls. At the same time, CD4+ T cell subsets critical for B cell function are activated, which can enhance B cell activation and plasma cell dysregulation. Personalized treatment based on the activity of each pathway in individual patients could potentially increase the efficacy of such treatments.

THU0240 GENE EXPRESSION SIGNATURES ARE RELATED TO SPECIFIC SUBSETS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Javad Wahadat1,2, Noortje Groot2, C.G. van Helden-Meeuwen2,3, Iris LA Bodewes2, Eriska Huijsjer4, Sylvia Kamphuis5, Marjan Vensers6, 1Erasmus University Medical Center, Department of Immunology, Rotterdam, Netherlands; 2Sophia Children’s Hospital, Erasmus University Medical Center, Department of Pediatric Rheumatology, Rotterdam, Netherlands; 3Erasmus University Medical Center, Department of Pediatric Rheumatology, Rotterdam, Netherlands

Background: Systemic lupus erythematosus (SLE) is a heterogeneous, lifelong autoimmune disease, with a more severe phenotype in children compared to adult-onset SLE [1]. To date, approved drugs are by far not effective enough and have significant side effects, especially due to the use of prednisone. Although profiling of the blood transcriptome revealed a prevalent IFN type I signature in SLE, blocking the IFN pathway only showed efficacy in a subset of adult-onset SLE patients. Recent studies revealed that other gene signatures like IFN type I-II (M5.12), B cell, plasmablast and neutrophil signatures are important in SLE as well and some could be linked to specific clinical phenotypes [2, 3]. Assessment of these novel gene signatures in SLE may help to distinguish specific disease phenotypes and guide treatment choices in the future.

Objectives: To determine and compare the expression of the IFN-, B cell-, plasmablast- and neutrophil signatures in pediatric and adult SLE patients.

Methods: The IFN-I-, M5.12-, neutrophil-, B cell- and plasmablast signatures were measured using real-time quantitative PCR expression on whole blood RNA samples. To identify correlated groups of genes and reduce data complexity, the expression of a selection of genes identified by blood transcriptional profiling was tested and subsequently added to a principle component analysis to obtain a limited set of genes (2-5 per signature), that reliably represent a specific signature.

These signatures were analyzed in three separate pilot cohorts of healthy controls (n=12), pediatric- (n=22; average disease duration=0.9 years) and adult SLE patients (n=38; average disease duration=17.4 years).

Results: IFN-I signature was significantly higher in SLE patients compared to healthy controls (p=0.001), M5.12 (p=0.005) and the B cell (p=0.001) signature showed a significant difference between the pediatric and adult cohort while there was no difference between the neutrophil- and plasmablast signatures in the two patient groups. Interestingly, the B cell gene signature, correlated with age (p=0.001, r = -0.49) and disease duration (p=0.001, r = -0.42). In addition, the possible correlation between the IFN-I signature and the other signatures was investigated. While the IFN-I signature in both adults and children showed a significant positive correlation to the M5.12- (p=0.001, r = 0.97; p=0.006, r = 0.61) and plasmablast (p=0.03, r=0.37; p=0.0037, r=0.62) signature expression, only adult patients had a significant positive correlation of the IFN-I signature to the neutrophil signature (p=0.001, r=0.55).

Conclusion: In this pilot study we found significant differences in gene expression signatures between pediatric and adult SLE patients. Additionally, age and disease duration were significantly correlated to the B cell gene signature. These findings indicate differences in transcriptional profiles in specific subsets of SLE patients which could have therapeutic consequences.

LUPUS PROGRESSION IS PREVENTED BY TREATMENT WITH VERDINEXOR, AN INHIBITOR OF THE NUCLEAR EXPORT-PROTEIN EXPORTIN-1, BY LIMITING GERMINAL CENTER FORMATION AND DEVELOPMENT OF AUTOREACTIVE ANTIBODY SECRETING CELLS

Javier Rangel-Morenos, Nida Meednus, Douglas Widman2, Savanna Gornisiewicz2, Sharon Tamis3, Jennifer H. Anolik1. 1University of Rochester School of Medicine, Division of Allergy, Immunology and Rheumatology, Rochester, United States of America; 2Karyopharm Therapeutics, Grants Management, Newton, United States of America

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by simultaneous activation of the innate and adaptive arms of the immune system. Recently the nuclear export protein exportin 1 (XPO1) has emerged as an inflammatory target for the treatment of SLE and other autoimmune disorders. Selective Inhibitor of Nuclear Export (SINE) compounds are potent, orally available and well-tolerated XPO1 inhibitors. SINE compounds inhibit the nuclear export of over 220 apoptotic and anti-inflammatory effects, particularly in dampening the NF-kB pathway underlies verdinexor’s ability to control the formation of germinal centers and limit the numbers of autoreactive antibody secreting cells (ASC) in a NZB/NZW F1 murine model of SLE.

Methods: To evaluate the minimal efficacious dose of SINE compounds in a preclinical recovery model of SLE, cohorts of lupus-prone mice with established disease (elevated anti-dsDNA antibody titer and proteinuria) were dosed with SINE compound or vehicle for eight weeks, at which time treatment groups were stratified, and escalating administration schedules (both dose and frequency) of verdinexor were examined for their ability to control recurrent disease. We used flow cytometry to enumerate dsDNA antibody-secreting cells (ASC) in the spleen and bone marrow and immunofluorescence to visualize germinal centers (GC) in spleen.

Results: We found that following induction therapy, treatment with verdinexor significantly maintained disease inhibition effectively at 7.5mg/kg administered weekly. Concomitantly, we observed significantly decreased levels of GC B cells, plasma cells and plasmablast levels in the bone marrow and the spleen 4 weeks after treatment groups were stratified. The potent effect of SINE compound monotherapy on GC and auto-reactive ASC showed that a pronounced elimination of GC and auto-reactive ASC was achieved after 4 weeks of treatment in all treatment groups. We found the effect of verdinexor treatment necessary to maintain disease inhibition after induction therapy.

Conclusions: We found that following induction therapy, treatment with verdinexor significantly maintained disease inhibition effectively at 7.5mg/kg administered weekly. Concomitantly, we observed significantly decreased levels of GC B cells, plasma cells and plasmablast levels in the bone marrow and the spleen 4 weeks after treatment groups were stratified. The potent effect of SINE compound monotherapy on GC and auto-reactive ASC showed that a pronounced elimination of GC and auto-reactive ASC was achieved after 4 weeks of treatment in all treatment groups. We found the effect of verdinexor treatment necessary to maintain disease inhibition after induction therapy.

OBJECTIVE: To examine the ability of verdinexor to control the formation of germinal centers and limit the numbers of autoreactive antibody secreting cells (ASC) in a NZB/NZW F1 murine model of SLE.

MIR-326 OVEREXPRESSIN IN T CELLS BREAKS TH17/ TREG BALANCE IN MRL/LPR MICE

Yuan Xia, Xuan Fang, Nan Xiang, Xiaojian Dai, Li Jin, Li Xiaomei, Jinhui Tao, Li Xiangpei. The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Department of Rheumatology and Immunology, Hefei, China

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease involving multiple organs leading to tissue damage1. T lymphocytes have been recognized as key contributors to disease pathogenesis2. Inflammatory Th17 subsets promote inflammation, while defects in regulatory T cells (Tregs) lead to uncontrolled immune responses3. Emerging data suggest that single miR species can profoundly alter the phenotype and outcome of immune responses in SLE4.

Objectives: We describe a role for miR-326 in driving deregulation of Th17/Treg balance in lupus mouse and highlight therapeutic advances of miR-326.

Methods: 3 groups of female MRL/lpr mice were injected with lentivirus-miR-326 (LV-326) or lentivirus-miR-326 specific inhibitor (LV-sponge) to increase or inhibit miR-326 expression, respectively, and lentivirus-negative (LV-ctrl) as control, 10 mice per group. The percentage of Th17 cells and Tregs in spleen CD4+ T cells and kidney were detected by flow cytometry. The levels of serum cytokine (IL-17A, IFN-γ, TGF-β) were detected by CBA. Urinary collections (24 h) were collected and assessed for albumin using ELISA. Immunohistochemistry labeled kidney IL-17A and TGF-β expression. Differences between groups were analyzed by SPSS 22.

Results: Day 7 analysis of differentiation of Th17 cells and Tregs in spleen after injection of lentivirus showed an increased percentage of Th17 in LV-326 mice, while reduction of percentage of Tregs in these mice. Testing the serum cytokines revealed that the significantly increased levels of IL-17A and IFN-γ in LV-326 mice, and decreased in LV-sponge mice, no different has been found in TGF-β between the groups. Moreover, LV-326 mice showed higher levels of 24h urinary albumin than LV-sponge and LV-ctrl mice in day 7 after injection of lentivirus. The lentivirus-miR-326 injection promoted the infiltration of Th17 cells and simultaneously increased the expression of IL-17A in kidney, no different has been found of TGF-β.

Conclusions: Our data reveal that miR-326 overexpression increased the differentiation of Th17 cells and decreased the differentiation of Tregs, and accelerated the renal injury in MRL/lpr mice. These suggest that miR-326 may play a catalytic role in the development of lupus-like changes in lupus model mouse by breaks Th17/Treg balance.

ROLE OF METHIONINE AND ITS TRANSPORTER CD98 IN HUMAN B CELL DIFFERENTIATION AND THE RELEVANCE TO PATHOLOGICAL PROCESSES OF SLE

Mingzeng Zhang, Shigeru Iwata, Maiko Hajime, Naokazu Ohkubo, Yasuyuki Todoroki, Hiroko Miyata, Shingo Nakayamada, Yamagata Kaoru, Yoshiya Tanaka. The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, Kitakyushu, Japan

Background: B cells play an important role in systemic lupus erythematosus (SLE). Several research protocols have focused in recent years on the topic of immunometabolism. Activation of immunocompetent cells depends on rapid synthesis of cell structure components and biomolecules, which requires enormous amounts of energy, nucleic acids and lipids. Amino acids are important ingredients of many metabolic processes. Moreover, the role of amino acids in plasmablast differentiation and their relevance to the pathogenesis of SLE remain elusive.

Objectives: To determine the role of essential amino acids in human B cell differentiation and relevance to the pathogenesis of SLE.

Methods: In the in vitro arm of the study, purified CD19+ B cells from healthy donors were cultured with TLR7/9 ligand (LOX or CpG), IFN-α and B cell receptor (BCR) cross-linking, in the presence or absence of amino acids. We determined 1) the types of amino acids that are important for PB differentiation, 2) the amino acid transporters that are important for PB differentiation, 3) the main signaling pathway(s) involved in the presence of amino acids, 4) the transcriptional factors used in the presence of amino acids. In the clinical arm of the study, peripheral blood mononuclear cells (PBMCs) were obtained from 24 patients with RA, 35 patients with SLE, and 28 age-matched healthy controls, and
subjected to flow cytometric analysis to determine the expression of amino acids-related markers.

Results: 1) Stimulation with the combination of BCR, IFN-α and TLR7/9 ligand induced PB differentiation accompanied by uptake of amino acids. PB differentiation was abrogated in the absence of essential amino acid methionine, and to a lesser extent leucine, but not in non-essential amino acid cystine. 2) LAT1 and CD98 are known amino acid transporters. Stimulation with BCR, IFN-α and TLR7/9 ligand induced CD98 expression but suppressed LAT1 expression. CD98 expression was higher in CD27<sup>−</sup>CD38<sup>+</sup> PB than in CD27<sup>+</sup>CD38<sup>−</sup> non-PB. 3) Previous studies reported that amino acids were perceived by the sensor, leading to mTORC1 phosphorylation. However, the mechanism by which amino acids activate other intracellular signaling pathways in B cells remains elusive. We found that methionine facilitated both the BCR and mTORC1 signals. In addition, the two signals synergistically induced EZH2 expression, which is involved in the epigenetic regulation as a transcriptional factor for histone modification via induction of H3K27me3, in the presence of methionine. 4) Methionine induced EZH2 expression, leading to suppression of BACH2, induction of BLIMP1, XBP1 and PB differentiation. These results indicate that EZH2 is a critical factor for PB differentiation in the presence of methionine. Assessment of the expression of amino acid transporters CD98, LAT1 and EZH2 in B cells in RA and SLE patients showed overexpression of CD98 and EZH2, but not LAT1, in SLE, compared with RA and control.

In SLE patients, EZH2 expression level correlated with that of CD98 in B cells. EZH2 expression also correlated with ESR and disease activity scores, such as of SLEDAI and BILAG, in SLE patients.

Conclusion: The results indicate that essential amino acid methionine plays an important role in PB differentiation through the CD98-EZH2-axis. The pathological process of SLE seems to involve essential amino acids and their metabolic/activation pathways throughout the process of PB differentiation.

SLE, Sjögren’s and APS – clinical aspects (other than treatment)

THU0244 PULMONARY MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

PLAZA NAHIA, María José Pérez, Sergio Rodríguez Montero, Carmen Trapero, Jose Luis Marenco. Valme Hospital, Rheumatology Department, Seville, Spain

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by inflammation and tissue damage mediated by the immune system. Respiratory manifestations are common in SLE, appearing in up to 50% of patients throughout their lives. Furthermore, it is associated with higher mortality.

Objectives: To describe the prevalence and characteristics of pulmonary involvement in patients with SLE

Methods: Observational, descriptive, cross-sectional, retrospective study performed in patients with SLE in follow-up by the Rheumatology Department of Valme Hospital. The following information is collected from medical records: age, sex, mean age at diagnosis, characteristics of pleuropulmonary involvement and ANA and antiDNA positivity.

Results: We studied 165 patients with SLE, with mean age of 37.01 +/- 14.65 years, predominance of the female patients 153 (92.72%). Thirty eight of them had pulmonary involvement (23.03%), with a total of 47 episodes related to lung manifestations. Mean age at diagnosis was 39.70 +/- 15.50 years. Below is shown information about lung involvement:

<table>

Eleven patients (28.94%) presented pulmonary involvement at the time of diagnosis; pleuritis (10.63%) and only one case of interstitial lung disease, varicella pneumonia, shrinking lung syndrome, pulmonary embolism (PE) and bronchiolitis obliterans with organizing pneumonia. Two patients (4.24%) died due to severe respiratory failure secondary to bilateral pneumonia. Three of the 5 patients with PE were diagnosed with antiphospholipid syndrome secondary to SLE. Regarding treatment, most of patients who required hospitalization were in basic treatment with synthetic DMARDs (78.57% in monotherapy and 21.43% with double therapy) and only 2 patients with biologic DMARDs (Rituximab and etanercept).

Six patients had no treatment because the pulmonary event was at time of diagnosis, 2 patients were with antiaggregating therapy and there was no information registered in two patients (episode before 1997). 91.10% of the patients presented positive for ANA, of which 37.14% (13 patients) also presented positive antiDNA. No information was collected about autoimmunity in one patient (2.12%).

Conclusion: Pulmonary involvement in SLE is prevalent, although a significant proportion may remain asymptomatic. The little prevalence of pulmonary manifestations in our series might be due to low mean age, according to the result of a recent systematic review where analysed more than 10000 patients and excluded pulmonary manifestations are more frequent in late-onset SLE. The differential diagnosis is broad and the infectious cause, the main cause of mortality in patients with SLE, must always be ruled out.

THU0245 LOW SPECIFICITY OF THE PROPOSED 2017 ACR- EULAR CLASSIFICATION CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) COMPARED TO PREVIOUS CRITERIA IN SLE PATIENTS WITH NEUROPSYCHIATRIC SYMPTOMS

Rory Monahan1, H.J.L. Beare1, Makia Gekemena, E. Grımlan2, L.J.J. Beart1, Maka Gegeneva1, E.G. Brilman1, L.J.J. Beart-van de Voorde1, Cesáro Magro Checa2, Thomas Huizinga1, G.M. Steup-Beekman1.
1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands

Background: New ACR-EULAR SLE criteria have been proposed in order to attempt to improve classification for clinical and translational research (1, 2).

Objectives: We evaluated the performance of the proposed 2017 ACR-EULAR classification criteria in a cohort of SLE patients with neuropsychiatric (NP) symptoms and compared to previous classification criteria.

Methods: Medical records of patients visiting the NP-SLE clinic of the Leiden University Medical Center (LUMC) between 2007-2017 were retrospectively evaluated. The performance of the proposed 2017 ACR-EULAR criteria, the 2012 SLICC criteria and the 1997 ACR criteria was evaluated using sensitivity and specificity.

Results: 360 patients were included, of which 294 were clinically diagnosed with SLE. The newly proposed 2017 ACR-EULAR showed a sensitivity of 87% (95% CI: 83-91%) and a specificity of 74% (95% CI: 62-84%) as shown in Table 1. The 2012 SLICC criteria had a sensitivity of 85% (95% CI: 80-89%) and a specificity of 76% (95% CI: 64-85%). The 1997 ACR criteria had a sensitivity of 89% (95% CI: 85-92%) and a specificity of 89% (95% CI: 80-96%). Sixty out of 294 patients fulfilled the proposed NP domain (delirium/psychosis/epilepsy). Using more specific criteria for NP symptoms related to SLE, as previously proposed by Bortoluzzi et al. (3), only 37 patients fulfilled this domain. However, this did not improve specificity, which remained 74% (95% CI: 62-84%).
In addition, the performance of the newly proposed criteria was evaluated including patients with more than 10 points, but negative ANA. This led to an increase of sensitivity to 90% (95% CI 86-94%), but also did not influence specificity.

**Proposed 2017 ACR-EULAR classification criteria in SLE patients with NP symptoms**

<table>
<thead>

**THU0246 ASYMPTOMATIC MYOCARDIAL DYSFUNCTION DETECTED BY SPECKLED TRACKING ECHOCARDIOGRAPHY (STE) IN ACTIVE SLE PATIENTS**

**Background:** Clinical myocarditis is seen in 10% of SLE patients, but autopsy studies have shown myocardial involvement in up to 50% of patients. Lupus myocarditis may be silent and can be detected by newer echocardiographic technique like STE especially when SLE is active.1,11

**Objectives:** To study asymptomatic myocardial dysfunction by STE in active SLE patients.

**Methods:** All consecutive active SLE patients having a SLEDAI score ≥ 6 without any cardiac symptoms with disease duration ≤ 5 years aging between 18- 45 years, who attended the Rheumatology and Clinical Immunology department (Outpatient and Inpatient) of Medanta, The Medicity, Gurgaon, from May 2016 to March 2018, were enrolled. They were evaluated for myocardial dysfunction by using a novel ultrasound technique - STE, which was reviewed by one observer cardiologist. Global longitudinal systolic strain (GLSS) was calculated by STE in all patients. GLSS>19.7 was considered as an indicator of myocardial dysfunction.2,3 Age and sex matched controls in the form of thirty healthy volunteer subjects were enrolled and their echocardiography findings were compared with active lupus patients. Atherosclerotic risk factors like hypertension, Diabetes Mellitus and age >45 years were excluded to avoid confounding effects.

**Results:** Fifty eight active lupus patients were analysed. In the cohort female: male ratio was 8.6:1, median duration of disease was 22 months (0.5 - 10.1 years) and mean SLEDAI was 11.02 ± 2.30. GLSS was significantly lower in active lupus patients compared to healthy controls (p=0.0001) suggestive of myocardial dysfunction. In active lupus patients, abnormal echocardiographic findings (myocarditis, non-bacterial thromboembolic, pulmonary arterial hypertension and pericarditis) were seen in 62.1%. Myocardial dysfunction was found in 27 (46.6%), 20 (34.5%) patients had low GLSS with normal left ventricular ejection fraction (LVEF) and these were significantly associated with APLA and anti Sm/RNP antibodies. Multivariate Logistic Regression analysis of myocardial dysfunction with SLEDAI and other system parameters showed that musculoskeletal, CNS, haematological and nephritis were associated with increased risk for developing higher disease activity and myocardial dysfunction, although it was not statistically significant.

**Conclusion:** Almost half of active lupus patients have silent myocarditis. GLSS is more sensitive in detecting asymptomatic myocardial dysfunction than LVEF. Regular Echocardiography with Speckled tracking should be performed in Lupus patients especially when disease is active.

**THU0247 LRRN4: A NOVEL PROGNOSTIC BIOMARKER OF RENAL OUTCOME IN LUPUS NEPHRITIS PATIENTS**

**Heng Can**, **Jin Lin**, **The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China**

**Background:** Lupus nephritis (LN) is the most common organ-threatening manifestation of systemic lupus erythematosus (SLE) and can result in kidney deterioration and end-stage renal disease (ESRD). Newly discovered biomarkers exhibit qualities of disease activity and damage, predict long term preservation of renal function.

**Objectives:** Combine the transcriptomics profile of kidney with long-term renal outcome in LN patients, to explore the novel non-invasive predictive biomarker for renal outcome.

**Methods:** The transcriptomics profile of kidney in 24 LN patients was obtained by using Affymetrix human HTA 2.0 gene expression chip. Random Forest method was used to screen the candidate mRNA biomarkers by correlate the gene expression profile with eGFR slope during the follow-up (Mean time 5.2±1.2 years). In addition, in an independent LN cohort enrolled 45 patients, qRT-PCR and immunochemistry staining was performed to validate the correlation of mRNA level and protein level of candidate gene with renal outcome.

**Table 1. Comparison of GLSS and LVEF between active SLE patients and healthy control group patients**

**Table 2. Myocardial dysfunction in active SLE based GLSS <19.7 %**

**Conclusion:** In a cohort of SLE patients with NP symptoms, the proposed 2017 ACR-EULAR classification criteria showed similar sensitivity as the 1997 ACR and the SLICC 2012 criteria, but lower specificity. Including ANA negative patients improved sensitivity.
Results: (1) There were 3212 gene was regulated in LN kidney (Fold change>1.5, FDR<0.05, compared with healthy control. DCBLD2, NPNT, CPVL, RGS5, and LRRN4 were found to have the leading correlation with eGFR slope of LN patients by using random forest method. (2) In the independent cohort, we validate that the mRNA and protein level of DCBLD2, NPNT, CPVL, RGS5, LRRN4 was significantly evaluated in tubulointerstitial component in LN kidney, compared with healthy controls (p<0.05), and also significantly correlated with eGFR slope [LRRN4(r=−0.715), P<0.001, DCBLD2(r=0.6280, P=0.001, CPVL(r=−0.517, P=0.004, RGS5(r=−0.485, P=0.016), NPNT(r=−0.412, P=0.016). In addition, the mRNA level of LRRN4 and DCBLD2 in kidney was correlated with SLEDAI score(r=0.611and r=0.512, respectively, P<0.01 and serum C3 level (r=0.501, r=0.435, P<0.05). LRRN4 mRNA level also significantly associated with tubulointerstitial fibrosis scoring(r=0.432, P=0.05;3 he protein of LRRN4 was expressed both in glomeruli and tubulointerstitial tissue. And IHC level of LRRN4 protein was significantly associated with eGFR slope (r=0.534, P<0.05 in LN patients.

Conclusion: LRRN4 in kidney may be used as a novel predictive biomarker of renal outcome in LN patients.

UTILITY OF A MOBILE PHONE BASED APPLICATION TO COLLECT PATIENT REPORTED OUTCOME INFORMATION FROM SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Brooke Williams1, Bridget Muckian2, Christine Peschken3, Richard Furie4, Elena Massarotti5, Vanja Sikirica6, Serena Fasano7, Luciana Pierro8, Alessia Borgia9, Melania Alessia Coscia10, Ranieri Formica11, Antonella Riccardi8, Francesco Ciccia2, Serena Fasano7, Luciana Pierro8, Alessia Borgia9, Melania Alessia Coscia10, Ranieri Formica11, Antonella Riccardi8, Francesco Ciccia2.

1AMPel BioSolutions, Charlottesville, VA, United States of America; 2Ampel Biosolutions, Charlottesville, VA, United States of America; 3University of Manitoba, Winnipeg, Canada; 4Northwell Health, Great Neck, NY, United States of America; 5Brigham and Women’s Hospital, Boston, MA, United States of America; 6Pfizer, Boston, MA, United States of America

Background: Patient Reported Outcomes (PROs) can provide important data about the impact of a disease on an individual subject and/or the quality of the response to medication. However, in most circumstances, PRO information is collected only intermittently and usually at the point of care or treatment. The development of mobile technology to collect PRO data provided the opportunity to acquire this information more frequently, in real-time, and in the subject’s normal environment.

Objectives: To test the utility of a smart phone application (app) to collect PRO information in subjects with systemic lupus erythematosus (SLE).

Methods: A smart phone app was developed that collects data from a number of PRO instruments, including FACIT-Fatigue, SF-36 (health-related quality of life) and patient global assessment (PGA). Subjects with SLE were involved in the initial development and evaluation of the acceptability of the app. To test the utility of this app, a multi-center clinical study (VALUE, NCT03142711) was carried out in collaboration with subjects with SLE, in whom PRO information was collected with the app daily for 5 years (PGA) or weekly for 3 months (FACIT-F and SF-36) in the subject’s environment, and also with the app and a standard paper form monthly at each clinical site. Demographic information, compliance and intra-class correlation coefficients between information collected with the app and using a paper form at the clinical site were assessed.

Results: Of the 60 subjects enrolled in this study, 91.3% were women; 57.5%, 16.3% and 17.5% identified themselves as of European, African or Asian ancestry, respectively. The mean age of the subjects was 42.6 years and the mean duration of education was 15.6 years. Overall compliance with completing the PRO instruments with the app at the scheduled time was 88%. To determine the consistency of information collected with the app, PRO instruments were completed on three occasions: a) in standard fashion using a paper form and b) using the app, separated by an interruption at the clinical site. The mean (SD) PGA scores at baseline, month 1 and month 2 were 3.3(2.4), 3.5(2.4) and 3.5(2.5) using the app and 3.2(2.4), 3.5(2.3) and 3.3(2.4) using the paper form. The Intra-class Correlation Coefficient (ICC) and 90%CI were 0.97 (0.96-0.98), 0.96 (0.94-0.97) and 0.95 (0.93-0.97) at the three time points, respectively. For the FACIT-F instrument, the mean (SD) score with the app was 33.2 (11.7), 31.0(12.6) and 32.3(12.7) and with the paper form was 34.1(11.6), 32.0(12.2) and 32.0(12.5) at the 3 time points with ICCs of 0.94 (0.91-0.96), 0.96 (0.95-0.98) and 0.96 (0.94-0.97), respectively. For the SF-36 Physical Functioning score, the mean (SD) with the app was 66.3(26.1), 65.5(26.9) and 67.4(25.8) and with the paper form was 68.4(25.1), 66.1 (26.6) and 67.6(25.8) for the 3 time points, respectively. The ICCs were 0.96 (0.94-0.97), 0.94 (0.91-0.96) and 0.96 (0.94-0.97) for the 3 time points, respectively.

Conclusion: Compliance with completion of PRO instruments using a mobile app was excellent and the content collected with the app conformed with that collected using a standard paper form. Since patient compliance with the use of a mobile app to collect PRO information and the consistency of the information obtained compared to that obtained in standard fashion using a paper form were high, the app affords the potential opportunity to acquire frequent and highly reliable information about the impact of disease and response to medication in individual subjects with SLE.

URINARY NEUTROPHIL GELATINASE ASSOCIATED LIPOCALIN AND PROSTAGLANDIN D-SYNTHETASE PREDICT DISEASE FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS

Serena Fasano1, Luciana Pierro2, Alessia Borgia2, Melania Alessia Coscia2, Ranieri Formica1, Antonella Riccardi8, Francesco Ciccia2.

1University of Campania Luigi Vanvitelli, Rheumatology, Naples, Italy

Background: Systemic Lupus Erythematosus (SLE) is a multisystem autoimmune disease commonly characterized by periods of flares and quiescence. Conventional markers of disease activity (serum complement and anti-dsDNA antibodies) have a limited predictive value of disease flares. Recent evidence suggests that urine biomarkers are able to discriminate between SLE patients with ongoing renal activity and those without nephritis (1). Objectives: To investigate if urinary Neutrophil Gelatinase Associated Lipocalin (NGAL) and Lipocalin-type Prostaglandin D-Synthetase (LP-GDS) are early biomarkers that could be used as flare predictors in SLE. Methods: Patients prospectively followed at our clinic from March 2017 to September 2018, who fulfilled classification criteria for SLE (3), were considered for the study. Flares were identified by SELENA-SLEDAI Flare Index (SFI) after 3 months of urine collection (4). NGAL and LP-GDS levels were measured in the second void urine sample by ELISA. Data were compared by the unpaired student’s t test or the Mann-Whitney U test as appropriate. Logistic regression analysis was used to assess the independent baseline predictors of flares. Receiver operating characteristic (ROC) analysis was used to calculate the area under the curve (AUC) with associated 95% confidence interval (CI) to find the best cut-off values. Results: Urine specimen was collected from 66 patients, including 64 females and 2 males with a median age at diagnosis of 27 years (IQR 21.5-38). During 3 months-follow-up, 18 (27%) out of the 66 patients experienced a single disease flare. Urinary levels of LP-GDS (Fig 1) and NGAL (Fig 2) significantly increased 12 weeks before a disease flare (p=0.0001 and p=0.002, respectively). Urinary NGAL levels correlated with anti-DNA antibody titre (r=0.254, p=0.042) and not with serum complement prior to the disease flare (p>0.05). Moreover, urinary LP-GDS slightly correlated with anti-DNA antibody titre (p=0.08), and was not associated with serum complement levels. Based on ROC analysis, urinary NGAL (AUC: 0.752) and LP-GDS (AUC: 0.811), outperformed conventional biomarkers (Table1). ROC analysis revealed that NGAL levels above 10.95ng/ml had a sensitivity of 84% and a specificity of 63% for flare prediction, while urine LP-GDS cut-off value in the ROC curve, 1500 ng/ml, predicted a flare with 78% sensitivity and 86% specificity. At multivariate analysis, NGAL and LP-GDS were independent predictors of flare with OR=10.34 (95% CI 1.46 – 73.03) and 24.85 (95% CI 4.32-
142.68), respectively. Increase in anti-dsDNA antibodies levels also predicted flares with an OR of 6.70 (p=0.040), while hypocomplementemia was not a significant risk factor.

Conclusion: Urine NGAL and L-PGDS perform better than conventional markers in predicting a lupus flare in its incipient phase, in particular preceding the corresponding change in serum complement. Urinary NGAL and L-PGDS levels seem to be potential tools for monitoring patients with SLE. Further studies are needed to determine their clinical utility in everyday practice.

EARLY IMPROVEMENT IN SLEDAI-2K RESPONDER INDEX-50 PREDICTS SRI-4 RESPONSE IN A RANDOMIZED PLACEBO-CONTROLLED TRIAL OF USTEKINUMAB (UST) IN SYSTEMIC LUPUS ERYTHEMATOSUS

Zahi Touma1, Dafta D Gladman1, Shawn Rose2, Kaylin Fei2, Y Irene Gregan2, Robert Gordon2, Kim Hung Lo2, Murray B Urowitz. 1Krembil Research Institute, Univ of Toronto, Toronto, Canada; 2Janssen Research and Development, LLC, Spring House, United States of America

Background: While traditional Systemic Lupus Erythematosus (SLE) Disease Activity Index 2000 (SLEDAI-2K) scoring assesses complete SLE response for individual disease manifestations, the SLEDAI-2K Responder Index-50 (S2K RI-50) evaluates responses using partial improvement (≥50%) in each of the 9 organ systems of SLEDAI-2K. Usteekinumab (UST), a monoclonal antibody that targets the shared p40 subunit of the cytokines IL-12 & IL-23, is being investigated in patients with active SLE. We have previously shown in a Phase 2 placebo (PBO)-controlled trial of UST in SLE1 that not only SLEDAI-2K and the SLE Responder Index 4 (SRI-4), but also S2K RI-50 can discriminate a treatment effect of UST vs PBO at week 24.2

Objectives: Here, we aimed to ascertain whether a minimal threshold of partial improvement in S2K RI-50 could be used as an early predictor of SRI-4 response.

Methods: This phase 2, PBO-controlled study enrolled adults with seropositive, active disease (SLEDAI score ≥ 6 with ≥ 1 BILAG A &/or ≥ 2 BILAG B scores) despite standard therapy. Patients (n=102) were randomized (3:2) to receive UST IV 6 mg/kg or PBO at week 0, followed by SC injections of UST 90mg or PBO q8w beginning at week8, both added to standard of care. We calculated S2K RI-50 response through week 24 in all patients, including 60 patients receiving UST and 42 patients receiving PBO, using increasing cut-offs of S2K RI-50 reductions from baseline. To help determining a minimal cut-off that discriminated a treatment effect reflecting partial improvement, nominal p values are reported for this post hoc analysis. Logistic regression models were used to evaluate the relationship between reduction in S2K RI-50 at week 12 or week 16 and SRI-4 response at week 24, followed by correlation of binary response data between the two instruments.

Abstract THU0250 – Table 1

Results: A 2-point reduction from baseline (improvement) in S2K RI-50 appeared to be the lowest threshold of response to demonstrate a treatment difference in the proportion of responders at week 24 with UST (93.5%) vs PBO (79.3%) (Δ14.2%, p=0.03). The relationship between 2-point improvement in S2K RI-50 at week 12 or week 16 and SRI-4 response at week 24 is presented in the total study population and by treatment group (Table). In the total population, 78/102 (76.6%) patients at week 12 and 74/102 (72.5%) of patients at week 16 had at least a 2-point improvement in S2K RI-50. Of those, 47/78 (60.3%, r=0.62) at week 12 and 48/74 (64.9%, r=0.76) at week 16 achieved an SRI-4 response at week 24. Odds ratios for the association between SRI-4 response at week 24 and 2-point or greater improvement in S2K RI-50 were 7.6 (CI 2.4-24.3, p=0.0007) at week 12 and 15.4 (CI 4.2-55.8, p=0.0001) at week 16. Similar analyses performed by treatment group demonstrated that these relationships were consistent in the UST and PBO groups (Table).

Conclusion: 2K RI-50 captures partial improvement of ≥50% in SLE disease activity and could be a useful outcome in clinical trials to predict early clinical response. These findings will be confirmed in an ongoing Phase 3 study.

ASSOCIATION OF SMOKING STATUS AND TOTAL AND INDIVIDUAL DAMAGE INDEX IN SYSTEMIC LUPUS ERYTHEMATOSUS

Romy Kallas, Li Jessica, Michelle A Petri. Johns Hopkins University, School of Medicine, Baltimore, United States of America

Background: Smoking is a risk factor for systemic lupus erythematosus (SLE). It has been associated with increased disease activity and decreased effectiveness of hydroxychloroquine in cutaneous lupus.

Objectives: The objective of the study was to determine the association between smoking status and total and individual damage items in SLE.

Methods: We analyzed data from the Hopkins Lupus Cohort. Damage was recorded using the Systemic Lupus Erythematosus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index. Fisher's exact test and Wilcoxon test were used in exploratory analysis. Logistic regression was used to estimate the association between damage and smoking status (ever/never). Odds ratios and 95% confidence intervals were reported. Stratification by ethnicity was done for individual damage items that were found to be significantly associated with smoking.

Results: The prevalence of ever smokers in our cohort was 36%. SLE patients who ever smoked had higher odds of total damage with higher mean total damage index scores (p <0.0001). Data for individual damage items significantly associated with smoking are presented in Table 1. The association between cataract and smoking was still present after adjusting for ethnicity, diabetes, and prednisone use in a multivariate analysis. Logistic regression was used to estimate the association between damage and smoking status (ever/never). Odds ratios and 95% confidence intervals were reported. Stratification by ethnicity was done for individual damage items that were found to be significantly associated with smoking.

Conclusion: Smoking is a modifiable factor for organ damage in SLE. It is already known that it interferes with the efficacy of hydroxychloroquine. Now we are able to prove that smokers have more cutaneous damage (scarring) even after stratification for ethnicity. As expected, smokers had more cardiovascular damage. New findings include associations with gastrointestinal damage, cataracts, pulmonary hypertension, pancreatitis and diabetes.

Objectives: To estimate the incidence of cancer in systemic lupus erythematosus (SLE) patients and to analyze factors associated with cancer differentiated between hormone-sensitive (HS) and non-HS cancers.

Methods: Multicenter retrospective study of a cohort of patients included in Spanish Society of Rheumatology Lupus Registry (RELESSER). The first cancer after the diagnosis of SLE, sociodemographic, clinical activity, cumulative damage, severity, comorbidity, treatments, and refractory disease data were collected. Cancers were classified into HS (prostate, breast, endometrial and ovarian) and non-HS (the rest). Standardized incidence ratio (SIR) was calculated and logistics regression models were built to identify factors associated with cancer.

Results: We included 3539 patients (90.4% women) with SLE (ACR-97 criteria), of whom 154 had cancer (91% women), and 44 were HS (100% women). The SIR for cancer was 1.37 (95% CI: 1.15-1.59), reaching higher values in women under 65 years [2.38 (95% CI: 1.84-2.91)]. The SIR in women with cancer vs. non-HS was 1.02 (95% CI: 0.91-1.91) and 1.93 (1.34-2.66) in HS. In HS vs. non-HS cancers, age at diagnosis of SLE [Odds ratio (OR) 1.04 (p = 0.002) vs. 1.04 (p = 0.019), respectively] and the evolution time [OR 1.01 (p < 0.001) vs. OR 1.00 (p = 0.029), respectively] were factors associated with cancer. SLE-ACR damage index [OR 1.27 (p = 0.022)] and Angiotensin-Converting Enzyme (ACE) inhibitors prescription [OR 2.87 (p = 0.048)] were associated with non-HS cancers.

Conclusion: The incidence of cancer in patients with SLE is increased compared to the Spanish population, specially in younger women. This increase might be due to non-HS cancers. SLE with more cumulative damage and more prescription of ACE inhibitors might associate with non-HS cancers.

EFFECT OF GLUCOCORTICOIDS ON DAMAGE ACCRUAL IN SLE PATIENTS WITH NO CLINICAL OR SEROLOGICAL DISEASE ACTIVITY

Diane Apostolopoulos1, Rangi Kandane-Rathnayake1, Worawit Louthrenoo2, Shue Fen Lu2, Yeong-Jian Wu3, Aisha Lateef4, Vera Golder1, Sargunan Sockalingam2, Sandra Navarra2, Leonid Zamora1, Laniyati Hamijoyo9, Yasuhiro Katsumata8, Masayoshi Hargai7, Madelynn Chan5, Sean O'Neill1, Fiona Goldbalt1, Alberto Hot1, Mandana Nikpour12, Eric F. Morand1, Monash University, Rheumatology, Melbourne, Australia; 2Chiang Mai University Hospital, Rheumatology, Chiang Mai, Thailand; 3Chang Gung Memorial Hospital, Rheumatology, Allergy and Immunology, Taiwan, Taiwan, Republic of China; 4University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia; 5University of Santo Tomas Hospital, Joint and Bone Care, Manila, Philippines; 6Padjadjaran University/Hasan Sadiron General Hospital, Division of Rheumatology, Java, Indonesia; 7Tokyo Women’s Medical University, Institute of Rheumatology, Tokyo, Japan; 8Tan Tock Seng Hospital, Department of Rheumatology, Singapore, Singapore; 9Liverpool Hospital, South Western Sydney Clinical School, Sydney, Australia; 10Finders Medical School, Rheumatology, Adelaide, Australia; 11Melbourne University, Rheumatology, Melbourne, Australia

Background: Observational studies have previously found associations between glucocorticoid therapy and irreversible organ damage in SLE. As glucocorticoid use and lupus disease activity are highly concordant, disease activity potentially confounds analysis of the contribution of glucocorticoid use to organ damage. This could be obviated through the study of damage accrual in patients without detectable disease activity.

Objectives: We studied whether glucocorticoids contribute to damage accrual in SLE in the absence of disease activity, by analysing the effect of glucocorticoids on SLE damage accrual in patients with no clinical or serological lupus disease activity (SLEDAI-2K=0).

Methods: 1907 SLE patients were recruited from 13 centres in 8 countries and followed longitudinally between 2013-2016. As per a standardised protocol, disease activity (SLEDAI-2K) and treatment details were recorded at each visit, and organ damage measured annually (SDI). Co-proportional hazards analyses were used to examine time-dependent associations of glucocorticoid use with damage accrual.

Results: 196/1707 (11.4%) patients had no clinical or serological disease for the entire study period (time adjusted mean (TAM) SLEDAI2K=0). Of these, 95% were female; median (IQR) age at diagnosis 36.5yrs (26.0-46.5) years, median (IQR) baseline SDI 0 (0-1). 68% were exposed to prednisolone, with a median (IQR) TAM-prednisolone dose 2mg/day (0-5). Despite SLEDAI2K=0 throughout, irreversible damage accrual occurred in 13% of the cohort, with 26 damage events captured over median (range) 1.9 years (1.0-2.2) followup. Prednisolone exposure at doses in the upper two quartiles was associated with damage accrual (HR 1.11 (1.02, 1.22), p=0.02)

Conclusion: Irreversible damage accrual occurs in patients with no clinical or serological disease activity as captured by SLEDAI-2K, and glucocorticoid use contributes to the risk of organ damage in these patients.

THU0254  TRENDS OF SEVERITY, PROGRESSION AND BURDEN OF DISEASE IN THE ‘ATTIKON’ SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) COHORT: EVIDENCE FOR THE RULE OF ‘ONE THIRD’ IN DISEASE SEVERITY

Dionisis Nikolaoupolou1, Antigoni Pieta1, Myro Kostopoulo2, Abdulmaset Erden2, Pelagia Katsimbi1, Dimitris Boumpas3, Antonis Fanourakis1. 1Rheumatology Clinic, Attikon University Hospital and BRIFAA, Athens, Greece, Athens, Greece; 2Department of Nephrology, General Hospital ‘G. Gennimatas’, Athens, Greece; 3Faculty of Medicine, Department of Rheumatology, Hacettepe University, Ankara, Turkey. 1 and 2, Ankara, Turkey

Background: SLE phenotype, severity and prognosis varies widely, while its course, progression and pattern of severity cannot be predicted with confidence.

Objectives: We analyzed the phenotype and severity patterns of a SLE cohort in the Attica area of Greece, based in “Attikon” University Hospital, and assessed whether these patterns change over the course of the disease.

Methods: Retrospective cohort study of 512 Caucasian SLE patients fulfilling the ACR 1997 and/or SLICC 2012 criteria. Data on clinical course, pattern of severity and SLICC damage index (SDI) were recorded for each patient at the time of diagnosis and at last evaluation. Severity of disease was stratified based on BILAG manifestations and patients were assessed for progression to a more severe phenotype over their disease course. Patients with disease duration < 12 months were excluded. Binary logistic regression was performed to identify independent predictors of such progression.

Results: More than half patients (53.7%, 275/512) presented with mild disease, while in approximately 20% (20.8%, n=106) lupus presented with severe manifestations at diagnosis. Median (IQR) follow-up was 96.5 (144) months. Of 246 patients with initially mild disease, 126 (56.4%) retained their mild phenotype, 73 (29.7%) progressed to a moderate phenotype, while the remaining 47 (19.1%) eventually developed severe lupus. Also, 30 patients (29.4%, 30/102) who initially manifested moderate severity patterns progressed to severe disease over time. At last evaluation, a nearly equal distribution in severity patterns was evident (mild 30%, moderate 34% and severe 36%). Independent factors for disease progression were older age at diagnosis (OR: 0.97 per 1-year, 95% CI 0.95-0.99), disease duration (OR: 1.10 per 1-year, 95% CI 1.06-1.13), positive anti-dsDNA (OR: 2.20, 95% CI 1.38-3.49) and presence of fever at diagnosis (OR: 1.67, 95% CI 1.00-2.77). By multivariate regression, only disease duration (OR: 1.09, 95% CI 1.05-1.12) and anti-dsDNA (OR: 1.73, 95% CI 1.05-2.85) were independently associated with disease progression.

Ninety-two subjects (18%) had organ damage at the time of diagnosis, mainly due to neuropsychiatric and thrombotic events. At last visit, mean (SE) SDI was 0.67 (0.57). Two-hundred eight patients (59.8%) had no damage (SDI=0), while high damage (SDI > 3) was measured in 25 subjects (7.2%).

Conclusion: In this SLE cohort of Caucasian patients, almost half of cases have mild disease at presentation; yet with significant damage accrual. Of patients with disease duration > 1 year, 43.1% progressed to more severe phenotypes, with patients distributed evenly in the mild, moderate and severe categories. These data reiterate the rule of one third for severity observed in other autoimmune diseases.

THU0255  IMPACT OF IL34, IFNA AND IFN-1 ON DISEASE ACTIVITY OF SLE PATIENTS IN EGYPT

Yasmin Adel Abdelalim Hussein1, Yousra Sadek2. 1 Mansoura University Hospital, Faculty Of Medicine, Rheumatology, Reabilitation and Physical Medicine, Mansoura, Egypt; 2 Mansoura University Hospital, Faculty Of Medicine, Clinical Pathology, Mansoura, Egypt

Background: SLE is a systemic inflammatory and autoimmune disease. IL-34 plays pivotal roles in the proliferation and differentiation of mononuclear phagocyte cells, osteoclastogenesis and inflammation [1]. IFN-α play an important role in SLE pathogenesis [2] and proportion of patients displays increased serum IFN-α and IFN-1 [3]. Interestingly, the gene signatures of IFN-1 and IFN-α overlap [4].

Objectives: Assessment of IL34, IFN-1 and IFN-α in SLE with relationship to clinical, laboratory parameters, treatment response and disease progression. We hypothesized a subgroup of patient with a concordance of high level of these cytokines that could have a different disease behavior.

Methods: 82 newly diagnosed SLE Egyptian patients. History, examination and laboratory investigation with assessment of disease activity. Pretreatment assessment of IL34, IFN-α and IFN-1 level by ILIZA. Patients started treatment (antiinflammation → steroid → immunosuppressive drugs) with response evaluation after six months.

Results: 14 male (17.1%) and 68 female (82.9%), age mean±SD (46 ±8.2). Mean±SD of IL34, INFα and INFβ were 175.9±125.9 pg/mL, 109.3±32.5 pg/mL and 227.9±144.8 pg/mL respectively. 21 patients (25.6%) had lupus nephritis, 32 patients (39%) with SLAM >6 and 22 patients (26.8%) with SLEDAI >6. IL34 was positively correlated with anti-dsDNA (P = 0.002) but inversely correlated with C3 level (P = 0.009). IL34 was highly presented with lupus nephritis (P = 0.005), SLAM >6 (P = 0.03), SLEDAI>6 (P = 0.007) and poor responder to treatment (P = 0.02). INFα was inversely correlated with C3 (P = 0.001). INFα was highly presented with lupus nephritis (P = 0.02) and poor responders (P = 0.01) however no relation with SLAM>6 nor SLEDAI>6. INFβ was positively correlated with anti-dsDNA (P = 0.02) but inversely correlated with C3 (P = 0.01). INFβ was highly presented with lupus nephritis (P = 0.001), high IL34 (P = 0.001) and high INF-1 (P = 0.001). We assigned high levels (i.e., > 75% or third quartile) of each cytokine. Triple high (IL34β>75%, INFα >75% and IFN-1 >75%) found in 17 patients (20.7%) and were positively correlated with anti-dsDNA (P = 0.001) but inversely correlated with C3 (P = 0.001). Triple cytokines level was highly presented with lupus nephritis (P = 0.001), SLAM >6 (P = 0.02), SLEDAI>6 (P = 0.03) and poor response to treatment (P = 0.01) indicating these patients have aggressive disease. 28 patients developed (3 – 8) accumulated clinical features during the disease course, out of them 15 patients (53.5%) have high level of the triple cytokines indicating a poor prognosis of these subgroup.

Conclusion: High pretreatment IL34 or IFN-1 has a prognostic significance in SLE. Patients with high IL34 or INFα or IFN-1 had more kidney affection and poor response to treatment. Triple cytokines elevation significantly associated with lupus activity, more kidney affection and poor response to treatment so, this aggressive phenotype may need combination of targets or multicytokines targeted therapy.

**THU0256**

**RISK OF LONG-TERM INCIDENT CARDIOVASCULAR EVENT AND MORTALITY IN PATIENTS WITH SLE AND POPULATION CONTROLS IS ASSOCIATED WITH A HIGHER CAROTID INTIMA-MEDIA THICKNESS**

Sofia Ajeagovva, Ingård Hafström, Johan Frostegård, Karolinska Institutet, Stockholm, Sweden; Vrije Universiteit Brussel, Brussels, Belgium

**Background:** Measurement of carotid intima-media thickness (cIMT) is promoted as one of the tools for cardiovascular (CV) risk assessment in primary prevention in general population. The diagnosis of systemic lupus erythematosus (SLE) is a strong risk factor for premature CV events and mortality. Whether assessment of cIMT has a value for prediction of CV morbidity and mortality in patients with SLE compared with population controls of similar age and sex is not established.

**Objectives:** To examine association of cIMT with risk of incident CV events and mortality in SLE and controls.

**Methods:** We used the cross-sectional SLEVIC (SLE vascular impact cohort study) cohort of consecutive patients with SLE aged <70 years who were regularly treated in a tertiary referral rheumatology center. Carotid ultrasound was performed at inclusion to the cohort (from September 2006 to January 2008) in 118 patients and in 122 population controls matched by age and sex. Incident CV events were defined as hospitalization for angina pectoris, myocardial infarction, bypass grafting, percutaneous coronary or peripheral artery intervention, ischemic stroke and TIA. Combined outcome of incident CV event and all-cause mortality was evaluated for a mean (SD) follow-up of 9.6 (1.5) years. Participants with prevalent CV before inclusion, n=18, and those who were lost to follow-up, n=14, were excluded from this analysis. Event-free survival rates in patients and controls were compared using Kaplan-Meier curves. Relative hazard ratios from Cox proportional-hazards regression models were used to estimate the effect of cIMT measurement on the outcome.

**Results:** At inclusion, mean age (SD) of the included 98 patients was 47 (13) years, 87% females, mean disease duration 12 (9) years, SLEDAI 4.0, and SLICC/ACR 1.0. Mean age of included 109 controls was 49 (12) years, 91% females. Baseline mean (SD) cIMT did not differ between the groups (p=0.345) and was 607 (127) µm in patients and 632 (118) µm in controls. During follow-up, 12 patients and 4 controls were defined with the outcome. The outcome was reached more often in patients than in controls, p=0.022. The mean time to outcome (SD) was 9.9 (0.2) years for patients and 10.3 (0.1) years for controls.

The hazard rate (HR) for the combined outcome of CV event and mortality was 3.7-fold (95% CI, 1.2-11.5) higher in patients than in controls, adjusted for age, sex and smoking history, p=0.025. A higher baseline mean cIMT was significantly associated with the outcome, HR 1.0 (95% CI, 1.0-1.01) per 1.0 µm increase in cIMT, p=0.040, irrespective of the group. Additional adjustment for traditional risk factors, disease duration, treatments, presence of anti-phospholipid antibodies and defining with carotid plaque yielded similar risk estimates.

**Conclusion:** In this analysis we confirm an elevated long-term risk of important adverse clinical events in patients with SLE compared with controls. A measure of cIMT is associated with incident CV event and mortality. This suggests that assessment with carotid ultrasound may have a value for CV risk stratification and would encourage validation in large-cohort prospective populations.

**DIAGNOSTIC PERFORMANCE OF 2002 AECG, 2012 ACR AND 2016ACR/EULAR CLASSIFICATION CRITERIA FOR SJÖGREN’S SYNDROME IN A HISPANIC POPULATION**

Nicola Alfaro1, Janett Carmen Riegatorres1, Cesar Vidal Soils1, David Vega Morales1, Brenda Roxana Vázquez Fuentes1, Mario Alberto Garza Elizondo1, Cassandra Michele Skinner Taylor1, Dionicio Ángel Galarza-Delgado1, Jesús Mohamed Noriega2, Karim Mohamed Noriega3, Hospital Universitario Dr. José Eleuterio Gonzalez, Department of Rheumatology and Clinical Immunology, Monterrey, Nuevo León, Mexico; Hospital Universitario Dr. José Eleuterio Gonzalez, Department of Ophthalmology, Monterrey, Nuevo León, Mexico

**Background:** Primary Sjögren’s syndrome (pSS) has several classification criteria, whose diagnostic performances vary depending on the studied population1. Concordance and differences among these criteria should be evaluated for independent populations to determine the diagnostic performance.

**Objectives:** To compare the performance among 3 classification criteria for pSS and determine the level of concordance among them.

**Methods:** Descriptive, retrospective, and cross-sectional study including 172 patients from the Rheumatology Service of the Hospital Universitario “Dr. José Eleuterio González”, who were studied for dry syndrome. The clinical criterion of the attending physician was considered as the gold standard for diagnosis. Different parameters were collected: presence of xerostomia, xerophthalmia, Schirmer’s test, sialometry, ocular staining, ANA, anti-Ro/SSA and anti-La/SSB antibodies, RF isotypes (IgA, IgM, IgG), and focal lymphocytic infiltrate in minor salivary gland biopsy. The criteria proposed by the American European Consensus Group (AECG), ACR and, ACR/EULAR were used to evaluate the classification. Compliance was determined for each set of criteria.

**Results:** Sociodemographic characteristics and clinical manifestations are shown in Table 1. For the AECG, ACR, and ACR/EULAR criteria, the sensitivity was 89.1%, 98.9% and 88% and the specificity was 93.8%, 71.3%, and 96.3%, respectively (Table 2). The ACR/EULAR criteria have an adequate level of agreement (κ=0.663, P<0.001) with those of the AECG and with respect to the ACR criteria a moderate level of agreement (κ=0.561, P<0.001).

NERVOUS SYSTEM INVOLVEMENT IN PRIMARY SJÖGREN’S SYNDROME

Jose Luis Andreu1, Carlos Sánchez-Piedra2, Monica Fernandez Castro3, Victor Martínez Taboada4, Alejandro Olive5, Jose Rosas6, Raúl Menor-Almagro7, Beatriz Tofol5,3, Alejandro Olive4, Jose Rosas5, Raúl Menor-Almagro6, Beatriz Tofol5,3

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease characterized by the involvement of the exocrine glands, mainly salivary and lacrimal glands. Approximately half of patients will experience extraglandular complications throughout their evolution.

Objectives: To characterize the involvement of the nervous system (NS) in patients with pSS.

Methods: Multicenter cross-sectional study of a cohort of patients with pSS, constructed by random selection of pSS patients fulfilling the 2002 American-European Consensus Criteria for pSS. A total of 33 rheumatology units. Through review of clinical records and interview with patients, demographic, clinical, analytical, therapeutic data and disease activity indexes were collected. Univariate analysis was done by Chi square test, Mann-Whitney U test and Student’s t test. Multivariate analysis was done by linear logistic regression. A p <0.05 was considered significant. Patients signed an informed consent. The study was authorized by the ethics committees.

Results: 437 patients were included (95% women, median age of 58 years). 65 patients developed NS involvement: 26 patients central NS, 31 peripheral NS and 8 both. Multivariate analysis showed association between NS involvement and atherosclerotic stroke (OR 10.4, 95% CI 2.8-38.5), ear disease (OR 2.1, 95% CI 1.1-4.2) and myopathy (OR 6.5, 95% CI 1.3-31.6). Patients with NS involvement had higher probability of being treated with glucocorticoids (OR 3.3, 95% CI 1.5-7.2) and cyclophosphamide (OR 6.8, 95% CI 1.5-31).

Conclusion: 15% of patients with pSS develop NS involvement that is associated with atherosclerotic stroke, ear disease and myopathy.

REFERENCE:
p=0.01) when compared to patients with both abnormal SGUS findings and LGS local lymphocytic sialadenitis.

**Conclusion:** SGUS and LSG histopathology showed only a moderate correlation in patients with pSS. SGUS may be useful to identify pSS patients with a more severe inflammatory LSG infiltrates, ultimately contributing to prevent non-invasive phenotyping of multiple subsets in pSS.

**THU0260**

**SYSTEMIC LUPUS ERYTHEMATOSUS AND CYTOPENIAS: THE KEY FINDINGS IN BONE MARROW**

Ana Barrera-Vargas1, Jonathan Campos-Guzmán1, Samuel Goeva-Peláez1, Aldo García-Ramos2, Roberta Demichelis-Gómez3, Christianne Bourlon4, Javier Merayo-Chalico1, Jorge Alocer-Varela1, 1Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Immunology and Rheumatology, Mexico City, Mexico; 2Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Hematology and Oncology, Mexico City, Mexico

**Background:** Cytopenias are common in systemic lupus erythematosus (SLE), and it is fundamental to determine their etiology in order to establish an adequate therapeutic strategy.

**Objectives:** To describe the findings in the bone marrow aspirations (BMA) and biopsies of patients with SLE and cytopenias, as well as clinical and laboratory features associated with the etiology of the hematological abnormalities.

**Methods:** We performed a retrospective study in a third-level hospital in Mexico City. We included patients who fulfilled ACR criteria for SLE, presented with cytopenias and had a BMA and biopsy performed before 2000 and 2016. We described the main aspirate and biopsy findings, and also analyzed the final diagnosis and its association with clinical, laboratory, and serological features.

**Results:** We included 101 patients; median age was 32 years and 81.2% were women. Leukopenia (<3000 cells/µL) was found in 47.5% of patients, with 29.7% having moderate or severe neutropenia (<1000 cells/µL). Lymphopenia (<1000 cells/µL) was a common finding (71.3% of patients). Moderate-to-severe thrombocytopenia (<50 K/µL) was present in 28.7% of patients. Finally, 25.8% of patients presented with pancytopenia. Regarding bone marrow findings, there was erythroid dysplasia in 50.5% of patients, granulocytic dysplasia in 28.7% and megakaryocytic dysplasia in 16%. Myelofibrosis was found in 2.6%. An increase in plasma cells (≥5%) was found in 21.8%. In 72.3% of patients, bone marrow interpretation was conclusive. The most common diagnoses were disease activity (24.8%) and drug-associated myelotoxicity (28.7%). When compared to other etiologies, in patients with cytopenias secondary to disease activity, it was more frequent for the bone marrow to be hypercellular (56 vs 23%, p=0.006) and to have increased megakaryocytes (40 vs 17.4%, p=0.048). Conversely, granulocytic dysplasia was less common in this group of patients (17.4% vs 54.3%, p=0.006).

We analyzed factors associated with both activity and toxicity as final diagnoses (Table 1). After multivariate analysis, a neutrophil count <1000 cells/µL was a protective factor for disease activity (OR 0.021; 95% CI 0.001-0.428, p=0.012). On the other hand, a history of renal activity (OR 0.012; 95% CI 1.3-14.2, p=0.024) and neutrophils less than 1000 cells/µL (OR 4.05; 95% CI 1.15-14.19, p=0.029) were found to be independent risk factors for myelotoxicity.

**Conclusion:** The main causes of cytopenias in our SLE patients were disease activity and bone marrow toxicity. Our findings suggest that when patients present with less than 1000 neutrophils/µL, it is unlikely for the cytopenias to be secondary to disease activity. Our study reinforces the diagnostic utility of BMA and biopsy, and the associations we described may assist clinicians to determine the etiology of cytopenias in SLE patients, in order to make appropriate therapeutic decisions.

**THU0261**

**THE URINARY CELLULAR PROFILE AS A BIOMARKER FOR LUPUS NEPHRITIS**

Amira El-Geiry1, Abeer Abdelatif1, Hanaa Donia1, Nouran Esbak1, 1Faculty Of Medicine Alexandria University, Internal Medicine – Rheumatology and Clinical Immunology, Alexandria, Egypt; 2Faculty Of Medicine Alexandria University, Clinical Pathology, Alexandria, Egypt

**Background:** Proliferative lupus nephritis is one of the most common and serious manifestation of SLE and is a major cause of morbidity. A search for the ideal biomarker for LN is still underway, one that can be used for early detection, and correlate with the class & activity of LN. Urine is normally devoid of leucocytes, however it has been observed that macrophages and T-lymphocytes are routinely present in the urine of LN patients and those with other proliferative renal diseases. This provided the idea for their potential use as biomarkers for proliferative LN.

**Objectives:** To study the urinary CD4+, CD8+ T Lymphocytes, and CD14 Monocytes in patients with proliferative lupus nephritis, and explore their use as a biomarker for LN.

**Methods:** Our subjects included 30 patients with biopsy proven proliferative LN and 30 SLE patients without clinical or lab evidence of LN as controls. Lab investigations included serum creatinine, urine analysis, protein, creatinine ratio, anti-ds DNA Ab, C3 and C4. For the flowcytometric analysis 100 ml of freshly voided urine in a sterile container were obtained from patients and controls. All samples were processed within 2-4 hours of collection to ensure viability of the cells. Urine mononuclear cell count was done using a hemocytometer. The urine samples were centrifuged then washed twice by phosphate-buffered saline/bovine serum albumin (PBS/BSA) and resuspended in about 300 µl PBS. The cells were stained with anti-CD8- FITC, anti-CD4- PE, anti CD14-PE/PerCP and anti-CD3-APC monoclonal antibodies. The flow cytometric analysis was done using Becton Dickinson, FACS Calibur multi-parameter flow cytometer equipped with BD CellQuest Pro software for data analysis.

**Abstract THU0261 – Figure 1**

**Scientific Abstracts**
Results: CD14+ cells were the most abundant cells in the urine of LN patients. The mean numbers of urinary CD6+, CD4+ and CD14+ cells/ml were significantly higher in patients with LN (405.6 ± 200.0, 281.1 ± 195.3, and 1554.7 ± 606.8 respectively) than in those without (39.30 ± 17.56, 34.33 ± 16.41, and 161.17 ± 90.91 respectively). AUC for ROC = 1.0 for all 3 markers with CD8+ >85 cells/ml, CD4+ >80 cells/ml, and CD14+ >400 cells/ml being observed exclusively in LN. The cell counts correlated significantly with the protein:creatinine ratio, but not with other markers of disease activity. The CD4:CD8 ratio was significantly lower in LN patients (0.65 ± 0.21) than in those without (0.91 ± 0.31). Urinary CD14+ cells seem to occur in much higher counts in Class IV (1736.7 ± 522.0) than Class III LN (898.5 ± 17.68). p=0.084. Figure 1 shows a dot plot of flow cytometric analysis of urinary T cells and monocytes (dim CD4 expression and CD14 positive/not shown)

Conclusion: Urinary CD6+, CD4+, and CD14+ cells are highly sensitive and specific markers for detecting proliferative LN. A low CD4:CD8 ratio provides a further clue. The cell counts correlate with proteinuria. CD14 cell counts may be a potential biomarker to differentiate between the different classes of proliferative LN.

THU0262

FATIGUE IN PRIMARY SJÖGREN’S SYNDROME AS A DISEASE MANIFESTATION REFLECTING THE DEGREE OF MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT) INVOLVEMENT

Saviana Gandolfo, Marco Binutti, Elena Doriguzzi Breatta, Cinzia Fabro, Salvatore De Vita, Rheumatology Clinic, Udine Academic Hospital “Santa Maria della Misericordia”, Udine, Italy

Background: fatigue in primary Sjögren’s syndrome (pSS) is a very common and complex symptom, heavily impairing a wide range of patient functions, quality of life and health policies. To date, measures of fatigue and other patient-reported symptoms/outcomes (PROs) poorly correlate with pSS disease activity assessed by ESSDAI. On the other hand, therapeutic interventions reducing pSS disease activity proved useful to improve fatigue burden in pSS.

Objectives: to evaluate if fatigue correlates to other pSS disease manifestations which may also reflect disease activity, by investigating if: a) higher levels of fatigue shows a higher frequency of a heavier involvement of mucosa-associated lymphoid tissue (MALT) documented by histopathology, persistent glandular swelling, or cryoglobulinemia (1); and b) if fatigue correlates to other pSS-related somatic symptoms, such as dryness and arthralgias.

Methods: among pSS patients undergoing clinical evaluation in our Sjögren’s Clinic in a six-months period, 86 consecutive unselected patients, fulfilling the latest ACR/EULAR pSS classification criteria, accepted to report their degree of fatigue, general dryness, ocular dryness, oral dryness and pain on 10-cm VAS (range 0-100), and to complete the ESSPRI (range 0-10), the PROFAD (range 0-28) and the EQ-5D scale (0-100) questionnaires. Four subgroups of fatigue severity were preliminarily defined representing, as previously described (3): no fatigue (VAS=0); 12.8% (n=11); low fatigue (VAS=1-24): 25.3% (n=19); moderate fatigue (VAS=25-74): 58.7% (n=44); high fatigue (VAS=75-100): 16% (n=12). As previously reported (3) no significant age or sex difference was present between subgroups, and potential contributors to fatigue, such as autoimmune thyroiditis, anemia and fibromyalgia did not play a role.

The frequencies of peculiar manifestations related to an increased activity in MALT involvement in pSS, such as persistent salivary gland swelling, cryoglobulinemia and biopsy-proven diagnosis of myoepithelial saliadenitis (MESA) or of pSS-related MALT lymphoma, at any time in the clinical history of patients, were evaluated for each subgroup.

Secondly, the correlations between fatigue VAS and PROs reflecting somatic symptoms were performed.

Results: pSS patients reporting moderate or high fatigue VAS showed significantly higher frequencies of salivary gland swelling (p=0.0274), of MESA or lymphoma proven by histological diagnosis (p=0.0397), if compared to pSS patients with no or low levels of fatigue. Cryoglobulinemia was not significantly increased, although more frequent, in patients with moderate or high fatigue (10.7%) compared to patients with no or low fatigue (6.6%).

Fatigue VAS score did not correlate with ESSPRI. Patients with higher levels of fatigue showed significant (p<0.0001) higher scores in total ESSPRI, dryness-ESSPRI, pain-ESSPRI, ocular dryness VAS, oral dryness VAS, pain VAS, somatic fatigue domain of PROFAD, arthralgia domain of PROFAD, total SSI and PROFAD-SSI-SF.

Finally, patients with higher levels of fatigue reported worst scores in quality of life EQ-5D-scale.

Conclusion: The severity of fatigue appears to mirror the degree of MALT involvement, and this involvement is the biological substrate of pSS itself. This represents a demonstration that fatigue is biologically related to pSS, and supports the notion that fatigue should be treated by disease-modifying drugs rather than only with symptomatic therapies in pSS. In addition, dedicated scores of pSS activity can be developed for pSS patients where fatigue is one of the dominant symptoms. Since fatigue may also correlate with pSS somatic symptoms, such as dryness and arthralgia, they could also be included.

THU0263

NOVEL SUBSETS OF SLE PATIENTS ENRICHED FOR RENAL MANIFESTATIONS IDENTIFIED BY CLUSTERING WITH EXPANDED AUTOANTIBODY PROFILES OF NATIVE AMERICAN (NA), AFRICAN AMERICAN (AA), AND EUROPEAN AMERICAN (EA) SLE PATIENTS

Carla Guthridge1, Tim Gross1, Magdalene Quinto1, Joseph Kheir1, Joel Guthridge1, Judith A. James1,2. 1Oklahoma Medical Research Foundation, Arthritis and Clinical Immunology, Oklahoma City, United States of America, 2University of Oklahoma Health Sciences Center, Medicine and Pathology, Oklahoma City, United States of America

Background: Autoantibodies (AAbs) are a hallmark of systemic lupus erythematosus (SLE). Common SLE AAbs show differences in specificity, levels and associations with clinical characteristics of disease which may be influenced by ethnicity.(1-2) NA SLE patients do not always exhibit classical AAb profiles.(2) Understanding how AAb profiles associate with clinical disease, including in NA patients, is important to better inform disease management.

Objectives: To identify patient subsets enriched for renal disease by clustering with expanded autoantibody profiles of Native American (NA), African American (AA), and European American (EA) SLE patients

Methods: Serum samples from 49 NA, 49 AA, and 49 EA age, sex and ANA tier-matched SLE patients who met ACR classification and 10 sex and age matched controls from each ethnicity were tested for AAb reactivity by autoantigen microarray. Normalized fluorescence intensity (NF) for AAB binding was determined for each individual for all autoantigens. Ratios of NFIs to total Igs were calculated and converted to Z-scores. Kruskal-Wallis analysis of Z-score transformed AAB ratios were used to identify AAbs that differed significantly between patients and controls for each ethnicity; these AAbs were used for hierarchical clustering of SLE subjects within each ethnicity. The enrichment of SLE clinical criteria within each cluster was determined by Fisher’s exact test.

Results: AAbs to nucleic acids and Ro52 were present in SLE patients of all three ethnicities. On average, NA SLE patients, but not EA or AA SLE patients, had lower levels of AAbs against extracellular matrix (ECM) antigens compared to controls. AA and EA, but not NA, SLE patients had significantly higher levels of AAbs to Sm, RNP and histones compared to matched controls. In each ethnicity four clusters of SLE subjects were identified by ethnicity-specific AAbs. All three groups had a cluster of subjects enriched in nucleic acid-specific AAbs and a cluster of subjects enriched in Ro52 AAbs. The NA group also had two clusters enriched in ECM AAbs. The AA group had an Sm/RNP AAb enriched cluster and a nucleolin/histone AAb enriched cluster. Two additional EA
SLE clusters had similar levels of nucleic acid-specific AAbs and Ro52 AAbs, but were distinguished by significant differences in histone 2A (H2A) AAb levels. Renal manifestations were significantly enriched in the NA Ro52 cluster and the AA nucleolin/histone cluster compared to other SLE patient clusters of the same ethnicity.

Conclusion: Expanded AAb profiles can be used to identify SLE subsets that are more likely to have renal manifestations of disease.

THU0265

IDENTIFYING COMORBID FIBROMYALGIA IN SYSTEMIC LUPUS ERYTHEMATOSUS USING PATIENT-REPORTED OUTCOMES

Frank Huang1, Sean O’Neill2,2,3, Ray Fang1, Matthew Nguyen1, Kathryn Gibson1,2,3,1 University of New South Wales, Sydney, Australia; 2Liverpool Hospital, Sydney, Australia; 3Ingham Research Institute, Sydney, Australia

Background: Fibromyalgia (FM) is disproportionately common in patients with systemic lupus erythematosus (SLE) and difficult to diagnose on a background of classical SLE symptoms [1]. The Multi-Dimensional Health Assessment Questionnaire (MDHQ) has been shown to be useful to recognise improvement over 2 months in a variety of rheumatic conditions including SLE [2] but has not previously been shown to be useful to alert the clinician to comorbid FM in the latter condition. Conversely, the 2011 FM self-report questionnaire is disease-specific and available for use in clinical and epidemiological studies. Administration of multiple forms may be difficult in a busy clinical setting.

Objectives: To identify comorbid FM in patients with SLE using patient-reported outcomes (PROs) from the routinely distributed MDHQ, in comparison to the 2016 revision of the 2010/2011 FM criteria.

Methods: Patients with SLE completed an MDHQ and the 2011 FM Criteria questionnaire. FM status was assigned using the 2016 revision of the 2010/2011 FM criteria as the gold standard. The MDHQ features 13 items with an 11-point numeric rating scale (NRS) designed to alert the clinician to comorbid FM in the latter condition. Conversely, the 2011 FM self-report questionnaire is disease-specific and available for use in clinical and epidemiological studies. Administration of multiple forms may be difficult in a busy clinical setting.

Objectives: To identify comorbid FM in patients with SLE using patient-reported outcomes (PROs) from the routinely distributed MDHQ, in comparison to the 2016 revision of the 2010/2011 FM criteria.

Methods: Patients with SLE completed an MDHQ and the 2011 FM Criteria questionnaire. FM status was assigned using the 2016 revision of the 2010/2011 FM criteria as the gold standard. The MDHQ features 13 items with an 11-point numeric rating scale (NRS) designed to alert the clinician to comorbid FM in the latter condition. Conversely, the 2011 FM self-report questionnaire is disease-specific and available for use in clinical and epidemiological studies. Administration of multiple forms may be difficult in a busy clinical setting.

Conclusion: SLE-PAH had 3.8-fold increase in mortality despite treatment with PAH specific therapy and immunosuppressants. Hyponatremia and renal disease were associated with poor survival outcome in SLE-PAH patients.

Disclosure of Interests: None declared

six main PROs: body pain, patient global and fatigue score on a 0-10 visual analogue scale, as well as a functional impact score, self-report joint count and symptom checklist while having a range of 0-10, 0-48 and 0-60 respectively. Composite indices consisting of either two or three of patient pain score 6, self-report joint count 16 and symptom checklist 16 or three of four of the same measures plus a fatigue score 6 have been described previously to provide clues to comorbid FM in other rheumatic diseases [4,9]. Individual PROs and these composite indices were compared between patients with and without FM by student’s unpaired t test and Area Under the Curve (AUC) analysis. The physician’s diagnosis of FM was analysed against the FM criteria using Cohen’s kappa. Physicians were blinded to the results of the 2016 FM criteria.

Results: 88 patients with SLE were studied, of whom 23 (26%) satisfied FM criteria. Those with FM reported higher scores in all PROs. A patient global of 6 could correctly classify 90% of patients and provided the highest AUC of 0.95, followed by the symptom checklist and body pain. An index of three measures (pain score, self-report joint count and symptom checklist) gave an AUC of 0.90. An index of four measures (additional fatigue criterion) gave an AUC of 0.93. Both indices correctly classified 89% of patients with a cut-off of 2 and 3 respectively. The physician’s diagnoses had moderate agreement with the FM criteria (kappa = 0.43).

Conclusion: Comorbid FM is prevalent in SLE yet often missed by physicians. In busy clinical settings, composite indices provide useful clues to coexisting FM in SLE, although a simple MDHAQ patient global is quick and potentially just as valuable in this patient group. These findings require further validation in a larger cohort.

THU0267

THE SLE DISEASE ACTIVITY SCORE (SLE-DAS) ENABLES ACCURATE DEFINITIONS OF SLE REMISSION AND LDA AS ACHIEVABLE TARGETS IN DISEASE MANAGEMENT

Diogo Jesus1,2, Ana Matos3,4, Carla Henriques5,3, Margherita Zen6, Maddalena Laosa6, Luca Iaccarino6, Andrea Doria5, Luis Inês3

1 Centro Hospitalar e Universitário de Coimbra, Rheumatology Department, Coimbra, Portugal; 2 University of Beira Interior, Faculty of Health Sciences, Covilhã, Portugal; 3 Polytechnic Institute of Viseu, School of Technology and Management, Viseu, Portugal; 4 Polytechnic Institute of Viseu, Center for Research in Digital Services, Viseu, Portugal; 5 University of Coimbra, Centre for Mathematics, Coimbra, Portugal; 6 University of Padova, Division of Rheumatology, Padova, Italy

Background: The treat-to-target strategy in Systemic Lupus Erythematosus (SLE) aims to achieve remission. However, to define a target based on the SLE Disease Activity Index (SLEDAI) is questionable, due to its limitations (especially its dichotomous nature). The SLE Disease Activity Score (SLE-DAS) is a recently validated continuous disease activity score which has a higher accuracy in measuring SLE activity and a higher sensitivity-to-change compared to SLEDAI.

Objectives: To assess the ability of SLE-DAS to define SLE remission and other disease activity states.

Methods: Cross-sectional study of SLE patients fulfilling the ACR/1972 and/or SLEDAI12 classification criteria and followed at the Padua Lupus Clinic from March to June 2018. Each outpatient visit, the attending clinician scored SLE disease activity (in the last 30 days) using Physician Global
Assessment (PGA) (0-3 points, 10 cm scale), SLEDAI-2K and SLE-DAS. A senior rheumatologist expert in SLE, blinded to the disease activity scores, classified each patient in 1 of 4 categories: (i) remission, (ii) low disease activity (LDA), (iii) mild disease activity and (iv) moderate/severe disease activity. The best cut-off values of SLE-DAS to define these categories were estimated using Receiver Operating Characteristic (ROC) curve analysis. Accuracy, precision, sensitivity and specificity values for these cut-off values were then calculated. The agreement between the SLE-DAS and physician’s classification was measured using Kappa coefficient. Statistical significance was set at 0.05.

**Results:** We included 221 patients (84.2% female, mean age of 45.4 ±13.5 years, mean disease duration of 15.4±9.5 years). In this preliminary study, the proposed cut-off values of SLE-DAS to define each disease activity category were: remission SLE-DAS≤2.08, LDA 2.08<SLE-DAS<3.77, mild disease activity 3.77<SLE-DAS<7.64, and moderate/severe disease activity SLE-DAS>7.64 for (Table 1). The overall accuracy of these SLE-DAS cut-off values to identify each disease activity state was 96.4%. The agreement between SLE-DAS and physician’s classification was very high (k=0.925, p<0.001). Distribution of SLE-DAS and SLEDAI-2K scores in each disease activity state is presented in Figure 1. According to the SLE-DAS cut-offs, 68.8% of the patients were in remission, 2.3% in LDA, 10.9% in mild disease activity and 18.1% in moderate/severe disease activity.

**Conclusion:** The SLE-DAS has a high precision in identifying remission, LDA, and other disease activity states in SLE. These results suggest that the SLE-DAS is an accurate tool in defining achievable targets in SLE management.

**THU0269**

**CLINICAL AND LABORATORY FEATURES OF PRIMARY SJÖGREN’S SYNDROME ASSOCIATED WITH ANTICENTROMEREB ANTIBODIES**

Julia Khvan1, Boogdan Chalcev1, Vladimir Vasiliev2, 1V.A. Nasanova Research Institute of Rheumatology, Moscow, Russian Federation; 2MEDSI, Moscow, Russian Federation

**Background:** The prevalence of ACA among patients with pSS ranges from 2% to 27%. Among experts, there is a lot of controversy about whether primary Sjogren’s syndrome with ACA is a separate disease subtype or overlap-syndrome with systemic sclerosis.

**Objectives:** To evaluate clinical and laboratory features of anticientromere antibody-positive (ACA) primary Sjögren’s syndrome (pSS); to evaluate the spectrum of autoantibodies in patients of this group; to evaluate conformity of the patients to the pSS and systemic sclerosis (SSc) classification criteria; to evaluate prevalence of salivary MALT-lymphoma in this group of patients; to evaluate prevalence of primary biliary cirrhosis (PBC)/biliary lesions in this group of patients.

**Methods:** From 2012 to 2018, we examined 83 patients with pSS and ACA. Inclusion criteria were conformity to the 2001 Russian Sjögren’s syndrome criteria and high ACA titer. We used ACR 2012 and ACR/EULAR 2016 criteria to evaluate conformity to the pSS, and ACR 2013 criteria to evaluate conformity to the SSc. Diagnosis of salivary MALT lymphoma was established on the basis of histological, immunohistochemical and PCR studies of biopsy specimens of parotid salivary glands.

**Results:** We found a low detection rate of anti-Ro antibodies (32.5%), anti-La antibodies (7.2%), RF (21.7%), increased ESR (14%), leukenopia (7%), hypergammaglobulinemia (17.6%), increased IgG (9.5%), increased IgA (18.7%) hypocomplementemia (16.1%) in the group of patients with pSS and ACA. Despite the low frequency of detection of the RF, some patients of this group had MALT-lymphoma: 14 patients had salivary MALT-lymphoma (16.8%), one patient had tonsil MALT-lymphoma with nodal involvement (1.2%). In addition, patients of this group are characterized by a high frequency of detection of AMA antibodies 17/52(32.7%), increased IgM (29.7%) and increased risk of biliary lesions (14.4%). According to our data increased risk of developing biliary lesions (28.5%), primary biliary cirrhosis (28.5%), autoimmune hepatitis (AIH) (28.5%), overlap-syndrome between PBC and AIH (14.5%) was observed in patients with functional signs of liver damage (ALT/AST, GGT, ALP >2N), AMA-positivity, high levels of IgM. Only two patients, who were diagnosed with liver disease according to studies of biopsy specimens, lacked AMA-antibodies. Damage to the nervous system, kidneys, antiphospholipid syndrome, rheumatoid arthritis, hypergammaglobulinemia, purpura and cryoglobulinemic vasculitis were much less common and were single. Also patients with pSS and ACA often have Raynaud’s phenomenon (54.9%) with capillaroscopic changes of the scleroderma type (68%) and an increased risk of developing limited form of systemic scleroderma (24%).

Conclusion: pSS associated with ACA is a subtype of the disease, significantly different from the “classic” in a number of clinical and laboratory signs and characterized by an increased risk of SSc and PBC/biliary lesions which in some cases leads to the underdiagnosis of pSS. ACA should be considered as pathogenetically related to pSS antibodies and all ACA-positive patients should be examined for pSS and PBC/biliary lesions regardless of whether they have SSc or not. Patients with a significant enlargement of salivary glands should be biopsied to confirm the presence of MALT-lymphoma before initiating hormonal, antilymphoproliferative and anti-B-cell therapy.

**SERUM IL-6 AND CIRCULATING IMMUNE COMPLEXES AS BIOMARKERS OF DISEASE ACTIVITY IN MULTI-ETHNIC ASIAN SYSTEMIC LUPUS ERYTHEMATOSUS**

Sheng Min Samuel Lee1, Hwee Giew Howel1, Bernard Yu-Hor Thong1, Kok Ooi Kong1, Hsik Hhe Ching1, Tsui Yee Lian1, Li-Ann Faith Chia1, Tang Ching Lau1,2, Weng Giap Law1,3, Ee Tzin Koh1,4, Pui Lam Bernard Leung1,3, Tan Tock Seng Hospital, Rheumatology, Allergy and Immunology, Singapore, Singapore; National University Hospital, Medicine, Singapore, Singapore; Singapore Institute of Technology, Health and Social Sciences, Singapore, Singapore

**Background:** IL-6 plays an important role in B cell hyperactivity and immunopathology of systemic lupus erythematosus (SLE), and may have a direct role in mediating tissue damage [1]. Elevated levels of serum
circulating immune complexes (CICs) have been described in SLE but the relationship with disease activity in our multi-ethnic Asian patients remains unclear.

Objectives: To determine the correlation between disease activity and the levels of CICs, serum and urine IL-6 in a Singapore cohort of multi-ethnic Asian SLE patients.

Methods: Serum levels of CICs, IL-6 and urine IL-6 were measured in 88 SLE patients using CIC-C1q and high sensitivity IL-6 ELISAs. All patients fulfilled the 1997 revised American College of Rheumatology (ACR) classification criteria. Clinical and laboratory manifestations, therapy, disease activity and damage at the time of sample collection was collated. Disease activity was scored with the SLE Activity Measure-revised (SLAM-R) and damage with the ACR/Systemic Lupus International Collaborating Clinic SLE damage index (SDI). The correlation between disease activity score and CICs, serum and urine IL-6 were assessed using Spearman’s correlation. Receiver operator characteristic (ROC) curve analysis was performed to assess the performance of the individual biomarkers in discriminating SLE disease activity.

Results: The cohort of 88 patients were predominantly female (n = 78, 89.6%), with a mean age of 40 years±13.1. The majority were of Chinese ethnicity (n = 73, 83%), 13% were Malay (n = 11) and 4 individuals were of other races. The mean disease duration was 98.4 months ± 86.4. The mean scores of SLAM-R and SDI were 2.9 ± 2.2 and 0.9 ± 0.9 respectively. SLE disease manifestations at the time of sample collection included mucocutaneous involvement (5.7%) and active urine sediment (28.7%). 77% had hypocomplementemia and 70.1% had elevated titres of anti-dsDNA antibody. The majority were on corticosteroids (75.9%) and hydroxychloroquine (65.5%). Immunosuppressive drugs included azathioprine in 37.9%, mycophenolate in 69.4%, intravenous pulse cyclophosphamide in 6.9% and cyclosporin in 1 patient. There was significant positive correlation between SLAM-R and serum CICs (R = 0.4121, p < 0.01), serum IL-6 (R = 0.4227, p < 0.01) and urine IL-6 (R = 0.3142, p = 0.01). Based on the area under the curve(AUC), CICs and urine IL-6 were better in discriminating active SLE (AUC 0.8002, p < 0.01 and AUC 0.7397, p < 0.01 respectively) compared to serum IL-6 (AUC 0.5554, p = 0.1718).

Conclusion: Our study observed significant correlation between levels of serum circulating immune complexes, serum and urine IL-6 with SLE disease activity in our multi-ethnic Asian SLE patient cohort. ROC curve analysis suggests that serum CICs and urine IL-6 may serve as sensitive biomarkers to identify SLE patients at risk of flares.

be the strongest inhibitor of TNF-α among cytokines involved in pSS pathogenesis, iii) results may explain the ineffectiveness of anti-TNF drugs in the treatment of pSS

FUNCTIONAL GASTROINTESTINAL DISORDERS IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Pamela Munguía Realpozo1,2, Claudia Mendoza Pinto1, Mario García Carrasco1,2, Socorro Méndez Martínez1, Tania Mogollán Delfín1, José Álvaro Montiel Jarquin1, Aurelio López Colombo1,3, CIBIOR-UMAE, Instituto Mexicano del Seguro Social, Systemic Autoimmune Diseases Research Unit, Puebla, Mexico; 2Medicine School, Benemérita Universidad Autónoma de Puebla, Rheumatology and Immunology Department, Puebla, Mexico; 3UMAE Instituto Mexicano del Seguro Social, Puebla, Mexico

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multisystemic involvement. Gastrointestinal (GI) manifestations are frequent in patients with SLE, but functional gastrointestinal disorders (FGIDs), a heterogeneous group of GI diseases have hardly been evaluated in SLE patients.

Objectives: We evaluated the prevalence of FGIDs in SLE patients compared with age-matched controls and the role of potential risk factors for FGIDs.

Methods: SLE patients who met the ACR classification criteria for SLE and age-matched controls completed the Rome III questionnaire to assess the prevalence of FGIDs. Exclusion criteria were organic gastrointestinal disorders. Patients completed a structured interview to assess sociodemographic, clinical and treatment variables. Logistic multivariate analysis was performed to determine potential clinical factors (alcohol ingestion and medications) for FGIDs.

Results: The study responders included 116 SLE patients and 122 controls. The prevalence of FGIDs was higher in SLE patients than in controls (74.1% vs. 54.1%; p = 0.01). The most frequent FGIDs were nausea and vomiting disorders, belching disorders and globus pharyngeus. Anorectal disorders, mainly anorectal pain, were more frequent in SLE patients than controls (14.7% vs. 5.7%). After adjusting for confounding variables, SLE was associated with globus pharyngeus (OR: 3.5, 95% CI: 1.3-9.3), functional heartburn (OR: 2.5, 95% CI: 1.5-4.4), nausea and vomiting disorders (OR: 7.1, 95% CI: 2.7-19.1) and anorectal disorders (OR: 3.4, 95% CI: 1.4-8.4). Overlap symptoms were present in 69.8% of patients vs. 31.6% of controls. When only SLE patients were evaluated, glucocorticoid therapy and non-steroidal anti-inflammatory drugs (NSAIDs) were associated with any FGID and functional bowel disorders, while alcohol ingestion was associated with gallbladder and sphincter of Oddi disorders.

Conclusion: There is a higher prevalence of FGIDs in patients with SLE and a wider distribution of various GI tract symptoms compared with controls. Medication that may alter gastrointestinal homeostasis, such as NSAIDs and protein pump inhibitors, were associated with FGIDs in SLE patients.

EVALUATION OF RELAPSE RATE AND LIFE PROGNOSIS AFTER INDUCTION THERAPY IN PROLIFERATIVE AND MEMBRANOUS LUPUS NEPHRITIS

Momoko Okamoto1, Kunihiro Ichinose1, Mineaki Kitamura2, Shuntaro Sato2, Keita Fujikawa2, Yoshiro Horai2, Naoki Matsuoka2, Masahiko Tsubo2, Fumiaki Nonaka1, Yukitaka Ueki6, Toshimasa Shimizu1, Tomohiro Koga1, Shin-ya Kawashiri2, Naoki Iwamoto3, Mami Tamai4, Hideki Nakamura5, Tomoki Oriuchi3, Tomoya Nishido4, Atsushi Kawakami1, Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology, Rheumatology, Nagasaki, Japan; 2Nagasaki University Hospital, Department of Nephrology, Nagasaki, Japan; 3Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; 4JCHO Ishaya General Hospital, Department of Rheumatology, Nagasaki, Japan; 5Nagasaki Medical Center, Department of Nephrology, Nagasaki, Japan; 6Nagasaki Medical Hospital of Rheumatology, Nagasaki, Japan; 7Nagasaki University Graduate School of Biomedical Sciences, Department of island and rural medical research, Nagasaki, Japan; 8Szasebo Chuo Hospital, Rheumatic disease center, Nagasaki, Japan; 9Nagasaki University Graduate School of Biomedical Sciences, Department of Rehabilitation Sciences, Nagasaki, Japan

Background: The most common cause of morbidity and mortality in systemic lupus erythematosus (SLE) is lupus nephritis (LN). Renal flares are disadvantageous to the renal function of patients with severe LN, and the flares contribute to morbidity in patients with SLE. The reported incidence of renal flares has varied with the populations studied, the distributions of histological classes of LN, the treatment administered and the definitions of renal flare.

Objectives: Here we evaluated the relapse rate and life prognosis after induction therapy in proliferative and membranous LN.

Methods: We retrospectively analyzed the cases of 151 patients who underwent renal biopsy at our hospital and community hospitals from 1993 to 2016. We determined the complete response (CR) rate at 6 and 12 months after induction therapy and evaluated the predictive factors for CR, relapse rate, and life prognosis in proliferative and membranous LN.

Results: We were able to evaluate the therapeutic response, relapse rate and life prognosis at 6 and 12 months after therapy was introduced in 140 cases. Most of the patients were female (84.3%). The median age at LN onset was 34.0 years (interquartile range [IQR] 25.3–45.0 years), and the disease duration of SLE was 42 months (IQR: 2.0–121.0 months). The median follow-up duration after renal biopsy was 96 months (IQR: 44.0–168.0 months). The renal pathology of 99 (70.7%) patients was classified as ISN/RPS Class III or IV, and 41 (29.3%) patients were ISN/RPS Class V. Thirty-five patients (35.4%) were Class III or IV, and 17 patients (41.5%) in Class V achieved a CR at 6 months. Fifty patients (50.5%) in Class III/IV and 22 patients (53.7%) in Class V achieved a CR at 12 months. A multivariate analysis showed that the relapse rate and life prognosis were not different between proliferative and membranous LN.

Conclusion: Our results suggest that the predictive factors for a CR at 12 months after induction therapy are a lower index of chronicity in class III/IV, and neutrophil infiltration and CH50 in Class V were predictive factors for achieving a CR at 12 months. A Kaplan-Meier analysis showed that the relapse rate and life prognosis were not different between proliferative and membranous LN.

THU0274 QUALITATIVE AND QUANTITATIVE ANALYSIS OF THE IMMUNOLOGIC CHARACTERISTICS OF THE MINOR SALIVARY GLAND BIOPSY IN SJÖGRÖN'S SYNDROME

Luisa Llorca1, Laura Martínez-Martínez1, Mª Berta Magallares1,2, Ivan Castellvi1, Cesar Díaz-Tormé1, Ana Laiz1, Patricia Moya2,3, Ana Milena Millán Acínegas1, Andrea García-Guillén1,1, Sylvie Jeria1, David Lobo1, Susana P. Fernandez-Sánchez1, Conceita Pitarlech1, Manel Riera1, María Carmen Hernández Lafuente1,2, Conchita Pitarch1,2, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; Hospital Dos de Maig, Barcelona, Spain

Background: Minor salivary gland biopsy (MSGB) is the most important diagnostic test of Sjögren’s Syndrome (SS). It demonstrates the presence of the inflammatory infiltration in the most affected site. It’s possible role as a biomarker in the disease is still unknown. The Immunology Department of our center conducts a detailed analysis of the MSGB about the leukocyte infiltration and quantities number of each cell.

Objectives: To describe the immunologic features of the MSGB and carry out an association analysis with clinical variables.

Methods: Clinical variables, ESSDAI index at the moment of diagnosis and laboratory parameters were recorded. As from the MSGB, number of infiltration focus (1, 2 or several), big infiltrations (>100 cells), number of B and T cells, CD4/CD8 ratio and presence of isolated lymphocyte were collected. Categorical variables were described as frequencies and analyzed using Fisher exact test. T patient and Wilcoxon Rank Sum Test were used for comparison of means (μ).

Results: In total, a mean of 104 MSGB were carried out in our center. Among them 58 were diagnosed as SS by medical and ACR/EULAR 2016 criteria. Finally 41 patients with SS and abnormal MSGB result were included for this study.

Biopsy: Patients with active disease (ESSDAI≥2) had greater amount of cells (μ 159 cells vs 509 cells; p=0.055) as well as those with extraglandular disease (μ 160 vs 488; p=0.08). Patients with active disease also had larger number of infiltration focus (p= 0.062). The presence of isolated CD8+ T cells was observed in 13 patients and they had lesser (μ 136 vs 381; p=0.35). In those with predominance of T cells over B cells had larger number of infiltrate focus (7/20; 35% vs 12/21; 57.14%; p<0.155). No association with disease activity or extraglandular manifestation was found.

Extraglandular manifestation and disease activity: 18 patients had extraglandular disease. Moderate or severe ESSDAI activity was found in 14 of these patients (34.2%, p=0.00). The biopsy of patients with extraglandular disease had larger amount of cells (μ 200 vs 145; p=0.01). Patients with active disease had more infiltrate focus (6/22 vs 11/19; p=0.047).

Disease evolution time was similar with a mean duration of 8-9 years in both groups.

Corticosteroids: There were 3 patients with active steroid treatment (>prednisone 10mg/d) at the moment of the biopsy. All 3 of them had >1 focus in the sample and 2 of them had large infiltrate with >150 cells. Eight of them had received steroids in the last 5 years, 6 of them had large infiltrate with >150 cells and 4 had >1 infiltrate focus in the biopsy. A study with more sample should be carried out to study the influence of steroids in the biopsy results.

Conclusion: Patients with extraglandular disease have larger amount of cells in the composition of infiltration. Those with more disease activity had more number of infiltration focus.

In 14 patients specific antibodies and antinuclear antibodies were negative. In these patients the biopsy is the most useful diagnostic test.

Possible association of those variables that were statistically not significant should not be ruled out due to the small sample size of the study.

THU0275 NEW PROSPECTIVE OF COGNITIVE IMPAIRMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A PRAGMATIC LANGUAGE EVALUATION

Carmelo Piro1, Fulvia Ceccarelli1, Concetta Mina2, Alfredo Masciolo2, Carlo Percione1, Barbara Mazzotta1, Laura Massaro1, Francesca Spinelli1, Cristiano Alessandri1, Guido Valesini1, Fabrizio Conti1, Sabrina Valenti1,1, Sapienza Università di Roma, Lupus Clinic, Dipartimento di Medicina Interna e Specialità Mediche, Roma, Italy; Sabrina Valenti1, Dipartimento di Neurologia e Psichiatria, Roma, Italy; Università degli studi di Roma Tor Vergata, Dipartimento di Neuroscienze, Clinica Neurologica, Roma, Italy

Background: Cognitive impairment (CI) in Systemic Lupus Erythematosus (SLE) is a frequent neuropsychiatric manifestation affecting several domains, even in apparently asymptomatic patients. Current research revealed that the typical CI pattern affects frontal-subcortical circuit and thus executive functions. The impairment of non-literal language or Pragmatic Language (PL), including metaphors, idioms, inferences or irony has been well described in several conditions such as autism disorders, Parkinson’s disease, brain injury and even in earlier phases of neurodegenerative processes. Even if PL neuro-anatomy remains controversial, correlation between executive dysfunctions and non-literal language involvement has been reported both in traumatic injury and mild cognitive impairment patients. Nonetheless, no specific study has been performed to evaluate PL impairment in SLE patients so far.

Objectives: We aimed at assessing the PL domain in a monocentric SLE cohort in comparison to healthy controls, matched to age and education, through a specific battery, BLED [1]. Secondly, we focused attention on possible correlations between CI and clinical and laboratory SLE-related features.

Methods: Forty adult patients affected by SLE, according to the ACR criteria, and thirty healthy subjects were enrolled consecutively in this cross-sectional study. The protocol included complete physical examination, extensive clinical and laboratory data collection (comprehensive of demographics, past medical history, co-morbidities, disease activity, chronic damage evaluation, previous and concomitant treatments) and cognitive assessment for five different domains: memory, attention, pragmatic language, executive and visuospatial functions. Self-reported scale for anxiety and depression were performed to exclude the influence of mood disorders on cognitive dysfunction.

Results: We enrolled forty Caucasian SLE patients (M/F 3/37; mean±SD age 45.9±10.1 years, mean±SD disease duration 120.8±81.2 months) and thirty healthy subjects (M/F 9/21; mean±SD age 41.3±13 years). According to the low level of disease activity and damage (mean±SD SLEDAI-2K of 1.3±2.3, mean±SD SDI of 0.2±0.5), only 30% of patients was on glucocorticoid treatment at the study entry. PL was the most compromised domain in terms of Mean Domain Z scores (Fig. 1). As regards the Domain Cognitive Dysfunction score, a deficit of PL was observed in 45% of participants and significantly prevalent than memory, executive and visuospatial functions impairment (P=0.0002, P=0.0002 and P<0.000001, respectively). According to Global Cognitive Dysfunction score 25% of patients experienced a mild impairment and 7.5% a moderate one. Anti-phospholipid antibodies positivity was significantly associated with memory impairment (P<0.0005), whereas the presence of other neuropsychiatric events was associated with executive dysfunctions (P<0.05); neither further significant association nor correlation were identified.
CHARACTERISTICS OF NEUROLOGIC INVOLVEMENT AND ITS RELATED FACTORS IN PRIMARY SJÖGREN SYNDROME

mindi qiu, Yutong Jiang, Wen Yang, Jieruo Gu. The third affiliated Hospital of Sun Yat-sen University, rheumatology, guangzhou, China

Background: Neurological manifestations seem common in primary Sjögren’s syndrome (pSS), but their reported prevalences vary in Chinese. And few studies reveal if the disease activity is associated with neurological involvement.

Objectives: To analyze the clinical neurological manifestations of primary Sjögren syndrome (pSS), and to evaluate the relationship with disease activity.

Methods: 112 patients (79 male, 33 female) who fulfilled the 2002 American-European Consensus Group criteria for pSS were enrolled in the study. For each patient, the clinical features were evaluated by medical data including clinical, laboratory and immunologic data, and neurological examinations including electromyography, magnetic resonance imaging, cerebrospinal fluid, and electroencephalogram. Statistical methods used were t-test, chi-square test and Logistic regression.

Results: Data were available for 112 patients, whose mean age was 55±10 years. Neurological involvement was noted in 19.6(22/112) patients, including 17(15.2%) with peripheral nervous system (PNS) manifestations and 2(1.8%) with central nervous system (CNS) manifestations and 2(1.8%) with both PNS and CNS involvements. Optic neuritis and trigeminal neuralgia were revealed frequently in cranial neuropathy. Anti-aquaporin 4 antibody was detected in two patients with optic neuritis. The clinical spectrum of peripheral neuropathies encountered in Sjögren’s syndrome patients was wide with sensory neuropathies being the most common. Tibal neuralgia, peroneal nerve and sural nerve were the most likely involved and lower limb involvement accounted for 68.4%(13/19). The frequency of Raynaud’s phenomenon was significantly higher(31.8%(7/22) vs 4.4%(4/90), P=0.01) as well as acroanesthesia(72.7% vs 8.9%, P=0.01) in pSS with neurological involvement than in pSS without neuropathy. The median values of EULAR Sjögren’s syndrome disease activity index (ESSDAI) were 5.6(range 2.6-7.6) and 3.2(range 1.4-5.2) in the NS and non-NS groups respectively(P<0.01). We found a significant rise of neuropathy risk associated with Raynaud’s phenomenon(relative risk 9.365, 95%CI 3.191 to 24.039, P<0.001) as well as acroanesthesia(relative risk 1.628, 95%CI 1.169 to 2.231, P=0.001). Elevated levels of rheumatoid factor(P<0.05) and ANA(P<0.01) were common in patients with neuropathy.

Conclusion: Neuropathy is not a rare manifestation of pSS. Prevalence of neurological involvement in pSS is 19.6%. Raynaud’s phenomenon and high disease activity may be the risk factors for neuropathy. Autoantibodies might contribute to the injury of the nervous system.

Clinic, IDIBAPS, Barcelona, Spain; 45H. CIMA- Sanitas, Barcelona, Spain

Objectives: To analyse how the age at diagnosis modifies the phenotype of primary Sjögren syndrome (SS). Methods: The Big Data Sjögren Project was formed in 2014 to take a high-definition picture of the main features of primary SS at diagnosis by merging international SS databases. By January 2019, the database included 11,420 patients from 24 countries of the 5 continents.

Results: Women (52.7 vs 54.6 yrs in men, p<0.001) and non-White patients (49.6 vs 53.5 yrs in Whites, p<0.001) were diagnosed at a younger age. Patients without sicca symptoms, with normal oral/ocular diagnostic tests and with positive biopsy were also diagnosed at younger ages (p<0.001 all comparisons).

REFERENCES:
Patients with positive immunological markers had a younger diagnostic age, except for cryoglobulins (p<0.001 all comparisons).

Patients without systemic activity (ESSDAI score = 0) were diagnosed at an older age (55.5 vs 52.1 yrs in those with systemic activity, p<0.001). There was a wide variation in the age at diagnosis of patients presenting with systemic activity according to the organ involved.

**Conclusion:** Age at diagnosis plays a key role in the glandular and systemic phenotype expressed by primary SjS patients at the time of diagnosis.

supplementation with omega-3 PUFAs might be beneficial. Omega-3 PUFAs can be metabolized to specialized pro-resolving mediators (SPMs) in inflamed tissues. PUFAs, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), give rise to protectins and E-series and D-series resolvins, respectively. These SPMs help promote tissue repair and healing in addition to reducing neutrophil infiltration.

**Objectives:** To investigate (1) if SPMs can be measured in lupus patient serum and plasma. Both EPA and DHA were significantly decreased in SLE patients compared to controls. (2) To evaluate if history of nephritis and disease activity were correlated with lower levels of PUFAs and some SPMs are associated with history of nephritis.

**Methods:** Blood samples were collected from 12 patients enrolled in the Autoimmune Disease Registry and Repository, a single center registry (1996-present) of patients meeting ACR SLE classification criteria. Samples were collected from 12 non-SLE-controls who were age (± 5 years) and race/ethnicity matched. Metabolomic profiling via tandem mass spectrometry (LC-MS-MS) was performed on serum and plasma to assess the PUFAs and SPM levels. Results: Levels of EPA and DHA were highly correlated in serum and plasma. Both EPA and DHA were significantly decreased in SLE patients compared to controls (Table 1). Neither plasma nor serum DHA or EPA levels was correlated with disease activity assessed by SLEDAI score. SPMs including D1 and RvE1 as well as their precursors, 17-HDHA and 18-HEPE, were identified in plasma and serum samples from SLE patients. Plasma levels of 17-HDHA, as well as serum levels of PD1, 17-HDHA, and 18-HEPE tended to be reduced in SLE (Table 1). The SLE patients with a history of nephritis had significantly lower levels of DHA (p<0.03), EPA (p<0.05), 18-HEPE (p<0.03), and 17-HDHA (p<0.04) than SLE patients without nephritis. Conclusion: SLE patients have lower levels of circulating EPA and DHA, the substrates for SPMs, relative to individuals without SLE. Lower levels of these PUFAs and some SPMs are associated with history of nephritis. Additionally, the levels of PD1, 17-HDHA, and 18-HEPE were measurable in SLE serum and plasma and tended to be reduced, especially in subjects with lupus nephritis. SPMs suppress the production of inflammatory mediators and promote resolution of inflammation. The lower levels of PUFAs and SPMs could contribute to the likelihood of developing lupus nephritis. Further evaluation of this relationship is warranted.

THU0280 SEXUAL FUNCTION IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE-CONTROL STUDY

**Griselda Serna-Peña**, Iris Jazmin Colunga-Pedraza, Miguel Angel Villarreal-Alarcon, Lila Cecilia Reynosa-Silva, Sergio Andrés Castillo-Torres, Dionicio Angel Galanar-Delgado, Hospital Universitario Dr José Eleuterio Gonzalez, Rheumatology, Monterrey, Mexico; 2Hospital Universitario Dr José Eleuterio Gonzalez, Neurology, Monterrey, Mexico

**Background:** Normal sexual function consists in the transition, during sexual activity, through the phases of excitement to relaxation without problems, and with a feeling of pleasure, satisfaction and fulfillment (1). The effect of systemic lupus erythematosus (SLE) in sexual function has been one of the least studied areas, but it is thought that some disease-related characteristics could have a negative effect. There are few previous studies that investigate sexual function in SLE, general results indicate a negative impact (2).

**Objectives:** The main aim of this study is to determine if there is an altered sexual function in Mexican women with SLE and compare it if it occurs in a greater proportion than in healthy women.

**Methods:** A case-control study with 102 Mexican women between 18 and 60 years, with SLE diagnosis (according to SLICC 2012 criteria) and a control group of healthy women (n=156) matched by age. Patients were excluded if they couldn’t answer the questionnaires reliably and pregnant women. They were asked about the presence of active sexual life in the last month and the Female Sexual Function Index (FSFI) self-questionnaire was applied. Variables between groups were compared with Chi-square and Mann U Whitney test.

**Results:** Baseline demographic characteristics between groups are shown in table 1. Women with SLE had less sexual activity, during the last month, than controls (63.7% vs 77.5%, p = 0.01). Out of the total women included, the FSFI was applied only to those that had an active sexual life, 65 with SLE and 121 healthy women. Sexual dysfunction (>26.5 points) was found in 28% women with SLE and in 22% of controls, with no significant differences (p=0.4). In the SLE group, a worse total score was found, as well as alteration in the desire and excitation domains when compared to healthy women (Table 2). In the multivariate linear regression analysis (using FSFI as the variable), no relationship was found with any demographic or disease-related variables.

Abstract THU0280 – Table 1. Comparison of demographic variables between the SLE and control group.

SALIVARY GLAND ULTRASOUND FINDINGS ARE ASSOCIATED WITH CLINICAL AND SEROLOGIC FEATURES IN PRIMARY SJÖGREN’S SYNDROME PATIENTS

Joana Silva1, Daniela Faria1, Joana Neves2, Marcos Cerqueira1, Joana Rodrigues1, Soraia Azevedo1, Sérgio Alcino1, José Tavares-Costa1, Carmo Afonso1, Daniela Peixoto1, Filipa Teixeira1.

Background: Primary Sjögren’s syndrome (pSS) is a multisystem immune-mediated disease characterized by hypofunction of salivary and lacrimal glands and possible multi-organ systemic manifestations. Over the past years, three sets of diagnostic criteria have been proposed, but none included salivary gland ultrasound (SGUS). However, SGUS has been recently applied for diagnosis and there are some reports regarding the correlation of SGUS findings with immunological and serological features in pSS patients (1, 2).

Objectives: To investigate the association of SGUS findings with clinical and analytical features of pSS patients.

Methods: A total of 54 patients diagnosed with pSS, fulfilling both the 2016 ACR/EULAR and 2002 AECG criteria for the disease, followed-up at our Rheumatology department, underwent SGUS evaluation. The par enchymal homogeneity of bilateral parotid and submandibular glands was graded using a score of 0 (normal) to 4 (gross inhomogeneity). Patients were classified into two groups according to the highest US score obtained. The grades 1 and 2 were considered to be normal and grades 3 and 4 to represent pathological SGUS findings. Demographics (age, sex and disease duration), European League Against Rheumatism Sjögren’s Syndrome Disease Activity Index (ESSDAI) and laboratory data (erythrocyte sedimentation rate, autoantibodies, rheumatoid factor, hypergammaglobulinemia, β2-microglobulin and complement levels) were collected and compared between the two SGUS groups.

Results: Differences between the group with pathological SGUS versus the group with normal SGUS are depicted in table 1. Multivariate logistic regression revealed that anti-SSB (OR = 6.6, 95% CI 1.7 to 25.8, p = 0.006) was independently associated with the presence of pathological features in SGUS.

Table 1. Comparison of demographics, clinical and serologic features of pSS according to SGUS.

</table>

Conclusion: In our study, pathological US findings were associated with higher disease activity and positivity for rheumatoid factor and anti-SSB. Additionally, anti-SSB antibody was strongly and independently associated with pathological US findings in the salivary gland of pSS patients. Further and larger studies are necessary to support these findings and include SGUS as part of the diagnostic criteria for Sjögren’s syndrome.

THU0282
ULTRASOUND FINDINGS IN THE SALIVARY GLANDS IN A COHORT OF PATIENTS WITH SUSPECTED SJÖGREN’S SYNDROME

Viktoria Fana, Uffe Møller Døhn, Lene Terslev, Rigshospitalet-Glostrup, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark

Background: Ultrasound has been shown to be a promising tool in the evaluation of salivary glands for parenchyma changes with the potential to improve diagnosis. The changes range from mild inhomogeneity of the glandular tissue to large vesicular changes almost eliminating all normal glandular tissue. American-European Consensus Group (AECG) classification criteria for SS are often used diagnostically (1).

Objectives: To describe ultrasound findings in salivary glands (SGUS) in a cohort of patients with suspected Sjögren’s syndrome (SS) and assess their positive and negative predictive value for the diagnosis.

Methods: 191 consecutive patients with suspected SS (ocular and/or oral dryness) referred to the department of Rheumatology between March 2017 and March 2018 were evaluated by SGUS as part of the initial evaluation. All had unstimulated sialometry, Schirmer’s test and laboratory test done (including autoantibodies (ANA screening, Rheumatoid factor and anti-cyclic citrullinated peptide, anti-Ro/SSA and anti-La/SSB), and screenings test for hepatitis B+C). In doubtful cases, a minor salivary gland (MSG) biopsy was performed. SGUS was performed with a GE Logiq E9 equipped with a linear ML6-15 probe and included grey-scale evaluation of the submandibular and parotid gland bilaterally. SGUS was considered abnormal when moderate to severe inhomogeneity with anechoic or hypoechoic areas was present in at least one gland.

Results: 63 patients were diagnosed with SS according to the AECG classification criteria - 57 patients with primary SS, 6 with secondary SS. 128 patients with sicca symptoms did not fulfill AECG criteria for SS and none were diagnosed with SS based on other parameters. Demographic data for the cohort is shown in table 1. 55 patients had MSG biopsy performed. The SGUS examination and evaluation was performed in less than 15 min per patient. The sensitivity of SS is 0.51 and the specificity 0.88; the PPV of SGUS for the SS diagnosis was 0.68 and the NPV was 0.78.

The sensitivity of SGUS for positive MSG biopsy was 0.29 and the specificity 0.82 – the PPV was 0.50 and the NPV was 0.65; for abnormal sialometry the sensitivity of SGUS was 0.32 and the specificity 0.82 – the PPV for SGUS was 0.64 and NPV was 0.55.

Table 2 shows the association between SGUS and final diagnosis, MSG biopsy and sialometry, respectively.

Background: Little is known about the patient related outcomes and disease activity in systemic lupus erythematosus. Damage and impact are issues that have not been associated with activity in lupus previously.

Objectives: In a large cohort of systemic lupus erythematosus (SLE) patients, to evaluate the association between a Patient Acceptable Symptoms State (PASS) and three different domains of the disease: activity, patients, PASS was associated with other domains of the disease: activity, impact and effect on patients life. PASS is a simple and reliable patient-reported outcome that can be a useful tool to evaluate patients well-being.

Conclusion: In the largest observational European Registry of SLE patients, PASS was associated with other domains of the disease: activity, impact and impact on patients life. PASS is a simple and reliable patient-reported outcome that can be a useful tool to evaluate patients well-being.

Uppsala University, Uppsala, Sweden; Eskisehir Jaime Calvo-Alen16, Osmangazi University Hospital, Eskisehir, Turkey; 3.Attikon University Hospital, Athens, Greece; 4.Rheumatology and Clinical Immunology Unit, Spedalì Civilì and University of Brescia, Brescia, Italy; 5.Centro Hospitalar de Lisboa Centro, Lisboa, Portugal; 6.University of Crete, Crete, Greece; 7.University of Pisa, Pisa, Italy; 8.Spedalì Civilì and University of Brescia, Brescia, Italy; 9.Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; 10.SWEedishSLENetwork, Stockholm, Sweden

Background: Detailed analysis of hematological manifestations are limited and their clinical impact on disease remain obscure.

Objectives: To scrutinize factors associated with different hematological abnormalities (HA) in SLE patients and their impact on infections, bleeding and damage accrual.

Methods: A dataset (GIPTSLE) originated from SLE patients in Europe was studied. The dataset consisted of six monthly visits of each patients for at least 2 years. Results were compared with another well-established SLE cohort from Sweden (Swedish SLE network). Patients in both cohorts fulfilled the ACR1997 SLE criteria. Variables collected at each visit included CBC, presence or absence of haemolytic anemia, all domains of SLEDAI\-2K, medications, infection or bleeding episodes, Systemic Lupus International Collaborating Clinics/ACR damage index (SDI), HA occurring at the beginning or during follow-up were defined according to the ACR criteria. HA was only considered in patients with no previous use of immunosuppressives or biologic agents at least 3 months before the first HA events. The Swedish confirmation cohort included all the variables of interest. We excluded all haematological domains from SLEDAI\-2K (SLEDAI) for the analysis. Based on six monthly change in SDI, each visit was labelled either “damage transition/or “non-damage transition”. Generalized estimating equations (GEE), multiple logistic regression, Chi-square test and independent samples t test were used where it was appropriate.

Results: Of the 1430 visits of 286 patients analysed from the first cohort (89.5% female, 95.8% Caucasian, 64.7% dsDNA positive) 60% had at least one HA. At the enrolment, the median (range) disease duration was 8 years (0-38), asSLEDAI\-2K was 6 (0-25) and SDI was 0 (0-6). Upon GEE analysis, lymphopenia was significant for SDI (OR=2.5, 1.0-5.9) Upon GEE analysis after further adjusting prednisolone exposure, HA found be significant for SDI was thrombocytopenia (OR=3.6, 1.04-12.1) but no significant evidence for the dependence of this relationship on time. The effect of lymphopenia was attenuated. HR for bleeding was significant when platelets were below 50K (HR=2.6, 1.15-6.1) Of the 1395 patients when platelets were below 50K (HR=2.6, 1.15-6.1) Of the 1395 patients analysed from the second set (86.8%female, 93.0% Caucasian, 61.6 dsDNA positive), 63.4% had HA. At the last visit, the median (range) disease duration was 14 years (1-65) and SDI was 0 (1-14). Upon multiple regression analysis after adjusting age, sex and prednisolone exposure both thrombocytopenia (OR=2.2, 1.3-3.6) and lymphopenia (OR=1.8, 1.2-
UMBILICAL ARTERIAL DOPPLER ULTRASONOGRAPHY PREDICTS LATE PREGNANCY OUTCOMES IN PATIENTS WITH LUPUS NEPHRITIS: A Multicenter Study From Southern China

zhongping zhan1, Dongying Chen1, Shiwen Yuan2, Xiaodong Wang3, Yanteng Zhan4
1The First Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology, Guangzhou, China; 2Guangzhou First People’s Hospital, Department of Rheumatology, Guangzhou, China; 3The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Department of Ultrasound, Guangzhou, China; 4The First Affiliated Hospital of Sun Yat-sen University, Department of Obstetrics and Gynecology, Guangzhou, China

Background: Compared with the general population, patients with lupus nephritis (LN) are still at high risk of adverse pregnancy outcomes (APOs). Umbilical artery is the last vessel upstream of the placenta and is particularly important for placental perfusion and foetal development. Increased umbilical artery resistance could be traced by Doppler velocimetry, which is frequently related to pre-eclampsia, intrauterine growth restriction (IUGR), and foetal distress. Umbilical artery Doppler is used as a screening tool for placenta-related diseases in the general population. However, the predictive value in complications of LN pregnancies has not been widely assessed.

Objectives: To investigate the fetal adverse pregnancy outcomes (APOs) and the predictive value of umbilical arterial Doppler ultrasonography in the third trimester in pregnant women with LN.

Methods: A retrospective cohort study enrolling 203 LN patients with pregnancies from 2007 to 2017 from three centers was performed. These patients received umbilical arterial Doppler ultrasound examination during 28-34 gestational weeks. Doppler velocity waveforms of the umbilical arteries were assessed with resistance index (RI), systolic-diastolic ratio (S/D) and pulsatility index (PI).

Results: Fetal APOs occurred in over half of the patients (103/203, 50.7%). Sixty-six pregnancies (66/203, 32.5%) ended with preterm births. The incidence rate of IUGR was 18.2% (37/203). Fetal distress was noted in 23 pregnancies (23/203, 11.3%). All the Doppler parameters were higher in patients with IUGR, fetal distress and composite APOs than in patients without any APOs. Patients with IUGR and fetal distress had significantly higher values of PI, RI and S/D. It was noted that PI, RI and S/D was higher in patients with premature delivery than those with full-term delivery. However, only the difference of RI and S/D reached statistical significance. RI indicated the highest risk of IUGR and composite APOs. The cut-off values were 0.66 and 0.67, respectively. Sensitivities were 51.4% and 33.7%, and specificities were 87.4% and 92.1%. S/D was also a best predictor for IUGR, with the optimal cut-off value of 2.88. Sensitivity and specificity were comparable with RI. PI over 0.84 was an ideal indicator for fetal distress with an optimal combination of sensitivity (89.5%) and specificity (51.6%).

Conclusion: Fetal complications were frequent in patients with LN. Umbilical arterial Doppler ultrasonography was a useful measure to predict late IUGR, fetal distress and the composite APOs.

ANEURYSM IN BEHÇET’S DISEASE: MANAGEMENT, PROGNOSIS AND MORTALITY

Berkan Armagan,1 Ertuşğan Çağrı Bölek2, Alper Sarı1, Gözde Kübfa Yardımcı1, Bayram Farsızoğlan1, Emre Bilgin1, Fatma Gonca Eldem2, Levent Kılıç3, Omer Karadayı4, Bora Peynircioğlu1, Barbaros Erhan Çil2, Metin Demircin3, Ali Akdoğan1, Sule Araş Bilgen1, Ali İhsan Ertenli1, Sedat Kiraz1, Umut Kalyoncu1, Bayram Farisoğlan1, Carmen Carrasco-Cubero1, Julio Sánchez, Santos Castañeda, Lara Sánchez-Bilbao1, Iñigo González-Mazón1, Monica Calderón-Gorbeck, D. Prieto-Peña1, Miguel Á. González-Gay, Ricardo Blanco2.

Abstract THU0287

Background: Arterial aneurysms are one of the unique features of Behçet’s disease (BD). Although arterial aneurysms are relatively rare, they carry risk of rupture and have poor prognosis.

Objectives: To evaluate the medical and interventional therapies and long-term outcomes of BD patients with extracranial arterial aneurysms.

Methods: We retrospectively reviewed the medical records of 441 BD patients according to ISG criteria between 2013 and 2018 at the Hacettepe University Vaşcitsus University (HUVAC). We determined 45 BD patients with an arterial aneurysm. Six patients with isolated carotid and/or cranial arterial aneurysms who were followed by other clinics excluded from the analysis. Overall, 39 BD patients with an extracranial and extra cranial arterial aneurysm included in the study. Data regarding demographic characteristics, clinical, laboratory and vascular imaging findings, history of medical treatments and outcomes were collected. Vascular intervention of patients were grouped as surgery or endovascular intervention. Radiological response after vascular intervention divided into 3 groups as regression, stable and progression according to radiological evaluation. Regression was defined as a decrease or disappearance of the aneurysm. Stable was defined as no change in the aneurysm diameter. Progression was defined as an increase in diameter of a previous aneurysm or occurrence of a new vascular event. We colligated the stable and regression groups and compared with the progression group. Relapse was defined the progression of the aneurysm which underwent an intervention.

Results: A total of 39 BD patients (Male, 80%) with an arterial aneurysm were analyzed in this study. Mean age and mean age of diagnosis patients were 40.8±11.0 and 29.7±7.7 years, respectively. The clinical features of BD was as follows; oral ulcer 100%, genital ulcer 80.6%, acneiform lesion 47.2%, erythema nodosum 33.3%, pathergy positivity 34.5%, arthritis 27.8%, fever 24.3%, uveitis 34.5%, neurological involvement 30.6% and gastrointestinal involvement 7.7%. Distribution of arterial aneurysms was 51% subclavian, 51% coronary artery & cardiac, 38.8% pulmonary, 10.3% thoracic aorta, 33.3% abdominal aorta, 5.1% renal, 25.6% iliac and 12.8% femoral. Induction and maintenance treatments are characterised in Table 1. Distribution of arterial involvement was as follows; carotid 34.5%, arthritis 27.8%, fever 24.3%, uveitis 34.5%, neurological involvement 30.6% and, gastrointestinal involvement 7.7%. Distribution of arterial involvement was as follows; carotid 34.5%, arthritis 27.8%, fever 24.3%, uveitis 34.5%, neurological involvement 30.6% and, gastrointestinal involvement 7.7%.

Conclusion: Arterial aneurysms in BD have poor prognosis and high mortality. Glucocorticoids, cyclophosphamide and interferon-α are the most preferred treatments for induction and maintenance therapy for aneurysm of the BD. Approximately 2/3 of the patients required a vascular intervention. Clinical and radiological progression was more prominent in the aorta and its branches. As expected, there is more progression in interventional procedures without medical treatment.

LONG-TERM FOLLOW-UP OF ANTI-IL-6-RECEPTOR TOCILIZUMAB IN REFRACTORY UVEITIS IN PATIENTS WITH BEHÇET’S DISEASE. MULTICENTER STUDY OF 14 PATIENTS IN CLINICAL PRACTICE

Background: Ocular involvement in Behçet’s disease (BD) is a potential severe and disabling complication. Anti-TNF-α agents have shown an improvement of visual outcome in BD-related uveitis refractory to conventional immunosuppressive (IS) drugs. However, these drugs do not achieve control of intraocular inflammation in all patients or are not well tolerated. Tocilizumab (TCZ) has shown efficacy in different refractory ocular inflammatory diseases.

Objectives: To assess the efficacy of long-term therapy with TCZ in refractory uveitis associated to extraocular manifestations (EOM) due to BD.

Methods: Multicenter study of patients with BD refractory to standard systemic therapies.

Results: We followed up 14 patients (9 men/5 women) (26 affected eyes); mean age 40.8±19.5 years. Pattern of ocular involvement: panuveitis (10); 4 with retinal vasculitis), anterior (3) and posterior (1) uveitis; 8 recurrent and 6 chronic; 9 with cystoid macular edema. At TCZ onset, the following EOM were present: oral and/or genital ulcers (10), arthritis (10), folliculitis/pseudofolliculitis (6), erythema nodosum (5), intestinal affection (1) and neurological involvement (3). Before TCZ, they had received corticosteroids (13 intraocular, 12 oral and 1 iv), conventional IS drugs and biologic agents: methotrexate (11), cyclosporine (8), azathioprine (10), colchicine (1), cyclophosphamide (2), mycophenolate mofetil (1), adalimumab (10), infliximab (6), golimumab (3), canakinumab (1), or etanercept (1). TCZ was used in monotherapy (7) or

Abstract THU0288 – Table 2.

Table 2. Figure 2. Evaluation of response according to vascular intervention and induction treatments.

** TCZ was used in monotherapy due to previous intolerance.
combined with conventional IS drugs (7) at 8 mg/kg/iv/4 w (11) or 162 mg/sc/w (3). 

Objectives: The aim of this study was to assess the persistency rate of MCS-related clinical and laboratory indexes after successful treatment with DAA.

Methods: CRESO (Cryoglobulinemia Eradication Study Observational) is a multicentre observational study promoted by the Italian Society of Infectious and Tropical Diseases (SIMIT) and the Italian Group for the Study of Cryoglobulinemias (GISC), aimed to assess the impact of DAA therapy on MCS symptoms and cryoglobulin production. Patients could be enrolled if they presented, during the 12 months before the enrolment, a cryocrit >0.5% and, at least, one episode of palpable purpura or, alternatively, arthralgia and fatigue with at least one symptom among peripheral neuropathy, Raynaud’s phenomenon, lower limb ulcers or nephropathy, and a C4 level <8 mg/dL.

Results: The present analysis was based on clinical and laboratory data of 94 patients (75.5% female with a median age of 67.5 years) that have been followed up for a median time of 24 weeks (IQR 12-24) after SVR12 achievement. At baseline the cryocrit was frankly positive in 85 (90.4%), detectable (>0.5%) in 4 and negative in 4 cases; patients with type II cryoglobulins and C4 levels <8 mg/dL were prevalent, respectively, with 81.5% and 75.9%. Low eGFR values (<45 mL/min/1.73m²) were present in 12 cases (12.8%), 10 patients (10.6%) had a history of B-cell non-Hodgkin’s lymphoma (NHL), and 1 of hepatocellular carcinoma, while liver cirrhosis was diagnosed in 22 cases (23.4%) and glomerulonephritis in 17 cases (18.1%). Patients were treated for 12 (72 cases) or 24 (21 cases) weeks with a total of ten different IFN-free DAA regimens. SVR12 was achieved in all 94 cases. Both prevalence and median cryocrit values decreased significantly after DAA treatment (p<0.0001), however, at the time of the last observation 56.4% of patients were still positive for MCS. The prevalence of purpura and fatigue significantly decreased (p<0.0001) as well sicca syndrome prevalence (p<0.015), while arthralgia and lower limb ulcers decrease did not reach statistical significance. In multivariate analysis, eGFR<45 mL/min/1.73m² was an independent predictor of persistence of cryoglobulin production (AOR 7.7, CI 95% 1.6-37.2; p=0.011). 

Conclusion: CRESO study data confirm the persistence of cryoglobulin production and MCS symptoms in some patients, despite the eradication of HCV. This finding rises questions about the possible further evolution of the disease over time regardless the persistency of its original trigger.

THU0290

DISEASE AND TREATMENT-RELATED MORBIDITY IN YOUNG AND ELDERLY PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Alvise Bert1, Mara Felicetti2, Sara Monti3, Augusta Orlotan3, Roberto Padovan3, Giuliano Brunoni4, Roberto Bortoloti4, Roberto Caporalì5, Carlomaurizio Montecucco6, Franco Schiavon7, Giuseppe Paolozzi7, Santa Chiara Hospital, Rheumatology, Trento, Italy; 6University of Padua, Rheumatology, Padua, Italy; 7University of Padua, Rheumatology, Padua, Italy

Background: Advancing age may be a risk factor for morbidity in antimalarials (ANCA)-associated vasculitides.

Objectives: We aimed to compare the rates and better characterize the type of disease- and treatment-related complications affecting young and elderly patients with AAV.

Methods: All new cases of granulomatosis with polyangiitis or microscopic polyangiitis diagnosed between 2000 and 2016 in referral centers in Northern Italy were included. Patients were stratified by age into young or elderly (<65 years old). Data were collected from time of diagnosis until end of follow-up, with scheduled annual visits or additional visits in case of relapse or complication requiring hospitalization.

Results: Of 141 patients included, 99 were young and 42 elderly at the time of AAV diagnosis. Median follow-up was 58.0 months (25-75% IQR, 31.0-60.0) in young and 48.0 months (25-75% IQR, 23.25-60.0) in elderly patients (p=0.05).

Overall, total chronic damage assessed by Vasculitis Damage Index (VDI) significantly increased in elderly patients compared to young ones during follow-up (+0.28, p<0.05). Although rates of the most common complications scored in the VDI (i.e. arterial hypertension, heart failure, ischemic cardiac vascular complications, diabetes, and malignancy) accumulated over time when analyzed singularly, no difference between the two age groups was observed (p>0.05). Sixty-three (44.7%) patients had acute kidney injury due to AAV-glomerulonephritis at diagnosis, 37 were young and 26 were elderly. In these patients, renal function recovery in the first 6 months was significantly lower for elderly (median 2eGFR (25-75% IQR), 5.3 (0.4-14) mL/min/1.73m² compared to young patients (22.8 (5.9-52.1) mL/min/1.73m², p=0.008) while on induction treatment. Stratification for
ANCA status (MPO-ANCA+ versus PR3-ANCA+), did not change these results. Despite similar immunosuppressive therapy approaches and relapse rates, elderly patients had a higher rate of severe infections compared to younger patients (OR 2.1, 95% CI: 1.1-4.4, p=0.043; Figure below).

Conclusion: Our findings indicate that elderly patients had higher susceptibility to morbidity related to vasculitis or its treatment than younger patients, particularly to worst renal function recovery and higher infection rate.

Conclusion: This is the largest cohort of pediatric BD reported to date. The disease manifestations and disease activity significantly differ among pediatric BD patients from Turkey and Israel which emphasizes the effect of the ethnicity on disease phenotype.

REFERENCE:

Disclosure of Interests: Yonatan Butbul: None declared, Ezgi Deniz Batu: None declared, Hatife Emine Sonmez: None declared, Betül Sözeri: None declared, Nuray Alçak Ayaz: None declared, Gil Amariylo: None declared, Seval Simsek: None declared, Liora Harel: None declared, Betül Bilginer: None declared, Seza Özen Consultant for: Seza Ozen is receiving consultancy fees from Novartis, Speakers bureau: Roche.

**Objectives:** In a series of patients with GCA who presented extracranial vessel involvement, our aim was to assess a) the vascular territories most frequently affected and b) correlation of a major extension of extracranial vascular involvement with a more severe clinical and analytical features.

**Methods:** Multicenter study of 68 patients with GCA who presented a compromise of extracranial vessels confirmed by PET/CT. Visual analysis of vascular uptake was performed on supra-aortic trunks (SAT), aortic arch (AA), thoracic aorta (TA), abdominal aorta (AbA), iliac arteries (IA), lower limb arteries (LLA), and upper limb arteries (ULA).

**Results:** We evaluated 68 patients with GCA (51±17m) with a mean age of 68±8.3 years. The vascular territories affected were: TA (n=58, 85.29%), SAT (n=38, 55.88%), AbA (n=28, 41.18%), AA (n=18, 26.47%), LLA (n=17, 25%), IA (n=13, 19.12%) and ULA (n=6, 8.82%). We considered 3 groups according to the number of vascular territories affected: a) 1 or 2 territories, b) 3 or 4 territories and c) 5 or more territories and made a comparative study between this groups. In patients with ≥5 vascular territories affected, we observed a higher baseline ESR, and the most frequent systemic manifestations were polymyalgia rheumatica and constitutional symptoms with statistical significance (TABLE). Distribution of categorical variables was compared by the Pearson Chi-squared test. Quantitative variables were analyzed using the ANOVA test.

**Conclusion:** In patients with GCA the involvement of TA is very frequent, followed by the SAT and the AbA. Regarding the laboratory findings, patients with higher levels of ESR presented a major extension of extracranial vascular involvement, as well as presenting PMR and/or constitutional symptoms was also related to more affection of extracranial territories.

TREATMENT PATTERNS, DISEASE BURDEN AND OUTCOMES IN PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA

Gary Craig1,2, Keith Knapp2, Bob Salim3, Shalini Mohan4, Margaret Michalska2,4
1Arthritis Northwest, Spokane, United States of America; 2Discus Analytics, Spokane, United States of America; 3Axio Research, Seattle, United States of America; 4Genentech, Inc., South San Francisco, United States of America; 5Genentech, Inc, South San Francisco, United States of America

Abstract THU294

Background: For patients with giant cell arteritis (GCA) and/or polymyalgia rheumatica (PMR), glucocorticoids are the mainstay of treatment. However, due to the chronic nature of these diseases, patients may require continued glucocorticoid treatment to achieve treatment targets or prevent disease relapse, over time resulting in high cumulative doses and associated adverse events.

Objectives: To assess patterns of glucocorticoid use and outcomes in patients with GCA, PMR or both.

Methods: This retrospective cohort study used electronic medical records from a single US community-based rheumatology clinic utilizing the Joint-Map rheumatology software application. Patients age ≥ 50 years with a diagnosis of either GCA or PMR and ≥ 1 entry for glucocorticoid following the diagnosis were included and followed until lost to follow-up or the end of the study period (30 Nov 2017). The index date was defined as the date of first glucocorticoid prescription received at or after the earliest GCA or PMR diagnosis date. Outcomes at 2 years included the proportion of patients achieving remission (defined as not receiving steroids for ≥ 6 months), time to remission, persistence of remission (defined as not receiving steroids for ≥ 6 months and still not receiving steroids at 2 years) and prednisone dose at follow-up, and were compared between patients with GCA only, PMR only or both GCA and PMR. P values are reported using F-test (ANOVA) for continuous variables and Chi-squared test for categorical variables.

Results: We identified 81 patients with GCA only, 779 with PMR only and 97 with GCA and PMR. Mean (SD) age was 70.0 (9.1) years; 64.2% were women. Mean (SD) daily prednisone dose at the index date was 46.7 (30.9) mg for patients with GCA only, 20.1 (14.2) for PMR only and 29.0 (23.4) for patients with both GCA and PMR. Two years after the index date, 32% of patients with GCA only, 32% with PMR only and 27% with GCA and PMR had achieved remission; 17%, 23% and 18% were in persistent remission, respectively (Table 1), with no significant differences between groups. Among patients who achieved remission, overall median time to first remission was 202.5 (0-635) days and was shorter for patients with both GCA and PMR (157 [0-619] days) vs GCA (213 [0-577] days) or PMR (203.5 [0-635] days) only. Kaplan-Meier estimates of time to remission for each group are shown (Figure 1). Most patients required a daily prednisone dose at 2 years, with similar doses observed between groups (Table 2).

Conclusion: Patients with either GCA and/or PMR are exposed to significant doses of prednisone. In this study, fewer than one-third of patients with GCA and/or PMR achieved remission; the majority of patients continued to require prednisone therapy for at least 2 years after its initiation. These data highlight the need for the use of more efficacious and steroid-sparing therapies in patients with GCA and/or PMR.

POLYMYALGIA RHEUMATICA ASSOCIATED WITH GIANT CELL ARTERITIS CONFIGURES A SUBTYPE WITH LOWER MORTALITY WITHIN GIANT CELL ARTERITIS

Carmen de Frutos Fernández1, Maria Angeles Martinez Huedo2, Irene Monjo3, Ezequiel de Miguel4, Carmen de Frutos Fernández5, 1Medicine Student Universidad Autónoma de Madrid. Rheumatology service, Hospital Universitario la Paz-IDiPaz., Madrid, Spain; 2U. Docencia e Investigación. Hospital Universitario La Paz. Madrid, Madrid, Spain; 3Rheumatology service, Hospital Universitario la Paz-IDiPaz., Madrid, Spain

Background: Giant cell arteritis (GCA) is the most frequent systemic vasculitis in older than 50 years old, with marked general state involvement or ischemic phenomena that can cause blindness to the patient’s death. Its form of presentation is heterogeneous however the therapeutic approach tends to be homogeneous. In recent years, the possible existence of subtypes of the disease has been pointed out and this can have important repercussions in the prognosis and approach of the disease. Two studies have suggested that the coexistence of GCA and Polymyalgia rheumatica (PMR) identifies a subgroup of patients at low risk for developing cranial ischemic symptoms. However, this was refuted by three other studies that did not find that effect.

Objectives: To study if, excluding the articular manifestations, the GCA against the association of PMR with ACG presents a phenotype with clinical differences relevant in clinical practice.

Methods: Retrospective observational study based on data from the Data-base of Hospital from the Spanish National Health Service with primary or secondary diagnostic of GCA between January 1st, 2005 and December 31st, 2015. In this substudy the data demographics and comorbidities and mortality, presenting patients with GCA were collected and compared with patients with GCA and PMR.

Results: The study cohort included 29.576 patients with GCA, of whom 4.189 had PMR as an associated diagnosis. The comorbidities associated with ACG and ACG/PMR and the statistical significance of the differences can be seen in the table. As a relevant fact, a lower risk of mortality was observed in patients presenting GCA along with PMR (OR 0.682 [95% CI 0.581-0.801]) and a lower frequency of cerebrovascular events and ischemic optic neuropathy.

Correlations Among Vascular Ultrasound Abnormalities of the Temporal and Large Arteries in Giant Cell Arteritis

Michael Dilorio1, Piotr Sobieszczynski2, Julia Ford1, William Docken1, Sara Tedeschi1.
1Bingham and Women’s Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; 2Bingham and Women’s Hospital, Division of Cardiovascular Medicine, Boston, United States of America

Background: Vascular ultrasound (VUS) is a sensitive and specific method for evaluating giant cell arteritis (GCA). Understanding patterns of temporal artery (TA) and large artery involvement may be important for aiding in diagnosis.

Objectives: To determine correlations among VUS abnormalities in patients with GCA.

Methods: We performed a retrospective study among 503 patients that underwent VUS to evaluate suspected or known GCA at an academic medical center, 2013-2017. Demographics, clinical features, VUS reports, and pathology data were extracted through electronic medical record review. Trained cardiovascular sonologists imaged the right and left temporal, common carotid (CCA), subclavian (SCA), and axillary (AXA) arteries. The superficial temporal arteries (STA) and their frontal (TA-F) and parietal (TA-P) branches were abnormal if halo sign or hyperechoic wall thickening was present; the CCA, SCA, and AXA were abnormal if those findings and/or stenosis or occlusion were present. Cardiovascular medicine physicians trained in VUS interpreted studies as acute arteritis, no arteritis, or hyperechoic wall thickening without acute arteritis. Among patients diagnosed with GCA by the treating physician (n=139), we determined correlations between abnormal vessels using phi coefficients (φ).

Results: Among 139 patients, 50% were diagnosed before VUS (median disease duration 17 months). Median age at VUS was 73 years; 75% were female and 93% White. Forty patients (29%) had TA biopsy-proven GCA; an additional 14 (10%) had biopsy-proven giant cell arteritis. Prevalence of abnormalities of TAs and large arteries were similar (20% of right and 27% of left TAs; 20% of right and 24% of left large arteries). VUS was consistent with acute arteritis in 32%, no arteritis in 53%, and hyperechoic without acute arteritis in 15%. Abnormalities in the STA, TA-F, and TA-P were moderately correlated ipsilaterally (φ = 0.46-0.62, p<0.0001) and contralaterally (φ = 0.51-0.58, p<0.0001) (Table). Abnormalities in the AXA and SCA were strongly correlated with the ipsilateral and contralateral AXA and SCA (φ = 0.64-0.82, p<0.0001). Correlation between right and left TAs was moderate (φ = 0.59, p<0.0001), while a stronger relationship was found between right and left large arteries (φ = 0.77, p<0.0001). Abnormalities in TAs were not correlated with large arteries (φ = 0 for all comparisons; not significant).

Conclusions: We observed moderate correlations of TA branches and strong correlations of large artery branches on VUS among GCA patients. Abnormalities in the TAs and large arteries were not correlated, under-scoring the importance of scanning both groups of vessels with VUS.

Table. Notable correlations between abnormal arteries on VUS among 139 GCA patients

Steroid Treatment May Improve Arterial Stiffness in Patients With Polymyalgia Rheumatica and Giant Cell Arteritis: A Prospective Cohort Study

Amir Emamifar1,2,3, Torkell Ellingsen4, Søren Hess5,6, Per Syrak Hansen2, Inger Marie Jensen Hansen2, Peter Thye-Rønn1,2. 1University of Southern Denmark, Clinical Research, Odense, Denmark; 2Svendborg Hospital, Diagnostic Center, Svendborg, Denmark; 3Svendborg Hospital, Rheumatology, Svendborg, Denmark; 4Odense University Hospital, Rheumatology, odense, Denmark; 5Hospital of Southwest Jutland, Radiology and Nuclear Medicine, Esbjerg, Denmark; 6University of Southern Denmark, Regional Health Research, Odense, Denmark

Background: Polymyalgia rheumatica (PMR)/Giant cell arteritis (GCA), common inflammatory diseases, are associated with increased risk of aortic stiffness, possibly due to an inflammatory process.1,2

Objectives: To evaluate the effect of steroid treatment on aortic stiffness in patients with PMR/GCA.

Methods: This is an ongoing 1-year prospective cohort study. 37 consecutive patients with newly diagnosed PMR/GCA were included. Aortic pulse wave velocity (PWV) and aortic augmentation index normalized to heart rate of 75 beats per minute (Aix@75) were measured at baseline and subsequently at 1st and 4th months of treatment initiation with oral prednisolone.

Results: Of 37 patients, 3 pts. were excluded from the study because of lack of interest or a change in the initial diagnosis. Of all included pts. 61.8% were female and mean age was 71 (69-74) years. At diagnosis, 24 pts. presented with pure PMR symptoms, 2 pts. with pure cranial GCA, 8 pts. with concurrent PMR and GCA. The mean of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) at baseline were 62.3±22.9 and 46.4±43.7, respectively. Aix@75 was significantly decreased after 4 months of treatment initiation (from 62.1±11.6 to 19.5±11.5, p=0.016). Though aortic PWV was decreased after 4 months of treatment initiation (from 12.3±2.4 to 11.6±2.4), the results was not statistically significant (p=0.070). We did not find any significant changes at 1st month, nor in aortic PWV neither in Aix@75.

Conclusion: Steroid treatment may improve arterial stiffness in PMR/GCA patients due to suppression of the inflammatory process. However this is a time consuming effect and may not be seen as early as the first month.

References:
Objectives: The aim of this study is to highlight the magnitude of this existing manifestations. Several patients initially have few of these manifestations, but were followed and treated for manifestations strongly suggesting Behçet's syndrome by surveying the frequency, presentation patterns and outcome of patients who did not fulfill ISG criteria when they presented to our clinic, but were followed and treated for manifestations strongly suggesting BS.

Methods: We conducted a retrospective chart review of all BS patients who were registered between 2003 and 2008. Among these 2385 patients, 199 (8%) BS patients who did not fulfill ISG criteria at their initial visit were included in this study. Patients were called and a standard form was used for collecting demographic characteristics, BS manifestations at initial visit and during follow-up and treatment.

Results: Among the 199 patients (M/W: 90/109, mean age: 34 ± 11 years) who did not fulfill ISG criteria when they presented to our clinic, 70 (35%) had major organ involvement. The types of major organ involvement that led to a diagnosis of BS at initial visit despite not fulfilling ISG criteria were eye involvement in 37, vascular involvement in 29 (venous thrombosis in 22, arterial aneurysms in 7), nervous system involvement in 3 and gastrointestinal (GI) involvement in 1 patient. Thirty-five patients (18%) had a family history of BS. Of 199 patients, 167 had at least one more visit with a median follow-up of 11 years (IQR: 7-12). We were able to contact 116 of these patients and saw that 73 had fulfilled ISG criteria in the meantime. Among the 51 patients that we were not able to contact, 17 had fulfilled criteria while they were being followed in our clinic. Thus, a total of 70 (42%) patients fulfilled ISG criteria after a median follow-up of 1.5 years (IQR: 1-4.25). All but 2 patients who developed eye involvement during the follow-up had fulfilled ISG criteria with a new mucocutaneous manifestation. After a median follow-up of 4 years (IQR: 1-7), 23 (14%) patients had developed at least one non-criteria BS manifestation, including vascular involvement in 10, arthritis in 13, neurologic involvement in 2 patients and GI involvement in 1 patient. Among the 81 patients who developed at least one new manifestation, 16 (20%) were under immunosuppressive or interferon-alpha treatment at the time they developed their new manifestation. The remaining 65 patients had only received colchicine. Among the 29 patients who had vascular involvement at initial visit, 7 (24%) had a vascular relapse at different vascular site. Three patients had another rheumatologic diagnosis (ankylosing spondylitis, seropositive rheumatoid arthritis and sarcoidosis) at the end of the follow-up.

Conclusion: In our 10-year follow-up cohort study, 42% of the 167 incomplete BS patients had fulfilled ISG criteria within a median duration of 1.5 years. Sixty-two (37%) of these had major organ involvement that could have caused severe morbidity and mortality if the diagnosis of BS was missed and patients were untreated.

IMPACT OF VASCULAR ULTRASOUND ON EVALUATION OF GIANT CELL ARTERITIS AMONG 503 PATIENTS IN AN ACADEMIC MEDICAL CENTER

Julia Ford1, Michael DiStazio2, William Docken3, Piotr Sobieszczynski4, Sara Tedeschi1.
1Brigham and Women’s Hospital, Department of Medicine, Division of Rheumatology, Allergy and Immunology, Boston, United States of America;
2Brigham and Women’s Hospital, Department of Medicine, Division of Cardiovascular Medicine, Boston, United States of America

Background: As vascular ultrasound (VUS) is increasingly used in evaluation of giant cell arteritis (GCA), its impact on clinical care is of great interest.

Objectives: To describe utilization of VUS in GCA evaluation at a large academic medical center and investigate impact of VUS on clinical impression.

Methods: We performed a retrospective cohort study of patients who underwent VUS at a single center in Boston, 2013-2017, to evaluate suspected or known GCA. Trained cardiovascular ultrasound technicians used a standardized protocol to image the temporal, carotid, subclavian, and axillary arteries for presence of hypoechoic circumferential wall thickening (halo sign), hypeechoic wall thickening, stenosis, and occlusion. VUS images were interpreted by trained cardiovascular medicine physicians as consistent with acute arteritis ("acute"), no evidence of arteritis ("none"), or hypeechoic wall thickening without halo sign ("hypeechoic"). Demographic, laboratory, medication, pathology and clinical data including the treating physician’s clinical suspicion for GCA pre- and post-VUS were obtained by electronic medical record review. Fisher’s exact test and Wilcoxon rank-sum tests compared baseline characteristics among patients with VUS positive for acute arteritis ("acute") vs. negative for acute arteritis ("none" or "hypeechoic"). We compared the treating physician’s pre- and post-VUS clinical suspicion for GCA among patients with no history of GCA or aneurysms.

Results: We identified 503 patients with median age 70.4 years; 69.0% were female and 87.5% White. VUS interpretation was acute in 48 patients (9.5%), none in 427 (84.9%), and hypeechoic in 28 (5.6%). Baseline characteristics are presented in Table 1. Weight loss, cranial symptoms, higher ESR, and steroid use were more common in patients with VUS positive for acute arteritis. Change in the treating physician’s clinical suspicion for GCA in 73/95 (77%) cases, and VUS negative for acute arteritis lowered suspicion for GCA in 303/396 (77%). Of 110 patients with a temporal artery biopsy after VUS, 16 (14.6%) biopsies showed active arteritis; 11 of these were in patients with VUS negative for acute arteritis.

Conclusions: VUS result changed the clinical suspicion for GCA in approximately 75% of patients in this large cohort.

Table 1. Characteristics at the time of VUS

SPLENIC INVOLVEMENT IS NOT RARE IN ANCA-ASSOCIATED VASCULITIS HOWEVER SPLENIC INFARCT MIGHT ONLY BE ASSOCIATED WITH GRANULOMATOSIS WITH POLYANGIITIS

Önay Gerçik1, Şebnem Karasu2, Dilek Solmaz1, Zeki Soyapaçak3, Fulya Çakalağaoğlu1, Servet Akar1,2. Izmir Katip Celebi University Faculty of Medicine, Rheumatology, Izmir, Turkey; Izmir Katip Celebi University Faculty of Medicine, Radiology, Izmir, Turkey; Izmir Katip Celebi University Faculty of Medicine, Nephrology, Izmir, Turkey; Izmir Katip Celebi University Faculty of Medicine, Pathology, Izmir, Turkey

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a systemic necrotizing vasculitis of small and medium-sized arteries. Although, upper and lower respiratory tracts and kidneys are predominantly affected; other organs/systems can also be involved in the course of the disease and in some cases, it might be difficult to differentiate subgroups based on the clinical presentation. Splenic involvement has been rarely reported, mainly in patients with granulomatosis with polyangiitis (GPA), in fact, it was thought to be underestimated, as it is often asymptomatic.

Objectives: In this study, we aimed to investigate systematically the frequency of splenic infarct and related factors in our AAV patients. We also evaluated the role of splenic involvement in the differentiation of AAV subgroups.

Methods: Patients with a diagnosis of AAV in whom abdomen/thorax computed tomography (CT) was performed were included in the study. An experienced radiologist examined CT images for the presence of splenic involvement. The clinical and demographic data were retrospectively collected.

Results: In total 70 (30 [43%] female and mean age 56.1 ± 15.7 years) AAV patients (38 [54%] had granulomatosis with polyangiitis (GPA); 20 [29%] microscopic polyangiitis; 11 [16%] renal-limited disease and 1 [1%] eosinophilic granulomatosis with polyangiitis) were included in the analysis. Splenic pathologies including splenomegaly, hypodense lesion/s, lobulation, and infarction were seen in 21 (30%) patients with AAV. Splenic infarct was observed in seven (10%) patients and all had GPA with renal involvement and PR3ANCA positive. Three of them had total splenic infarct or auto-splenectomy. None of these patients had a history of endocarditis, shock or malignancy before CT. Splenic infarction was found to be negatively correlated with age at diagnosis (p=0.017; rho=–0.285), and positively associated with ENT (ear-nose-throat) (p= 0.002; rho=0.370) and eye involvements (p=0.013; rho=0.324).

Conclusion: Our results show that splenic pathologies might not be rare in AAV however, infarction can help to separate GPA from other AAVs. In young GPA patients, in particular, those with ENT and eye involvement, physicians should remember splenic infarction. Since almost half of our cases had severe infarction or auto-splenectomy, clinicians might consider immunization in GPA patients for vaccine-preventable infections.

OUTCOMES OF PREGNANCY IN BEHCET’S DISEASE

Zemfrira Alekberova1, Regina Golova2, Alexander Lita2, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia., Moskow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia., Moskow, Russian Federation

Background: Behcet’s disease (BD) is multisystemic disease of unknown cause. The relationship between BD and pregnancy is reported in limited number of studies.

Objectives: To evaluate outcomes of pregnancies in BD patients (pts).

Methods: We retrospectively collected data of 22 women with BD diagnosis (according to ISGBD 1990 and ICBD 2014) and their 68 pregnancies. Pts’ mean age was 30 [26;35] yrs, disease duration 7 [2;10] yrs. Ten (45,5%) pts had severe BD according to Ch.Zouboulis classification (due to generalized uveitis, retinal vasculitis and parenchymatous CNS lesions), while other 10 (45,5%) pts had mild disease with mainly dermal-mucous manifestations, and remaining two (9%) pts had moderate disease. These patients did not receive cytotoxic therapy.

Results: Sixty-eight pregnancies in 22 pts resulted in 45 live birth (4 cesarean section in 2 pts). Four patients had 11 medical abortions on request before 12 weeks of gestation, one patient - due to medical reasons. Unfavorable outcomes of pregnancy were documented in pts with splenic infarction; transverse (a) and coronal images (b) show an irregular contoured shrunken spleen (arrows).

THU0303
THE OMERACT CORE DOMAIN SET FOR CLINICAL TRIALS IN BEHÇET’S SYNDROME
Gulen Hatemi1, Alexa Meara2, Yesim Ozguler3, Haner Direskeneli4, Alfred Mahf4, Beverley Shea5, Esen Cam6, Ahmet Gül7, Yusuf Yazici8, Peter Tugwell5, Hasan Yazici9, Peter Merkel10.

Objectives: The Outcome Measures in Rheumatology Clinical Trials (OMERACT) Behçet’s Syndrome Working Group has worked to advance the creation of a data-driven Core Domain Set for use in all clinical trials.

Methods: The Core Domain Set was developed through a comprehensive, iterative, multi-stage, multi-year project that followed the methodologically rigorous processes and standards set forth by OMERACT; i) a systematic review; ii) a survey among experts in BS; iii) an outcomes interest group meeting during the International Conference on Behçet’s Disease; iv) qualitative patient interviews; v) a three-round modified Delphi exercise involving both patients with BS and a multidisciplinary set of physicians expert in BS, focused on obtaining consensus on the domains of illness necessary in the study of BS; and vi) utilization of the data, insight, and feedback generated by the outlined processes to develop a final Core Domain Set. The final Core Set was presented and put up for a vote of endorsement at the 2018 OMERACT meeting.

Results: All steps in the processes outlined were completed. The systematic review clearly demonstrated the substantial variability in the domains studied in clinical trials of BS and a lack availability of validated outcome measures in BS. The survey of physicians, the in-person meeting of experts, and the qualitative research with patients all helped generate an extensive list of candidate domains and sub-domains to consider for use in clinical trials. It also become clear that there was a need and strong interest in delineating domains across the several major organ systems involved in this disease and in recognizing that clinical trials in BS often focus on specific manifestations and not the disease in its entirety. The Delphi involved 74 physicians expert in BS from 21 countries and from a wide range of specialties, and 64 patients from 10 countries. The Delphi utilized both ratings and rankings to prioritize the 56 domains and sub-domains originally under consideration.

The final proposed Core Set included 5 sub-domains mandatory for study in all trials in BS, with additional sub-domains mandatory for study of specific organ systems when that system is the focus of a trial: mucocutaneous (2 additional sub-domains), ocular (4), central nervous system (3), musculoskeletal (2), vascular (4), and gastrointestinal (2). The final Core Set was strongly endorsed at the 2018 OMERACT meeting.

THU0304
PREVALENCE AND MANAGEMENT OF CARDIOVASCULAR RISK FACTORS IN ANCA-ASSOCIATED VASCULITIS: A CROSS-SECTIONAL STUDY IN THE NETHERLANDS AND CANADA
Eline Houben1, Arielle Mendel2, Joost van der Heijden3, Suat Simsek1, Willelm Bax1, Simon Carette2, Alexandre Voskuyl4, Christian Pagnoux5, Erik Penne6,7, NorthWest Clinics, Internal Medicine, Alkmaar, Netherlands, 8Mount Sinai Hospital, Vascular clinic, Department of Medicine, Toronto, Canada, 9Amsterdam UMC, Nephrology, Amsterdam, Netherlands, 10Amsterdam UMC, Rheumatology, Amsterdam, Netherlands

Background: Patients with ANCA-associated vasculitis (AAV) are at increased risk of cardiovascular (CV) disease.

Objectives: The aim of the present study was to determine the prevalence of CV risk factors in patients with AAV and to evaluate the management of CV risk factors according to current guidelines.

Methods: A cross-sectional study was performed in patients with AAV in the Netherlands and Canada. Information on traditional CV risk factors, as well as markers of inflammation and kidney function, were collected. Their prevalence and treatment were studied and compared with recommendations in current guidelines.

Results: A total of 144 consecutive patients with AAV were included (71 from the Netherlands; 73 from Canada). Mean age was 62 ± 15 years, and 56% were male. The disease duration was 7.0 ± 6.6 years; 69% had granulomatosis with polyangiitis, 17% microscopic polyangiitis, and 14% eosinophilic granulomatosis with polyangiitis. Mean body mass index was 28 ± 6 kg/m² and 65 patients (45%) had an estimated glomerular filtration rate <60 ml/min. The mean C-reactive protein was 6.5 ± 12.3 mg/l. Dyslipidemia was present in 69% and hypertension in 72%. In 36% and 25% of the included patients, blood pressure and dyslipidemia, respectively, were not managed in accordance with national guidelines.

Conclusion: Patients with AAV have a high prevalence of traditional CV risk factors. Whether past or persistent inflammation and chronic kidney disease further increases the CV risk remains to be studied. Strict adherence to CV risk management guidelines should be encouraged.

THU0306
NEUTROPHIL ADHESION MOLECULES AND INFLAMMATORY CYTOKINES AS BIOMARKERS FOR MONITORING DISEASE PROGRESSION IN GIANT CELL ARTERITIS
Tadeja Kurz1,2, Katja Lakota1,3, Gerhard Thallinger4,5, Polona Zigon1, Sasa Cučić1,2, Matija Tomsić1,6, Snežna Sodin-Senn7,8, Alojzija Hocevar1.

1University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia, 2University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia, 3University of Primorska, FAMNIT, Koper, Slovenia, 4Graz University of Technology, Institute of Computational Biotechnology, Graz, Austria, 5OMICS Center Graz, Graz, Austria, 6University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: Monitoring giant cell arteritis (GCA) activity with appropriate biomarkers is important, as current evaluation, based mainly on clinical symptoms/signs and traditional markers of inflammation, is not always sufficient and reliable.

Objectives: Our goal was to identify cellular and molecular biomarkers that could help clinicians to closely monitor GCA progression and/or treatment response.

Methods: Peripheral blood was obtained from 27 GCA patients at time of diagnosis (before glucocorticoid (GC) treatment), and subsequently at...
weeks 1, 4, 12, 24 and 48 of follow-up (FU). At diagnosis, all patients received GC in line with EULAR recommendations with a slow GC tapering starting after week 4. At week 12, some of the patients (16/27) received additionally leflunomide (10 mg). Whole blood samples were stained, lysed, fixed and analyzed by flow cytometry. The expression of adhesion molecules (CD62L, CD11b) was determined on neutrophils. Serum levels of serum amyloid A (SAA) and IL-6 were measured by nephelometry and ELISA, respectively. Levels of IL-6, IL-18, IL-23, L-selectin and CHI3L1 were determined by MagPix using human pre-mixed multi-analyte kits.

Results: At weeks 1 and 4 of FU we detected a decrease in neutrophil expression of CD62L and CD11b, as well as in sera levels of SAA, IL-6, IL-8, IL-18, L-selectin and CHI3L1 in all GCA patients. At week 12 (8 weeks after GC tapering) an elevation of CD11b, SAA, IL-6 and IL-23 as compared to week 4 was observed (Figures 1 and 2). At weeks 24 and 48 of FU we identified four different groups of biomarkers. The first group consisted of neutrophil CD62L (p<0.05) and serum IL-6, that showed a marked increase in patients receiving GC therapy only, while decreasing in patients receiving GC in combination with leflunomide. The second group is represented by neutrophil CD11b and serum IL-8 that were higher at week 24 in the GC-treated group (the first FU after receiving leflunomide), however their levels were equal at week 48 in both groups of GCA patients (Figures 1 and 2). In the third group, the serum levels of SAA, IL-18 and L-selectin decreased at week 24 and remained stable through week 48, regardless of therapy used. The fourth group of biomarkers included serum IL-23 and CHI3L1, levels of which declined at weeks 24 and 48 in patients receiving GC only and substantially increased in patients receiving leflunomide and GC (Figure 2).

Conclusion: Neutrophil surface markers CD62L and CD11b together with inflammatory parameters (SAA, IL-6, IL-8 and IL-23) could represent informative biomarkers for monitoring disease progression in GCA patients. Important biomarker differences were observed between GC-treated GCA patients, in the presence and absence of leflunomide, serving as a good basis for predicting relapses.
Methods: The patients, fulfilling the International Criteria for Behçet’s disease (ICBD), and healthy controls, of a comparable age, were evaluated in the Rheumatology and Urology Clinics. The demographic and clinical data was collected. Disease activity of the patients was assessed using Behçet’s Syndrome Activity Score (BSAS). For both groups, the sexual function and the psychological status were evaluated using the Internationa l Index of Erectile Functions (IIIF-5) and the Beck Depression Inventory (BDI), respectively. Spearman’s ρ, Chi-Square and Mann-Whitney U tests were used as appropriated.

Results: The number of BD patients was 26 and that of the controls was 27. The mean age of the patients was 36±7.4 and that of controls was 40.9±5.2. Though BD patients were younger in age they exhibited significantly lower scores in sexual function, and scored higher in depression as illustrated in Table 1.

Abstract THU0308 – Table 1. Demographic and clinical data of the participants

<table>
<thead>
<tr>
<th>Patients (n=26)</th>
<th>Controls (n=27)</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>

<td>20 (20-25)</td>
</tr>
<tr>
<td>Depression score (Beck questionnaire), median (IQR)</td>
<td>13 (9-18)</td>
<td>9 (7-14)</td>
</tr>
</tbody>
</table>

There were no associations between the disease duration, smoking status or different clinical phenotypes and the sexual or psychological functions. However, there was an inverse relationship between BSAS and the sexual function (rho = -0.45, p = 0.024). The duration of corticosteroids intake was negatively correlating with the sexual function (rho= -0.604, p= 0.001) as well. The depression scores correlated significantly with the presence of inflammatory back pain (rho= -0.413, p=0.036). There was no association between the severity of sexual dysfunction and that of depression. The patients showed different degrees of depression, and there was a tendency towards increased rates of erectile dysfunction in all groups as shown in Table 2.

Abstract THU0308 – Table 2. Correlation of IIIF-5 and BDI

<table>
<thead>
<tr>
<th>Sexual function</th>

<td></td>
<td>10 (71.4%)</td>
</tr>
</tbody>
</table>

ED; erectile dysfunction.

Conclusion: BD has a negative impact on men’s psychological state and sexual function. Severe disease states, evident in the long duration of corticosteroids use and the high activity scores, are linked to sexual dysfunction.

Methods: Rituximab pharmacokinetics was described in 92 AA patients from the RAVE trial (rituximab for ANCA- associated vasculitis) using a population modeling approach. A semi-mechanistic model including a latent target antigen turnover allowed the estimation of specific target-mediated elimination of rituximab in addition to its non-specific elimination. Sex, body surface area (BSA), BVAS/WG score, and status newly diagnosed on pharmacokinetic parameters were investigated as covariates.

Results: A two compartments model including target mediated elimination best described rituximab pharmacokinetics. The mean (individual standard deviation) estimated central volume of distribution was 3.06 L (2.61%), systemic clearance was 0.135 L days⁻¹ (6.43%), and target-mediated elimination rate constant was 19.13 x 10⁻⁶ nmol⁻¹ days⁻¹ (fixed to 0). The initial activity of the disease was higher in male than in female (p=4.09 x 10⁻¹⁰). Moreover, systemic clearance was slightly lower in granulomatosis with polyangiitis group than in other AAV groups (p=3.6 x 10⁻³). Neither BVAS/WG score nor BSA were significant covariates in a multivariate analysis.

Conclusion: We report a nonlinear target-mediated elimination of rituximab in AAV patients. Granulomatosis with polyangiitis patients have a lower global clearance of rituximab than other AAV groups. Our study not support the utility of BSA based individualized dosing protocols, as previously reported (1).

THU0310

OPTIMAL INITIAL DOSE OF GLUCOCORTICOID FOR ELDERLY-ONSET ANCA ASSOCIATED VASCULITIS: SAFETY OUTCOME ANALYSIS OF TWO NATIONWIDE, PROSPECTIVE, INCEPTION COHORT STUDIES

Kei Ohashi1, Kenji Sada1, Youseke Asano1, Keigo Hayashi1, Sumie Hiramatsu Asano1, Yuriko Yamamura1, Michiko Morishita1, Haruki Watanabe1, Marko Narasalk1, Yoshinori Matsumoto1, Tomoko Kawabata1, Jun Wada1, Masayoshi Hargai2, Hirofumi Makino1, On behalf of Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis Syndrome (JPVAS). 1Okayama University, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; 2School of Medicine, Tokyo Women’s Medical University, Department of Rheumatology, Tokyo, Japan; 3Okayama University, Okayama, Japan

Background: Glucocorticoid (GC) is still the mainstay of treatment for antineutrophil cytoplasmic antibody (ANCA) -associated vasculitis (AAV) while GC use, disease severity, and older age are risk factors for accrual of damage and infection in AAV(1,2). Objectives: To explore optimal initial dose of GC for patients with elderly-onset AAV based on safety outcome analysis using data from two nationwide prospective inception cohort studies (RemIT-JAV and RemIT-JAV-RPGN).

Methods: RemIT-JAV and RemIT-JAV-RPGN enrolled consecutive patients with newly diagnosed AAV fulfilling the criteria for primary systemic vasculitis as proposed by the European Medicines Agency algorithm and requiring immunosuppressive treatment. From the cohort studies, elderly-onset (<65 years) patients with microscopic polyangiitis and granulomatosis with polyangiitis, classified as generalized or severe disease type according to the European Vasculitis Study Group-defined disease severity, were enrolled in this analysis. The primary outcome measures were Vasculitis Damage Index (VDI) at 24th month and serious infections during 2 years after starting treatment for AAV. The patients were divided into three groups based on initial dose of GC: high-dose (HD) group, prednisolone (PSL) >0.8 mg/kg/day; medium-dose group (MD), 0.6: PSL <0.8 mg/kg/day; low-dose (LD) group, PSL <0.6 mg/kg/day. The VDI were classified into treatment-related VDI(3) and disease-related VDI.

Nonlinear Pharmacokinetics of Rituximab in Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis

Denis Mulleran1,2, Amina Bensalem1, David Ternant3,1, Gilles Paintaud1,3, Divi Comec1,2, Ulrich Specks1.

Rituximab (RTX) was approved in patients with anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), to describe the pharmacokinetics of rituximab in AAV patients and to explore its sources of variability.
PERSISTENT LOW-GRADE VASCULAR INFLAMMATION IN LARGE VESSEL VASCULITIS: A LONGITUDINAL STUDY USING FULLY INTEGRATED 18F-FDG PET/MR

Roberto Padovan1, Mara Felicetti1, Filippo Cimar1, Federica Padovan2, Carmelo Lacognata3, Diego Cecchin1, Pietro Zucchetta1, Franco Schiavon1.

1Operative Unit of Rheumatology, Department of Medicine DIMED, University of Padova, Italy, 2Operative Unit of Radiology, Department of Medicine DIMED, University of Padova, Italy, 3Operative Unit of Nuclear Medicine, Department of Medicine DIMED, University of Padova, Italy, Padova, Italy

Background: Persistent low-grade vascular inflammation in large vessel vasculitides (LVV) treated patients could represent the expression of persistent subclinical disease activity or post-inflammatory vascular remodelling. Whether these findings have any impact on future vascular outcomes is still an unmet need.

Objectives: To evaluate the frequency and evolution of the low-grade vascular inflammation using a fully integrated 18F-FDG PET/MR in a longitudinally followed cohort of LVV patients.

Methods: All consecutive patients with LVV who underwent at least 2 PET/MR scans (median time 9[6] months) between January 2015 and February 2019 were included. For each scan vessel’s metabolic activity was assessed using the Meller’s grading and the standard uptake value. Low-grade inflammation was defined as Meller 1 and 2 (inferior or equal to liver), as previously reported. Demographic and clinical data, as well as disease remission or flares, were recorded and compared to vascular metabolic activity.

Results: In total, 107 PET scans were performed (from min. 2 scans to max. 5 scans per patient), mainly during follow-up (78.6%) in 33 LVV patients (72.7% GCA, 27.3% TAK), predominantly female (84.8%), with a regular BMI (24[5.5]) and with a long-standing disease (30[29] months). At PET examination, low-grade metabolic activity was reported in 60% of the cases (86.4% GCA and 13.6% TAK), while complete remission in 15% and highly pathological in 25%. Comparing patients with low-grade vascular inflammation to those with complete remission (Meller 0), they resulted significantly older (64[12] vs 57[33] years, p<0.005), with a lower disease duration (26.5[21.4] vs 52.5[34.8] months, p<0.001) and with higher daily prednisone dosage, but without significance (5[7.5] vs 2.5 [8.75], p=0.096). No significant differences were noted in acute phase reactants and type of treatment. Moreover, when compared to those with high metabolic activity (Meller 3), patients with low-grade inflammation resulted significantly older (64[12] vs 62[25] years, p<0.025), with a lower disease duration (26.5[21.4] vs 33[46] months, p=0.041), lower CRP level, but without significance (3.03[5.92] vs 10.35[13.75], p=0.069). Clinical remission, before PET examination, was registered in 55.6% of patients with Meller lower activity, significantly lower compared to those with Meller 1+2 (87.5%, p=0.002). Steroids and immunosuppressants tapering rate did not differ between patients with low-grade metabolic activity and those without activity.

Among all patients with low-grade vascular inflammation, 60% underwent to steroids or immunosuppressants tapering. At the subsequent PET examination, a persistence/worsening of metabolic activity was found in 88.5% of them. Change or increase of the treatment regimen led to an improvement (complete remission) in 58.9% of the cases. Low-grade metabolic activity was associated with a significant increased risk of worsening/flare at the subsequent PET examination (RR 5.29[1.87-16.11], p=0.002).

Conclusion: Low-grade vascular inflammation at PET examination is a common feature in LVV treated patients, especially GCA. It is significantly associated with an older age, lower disease duration and clinical remission. However, steroids or immunosuppressants tapering is these patients is associated with an increased risk of worsening/flare. Further research is urgently needed to address this issue.

ADVENTITIAL FIBROBLAST, AN IMPORTANT PLAYER IN GIANT CELL ARTERITIS

Simon Perreau1, Nicolas Vedrenne2, Alexis Régent3, Laurence Richard4, Philippe Sindou5, Luc Mouton5, Anne-Laure Fauchais1, Marie-Odile Jauberteau2, Marie-Noëlle Nava1, Kim-Heang Ly2, Dupuytren Hospital University Center, Limoges, France, 2Cochin Hospital, Paris, France

Background: Giant cell arteritis (GCA) is a systemic vasculitis affecting large vessels. The diagnosis is based on the temporal artery biopsy (TAB) which shows a segmental and focal arterial infiltration composed of CD4 T cells and macrophages. It is accompanied by a destruction of the internal elastic layer of the media and a hyperplasia of the intima by proliferation of myofibroblasts (Weyand). The origin of these myofibroblasts is controversial (Ly). Evidences suggest the activation of adventitial fibroblasts into myofibroblasts and their migration into the intima (Stenmark).

Objectives: The objective of this study was to determine whether adventitial fibroblasts migrate to the intima and thereby contribute to intimal hyperplasia during GCA.

Methods: Arterial sections from TAB of patients with GCA (n=24) and control subjects (n=24) were analyzed. Immunohistochemical analysis was
performed using antibodies directed against fibroblasts (CD90, vimentin), myofibroblasts (alpha smooth muscle actin (ASMA)) and vascular smooth muscle cells (desmin). Staining of prolly-4-hydroxylase (P4H) and myosin were also performed. Stainings were quantified using the ODPviewer® software (Kamax Innovative System, France) by two double-blind observers. Moreover, co-expression of CD90 with different stainings (ASMA, myosin and P4H) was also performed. Cells in culture were identified by immunocytochemistry using anti-CD90 and markers of activity such as myosin and P4H. Functional assays were performed using culture cells obtained from GCA patients’ BATs (n=4) and controls (n=4). The BATs were dissected to separate the adventitia from the other two layers. Each dissected fragment was seeded separately. The proliferation was studied using a bromodeoxyuridine incorporation test under different conditions: DMEM, fetal calf serum (FCS), PDGF and supernatants of cells in culture. The study of migration was performed using a scratch test under the same conditions.

Results: CD90 was significantly higher in GCA than controls in adventitia and intima. Vimentin and ASMA were significantly higher in the 3 tunics of patients with GCA. Expression of desmin was only present in the media for both groups with no significant difference. P4H was present in adventitia with significant differences between both groups. The adventitial and intimal CD90+ cells co-expressed P4H, ASMA and myosin more importantly during GCA. Cultured cells from BATs’ adventices expressed CD90 and did not express desmin. These cells had a greater myosin staining during GCA and had an increased proliferation ability during GCA in the presence of FCS, PDGF and fibroblast supernatants of control or GCA patients. The migration rates of these cells were also significantly increased during GCA in the presence of FCS or PDGF.

Conclusion: Vascular remodeling during GCA would start in the adventitial layer with a key role of fibroblasts. Advenitial fibroblasts could be activated into myofibroblasts and acquire proliferative and migratory abilities. They would participate in the intimal hyperplasia, responsible for ischemic complications. Their inhibition could be a therapeutic way to limit these complications. The activating signal of adventitial fibroblasts into myofibroblasts is not yet known during GCA and requires further studies.

THU0313 COMPARATIVE STUDY OF CLINICAL, ANALYTICAL AND VASCULAR 18F-FDG UPTAKE EVOLUTION IN PATIENTS WITH GIANT CELL ARTERITIS TREATED WITH METHOTREXATE VS TOCILIZUMAB

Background: Glucocorticoids remain to be the cornerstone therapy in giant cell arteritis (GCA). However, relapses are common when the prednisone dose is tapered. Thus, additional therapies are required in relapsing GCA. The most widely used conventional immunosuppressive drug is methotrexate (MTX) which efficacy is modest. Consequently, in some cases biological therapy in needed. Among them, the most frequently used is the recombinant humanized anti-IL6 receptor antibody tocilizumab (TCZ).1

Objectives: To compare clinical evolution, normalization of acute phase reactants and normalization of vascular 18F-FDG uptake assessed by PET/CT in patients with GCA treated with MTX vs TCZ.

Methods: Comparative multicentric study of 23 patients with GCA treated with MTX vs 36 patients with GCA treated with TCZ who had a baseline and follow-up PET/CT scan. We assessed clinical improvement (no improvement/partial/complete), normalization of acute phase reactants (CRP ≤ 0.5mg/dl, and/or ESR ≤ 20 mm/1st hour) and reduction of 18F-FDG uptake in PET/CT (no reduction/partial/complete normalization). Images were evaluated qualitatively by experienced nuclear medicine physicians. Prednisone tapering was also assessed. Statistical analysis was performed with SPSS. Student’s t test or Mann-Whitney U test was used to compare continuous variables, and Chi-squared test or Fisher’s exact test for categorical variables as appropriate.

Results: We included 23 patients with GCA treated with MTX (20 women/3 men); mean age 65.6 ± 7.9 years; and 36 patients treated with TCZ (27 women/9 men); mean age 67.5 ± 8.3 years. Clinical, analytical and vascular 18F-FDG uptake evolution is shown in the TABLE. After one year of treatment, the percentage of patients who experienced complete clinical improvement was higher in those who received TCZ (88.9% vs 44.4%; p=0.003). Normalization of acute phase reactants was also more frequent in patients who received TCZ (92.6% vs 47.6%; p=0.001). In regard with reduction of vascular 18F-FDG uptake, complete normalization was only achieved in 25% of patients who received TCZ and 14.3% of those who received MTX.

Conclusion: Patients with GCA who received TCZ experienced a more rapid and effective clinical and analytical improvement than patients who received MTX. Besides, prednisone tapering was quicker in patients with TCZ. However, no significant differences were found in complete normalization of 18F-FDG vascular uptake between both treatments.

Outcomes of patients treated with tocilizumab or abatacept as steroid-sparing agents with giant cell arteritis

Daniela Rossi, Irene Cecchi, Elena Rubini, Massimo Radin, Savino Sciascia, Dario Roccatello, University of Turin, Turin, Italy

Background: Giant cell arteritis (GCA) is a common form of systemic vasculitis. The current mainstay of GCA management is glucocorticoid (GC) therapy. Recently, at least 2 biological therapies (tocilizumab (TCZ) and abatacept (ABA)) have been proven to be effective in the management of GCA in randomized controlled trials. Nevertheless, their use as steroid sparing agents might need further investigation.

Objectives: We aimed to investigate the steroid-sparing effect of biological therapies, namely TCZ and ABA, in a cohort of GCA patients when compared to standard GC treatment.

Methods: We retrospectively collected data from GCA patients who attended the S.G. Bosco Hospital, Turin, Italy, who were treated with TCZ, both intravenous (IV) and subcutaneous (SC), and/or ABA SC (8 mg/kg/month, 162 mg/week, and 125 mg/week respectively). These therapies were prescribed as first line agents or as second line when patients refractory/intolerant/contraindicated to standard immunosuppressive therapies. Complete response to the treatment was defined as a clinical and serological remission after 12 months of therapy; partial response was defined as clinical or serological remission after 12 months of therapy.

Results: This retrospective study included 33 GCA patients (mean age 74 (range 85-57), females 63%, mean follow-up from GCA diagnosis 44.4-33.5 months). Table 1 resumes the characteristics of the GCA patients included in the study. Twenty-eight patients out of 33 (85%) received one biologic agent. Five patients (15%) needed a therapeutic switch (one patient from TCZ to ABA, and 4 patients from ABA to TCZ). Patients were treated as follow: 9 with TCZ IV, 11 with TCZ SC, and 18 with ABA. Among the TCZ IV group, all patients experienced a response (57% complete response, and 43% partial response). Among the TCZ SC group, 83% experienced a response (67% complete response, and 16% partial response). Among the ABA group, 86% experienced a response (36% complete response, and 50% partial response). After 12 months of therapy, 100% of patients in TCZ groups, both IV and SC, and 64.2% of ABA group were treated with low doses of oral prednisone (≤ 7.5 mg/day) as maintenance. We noticed a significant reduction of inflammatory parameters [C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)] after 12 months of therapy with TCZ (TCZ IV group: mean baseline CRP (mg/dl) 1.9±2.3, mean CRP after 12 months of therapy 0.3±0.2; mean baseline ESR (mm/h) 58.1±25.6, mean ESR after 12 months 9.5±4.2; TCZ SC group: mean baseline CRP 4.5±3.8, mean CRP after 12 months 0.2±0.2; mean baseline ESR 51.9±27, mean ESR after 12 months 6.5±6]. When compared to standard GC regimen [1], in patients treated with TCZ, both IV and SC, we estimated a median steroid-sparing effect quantifiable in 30 mg/daily in the first month and an overall steroid-sparing effect of 15 mg/daily when assessed in 12 months.

Conclusion: This retrospective study confirms the efficacy of biological therapies in the management of GCA. Besides, in our experience TCZ allowed a significant reduction of GCs use, especially in the first month of therapy, when compared to standard GCs based regimens.

Disclosure of Interests: None declared

induction therapy was more common in severe patients (71.8% of patients having at least one comorbidity) compared to mild patients (55.1%). Since BVAS was not measured routinely, clinical response was categorized as full (no vasculitis activity and GC taper on track), partial (reduction in vasculitis activity and major organ damage arrested) and no response (no improvement in vasculitis). Clinical response is presented below (% patients) for combination of incident and relapsing patients demonstrating that response varied with many patients having slow and/or incomplete response. Response varied by severity of the disease when induction therapy commenced.

**Conclusion:** Incident and relapsing AAV patients have variable disease severity at the time of induction therapy. Response to induction therapy is with few exceptions better in patients with milder AAV but overall many patients are slow to respond or have only a partial response to current induction therapy.

**THU0316 PROTEINASE-3 REGULATING MICRO-RNA IN GRANULOMATOSIS WITH POLYANGIITIS**

Susanne Schinke1, Nick Reichard2, Barbara Russo2, Antje Müller3, Martin Lauden4, Robert Häsl4, Gabriela Riemekasten1, Peter Lamprecht1.

1University Lübeck, UKSH Campus Lübeck; 2Rheumatology and Clinical Immunology, Lübeck, Germany; 3University Lübeck, Lübeck, Germany; 4University Hospital and School of Medicine, Immunology and Allergy, Geneva, Switzerland; 5Christian-Albrechts-University Kiel, Kiel, Germany

**Background:** Dysregulated miRNA expression profiles have been described in diverse chronic inflammatory diseases. We previously did a microarray screening of 847 miRNAs in nasal tissue from GPA patients and we found a disease associated alteration of miRNA expression compared to healthy controls (HC) and chronic rhinosinusitis (CRS).

**Objectives:** In order to identify new miRNA targets of potential pathophysiological relevance in GPA, we validated dysregulated miRNAs by qPCR in GPA nasal tissue biopsies and sera. Moreover, we screened GPA associated miRNAs for their potential to regulate proteinase-3 (PTRN3).

**Methods:** In an independent validation cohort (tissue and sera from 14 GPA-patients, 10 disease controls: CRS and Crohn’s/CD) 12 miRNAs were examined by qPCR. Validated and computational miRNA targets were identified by miDIP algorithms. The inhibitory capacity of miRNAs on Proteinase-3 (PTRN3) was estimated by a dual-luciferase reporter system (Promega®). The 3’UTR-PTRN3 sequence was cloned and inserted into the pmirGlo vector and co-transfected with the hsa-mirna mimics (Dharmacon®) into HeLa cells. As a second method, the effect of miR-184 transfection on the endogenous PRTN3 expression in the human myeloid leukemia cell line HL-60 was estimated by western blot.

**Results:** Microarray screening revealed alteration of 24 miRNAs in GPA nasal tissue compared to HC and CRS. qPCR confirmed dysregulation of 6 tissue related miRNAs also in GPA sera. Compared to CD 4 miRNAs (miR-10b, -99a/100, -125b, -532-3p) were down regulated in GPA tissue. The miRNA with the highest expression level in nasal tissue from GPA was miR-184. miR-184 along with miR-708 and miR-214-5p were also predicted to target PRTN3 by the miDIP algorithm. The dual-luciferase reporter assay revealed a significant reduction of PRTN3 expression by miR-184, while these effects could not be observed for miR-708 or miR-214-5p. The transfection of miR-184 into HL-60 cells resulted in a dose-dependent knockdown of PRTN3 expression as detected by Western blot.

**Conclusion:** Characteristic miRNA signatures in GPA, CRS and CD suggest distinct pathophysiological mechanisms. It indicates at a local miRNA dysregulation in inflamed GPA tissue with a corresponding serum signature that might serve as novel biomarkers. To our knowledge this is the first analysis that attempts to correlate GPA-associated miRNA expression patterns in tissue with serum. Moreover, this is the first description of a miRNA (miR-184) that potentially regulates the expression of the GPA autoantigen PRTN3.

**THU0317 IDENTIFICATION OF ENDOTHelial PROTEIN C RECEPTOR AND SCAVENGER RECEPTOR CLASS B TYPE 1 AS MAJOR AUTOANTIGENS IN TAKAYASU ARTERITIS**

Tsuyoshi Shiri, Tomoyuki Mutoh, Tomonori Ishii, Hiroshi Fujii, Hideo Harigae.

**Background:** Takayasu arteritis (TAK) affects the aorta and its major branches. It has been recognized that high numbers of patients with TAK possessed endothelial cell antibodies (AECA), which have potential to induce vascular lesion. However, their major target antigens remain unclear. The target antigens of AECA are plasma membrane proteins, and traditional methods to identify autoantigens do not differentiate between cell-surface molecules and intracellular molecules. To overcome this problem, we have developed an expression cloning system to identify cell-surface antigens: serological identification system for autoantigens using a retroviral vector and flow cytometry (SARP)-3,5. Because there...
exists no disease-specific testing for TAK, identification of autoantigens would be extremely important.

Objective: To identify major autoantigens in TAK using SARF and analyze clinical significance of autoantibodies

Methods: Two hundred and seventy-eight patients with collagen diseases were enrolled: 20, TAK; 10, giant cell arteritis (GCA); and 188, other collagen diseases. A cDNA library of human umbilical vein endothelial cells (HUVECs) was retrovirally transfected into a rat myeloma cell line. Cells expressing the cDNA library were stained with prototype AECA and fluorescence-conjugated secondary anti-human IgG, and cells with fluorescence were sorted with flow cytometry. Autoantigen identification was performed by analyzing the cDNA inserted into the sorted cells. Cells expressing the identified autoantigens were generated, and the presence of autoantibodies was confirmed. The autoantibodies against identified autoantigens were measured in TAK and other collagen diseases, and the prevalence and clinical characteristics of each autoantibody were evaluated.

Results: AECA activity against HUVECs were measured in patients with TAK and nine AECA serum samples were selected for subsequent SARF. Four distinct AECA-positive clones were successfully isolated using serum IgG from TAK patients. Two clones were identical to the cDNA of PROCR encoding protein C receptor (EPCR), and others, to SCARB1 encoding scavenger receptor class B type 1 (SR-BI). A validation experiment involving 52 patients with TAK confirmed disease specificity in TAK; autoantibodies against EPCR or SR-BI accounted for 34.6% or 36.5% cases, respectively, with minimal overlap (3.8%). Measurement of these autoantibodies in other collagen diseases was performed, and the sensitivity and specificity of these two autoantibodies were 67.3% and 96.5%, respectively. Importantly, these autoantibodies were not detected in patients with GCA who were positive for temporal artery biopsy. TAK was classified into three subtypes based on the profile of these autoantibodies. Anti-EPCR positive group showed high prevalence of stroke, ulcerative colitis, and type II artery lesion. Anti-SR-BI positive group presented higher levels of inflammatory markers, type V artery lesion, and older age at onset. Aortic regurgitation was rare in anti-SR-BI positive group. Double-negative group presented higher rates of vascular surgery.

Conclusion: We identified EPCR and SR-BI as novel autoantigens in TAK. Autoantibodies against EPCR or SR-BI were observed in 66.7% of patients, and different types of autoantibodies showed distinct clinical characteristics. These autoantibodies would aid in clinical application and elucidating pathomechanisms.

THU0318 ANCA-ASSOCIATED GLOMERULONEPHRITIS WITHOUT CRESCENT FORMATION HAS ATYPICAL CLINICOPATHOLOGICAL FEATURES: A MULTICENTER RETROSPECTIVE STUDY

Kazuyuki Suzuki, Takeshi Zoshima, Hajime Sanada, Fae Suzuki, Satoshi Hara, Mitsuhiro Kawano, Kanazawa University Hospital, Kanazawa, Japan

Background: The most typical histopathological feature of ANCA-associated glomerulonephritis (ANCA-GN) is crescentic GN. However, ANCA-GN is also complicated by other renal lesions, including vascular ones (arteritis and arteriolitis) and tubulointerstitial ones (tubulitis and peritubular capillaritis) [Reference 1], and tubulointerstitial or vascular dominant inflammation without glomerulopathy sometimes exists. Few reports have focused on ANCA-GN without crescent formation in a large multicenter study.

Objectives: To identify the clinicopathological features of ANCA-GN without crescent formation.

Methods: We enrolled 122 Japanese ANCA-GN patients who were subjected to renal biopsy in 16 hospitals from 2001 to 2018. We measured various clinical parameters at the time of renal biopsy, including creatinine (Cr), estimated glomerular filtration rate (eGFR), C-reactive protein (CRP), MPO-ANCA, PR3-ANCA in the sera, urinalysis findings, and presence of comorbidities (hypertension, hyperlipidemia, diabetes mellitus, and hyperuricemia). Renal biopsy findings were evaluated by light microscopy. We also measured serum Cr and eGFR at the last patient visit, and recorded medications prescribed for ANCA-GN. We retrospectively compared these clinical and histological findings between those with crescent (C+ group) and without crescent (C- group). The primary endpoint was the cumulative percentage of patients who died from any cause.

Results: Of 122 patients (63 females; mean age 69.5 years; observation period 37.1±14.8 years), C- group included 20 (16.4%). Although C+ group had higher CRP levels (11.2±8.5 vs 6.6±5.2 mg/dl, p=0.01), they had less proteinuria (0.8±0.9 vs 1.6±1.7 mgCr, p=0.04) and better renal function (eGFR; 52.1±29.5 vs 30.2±25.4 ml/min/1.73m2, p<0.01) than C+ group. There were no significant differences in any other clinical findings including ANCA serology. In histological findings, C- group had a higher frequency of arteritis (40.0% vs 16.8%, p=0.03), while other histological findings such as arteriolitis, tubulitis and peritubular capillaritis did not differ. There were no significant differences in medications or observational period. C+ group had better latest renal function (eGFR; 57.3±27.8 vs 39.0±23.6 ml/min/1.73m2, p=0.02) than C+ group. However, overall survival rate did not differ (68.4% vs 78.7%, p=0.37).

Conclusion: ANCA-GN without crescent formation had specific clinicopathological features including higher systemic inflammation and frequency of renal arteritis than ANCA-GN with crescent formation. Though renal function throughout the clinical course was better in ANCA-GN without crescent formation, overall survival rate was similar with ANCA-GN with crescent formation.

THU0319 TAKAYASU’S ARTERITIS: BEYOND THE VESSELS

Alessandro Tomelleri, Corrado Campochiaro, Silvia Sartorelli, Veronica Bandini, Elena Baldissera, Lorenzo Dagna. San Raffaele Hospital, Milan, Italy

Background: Takayasu arteritis (TAK) is an inflammatory disease which primarily affects large vessels1. However, as a systemic disease, the spectrum of its manifestations is not limited to the arterial wall2.3.

Objectives: To describe characteristics of extravascular manifestations of TAK patients from a single Italian Centre.

Methods: Data records of TAK patients diagnosed according to the 1990 ACR criteria and followed-up at our Large Vessel Vasculitis Clinic were reviewed. Any significant inflammatory/autoimmune comorbidity and family history for inflammatory/autoimmune diseases were considered. For each comorbidity, temporal correlation with TAK diagnosis was assessed. Need for biological therapy for TAK control, as an indirect measure of TAK aggressiveness, was evaluated. Non-parametric statistic tests were used.

Results: In our cohort of 129 TAK patients, 46 patients (37.5%) were identified as having an inflammatory/autoimmune comorbidity, for a total of 64 comorbidities (14 patients experienced >1 comorbidity). Comorbidities were classified into 6 categories: systemic inflammatory diseases (17.2%); gastrointestinal (9.4%), articular (10.9%), ocular (20.3%) and mucocutaneous (39.1%) involvement; miscellaneous (autoimmune hepatitis (1.6%), retroperitoneal fibrosis (1.6%). In 33 cases (51.6%) the comorbidity onset preceded, in 25 (39%) followed and in 6 (9.4%) was synchronous with TAK diagnosis (Table 1). In 25 patients (54.3%) use of a biological therapy to control TAK activity was needed (versus 35.4% in patients without comorbidities, p=0.042). Having a comorbidity increased the risk for the introduction of a biologic therapy, odds ratio=2.176 (1.6%-4.541). Of the 129 TAK patients, 17 (13.2%) had a positive family

THU0320 RISK FACTORS OF INTRAVENOUS IMMUNOGLOBULIN RESISTANCE AND CORONARY ARTERIAL LESIONS IN TURKISH CHILDREN WITH KAWASAKI DISEASE

Sercan Turkucu1,1, Kaan Yıldız2, Ceyhun Acan1, Hatice Adıgüzel Dundar2, Mustafa Kır3, Erbil Unsal4, 1Dokuz Eylül University, Department of Pediatric Rheumatology, İzmir, Turkey; 2Dokuz Eylül University, Department of Pediatric Cardiology, İzmir, Turkey

Background: Kawasaki Disease (KD) is an acute, systemic, febrile vasculitis that occurs during infancy and is the most common cause of childhood coronary artery disease. The incidence of coronary artery lesions (CALs) has declined with the routine use of intravenous immunoglobulin (IVIG) treatment, but there is still considerable risk for resistance to IVIG treatment and development of CALs (1). Objectives: Previously defined risk scoring systems have limited predictive capacity for IVIG resistance of KD in Turkish children. The present study was aimed to determine the risk factors in Turkish children with IVIG resistant KD and coronary artery involvement. Methods: Clinical, laboratory and echocardiographic data were retrospectively analyzed in 94 Kawasaki patients. IVIG resistant and responsive groups were compared. Results: Of the 94 patients included in the study, 55 (58.5%) were male and 39 (41.5%) were female and the ratio was 1.41. The median (25–75 percentage) age at the time of diagnosis was 35 (19-52) months. CALs were observed at echocardiographic evaluation in 31 patients (33%) and 17 patients (18.1%) were IVIG resistant. IVIG resistant group had a higher rate of CALs compared to the IVIG responsive group (p<0.05). When two groups were compared prior to IVIG, neutrophil/lymphocyte ratio (NLR) and C-reactive protein (CRP) parameters were statistically higher in IVIG resistant group. NLR values still remained as statistically higher in the IVIG-resistant group after initial IVIG. Regarding IVIG resistance, duration of fever ≥ 9.5 days, CRP ≥ 88 mg/L and NLR > 1.69 were the best cutoff values. The criteria for at least two of these three predictors were considered to be statistically significant risk factors for detecting IVIG resistance in KD before treatment (76.47% sensitivity, 71.05% specificity and 95% confidence intervals were 50.1-93.19% and 59.51-80.89%, respectively). Regarding risk for CALs, duration of fever ≥ 9.5 days before IVIG, (OR: 3.4) and Pit count after IVIG ≥ 670x10⁴/mL, (OR: 5.5), were the best cutoff values.

Abstract THU0320 – Table 1. ROC analyses and Odds ratios for best cut-off values of variables for predicting IVIG resistance before IVIG treatment.

p<0.05
Conclusion: This study defined three criteria for IVIG resistance in KD prior to treatment: Duration of fever before IVIG > 9.5 days, CRP > 88 mg/L and NLR value > 1.69. Presence of two of these three criteria were found as a significant risk factor for IVIG resistance. Following initial therapy with IVIG, if NLR value is > 1.25, it also predicted ongoing inflammation and IVIG resistance, possibly a need for steroid therapy instead of second IVIG.

Based on the clinical and laboratory features, we established a new risk-scoring system for predicting IVIG resistance in Turkish children with KD. This may be useful for choosing optimal treatment for KD before corona artery involvement.

THU0322

Clinical characteristics of biopsy-proven IGA vasculitis in children and adults: A retrospective cohort study

Michel Villatoro Villar1, Cynthia S. Crowson1,2, Ashima Makol1, Kenneth J Warrington1, Steven R. Ytterberg1, Matthew Koster1

Rheumatology, Rochester MN, United States of America; Mayo Clinic, Rochester MN, United States of America; Mayo Clinic, Health Sciences Research, Rochester MN, United States of America

Background: Differences in both presentation and outcome based on age of diagnosis have been described in patients with IGA vasculitis (lGAV) but data are limited due to cohort size and follow-up duration.

Objectives: To describe the differences in clinical characteristics and outcome between adult- and child-onset biopsy-proven IGA vasculitis (lGAV) in North America.

REFERENCE:
Methods: Patients with IgAV from January 1, 1997, through December 31, 2016 were retrospectively identified. Clinical characteristics, laboratory parameters and outcomes were abstracted from direct medical chart review. Proteinuria was classified as non-nephrotic (>0.2 g/dl, >3.5 g/dl) or nephrotic (>3.5 g/dl). Microscopic hematuria was defined as ≥5 RBCs/hpf or ≥2+ on dipstick. Disease activity at each follow-up visit was categorized as complete response (normalization of all baseline abnormalities due to IgAV), partial response, non-response (lack of improvement of any abnormalities) or relapse (development of clinical signs of IgAV after a symptom-free period of at least one month). Prevalence of disease activity and competing risks were estimated using multi-state models.

Results: A total of 243 IgAV patients were identified (97% Caucasian, 58% male). 174 patients were adults (>21 years) and 69 were <21 years. Compared to patients <21 years, adults at baseline had more frequent ulcerative skin lesions (11% vs. 9%; p=0.02) and nephrotic-range proteinuria (22% vs. 3%; p=0.007) but less commonly had abdominal pain (34% vs. 61%; p=0.01), ischemic gastrointestinal involvement (10% vs. 20%; p=0.04) and arthralgias (38% vs. 61%; p=0.001). Frequency of microscopic hematuria was similar between groups (47%). Oral corticosteroids were the most common initial treatment used (80%). Dialysis was required in 13 patients (8 adults) and renal transplant was performed in 4 cases (1 adult). Of 137 patients with hematuria during the study, 72% had complete resolution by 1 year after onset, compared to 50% of 179 patients with proteinuria. The prevalence of disease activity state at each follow-up time point is shown in figure 1. During 389 person-years of follow-up, 29 deaths were observed. The main causes of death were cancer, cardiovascular disease, infection and vasculitis. Five person-years of follow-up, 29 deaths were observed. The main causes of death were cancer, cardiovascular disease, infection and vasculitis. Five year survival rates (95% CI) for patients aged <21, 21-50, and 51+ years were 100%, 94% (87, 100) and 40% (26, 63), respectively (p<0.001). Standardized mortality ratio for patients aged 21-50 years at diagnosis was 5.62 (0.68, 20.3) and 7.60 (5.0, 11.1) for those 51 or older.

Conclusion: IgAV in adults is associated with more severe skin/kidney involvement and poorer renal outcome. Among adults with IgAV, patients aged 51 years or older at diagnosis have significantly higher mortality.

AXONAL DYSFUNCTION IN CEREBRAL WHITE MATTER IN SYSTEMIC SCLEROSIS: A PROTON MAGNETIC RESONANCE SPECTROSCOPIC IMAGING (1H-MRSI) STUDY

Danilo Pereira, Mariana Freschi, Renan Frittoli, Tiago Amaral, Sergio Dertkigil, Ana Paula del Rio, Gabriela Castellano, Fernando Cendes, Leticia Rittner, Simone Appenzeller. University of Campinas, Campinas, Brazil

Background: Systemic sclerosis (SSc) is a diffuse connective tissue disease characterized by varying degrees of cutaneous and visceral fibrosis, presence of autointerandies and vasculopathy. In addition, central nervous system (CNS) involvements are often observed [1].

Objectives: The aim of the present study was to investigate the presence of axonal dysfunction in systemic sclerosis (SSc) and to determine if clinical, laboratory and treatment features are associated with its occurrence.

Methods: In this longitudinal study we included 38 SSc patients (32 woman, mean age of 50.86, SD=11.66 years; range 31-74) and 38 healthy volunteers (32 woman, mean age of 49.23, SD=12.03 years; range 26-77). All individuals were evaluated (neuropsychiatric evaluation and MRI) at study entry and after 12 months. Cognitive evaluation was performed using the Montreal Cognitive Assessment (MoCA), mood disorders were determined through Beck’s Depression (BDI) and Beck’s Anxiety Inventories (BAI). Individual with scores: MoCA ≥26, BDI ≥11 and BAI ≥7 were considered impaired. SSc patients were further assessed for clinical and laboratory SSc manifestations, disease activity (Medsger Activity Index), severity activity (Medsgier Severity Index). We performed multi-voxel 1H-MRSI over the superior-posterior region of the corpus callosum. Our MR/MRSI protocol consisted of: T1-weighted images; 2D pulse sequence (PRESS); excitation angle of 90˚. Our MRI/MRSI protocol consisted of: T1-weighted images; 2D pulse sequence (PRESS); excitation angle of 90˚.

Results: We observed a significant reduction in NAA/Cr (mean value=1.72; SD=2.4) and Cho/Cr(mean value=2.4; SD=2.04) ratio in SSc when compared to controls (NSC/Cr mean value=1.85; SD=2.7; p = 0.36; Cho/Cr mean value=0.377; SD=0.169; p<0.001). Reduction in NAA/Cr ratio was associated with cognitive impairment (p = 0.017), presence of migraine (p = 0.001), current use of prednisone (p=0.010) and current use of methotrexate (p < 0.001). NAA/Cr ratio correlated with MoCA scores (r=0.4; p=0.015).

Follow up study showed a reduction in NAA/Cr values when compared to patients’ baseline values (p = 0.0341).

Conclusion: Our results showed a significant reduction in NAA/Cr ratio in SSc patients associated with cognitive impairment and the use of some drugs (MTX and prednisone) during the treatment. Therefore, NAA/Cr ratios may be a useful biomarker in follow-up studies of SSc.

THU0325 THE HMGB1/AGE-RAGE AXIS IN SYSTEMIC SCLEROSIS PATIENTS: A POTENTIAL ROLE IN ITS VASCULOPATHY?

Isabella Atzeni1, Amaan Emam Abdullah1, Anniek van Roon1, Gilles Diercks2, Harry van Goor3, Andreas Smil1, Johanna Westra4, Douwe J Mulder4. 1University of Groningen, University Medical Center Groningen, Internal Medicine, Division of Vascular Medicine, Groningen, Netherlands; 2University of Groningen, University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands; 3University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Systemic sclerosis (SSc) is a progressive fibro-inflammatory autoimmune disease of which the pathogenetic pathways are incompletely understood. Advanced glycation endproducts (AGEs) are oxidative stress derived compounds with potential proinflammatory effects. Their exact role in fibrosis remains unknown. The receptor for AGEs is RAGE, which is also the receptor for high mobility group box 1 (HMGB1), a nuclear protein, which is proinflammatory when released from activated or apoptotic cells. We hypothesize that AGEs and HMGB1 may promote inflammation and profibrotic processes, presumably mediated by RAGE.

Objectives: To study the role of the HMGB1/AGE-RAGE axis in the pathogenesis of SSc.

Methods: Distribution of N-(carboxymethyl)lysine (CML) and N^ε-(5-hydroxymethyl-4-imidazol-2-yl)-ornithine (MG-H1) was assessed by immunohistochemistry in skin biopsies of 12 SSc patients [median age 56 years (IQR 52-61); 6 of affected, 6 of unaffected skin]. The intensity was assessed semi-quantitatively on endothelium and fibroblasts. In vitro experiments were performed on healthy human dermal fibroblasts, which were stimulated with 0 μg/ml HMGB1. All cells were treated for 24 hours. Detection was performed using the 1H-MRSI protocol consisting of: T1-weighted images; 2D pulse sequence (PRESS); excitation angle of 90°; Long TE: 144ms and TR: 2000ms; VOI (MRSI) size (mm³) = (116 x 79 x 16) grid with 208 voxels. Scans were performed with a Philips 3.0T MRI scanner. We measured signals from N-acetyl-compounds (NAA), creatine (Cr), choline (Cho), glutamate (Glu), glutamine (Gln) and Glx (the sum of Glu and Gln) using TROQUIN software.

Statistics was performed according nature of the variable.

Results: We observed a significant reduction in NAA/Cr (mean value=1.72; SD=2.4) and Cho/Cr (mean value=2.4; SD=2.04) ratio in SSc when compared to controls (NSC/Cr mean value=1.85; SD=2.7; p = 0.36; Cho/Cr mean value=0.377; SD=0.169; p<0.001). Reduction in NAA/Cr ratio was associated with cognitive impairment (p = 0.017), presence of migraine (p = 0.001), current use of prednisone (p=0.010) and current use of methotrexate (p < 0.001). NAA/Cr ratio correlated with MoCA scores (r=0.4; p=0.015).

Follow up study showed a reduction in NAA/Cr values when compared to patients’ baseline values (p = 0.0341).

Conclusion: Our results showed a significant reduction in NAA/Cr ratio in SSc patients associated with cognitive impairment and the use of some drugs (MTX and prednisone) during the treatment. Therefore, NAA/Cr ratios may be a useful biomarker in follow-up studies of SSc.

**THU0325**  
**ANALYSIS OF PHOSPHATIDYLINOSITOL 3-KINASE PATHWAY IN B CELL ACTIVATION OF SYSTEMIC SCLEROSIS PATIENTS**

Judith Rapp, Vivien Telek, Tunde Minier, László Czirják, Times Berki; Diana Simon.  
University of Pécs Medical School, Pécs, Hungary

**Background:** B cell activation is an early event in the development of systemic sclerosis (SSc) as transcriptome profiling identified local B-cell activation in early diffuse cutaneous (dc) SSc skin biopsies. Autoantibody production is a widely investigated function of B cells in SSc but less attention has been devoted to the role of innate immune molecules and their receptors, like Toll-like receptors (TLRs). The classical B cell activation downstream of BcR and CD19 co-receptor engagement involves phosphatidylinositol-3 kinases (PI3K) signaling pathway that integrates the effects of multiple co-stimulatory receptors.

**Objectives:** Our goal was to examine PI3K signaling by investigating the mRNA expression of 92 pathway related genes in B cells from early dcSSc patients. Akt is a central element of PI3K pathway, but it can also converge into innate receptor mediated pathways such as mTOR and MAPK. Thus for functional relevance we also analyzed the phosphorylation of Akt, S6 and NF-κB in B cells from early dcSSc patients.

**Methods:** Twenty-one patients with early dcSSc were enrolled with disease duration of 2.0 (±1.2) years based on the date of the first non-Raynaud’s symptom. 30% of patients received immunosuppressive therapy. Peripheral blood CD19+ B cells were purified from dcSSc patients and age- and sex-matched healthy controls (HC, n=15). mRNA expression of 92 B cell specific PI3K pathway related genes was measured using a Taqman qPCR array and was validated by individual qPCR. Isolated B cells were activated through BcR using anti-IgG/M antibody or anti-CD180 antibody, and their combination followed by flow cytometric analysis of phospho-Akt (S473), phospho-S6 (S235/S236) and phospho-NF-κB p65 (S529) positive cells.

**Results:** Analyzing the expression of 92 PI3K pathway associated genes we found altered expression of molecules playing a role in alternate B cell activation and innate signaling. The expression of both IL-4 receptor and osteopontin (SPP1) was upregulated in B cells of untreated dcSSc patients, but became downregulated upon immunosuppressive therapy. Innate molecules like TLR4 and complement component 3 remained highly upregulated and the downregulation of CD180 was not inhibited by immunosuppressive treatment, thus may preserve the activated state of B cells in dcSSc. We aimed to model B cell activation via TLR4 and CD180 and pus and endogenous ligands of TLR4 failed to activate isolated B cells. Since there are not known ligands of CD180, we investigated the effects of anti-CD180 itself and also its combination with BcR mediated stimulation of B cells. Analyzing the phosphorylation of the PI3K pathway-associated molecules revealed an impaired responsiveness of dcSSc B cells to anti-CD180 alone, and the combination of anti-CD180 and anti-Ig induced different phosphorylation patterns of Akt, S6 and NF-κB molecules in dcSSc and healthy controls (HC).

**Conclusion:** Analysis of B cells from early dcSSc patients revealed that B cells possess molecular changes in PI3K pathway that involves innate immune components. Gaining new insight into innate B-cell activation in SSc could be helpful for finding new therapeutic targets.

**THU0326**  
**ANALYSIS OF PHOSPHATIDYLINOSITOL 3-KINASE PATHWAY IN B CELL ACTIVATION OF SYSTEMIC SCLEROSIS PATIENTS**

Diercks: None declared, Harry van Goor: None declared, Andries Smit Abdulle : None declared, Anniek van Roon: None declared, Gilles Diercks: None declared, Harald van Goor: None declared, Andries Smit

**Background:** AUTOANTIBODIES PRODUCED BY PATIENTS WITH SYSTEMIC SCLEROSIS (SSC) contribute to the pathogenesis of the disease. Autoantibodies targeting Topo-I and Cenp B to directly induce pro-fibrotic activation of fibroblasts.

**Methods:** Dermal fibroblasts were isolated from unaffected and affected skin samples of (n=10) limited cutaneous SSc (LCSSc) patients, from affected skin samples of (n=10) diffuse cutaneous (DcSSc) patients and from (n=20) healthy subjects. Fibroblasts were stimulated with serum-isolated fractions of Topo-I, Cenp B and control IgGs in ratios 1:100 and with Cenp B and Topo-I IgGs and with Cenp B+ and Topo-I+ sera statistically increased all the profibrotic markers compared to control ones. Stimulation with Cenp B and Topo-I (p<0.01) IgGs reduced unaffected LCSSc and control fibroblast viability in a time- and dilution-dependent manner compared to control IgGs. Similar results were obtained with Cenp B+ (p<0.05) and Topo-I+ (p<0.05) sera compared to control sera. Flow cytometry analysis revealed that both Cenp B/Topo-I IgGs and Cenp B+/Topo-I+ sera induce apoptosis in unaffected LCSSc and control fibroblasts only, while affected LCSSc/DcSSc fibroblasts showed apoptosis resistance. qPCR showed that basal levels of pro-fibrotic markers ACTA2, COL1A1 and TGFBI were upregulated in affected LCSSc/DcSSc fibroblasts correlated with LCSSc unaffected and to control ones. Stimulation with Cenp B and Topo-I IgGs and with Cenp B+ and Topo-I+ sera statistically increased all the profibrotic markers compared to control IgGs (p<0.05) and to control sera (p<0.05). ICC proved that α-SMA, Coll-I and SM22 levels were upregulated in a time- and dilution-dependent manner in unaffected LCSSc and control fibroblasts upon stimulation with Cenp B and Topo-I IgGs and with Cenp B+ and Topo-I+ sera, while they remained stably high in affected LCSSc/DcSSc fibroblasts.

**Conclusion:** This study demonstrates the pathogenetic role of antibodies targeting Topo-I and Cenp B to directly induce pro-fibrotic activation of fibroblasts. Therefore, besides the diagnostic and prognostic use of those autoantibodies in SSC, these data justify the importance of therapeutic use of immunosuppressive drugs in the early stages of the disease.

DO PATIENTS WITH SYSTEMIC SCLEROSIS HAVE ULTRASONOGRAPHIC MODIFICATIONS OF SALIVARY GLANDS SUGGESTIVE OF SJOGREN SYNDROM?

Marion Couderc, Anne Toumadre, Sylvain Mathieu, Martin Soubrier, Jean-Jacques Dubost, CHU Clermont-Ferrand, Rheumatology, Clermont-Ferrand, France

Background: Modificiations in ultrasonographic aspect of major salivary glands have been reported in patients with primary Sjogren Syndrome (pSS) with good diagnostic accuracy. Sicca symptoms are frequently observed in Systemic sclerotic (SSc).

Objectives: To assess the ultrasonographic echostructure of major salivary glands in patients with SSC and compare the modifications with those of patients with pSS or controls with sicca symptoms.

Methods: We performed a mononcentre case-control study between 2014 and 2017 in the university hospital of Clermont-Ferrand (France). Patients with SSc and pSS were fulfilling the American College of Rheumatology/European League against Rheumatism (ACR/EULAR) 2013 and the ACR 2012 classification criteria respectively. Controls patients were complaining of sicca symptoms but did not meet the ACR 2012 criteria. Bilateral parotid and submandibular glands ultrasound (US) were performed in all patients by the same operator blinded to the diagnosis. Inhomogeneity of each of the 4 major salivary glands in B-Mode was graded using the Jousse-Joulin scoring system (scale of 0 to 4) as previously described.[1] The highest grade among the 4 glands was retained as suggestive of Sjogren Syndrome if ≥ 2.

Results: A total of 108 patients were included: SSc (n=25), pSS (n=48) and controls (n=35). Among the 48 patients with pSS, 12 were receiving hydroxychloroquine, 4 an immunosuppressor, 77% had antinuclear antibodies at a significant level (≥1:640), 26 (54%) anti-SSA antibodies, 40/45 (89%) had a labial salivary biopsy suggestive of pSS (Chisholm and Mason score ≥3). Comparing the pSS and the control groups, performance of a US echostructure grade ≥ 2 for the diagnosis of pSS was good: Se=75%, Sp=91.4%, positive predictive value= 92.3%, negative predictive value= 72.7%.

Among the 25 SSc patients, 7 had immunosuppressor therapy, 8 had a localized SSc. Shimier’s test ≤ 5 mm in 5 minutes was present in 9/18 (53%), unstimulated salivary flow ≤ 0.1 mL/minute in 8/14 (57.1%). In the SSc group, 12 patients had an US echostructure grade 0, 6 grade 1, and 7 patients (28%) had an US echostructure grade of ≥ 2: US score=3 (n=5), US score=4 (n=2). Anti-SSA antibodies were found in 1/7 patients with an US echostructure grade ≥ 2 and 2/18 patients with US echostructure grade 0 or 1.

Conclusion: Nearly one third of patients with SSc have US echostructure changes suggestive of Sjogren Syndrome regardless of the presence of anti-SSA antibodies.

THU0329

RED FLAG SIGNS OF SYSTEMIC SCLEROSIS ARE PREVALENT IN SUBJECTS WITH RAYNAUD’S PHENOMENON: THE GENERAL POPULATION AND MAY BE A PROXY FOR LUNG INVOLVEMENT

Amaal Eman Abdulle1, Elisabeth Brouwer2, Harry van Goor3, Johanna Westra2, Karina de Leeuw2, Douwe J Mulder1, 1University of Groningen – University Medical Center Groningen, Internal Medicine, division Vascular Medicine, Groningen, Netherlands; 2University of Groningen – University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 3University of Groningen – University Medical Center Groningen, Pathology and Medical Biology, Section Pathology, Groningen, Netherlands

Background: Pulmonary involvement in systemic sclerosis (SSc) is very difficult to treat when diagnosed too late. Therefore, in order to optimally use the “window of opportunity” more attention should be given to the early identification of SSc. To the best of our knowledge, no studies exist that have structurally assessed the epidemiology of red flag signs and potential signs of pulmonary involvement in patients with Raynaud’s phenomenon (RP).

Objectives: To assess the prevalence of red flag signs in patients with RP. Moreover, we aim to investigate the occurrence of pulmonary signs and symptoms in participants with red flag signs.

Methods: We retrospectively analyzed data from the LifeLines Cohort Study, which is a large population-based cohort study in the Northern parts of the Netherlands. A total of 74011 participants completed the connective tissue disease questionnaire. The presence of RP and red flag signs for SSC (i.e., puffy fingers, skin thickening distal, skin thickening proximal, and pitting scars) were obtained. Participants were classified as having red flag signs by the presence of at least one red flag sign in addition to RP. In addition, patient characteristics, self-reported pulmonary complaints, spirometry (screening for interstitial lung disease (ILD)), and uric acid (global screening for pulmonary arterial hypertension (PAH)) were also obtained. Three groups of participants were formed, namely: participants with RP and red flag signs (n=981), participants with RP without red flag signs (n=2946), and participants without RP and without red flag signs (n=70037).

Results: The prevalence of red flag signs was 5 fold higher in participants with RP, as compared to the non-RP group: RP 25% [23.7-26.4], non-RP 5% [4.9-5.2], p<0.001. A total of 413(42.1%) of the participants with RP and red flag signs reported dyspnea, which was 1.5 fold higher than in those with RP but without red flag signs, and two-fold higher compared to participants without RP and without red flag signs (p<0.001). Moreover, dyspnea in rest and after exertion was more prevalent in participants with RP and red flag signs (p<0.001). In addition, participants with RP and red flag signs more frequently reported to suffer from pulmonary fibrosis (p<0.001, table 1), and had the lowest forced vital capacity, as compared to the other groups (p<0.001). Conversely, uric acid was not found to be elevated in participants with RP and red flag signs.

Conclusion: This unselected cohort study from the general population demonstrates that the prevalence of red flag signs in subjects with RP may be as high as 25%. Potential signs and symptoms of pulmonary complaints are more prevalent in participants with RP who also reported red flag signs. This could indicate an increased risk of pulmonary involvement (i.e., ILD and PAH) in RP patients with red flag signs, although additional specific tests are mandatory to substantiate definite disease.

Abstract THU0329 – Figure 1. Prevalence of red flag signs in participants with and without Raynaud’s phenomenon.

Disclosure of Interests: Amaal Eman Abdulle : None declared, Elisabeth Brouwer Speakers bureau: Dr. Brouwer as an employee of the UMCG received speaker fees and consulting fees from Roche which were paid to the UMCG, Harry van Goor: None declared, Johanna Westra: None declared, Karina de Leeuw: None declared, Douwe J Mulder Grant/ Research support from: My University has received research grants for my research from: Boehringer Ingelheim and Actelion, Speakers bureau: My University has received speakers fee from: Sanofi
Background: Although several previously conducted studies reported on the prevalence of Raynaud’s phenomenon (RP) in different regions of the world, these studies often included a limited number of selected individuals. Moreover, no studies exist that have systematically assessed the relative contribution of known etiological factors of RP in the general population of the Netherlands.

Objectives: To assess the prevalence of RP, and gender-specific etiological factors associated with RP in the Northern parts of the Netherlands.

Methods: Data from the Lifelines cohort were analyzed, in which all participants completed the self-administered validated connective tissue disease questionnaire. Subjects who reported cold-sensitive fingers and biorhythmic colour changes in response to cold were considered to suffer from RP. Known etiological factors such as hormonal status, body mass index (BMI), smoking behaviour, and comorbidities were all assessed in a standardised way.

Results: In total 93,935 participants completed the questionnaire (mean age 45.6 ±12.9). The prevalence of RP was 4.2% [95% CI 4.1-4.4] which was approximately three-fold higher in females (5.7%, 95% CI [5.5-5.9]), as compared to males (2.1%, 95% CI [1.9-2.2] p-value <0.001, figure 1). Regarding gender-specific risk factors associated with RP, we observed that BMI <18.5 (OR 4.6 [2.4-8.7], p<0.001), cardiovascular disease (OR 1.93 [95% CI 1.31-1.78], p<0.001), history of cancer (OR 1.40 [1.00-1.95], p=0.049), use of beta-blockers (OR 1.39 [1.06-1.83], p=0.01), and smoking (OR 1.28 [1.09-1.51], p=0.003) were associated with an increased odds of RP in men. Conversely, alcohol consumption, diabetes and age were not associated with RP in men. In females, BMI<18.5 (OR 2.8 [2.2-3.64], p<0.001), cardiovascular disease (OR 1.42 [1.32-1.54], p<0.001), receiving hormonal contraception (OR 1.17 [1.08-1.26], p<0.001), and hormonal replacement therapy (OR 1.14 [1.04-1.25], p=0.007) were associated with increased odds of RP. Moreover, smoking behavior, use of beta-blockers, alcohol consumption, and diabetes were not associated with RP in women. A BMI<30 was associated with a strongly decreased odds of RP in both men (OR 0.22 [0.11-0.42], p<0.001) and women (OR 0.35 [0.28-0.44], p<0.001).

Conclusion: This large cohort study found a prevalence of 4.2% of RP in the Northern part of the Netherlands, with an expected predominance in young female subjects. Moreover, the etiologic risk factors of RP are multifactorial and clearly gender-specific (e.g., hormonal status in women, smoking behavior and use of beta-blockers in men), with underweight strongly increasing and obesity strongly decreasing the likelihood of RP in both sexes. This might suggest that different mechanisms influence the expression of RP in men and women.

THU0331 SKELETAL TROPOIN I A POSSIBLE NOVEL BIOMARKER FOR MANAGEMENT OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Kathrina Bamberg1, Laura Mehtälä1, Olli Arola2, Seppo Laitinen3, Paulina Nordling4, Marjatta Strandberg5, Niko Strandberg6, Johanna Paltta7, Mariku Mali8, Fabricio Espinosa-Ortega9,10,11, Laura Pirilä1, Ingrid E. Lundberg1, Tanja Savukoski1, Kim Pettersson1, University of Turku, Department of Biochemistry/Biotechnology, Turku, Finland, 2Turku University Hospital, Intensive Care Medicine and Pain Management, Turku, Finland, 3Regional Laboratory, Nordiab Kajaani, Kajaani, Finland, 4Turku University Central Hospital, Heart Center, Turku, Finland, 5Turku University Central Hospital, Department of Orthopaedic Surgery, Turku, Finland, 6Turku University Central Hospital, Department of Rheumatology, Turku, Finland, 7Karolinska Institute, Division of Rheumatology, Department of Medicine, Stockholm, Sweden

Background: The current biomarkers for the diagnosis and monitoring of diseased and injured skeletal muscles, such as creatine kinase (CK), have limited tissue specificity and incapability to differentiate between pathological and physiological changes. Thus, new biomarkers with improved diagnostic certainty are needed. Skeletal troponin I (skTnI) is a promising new biomarker for injured and diseased skeletal muscle tissue. Although studies have reported that circulating skTnI levels are elevated in response to trauma, exercise and various muscular diseases (1), its clinical utility to serve as a diagnostic indicator has largely been unexplored.

Objectives: Our aim was to develop and validate a novel assay for skTnI and to assess its clinical performance with idiopathic inflammatory myopathy (IIM) patients.

Methods: A two-step fluorimunoassay was used to analyze the levels of skTnI in samples from healthy reference individuals (n=125), trauma patients (n=151), and patients with IIM (n=94). Later, skTnI and CK levels in patients with IIM were compared according to their disease activity status (active, pre-active or stable).

Results: The limit of detection was 1.2 ng/ml, and the upper reference limit (90th percentile) was 5.4 ng/ml. The median skTnI concentrations were <LoD, 2.7 ng/ml, and 9.8 ng/ml in reference, trauma, and IIM cohorts, respectively. Differences in measured skTnI levels were statistically significant between all three study cohorts (Mann-Whitney p<0.001 for all). skTnI and CK had a strong positive correlation (Spearmans’s r=0.848, p<0.001). With skTnI, patients in both pre-active and active IIM were differentiated from stable phase patients (33.9 and 34.5 ng/ml vs 5.1 ng/ml, p<0.001 for both). This was not possible with CK as significantly elevated CK levels were mainly present in active IIM (median 16.5 ikat/L) and the medians of pre-active and stable phase skeletal muscle tissue (i.e., skat/L vs 1.7 ikat/L, p=0.060) remained close to normal reference ranges. The area under the receiver operator characteristic curve was 0.87, 0.84, and 0.87 for skTnI and CK individually and combined, respectively.

Conclusion: With the developed skTnI assay, IIM patients were identified from healthy individuals and from patients with traumatic muscular injuries. Also, skTnI was shown to outperform CK in detecting IIM patients in different disease activity statuses.

ABSOLUTE REDUCTION OF REGULATORY T CELLS AND EFFICACY OF SHORT-TERM AND LOW-DOSE IL-2 IN PATIENTS WITH DERMATOMYOSITIS OR POLYMYOSITIS

Min Feng1, Xiang-Cong Zhao1, Chong Gao2, Jing Luo1. 1The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China; 2Brigham and Women’s Hospital, Harvard Medical School, Pathology, Boston, United States of America

Background: Dermatomyositis (DM) and polymyositis (PM) are heterogeneous, chronic and progressive autoimmune disorders characterized by symmetrical, proximal muscle weakness[1,2]. Although the pathogenesis of PM/DM remains unclear, immune intolerance caused by the deficiency of regulatory T (Treg) cells may be an important cause of PM/DM, and quantitative status of peripheral Treg cells is unclear in this disease. Low-dose interleukin-2 (ld-IL2) has been found to enhance proliferation, function and survival of Treg cells to regulate immune tolerance[3]. However, the therapeutic effect of ld-IL2 on PM/DM has not been reported.

Objectives: To investigate whether peripheral Treg cells are reduced and whether ld-IL2 has therapeutic efficacy in PM/DM.

Methods: Total 71 PM/DM inpatients (10 PM and 61 DM) were retrospectively studied. Five PM and 35 DM patients were treated with ld-IL2 (5.0*10^5 international units (IU) per day for 5 days) accompanied by conventional therapy, while the rest PM/DM patients only with conventional therapy. Thirty of age- and gender-matched healthy adults were regarded as healthy controls (HCs). CD3+T, CD4+T, CD8+T, B, NK, Th1, Th2, Th17 and Treg cells, as well as cytokines [interleukin-2 (IL-2), interleukin-4 (IL-4), interleukin-6 (IL-6), interleukin-10 (IL-10), tumor necrosis factor-α (TNF-α), interferon-γ (IFN-γ) and interleukin-17 (IL-17)] were measured by flow cytometry. The correlation coefficients between various indicators and Myositis Disease Activity Assessment Visual Analogue Scale (MYOACT) were calculated by Spearman correlation test.

Results: Both PM and DM patients had significantly lower number of CD3+T (P=0.018, P=0.003) and CD4+T cells (P=0.035, P=0.016) than HCs, as well as the number and percentage of Treg cells (P<0.001) in PM/DM and these of NK, Th1 cells in DM, while Th2 and Th17 cells didn’t exhibit any significant difference. In addition, the ratio of Th1/Th2 in DM (P<0.015, P=0.001). Meanwhile, the production of serum IL-2 was reduced in PM/DM (P=0.001), while, in contrast, IL-4, IL-6, IL-10, TNF-α, IFN-γ and IL-17 increased. ld-IL2 could significantly increase the number of Treg cells but have little effect on Th17 cells in DM. In addition, MYOACT was correlated with the number of CD3+T, CD4+T, CD8+T, Th1, Th2, Treg cells, PLT and lymphocyte (r=-0.388, P=0.002; r=-0.360, P=0.004; r=-0.364, P=0.004; r=-0.386, P=0.002; r=-0.282, P=0.028; r=-0.262, P=0.041; r=-0.311, P=0.015; r=-0.388, P=0.002; respectively) negatively, as well as the percentage of CD3+T and CD8+T cells (r=0.277, P=0.030; r=-0.291, P=0.023), opposite to aspartate transaminase (AST) (r=0.289, P=0.025) in DM.
2-CARBA CYCLIC PHOSPHATIDIC ACID (2CCPA) SUPPRESSES PROFIBROTIC ACTIVITY IN SYSTEMIC SCLEROSIS SKIN FIBROBLASTS AND BLEOMYCIN-INDUCED SKIN FIBROSIS IN MICE

Tomoaki Higuchi1, 2, Kae Takagi3, Akiko Tochimoto1, Yuki Ichimura1, Takanari Norose1, Yasuhiro Katsumata1, Ikuko Masuda4, Hisashi Yamakawa5, Toshihiro Moroboshi6, Yasushi Kawaguchi7, Tokyo Women’s Medical University, Department of Rheumatology, Tokyo, Japan; 8SANSHO, Co., Ltd, Tokyo, Japan

Background: Systemic sclerosis (SSc) is a connective tissue disorder with progressive fibrosis in multiple organs including skin, lung and the gastrointestinal tract. Fibrosis is thought to be driven by activated fibroblasts. Therefore, inhibition of the profibrotic activity of activated fibroblasts may be a promising therapeutic approach in skin fibrosis in SSc. The autotaxin (ATX)/lysophosphatic acid (LPA) axis is reportedly involved in fibrotic pathogenesis in SSc1, 2-carba cyclic phosphatic acid (2ccPA) is a naturally occurring lipid mediator and one of its pleiotropic properties is to inhibit the ATX/LPA axis. Therefore, we investigated the anti-fibrotic effect of 2ccPA on human SSc skin fibroblasts and bleomycin-induced skin fibrosis in mice.

Methods: This study was approved by the ethics committee and the ethical review committee of animal experiments of Tokyo Women’s Medical University. We informed all participants of the content of this study, and written consent was obtained. Skin fibroblasts were obtained from SSc patients and adult healthy individuals were purchased. The cells were incubated with 1-10 μM 2ccPA in the presence or absence of 10 ng/ml transforming growth factor-β1 (TGF-β1). Messenger RNA (mRNA) and protein expression for type I collagen, connective tissue growth factor (CTGF), α smooth muscle actin (αSMA), fibronectin (FN) and TGF-β1 were assessed by qRT-PCR or Western blotting. Procollagen type I (CPII), procollagen E3 (PGE3) and hepatocyte growth factor (HGF) levels in the supernatant were assessed by ELISA. Intracellular cyclic adenosine monophosphate (cAMP) levels were calculated using a commercially available EIA kit. Forskolin was used to increase intracellular cAMP levels in cultured SSc skin fibroblasts. An inhibitor of denylate cyclase (AC), 2′-deoxyadenosine, was used to investigate whether the anti-fibrotic effect of 2ccPA was mediated via the AC/cAMP pathway. Furthermore, we used a mouse model of bleomycin-induced skin fibrosis to investigate the safety and anti-fibrotic effects of 2ccPA.

Results: Ten μM 2ccPA significantly reduced mRNA and protein expression for type I collagen, CTGF, αSMA in SSc skin fibroblasts and adult healthy skin fibroblasts treated with TGF-β1. PGE2 and HGF levels in the supernatant of SSc skin fibroblasts were also reduced by 2ccPA treatment. 2ccPA increased intracellular cAMP levels as well as the AC stimulator, forskolin. In addition, forskolin decreased the mRNA expression of profibrotic markers. Reduction of COL1A1 mRNA expression by 2ccPA was blocked by treatment with 2′-deoxyadenosine in cultured SSc skin fibroblasts, suggesting that the anti-fibrotic activity of 2ccPA was partially mediated via AC stimulation. In mouse experiments, intraperitoneal injection of 10 mg/kg 2ccPA significantly reduced the development of skin thickness, collagen content and αSMA-positive cell counts.

Conclusion: 2ccPA suppressed the profibrotic activity of SSc skin fibroblasts and the development of bleomycin-induced skin fibrosis. Our experiments suggested that the anti-fibrotic property of 2ccPA was at least in part due to increased intracellular cAMP levels in skin fibroblasts. 2ccPA has been reported to be well tolerated in clinical trials of other diseases and may be expected for the treatment of fibrotic lesions in SSc.

Disclosure of Interests: None declared.

Background: In inflammatory diseases, such as rheumatoid arthritis, early treatment has demonstrated to improve disease control and decrease mortality. It is not known if an early treatment could have similar effects on inflammatory myositis (IM) patients.

Methods: All patients from REMICAM were included (1). The influence of time elapsed between initial symptoms and diagnosis or start of therapy, and the year of diagnosis (before or after 2000), on mortality and disease control (defined as the possibility of glucocorticoid (GC) withdrawal due to IM improvement), was studied by means of survival analysis and regression proportional hazard bi and multivariate Cox models. All factors with p<0.2 in bivariate analysis were included in multivariate models. The mortality analysis was controlled for age, sex, and other known mortality factors: cardiovascular risk factors, interstitial lung diseases (ILD), cardiac involvement and cancer. The disease control analysis was controlled for age, sex, and other known severity factors such as ILD, cardiac involvement and IM subtypes.

Results: From 479 patients (74% females, 52% polymiositis, 44±22 years at diagnosis, 10±8 years follow up), 208 (43%) were diagnosed before year 2000, and 271 (57%) after year 2000. Mortality was independently associated with less ILD presence, lower n° of therapies and a shorter time between the initial symptoms and the start of IS therapy (Table 1). Risk factors for mortality were age, male sex and cancer, but not the delay in diagnosis or in the start of therapy (Table 2).

Conclusion: In the REMICAM cohort, disease control is more frequent in younger patients, diagnosed after 2000, with early initiation of IS therapy. Mortality was not associated with the delay in diagnosis or therapy in our study. Our data support the hypothesis that, in IM, as in other inflammatory diseases, an early treatment is essential to decrease inflammation and achieve disease control.
Objectives: This pilot study aims to establish a novel ex vivo experimental model that can demonstrate fibrotic change in mouse skin and represent ADSC loss within days rather than within weeks needed for current models.

Methods: Six B6 mice were sacrificed at between 12-16 weeks of age and skin tissues were obtained from the back by 8mm punch biopsies. Skin samples were immersed in Dulbecco’s Modified Eagle’s Medium containing either bleomycin (5 or 10mU/ml) or PBS as control for one or three days. After harvesting, H&E staining was performed on skin samples to assess phenotypic fibrotic changes. Flow cytometry (FACS Canto) was used to measure the viability, total cell number and ADSC change. A total collagen assay quantified collagen production in samples.

Results: On H&E staining, compared to controls, samples cultured with 5mU/ml bleomycin for a day showed increased density of dermis and deposition of amorphous pink material, likely representing increased collagen. With 10mU/ml bleomycin, these changes were greater and especially affected the upper dermis. On day 3, samples in 5mU/ml and 10mU/ml bleomycin appeared to have denser fibrosis, broader dermis band, and narrower DWAT layer. The histopathological change was most prominent on day 3 sample in 10mU/ml bleomycin, with the dermis layer 40% thicker and the DWAT layer 37% narrower than the control. However, all the samples on day 3 showed stress, such as epidermis detachment and apoptosis in the epidermis. On the Total Collagen Assay, collagen deposition on day 1 in control sample was 7.7ug/mm, compared to 33ug/mm from sample in 10mU/ml bleomycin. On day 3, collagen deposition in 10mU/ml bleomycin was 37ug/mm which was 2.5 to 5 times higher than control. On FACS, the decrease in ADSC level correlated to the increase in concentration of bleomycin and the number of days treated, with the greatest drop in samples in 10mU/ml bleomycin on day 3.

Conclusion: Our results thus far suggest that we are creating a novel ex vivo model of skin fibrosis that can help better understand how ADSCs can be of therapeutic benefit in SSc. This rapid ex vivo model will complement the existing in vivo model. Our next step will be to investigate the changes of profibrotic cytokines before and after applying ADSCs purified from healthy mice to understand how skin fibrosis can be reversed.

**COMPARISON OF THE EFFICACY OF TWO RITUXIMAB SIMVASTATIN-CONJUGATED NANO PARTICLE REGIMENS IN THE PATIENTS WITH SYSTEMIC SCLEROSIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE**

Olga Ovsyannikova, Mayya Starovoytova. Disclosure of Interests: None declared

**Background:** Rituximab (RTM) is considered as a promising therapeutic agent for treatment of interstitial lung disease (ILD) in the patients with systemic sclerosis (SSc). However, the limited number of RTM-treated patients, heterogeneity of the studies in relation to main parameters, considerably different dose regimens, cumulative doses, and observation periods does not allow univocal conclusions on RTM efficacy or definitive recommendations on RTM use in the patients with SSc. The question whether to combine RTM with immunosuppressants (IS) or it is possible to use it as a single-agent therapy in the patients with SSc associated with ILD is still relevant.

**Objectives:** To compare the time courses of pulmonary function parameters and dermal fibrosis parameters during the use of RTM in combination with IS and as a single-agent therapy in the patients with SSc associated with ILD in the open-label prospective non-randomized study. **Methods:** 90 patients with the confirmed SSc diagnosis and ILD evidence associated with ILD in the open-label prospective non-randomized study. **Results:** In Groups A and B during the therapy significant decrease in mRss was observed. The treatment groups did not differ significantly in the median FVC increments, clinically meaningful FVC and DLCO increments of decrements, and EScSG and mRss time courses.

**Conclusion:** RTM administration both in combination with IS and as a single-agent therapy in the patients with SSc associated with ILD effectively alleviated skin induration and EScSG, improved or stabilized the pulmonary function parameters. The absence of statistically significant difference in the time course of evaluated parameters between the groups substantiate potential RTM use as a single-agent therapy that, this is most important for the patients with poor tolerability or contraindications to IS administration.

**SIMVASTATIN-CONJUGATED NANO PARTICLE ENHANCES THE THERAPEUTIC EFFECT OF ADIPOSE-DERIVED STEM CELLS ON INTERSTITIAL LUNG DISEASE**

Takuya Koizumi, Takayasu Suzuka, Shogo Matsuoka, Il Masaaki, Tohru Takeuchi, Shigeaki Arawaka. Osaka Medical College, Takatsuki, Japan

**Background:** Interstitial lung disease (ILD) associated with connective tissue disease is a life-threatening pathological condition that causes respiratory failure when it progresses. Lung inflammation is treated with corticosteroids and immunosuppressants, and pulmonary fibrosis is treated with anti-fibrosis agents such as pirfenidone and nintedanib. However, many cases are treatment-resistant and the outcome is poor. Moreover, adverse effects such as infections resulting from immunosuppressive therapy are problematic. The development of new treatments is thus required for ILD from the viewpoint of the poor effect and adverse effects of the currently available treatments. Research and development with adipose-derived stem cells (AdSCs) in immunosuppressive therapy have progressed for autoimmune diseases, and favorable outcomes have been reported. In recent years, the effectiveness of AdSCs in ILD model mice has been demonstrated (ref). The statin preparation has not only an anti-fibrotic action but also an action of promoting a cellular function including angiogenesis promoting action, an immunosuppressive action, an anti-fibrotic action, an action of promoting a cellular function including angiogenesis promoting action, an immunosuppressive action, and favorable outcomes have been reported. In recent years, the effectiveness of AdSCs in ILD model mice has been demonstrated (ref).

**Methods:** To compare the time courses of pulmonary function parameters and dermal fibrosis parameters during the use of RTM in combination with IS and as a single-agent therapy in the patients with SSc associated with ILD in the open-label prospective non-randomized study. **Results:** In Groups A and B during the therapy significant decrease in mRss was observed. OBJECTIVES: We have investigated the hypothesis that statin, an agent with pleiotropic effects, could augment the therapeutic potential of AdSCs. Methods: ILD was induced by bleomycin (BLM) in C57BL/6 mouse, and the mice were assigned in the following groups: 1) Control, 2) NP-AdSCs (2.5×10⁶ cells), and 3) STNP-AdSCs (2.5×10⁶ cells). Results: Simvastatin-conjugated nanoparticles (STNP) significantly promoted the migration activity and cell survival without changing the proliferation activity, and up-regulated transforming growth factor (TGF)-β1 in vitro assays. Lung inflammation and fibrosis assessed were significantly suppressed at 4 weeks after starting BLM administration in STNP-AdSCs group (Figure). The levels of IL-4, IFN-gamma, TNF-alpha, CCL1A1, and TIMP1 mRNA expression at 28 days after BLM administration were significantly lower in STNP-AdSCs group compared with that in other groups. Conclusion: Simvastatin-conjugated nanoparticles enhanced the therapeutic effect of a small number of AdSCs transplantation.

PULMONARY INVOLVEMENT AND OUTCOME IN SYSTEMIC SCLEROSIS (SSC) – ILD-PH AS AN IMPORTANT SUBSET

Michael Kreuter,1 Francesco Bonella,2 Ulf Müller-Ladner,3 Elise Siegert,4 Jörg Henes,5 Gabriela Riemekasten,6 Norbert Blank,7 Marc Schmälzeg,8 Ina Koetter9, Claudia Guenther,10 Tim Schmeiser,11 Gabriele Zeidler12 Alexander Kreuter13, Margitta Worm14, Laura Susok,15 Aaron Juche16, Ina Koetter9, Claudia Guenther10, Tim Schmeiser11, Gabriele Zeidler12

Background: Pulmonary involvement is the leading cause of death in SSc and can manifest as interstitial lung disease (ILD), pulmonary hypertension (PAH) or a combination (ILD-PH). Aim of this analysis was to determine prevalence, clinical characteristics and outcomes of different forms within the German SSC network.

Objectives:
Methods: SSC patients were analyzed for pulmonary involvement, clinical characteristics and outcome.

Results: There were 3699 pts in 42 centers with a mean follow-up time of 34.4±12.6 months. At baseline, ILD was frequent (29.5%), while ILD-PH and PAH had lower prevalences (7.5%, 6.1%). At the end of follow-up, 32% of SSC pts had ILD, 13% ILD-PH and 7% PAH. ILD and ILD-PH were more frequent in the diffuse form (47%, 12%), while PAH did not differ between subforms. Significant differences in baseline characteristics between PAH vs. ILD-PH vs. ILD were found for age (62, 59, 54 years), sex (males: 15%, 22%, 24%) and smoking prevalence (non-smokers 49%, 63%, 57%). Mean DLCO and FVC were 56%/93% for PAH, 49%/78% for ILD-PH and 56%/81% for ILD. Significant decreases for DLCO (≥15%) and FVC (≥10%) were found in 45%/26% in PAH, 45%/26% for ILD-PH and 36%/16% in ILD. All-cause mortality was 8.1% for the total cohort and differed significantly between patients without pulmonary involvement (4%), ILD (7.8%), PAH (14.2%), and ILD-PH (21%, p<0.001).

Conclusion: ILD is the most prevalent pulmonary involvement in SSC, while PH-ILD is associated with the most detrimental survival. Significant differences in baseline characteristics of types of pulmonary SSC involvement may help to identify patients at risk in the future.

IMPACT OF LANIFIBRANOR, A PAN-PPAR AGONIST, ON THE PULMONARY VASCULAR TONE

Chandran Nagaraj1, Neha Sharma2, Benoe Nagy1, Jean-Louis Junien3, Pierre Broqua4, Irena Konstantinova5, Andrea Olschewski2,6
Grazyna Kwapiszewska1,2, Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria; 3Medical University of Graz, Department of Pulmonology, Graz, Austria; 4Inventiva, Daix, France; 5Otto Loewi Research Center, Medical University of Graz, Graz, Austria

Background: Pulmonary hypertension (PH) is common in patients with fibrosing interstitial lung diseases (ILDs) such as systemic sclerosis (scleroderma) and has a significant impact on survival. The pan-peroxisome proliferator-activated receptor (PPAR) agonist lanifibranor is currently being tested in a phase II clinical trial in scleroderma patients. Although, the antifibrotic effects of lanifibranor have been previously shown in preclinical mouse models of scleroderma and related PH (1), its effects in modulating the pulmonary vascular tone are largely unknown.

Objectives: To evaluate the acute effect of lanifibranor (pan-PPAR agonist) and selective PPAR agonists on the pulmonary vascular tone.

Methods: Freshly isolated intra-pulmonary arteries from explanted human and rat lungs were used in wire myography experiments to assess the acute effect on pulmonary vascular tone of pan-PPAR agonist -lanifibranor and the selective PPAR agonists PPARγ -GW50156 and PPARγ -GW50156 and PPARγ -trogoltiazine (0.01M-30μM) versus vehicle (DMSO). The intra-pulmonary arteries were pre-constricted with 300M of the thromboxane A2 receptor agonist U46619. The contribution of endothelium and nitric oxide was investigated using both native and endothelium-denuded vessels, with and without the nitric oxide synthase inhibitor L-NAME.

Results: Isometric tension measurements in rat pulmonary arteries showed that lanifibranor and the selective PPAR agonists PPARγ -GW50156 and PPARγ -trogoltiazine, induced a significant relaxation compared to their vehicle controls, whereas the PPARα agonist fenofibrate did not show any vasoactive effect on the pre-constricted arteries. Lanifibranor showed a significant vasodilatory effect already at 1μM whereas GW50156 and troglitiazine showed significant vasodilator effects starting from 10μM as compared to their vehicle controls. At the maximum concentration used (30μM), lanifibranor caused a relaxation response of ~85% whereas GW50156 and troglitiazine caused just ~45% and ~50% vasorelaxation (n=6), respectively. The vasodilation induced by pan-PPAR and selective PPAR agonists remained unaffected by pre-treatment of L-NAME or denuded endothelium. Lanifibranor had vasodilatory effects that were strongly superior to any of the selective PPAR agonists in the isolated pulmonary artery from the explanted human lungs (n=3).

Conclusion: The current study revealed that the pan-PPAR agonist lanifibranor caused a rapid dose-dependent relaxation in both rat and human intra pulmonary arteries which were superior to any other PPAR agonists suggesting additive effects of the pan-PPAR agonism. The observed vasoactive effects of pan-PPAR are independent of nitric oxide and endothelium, delineating the specific effect of PPAR agonism on the pulmonary artery smooth muscle cells. These results suggest that lanifibranor could be a promising therapy for vasculopathies such as PH observed in scleroderma patients.

MICRONR27A3P REGULATES WNT SIGNALLING BY TARGETING SFRP-1 IN SYSTEMIC SCLEROSIS

Steven O'Reilly, Northumbria University, Newcastle, United Kingdom

Background: Systemic sclerosis (SSc) is an autoimmune idiopathic connective tissue disease that results in fibrosis of the skin and lungs. Wnt signalling is a highly conserved signalling pathways that is involved in organogenesis and tissue homeostasis. In recent years it has emerged that aberrant Wnt signalling is key in SSc and animal models of the disease. The Wnt pathway comprises of secreted glycoproteins that bind to specific receptors that initiate the pathway and result in beta catenin stabilization. However, secreted antagonists are secreted to block and negatively regulate Wnt signalling. We and others have found reduced sSFRP-1 in SSc, a key Wnt antagonist. Although lower in SSc skin and isolated fibroblast from patients the mechanism governing this is unknown. This work seeks to identify epigenetic mechanisms.

Objectives: Determine the epigenetic regulation of sSFRP-1 in SSc.

Methods: Serum sSFRP-1 was measured in healthy and diffus SSc patients to ascertain the levels of sSFRP-1. Mir27a was identified as a possible microRNA that targets sSFRP1 using siRNA and miRNA. mir27a was transfected into healthy dermal fibroblasts using transfection methods and sSFRP-1 was measured. Collagen was also measured by western blotting after transfection. Mir27a was also measured in SSc dermal fibroblasts using specific Taqman probes and normalized to RNU4 miR. Cloning of the 3’UTR of sSFRP1 into a luciferase reporter vector was performed and then transfected into HEK293 cells with mir27a mimics or with concentration matched scramble and after 24 hours luciferase was monitored.

Results: Significantly reduced expression of sSFRP-1 was found in SSc serum compared to controls (n=10). SSc dermal fibroblasts had 3 fold higher levels of mir27a compared to healthy fibroblasts. Increased mir27a in healthy dermal fibroblasts resulted in significantly less sSFRP-1 secreted into conditioned media and this was co-incident with an increase of collagen1 levels. Finally cloning of the 3’UTR binding site in a luciferase plasmid and overexpression of mir27a led to reduced levels of luciferase in HEK293 cells in vitro.

Conclusion: Reduced sSFRP-1 in systemic sclerosis is mediated by mir27a and this leads to fibrosis via enhanced Wnt signaling. Targeting the epigenetic changes that mediate this may be a therapy in SSc.

SYSTEMIC SCLEROSIS IS A DISEASE OF A PREMATURELY SENESESCENT, INFLAMMATORY AND ACTIVATED IMMUNOME

Bharavy Palojia1, Andrea Low2, Pavanish Kumar3, Suzan Saidin3, Ahmad Lajam3, Sharifah Nur Hazira1,2, Camillus Chua3, Lyuin Lai3, Salvatore Albani3,4
1Translational Immunoology Institute, Singapore; Duke-NUS Academic Medical Centre, Singapore; Singapore General Hospital, Singapore; Singapore General Hospital, Singapore

Background: Systemic sclerosis (SSc) is an autoimmune disease characterised by excessive fibrosis of skin and internal organs, and vascular dysfunction (1). Association of T and B cell subsets have been reported in SSc, however there is lack of systematic studies of functional relations between immune cell subsets in this disease (2,3,4). This lack of mechanistic knowledge hampers targeted intervention.

Objectives: In the current study we sought to determine differential immune cell composition and their interactions in peripheral blood of SSc patients and its impact on disease severity and progression.

Methods: Mononuclear cells from blood of SSc patients (n=20) and healthy controls (n=10) were analysed by mass cytometry using a 36 marker (cell-surface and intracellular) panel to aid in identification of major PBMC lineages including T cells, B cells, monocytes and NK cells and their subsets. Transcriptome analysis (m-RNA sequencing) was performed on sorted T and B cell subsets. Unsupervised clustering of mass cytometry data was performed using in-house developed analysis software MARVIS. This software combines dimension reduction and clustering steps to identify all possible cellular subsets. Further, custom R scripts helped in identifying nodes that were differentially expressed between the study groups and also phenotype of these nodes.

Results: Unsupervised clustering analysis revealed significant differences in the frequencies of T and B cell subsets in patients. Correlation network analysis highlighted an overall dysregulated immune architecture coupled with domination of inflammatory senescent T cell modules in SSc patients. Transcriptome analysis of sorted immune cells revealed an activated phenotype of CD4 and MAIT cells in patients, accompanied with increased expression of inhibitory molecules, reminiscent of
PU.1 INHIBITOR DB1976 CONTROLS FIBROBLAST POLARIZATION IN SYSTEMIC SCLEROSIS AND LEADS TO REPRESSION OF FIBROSIS IN DIFFERENT MODELS OF ORGAN FIBROSIS

Thomas Wohlfahrt1, Simon Rauber1, Markus Luber1, Alina Soare1, Stefanie Weber1, Alexandre-Emil Matei1, Chih-Wei Chen1, Emmanuel Karouzakis2, Hans Kienzer2, Elena Pachera2, Clara Dees1, Alexander Kreuter1, Astrid Juengel2, Steffen Gay1, Oliver Distler2, Georg Schett1, Jörg Distler2, Andreas Ramming3, 1Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 2University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland; 3Medical University Vienna, Division of Rheumatology, Department of Medicine III, Vienna, Austria; 4University Witten-Heerdeke, HELIOS St. Elisabeth Kliniek Oberhausen, Oberhausen, Germany

Background: Persistent activation of fibroblast with excessive release of extracellular matrix is a hallmark of systemic sclerosis (SSc). Fibroblasts can either acquire a “pro-fibrotic” phenotype with excessive matrix production or a “pro-inflammatory” phenotype with releasing of matrix-degrading enzymes and subsequent tissue destruction. Despite these well-characterized phenotypic differences, the molecular mechanisms that drive polarization of fibroblasts into these two functionally opposing phenotypes remain enigmatic.

Objectives: We aimed to evaluate the transcriptional network that promotes the extracellular matrix-producing fibroblast fibrotic fate.

Methods: We established the transcriptional network that induces the pro-fibrotic phenotype of fibroblasts by in silico and immunofluorescence analyses of human fibrotic skin, lung, liver and kidney, and performed functional assays to address the fibrogenic potential of fibroblasts in vitro and in several mouse models of systemic sclerosis. The heterocyclic diazidine DB1976 was used as new therapeutic compound to induce regression of fibrosis.

Results: We identified the ETS transcription factor PU.1 as molecular checkpoint for acquisition of a “pro-fibrotic” phenotype of fibroblasts. Our data demonstrate that expression of PU.1 is effectively silenced in fibroblasts during tissue homeostasis. When the epigenetic control of PU.1 is lost and PU.1 expression is induced, fibroblasts differentiate into a fibrotic phenotype that includes the transcription of numerous pro-fibrotic mediators. PU.1 polarized resting fibroblasts and even repolarized extracellular matrix-degrading inflammatory fibroblasts to an extracellular matrix-producing fibroblastic phenotype. PU.1 is associated with a network of pro-fibrotic factors including members of the TEAD-HIPPO, canonical TGF-β–SMAD and AP1 signaling pathways. Other transcription factors with fibrotic abilities, such as SNAI2 and myocyte enhancer factor (MEF) 2, bind in close vicinity to PU.1-binding sites within the genome and contribute to the recruitment of the transcription machinery that drives the switch towards the fibrotic phenotype. PU.1 has a major coordinating role within this complex network of transcription factors in fibroblasts, as the inactivation of PU.1 alone is sufficient to prevent fibrotic polarization in vitro and in vivo. Finally, we investigated pharmacological targeting of PU.1 as a potential strategy to prevent uncontrolled fibrotic tissue remodeling. DB1976 showed anti-fibrotic effects in vivo in various fibrosis models and across several organs. Treatment with DB1976 not only prevented bleomycin-mediated skin fibrosis, but also induced regression of pre-established fibrosis, and was well tolerated.

Conclusion: These findings suggest that PU.1 inhibition may represent a novel and effective therapeutic approach to treat a wide range of fibrotic diseases. Inactivation of PU.1 effectively reverted the fibrotic phenotype of fibroblasts to a resting state and induced the regression of tissue fibrosis.

THU0344 A PILOT STUDY ASSESSING THE EFFECT OF AIR POLLUTION ON EXTRACELLULAR VESICLES IN SYSTEMIC SCLEROSIS

Tommaso Chioppi1, Mirjam Hoix2, Simona Iodice3, Laura Pergoli4, Orazio De Lucia5, Antonella Murgio5, Luca Ferrari5, Valentina Bola5, Francesca Ingegnoli1,2, ASST Pini-CTO, Division of Clinical Rheumatology, Milano, Italy; 2Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milano, Italy

Background: Systemic sclerosis (SSc) is a severe autoimmune disease characterized by a progressive multi-organ fibrosis. The identification of specific diagnostic and prognostic biomarkers remains an unmet need. Over the past few years, it has been suggested that extracellular vesicles (EVs) and environmental toxicants, such as particulate matter (PM), may have an important role in the pathogenesis of autoimmune diseases. At present, no data are available on the impact of PM exposure on EVs from patients with SSc.

Objectives: Our aim was to evaluate the effects of PM with aerodynamic diameter ≤ 10 μm (PM10) and ≤ 2.5 μm (PM2.5) on EVs in SSc and osteoarthritis (OA) as control.

Methods: Plasma EVs were analyzed by Nanosight and flow cytometry after labeling with the following markers: CD14 (monocyte), CD61 (platelet), CD25 (T-reg), human endogenous retrovirus w (HERV-w), human leukocyte antigen G (HLA-G). Demographic and clinical data were collected for each patient. Plasma EV concentrations were measured in SSc and OA patients and were analyzed by generalized linear regression models. Daily PM concentrations, estimated by Regional Environmental Protection Agency at municipality resolution, were used to assign short-term exposure (mean of the 7 days preceding the evaluation) to each study subject.

Results: 12 consecutive patients with limited cutaneous SSc (11 female, median age 66.8, median disease duration 12.3, 7 anti-centromere positive, median mRSS 3.5) and 12 patients with OA (median age 67.1, median disease duration 9.3, 8 female) were enrolled. The increase of PM2.5 led to a decrease of HERV-w+ microvesicles (MV) in both SSc (β=-0.10; p<0.01) and OA (β=-0.09; p=0.01) and of HLA-G+ (β=-0.11; p<0.01) only in SSc. Similar results were observed analyzing PM10 exposure. Analysis of EVs concentration according to their dimension showed a negative association in the size range of exosomes (83-
TEXTURE-BASED RADIOMICS FEATURES DISCRIMINATE DIFFERENT STAGES OF EXPERIMENTAL INTERSTITIAL LUNG DISEASE

Janine Schniering1, Matthias Brunner1, Oliver Distler1, Matthias Guckenberger2, Stephanie Tanadini-Lang2, Britta Mauren1. 1Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2Department of Radiation Oncology, University Hospital Zurich, Zurich, Switzerland.; 3Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen-PSI, Switzerland; 4Institute of Diagnostic and Interventional Radiology, University Hospital Zurich, Zurich, Switzerland.

Background: Interstitial lung disease (ILD) is a life-threatening complication of systemic sclerosis (SSc). There is an unmet need for validated, routinely available biomarkers for disease staging and individualized patient stratification. In that respect, high-resolution computed tomography (HRCT), routinely performed in the work-up of SSc-ILD patients, has great potential as a source for non-invasive imaging biomarkers. Recently, radiomics, the quantitative extraction of hundreds of radiologic image features has great potential to provide biological and stage-specific quantitative information on lung (micro-)architecture and thus could serve as quantitative imaging biomarkers for guided decision making in SSC-ILD.

Objectives: To evaluate the performance of CT-based radiomics for differentiation of IIM subtypes.

Methods: The study included 464 patient samples collected at Hospital Vall d’Hebron, Autonomous University of Barcelona, most of whom had a diagnosis of IIM (n=264). As controls, samples from patients with myositis like conditions (ML, n=20), rheumatoid arthritis (RA, n=33), systemic lupus erythematosus (SLE, n=40), Sjogren’s syndrome (SS, n=25), infectious diseases (ID, n=40) and healthy individuals (HI, n=42) were included. All samples were tested using a novel fully automated particle-based multi-analyte technology (PMAT, Inova Diagnostics, research use only; Jo-1, PL-7, PL-12, EJ, Mi-2b, NXP2, SAE, TIF1y, MDA5, HMGCR, SRP) which utilizes paramagnetic particles with unique signatures and a digital interpretation system.

Results: CT imaging visualized morphological changes of the lung architecture in BLM-treated mice, as evidenced by a time-dependent increase of grey areas on chest CT images and a gradual increase in tissue density on density-masked lungs. Accordingly, 6 out of 17 classical histogram features (e.g. mean CT density, skewness and kurtosis) distinctly distinguished diseased from healthy mice with area under the curve values (AUCs) >0.87 (p<0.05) and thus detected lung remodelling. However, histogram-based features failed to differentiate between the different time points and thus stages of experimental lung fibrosis as investigated by receiver operating characteristic curve analysis and by hierarchical clustering. In contrast, 59 out of 137 texture-based radiomics features, including features describing image homogeneity or contrast detected ILD and distinguished the different stages with excellent accuracy (AUCs>0.84; p<0.05) thus outperforming the classical histogram features.

Conclusion: We confirmed the potential of CT-based texture features for diagnosis and also help to stratify idiopathic inflammatory myositis (IIM) patients with particular clinical features, treatment responses, and disease outcome. Standardization of MSA detection is of high importance because these antibodies also have the potential to be used in classification criteria.

Disclosure of Interests: None declared, Britta Maurer Grant/research support from: Prof. Distler has/had consultancy relationship within the last 3 years with Actelion, AnaMar, Bayer, Boehringer Ingelheim, ChemomAb, espereRare founda, Genentech/Roche, GSK, Inventiva, Ipsilarmaco, iQvia, Lilly, medac, Medimmune, Mitsubishi Tanabe Pharma, Pharmavcylc, Novartis, Pfizer, Sanofi, Sero-dapharm and UCB in the area of potential treatments of sclerosis and its complications. In addition, he had/has consultancy relationship within the last 3 years with A. Menarini, Amgen, Abbvie, GSK, Mepha, MSD, Pfizer and UCB in the field of arthritis and related disorders, Matthias Guckenberger Grant/research support from: Grant/research support by Varian Medical Systems and Siemens Healthcare, Britta Maurer Grant/research support from: Grant/research support from Abbvie, Protagen, Novartis; congress support from MSD, Pfizer, Roche, and Actelion.
Results: The sensitivity/specificity of the individual MSA were: 19.7%/100% (Jo-1), 7.2%/100.0% (M2), 3.0%/99.0% (NXP2), 3.8%/100.0% (SAE), 2.7%/100.0% (PL-7), 1.9%/99.5% (PL-12), 1.1%/100.0% (EJ), 15.5%/99.5% (TIF1Y), 8.3%/98.5% (MDAS), 6.1%/99.0% (HMGCR) and 1.9%/98.5% (SRP). The overall clinical performance was: sensitivity 68.2% (95% confidence interval 62.3-73.5%), specificity 94.0% (95% CI 89.8-96.5%) and odds ratio 33.8. In the table below, the sensitivity and specificity of each analyte for IIM subtypes was calculated along with odds ratio.

Conclusion: The novel PMAT used to detect a spectrum of MSA in IIM on a fully automated system showed good sensitivity and specificity in line with the known associations of MSA. Sensitivities and specificities of the individual MSA are within expected ranges. Lastly, the individual markers help to stratify patients into IIM subtype which is important for management of the patients.

Background: The fibrosis in systemic sclerosis (SSc) progresses from microvascular alterations, immune system activation, and increased extracellular matrix protein synthesis into the skin and internal organs, primarily mediated by myofibroblasts.1 Myofibroblasts are characterized by a high expression of α-smooth muscle actin (αSMA) and by the overproduction of type I collagen (COL1) and fibronectin (FN).2 Although myofibroblasts primarily derive from fibroblasts Varela-Smires et al.1 Varela-Smires et al.1, Stefano Soldano1

1University of Genova, IRCCS Polyclinic San Martino Hospital, Research Laboratory and Academic Division of Clinical Rheumatology, Dept. of Internal Medicine, Genoa, Italy; 2University of Genova, IRCCS Polyclinic San Martino Hospital, 2Clinical Immunology, Dept. of Internal Medicine, Genoa, Italy; 3Ghent University Hospital, Dept. of Rheumatology, Ghent University Hospital, Ghent, Belgium; 4Dept. of Internal Medicine, Ghent University, Dept. of Internal Medicine, Ghent, Belgium; 5VB Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium

Background: Systemic sclerosis (SSc) is characterized by immune system alterations, vascular damage and fibrosis (1). Macrophages seem to play an emerging role in SSc, and the characterization of their polarized phenotype, starting from the dichotomous definition of classically activated (M1) or alternatively activated (M2) macrophages, is a recent research topic of interest (2).

Objectives: The study investigated a possible imbalance in the distribution of circulating cells expressing M1 and M2 markers in SSc patients (pts) compared to healthy subjects (HSs), and the presence of circulating cell co-expressing M1 and M2 surface markers. Possible correlations between their percentage and selected SSc clinical aspects were investigated.

Methods: In the study 55 SSc pts (50 females/5 males, mean age 64 ± 13 yrs), fulfilling the new EULAR/ACR criteria for SSc diagnosis, and 27 age-matched HSs (25 females/2 males, mean age 57±7 yrs) were enrolled. Blood and skin biopsies were performed. In particular, circulating cells belonging to the leukocyte and monocyte populations (CD45+ and CD14+ cells) were investigated by flow cytometry (FC) using the surface markers characterizing M1 (CD80, CD86, TLR2, TLR4) and M2 phenotypes (CD204, CD206, CD163). Statistic analysis was performed using Mann-Whitney and Kruskal-Wallis tests, and correlations were explored by bivariate Pearson’s analysis.

Results: Increased circulating cells showing an M2 phenotype and characterized as CD204+CD206+CD163+cells was observed in SSc pts compared to HSs (p<0.0001), whereas no difference in CD80+CD86+TLR2+TLR4+ (M1) cell percentage was observed. A significant higher percentage of circulating cells showing a hybrid M1/M2 phenotype (CD204+CD206+CD163+TLR4+CD80−CD86− cells) was observed in SSc pts compared to HSs. These hybrid M1/M2 cells were significantly increased in SSc pts either treated with steroids or under no immunosuppressive treatment (p<0.01; p<0.05, as well as in ScI70+ pts (p<0.05 vs. ScI70- pts)
and SSc pts with interstitial lung disease (ILD) and high systolic pulmonary artery pressure (PAP). A linear negative correlation between the high hybrid M1/M2 cell percentage and diffusing capacity of the lungs for carbon monoxide (DLCO)%, and the forced vital capacity (FVC)/DLCO ratio higher than 1.5 was observed. No significant correlations were reported with SSc duration, other treatments, NVC patterns, renal artery resistive index, heart and kidney involvements, digital ulcers, telangiectasias, calcinosis.

Conclusion: The study identified a circulating cell population expressing both M1 and M2 surface markers, which is increased together with circulating M2 cells in SSc pts, in particular affected by ILD and high PAP, suggesting their possible involvement in the pathogenesis of those disease complications. Further evaluations are in progress.

AUTOLOGOUS FAT GRAFTING IN THE TREATMENT OF PATIENTS WITH SYSTEMIC SCLEROSIS: CURRENT EXPERIENCE AND FUTURE PROSPECTS

Amelia Spinella1, Marco Pignatti2, Giorgia Citriniti1, Federica Lumetti1, Emanuele Cocchiara1, Adalgisa Palermo3, Gianluca Sighinolli1, Lucrezia Pacchioni3, Giovanna Zaccaria3, Irene Laura Lusetti3, Carlo Solarvanir1, Dilia Giuggioli1.

Scleroderma Unit, Chair of Rheumatology, University of Modena and Reggio Emilia, Modena, Italy; 3Department of Experimental Diagnostic and Specialty Medicine, S.Orsola-Malpighi University Hospital, Modena, Italy; 4Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background: Systemic Sclerosis (SSc) is a connective tissue disease, characterized by endothelial dysfunction and fibrosis, potentially affecting internal organs and reducing life expectancy. Digital ulcers (DUs), as well as hand and face skin thickening, are the hallmarks of the disease. These alterations lead to pain, functional impairment, aesthetic damages, and psychological distress. Autologous fat grafting (AFG) is a surgical technique used also to promote tissue regeneration. In the last decade, AFG has been successfully developed to treat clinical conditions characterized by skin atrophy or fibrosis. AFG composition of multipotent cells, carrying angiogenic, and immunogenic properties, may be able to restore the damaged tissues.

Objectives: Evaluate our experience with AFG to treat and prevent damage and disability due to DUs and SSc skin complications.

Methods: We analyzed 25 SSc patients, extrapolated from a larger series of 45 subjects, complaining about mouth and/or hand impairment, due to skin involvement, and, in some cases, long-lasting DUs (M/F 6/19, mean age 55.69±9.25 SD-years, mean disease duration 184.68±121.09 SD-months, L/D cutaneous subsets 21/4). Surgical procedures consisted in the injection of centrifuged and purified autologous fat, harvested from hips or abdomen. 2ml of fat were grafted in each of the 8 sites around the mouth, while 0.5 or 1 ml around the neurovascular bundle at the base of each finger. The study included: preoperative data collection; 2 or 3 surgical sessions at a distance of 6 months one from the other; data collection at 3 months after each surgical session; data collection at 3 and 6 months of follow up-FU after the last surgical procedure. Data collection consisted of clinic-serological SSc features and clinimetric measures of MODA and the following: 1. Control (BLM-SSc), 2. mAdSCs (1.0×10⁴ cells), 3. mAdSCs (1.0×10⁵ cells). After the administration of BLM, mAdSCs were injected via a tail vein on day 7. The mice were sacrificed at 14 days after mAdSCs injection, and the skins were harvested for histological analysis.

Results: In mAdSCs (1.0×10⁵ cells) group, thickening of skin, hydroxyproline content, infiltration of inflammatory cells, gene expression of inflammatory cytokines, and fibrotic factors were significantly reduced compared with control group (Figure). In mAdSCs (1.0×10⁴ cells) group, there were no reduction of them. mAdSCs did not accumulate in skin. The levels of MMP-2, MMP-9, and COL1A1 mRNA expression at 21 days after BLM administration were significantly lower in mAdSCs (1.0×10⁵ cells) group compared with those in control group.

Conclusion: Intravenous mAdSCs inhibited both skin inflammation and fibrosis of BLM-SSc mice in a dose-dependent manner.

ANTI-INFLAMMATORY AND ANTI-FIBROTIC EFFECTS OF INTRAVENOUS ADIPOSE-DERIVED STEM CELL TRANSPLANTATION IN A MOUSE MODEL OF BLEOMYCIN-INDUCED SCLERODERMA

Takayasu Suzuki1, Takuya Kotani1, Shogo Matsuda2, II Masaaki1, Tohu Takeuchi1, Shigeki Arawaka1, Koji Naga1, Yumiko Wada1, Osaka Medical College, Tatekatsuki Osaka, Japan

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease characterized by microvascular damages and fibrosis. The main lesions of SSc are peripheral circulation insufficiency, scleroderma, and interstitial pneumonia. Skin lesions are related to patient’s ADL and QOL, however there is no effective treatment for normalizing the disease state. Adipose-derived stem cells (AdSCs) have recently been considered a useful treatment tool for autoimmune disease because of their anti-inflammatory and immunosuppressive effects (ref).

Objectives: We investigated the therapeutic effect of intravenous mouse AdSCs (mAdSCs) transplantation in a SSc mouse model.

Methods: SSc was induced by bleomycin (BLM) in Balb/c mice, and the mice were assigned in the following groups: 1. Control (BLM-SSc), 2. mAdSCs (1.0×10⁴ cells), 3. mAdSCs (1.0×10⁵ cells). After the administration of BLM, mAdSCs were injected via a tail vein on day 7. The mice were sacrificed at 14 days after mAdSCs injection, and the skins were harvested for histological analysis.

Results: In mAdSCs (1.0×10⁵ cells) group, thickening of skin, hydroxyproline content, infiltration of inflammatory cells, gene expression of inflammatory cytokines, and fibrotic factors were significantly reduced compared with control group (Figure). In mAdSCs (1.0×10⁴ cells) group, there were no reduction of them. mAdSCs did not accumulate in skin. The levels of MMP-2, MMP-9, and COL1A1 mRNA expression at 21 days after BLM administration were significantly lower in mAdSCs (1.0×10⁵ cells) group compared with those in control group.

Conclusion: Intravenous mAdSCs inhibited both skin inflammation and fibrosis of BLM-SSc mice in a dose-dependent manner.

THE ROLE OF PRURITOGENIC MEDIATORS IN DERMATOMYOSIS RELATED ITCH

Anet Vincze1, Erika Herczeg-Lisztes2, Katalin Szabó1, Melinda Nagy-Vincze1, Tamás Biró1, Katalin Dávid1, István Balázs Tóth1, Zoltán Grenger1, 1Faculty of Medicine, University of Debrecen, Division of Clinical Immunology, Department of Internal Medicine, Debrecen, Hungary, 2Faculty of Medicine, University of Debrecen, Department of Physiology, Debrecen, Hungary, 1Faculty of Medicine, University of Debrecen, Department of Immunology, Debrecen, Hungary

Background: Pruritus is a common symptom in systemic autoimmune diseases like dermatomyositis (DM). Recent researches have indicated that interleukin-31 (IL-31), IL-33, IL-6, or inflammatory cytokines, such as tumor necrosis factor (TNFα), peroxisome proliferator-activated receptor γ (PPARγ) and ion channels belonging to the transient receptor potential (TRP) family are involved in pruritogen mediated itch. The objective of the present study was to evaluate a novel highly selective orally available 5-HT2B receptor antagonist, AM1476, for its ability to reduce pulmonary and dermal fibrosis in the sclerodematous animal model of dermatomyositis related itch.

Methods: Gene expression of TNFα, PPARγ, IL-33, IL-6 and TRPV channels in lesional DM skin was evaluated by RT-qPCR and was compared with non-lesional DM skin samples. Pruritus and disease activity of DM was evaluated by the 5-d itch scale and Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI), respectively. Statistical analysis was performed with IBM SPSS 20.0 software.

Results: Skin samples of 17 active DM patients were analyzed. We could show, that itching index in DM was positively correlated with CDASI score with a correlation coefficient of 0.82 (p=0.001). TNFα gene expression was significantly higher (34.87%) in lesional DM skin than non-lesional DM skin (p=0.03). The normalized TNFα mRNA expression was positively correlated with itch scale (R= 0.605, p=0.022) and its level was significantly higher in skin samples of patients with severe itch (itch score: 15-20) versus mild itch (itch score: 5-10) (2.02±0.38 vs. 1.12±0.20; p<0.01). The level of PPARγ was decreased in lesional DM skin, but this was statistically not significant. The mRNA expression of normalized PPARγ was negatively correlated with itch scale (R= -0.518, p=0.019), and its level was significantly lower in skin samples of patients with severe itch versus mild itch (0.28±0.36 vs. 1.53±0.98; p=0.038). Lesional IL-6 mRNA levels were associated with CDASI activity score (R=0.619, p=0.018). The mRNA levels of TRPV1-4 channels were not associated with 5-D itch score, but normalized TRPV1 and TRPV4 mRNA expressions were positively correlated with CDASI damage score (R=0.699, p=0.008; R=0.789, p=0.001). Interestingly, itching sensation of DM patients was not correlated with IL-33 mRNA levels measured in skin samples.

Conclusion: Our results argue for that higher cutaneous disease activity generate pruritus. TNFα and PPARγ might play a determining, but opposite role in DM-associated itch. Furthermore IL-6, TRPV1 and TRPV4 channels might participate in pathomechanism of cutaneous manifestation of the disease.

chronic graft-versus-host disease model and dermal fibrosis in the tight-skint-1 model of systemic sclerosis. Effects on the TGF-β-Smad signaling pathway were investigated in vivo. Exposure of AM1476 was measured to ensure proper target engagement.

Methods: The murine sclerodermatous chronic graft-versus-host disease (cGvHD) model was used to evaluate anti-fibrotic effects after therapeutic dosing of the 5-HT2B receptor antagonist, AM1476. The compound was orally administered at 1, 10 and 30 mg/kg b.i.d. from day 21, several days after the first skin biopsies were collected. In cGvHD model, myofibroblast counts and collagen production were used to evaluate dermal fibrosis. Effects on pulmonary fibrosis were measured using hydroxyproline content, Sirius Red staining and Ashcroft score. Plasma was collected for PK analysis at different timepoints in each treatment group using sparse sampling, on the last day of the experiment. The tight-skint-1 model was used to evaluate anti-fibrotic effects after therapeutic treatment. AM1476 was orally administered at 10 mg/kg, b.i.d. from week 5 to week 10. Hypodermal thickening, myofibroblast counts and hydroxyproline content in skin biopsies were evaluated at the end of the treatment period. The number of phosphorylated Smad3 (pSmad3) positive cells was used to evaluate inhibition of TGF-β signaling.

Results: The 5-HT2B receptor antagonist AM1476, significantly reduced all measured dermal and pulmonary fibrosis readouts in the cGvHD model using an oral therapeutic treatment approach. Pharmacokinetic analysis of plasma samples supported 5-HT2B receptor engagement. Therapeutic treatment of dermal fibrosis in the tight-skint model effectively and significantly reduced hypodermal thickening, number of myofibroblast and hydroxyproline content. The number of pSmad3 positive cells was significantly reduced in skin samples isolated from treated animals.

Conclusion: Inhibition of 5-HT2B receptor activity resulted in pronounced anti-fibrotic effects in pulmonary and dermal fibrotic tissues. AM1476 was well tolerated without obvious signs of toxicity. Effects on pSmad3, reflecting TGF-β-inhibition, will be evaluated as a potential biomarker in upcoming clinical trials. The highly selective 5-HT2B receptor antagonist AM1476 represents a promising drug candidate for treatment of fibrotic conditions and is currently in development for systemic sclerosis.

THU0354 MACHINE LEARNING CLASSIFICATION OF SKIN GENE EXPRESSION IDENTIFIES A SUBSET OF SYSTEMIC SCLEROSIS PATIENTS MOST LIKELY TO SHOW CLINICAL IMPROVEMENT IN RESPONSE TO ABATACEPT

Jennifer Franks1, Bhaven Mehta1, Veronica Berrocal2, Yue Wang2, Tammary Wood3, Christopher Denton3, Robert Lavyatis4, David Fox5, Dinesh Khanna6, Michael Whitfield2, 1Geisel School of Medicine at Dartmouth, Hanover, United States of America; 2University of Michigan, Ann Arbor, United States of America; 3Royal Free Hospital, London, United Kingdom; 4University of Pittsburgh, Pittsburgh, United States of America

Background: A prior pilot study of abatacept in SSc with molecular gene expression data in skin (1) found that four of five patients who improved on abatacept, as determined by change in mRSS, were in the inflammatory intrinsic gene expression subset. Improvement was accompanied by a decrease in gene expression for immune pathways, including the CD28 and CTLA4 receptors—the target of abatacept. Here we tested our a priori hypothesis that the inflammatory subset shows a significant decline in mRSS during abatacept therapy.

Objectives: ASSET (Abatacept Systemic Sclerosis Trial) is a Phase 2 study designed to assess the efficacy of subcutaneous abatacept to treat diffuse cutaneous systemic sclerosis. We performed RNA-sequencing (RNA-seq) analysis of skin biopsies and analyzed associations between intrinsic molecular subsets and clinical outcomes in the ASSET trial.

Methods: RNA-seq was performed on skin biopsies from 84 participants in the ASSET trial. A machine learning classifier was trained on independent cohorts and used to objectively classify patients into intrinsic gene expression subsets prior to study unblinding (2). Treatment differences in longitudinal outcomes were assessed using linear mixed effect models.

Results: 84 participants were assigned to intrinsic subset at baseline resulting in 33 inflammatory, 18 fibroproliferative, and 33 normal-like samples. Change in mRSS over 12 months was significantly different between the abatacept and placebo treatment arms for the inflammatory (p<0.001) and normal-like (p=0.03) subsets, but there was no difference in the fibroproliferative subset of patients (p=0.47) (Figure 1). For FVC% predicted, the fibroproliferative subset showed a numerical increase in FVC% in the abatacept arm (p=0.19) while all other groups showed decreases in FVC%. All gene expression subsets showed decreases in HAQ-DI in the abatacept arm not observed in the placebo arm, with the most robust changes occurring in the inflammatory (p=0.09) and normal-like (p=0.06) subsets.

Conclusion: There was a marked divergence of the trajectory for mRSS change for the inflammatory subset and no apparent impact for the fibroproliferative subset (1). In contrast, only the fibroproliferative subset showed a clinically meaningful FVC change for abatacept. For the broader functional measure of HAQ-DI, there were similar impacts of abatacept on all three intrinsic skin gene expression subsets but is numerically greatest for the normal-like and fibroproliferative subsets. Together these data show for the first time in a placebo-controlled trial that intrinsic skin gene expression subsets may predict differential response to a targeted biological therapy, and also that this may reflect impact on different facets of SSc pathogenesis in skin or lung. This suggests that stratification of cases according to intrinsic gene expression subsets may maximize the number of informative SSc cases in clinical trials, and potentially improve future clinical practice.

THU0355  IGURATIMOD MIGHT TREAT SCLERODERMA WITH INTERRUPTED EGR1-TGF-β LOOP

Qingran Yao1, Lichong Shen1 Daniel Morales-Cano1 Xiaoxiang Chen1. 1 Renji Hospital, Shanghai Jiaotong University, School of Medicine, Department of Rheumatology, Shanghai, China

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized with multiple organ fibrosis. Previous studies showed transcription factor early growth response 1 (Egr1) overexpressed in the lesional skin of SSc patients, as well as Egr1 inducible genes. Egr1 forms a positive feedback loop with master pro-fibrolic cytokine TGFβ and thus promotes fibrosis.

Objectives: To investigate the anti-fibrotic effect of a novel DMARD iguratimod in scleroderma models and patient skin grafts.

Methods: We used iguratimod to treat TGFβ-stimulated human skin fibroblast, bleomycin induced mice, tight skin 1 (Tsk-1) mice and SSc skin grafts. The bleomycin model contained pre-establish fibrosis and late onset treatment. The skin grafts came from three SSc patients and was planted into irradiated nude mice.

Results: Igarutimod down-regulated egr1 expression in human skin fibroblast with decreased collagen production and α-SMA expression. Knocking down Egr1 in fibroblast could mimic these effects. Both oral and topical iguratimod could reduce dermal thickening and collagen deposition in bleomycin induced skin fibrosis. α-SMA (+) myofibroblast counts, as well as Egr1 (+) and/or TGFβ (+) fibroblast counts in iguratimod treated groups were significantly less than the controls. Similarly, topical iguratimod ameliorated fibrosis with deduced dermal thickening in bleomycin induced skin fibroblast, α-SMA (+) myofibroblast counts, as well as Egr1 (+) and/or TGFβ (+) fibroblast counts in iguratimod treated groups were significantly less than the controls. Furthermore, inhibition of endocytosis by pigmmalinolide B12, an inhibitor of α-SMA, reduced the induction of Egr1 and TGFβ in skin tissue were inhibited after iguratimod treatment simultaneously.

Conclusion: We found the potential of iguratimod to treat SSc, which was characterized as an Egr1 inhibitor. Further clinical investigation is needed to establish its safety and efficacy.

THU0356  STAPHYLOCOCCUS AUREUS REGULATES FIBROBLAST FUNCTIONS – IMPLICATIONS FOR TISSUE REPAIR IN CHRONIC DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

Masaya Yokota1, Matthew Kassier1, Nicola Höffner1, Matthias Brunner1, Janine Schniering1, Oliver Distler1, Annelies S. Zinkernagel2, Britta Mauren1. 1Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2Department of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland

Background: Chronic digital ulcers (DU) are a major complication in systemic sclerosis (SSc). Non-healing wounds are characterized by persistent inflammation, defective re-epithelialization and impaired matrix remodeling, and are often accompanied by bacterial colonization. In DU, the breach of the basement membrane exposes tissue and cell layers to commensal and pathogenic bacteria.

Objectives: To investigate whether interactions between commensal skin bacteria and dermal fibroblasts affect tissue repair mechanisms.

Methods: Dermal fibroblasts isolated from healthy controls (HC) and patients with diffuse cutaneous SSc (dcSSc) (n=3, each) were co-cultured with Staphylococcus aureus (SA) for 3 h at using a lower inoculum rather representing colonization (1 x 10⁶ CFU/ml) and a higher inoculum reflecting infection (1 x 10⁷ CFU/ml). Thereafter, fibroblasts were cultured with flucloxacillin-containing medium to kill extracellular and adherent bacteria. For mechanistic studies, a fibroblast cell line (Bi-5ta) was used. IL-6, IL-8, pro-collagen Iα1, and interferon (IFN)-β proteins in culture supernatants were measured by ELISA.

Results: SA increased pro-collagen Iα1 secretion by 5.2/2.5-fold (HC/dcSSc; p=0.08/<0.05). Staining of Egr1 and TGFβ in SA treated fibroblasts were 8.4/31.7-fold (HC/dcSSc; p<0.05 each). SA induced apoptosis and necrosis. SA invaded fibroblasts via endocytosis (25-50% of inoculated SA). TNFα secretion was induced 8.4/31.7-fold (HC/dcSSc; p<0.05 each). The genes of cytosolic dsDNA sensor molecules such as cyclic GMP-AMP synthase (cGAS) were upregulated 11.9/8.6-fold (HC/dcSSc; p<0.05 each). TLR9, an endosomal DNA sensor, was constitutively expressed. Knockdown of STING or MYD88, downstream mediators of cGAS and TLR9 respectively, reduced the induction of IFN-β (down to 24.6%; p<0.05), IL-6 (down to 34.9%; p<0.05), and IL-8 (down to 27.6%; p<0.05). In contrast, inhibition of endocytosis did not affect induction of apoptosis. This suggests that the invasion of fibroblasts by SA and the subsequent intracellular DNA sensing are crucial for the induction of these genes independently of apoptosis.

Conclusion: Invasion of dermal fibroblasts by SA with activation of the cGAS/STING and TLR9-MYD88 pathways is a key element in the impairment of tissue repair responses.

THU0357  VENTRICULAR-ARTERIAL COUPLING AS A PREDICTOR OF CARDIOVASCULAR EVENTS IN SYSTEMIC SCLEROSIS

Elisabetta Zanatta1, Pamela Polito1, Giulia Famoso2, Franco Cozzi1, Andrea Doria1, Francesco Tona1, 1Rheumatology Unit, Department of Medicine – DIMED, Padova, Italy; 2Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy

Background: Standard Transthoracic Echocardiography (TTE) parameters have shown a low sensitivity in the detection of primary myocardial involvement (PMI) in systemic sclerosis (SSc). Arterial-ventricular coupling (VAC) is calculated by TTE as the ratio between arterial elastance (Ea) and ventricular end-systolic elastance (Ees), which reflects left ventricle stiffness. VAC is a central determinant of cardiovascular performance.

Objectives: We aimed to assess TTE-derived measures of cardiac mechanics and the prognostic role of VAC in SSc.

Methods: 75 patients affected by SSc without symptoms of cardiac involvement and 10 controls matched for sex and age were retrospectively evaluated. We collected data at the first TTE examination. Arterial-ventricular coupling (VAC=Ees/Ea), arterial elastance (Ea), ventricular arterial coupling (VAC=Ees/Ea), and diastolic elastance (Eed) were considered. A value of VAC > 0.62 was considered indicative of altered VAC (i.e. uncoupling), whereas a lower value as normal (i.e. coupling). Finally, we considered the hospitalization for cardiovascular event during a mean follow-up of 10.6±1.8 years.
Results: Among the 75 patients 42 (59.2%) had a diffuse cutaneous form of SSC (dSSc) and 64 (85.3%) were female; in SSC patients the median age was 53 (12.1) yrs and the mean disease duration 10.1±2.3 yrs. 36 (52.2%) patients had positive SCl70, 31 (44.9%) ACA, and 2 (2.9%) anti-RNA pol III. Compared to controls, SSC patients had higher Ea (2.28 vs 0.95 mmHg/ml, p=0.003) and Ees (3.95 vs 2.98 mmHg/ml, p=0.05), and increased diastolic stiffness (Eed) (0.210 vs 0.146 mmHg/ml, p=0.01). VAC was consequently comparable to controls. SSC patients affected by dcSSc had a lower Ees (2.90 vs 4.367, p<0.001) and Eed (0.34 vs 0.17; p=0.032) and a higher VAC (0.52 vs 0.70; p=0.01) compared to lSSc. No differences were found between patients with anti-Scl70 and ACA. At 10 years, 23% of patients was hospitalized for at least one cardiovascular event. The analysis of survival free hospitalization or death in all SSC patients demonstrated a worse outcome and poor prognosis in patients with an altered VAC (31, 47.7%) compared to those with a normal VAC (34, 52.3%) (Figure 1).

Conclusion: Our study suggests that both ventricular and arterial stiffness may be increased in SSC patients without signs and symptoms of heart disease. Since VAC seems to have a prognostic role in the prediction of cardiovascular events in SSC, it could be helpful to define an early therapeutic strategy to prevent or delay cardiac manifestations in these patients.

THU0358 DEVELOPMENT OF A SET OF ASAS QUALITY STANDARDS FOR ADULTS WITH AXIAL SPONDYLOARTHRITIS

Uta Kitzl1,2, Robert B. M. Landewé1, Désirée van der Heijde4, Martin Rudwaleit5, Maxime Dougados6, Nurulrah Akkoc1, Annelies Boonen9, Jan Brandt-Juergens11, Philippe Caroon10, Laure Gosses1, Meryn Jongkees12, Pedro Machado13, Nurullah Akkoc1, Anna Moltó6, Victoria Navarro-Compán11, Karin Niedernmann Schneider16, Percival D. Sampaio-Barros17, Gabe Slodobit8, Filip van den Bosch19, Astrid van Tubergen8, Michael Weisman21, Robert B.M. Landewé1, Laure Gosses1, Meryn Jongkees12, Pedro Machado13, Helena Marzo-Ortega14, Anna Moltó6, Victoria Navarro-Compán11, Karin Niedernmann Schneider16, Percival D. Sampaio-Barros17, Gabe Slodobit8, Filip van den Bosch19, Astrid van Tubergen8, Martin Rudwaleit Consultant for: AbbVie, BMS, Celgene, Janssen, Lilly, MSD, Novartis, Pfizer, Roche, and UCB, Consultant: for AbbVie, Chugai, Eli Lilly, Grünenthal, Janssen, MSD, Novartis, Pfizer, Roche, and UCB, Consultant: for AbbVie, Chugai, Eli Lilly, Grünenthal, Janssen, MSD, Novartis, Pfizer, Roche, and UCB.

The ASAS QS group, established in 2015, developed a stepwise approach starting with (I) an overview and open discussions resulting in a proposal for possible key areas for quality improvement. Thereafter, (II) ASAS members and invited patients discussed and commented on a provisional list via a web-based survey with the possibility to propose additional key areas for quality improvement. (III) The complete list was then evaluated by ASAS members and invited patients. (IV) Then, the ASAS QS group prioritized key areas for which quality statements and measures are to be developed, and (V) phrased QS for the most important key areas. Finally (VI), a draft version was commented on, discussed and finally agreed by the ASAS members at the Annual ASAS Meeting 2019. Results: The ASAS QS group, consisting of 20 rheumatologists, 2 physiotherapists and 2 patients, provided 34 potentially key areas for quality improvement which were commented by 140 participants (86 physicians, 42 patients). Within that process 3 new key areas were proposed and all 37 key areas for improvement were again evaluated by 120 participants (86 physicians, 29 patients). Five key areas were identified to be most important to phrase QS: referral, rheumatologic assessment, treatment, education/self-management and comorbidities. Altogether, 9 QS, each accompanied by a rationale and a measure (figure), were endorsed by ASAS.

Conclusion: ASAS successfully developed the first QS set for improvement of health care provided for adults with axSpA. All QS are achievable in daily care in an optimized situation and intended to minimize variation in quality of care. It is emphasized that ASAS is well aware that all QS are ideal visions of an optimal care which may currently not be realistic in many countries.

THU0358 – Figure 1. ASAS quality standards for patients with axial spondyloarthritis

WHAT IS THE LEVEL OF AGREEMENT BETWEEN LOCAL AND CENTRAL READERS IN THE DETECTION OF ACTIVE AND STRUCTURAL LESIONS ON MRI OF AXIAL Spondyloarthritis? DATA FROM THE ASAS CLASSIFICATION COHORT STUDY

Walter P Maksymowych1,2, Xenofon Baraliakos3, Robert G Lambert, 1Ulrich Weber4, Joachim Sieper5, Susanne Juhl Pedersen1, Pedro Machado7, Mikkel Østergaard6, Joel Paschke2, Susanne Juhl Pedersen1, Pedro Machado7.

1University of Alberta, Edmonton, Canada; 2Copenhagen Center for Arthritis Research, Copenhagen, Denmark; 3Charité Universitätsmedizin, Berlin, Germany; 4Copenhagen Center for Arthritis Research, Copenhagen, Denmark; 5University College London, London, United Kingdom

Background: There has been no central reader evaluation of MRI scans from the ASAS Classification Cohort (ASAS-CC) to compare detection of lesions in the sacroiliac joints (SIJ) between central and ASAS-CC local site readers. Active MRI lesions typical of axSpA were reported in 61.6% and 2.2% of patients from this cohort diagnosed with axSpA and non-axSpA back pain, respectively1. Structural lesions were recorded but not reported in the literature.

Objectives: We aimed to compare detection of active and structural lesions on MRI images of the SIJ from the ASAS-CC between ASAS-CC local site readers and central readers from the ASAS-MRI group.

Methods: MRI images were available from 258 of the 495 cases who had MRI performed in the ASAS-CC and also had a local rheumatologist diagnosis. Seven central readers recorded MRI lesions in an eCRF that included wording of lesions defining active and structural lesions typical of axSpA that was exactly the same as in the original ASAS-CC eCRF permitting comparisons between central and local readers. In addition, lesions that met the criteria for an ASAS positive MRI were recorded by central readers. Active and structural lesion frequencies were assessed descriptively according to majority agreement (r4/7) of central reader data and also any 2 central readers. Reliability of detection of MRI lesions was compared between central and local readers using the kappa coefficient.

Results: Significant differences in lesion frequencies were observed according to diagnostic category (Table 1). The frequency of active lesions reported by local readers (61%) was greater than for central readers that agreed on the presence of an active lesion (49.7%). Structural lesions were reported less frequently by local readers (44.0%) compared to central readers that agreed on the presence of a structural lesion (54.9%). Reliability of local readers for detection of active lesions was good but only fair for structural lesions (Table 2).

Conclusion: Local readers may have overestimated the presence of active lesions and underestimated the presence of structural lesions in the ASAS-CC. Their reliability for detection of structural lesions was limited which could reflect lack of awareness of structural lesions related to axSpA.

THU0360

INCREASING IMPACT ON STRUCTURAL DAMAGE WITH INCREASING CUMULATIVE INFLAMMATION AT THE SI-JOINT QUADRANT LEVEL IN AXIAL SPONDYLOARTHRITIS – 5-YEAR DATA FROM THE DESIR COHORT

Santiago Rodríguez-Manicà,1,2 Alexandre Sepriano,2, Sofia Ramiro,4, Robert B. M. Landewé,6 Pascal Claudépière,6 Anna Molto,6 Maxime Dougdas,6, Miranda van Lunteren,6 Désirée van der Heijde,6 Hospital Egas Moniz, Rheumatology, Lisboa, Portugal; 7CEDOC, Lisboa, Portugal; 5Leiden University Medical Centre (LUMC), Leiden, Netherlands; 2Academic Medical Centre, Amsterdam, Netherlands; 5Hospital Henri Mondor Ap-Hp, Créteil, France; 7University Paris Descartes, Paris, France

Background: Axial inflammation is a key feature in axial SpA (axSpA). There is lack of data relative to the persistence of BME in the same anatomical quadrant (Q, 8 in total for both SIJ together), regardless of the overall presence of BME.

Objectives: This study aims to investigate particular patterns of distribution of SIJ-BME across quadrants over time, their persistence over time, and their impact on clinical and structural outcomes.

Methods: Patients from the DESIR cohort (early axSpA according to the rheumatologist) with MRI-SIJ available at baseline, 2 and 5 years were included. Each image was scored by 3 trained central readers blinded to chronological order. BME was considered positive if detected in ≥1/6 slices in each of the 8 quadrants, according to each individual reader. Four different patterns of BME over time were defined (no BME, sporadic pattern, fluctuating BME and persistent BME) considering all 8 quadrants (Figure). The effect of BME patterns on 5-year structural (mNY, mSASSS, ≥5 erosions and/or fatty lesions in MRI-SIJ) and clinical outcomes (BASI, BASMI and ASQoL) was evaluated using multilevel generalised estimating equations (GEE) models (taking the individual reader data into account) and linear regression (using the agreement of ≥2 out of 3), as appropriate. All models were adjusted for relevant confounders including treatment (Table).

Results: In total, 136 patients were included (age 34 (SD 9) years, 50% male, and 63% HLA-B27 positive). No BME was seen in 63 patients (46%), the ‘sporadic pattern’ in 34 patients (25%), the ‘fluctuating pattern’ was seen in 21 patients (15%) and the ‘persistent BME pattern’ was seen in 18 patients (13%). Compared to the ‘no BME’ pattern (reference), the ‘sporadic’ [OR (95% CI): 2.1 (1.0;4.5)], ‘fluctuating’ [OR: 5.6 (2.2;14.4)] and ‘persistent’ [OR: 7.5 (2.8;19.6)] patterns were associated with higher likelihood to be mNY positive at 5-years, suggesting a gradient between cumulative inflammation and damage. Similar findings were observed for mSASSS as a continuous outcome variable and for ≥5 erosions and/or fatty lesions in MRI-SIJ (Figure). The effect of BME patterns on 5-year structural (mNY, mSASSS, ≥5 erosions and/or fatty lesions in MRI-SIJ) and clinical outcomes (BASI, BASMI and ASQoL) was evaluated using multilevel generalised estimating equations (GEE) models (taking the individual reader data into account) and linear regression (using the agreement of ≥2 out of 3), as appropriate. All models were adjusted for relevant confounders including treatment (Table).

Conclusion: Only 13% of the patients showed persistent inflammation in the same Q over a 5-year period and in 15% inflammation was fluctuating across different Qs. More structural damage was found in patients with increasing cumulative level of local inflammation in the quadrant. Even when BME (temporarily) disappears there is an important effect on structural outcomes, and that effect t is independent of treatment.

THU0361

DIAGNOSTIC PERFORMANCE OF MRI LESIONS IN THE SACROILIAC JOINTS ACCORDING TO UPDATED ASAS LESION DEFINITIONS: A CENTRAL READER ASSESSMENT OF MRI SCANS FROM THE ASSESSMENTS IN SPONDYLOARTHRITIS CLASSIFICATION COHORT

Walter P. Maksmymowycz,1,2 Robert G Lambert,1 Xenofon Baraliakos,3 Susanne Juhl Pedersen,4 Pedro Machado,5 Joachim Sieper,6 Stephanie Wichu,7 Denis Poddubnyj,8 Joel Paschke,9 Mikkel Østergaard,10 Ulrich Weber,11 University of Alberta, Edmonton, Canada; 2CaRe Arthritis, Edmonton, Canada; 3Rheumazentrum Ruhrgebiet, Herne, Germany; 4Righospitalet University of Copenhagen, Copenhagen, Denmark; 5University College London, London, United Kingdom; 6Charité Universitätsmedizin Berlin, Berlin, Germany; 7University of South Denmark, Odense, Denmark

Background: The ASAS MRI group has generated updated lesion definitions for MRI lesions in the SI. While the ASAS definition of a positive MRI for classification purposes remains unchanged, these additional ASAS definitions for active and structural lesions may also be of diagnostic value. It is important to understand their relative contribution and complementarily as diagnostic indicators.

Objectives: To determine optimal cut-offs for the number of SIJ quadrants with MRI lesions reflecting diagnosis of axSpA in patients with undiagnosed back pain.

Methods: MRI lesions on baseline scans from the ASAS Classification Cohort were recorded by 7 experienced readers from the ASAS-ASAS MRI group. Detailed scoring of lesions per SIJ quadrant (SPARCC SIJ quadrant method) was available for assessment of bone marrow edema (BME) and structural lesions in 158 and 146 cases, respectively, who were diagnosed by the local rheumatologist at baseline. Of these, 86 and 79 cases with BME and structural lesion data, respectively, were also diagnosed by the local rheumatologist at follow up (mean 4.4 years). We calculated sensitivity and specificity for varying numbers of SIJ quadrants with MRI lesions with rheumatologist diagnosis of axSpA at baseline and follow up as gold standard.

Results: Rating cut-offs based on BME were most sensitive for diagnosis at baseline and follow up but erosion- and fatty-lesion cut-offs were more specific (Table). At least 2 SIJ quadrants with erosion or fat metaplasia were associated with >90% specificity for the diagnosis of axSpA. There was also a consistent improvement in the sensitivity and specificity performance of cut-offs based on erosions and fatty lesions according to diagnosis at baseline and at follow up after 4.4 years but not for cut-offs based on BME. Lesion cut-offs that combined BME and/or erosion enhanced sensitivity without compromising specificity.
Conclusions: The updated ASAS definitions based on the presence of MRI lesions in 2-3 SIJ quadrants have comparable diagnostic performance. This performance improves for erosion and fatty lesion cut-offs after follow-up.

DO ILLNESS PERCEPTIONS AND COPING CHANGE OVER TIME IN PATIENTS RECENTLY DIAGNOSED WITH AXIAL SPONDYLOARTHRITIS? A 2-YEAR FOLLOW-UP STUDY IN THE SPACE COHORT

Miranda van Lunteren1, Robert B.M. Landewé2,3, Camilla Fongen4, Roberta Ramonda5, Desirée van der Heijde1, Floris A. van Gaalen1,1, LUMC, Leiden, Netherlands; 2ARC, Amsterdam, Netherlands; 3Zuyderland Hospital, Heerlen, Netherlands; 4Diakonhjemmet Hospital, Oslo, Norway; 5University of Padova, Padova, Italy

Background: In recently diagnosed axial spondyloarthritis (axSpA), illness perceptions are important in the relationship between back pain and Health-Related Quality of Life (HRQoL). Illness perceptions and coping remain stable over time. However, hardly any information is available, especially for early axSpA, as the few studies that have been conducted mostly had a cross-sectional design and investigated patients with long-standing radiographic axSpA.

Objectives: To investigate if illness perceptions and coping strategies change in the first 2 years after diagnosis of axSpA.

Methods: Patients diagnosed with axSpA and ≥1 follow-up visit (1 year and/or 2 years) in the SPACE cohort were included in the analysis. Mixed linear models were used to test if illness perceptions (measured by the Revised Illness Perception Questionnaire (IPQ-R, scale 1-5)), coping did not have an additional impact on this relationship, but was associated with HRQoL. Therefore, health outcomes might be improved by influencing illness perceptions and possibly coping. With respect to disease management, it is important to know if illness perceptions and coping remain stable over time. However, hardly any information is available, especially for early axSpA, as the few studies that have been conducted mostly had a cross-sectional design and investigated patients with long-standing radiographic axSpA.

Results: In total, 150 axSpA patients (mean age 30.4 years, 51% female, 65% HLA-B27+) were analysed. Baseline mean back pain (SD) was 4.0 (2.5), PCS was 28.8 (14.0), MCS was 47.8 (12.4), WPL was 34.1% (29.8) and activity impairment was 38.7% (27.9). Illness perceptions and coping strategies showed minimal changes over time (Table 1, 2). Over two years patients remained having negative illness perceptions (which were important in the association between back pain and health outcomes in the previous study). For example, over 2 years patients had strong beliefs in severe consequences (‘consequences’), had still negative emotions towards their disease (‘emotional representation’) and had strong beliefs in chance (‘chance’) as a cause for axSpA.

Conclusion: Despite clear improvements in back pain and health outcomes over 2 years, illness perceptions experienced and coping strategies applied by the patients showed little change in recently diagnosed axSpA patients. Further research is recommended why despite improved outcomes illness perceptions do not change, to investigate the impact of these unchanged illness perceptions and coping strategies on health outcomes and how these negative perceptions can be improved.

THE DIAGNOSTIC UTILITY OF THE RELATION BETWEEN MRI BONE MARROW EDEMA AND OTHER TYPES OF MRI LESIONS IN THE SACROILIAC JOINTS IN AXIAL SPONDYLOARTHRITIS

Serejil Seven1, Pernelle Hededå2, Mikkel Østergaard3, Lone Morselt-Cartensen4, Inge Juul Sørensen5, Birthe Bonde5, Gorm Thamsborg5, Jens Jørgen Lykkegaard5, Oliver Hendricks4, Niklas Rye Jørgensen5, Susanne Juul Pedersen4, Roberta Ramonda5, Désirée van der Heijde1, Floris A. van Gaalen1,1, LUMC, Leiden, Netherlands; 2Aalborg Rheumatism Hospital, Gråsten, Denmark; 3Aalborg Rheumatology and Spine Diseases, Glostrup, Denmark; 4Rigshospitalet – Glostrup, Copenhagen Center for Arthritis Research Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 5Rigshospitalet – Glostrup, Department of Radiology, Glostrup, Denmark; 6Bidragende klinikker, Köbenhavn, Denmark; 7King Christian X’s Rheumatism Hospital, Gråsten, Denmark; 8Rigshospitalet – Glostrup, Department of Clinical Biochemistry, Glostrup, Denmark

Background: MRI detected bone marrow edema (BME) plays a central role in the ASAS (Assessment of Spondyloarthritis International Society) classification criteria for axial spondyloarthritis (axSpA)[1, 2]. However, BME in the sacroiliac joints (SIJs) is also present in other conditions[3-7].

Objectives: The aim was to investigate the diagnostic utility of MRI BME and its relation to different types of MRI SIJ lesions to separate patients with axSpA from persons with other conditions.

Methods: The MASH study is a prospective cross-sectional study of 204 participants, aged ≤45 years. The study included patients with axSpA (n=41), women with (n=46) and without (n=14) postpartum pain, patients with lumbar disc herniation (n=25), persons with hard physical labor (cleaning assistants) (n=25), long-distance runners (<30 km/week) (n=23) and healthy men (n=29). Participants with pain should all have VAS pain >2 (on a scale 0-10) for ≥2 months. Participants in the non-axSpA groups were not allowed to have any clinical SIJ features or rheumatological conditions.

Participants underwent clinical, laboratory and MRI examination (semi-structural STIR and T1W sequences) of the SIJs. MRIs were evaluated for BME, erosion, fat, ankylosis, and sclerosis according to the SPARCC MRI definitions of lesions[8, 9] by two independent readers. In nine slices of the cartilaginous compartment each SIJ was separately assessed for the presence of BME in relation to joint space and each of the above-mentioned structural lesions (range of total score per patient: 0-18).

Results: The table shows the clinical characteristics of each group, the mean MRI scores and MRI cut-off levels for the concordant reads. BME were more frequent in patients with axSpA, but these lesions were also seen in the other study groups, mainly women with postpartum pain. When increasing amounts of lesions were required (higher cut-offs),...
almost only AxSpA patients fulfilled the requirements. BME adjacent to sclerosis was most frequent in women with postpartum pain, whereas BME adjacent to fat was most frequently, but not exclusively, occurring in patients with axSpA, whilst BME adjacent to sclerosis was most frequent in women with postpartum pain. Detailed analysis of lesions and their anatomical location may help differentiate axSpA from other conditions.

Results: A total of 1,729 patients with axSpA were included in the analyses; mean age was 55.9 years and 46.1% were female. The prevalence was 9% (27%) for recent (ever) uveitis, 10% (15%) for recent (ever) psoriasis, and 6% (9%) for recent (ever) IBD. In 0.5% of the patients, all three conditions were recently (ever) present.

Background: Uveitis, psoriasis and inflammatory bowel disease (IBD) are common in axial spondyloarthritis (axSpA) and data on their impact on activity of musculoskeletal manifestations and functional status in general are contradictory.

Objectives: The aim of this study was to assess the impact of uveitis, psoriasis and IBD on disease activity and functional status in a population-based cohort of patients with axSpA.

Methods: A stratified random sample of subjects with a diagnosis of axSpA (ICD-10 M45) was drawn from health insurance data in Germany. These patients received a questionnaire on disease-related, demographic and socioeconomic parameters. Age, sex, drug prescriptions and non-pharmacological treatment were retrieved from claims data and linked to the questionnaire data. Information on recent occurrence of uveitis, psoriasis and IBD (within one year) was obtained from claims data; in addition, information on history of uveitis, psoriasis and IBD was obtained from survey data. Patients with uveitis, psoriasis or IBD were compared to those without uveitis, psoriasis or IBD. Separate multivariable linear regression models were calculated to determine the effect of uveitis, psoriasis and IBD on disease activity and functional status, and further adjustment was performed for other relevant parameters including treatment.

Conclusion: Disease activity and functional impairment are higher in axSpA patients with a history of psoriasis or IBD, whereas history of uveitis was associated with lower disease activity according to the BASDAI even after adjustment for treatment.
MAGNETIC RESONANCE IMAGING IN COMPARISON WITH CONVENTIONAL RADIOGRAPHY FOR DETECTION OF STRUCTURAL CHANGES TYPICAL FOR SPA – DATA FROM THE ASSESSMENT OF Spondyloarthritis International Society (ASAS) COHORT

Mikhail Protopopov1, Denis Podudubnyy2,3, Fabian Prof1, Stephanie Wichuk3, Pedro Machado4, Robert G Lambert 5, U l r i c h W e b e r 6,7, Susanne Juhl Pedersen8,9, 10Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany; 2German Rheumatism Research Centre, Berlin, Germany; 3University of Alberta, Department of Medicine, Edmonton, Canada; 4University College London, Centre for Rheumatology and MRC Centre for Neuromuscular Diseases, London, United Kingdom; 5University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; 6King Christian 10th Hospital in Denmark; 7University of Southern Denmark, Institute of Regional Health Research, Odense, Denmark; 8Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen, Denmark; 9University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; 10Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany

Background: In axial spondyloarthritis, magnetic resonance imaging (MRI) is useful for depicting active inflammatory lesions. The utility of MRI to display structural changes is not that well established.

Objectives: Comparison of MRI and conventional radiography of the sacroiliac joints (SIJs) for detection of structural lesions typical for axial spondyloarthritides (axSpA) in an international multireader exercise.

Methods: Patients from the ASAS Cohort with symptoms suggestive of axSpA and both radiographs and T1-weighted MRIs of SIJs available for central reading were included. SIJs radiographs were scored by 3 central readers according to the modified New York (mNY) criteria grading system. Structural damage on radiographs was defined as fulfillment of the mNY criterion (patient level) or presence of grade 2 sacroiliitis (single joint level) (majority decision). MRI scans were assessed for structural changes compatible with axSpA (global statement) and separate changes (erosion, sclerosis, periarticular fat metaplasia and ankylosis) by 7 central readers (majority decision). Absolute agreement between MRI and radiography (Table 1).

Results: Overall, 199 patients (398 joints) were included, 149 (74.9%) had a diagnosis of axSpA. 102 (51.3%) had definite radiographic sacroilitis, 65 (32.7%) had structural changes suggestive of SpA on MRI (global assessment). The absolute agreement between MRI and radiography was 69.3%, kappa - 0.39 (Table 1). Structural damage on radiographs often (48.1% of cases) could not be confirmed by MRI. Among structural lesions, erosions on MRI showed the best discriminative capacity regarding the structural damage on radiographs (Table 1).

Conclusion: Only modest agreement between MRI and conventional radiography in detection of structural changes typical for SpA in the SIJs was revealed; erosions on MRI showed the best agreement with the presence of definite structural damage on radiographs.

ANALYSING IMPAIRMENTS IN PHYSICAL PERFORMANCE (AS ASSESSED BY THE AS PERFORMANCE INDEX (ASPI)) IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Eerik Ahomaa,1,2 Uta Kiltz,1,2 Björn Bühring,1,2 Xenofon Baraliakos1,2 Salima van Weely,1,2

BACKGROUND: In patients with axial spondyloarthritis (axSpA) physical functioning is often impaired. The current gold standard to assess physical functioning is self-reported questionnaires (i.e. BASFI), which can be influenced by patients' subjective feelings. Therefore, a performance-based test-battery was designed to measure physical functioning more objectively: the ankylosing spondylitis (AS) Performance Index (ASPI) [1]. Based on domains taken from BASFI tasks were designed to imitate activities of daily living (ADL). Although the ASPI has been evaluated for a thorough analysis of the deficits of physical functioning and factors which influence the performance of patients with axSpA has not been performed to date.

OBJECTIVES: The aim of the present study assesses the relation between self-reported assessments of physical functioning and actual performance of patients, and to detect influencing factors.

METHODS: Consecutive axSpA patients underwent standardized assessments concentrating on the following variables: patient and disease characteristics, patient-reported outcomes (ASDAS, BASFI, BASMI, ASAS Health Index (ASAS HI), PHQ-9, IPAQ), mSASSS and ASPI (ASPI 1: Bending, 2. Putting on socks, 3. Getting up from the floor) [1]. The performance was measured in seconds as time to complete a task based on published instructions. Impairment in physical performance was defined as inability of patients to perform > 1 ASPI test. Spearman Rho correlation was used to compare self-reported functioning and performed physical functioning. Logistic regression analysis was used to identify factors associated with impaired physical performance.

RESULTS: A total of 200 patients (AS 66%, nr-axSpA 34%) was included: 69% males, 44.3±12.5 years old, mean symptom duration 17.9±12.6 years, BMI 27.2±5.5, mean ASDAS 2.5±1.1, BASFI 4.0±2.7, BASMI 3.5±1.8, ASAS HI 7.0±4.1, PHQ-9 8.8±6.2, and mSASSS (n=157) 10.2±18.8. 133 patients were treated with bDMARDs (66.5%). In total 44 patients (22%) were not able to perform one or more ASPI tests. The mean time for bending was 18.5±5.5 sec (n=179/90%), for putting on socks 12.8±6.4 sec (n=156/78%), and for getting up from floor 6.5±5.0 sec (n=187/94%). A significant correlation was found for all three ASPI tests with BASFI (0.5-0.7), ASAS HI (0.4-0.6) and spinal mobility as assessed by BASMI (0.4-0.7). Self-reported physical activity (IPAQ) correlated weakly with ASPI (all 0.2) and structural damage correlated only with the test putting on socks (r=0.3), whereas the other tests did not correlate. Logistic regression showed influence of obesity, spinal mobility and global functioning on actual performance but not of disease activity and self-reported physical function, (Figure 1).

CONCLUSION: This study confirms a good correlation of the ASPI with standard questionnaires but it showed a substantial floor effect strongly suggesting that additional information on actual performance is needed. Thus, to obtain a complete picture of function and impairments of patients with axSpA the actual performance needs also to be assessed. Moreover, obesity should be addressed as a potential modifying factor contributing to limitation in actual performance.

THU0368 
THE IMPACT OF PROFESSIONAL ACTIVITY IN ANKYLOSING SPONDYLITIS

ANDRONACHE IULIA1, Victoria Cristina Suta2,3, Sabina Cocodeli2, Maria Suta4.
1‘Dr. Alexandru Gaftenco’ Emergency Military Hospital, Rheumatology, Constanta, Romania; 2St. Apostol Andrei Emergency Clinical County Hospital Constanța, 2nd Internal Medicine Clinic,–, Constanta, Romania; 3Faculty of Medicine, Ovidius University Constanța, Constanta, Romania

Background: The mechanical stress due to strenuous professional activity cannot be easily quantified, yet it may lead to a wide range of musculoskeletal complaints. In ankylosing spondylitis (AS) patients, mechanical stress may lead to the occurrence and the aggravation of enthesitis (1) and a profession involving an intense physical strain is correlated with the radiologic progression (2). While studies regarding the professional activities in ankylosing spondylitis patients are focused on the disease's impact on the work capacity, the type of labor may also influence the disease progression (3).

Objectives: To assess the relationship between the professional activity in AS patients, disease activity and radiological changes.

Methods: We enrolled 193 patients with AS admitted in the Rheumatology Department of the “St. Apostol Andrei” Emergency Clinical County Hospital. Patient evaluation was performed by a rheumatologist. All the data obtained from the medical history, clinical examination, laboratory tests and imaging studies was recorded at the same date. Data regarding the professional history, type of labor involved was also recorded. The physical strain due to professional activity was done using the methodology established by the National Institute for Medical Expertise and Recovery of Work, which takes into account the amount of energy used in order to perform certain tasks.

Results: We included 193 patients, mostly men, 171 men (81.9%), with a mean age of 47.9±12.04 years and a mean disease duration of 20.07±11.18 years. At the moment of the evaluation, 49.7% were still employed and 50.3% were retired due to work disability. Most patients had a professional qualification (89.2%), and manual labor was identified in 132 (6.4%) of the patients. In the study cohort the professional physical strain was mostly low (39.4%) and medium (50.8%). Manual laborers (77.3%) had an active disease, with a mean BASDAI of 5.6±1.0, and a mean ASDAS-PCR of 3.2±1.23, the high and very high disease activity (ASDAS-PCR >2.1) being registered in 86.1% of them (p=0.001). Manual workers had an important functional deficit (BASFI=6.3±2.41) (p=0.001). Regarding radiological features, manual laborers had stage IV sacroiliitis in 68.9% of the cases, 82.6% had syndesmophytes, which were generalised in 59.8% of the cases (p=0.005).

A high professional physical strain correlates with active disease (BASDAI=4.1), with the presence of bridging syndesmophytes (81.8%, p=0.009), and generalized syndesmophytes (68.8%, p=0.007).

Conclusion: Manual labor, with strenuous physical activities correlates with high disease activity, severe functional impairment and radiological changes in AS patients.

THU0369 
INCREASED PREVALENCE OF CARDIAC DISORDERS IN DUTCH ANKYLOSING SPONDYLITIS PATIENTS: THE CARDAS STUDY

Milad Baniaamam1, Sjoerd C. Heslinga2, Thelma Konings3, Otto Kamp1, Vokko P. van Halm2, Irene van der Horst-Bruinsma1.
1Amsterdam Rheumatology and Immunology Center, location Reade, Department of Rheumatology, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology Center, location VUmc, Department of Rheumatology, Amsterdam, Netherlands; 3Amsterdam University Medical Center, location VUmc, Department of Cardiology, Amsterdam, Netherlands

Background: The overall mortality rate in ankylosing spondylitis (AS) patients is increased by 60–90% compared with the general population. This higher mortality rate is predominately caused by cardiovascular disease (CVD) comprising both by increased prevalence of cardiac diseases such as valvular heart disease, conduction disturbances and cardiomyopathies as well as atherosclerotic diseases such as myocardial infarctions. However, there is some diversity in the literature and there is a lack of contemporary studies. Therefore, we investigated current prevalences of cardiac disorders in a well characterized cohorts of Dutch patients with AS.

Objectives: The CARDAS study aims to describe the prevalence of CVD in AS patients in a Dutch cohort.

Methods: We performed a cross-sectional study in consecutive AS patients between 50-75 years. Subjects were recruited from a large rheumatology outpatient clinic (Reade) in Amsterdam, the Netherlands. Patients underwent echocardiography with 2D, spectral and Color Doppler imaging. Diastolic dysfunction was evaluated by an experienced cardiologist based on the 2008 ASE guideline. Furthermore, an ECG, blood sample, surveys and physical examination were performed. Disease activity and function were measured with the BASFI, BASDAI and the ASDAS-PCR.

Results: 191 Consecutive AS patients were included with a median age of 58 years (54-65) of which mostly men (136/191, 71%) (Table 1). The mean disease duration was 34.9 years (+11.9) The disease activity measures, BASDAI, ASDAS-PCR and BASFI, indicated moderate disease activity and were, respectively 3.1 (+2.3), 2.1 (+1.0) and 3.5 (1.6-5.7). The percentage of AS patients was present in 42% of the AS patients. As cardiac manifestations are age related, AS patients were divided in 3 age categories, respectively 50-59 years, 60-69 years and 70-75 years. Hypertension was diagnosed in respectively 45.3%, 64.1% and 85.7%. History of CVD described as angina pectoris, myocardial infarction, stroke and/or peripheral ischemia were present in respectively 7.5%, 9.4% and 19%. Diastolic dysfunction was present in respectively 40.4%, 61.9% and 89.5% of the AS patients. The diastolic dysfunction present in this population was mainly mild with 60.2% of patients presenting with grade 1 and 39.8% with grade 2 diastolic dysfunction. Moderate to severe aortic regurgitation was present in respectively 10.4%, 12.5% and 42.9% of the AS patients. These prevalences are substantially increased in comparison to the general Dutch population.

Conclusion: We demonstrated increased prevalences of diastolic dysfunction, aortic valve regurgitation, mitral valve regurgitation and hypertension in Dutch AS patients compared to age matched general population. Although our results suggest mandatory echocardiography screening, this first needs to be established in prospective follow-up studies.

Scientific Abstracts

468 Thursday, 13 June 2019
Conclusion: The ASDAS demonstrated similar construct validity in all patients with pSpA and axSpA in clinical practice. Therefore, the ASDAS can also be used to measure disease activity in pSpA in daily practice.

REFERENCE:

Disclosure of Interests: None declared

predictors of improvement in work productivity at 6 months, while increased baseline work productivity was a positive predictor of improvement. In the PsA group, other than higher baseline work productivity (positive predictor of improvement), no significant predictors were identified at 6 months. However, a negative trend was observed for the presence of depression (LSM: -0.4% vs. -2.5%; p=0.068).

Conclusion: We observed a significant proportion of AS and PsA patients unemployed in this real-world Canadian cohort. Treatment with adalimumab or non-biologic DMARDs was associated with significant improvement in work productivity irrespective of potential risk factors. Presence of depression was identified as an independent negative predictor of improvement in work performance/productivity.

THU0372 NEUROPATHIC PAIN IN THE PATIENTS WITH SPONDYLOARTHRITIS: RELATIONSHIP WITH FATIGUE, SLEEP QUALITY AND QUALITY OF LIFE

Meral Bayram, Gamze Alaylı, Ayhan Elgün, Dilek Durmuş, Ömer Kuru. Ondokuz Mayıs University Medical Faculty, Physical Medicine and Rehabilitation, Samsun, Turkey

Background: Neuropathic pain is defined as the pain that arises as a direct consequence of a lesion or diseases affecting the somatosensory system. Low back pain has nociceptive, neuropathic or mixed components. Inflammatory back pain is one of the key clinical criteria for the classification of spondyloarthritis (SpA). There are no accurate data for the overall prevalence of neuropathic pain in the inflammatory disorders.

Objectives: In the present study we aimed to determine whether there is a neuropathic component in SpA and also to determine the relationship with disease activity, clinical findings, fatigue, sleep quality and quality of life.

Methods: Eighty SpA patients fulfilling the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for SpA (MF=42/38) (37.±11.7 years), 53 patients with chronic low back pain (CLBP) (MF=22/31) (45.5±13.6 years) and 50 healthy controls (MF=28/22) (38.1±12.7 years) were enrolled in the study. Pain was assessed with visual analogue scale (VAS rest and activity), disease activity with Ankylosing Spondylitis Disease Activity Index (BASDAI), functional capacity with Bath Ankylosing Spondylitis Functional Index (BASFI), fatigue with multidimensional assessment of fatigue (MAF), sleep quality with Pittsburgh Sleep Quality Index (PSQI) and quality of life was assessed with Short Form 36 (SF-36). Neuropathic pain was determined by using pain-Detect questionnaire, a simple and reliable screening questionnaire. Scores ≤12 indicate that a neuropathic pain component is unlikely, and scores ≥19 indicate that neuropathic component is very likely to be present. Scores between 12 and 19 suggest that the result is unclear.

Results: The PainDetect score of the SpA patients, CLBP patients and healthy controls were 12.06±5.9, 13.8±7.5, 2.6±4.2, respectively. While there was no significant difference between the patients with SpA and CLBP (p=0.05), the SpA patients had significantly higher scores than the healthy controls (p<0.0001). 14 (17.5%) of the SpA patients, 14 (26.4%) of the CLBP patients and none of the healthy controls had PainDetect score ≥19 (p=0.05). The MAF score and all subscales of SF 36 all components were significantly different in the three groups (p<0.05).

There were also statistically significant differences between three groups for all subscales of PSQI except duration of sleep and need medications to sleep (p<0.05). PainDetect score was positively correlated with VAS rest, BASDAI, and BASFI in the patients with SpA. While PainDetect score was positively correlated with VAS rest (p<0.05). PainDetect score was positively correlated with VAS rest and activity, depression was identified as an independent negative predictor of improvement in work performance/productivity.

THU0373 ACTIVE SACROLILITIS ON MAGNETIC RESONANCE IMAGING IN PATIENTS WITH ANTERIOR UVEITIS

Kristyna Bubová 1, Monika Gregoryová 1, Katelina Zegzulková 1, Karol Pavelka 2, Jarmlsa Heissigová 1, Ladislav Šenok 1. 1Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic; 2Department of Ophthalmology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic

Background: Anterior uveitis (AU) is a common extraarticular manifestation in spondyloarthritis (SpA). The disease can precede the typical axial and peripheral features. Additionally, some studies had described positive bone marrow edema (BME) in patients with AU lacking chronic back pain.

Objectives: The aim of this study was to examine patients with AU, to determine whether the patients already fulfill criteria for axial and/or peripheral SpA and compare the findings to healthy controls (HC).

Methods: We recruited 65 patients without prior rheumatologic diagnosis who developed at least one episode of AU and 33 age and sex matched HC. The clinical data were collected and rheumatology examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJ) was read by trained rheumatologist who was blinded to the patient’s data. Patients were divided into SpA subsets (axial: imaging and clinical arm and peripheral SpA) fulfilling The Assessment of SpondyloArthritis international Society (ASAS) classification criteria and non-SpA subset. The ASAS modified Berlin algorithm for diagnosis of axial SpA (axSpA) was also applied.

Results: Altogether, 72% (n=47) patients referred back pain including 22.0% (n=14) patients referring inflammatory back pain. 28% (n=18) did not refer back pain. Similar results were found in HC subset. Bone marrow edema (BME) was found in 51% (n=33) of all patients with AU, however 35% (n=23) had highly suggestive BME (hsBME) corresponding to typical findings in sacrolilitsis compared to HC where 30% (n=10) had BME, however none had hsBME (p=0.08, p< 0.0001, respectively). Furthermore, patients with AU had higher serum CRP levels compared to HC (p<0.001); no other significant differences were observed. The diagnosis of SpA was confirmed in 46% (n=29) of all patients with AU, 34% (n=22) patients fulfilled the imaging arm and 12% (n=7) fulfilled the clinical arm of ASAS classification criteria for axSpA. 3% (n=2) patients fulfilled ASAS classification criteria for peripheral SpA. Two patients lacking back pain developed hsBME on SIJ. The diagnosis of axSpA according to the ASAS modified Berlin algorithm was confirmed in 42% (n=27) patients. Analysis of clinical characteristics showed significant difference between baseline BASDAI in SpA vs. non-SpA (1.6±1.5 vs. 0.8±1.0, p=0.007 respectively), and remained significant in those fulfilling imaging arm of axial SpA (p=0.04). The levels of CRP were significantly higher in SpA compared to non-SpA subsets (8.6±9.7 vs 2.6±2.7 mg/L, p=0.003). Presence of back pain and inflammatory back pain were more often in SpA compared to non-SpA subsets (79% and 43% vs. 51% and 3%, p=0.001 and p<0.001 respectively). Patients with hsBME had significantly higher serum CRP levels compared to patients lacking hsBME (9.0±10.4 vs 3.3±4.2 mg/L, p=0.005) no other significant differences were observed.

REFERENCES:

Disclosure of Interests: None declared
Conclusion: More than one third of patients with AU fulfilled the criteria for axial or peripheral SpA. Furthermore, the prevalence of back pain, increased BASDAI and serum CRP levels was significantly higher in AU patients with SpA compared to non-SpA subjects and HC. Inflammatory back pain was significantly more often in patients with AU classified as axSpA. Patients with hsBMI had significantly higher serum CRP levels compared to the rest of the patients.

GENDER DIFFERENCE IN ASAS HEALTH INDEX IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Hsin-Hua Chen1,2, Ting-I Pan3, Yi-Ming Chen1, Kuo-Lung Lai1, Tsu-Yi Hsieh4, Ching-Tai Lin5, Wei-Ting Hung4, Yin-Yi Chou2, Chih-Wei Hsieh1, Wen-Nan Huang2, Yi-Hsing Chen2, Der-Yuan Chen5, Ching-Tsai Lin2, Wei-Ting Hung4, Yin-Yi Chou2, Chih-Wei Tseng2, Yi-Da Wu2, Patrick C. Chung3, Yung-Chieh Chang1.

Background: The Assessment of Spondyloarthriss international Society Health Index (ASAS HI) has been developed and validated to assess health and function in patients with spondyloarthritis. However, whether ASAS HI differs between men and women is unknown. The aim of this study was to compare ASAS HI between men ans women in patients with ankylosing spondylitis (AS).

Objectives: The aim of this study was to compare ASAS HI between men ans women in patients with ankylosing spondylitis (AS).

Methods: Since November 2016, we measured and recorded data of demography, comorbidity, family history, medication use, the Ankylosing Spondylitis Disease Activity Score (ASDAS), the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Bath Ankylosing Spondylitis Functional Index (BASFI), the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) and the ASAS HI for AS patients in clinical prac-
tice using an electronic patient reported data system linked to an electronic medical record system in Taichung Veterans General hospital (TVCGH). We retrieved the last recorded data of AS patients in TVCGH during 2017/11–2018/10. We assessed the association between gender and the ASAS HI using a multivariable linear regression model. Variables from the univariable linear regression analysis with p < 0.2 were included in then multivariable analysis. We used a forward selection method to build the models.

Results: A total of 307 AS patients [62 (20.2%) females, mean age 46.4 years (S.D. 13.3), mean symptom duration 20.6 years (S.D. 12.1)] were included. Female patients had an older age at onset (29.2 ± 12.6 vs 24.9 ± 9.6 years, p = 0.015), a shorter symptom duration (15.7 ± 11.6 vs 21.8 ± 12.0 years, p < 0.001), a lower proportion of smoking (65.8% vs 48.2%, p < 0.001), higher ASAS HI (5.9 ± 3.8 vs 4.3 ± 3.4, p = 0.001), higher ASDAS-ESR (1.9 ± 0.8 vs 1.5 ± 0.8, p < 0.001) and lower mSASSS (6.0 ± 11.4 vs 21.8 ± 23.1, p < 0.001) than male patients. There were no significant differences in BASFI (1.1 ± 1.5 vs 1.6 ± 1.7, p = 0.26), ASDAS-CRP (1.5 ± 0.8 vs 1.5 ± 0.9, p = 0.972) and BASDAI (2.4 ± 1.8 vs 2.0 ± 1.4, p = 0.115) between females and males. In multivariable analysis, male gender was significantly associated with a better ASAS HI (β = -1.73, 95% CI: -2.55, -0.91, p < 0.001). Other significant predictors of ASAS HI included BASDAI (β = 1.29, 95% CI: 1.07, 1.50, p < 0.001), disease duration (β = 0.04, 95% CI: 0.01, 0.06, p = 0.015), mSASSS (β = 0.01, 95% CI: 0.00, 0.02, p = 0.003) and hepatitis B (β = 0.99, 95% CI: 0.03, 1.96, p = 0.044).

Conclusion: This single center, cross-sectional study revealed that male gender was significantly associated with lower ASAS HI in AS patients.

CLINICAL FEATURES OF AXIAL SpondyloarthritIS PATIENTS DiAGNOSED IN PERIPHERAL VERSUS AN ACADEMIC HOSPITAL

Ann-Sophie De Craemer1,2, Thomas Renson1,2, Philippe Carron1,2, Peggy Jacques1,2, Jan Lenaerts3,4, Lieve Gyselbrecht5,6, Rik Jooss1,6, Filip van den Bosch1,2, Dirk Elewaert1,2, Be-Giant consortium; Ghent University Hospital, Gent, Belgium; “VIB Inflammation Research Center, Gent, Belgium; “Reuma Institut, Hasselt, Belgium; “University Hospital Gasthuisberg, Leuven, Belgium; “Algemeen Stedelijk Ziekenhuis, Aalst, Belgium.”

Background: Diagnosis of axial spondyloarthritis (axSpA) often relies on a positive magnetic resonance image of the sacroiliac joints (MRI-SIJ). However, pitfalls in interpretation of MRI-SIJ were recently acknowledged (1). Thus reader’s expertise might be a source of heterogeneity in patient populations diagnosed with non-radiographic axSpA.

Objectives: We compared clinical characteristics of axSpA patients diagnosed in peripheral hospitals (MRI evaluation by local experts) versus an academic hospital (MRI central reading by trained radiologists and rheumatologists).

Methods: Patients originate from the Be-Giant cohort, a Belgian nation-
wide observational registry of axSpA patients diagnosed by expert opin-
ion. Included patients fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA and are anti-
tNF-κBp province to inclusion. Patient enrollment started in 2010 and 2012 at the outpatient clinic of 1 academic and 7 peripheral hospitals respectively. Patients were free to visit a rheumatologist of their choice without necessity for referral by a general practitioner.

Results: By January 2019, 291 axSpA patients were included. Table 1 presents demographic and clinical characteristics according to the diag-
nostic echelon. The patient fraction fulfilling the imaging arm of the ASAS classification criteria was similar in both settings (75.4% vs. 88.7%, p = 0.21). However, because of a higher HLA B27 positivity rate in patients diagnosed in an academic versus peripheral hospitals (73.5% vs. 57.4%, p = 0.01), a significantly higher fraction of patients fulfilled both the clinical and imaging arm in the former diagnostic setting (63.0% vs. 37.7%, p = 0.01).

Conclusion: Patients diagnosed with axSpA in peripheral versus an aca-
demic hospital generally show similar demographic and clinical charac-
teristics. In an academic center, patients diagnosed with axSpA are more likely to be HLA B27 positive and to fulfill both ASAS classification arms, suggesting that rheumatologists in peripheral hospitals seem to assign more value to MRI findings compared to HLA B27 status in the diagnost-
ic process.

THU0376

THE VALUE OF SACRILIC JOURNAL RADIOGRAPHS IN THE EARLY SPONDYLOARTHROPATHIES: RESULTS FROM THE ASAS-COMOSPA STUDY

Eugenio de Miguel1, Beatriz Joven-Ibáñez2, Eva Galindez3, Claudia Urrego-Laurín4, Maria Luz García-Vivar5, Cristina Fernández-Carballedo6, Jose Francisco Garcia Llorente7, Maria del Carmen Castro Villegas8, Carolina Torner9, Xavier Juanola-Roura10, Esperanza Working Group, La Paz University Hospital, Rheumatology, Madrid, Spain; 12 de Octubre University Hospital, Madrid, Spain; 2Basurto University Hospital, Rheumatology, Bilbao, Spain; 3Moncloa University Hospital, Madrid, Spain; 4San Juan University Hospital, Rheumatology, Alicante, Spain; 5Galdakao University Hospital, Rheumatology, Bilbao, Spain; 6Reina Sofia University Hospital, Rheumatology, Córdoba, Spain; 7Bellvitge University Hospital, Rheumatology, Barcelona, Spain

Background: X-Ray sacroiliitis is the cornerstone in the diagnosis of the ankylosing spondylitis (AS). It is clear that the presence of sacroiliitis is a specific lesion in long standing AS, but little evidence exists on the reliability of this image technique in early axial spondyloarthritides (axSpA), which associates with reduced structural damage. It is relevant because some rheumatologists and pharmaceutical authorities feel more confident with the diagnosis of AS rather than with non radiographic axial spondyloarthritides (nr-axSpA) forms. On the other hand, according to various research studies, clinicians are subject to potential bias when interpreting radiographs, influenced by their pretest clinical judgment.

Objectives: The aim of this study is to determine the value of X-Ray sacroilitis in the early diagnosis of axSpA.

Methods: This study included 290 radiographs of the SI joints from patients in the ASAS-COMOSPA cohort. Nine readers, blinded for the diagnosis, participated in the reliability exercise, all of them experienced rheumatologists and members of the Spanish spondyloarthritides working group (GRESSER). Patients with axSpA were classified as having AS if the radiographic criteria of the modified NY criteria (presence of radiographic changes in the SIJ of at least grade II bilaterally or at least grade III unilaterally) were fulfilled. The gold standard was the categorical opinion of at least five of the expert readers. For the statistical analysis, the Chi-square and Kappa tests were performed.

Results: The radiographic diagnosis, sensitivity, specificity, likelihood ratio, grade of agreement and mean K values compared to gold standard are shown in table 1. The concordance Kappa test was highly variable among the readers, ranging from fair to excellent. The agreement with the gold standard varied from 68 to 94% and the sensitivity and specificity, from 50-100% and 64-96%, respectively. Additionally, the number of AS was 61, with an inter-reader variability rate of 31 to 138. Larger discrepancies were observed when assessing sacroilitis grade 2.

Conclusion: The diagnosis of AS in early axSpA is characterized by a marked variability. At least in doubtful cases, a second central evaluation performed by highly qualified experts should be advisable.

THU0377

THE CARDIOVASCULAR ASSOCIATIONS WITH ENTHESITIS AND DACTYLITIS IN PATIENTS WITH SPONDYLOARTHROPATHIES: RESULTS FROM THE ASAS-COMOSPA STUDY

Mohammad H. Derakhshan1, Nicola Goodson2, Jonathan Packham2, Raj Sengupta3, Anna Mollo4, Helena Marzo-Ortega5, Stefan Siebert6, On behalf of BRITSpA and the ASAS-COMOSPA investigators. 1University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2University of Liverpool, Department of Rheumatology, Liverpool, United Kingdom; 3Keele University, Haywood Rheumatology Centre, Stoke on Trent, United Kingdom; 4Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; 5Hopital Cochin, Paris, France; 6University of Leeds, NIHR LBRC, Leeds, United Kingdom

Background: Enthesitis and dactylitis are considered characteristic inflammatory musculoskeletal manifestations of spondyloarthritides (SpA). These manifestations are usually assessed in the context of their assumed underlying specific condition rather than as distinct entities. Data from the ASAS-COMOSPA cohort have recently been shown that duration of SpA disease is associated with higher odds of hypertension particularly in axial SpA (1).

Objectives: To evaluate the possible associations of dactylitis and enthesitis phenotypes with cardiovascular comorbidities in a heterogeneous cohort of patients with SpA.

Methods: ASAS-COMOSPA is a global cross-sectional study assessing comorbidities in 3984 patients with SpA. History of enthesitis or dactylitis was based on self-report with confirmation using the medical records. Associations between dactylitis or enthesitis with hypertension, dyslipidemia, diabetes, ischemic heart diseases (IHD) and stroke were analysed by separate logistic regression models unadjusted, adjusted for age and sex (models 1), and adjusted for age, sex and BMI (model 2).

Results: The data of 3905 participants were available for analysis. There were 1480 (37.9%) with history of enthesitis and 611 (15.6%) with dactylitis, while 1814 (46.5%) had neither. Presence of dactylitis was associated with hypertension in the univariable analysis [OR=1.68; 95%CI: 1.39–2.03]. The association remained significant when adjusted for age and sex, but not following further adjustment for BMI (Table). Similarly, enthesitis was associated with hypertension in the univariable analysis [OR=1.36; 95%CI: 1.17-1.59], which remained after adjusted for age and sex, as well as after further adjustment for BMI (Table). Similar associations were seen for dyslipidemia and dactylitis [OR=1.60; 95%CI: 1.29–1.98] or enthesitis [OR=1.50; 95%CI: 1.26–1.77], with the association with dactylitis lost after further adjustment for BMI while the association with enthesitis remained significant (Table). While there were significant associations between dactylitis and diabetes [OR: 1.50 (95% CI: 1.07–2.11)], and between enthesitis and diabetes [OR=1.35; 95%CI: 1.02-1.78] in unadjusted models, no associations were
COEXISTENCE OF ANKYLOSING SPONDYLITIS AND DACTYLITIS

Both ankylosing spondylitis and rheumatoid arthritis are common entities. The coexistence of both diseases in the same person is not known exactly, however, with the data obtained, there seems to be a greater aggressiveness in the evolution, since most of them present an erosive radiological pattern, positivity for RF, involvement of the axial skeleton and presence of rheumatoid nodules in a frequency higher than that which occurs in patients with diagnosis isolated from either of the two entities.

Disclosure of Interests: Mohammad H. Derakhshan: None declared, Nicola Goodson Grant/research support from: Research support grant from Novartis, Speakers bureau: Paid speaker UCB, Jonathan Packham Consultant for: Educational speaker grant from Abbvie, Raj Sengupta Grant/research support from: Celgene, Novartis, Consultant for: Abbvie, Biogen, Celgene, Novartis, UCB, Speakers bureau: Abbvie, Biogen, Celgene, Novartis, UCB, Anna Moltõ: None declared, Helena Marzo-Ortega Grant/ research support from: Janssen, Novartis and Pfizer, Consultant for: Abbvie, Celgene, Janssen, Eli-Lilly, Novartis and UCB, Speakers bureau: Abbvie, Biogen, Celgene, Novartis, UCB, Anna Moltõ: None declared, Helena Marzo-Ortega Grant/ research support from: Janssen, Novartis and Pfizer, Consultant for: Abbvie, Biogen, Celgene, Janssen, Eli-Lilly, Novartis and UCB, Stefán Siebert Grant/research support from: AbbVie, Novartis, Pfizer, Janssen, BMS, Celgene, UCB, and Boehringer Ingelheim, Consultant for: Abbvie, UCB, Pfizer, Janssen, Boehringer Ingelheim, Celgene, and Novartis, Speakers bureau: Abbvie, UCB, Pfizer, Janssen, Boehringer Ingelheim, Celgene, and Novartis

Conclusion: In patients with SpA, both dactylitis and enthesitis are associated with higher risk of hypertension and dyslipidaemia. The loss of associations with dactylitis with adjustment for BMI could suggest a potential shared underlying metabolic mechanism.

THU0378

COEXISTENCE OF ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS (ANALYSIS OF 73 CASES)

Bryan-Josué Flores Robles, Valvanera Pinillos, Angel Elena-Ibáñez, Ezditen Labrador-Sánchez, Leticia Merino-Meléndez, Juan Antonio López-Martín, Enrique Ramalle-Gomara

Hospital San Pedro, Logroño, La Rioja, Spain

Background: The coexistence of rheumatoid arthritis (RA) and ankylosing spondylitis (AS) in the same person is a rarely described phenomenon. Both ankylosing spondylitis and rheumatoid arthritis are common entities in the field of rheumatic diseases with a high impact on the patient’s quality of life and morbidity and mortality. The possibility of the coexistence of both diseases in the same person is not known exactly, however, with the data published to date, it is estimated that it ranges from 1 in 500,000 to 1 in 2,000,000.

Objectives: The epidemiological, clinical and study characteristics (radio-graphic/laboratory) of 73 patients with coexistent diagnosis of RA and AS are described. It includes 71 patients detected in the literature (32 articles) and 2 own cases

Methods: The platforms used for the search using the terms AR and AS (coexistence/concomitance/concurrency) were PubMed, Medline, Embase, Scopus, hospital virtual libraries, non-indexed journals and a secondary manual search. All the articles were taken into account, regardless of the language in which they were written, making the relevant translations (1 article in French, 1 article in Portuguese, 1 article in Spanish and the rest in English), and only those well documented cases were included.

Results: Of the total of registered cases, 55 patients were men (75.3%), with a mean age of 54 years, and a mean age of onset of the disease at 35.7 years (SD 14.0). Ankylosing spondylitis was the first of the two diseases diagnosed in 52.2% of cases (35/67). The mean duration of the disease (RA or AS) up to the time of diagnosis of both was 19 years. The first symptom of onset was low back pain in 50% of cases (34/68), followed by arthritis in 46% of cases (32/68), 56% of patients (36/64) had nodules rheumatoid and 85% of patients had presented low back pain at some point of their assessment. In 15% of the patients (11/73) the presence of uveitis was documented (in some old articles the term of iritis was limited), in 22% of cases there was extra-articular involve-ment (16/73), being the most frequent was the presence of Felty syndrome with 4 cases. (table 1)

Regarding the findings in the imaging studies, up to 78% of the patients had syndesmophytes in the spine (either in plain radiography). 88% (62/70) presented erosions in the X-rays of the hands and/or feet. The Radiological sacroiliitis was present in almost all patients 72/73, RA was positive in 90%, in 9 of the 11 patients in whom anti-CCP was performed were positive, and, in addition, almost 90% of the cases were HLA B-27 positive

Conclusion: The coexistence of AR and SpA is highly uncommon. With the data obtained, there seems to be a greater aggressiveness in the evolution, since most of them present an erosive radiological pattern, positivity for RF, involvement of the axial skeleton and presence of rheumatoid nodules in a frequency higher than that which occurs in patients with diagnosis isolated from either of the two entities.

THU0379

DEPRESSIVE SYMPTOMS AND FUNCTIONAL IMPAIRMENT ARE FREQUENT AND AFFECT QUALITY OF LIFE IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS: A QUESTIONNAIRE-BASED ASSESSMENT OF 300 PATIENTS COMPARED WITH 150 PATIENTS WITH PSORIASIS AND 150 PATIENTS WITH MECHANICAL BACK PAIN

Natalie Friede1, Sonja Hiestand1, Franziska Schauer2, Christoph Schempf2, Georg Herget2, Dominique Endres3, Ludger Tebartz van Elst4, Reinhard Völ3, Jens Thiel1, Nils Venhoff1, 1Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg im Breisgau, Germany; 2Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Dermatology, Freiburg im Breisgau, Germany; 3Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Orthopedic and Trauma Surgery, Freiburg im Breisgau, Germany; 4Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Section for Experimental Neuropsychiatry, Department of Psychiatry and Psychotherapy, Freiburg im Breisgau, Germany

Background: Axial ankylosing spondylitis (axSpA) and psoriatic arthritis (PsA) constitute chronic inflammatory conditions affecting the axial skeleton as well as peripheral joints. Insufficient treatment may lead to joint destruction associated with a high rate of disability. Extra-articular manifestations contribute to morbidity and a reduced quality of life.

Abbreviations: DT= Typical deviation
Furthermore, both, axSpA and PsA have been associated with an increased risk of depression.

Objectives: The aim of this project was to assess quality of life, functional impairment in everyday life as well as the prevalence of depression in axSpA and PsA and determine associated factors.

Methods: A questionnaire-based screening tool (FBBH, WHOQOL-BREF, Phq9, GHQ-12) was used to assess 150 patients with PsA and 150 patients with axSpA as well as 300 controls (150 with skin psoriasis only and 150 mechanical back pain patients) for quality of life, functional impairment as well as signs of depression.

Results: Both, SpA and PsA patients had a significantly reduced health-related quality of life compared to published normal values as well as psoriasis only patients (p<0.0003). Pain and functional impairment in everyday life correlated highly with perceived overall quality of life (r=0.8). Both, physical health as well as psychological health in turn highly correlated with the presence of depressive symptoms. In total, 35.4% of SpA and 41.2% of PsA patients had mild signs of depression, whereas 25% respectively 28.4% of SpA and PsA had patients moderate to severe signs of depression. Patients with active disease (BASDAS4) at the time of evaluation showed significantly more frequent depressive symptoms compared to patients with no or low disease activity (p<0.0001). Female patients had a significantly reduced physical and psychological health-related quality of life compared to male patients (p=0.0190). In our cohort, also age correlated with perceived quality of life. SpA and PsA patients <45 years of age reported a significantly higher perceived overall quality of life compared to patients >45 years (p=0.0001). Quality of life regarding physical health, mental health as well as social relationships was significantly better in younger patients (p=0.0014, p=0.0109, p=0.0196 respectively). However, this did not translate into a reduced rate of depressive symptoms in young patients. Body mass index (BMI) was associated with reduced health-related quality of life and psychological wellbeing, but did not correlate with depression. Smoking was neither associated with quality of life nor depression.

Conclusion: Despite treatment many SpA and PsA patients suffer from a reduced quality of life. Depression constitutes an important comorbidity, which needs to be addressed. Adequate therapy is not only important to reduce irreversible joint damage and disability but may also have a role in avoiding comorbidities such as depression.

Disclosure of Interests: None declared

THU0380 LUMBOPELVIC RHYTHM IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS COMPARED WITH LOW BACK PAIN AND HEALTHY SUBJECTS

Juan L. Garrido-Castro1, Inmaculada Concepcion Aranda-Valera1, Sandra Alcaraz-Ciurana1, Luzdary Garcia-Luque2, Diana Rodriguez-de-Souza2, Cristina Gonzalez-Nava3, Francisco Alburquerque-Sendin3, Philip Gardiner3, Eduardo Collantes Estevez1, 1IMIBIC, Cordoba, Spain; 2University of Cordoba, Cordoba, Spain; 3WHSCF, Londonerney, United Kingdom

Background: Lumbar back pain reduces spinal mobility in patients. Although there are some symptoms that characterise ‘back pain’, these are non-specific and the diagnosis is often delayed. It is not clear if there are kinematic differences between axial Spondyloarthritis (axSpA) and other types of back pain. Inertial motion sensors are now available that can accurately and reliably measure spinal mobility. The ViMove system uses two inertial sensors located at L1 and S1 allowing spinal flexion to be separated into its lumbar and pelvic components. The relation between different parts of the spine during a full flexion movement is known as lumbopevic rhythm. The trunk sensor measures the total flexion, whilst the contribution of hip is measured by the pelvic sensor leaving lumbar flexion as the difference between the two angles.

Objectives: To analyse relation of lumbopevic angles in axSpA patients, LBP patients and healthy controls.

Methods: 92 subjects were included in our study: 56 axSpA (from the COSPAR cohort of the Reina Sofia University Hospital), 14 LBP and 22 healthy controls. Inertial based system, the ViMove, was used to measure mobility. axSpA patients were stratified in three groups according their overall mobility using the BASMI: axSpA Low (< 2), Med (2-4) and High (>4).

Results: Table shows the results of spinal mobility tests in each group. The trunk, pelvis and lumbar angles are expressed in degrees (Mean and SD). cPelvis is the contribution of pelvis to the overall movement as percentage. Three of the five measurements in BASMI are outside the lower back so unlikely to be affected in LBP patients.

</tbody>
</table>

There were significantly differences in the trunk, lumbar and pelvis angles between control and axSpA patients (p<0.01). The only significant difference between LBP and axSpA was in the lumbar angles (p<0.05).

Conclusion: A reduction in spinal flexion was found in all patient groups, but there are interesting differences in the pattern of movement. LBP patients were characterised by a greater reduction in pelvic movement compared to the axSpA patients, although the final trunk flexion angle is actually lower in axSpA. When we compared more and less affected axSpA patients (according to BASMI), the most severely affected had severe restriction in lumbar movement whilst pelvic movement was increased. Lumbo-pelvic rhythm can also be analysed throughout early, middle and the end of the movement. Investigating spinal kinematics could help us to understand better axSpA and how it affects spinal mobility.

THU0381  PATIENT-REPORTED IMPACT OF AXIAL SPONDYLOARTHRITIS ON WORKING LIFE: RESULTS FROM THE EMAS SURVEY

Marco Garrido-Cumbrea1,2, Laure Gossec3,4,5, David Gálvez Ruiz1, Christine Bundy5, Raj Mahapatra4, Souzi Makri6, Sergio Sanz-Gómez1, Carlos Delgado Domínguez1, Denis Poddubny4,10, EMAS Working Group. 1Universidad de Sevilla, Health and Territory Research (HTR), Seville, Spain; 2CEADE, Madrid, Spain; 3Sorbonne Université, Paris, France; 4Pitié Salpêtrière Hospital, AP-HP, Rheumatology Department, Paris, France; 5Hospital Universitario La Paz, IDI-Paz, Madrid, Spain; 6Cardiff University, Cardiff, United Kingdom; 7Arthritis Research UK National Biomechanics Centre, London, United Kingdom; 8Cyprus League Against Rheumatism, Nicosia, Spain; 9Charité-Universitätsmedizin Berlin, Berlin, Germany; 10German Rheumatism Research Centre, Berlin, Germany

Background: Axial spondyloarthritis (axSpA) impacts multiple dimensions of patients’ lives, including working life.

Objectives: To evaluate work-related issues, their associations and determinants among European axSpA patients.

Methods: The European Map of Axial Spondyloarthritis (EMAS), conducted from July 2017 to February 2018, was a cross-sectional on-line survey of unscreened patients with self-reported axSpA from Austria, Belgium, France, Germany, Italy, Netherlands, Norway, Russia, Slovenia, Spain, Sweden, Switzerland, and the UK. Participants were recruited through an on-line panel and patient organizations. Participants were classified as active (employed, unemployed between 15-64 years) or inactive (retirees, on sick leave, students and homemakers). Those employed were asked to report work-related issues (sick-leave, difficulty fulfilling work hours, missing work for doctors’ appointments, reducing working hours or taking days off) in the past 12 months. Disease activity (BASDAI), self-reported spinal stiffness, diagnostic delay and psychological distress (General Health Questionnaire, GHQ-12) were compared between employed patients with or without work-related issues using a Mann-Whitney and Kruskal-Wallis test. Two-stage regression analysis was conducted to determine explicative sociodemographic (using stepwise method for income, age, gender, education) and disease-related factors (enter method for BASDAI, self-reported spinal stiffness, functional limitation) over work-related issues.

Results: 2846 axSpA patients participated in EMAS: mean age was 44 ±12 years. 61.3% were female and 48.1% were university educated. Mean disease duration and diagnostic delay were 17.2±12.4 and 7.4±8.4 years, respectively, and mean BASDAI was 5.5±2.0. 61.3% (n=1653) were considered active, of which 87.7% (n=1450) were employed. Of those employed, 67.7% reported a work-related issue, specifically 56.3% took sick leave, 44.6% had difficulties in fulfilling the working hours, 34.6% missed work due to doctor’s appointments, 31.6% requested days off, and 25.7% reduced their number of working hours (Table 1). Among all patients, 74.1% faced or believed they would face difficulties finding a job due to axSpA. Experiencing work-related issues due to axSpA was significantly associated with higher disease activity, self-reported spinal stiffness, longer diagnostic delay, and higher level of psychological distress (p<0.001). First regression step showed gender and educational level as explanatory sociodemographic control factors, while educational level and BASDAI were the only statistically significant explanatory factors in the second step (p<0.001) (Table 2).

Conclusion: Nearly two-thirds of employed patients experienced work-related issues due to axSpA. The strongest factor associated with work-related issues was high disease activity. Understanding the determinants of work-related issues is needed to ensure that patients have adequate workplace and holistic medical support to lead productive work-lives.

THU0382  FACTORS ASSOCIATED WITH POOR WORK OUTCOMES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS IN SINGAPORE

Yiuh Goh1,2, Yu Heng Kwan3, Ying Ying Leung1, Warren Feng4,5, Peter Cheung1,2, Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore; 3Division of Rheumatology, National University Hospital, Singapore, Singapore; 4Program in Health Services and Systems Research, Duke-NUS Medical School, Singapore, Singapore; 5Duke-NUS Medical School, Singapore, Singapore; 6Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background: Axial spondyloarthritis (axSpA) can lead to significant limitation of mobility and function, resulting in poor work outcomes.1 Factors associated with poor work outcomes have not been identified in an Asian population. Singapore is an urban Asian city with a low unemployment rate and a healthcare model with heavy emphasis on self-reliance.2 This socio-cultural context may influence risk factors for poor work outcomes.

Objectives: To identify factors associated with poor work outcomes in patients with axSpA in Singapore.

Methods: A cross-sectional study was performed in two tertiary centres in Singapore. Patients ≥21 years fulfilling Assessment in Spondyloarthritis International Society (ASAS) 2009 criteria for axSpA were included. We collected sociodemographic, clinical data, treatment modalities and patient reported outcomes, including the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), EQ-5D index, and Work Productivity and Activity Impairment scale (WPAI:SpA). WPAI:SpA was used to derive scores for presenteeism (reduced productivity while at work), absenteeism (time absent from work), work impairment (combining presenteeism and absenteeism scores) and activity impairment (impairment in activities performed outside of work). Univariable and multivariable linear regressions were used to

*Fig 2a* and Mann-Whitney to indicate if there is an association between the variables.
examine factors associated with presenteeism, absenteeism, work impairment and activity impairment.

Results: A total of 156 patients with axSpA were included: 72.4% employed, 80.1% male, 86.5% Chinese, mean age 39.2 (13.0) years, mean disease duration 8.5 (8.9) years. The mean BASDAI was 3.2 (2.0), mean BASFI was 2.1 (2.1), mean EQ-SQD was 0.8 (0.1) and mean activity impairment was 28.2%. Among employed patients, mean absenteeism was 4.5%, mean presenteeism was 24.9% and mean work impairment was 27.6%. In multivariable analysis, absenteeism was associated with disease duration (ß: -0.44; 95% CI: -0.80, -0.07;p=0.02) and EQ-SQD (ß: -46.28; 95% CI: -89.63, -2.92; p=0.04). Presenteeism was associated with BASDAI:4 (ß: 8.23; 95% CI: 0.24, 16.22; p=0.04), BASFI (ß: 3.59; 95% CI: 1.25, 5.92; p<0.01) and EQ-SQD (ß: -64.40; 95% CI: -115.79, -13.02; p=0.02). Work impairment was associated with BASFI (ß: 3.57; 95% CI: 0.04; 6.84; p=0.04), EQ-5D (ß: -88.00; 95% CI: -150.87, -25.13; p<0.01). Activity impairment was associated with age (ß: -0.21; 95% CI: -0.41, -0.01; p=0.04), BASDAI:4 (ß: 19.94; 95% CI: 13.79, 26.09; p<0.01), BASFI (ß: 3.29; 95% CI: 1.63, 4.95; p<0.01), EQ-SQD (ß: -82.28; 95% CI: -125.15, -39.41; p<0.01).

Conclusion: Factors such as active disease, reduced physical function and poorer quality of life are associated with reduced work outcomes in patients with axSpA in Singapore. These factors need to be addressed to improve work outcomes.

THU0383 PREVALENCE OF SPONDYLOARTHRITIS IN FIRST DEGREE RELATIVES OF PATIENTS WITH ANKYLOSING SPONDYLITIS

Monika Gregová1, Kristyna Bubova1, Katefina Zegzuklová2, Karel Pavelka1, Ladislav Šenolt1, Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic; Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic

Background: Ankylosing spondylitis (AS) is a common rheumatic disease with higher prevalence in relatives of patients already diagnosed with the disease. HLA-B27 positivity in twins is estimated to 90%.

Objectives: The aim of this study was to examine first degree relatives (FDR) of AS patients, to determine whether the patients already fulfill criteria for axial and/or peripheral spondyloarthritis (SpA) and compare the findings to healthy controls (HC).

Methods: We recruited 32 patients without prior rheumatologic diagnosis with first degree relative treated for AS and 20 age and sex matched HC. The clinical data were collected and rheumatology examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJ) was read by trained rheumatologist who was blinded to the patient’s data. Patients were further divided into the subsets of axial SpA (imaging and clinical arm) and peripheral SpA fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial and/or peripheral SpA.

Results: Altogether, 78% (n=25) FDR referred back pain, 34% (n=11) referred inflammatory back pain (IBP), and 22% (n=7) did not refer back pain, which was significantly different from that in HC (65% referred back pain, 0% referred IBP, 35% referred no back pain, p=0.0038 and p=0.03, respectively). Bone marrow edema (BME) was found in 50% (n=16) of FDR, and 22% (n=7) had highly suggestive BME (hsBME) corresponding to typical findings of active sacroiliitis compared to HC where 10% (n=2) had BME, and none had hsBME (p=0.063, p=0.035, respectively). Furthermore, FDR had higher BASDAI and higher prevalence of HLA-B27 positivity compared to HC (2.0 (±1.5) and 75% vs. 0.4 (±0.6) and 5%, p= 0.001 and p= 0.001, respectively). No other significant differences were observed. The diagnosis of SpA was confirmed in 37% (n=12) of all FDR, 25% (n=8) patients fulfilled the imaging arm and 6% (n=2) fulfilled the clinical arm of ASAS classification criteria for axSpA, 6% (n=2) patients fulfilled ASAS classification criteria for peripheral SpA. The diagnosis of axSpA according to the ASAS modified Berlin algorithm was confirmed in 41% (n=13) patients. Analysis of clinical characteristics showed significant difference between serum CRP levels in SpA vs. non-SpA (8.2 (±12.5) vs. 2.3 (±4.4), p=0.02, respectively) and HLA-B27 positivity (100% vs. 60%, p=0.01, respectively). Presence of back pain and inflammatory back pain were more often in SpA compared to non-SpA subsets (100% and 67% vs. 65% and 15%, p=0.03 and p=0.06, respectively).

Conclusion: More than one third of first degree relatives of patients with AS fulfilled the criteria for axial or peripheral SpA, and had significantly higher prevalence of inflammatory back pain and increased BASDAI compared to HC. Based on these data, screening of family members of patients with AS should be recommended.

THU0384 IMAGING OF SACRIOILIAC JOINTS IN EARLY SPONDYLOARTHRITIS: SHOULD WE CHOOSE COMPUTED TOMOGRAPHY OR MAGNETIC RESONANCE IMAGING?

Wafa Hamdi1, Dora Ben Nessib1, Dhiya Kaffel1, Kaouther Maatallah1, Hanene Ferjani1, Hend Riahi2, Med Montacer Kchir1, Kassab Institute, Tunis, Tunisia; 2Kassab Institute, Radiology, Manouba, Tunisia

Background: In view of the limited utility of pelvic radiography to recognize sacroiliitis in its earliest stages, magnetic resonance imaging (MRI) has been considered as a reliable imaging modality to detect acute subchondral inflammation at disease onset. However, several recent studies reported a high proportion of false-positive of sacroiliac joints (SIJ) MRI. Other studies demonstrated that computed tomography (CT), by its ability to detect early structural damage, may be helpful. Consequently, strengths and limitations of each imaging technique need to be considered when choosing the most appropriate first-line modality in clinical practice.

Objectives: We aimed to assess the performance of CT scanning and MRI for detecting sacroiliitis in early SpA by estimating the sensitivity and specificity of each imaging technique.

Methods: Consecutive patients, aged 16 years and over, referred for symptoms suggestive of SpA from February 2014 to February 2017 were enrolled in this cohort. After excluding patients whose conventional radiography showed a confirmed sacroiliitis, eligible patients underwent SI CT and/or MRI. The CT and MR images were reviewed by 2 musculoskeletal radiologists blinded to clinical findings. Then, 2 rheumatologists recorded from the clinical files if patients fulfilled the ASAS (Assessment of SpondyloArthritis international Society) classification criteria for SpA. This classification was considered as the gold standard of this study.

Results: Fifty-three patients were included: 14 men and 39 women. The mean age was 36 years. The prevalences of HLA-B27 and elevated C-reactive protein (CRP) levels were 37.4% and 16.3%, respectively. Fifty-eight percent of the patients (n=31) fulfilled the ASAS criteria for axial SpA. Among these patients, 30 patients underwent SI CT and 27 underwent SI MRI. Sacroiliitis was visualized by CT in 28 out of 30 patients (93.3%) and by MRI in 17 out of 27 patients (63%). Among the 22 patients who did not
fulfill the ASAS criteria for SpA, 21 patients underwent SU CT and 20 underwent SU MRI. Sacroiliitis was not visualized by CT in any patients and was visualized by MRI in 2 out of 20 patients (10%). Sensitivity, specificity, positive and negative likelihood ratio of CT calculated with ASAS classification as golden standard were respectively estimated at 93.3%, 100%, 90% and 91.3%. Youden index was estimated at 0.93 and Q Yule coefficient at 1. Sensitivity, specificity, positive and negative likelihood ratio of MRI calculated with ASAS classification as golden standard were respectively estimated at 62.9%, 90%, 89.5% and 64.3%. Youden index was estimated at 0.53 and Q Yule coefficient at 0.88.

Conclusion: In our study, the evaluation of sacroiliitis by CT, in comparison with MRI, has shown to be more sensitive and more specific. However, other factors should also be taken into account while comparing CT and MRI such as the high radiation exposure of CT scanning in the one hand and the cost and the restricted accessibility of MRI in the other hand.

**COMPARISON OF CLINICAL AND DEMOGRAPHIC FEATURES OF JUVENILE SPONDYLOARTHRITIS BETWEEN ISRAELI AND US CHILDREN**

Merav Heshin-Bekenstein1, Naseem Ghantous2, Irir Tiross3, Yonatan Butbul2, Liora Harel2, Yaniv Lakovsky2, Pamela Weiss4, Nadav Rappoport3, Kimberly Dequatro2, Emily von Scheven1, Lianne S. Gensler1, Amir Hendel2, John MacKenzie1, Gil Amaramy2, 1University of California San Francisco, San Francisco, United States of America; 2Tel Aviv University, Tel Aviv, Israel, 3Rambam Medical Center, Haifa, Israel, 4Children’s Hospital of Philadelphia, Pennsylvania, United States of America

**Background:** Clinical observations among Israeli pediatric rheumatologists reveal that some of the clinical and demographic features of Israeli children diagnosed with Juvenile Spondyloarthritis (JSpA) are different as compared to the typical characteristics described in US studies.

**Objectives:** In this study, we compared clinical, laboratory and radiographic features to determine whether differences occur between the two populations of JSpA.

**Methods:** We performed a retrospective, cross-sectional, multicenter comparison of JSpA patients from 3 large Israeli pediatric rheumatology centers and a large US pediatric rheumatology center. Patients with a diagnosis of Juvenile Ankylosing Spondylitis (JAS) and/or Enthesitis-related Arthritis (ERA) were included. The demographic, clinical and imaging features of the subjects upon presentation were compared, including MRI of the sacroiliac joints. Inter Center Comparison (ICC) between the Israeli and US musculoskeletal radiologists was conducted.

**Results:** Overall 87 patients met the inclusion criteria (39 Israeli, 48 US). As compared to the US population, the Israeli population was less likely to be male (56% vs. 75%, p<0.11), and more likely to be older at time of diagnosis (14.3 vs. 11.9 years, p<0.001). Upon presentation, axial symptoms (inflammatory back pain) and physical examination findings consistent with sacroiliitis (SU tenderness, modified Schober test), were significantly more prevalent among Israeli patients (59% vs. 35.4%, 48.7% vs. 16.7%, and 41.2% vs. 21.5%, respectively, all p<0.05), whereas peripheral arthritis and enthesitis were significantly more prevalent among the US patients (43.6% vs. 91.7% and 7.7% vs. 39.6% in Israeli patients vs. US patients, p<0.05). For HLA-B27, 32% of the Israeli patients vs. 66.7% of the US patients were positive (p<0.007). In addition, of those who had imaging (N=30 and N=37 for Israeli and US cohorts) 96.7% of the Israeli patients versus 29.7% of the US patients demonstrated positive MRI findings that were consistent with sacroiliitis (p=0.005, overall N=67). An excellent level of agreement was observed between the Israeli and US musculoskeletal radiologists (kappa=0.9).

**Conclusion:** We found important distinctions between two populations with JSpA. Israeli children were more likely to present with axial disease, less likely to demonstrate HLA B27 carrier positivity, and more likely to demonstrate sacroiliitis on MRI than US children, who more commonly presented with peripheral arthritis and enthesitis, HLA-B27 positivity and negative MRI findings. These unique findings of the Israeli JSpA population, also as compared to descriptions of JSpA patients in the medical literature, point to environmental and/or cultural factors that merit additional studies in order to unravel the differences in disease presentation between the two countries.

**CHILEAN AXIAL SPONDYLOARTHRITIS PATIENTSREPORT HIGH DISEASE BURDEN AND IMPAIRED WORK ACTIVITY – AN INTERNET SURVEY IN 472 PATIENTS**

Sebastian Ibáñez1, Rianne van Bertum2, Omar Valenzuela3, Irene van der Horst-Bruinisma4, 1Universidad del Desarrollo – Clínica Alemana Medicine Faculty, Rheumatology, Santiago, Chile, 2Amsterdam Rheumatology and Immunology Center, Amsterdam UMC, VUMc, Amsterdam, Netherlands

**Background:** Axial spondyloarthritis (axSpA) can be associated with significant burden and impaired work activity. In Chile, several barriers impede adequate treatment, such as insufficient access to specialists and biological treatment. Furthermore, there is an important lack of insight into the local situation. This hampers the development of adequate national treatment standards and financial support.

**Objectives:** 1. To evaluate the disease burden, quality of life and work participation in Chilean axSpA patients. 2. To assess gender differences in disease burden and 3) compare patients with and without biologics.

**Methods:** A cross sectional online survey among Chilean SpA patients, recruiting via the internet website and associated social media of the Chilean SpA Patient Foundation (“Espondilitis Chile”). The survey was written in Spanish and requested information, mostly via multiple choice options, on gender, age, disease characteristics (diagnosis, disease duration, treatment), disease burden (BASDAI and BASFI), quality of life (ASAS Health Index) and work participation (WPAI). Only axSpA patients were included for further analyses. The association between BASDAI, quality of life or work participation (presenteeism, absenteeism) and subgroups (gender, biologics) was assessed through univariable regression and subsequently multivariable regression analyses, correcting for age, disease duration and concomitant treatment (NSAIDs, DMARDs, opiates).

**Results:** Between July and October 2018, 625 patients completed the website survey, of whom 472 reported a diagnosis with axSpA (91% radiographic axSpA, 37% male, mean age 42 years, 83% BASDAI>4, table 1). Twenty percent used a biological and patients with biologics were more likely to have a paid job (p<0.01) and had significantly lower BASDAI, BASFI, ASAS HI and risk of absenteeism. In multivariable analyses, biologics remained significantly associated with a lower BASDAI.

**Conclusion:** The results of the web survey demonstrate a high level of disease burden and work impairment in Chilean axSpA patients. The use of biologics is low, although its use is independently associated with having a lower disease activity. Women used significantly less biologics despite reporting a worse disease state (BASDAI, ASAS HI) and greater work disability, suggesting inequality in access to treatment.
Enteropathic arthritis patients under biMDrm treatments had frequently radiographic sacroilitis: Hur-Bio real-life results

Gözde Kübra Yardımcı, Bayram Farişoğlu, Alper San, Levent Kılıç, Berkan Amagan, Emre Bilgin, Ertuğrul Çağrı Bölek, Ömer Karadag, Ali Akdoğan, Süleyman Bilgen, Sedat Kiraz, Ali İhsan Erenteli, Umut Kalyoncu, Hacettepe University Medical School Internal Medicine, Rheumatology, Ankara, Turkey

Background: Enteropathic spondylarthritis (eSpA) is one of the diseases in the Spondyloarthritis (SpA) spectrum and occurs in patients with inflammatory bowel disease (IBD). Sacroilitis is frequently found in patients with IBD and can be over-looked because of focusing on IBD.

Objectives: Aim of this study is to evaluate the general features of eSpA and compare with psoriatic spondylitis (PsA), and ankylosing spondylitis (AS).

Methods: Hur-Bio (Hacettepe University Rheumatology Biologic Registry) is a prospective, single-center database of biological treatments since 2005. eSpA patients were enrolled from Hur-Bio registry. Sacroilitis was defined as modified New York criteria or based on ASAS magnetic resonance imaging criteria. Age and disease duration matched 128 ankylosing spondylitis and 96 psoriatic spondylitis patients were selected as a control group from Hur-Bio database. Demographic, clinical, laboratory, therapeuetic data and imaging features were collected from this database: age, gender, age at disease onset, disease duration, type of IBD, Baseline disease activity before the first biologic therapy use was assessed with BASDAI, BASFI, VAS-patient global assessment, ESR and CRP.

Results: Hur-Bio Bio registry included 2576 SpA patients, and 90 (3.5%) patients had enteropathic arthritis (EA). Sixty four of 90 (71.1%) patients had sacroilitis according to modified NY criteria, and these patients were included in the study. Of the 64 patients with eSpA, IBD type was ulcerative colitis (UC) in 34 (53%) patients, Crohn’s disease (CD) in 30 (47%) patients. For eSpA patients, initial biological DMARDs were infliximab in 26 (40.6%), adalimumab in 23 (35.9%), etanercept in 10 (15.6%), golimumab in 4 (6.3%), and certolizumab in 1 patient (1.6%). The proportion of bDMARDs were similar with control group. Baseline disease activity were similar between eSpA and control group. However, baseline ESR levels were higher in eSpA than AS (p=0.037) and psoriatic spondylitis (p=0.001), as well. Baseline demographic and clinical features were summarized in Table 1.

Conclusion: Enteropathic spondylarthritis was present only a small part of all SpA patients. Sex, SpA family history, and uveitis were different from other SpA subgroups. Disease activities were similar with other spondylarthritis, but particularly ESR level was higher in eSpA probably due to bowel disease activity. Sacroilic and spine involvement seems to be the main reason for starting biDMARD in IBD patients, rather than peripheral arthritis.

Data were given as mean (standard deviation) or median (min-max)

HLA-B27 were assessed in 27 eSpA, 52 AS and 33 PSA patients.

THU0388

Clinically relevant deficits in performance tests in patients with axial spondyloarthritis (axSpA): More than collecting questionnaires needs to be done

Üta Klett1,2, Eerik Ahomaa1,2, Björn Böhring1,2, Xenophon Basiliakos1,2, Juergen Braun1,2,1 Rheumazentrum Ruhrgebiet, Herne, Germany; 2Ruh-University, Bochum, Germany

Background: Physical function in axial spondyloarthritis (axSpA) usually assessed by the BASFI questionnaire is an established core domain of that disease. There is evidence that self-reported physical function is not equivalent with the actual performance of patients. Physical performance can be assessed as a single task such as grip strength or single stance, or as a generic compound measure such as the short physical performance battery test (SPPB). SPPB comprises a chair rising test, a balance test and gait speed.

Objectives: To investigate which performance tests are most frequently impaired in patients with axSpA.

Methods: Consecutive axSpA patients presenting to our tertiary hospital underwent a standardized assessment including patient and disease characteristics, patient-reported outcomes (ASDAS, BASFI, BASMI, ASAS Health Index (ASAS HI), PHQ-9) and performance tests (SPPB, grip strength and single stance). Structural damage was assessed by mSASSS. Validated cut-offs were used for SPPB, chair rise test, grip strength and gait speed. Impairment of performance tests as well as discrimination between subgroups was analysed.

Results: A total of 200 patients (n=axSpA 65.5%, nr=axSpA 34.5%) were included: 69% males, 44.3±12.5 years of age, mean symptom duration

A SYSTEMATIC REVIEW OF PREGNANCY OUTCOME IN ANKYLOSING SPONDYLITIS

Gangarathna Krishna1, Anuradha Shajpal2, Pip Dival3, Manjiri Khare4, Anuragam Moorthy5. 1. University hospitals of Leicester, Rheumatology, Leicester, United Kingdom; 2. University hospitals of Leicester, Obstetrics and Gynaecology, Leicester, United Kingdom; 3. University Hospitals of Leicester, Library, Leicester, United Kingdom; 4. University hospitals of Leicester, Fetal Maternal Medicine, Leicester, United Kingdom

Background: Ankylosing spondylitis (AS) is a chronic, systemic inflammatory arthritis predominantly affecting spine and sacroiliac joints. AS affects young individuals in their third and fourth decades of life. Pregnancy poses challenges in AS patients. Unlike other chronic autoimmune diseases, not much is known regarding pregnancy outcome in AS and a systematic review would help treating clinicians and health professionals.

Objectives: Our main objective was to evaluate the pregnancy outcomes in ankylosing spondylitis. We reviewed the management and care related to preconception counselling, antenatal, intrapartum and postpartum period, particularly disease activity, medications and birth outcomes.

Methods: A systematic search of PUBMED and EMBASE was performed. Relevant peer-reviewed papers were identified using inclusion criteria which included articles on pregnancy outcomes in AS patients above 16 years. We included only English articles covering systematic reviews, randomized control trials, case reports, observational studies published in medical literature between 1970 and March 2017. We excluded papers discussing general management of AS and articles on other autoimmune diseases and pregnancy. Each author screened the titles and abstracts individually based on our criteria. A standardized data collection form was used for assessment of study quality and evidence synthesis. Systematic review was registered in PROSPERO and we followed the PRISMA flow chart.

Results: Our search yielded 544 papers. After initial screening of the titles and abstracts 443 papers were identified of which 42 potentially relevant papers were selected for full text review. 18 papers were finally included. Our initial results are based on individual papers. Zhou et al. studied 12 AS patients retrospectively with no adverse outcomes, all had term pregnancies with 5 normal vaginal delivery, 7 caesarean delivery was based on obstetric reasons. Nai Lee Lui et al. observed a reduction in pain in the first trimester, first month postpartum, in the second and third trimester and in up to 6 months postpartum. Monika Ostensen et al. observed unaltered or aggravated disease symptoms during pregnancy in 80%. Delivery was mainly uncomplicated and was normal in most cases. A postpartum flare during the first 3 months occurred in 90% of AS pregnancies. Hakan Timur et al. did not notice any adverse pregnancy outcomes. Worsening of symptoms was seen in 60-90% of patients up to 6 months after delivery. Jakobsson et al. noticed women with AS had a higher prevalence for several adverse birth outcomes with an influence by both disease severity and comorbidities. Case reports highlighted anaesthetic difficulties during delivery. There was paucity of articles studying the treatment aspects and complications only in AS patients.

Conclusion: To the best of our knowledge, this systematic review is the first one reviewing the outcome of pregnancy in ankylosing spondylitis. As the studies were heterogeneous, the pregnancy outcome was not consistent. There is paucity of data about pregnancy management for women with AS and further research is needed in this area to guide evidence based management of these pregnancies.

REFERENCE:
THU0390  GENETIC STUDY OF MEDICAL IMAGE PROGRESSION IN A CHINESE AS POPULATION FOR SIX MONTHS’ FOLLOW-UP

LIU JING1, Qi Zhu2, Weilin Pu1, Dongyi He2, Heijan Zou1, Xiaodong Zhou1, John D Reveille1, Jiucun Wang1,2, Fudan University, State Key Laboratory of Genetic Engineering, Collaborative Innovation Center for Genetics and Development, School of Life Sciences, Shanghai, China; 2Guanghua Integrative Medicine Hospital, Shanghai, China; 3Fudan University, Huashan Hospital, Shanghai, China; 4The University of Texas Health Science Center at Houston, Houston, United States of America

Background: Genetic factors accounts for about 90% pathogenesis of ankylosing spondylitis (AS), and may predict the disease progression. MRI is an important tool for evaluating disease progression and assessing treatment response in patients with AS.

Objectives: This study aims to define correlation between AS-associated genetic variations and MRI scores of AS patients in Chinese population.

Methods: A total of 62 AS patients treated with TNF blockers from Guanghua medical center (Shanghai, China) were recruited in this study. All of AS patients were evaluated for disease progression with MRI (SPARCC) [1-3]. Measures of inflammation (bone marrow edema (BME) of sacroiliac joints (SIJ) and spine) and structural damage (fat metaplasia, erosion, backfill and ankylosis of SIJ) were recorded at baseline and six months’ follow-up. The changes of MRI scores were defined as the score of six months’ follow-up minus that of baseline. All of patients were examined with whole exon sequencing for genetic polymorphisms. Logistic regression analysis was performed and genetic variants with p < 1E-4 were considered as significant.

Results: The results showed that seven genetic variants significantly enriched in extracellular matrix pathways were associated with the changes of BME score of SIJ and spine. Four genetic variants regulating bone homeostasis, such as ABCA4, were significantly associated with the changes of fat metaplasia. Twelve variants were associated with the changes of erosion, one of which regulated expression of FBFI according to GTex database (p-value = -5.0/1.1E-5). Mouse with Fat4 knockout showed abnormality in insulin metabolism and skeleton (MGI database). Genetic variants of the adipose related gene (CTBP2) and bone related genes (RGMA, BMP8A) were associated with the changes of backfill. In addition, genetic variants of FAT4 was associated with the changes of ankylosis (p-value = 6.8/1.4E-8). Mutation of FAT4 caused two bone related diseases and mouse with Fat4 knockout showed severe abnormality of skeleton (MGI database).

Conclusion: Overall, the results suggested that the polymorphisms of genes involved in extracellular matrix were associated with BME, and genetic variants involved in adipose and bone metabolism were associated with structural damage in AS patients.

THU0391  COMPARISON OF CHARACTERISTICS AND BURDEN OF DISEASE IN PATIENTS WITH RADIOGRAPHIC AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

Clementina López-Medina1,2, Sofia Ramiro3,4, Désirée van der Heijde3, Maxime Douadiou1, Anna Molt1, 1Cochin Hospital, Rheumatology, Paris, France; 2Universidad de Córdoba, Córdoba, Spain; 3LUMC, Leiden, Netherlands; 4Zuyderland MC, Heerlen, Netherlands

Background: In 2009, the ASAS criteria allowed to classify patients with radiographic (r-axSpA) and non-radiographic (nr-axSpA) axial Spondyloarthritis (axSpA), and enhanced the concept of axSpA as a whole disease with different phenotypic presentations. However, some have claimed that the burden of r-axSpA and nr-axSpA is so different that they should be considered as different forms of the same disease.

Objectives: To compare the characteristics, burden of disease and treatment effect in patients with r-axSpA and nr-axSpA.

Methods: A systematic literature review until October 2018 was performed using PubMed, EMBASE and Cochrane databases. The PICO approach was used to formulate the research questions: P (r-axSpA patients), I (no intervention/drugs (only for the treatment effect evaluation), C (nr-axSpA patients), O (clinical presentation, disease activity, structural damage, function, quality of life, mobility, treatment modalities and treatment effect). Only observational studies and Randomized Controlled Trials (RCT) published after 2009 (year of publication of the ASAS criteria) were included. For the evaluation of the treatment effect, only RCT were considered. Risk of bias was evaluated on each manuscript with the Cochrane Risk of Bias tool for RCT and Hayden tool for observational studies. Pooled analysis was performed (Standardized Means Differences (SMD) and Relative Risk (RR) for continuous and binary variables, respectively) with a random effects model after evaluation of the heterogeneity of the studies.

Results: A total of 60 studies out of 787 references were included. Clinical presentation, disease activity, burden of disease (function, quality of life and mobility), treatment and treatment effect were evaluated in 54 (90.0%), 40 (67.7%), 37 (61.7%), 18 (30.0%) and in 9 (15.0%) manuscripts, respectively. Only 3 cross-sectional studies were classified as high risk of bias. Pooled analysis comparing continuous and binary variables are represented in tables 1 and 2. Only two RCTs (Etanercept vs. Sulfasalazine and Cetolizumab vs. Placebo) directly compared the treatment effect between both groups, and none of them showed differences regarding ASAS partial remission, ASDAS major improvement and ASAS 40.

Conclusion: Published data suggest that r-axSpA and nr-axSpA patients share a similar clinical presentation except for peripheral manifestations (which are more prevalent among nr-axSpA), males and smokers (which are more frequent among r-axSpA). Disease activity and burden of disease are identical in both groups, except mobility, which is poorer among r-axSpA. The treatment effect was similar in both groups.

Results: A total of 246 patients were recruited, 47.6% were diagnosed with axSpA, and these included 85.8% of B27 positive patients (Table 1). Diagnosis of axSpA was established in 45.7%, 61.6%, and 40.2% of patients, while ASAS classification criteria were met by 26.1%, 71.2%, and 27.6% of patients with psoriasis, AAU, and IBD, respectively. Features of inflammatory back pain, male gender, and B27 positivity, but not physical measures discriminated axSpA from other causes of back pain (Table 2).

Conclusion: Patients with extra-articular manifestations and undiagnosed back pain have a high prevalence of axSpA and refer to a rheumatologist should constitute standard of care, especially if B27 positive.

Disclosure of Interests: Walter P Maksymowycz Grant/research support from: AbbVie, Pfizer, Janssen, Novartis, Consultant for: AbbVie, Eli Lilly, Boehringer, Galapagos, Janssen, Novartis, Pfizer and UCB Pharma; Chief Medical Officer for Canadian Research and Education Arthritis, Raj Carmona Grant/research support from: Amgen, Abbvie, BMS, Eli Lilly, Merck, Novartis, Janssen, Takeda, UCB, James Yeung: None declared, Jon Chan Grant/research support from: Janssen, UCB, Novartis, Pfizer, Celgene, Consultant for: Amgen, Celgene, UCB, Novartis, Janssen, Sanofi, Diagne Mosher: None declared, Ariel Masetto Consultant for: Abbvie, Celgene, UCB, Novartis, Janssen, Sanofi, Dianne Mosher: None declared, Ariel Masetto Consultant for: Abbvie, Celgene, UCB, Novartis, Janssen, IBD, Psoriasis, Acute Anterior Uveitis, and Inflammatory Bowel Disease Presenting with Undiagnosed Back Pain

Walter P Maksymowycz, Raj Carmona, James Yeung, Jon Chan, Lynam Martin, Sibel Aydin, Dianne Mosher, Ariel Masetto, Stephanie Keeling, Olga Ziouzina, Sherry Rohekar, Joel Paschke, Amanda Carapellucci, Robert G Lambert
1University of Alberta, Edmonton, Canada; 2CaRE Arthritis, Edmonton, Canada; 3McMaster University, Hamilton, Canada; 4James Yeung Rheumatology, Vancouver, Canada; 5Artus Health Center, Vancouver, Canada; 6University of Calgary, Calgary, Canada; 7University of Ottawa, Ottawa, Canada; 8University of Sherbrooke, Sherbrooke, Canada; 9Lawson Health Research Institute, London, Canada

Background: There are limited prospective data as to the frequency of axial spondyloarthritis (axSpA) in unselected patients referred to rheumatologists with undiagnosed back pain. It is also unclear which clinical features discriminate between axSpA and non-specific causes of back pain that might inform the development of a screening strategy.

Objectives: To determine the prevalence of axSpA in unselected patients referred with undiagnosed back pain presenting with AAU, psoriasis, or colitis and determine which clinical characteristics define patients with axSpA.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at facilitating early detection of axial SpA. First and last patients were recruited on February 2013 and March 2018, respectively. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis had routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation ordered per rheumatologist decision. Differences in clinical characteristics between those who were diagnosed as axSpA or non-specific back pain were analyzed using chi-squared and t-tests.

Conclusion: Patients with extra-articular manifestations and undiagnosed back pain have a high prevalence of axSpA and refer to a rheumatologist should constitute standard of care, especially if B27 positive.

PERFORMANCE OF THE ASAS CLASSIFICATION CRITERIA PRESENTING WITH UNDIAGNOSED BACK PAIN: DATA FROM THE SCREENING IN AXIAL SPONDYLOARTHRITIS IN PSORIASIS, IRITIS, AND COLITIS (SASPIC) COHORT

Walter P. Maksymowych1,2, Raj Carmona3,4, James Yeung4, Jon Chan5, Stephanie Keeling1, Robert G Lambert1, University of Alberta, Edmonton, Canada; 3California Pacific Medical Center, San Francisco, California; 4McMaster University, Hamilton, Canada; 5University of Calgary, Calgary, Canada; 6University of Ottawa, Ottawa, Canada; 7University of Sherbrooke, Sherbrooke, Canada; 8Lawson Health Research Institute, London, Canada

Background: Classification criteria for axial spondyloarthritis (axSpA) that capture the spectrum of disease present challenges due to the frequency of back pain, the relative infrequency of axSpA, and limited physical and laboratory findings in early disease. Several cohorts have reported the performance of the ASAS classification criteria in settings where patients have been selected for certain features such as the presence of inflammatory back pain and/or short symptom duration.

Objectives: We aimed to test the performance of the ASAS classification criteria in unselected patients referred with undiagnosed back pain who have presented with acute anterior uveitis (AAU), psoriasis, or colitis to their respective specialists and whether performance varied according to demographic factors and symptom severity.

Methods: We multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at early detection of axial SpA. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation is ordered per rheumatologist decision. The rheumatologist determines the presence or absence of axial SpA and the degree of confidence in the diagnosis (-10 (definitely not SpA) to +10 (definite SpA)) at 3 consecutive stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. Assessment of imaging was conducted by local and central readers. We calculated the sensitivity and specificity of the ASAS criteria and the component imaging and clinical arms using the stage 3 diagnostic assessment by the local rheumatologist as gold standard.

Results: A total of 246 patients were recruited, 47.6% being diagnosed with axSpA (61.5% male, age 33.7 years, symptom duration 7.6 years, B27 positive 52.1%), after stage 3 evaluation. Sensitivity/specificity of the ASAS criteria, imaging arm, clinical arm were 74.4/79.8%, 55.6/93.8%, 50.4/82.2%, respectively (Table). For patients diagnosed with a high degree of confidence sensitivity/specificity was 87.5/82.7%, 68.8/94.5%, 56.3/84.5%, respectively. Specificity, especially for the clinical arm, was notably higher in patients with a higher degree of back pain (≥5/10), and in those with longer symptom duration (>5 years).

Conclusion: The performance of the ASAS criteria in the SASPIC cohort is comparable to the findings in the original ASAS classification study. Performance may vary according to symptom duration and severity of symptoms which likely impacts diagnostic ascertainment.

THE PREVALENCE OF EXTRA-ARTICULAR MANIFESTATIONS IN AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS IS ASSOCIATED TO DISEASE DURATION: RESULTS FROM THE LEEDS SPECIALIST SPONDYLOARTHRITIS SERVICE

Xavier Michelena-Vegas1,2, Saaym Dubash3, Ann Morgan4, Helena Marzo-Oteng4, 1NHI Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, LIRRM and LACIM, University of Leeds, Leeds, United Kingdom; 2Bellvitge University Hospital (IDIBELL), Barcelona, Spain

Background: Psoriasis, uveitis and inflammatory bowel disease (IBD) are extra-articular manifestations (EAMs) that can occur in both axial Spondyloarthritis (axSpA) and psoriatic arthritis (PsA). Their prevalence has been outlined independently in a recent meta-analysis1 for axSpA and in several series in PsA with variable results. Although the diagnostic delay of inflammatory arthritis has been reduced in the last years, it remains a significant unmet need, particularly in axSpA. There are limited data on the relationship between diagnostic delay and the appearance of EAMs.

Objectives: To explore the prevalence of EAMs in a cohort of axSpA and PsA patients, and its relationship to disease duration and possible diagnostic delay in both groups.

Methods: Cross-sectional, single centre, observational cohort study of consecutive patients attending a large tertiary specialist clinic. All subjects provided written consent (2005-2018). Only patients fulfilling the modified New York (mNY) criteria for ankylosing spondylitis and CASPAR criteria for PsA were considered for this analysis. Demographic and clinical data were retrieved during enrolment and cross-referenced with the clinical notes to explore the relationship between presence of EAMs and diagnostic delay in both groups.

Results: Data from 988 patients were available for analysis (n= 418 axSpA, n=570 PsA). Demographic and clinical characteristics are summarised in Table 1.

In the axSpA group, 187 cases (44.7%) presented with EAMs (including psoriasis) and 67 (16.02%) of these had more than 1 EAM. In the PsA group, 32 cases (5.6%) presented with EAM (excluding psoriasis) and only 3 cases (0.5%) had more than one EAM. In the PsA group, a median delay of 4 years (IQR 2-9) was observed between psoriasis onset and PsA. In 42 cases the psoriasis appeared after the PsA onset. The predominant PsA phenotype was polyarticular (n=298; 52.3%) of which n=118, 20.7% had erosive disease. 101 (17.7%) had a predominantly axial phenotype.

Conclusion: Disease duration and delay to diagnosis were longer in the axSpA group (p<0.0001). Further univariate analysis showed an association between disease duration and the presence of EAMs when analysing the whole cohort (p<0.001) and the axSpA group (p<0.001), but not in the PsA group (p=0.832). The diagnostic delay was associated to the presence of EAMs in the whole cohort (p<0.001), but not in the individual disease groups. In the multivariate analysis only disease duration was related to presence of EAMs in the whole cohort (OR 1.064 95%IC 1.044-1.086) and axSpA group (OR 1.043 95%IC 1.016-1.070).

Conclusion: The prevalence of EAMs (uveitis and IBD) in this cohort appears higher in axSpA than PsA and is related to disease duration. Diagnostic delay occurs in both groups being more significant in axSpA, and should be highlighted as a priority research area in order to improve the outcome of people affected by SpA.

REFERENCES:

and little has been explored in the alterations at the level of the jejunum. The tests for its detection are expensive, unavailable and invasive. The breath test is used to detect small intestine bacterial overgrowth (SIBO), being a non-invasive, simple and inexpensive test.

Objectives: To determine the frequency of SIBO and the relation to the clinical activity of SpA.

Methods: An analytical cross-sectional study was conducted in the period March 2018–October 2018. Patients older than 18 years, who signed informed consent, who met modified New York criteria and Caspar criteria were included. Patients were excluded who were diagnosed with active lung infection, active oral infections, interstitial lung disease, chronic obstructive pulmonary disease, acute diarrheal disease, short bowel syndrome, abdominal surgery in less than 6 months, and oral or IV antibiotics used one month before the test.

Patients who fulfilled the inclusion criteria were collected demographic and clinical data, gastrointestinal manifestations were interrogated and ASDAS pcr, BASMI, BASDAI, BASFI activity scales were measured. The breath test was performed by a gastroenterologist. The concentrations of hydrogen produced by bacteria were measured by GASTROLYZER® according to the recommendations of the consensus of the American Gastroenterology Association. It was considered a positive test to change the concentrations of more than 20 ppm with respect to the basal test. To compare the frequency of SIBO, a historical cohort of patients without rheumatic diseases matched by age was taken. The data were presented in means and percentages. Student’s T and Mann-Whitney U were performed for numerical variables. Groups with chi square were compared.

Results: We studied 20 patients with ankylosing spondylitis (M/F 9/11) and 11 psoriatic arthritis (M/F 1/12), mean age 54.45 ±13.52. 33 healthy controls matched by age. Positive test was found in 11 (33%) patients (8/3 EA/APS) vs 1 (3%) in controls. When comparing groups with positive test versus negative test groups, patients with SIBO consumed less SSZ (72.7 vs 90.9, p 0.008), had higher frequency of irritable bowel (54 vs 9, p 0.004), antecedent of cholecystectomy (27.3 vs 9.1 p 0.01), steatorrhea (18.2 vs 0, p 0.001), and higher activity: ASDAS> 2.1 (100% vs 86.4%, p 0.199), BASMI> 4 (36.4% vs 31.8% p 0.79), BASFI> 4 (72.7% vs 50%, p 0.21), enthesitis> 1 (45.5% vs 13.6%, p 0.61).

Conclusion: We found a higher frequency of SIBO in patients with SpA compared to healthy controls, but not related to disease activity. This is the first study to investigate SIBO by breath test in patients with SpA.

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease characterized by a progressive mobility reduction of the rachis. The posture changes may cause balance problems with gait repercussions. However, we lack information during the early years of the disease regarding gait pattern and the possible variables that may influence gait parameters.

Objectives: In order to gain insight into the gait patterns in patients at early stages of axSpA and the potential influence of some patient-specific features, the aim of this study was therefore to evaluate: (i) the 3D gait signature in patients at early years of axSpA; and (ii) the relation between gait parameters, and body composition and muscle performance variables.

Methods: A cross-sectional study was conducted on 46 participants (18-50 years old), 23 patients with axSpA (according to ASAS criteria, with less than 10 years since symptoms onset) and 23 healthy controls, matched by gender and age, with a mean age of 37±7.5 years, predominantly males (60%). The patients with axSpA had 5±3.2 years of disease duration, with BASDAI and BASFI of 3±2.2 and 2±2.9, respectively. Subjects’ movement was reconstructed using a 3D full-body kinematic model (Kinetikos, Coimbra, Portugal) fed by 15 inertial sensors placed in the head, arms, trunk, pelvis, thighs, shanks and feet. The primary outcomes comprised the general gait parameters such as gait pattern (step length, cadence, stance duration, body vertical regularity (sample entropy), step length, range of movement and peak velocity of the different joints. Body composition was assessed by performing octopolar multifrequency bioelectrical impedance analysis (BIA; InBody 770). Muscle performance was assessed with a 60 second sit-to-stand test (STS60), while physical activity was controlled by the international physical activity questionnaire (IPAQ). Variables (except age, disease duration, BASDAI, BASFI) are presented as median. Non-parametric tests were used to compare groups. Correlations between gait, body composition and skeletal muscle function parameters, were performed.

Results: Gait analysis showed statistically significant differences between axSpA and healthy control groups on gait deviation index (median 83 vs 87%, p=0.022, with higher score values representing similar performance to normal movement), speed (median 0.79 vs 0.85m/s, p=0.015), stance duration at the left side (median 68 vs 67s, p=0.027), left step length (median 0.47 vs 0.49m, p=0.008), and vertical regularity (median 0.39 vs 0.33, p=0.029 with higher values representing a less regular and predictable movement pattern). At the sagittal plane, patients showed higher values of left arm maximum flexion (median 14° vs 10°, p=0.011), lower lumbar extension peak velocity (median 45° vs 60°s, p=0.016) and higher ankle angular peak velocity on right side (median 530° vs 299°s, p=0.020). However, no statistically significant differences between groups were found for physical activity parameters. Reduction in statistically significant correlation was found between the gait parameters and weight, body fat, torso fat, visceral fat, body mass index, total body water, extracellular water, fat free mass, lean mass, bone mineral content and STS60.

Conclusion: These results provide evidence that although young axSpA patients at early years of the disease display a particular gait pattern...
and this behavior does not seem to be influenced by the body composition and muscle performance. The main determinant for this gait pattern remains an open question.

THU0399 DEVELOPMENT OF AN OPTIMIZED ONLINE SELF-REFERRAL TOOL FOR EARLY RECOGNITION OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA) – DATA FROM THE ‘OPTIREF’-STUDY

Fabian Proft1, Laura Spiller1, Mikhail Protopenov1, Valeria Rios Rodriguez1, Burkhard Muche1, Judith Rademacher1, Susanne Lüders1, Anne Katrin Weber1, Imke Redeker1,2, Denis Poddubnyy1,2.

Background: One of the major reasons for a long diagnostic delay in axial spondyloarthritis (axSpA) is the late referral of patients by primary care physicians dealing with patients with chronic back pain. We developed and implemented an online self-referral tool (www.bechterew-check.de), which gave access to a rheumatological consultation if patients declared suffering from chronic back pain (≥ 3 months) with a symptom onset ≤ 45 years of age, and at least one feature indicative of SpA. In the prospective “Identification of the Optimal Referral Strategy for Early Diagnosis of Axial Spondyloarthritis (OptiRef) Study” we could diagnose axSpA in 19% of the self-referred patients [1].

Objectives: To optimize the online-self-referral tool for recognition of patients with high suspicion of axSpA in order to increase the specificity by keeping the high level of sensitivity.

Methods: 181 patients who had fulfilled the online self-referral strategy were included and underwent a standardized rheumatological examination. The final diagnosis of axial SpA/no axial SpA by the rheumatologist served as the gold standard. The performance of all possible combinations of the referral parameters (13 parameters in total including 5 features of inflammatory back pain (IBP) and 8 other SpA features) added to both stem parameters (chronic back pain, starting at age of ≤ 45 years) was tested. In addition, the following pre-specified combinations were evaluated: 1) ≥ 1 IBP parameter AND ≥ 1 other SpA parameter, 2) ≥ 1 IBP parameter OR ≥ 1 other SpA parameter. For all combinations, a sensitivity, a specificity, positive and negative predictive values (PPV and NPV), as well as a positive and negative likelihood ratio (LR+ and LR-) were calculated. We targeted the maximal specificity by acceptable sensitivity (defined as ≥ 90% of the original strategy).

Results: For 163 of the included patients, full data of the online questionnaire as well as of rheumatology examination including the final diagnosis of Axial Spondyloarthritis were available. 31 (19%) of them were diagnosed with axial SpA.

For 163 of the included patients, full data of the online questionnaire as well as of rheumatology examination including the final diagnosis of Axial Spondyloarthritis were available. 31 (19%) of them were diagnosed with axial SpA.

Conclusion: The data-driven optimized online self-referral tool (figure 1) requires the following parameters to be positive: chronic back pain (≥ 3 months) plus back pain onset before 45 years of age plus ≥ 2 IBP parameters plus ≥ 1 other SpA feature. The performance of this tool should be confirmed in a prospective study.

THU0400 COMPLICATIONS OF ANTERIOR UVEITIS ASSOCIATED WITH HLA-B27 ANTIGEN IN PATIENTS WITH AND WITHOUT SPONDYLOARTHRITIS

Irina Razumova1, Alla Godzenko2, Irina Guseva2, Research Institute of Eye Disease, Moscow, Russian Federation; 2Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: HLA-B27-associated anterior uveitis (AU) can be an isolated disease or part of a systemic inflammatory process, such as spondyloarthritis. Differences in the outcome of uveitis with and without spondyloarthritis still under research.

Disclosure of Interests: Fabian Proft Grant/research support from: Novartis, Consultant for: yes but less than 10.000, Paid instructor for: yes but less than 10.000, Speakers bureau: yes but less than 10.000, Laura Spiller: None declared, Mikhail Protopenov: None declared, Valeria Rios Rodriguez: None declared, Burkhard Muche Speakers bureau: Yes less than 10.000, Judith Rademacher: None declared, Susanne Lüders: None declared, Anne Katrin Weber: None declared, Denis Poddubnyy Grant/research support from: AbbVie, Merck Sharp & Dohme, Novartis, Consultant for: AbbVie, Bristol-Myers Squibb, Janssen, Merck Sharp & Dohme, Novartis, Pfizer, UCB Pharma, Speakers bureau: AbbVie, Bristol-Myers Squibb, Janssen, Merck Sharp & Dohme, Novartis, Pfizer, Roche, UCB Pharma.

This abstract is a summary of a recent publication in which the following results were found:

- **EULAR 2018 abstract abstract THU0230**
  - **Objective:** To optimize the online-self-referral tool for recognition of patients with high suspicion of axSpA in order to increase the specificity by keeping the high level of sensitivity.
  - **Methods:** 181 patients who had fulfilled the online self-referral strategy were included and underwent a standardized rheumatological examination. The final diagnosis of axial SpA/no axial SpA by the rheumatologist served as the gold standard. The performance of all possible combinations of the referral parameters (13 parameters in total including 5 features of inflammatory back pain (IBP) and 8 other SpA features) added to both stem parameters (chronic back pain, starting at age of ≤ 45 years) was tested. In addition, the following pre-specified combinations were evaluated: 1) ≥ 1 IBP parameter AND ≥ 1 other SpA parameter, 2) ≥ 1 IBP parameter OR ≥ 1 other SpA parameter. For all combinations, a sensitivity, a specificity, positive and negative predictive values (PPV and NPV), as well as a positive and negative likelihood ratio (LR+ and LR-) were calculated. We targeted the maximal specificity by acceptable sensitivity (defined as ≥ 90% of the original strategy).
  - **Results:** For 163 of the included patients, full data of the online questionnaire as well as of rheumatology examination including the final diagnosis was available. 31 (19%) of them were diagnosed with axial SpA.
  - **Conclusion:** The data-driven optimized online self-referral tool (figure 1) requires the following parameters to be positive: chronic back pain (≥ 3 months) plus back pain onset before 45 years of age plus ≥ 2 IBP parameters plus ≥ 1 other SpA feature. The performance of this tool should be confirmed in a prospective study.

**Table 1: Performance of self-referral strategies based on combinations of SpA parameters in addition to the stem parameters (chronic back pain starting at age of 45 years).**

OBJECTIVES: To compare the incidence of complications in HLA-B27- associated anterior uveitis patients with and without spondyloarthritides (SpA).

METHODS: 189 patients with HLA-B27- associated anterior uveitis were observed in Research Institute of Eye Disease for 10 years. The pts were underwent standard ophthalmological examination, and, if necessary, computer perimeter, ultrasound examination (B-scan), optical coherence tomography of the retina and optic nerve (OCT), fluorescence fundus angiography (FAGD) and electrophysiological studies (EFEI). All pts were examined for clinical and imaging signs of SpA: inflammatory back pain, arthritis, enthesitis, sacroiliitis.

Different variants of SpA were diagnosed in 108 pts: ankylosing spondylitis – in 48 (44,4%), reactive arthritis – in 9 (8,3%), psoriatic arthritis - in 9 (8,3%), inflammatory bowel disease – in 2(1,9%), juvenile SpA – in 4 (3,7%), undifferentiated SpA - in 36 (33,3%). In 81 pts SpA was not confirmed: 11 had a viral infection (13,5%), 7- bacterial infection (8,6%), 1 (1,2%)-multiple sclerosis, 3 (3,7%) -psoriasis, 59 (72.8%) -idiopathic AU.

RESULTS: Complications were identified in 74 of 110 (67.3%) eyes in SpA-group and in 39 of 81(48,1%) – 110 eyes in group without SpA. Cataract was identified in 89 (60,5%) of 147 eyes in SpA-group and in 35(1,8%) of 110 eyes in group without SpA, p=0,0001;glaucoma – in 24(16,3%) and in 8 (7,3%) of 110 eyes in group with SpA respectively, p=0,021;vitreous detachment - in 59(40,1%) and in 26 (23,6%), p=0,005. Maculopathy, optic atrophy, corneal degeneration, panuveitis were observed more often in SpA-group, but the differences were not significant. Combinations of several complications were detected in 59 (40,1%) in SpA-group and in 31 (28,2%) in group without SpA, p=0,03.

Conclusion: Women with SpA have higher RAPID3 scores than men, in contrast to a modified ASDAS-CRP based on scores from the MDHAQ which did not show gender differences. These data suggest that RAPID3 scores in women may be attributable in part to a gender bias rather than clinical severity and a careful interpretation in the context of gender is necessary.

AXIAL SPONDYLOARTHRITIS INDUCES MUSCLE DISFUNCTION, THE ROLE OF BODY COMPOSITION PARAMETERS: MYOSPA STUDY

Maria Luisa Sequeira1, Inês Da Costa Santos2, Rita Amador1, Lucia Domingues1, Carolina Crespo1, Santiago Rodrigues-Manica1, José Ribeiro1, Andreia Sepeirano1, Diana Teixeira1, Agena Neto1, Rita Pinheiro Torres1, Conceição Calhau1, Jaime Branco1, Fernando Pimentel Dos Santos1, NOVA University of Lisbon, CEDOC NOVA Medical School | FCM, Lisboa, Portugal. 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands. 2CHLO, Hospital de Egas Moniz, Rheumatology Department, Lisboa, Portugal

Background: Sarcopenia as well as abnormalities in body composition are common features in several chronic diseases and have been shown to lead to increased morbidity and mortality. However, their assessment in young patients with axial spondyloarthritis (axSpA) has not been performed thus far.

Objectives: To assess the skeletal muscle mass, strength and performance as well as body composition in patients with axSpA compared to healthy controls.

Methods: Patients between 18 and 50 years of age with the diagnosis of axSpA and short disease duration (under 10 years) and classified as male (34%) and type 1 back (2%). Spinal deformities were more frequent in women (p=0.004) and associated with a longer duration of the disease (p<0.0001) and a longer duration before initiation of treatment (p<0.0001) (Table 1).

Conclusion: Our study showed that the EOS system was a useful technique in assessing pelvic and spinal stature in patients with SA.

DICKKOPF-1 SERUM LEVELS AND THEIR CORRELATION WITH ACTIVE AND CHRONIC MRI-CHANGES OF SACROILIAC JOINTS AND CLINICAL INDICES IN PATIENTS WITH SPONDYLOARTHRITIS

Julia Shynkanych1, Olegr Marenko2, Dmitry Fedkov1, Kateryna Larenko1, 1Bogomolets National Medical University, The Department of Internal Medicine#3, Kyiv, Ukraine; 2Oleksandrivska City Clinical Hospital, The Laboratory Department, Kyiv, Ukraine

Background: The lack of valid biochemical markers for spondyloarthritis (SpA) patients requires searching the additional options to increase sensitivity of clinical and radiological methods in validation of changes in sacroiliac joints (SI). The molecular basis for the link between inflammation and new bone formation in SpA is still not clear. It has recently been shown that low serum levels of the Dickkopf-1 (Dkk-1), the natural inhibitor of Wnt protein, is associated with the formation of new syndesmophytes in patients with SpA [1]. Dkk-1 may be a main factor in blocking new bone formation [2], and might play a role of potential biomarker in SpA patients.

**Background:** Joint pain is frequently reported by IBD patients and can be associated to extra-intestinal manifestations of diseases or adverse events associated to anti-TNF or vedolizumab therapy and also associated with other non-SpA-disease related factors including mechanical/degenerative problems. The appropriate rheumatological referral pathway is crucial to drive therapeutic strategy in case of concomitant spondyloarthritis (SpA). Fibromyalgia is a frequent cause of chronic pain that needs to be identified in order to not overestimate the prevalence of SpA in IBD patients.

**Objectives:** The aim of the study was to assess the prevalence of FM in a cohort of IBD outpatients.

**Methods:** Consecutive patients of the IBD Unit coming for a routine visit were screened by a rheumatologist in order to identify cases presenting the 2010 ACR criteria for FM or ASAS criteria for SpA. Patients affected by other rheumatic conditions such as rheumatoid arthritis and crystal arthropathies were excluded from the study. The rheumatological assessment included a 26 swollen joint count (SJC) and 6 TJC, MASEI, LEI and the fibromyalgia tender points examination. The patient completed BASDAI and BASFI on the day of clinical evaluation. Imaging exams (MSK ultrasound, MRI) and HLA-B27 determination were requested if needed for diagnostic confirmation.

**Results:** Between January to May 2018, 210 patients were enrolled in the study and 181 completed the clinical and imaging/laboratory assessment. A total of 44 patients (24.3%) in the IBD cohort met the ACR 2010 criteria for FM, 34 patients (18.8%) met the criteria for primary FM, and 10 patients (5.5%) presented FM and SpA. Of note, FM patients presented LEI; BASDAI and BASFI scores higher than SpA patients.

**Conclusion:** FM is a common comorbidity in IBD patients and can be associated to SpA. An appropriate rheumatological referral is crucial to exclude a concomitant SpA and to manage FM.

**THU0406**

**ULTRASONOGRAPHIC INVOLVEMENT OF THE ANTERIOR CHEST WALL IN SPONDYLOARTHITIS, A FIVE YEARS FOLLOW UP STUDY**

Frank Verhoeven¹,², Maxime Sonia³, Mickael Chouk¹, Clément Prati¹,², Daniel Wendling¹,², CHRU Besancon, Rheumatology, Besancon, France; Université de Bourgogne – Franche Comté, EA 4287 PEPITE, Besancon, France

**Background:** Spondyloarthritis is characterized by inflammatory back pain. Anterior chest wall pain is common and a previous study reports a prevalence à 37% of ultrasonographic lesions of this anatomical region [1].

**Objectives:** The objective of this study is to evaluate, in patient with Spondyloarthritis, the prevalence of ACW ultrasonographic lesions after a follow up of 5 years and to identify factors associated with the development of new lesions.

**Methods:** This is a monocentric and prospective study including patients with Spondyloarthritis meeting the ASAS 2009 criteria. Patients were followed during five years. ultrasound B mode and power Doppler examination of the two sternoclavicular joint and the manubrio-sternal joint were performed by the same two examiners at baseline and five years later. The presence of erosion, synovitis, ankylosis, power Doppler signal, joint effusion and bone margin narrowing were assessed. Clinical characteristics and disease activity were evaluated at 5 years.

**Results:** In the 136 patients at baseline, 58 patients were evaluated 5 years later. The mean age was 48.2 +/- 11.9 years old, with 86% male and 89% HLA B27. 60.3% of these patients had a history of pain of the ACW. The prevalence of ultrasonographic involvement of the ACW was 34% at baseline and 67.2% five years later. The most frequent lesions were ankylosis of the manubriotelial joint (38%) and erosions of the sternoclavicular joint (29%). At 5 years, patients with lesions of the ACW are significantly older (51.4 +/- 11.5 VS 41.5 +/- 9.98, p<0.01). There were no differences concerning the presence of HLA B27 and the presence of a radiographic sacroiliitis or syndesmophytes. Among these 58 patients, 31 (53%) developed a new lesion of the ACW. There is a statistically significant association between a higher ASAS CRP and new lesions of the ACW (1.56 +/- 1.07 VS 3.0 +/- 2.17 p < 0.001) and with the level of CRP (5.34 +/- 7.85 VS 16.2 +/- 35, p = 0.035). Baseline ASAS CRP is not a predictor of new chest wall lesions prior to 5 years of age. Nevertheless, poor control of disease activity is associated with the development of new lesions. Patients with new lesions have an ASAS CRP score that increase (0.882 +/- 2.48) between 2013 and 2018, while patients with no new lesions have an ASAS CRP score that decrease (-0.641 +/- 1.50) between 2013 and 2018.

**Conclusion:** The prevalence of ultrasonographic lesions of the ACW increased after 5 years of follow up. The development of new lesions is associated with a higher disease activity, a higher CRP and an increased disease activity over 5 years.

ACHIEVING DISEASE REMISSION IN AXIAL SPONDYLARTHROPATHY: A TWO-CENTRE RETROSPECTIVE ANALYSIS OF RELEVANT BASELINE PATIENT CHARACTERISTICS

Thomas Williams 1, Karl Gaffney 2, Alison Waleyde 2, Charlotte Cavill 1, Mandy Freeth 1, Alan Brooksby 3, Raj Sengupta 1. 1 Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; 2 Norfolk and Norwich University Hospital, Norwich, United Kingdom; 3 Bath Spa University, College of Liberal Arts, Bath, United Kingdom

Background: ASAS-EULAR Axial Spondyloarthritis (AxSpA) guidelines recommend that AxSpA treatment should be guided according to a predefined target 1, following increasing evidence that persistent, uncontrolled inflammatory disease activity results in long-term damage and poor outcomes 2-3. Despite this, there remains no single definition for ‘remission’ in AxSpA.

Objectives: To identify baseline characteristics of individuals achieving AxSpA disease ‘remission’ 6 months after initiation of biologic disease-modifying therapy (bDMARD).

Methods: A two-centre retrospective cross-sectional analysis was performed, of AxSpA patients receiving their first bDMARD at the Royal National Hospital for Rheumatic Diseases, Bath, and Norfolk and Norwich University Hospital, Norwich. AxSpA ‘remission’ was defined as Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) <1; Bath Ankylosing Spondylitis Functional Index (BASFI) <3.8 or serum C-reactive protein (CRP) <5. A non-parametric (2-tailed Chi-Square) test was applied to identify differences in baseline characteristics which distinguished those patients achieving ‘remission’ after 6 months bDMARD treatment from others.

Results: 538 patients were included. Sufficient BASDAI data was available for 440, CRP data for 448 and BASFI data for 354. Overall, 42 (9.5%) patients achieved BASDAI <1; 275 (61.4%) achieved CRP <5 and 206 (58.2%) achieved BASFI <3.8. The differences in baseline characteristics of individuals achieving these AxSpA ‘remission’ outcomes compared with others are summarised in Table 1, with statistically significant results at the 95% level highlighted.

Abstract THU0408 – Table 1. p-values of 2-tailed non-parametric test comparing baseline characteristics of individuals achieving AxSpA ‘remission’ outcomes after 6 months versus others.

Conclusion: Our self-defined measures of BASDAI and CRP remission were most achievable in our cohort for patients with lower CRP and less functional limitation before bDMARD initiation. This may reflect remission being more achievable when treating milder disease. Functional ‘remission’ was influenced by baseline BASMI and BASDAI in our cohort, highlighting the importance of both disease activity and pre-existing structural damage on functional outcomes. Further work could include longitudinal follow-up of outcomes in these patients to establish the relevance of target achievement. ‘BASDAI remission’ was very narrowly defined in this study, and this analysis could be repeated with a more achievable target eg BASDAI <3.

PATTERN AND INFLUENTIAL FACTORS IN PROMOTING TREAT-TO-TARGET (T2T) FOR FOLLOW-UP ANKYLOSING SPONDYLITIS (AS) PATIENTS WITHIN A RHEUMATIC DISEASE-PATIENT INTERACTIVE SMART SYSTEM OF DISEASE MANAGEMENT (SSDM): A COHORT STUDY FROM CHINA

Jing Yue 1, Hui Song 1, Jing Yang 1, Zhenchun Zhang 1, Li Hongbin 2, Junli Zhang 2, Zongzhou Huang 4, Wei Wang 5, Hua Wu 6, Li Yang 6, Li Zhijun 6, Lijun Liu 6, Yuhua Jia 6, Fei Xiao 6, Huaxiang Wu 6. SSDM Collaboration Group, China; 1 The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; 2 Beijing Jishuitan Hospital, Beijing, China; 3 Central Hospital of MianYan, MianYang, China; 4 Linyi people’s Hospital, Linyi, China; 5 The Affiliated Hospital of Inner Mongolia Medical University, Huhehaote, China; 6 The First Affiliated Hospital of Anhui Medical University, Hefei, China; 7 The First Affiliated Hospital of The Fourth Military Medical University, Xi An, China; 8 Dongguang Donghua Hospital, Dongguan, China; 9 Beijing Hospital of Traditional Chinese Medicine (TCM), Beijing, China; 10 Jilin Jiangsu People’s Hospital, Yanzhou, China; 11 Zhejiang Provincial People’s Hospital, Hangzhou, China; 12 The First Affiliated Hospital of Bengbu Medical College, Bengbu, China; 13 Yong Liao City Hospital, Tongliao, China; 14 Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China

Background: Ankylosing Spondylitis Disease Activity Score (ASDAS) is adopted to evaluate the degree of disease activity and the inflammatory response in AS patients. ASDAS score ≤ 1.3 represents inactive disease status and achievement of T2T.

Objectives: To evaluate the patterns of T2T and related influential factors among AS patients after applying SSDM in the real world.

Methods: SSDM is a mobile application for disease management. Patients were trained to master SSDM by healthcare professionals and to conduct ASDAS self-assessments. Patients were also required for repeating self-evaluation after leaving the hospital. After entry by patients, data can be synchronized to the SSDM terminal of authorized rheumatologists.

Results: From Jan 2015 to Jan 2019, 667 AS patients across China were followed up for more than 6 months through SSDM. The results at baseline and in final follow up were summarized in Table 1. The rate of T2T achievers were 28.49% (190/667) at baseline, and improved significantly to 41.38% (276/667) after 6 months follow up, p<0.01. Among T2T achievers at baseline, 64.21% (122/190) maintained T2T, 35.79% (68/190) relapsed. Of patients who didn’t achieve T2T at baseline, only 32.29% (154/477) of the other AS patients achieved T2T after 6 months follow up. We further analyzed the impact of the times of self-assessment for ASDAS on T2T. The patients were stratified according to their frequency of self-assessment: more than 3 times, less than or equal to 3 times. After adjusting for 6 months follow-up. Results show that the more frequent of the self-assessment, the higher improvement of T2T rate than others. Significance analysis of variables in three times of self-assessment and parameter estimation was conducted by least square method. The improvement of T2T rate(y) was positively correlated with times of self-assessment for ASDAS(x) independently (Figure 1).

Conclusion: Significant improvement was observed under applying SSDM through empowering AS patients. After proactive disease management via SSDM for more than 6 months, Patients with ASDAS≥1.3 score at baseline had a significantly higher retention rate of disease activity. The patients who performed more self-assessments through SSDM had lower probability of relapse and higher rate of T2T. SSDM is a valuable tool for long term follow-up through empowering patients.
UVEITIS RELATED FACTORS IN PATIENTS WITH SPONDYLOARTHRITIS

Background: Uveitis is the most common extra-articular feature of spondyloarthritis (SpA). Sometimes uveitis may be the only clinical finding of SpA leading to diagnosis. In the current literature, there is information about frequency and characteristics of uveitis in SpA patients; however, factors associated with uveitis are not clear.

Objectives: Our aim in this study was to analyze uveitis-related factors in a large cohort of SpA patients.

Methods: This multicenter, prospective observational cohort study used the TReasure database in which web-based registration of rheumatoid arthritis and SpA patients are being performed in 15 centers across different regions of Turkey. Age, gender, duration of illness, delayed onset, SpA clinical findings, HLA B27 and acute phase responses (erythrocyte sedimentation rate and C-reactive protein, BASDAI and BASFI values, clinical findings and direct X-ray findings of SpA patients with and without uveitis were retrospectively evaluated.

Results: As of January 2019, there were 4557 registered SpA patients. Overall, 491 (10.8%) patients had experienced one or more episodes of uveitis. The median (Q1-Q3) uveitis onset age was 46 years (38-53 years) and the median (Q1-Q3) uveitis attack number was 2 (1-4). Uveitis was usually unilateral (74.2%). Records of eye damage was available in 373 patients, of whom 45 (12.1%) had permanent damage in the eye. Patients with permanent eye damage had more frequent uveitis attack (3 (2-6)) vs. 2 (1-3), p=0.003) and had tendency of bilateral uveitis attack (41.5% vs 24%, p=0.017).

Duration between the first uveitis attack and onset of SpA symptoms was 68 months (7-141). On the other hand, the mean duration between the first uveitis attack and SpA diagnosis is 7 months (17-68 months). In 320 (70%) patients, uveitis was diagnosed before the onset of SpA symptoms and 52% (n=240) of the patients had uveitis before SpA diagnosis.

Demographic and clinical features of the patients are given in Table 1.

Conclusion: In our cohort, genetic background, radiographic severity, and disease duration may be related with uveitis. HLA B27 positivity and family history may be risk factors for development of uveitis. First attack of uveitis is nearly always before the onset of symptoms and diagnosis of SpA. Although uveitis is usually self-limited; however, almost 10% of SpA patients may have permanent eye damage. Thus, patients with uveitis should be carefully investigated because it may be the diagnostic feature of SpA.

Disclosure of Interests: None declared

Background: Delayed diagnosis in patients with axial spondyloarthritis (AxSpA) has been shown to negatively impact disease prognosis and contribute to worse economic and quality of life outcomes; however, there is limited evidence available regarding the association of delayed diagnosis of AxSpA with the comprehensive burden of disease.

Objectives: To identify and summarize current published literature evaluating the clinical, economic, and humanistic burden associated with delayed diagnosis in patients with AxSpA.

Methods: This systematic literature review was conducted and reported according to the PRISMA guidelines (Figure 1).1 Publications were retrieved from the MEDLINE®, Embase® and Embase databases. English-language publications of original research articles (up to July 12, 2018) and conference abstracts (2014 to 2018) reporting studies of delayed diagnosis of adult patients with AxSpA associated with clinical, economic, or humanistic burden were eligible for inclusion. Abstracts from all records retrieved from the literature search were screened by two independent reviewers (first-level screening) (Table 1). Patents with delayed diagnosis of AxSpA generally had worse clinical outcomes, including higher disease activity (Bath Ankylosing Spondylitis Disease Activity Index), poorer mobility and physical function (Bath Ankylosing Spondylitis Functional Index), and more structural damage, compared with patients who had an earlier diagnosis (Table 1). Patients with delayed diagnosis also had higher healthcare costs, including costs of unnecessary treatments, and greater likelihood of work disability compared with those who had an earlier diagnosis (Table 1). Delayed diagnosis was associated with worse quality of life, including greater likelihood for depression and negative psychological impact (Table 1).

Conclusion: Delayed diagnosis in patients with AxSpA demonstrated a decrease in physical function, higher direct and indirect costs, and poorer quality of life. This study highlights the importance of early recognition and diagnosis of AxSpA in order to improve outcomes and mitigate extensive burden on patients and society. Therefore, further efforts by the healthcare community are warranted to increase awareness of early signs of disease and reduce the delay in diagnosis of AxSpA.

Abstract THU0411 - Figure 1

REFERENCE:

Acknowledgement: This study was sponsored by Novartis Pharmaceuticals Corporation, East Hanover, NJ.
1 and STT joints were assessed for synovitis (0-3) and bone marrow lesions (BMLs; 0-6 and 0-9, respectively). Radiographs were assessed for the presence of osteophytes in CMC-1 and STT joints following the OARSI atlas by two readers. Since pain was assessed for the TB as a whole, imaging scores of CMC-1 and STT joints were combined, comparing no change in both joints (i.e. ‘stable’) versus change in at least one joint. In TBs without maximum baseline pain, associations between increase in MRI features and increase in TB pain were investigated using logistic regression, presented as odds ratios (ORs) with 95% confidence intervals (CIs). Similarly, in TBs with pain and MRI features present at baseline, associations between decrease in imaging features and decrease in TB pain were investigated.

Results: Out of 161 patients (82.6% women, mean age 60.8 years, 91.3% fulfilling ACR hand OA criteria) 64 had TB pain at baseline (of whom 11 with maximal score). At the two-year follow-up visit, pain had decreased in 31 patients and increased in 33 patients. The majority had stable synovitis (n=106) and BML (n=96) scores over two years, although decreased (n=22, n=26, resp.) and increased (n=29, n=36, resp.) scores were common. Increase in radiographic osteophytes was rarely (n=10) observed. Increase in synovitis or BML was associated with increased pain, also after adjusting for baseline osteophyte status (Table). A decrease in BML was associated with a decrease in pain, although it did not reach statistical significance. Presence of osteophytes on baseline radiographs was weakly associated with change in pain in univariate analyses and attenuated when adjusting for the change in MRI features. Decrease of synovitis in patients with baseline pain was scarce (n=7), therefore ORs were not computed.

Conclusion: In this cohort of hand OA patients, thumb base pain levels varied over the course of two years in approximately forty percent of patients. Changes in MRI-defined synovitis and BMLs of the TB joints were positively associated with change in pain on palpation. Baseline osteophytes were not significantly associated with change in pain. While cross-sectionally MRI-defined inflammation may be a less important determinant of pain than radiographic damage, this study shows that a change in inflammatory features may indeed be relevant.

THU0414  COMPARISON OF INTRA-ARTICULAR SHAM AND VEHICLE INJECTIONS FROM A PHASE 2B TRIAL OF SM04690, A SMALL-MOLECULE WNT PATHWAY INHIBITOR FOR KNEE OSTEOARTHRITIS

Yusuf Yazici1, Jeyanesh Tambiah1, Christopher Swearengen1, Sarah Kennedy1, Vibeke Strand2, Brian Cole3, Marc Hochberg4, Raveendhara Bannuru2, Timothy McAlindon5, 1Samumed, LLC, San Diego, United States of America; 2Stanford University School of Medicine, Stanford, United States of America; 3Rush University, Chicago, United States of America; 4University of Maryland, Baltimore, United States of America; 5Tufts Medical Center, Boston, United States of America

Background: Intra-articular (IA) saline, commonly used as a placebo (PBO) comparator in knee osteoarthritis (OA) trials, has consistently shown improvements from baseline in patient-reported outcomes (PROs). These effects have been attributed to contextual and/or physiological benefits of saline, thus causing interpretation of potential IA therapeutics trial results to be questioned.1,2

Objectives: A prospective, randomized, controlled, 24-week phase 2b study compared effects of vehicle PBO to sham and SM04690 (an IA Wnt pathway inhibitor in development as a potential disease-modifying knee OA drug (DMOAD)) injections. Potential unblinding impact of PBO or sham was also tested. Primary study results are presented separately.

Methods: Knee OA subjects with Kellgren-Lawrence (KL) grades 2-3 and Pain Numeric Rating Scale (NRS) ≥4 and ≥8 in the target knee and <4 in the contralateral knee were randomized to receive a single blinded IA injection of 2 mL vehicle (PBO, 0.5% carboxymethylcellulose sodium, 0.05% polysorbate 80 in pH 7.4 saline), sham (dry needle), or SM04690 in the target knee on Day 0. PROs included change from baseline in weekly average of daily pain in the target knee by NRS, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain, WOMAC Physical Function, and Patient Global Assessment (PGA). Subjects were asked which treatment assignment they thought they received; their accuracy was compared using Bang’s Blinding Index (BBI), a method used to evaluate blinding across clinical trial treatment arms. The index scale is -1 < 0 < +1, with values toward -1 indicating more subjects incorrectly guessing treatment allocations, toward 0 indicating perfect blinding, and toward +1 indicating more subjects correctly identifying treatment allocations.

Results: In the full analysis set of PBO and sham subjects (N=233; 207 [89%] completed), both groups showed clinically relevant improvements in the full analysis set of PBO and sham subjects (N=233; 207 [89%] completed), both groups showed clinically relevant improvements from baseline at first measurement that persisted [89%] completed), both groups showed clinically relevant improvements from baseline at first measurement that persisted.

Conclusions: Subjects with knee OA receiving a single IA injection of PBO reported no differences in changes from baseline in knee OA PROs compared to subjects who received sham injections. These data suggested the effects were “contextual,” meaning they resulted from the injection procedure, rather than from direct therapeutic effects of PBO or saline in the joint.

THU0415  EXPLORATORY PROTEIN PROFILING OF HUMAN SYNOVIAL FLUID FROM KNEE OSTEOARTHRITIS

Neserin Ali1, Jon Tjörnstrand2, Paul Neuman2, Elin Folkeson1, Velocity Hughes1, Patrik Onnerfjord1, Martin Englund1, 1Lund University, Lund, Sweden; 2Skåne University Hospital, Lund, Sweden

Background: There is a lack of valid and robust biomarkers in the field of OA diagnosis, prognosis, and treatment evaluation [1]. Synovial fluid is in direct contact with articular cartilage, ligament, meniscus and joint capsule it is therefore an excellent sample to explore the protein profile in which could provide pathogenesis information from several surrounding parts.

Objectives: The aim with this project was to perform mass spectrometry (MS) of human synovial fluid using a global discovery approach, to identify biomarker candidates associated with meniscus degradation and/or knee OA.

Methods: Synovial fluid was sampled from 3 different subject groups: i) end-stage medial compartment knee OA patients undergoing arthroplasty (n=11, age range 55-80 years), ii) knee arthroscopy patients who typically had a degenerative meniscal tear (n=7, age range 50-64 years), and iii) deceased human donors without known chronic knee disease (n=13, age range 19-79 years). All synovial fluids were centrifuged and freshly frozen and stored at -80°C. For the analysis, 50 μL of synovial fluid was mixed with MS-safe protease inhibitor cocktail, hyaluronidase, depleted, reduced, alkylated, precipitated, digested with sequencing grade trypsin (Promega), filtered and desalted. The samples were further analyzed with an EASY-nLC 1000 coupled to an Orbitrap Fusion mass spectrometer.

Figure: Observations over time depicting mean improvements (± 95% CI) of PBO compared to sham injection adjusted for baseline. A. Pain NRS, B. WOMAC Pain, C. WOMAC Function, and D. Patient Global; in all subjects.

using data-independent acquisition. The raw MS data were further analysed with Spectronaut™ for protein identification and quant data extraction. Differences in protein levels were analyzed in two steps: 1) Donors vs arthroplasty 2) Between all 3 different groups. Analyses were adjusted for age, gender and weight. Differentially expressed proteins between the groups were clustered using Pearson correlation coefficient as the distance metric.

Results: In total, 529 proteins were identified in the 31 different synovial fluid samples analyzed. Principal component analysis suggested a profound difference between the protein profiles of synovial fluid from donors vs arthroplasty patients, while the arthroscopy group had a protein profile that was in-between donors and the arthroplasty group (Figure 1A). Statistical differential analysis yielded significant differences in the levels of 43 proteins comparing donors vs arthroplasty patients. 36 proteins differed between the 3 groups when comparing all groups in the same statistical model. Extracellular matrix proteins like collagens and aggrecan showed higher expression in donors than in arthroplasty patients. Collagen on the other hand was higher in arthroscopy patients compared to donors. Decorin was significantly higher in donors compared to both arthroscopy and arthroplasty patients. The differentially expressed proteins associated with the inflammatory response were higher in the arthroscopy group compared to both donors and arthroplasty patients. Generally, extracellular matrix proteins like collagens and aggrecan showed higher expression in donors than in arthroplasty patients. Collagen on the other hand was higher in arthroscopy patients compared to donors. Decorin was significantly higher in donors compared to both arthroscopy and arthroplasty patients. The differentially expressed proteins associated with the inflammatory response were higher in the arthroscopy group compared to both donors and arthroplasty patients. Generally, extracellular matrix proteins like collagens and aggrecan showed higher expression in donors than in arthroplasty patients. Collagen on the other hand was higher in arthroscopy patients compared to donors. Decorin was significantly higher in donors compared to both arthroscopy and arthroplasty patients. The differentially expressed proteins associated with the inflammatory response were higher in the arthroscopy group compared to both donors and arthroplasty patients. Generally, extracellular matrix proteins like collagens and aggrecan showed higher expression in donors than in arthroplasty patients. Collagen on the other hand was higher in arthroscopy patients compared to donors. Decorin was significantly higher in donors compared to both arthroscopy and arthroplasty patients. The differentially expressed proteins associated with the inflammatory response were higher in the arthroscopy group compared to both donors and arthroplasty patients. Generally, extracellular matrix proteins like collagens and aggrecan showed higher expression in donors than in arthroplasty patients. Collagen on the other hand was higher in arthroscopy patients compared to donors. Decorin was significantly higher in donors compared to both arthroscopy and arthroplasty patients.

Conclusion: There is a profound difference in the protein profile of synovial fluid in donors vs knee OA patients (Figure 1). The inflammatory response seems to be higher in the early stages of OA than in later stage. Our findings emphasize the importance of OA staging in the development and use of biomarkers.

REFERENCE:
HOA cohort showed a positive association between soft tissue swelling, tenderness upon pressure with pain and radiographic progression.6

Objectives: To identify new prognostic factors and to confirm existing evidence on already identified prognostic factors for radiographic progression in HOA.

Methods: All 270 patients from this cohort were contacted to participate in a second follow-up visit after ten years at the Ghent University Hospital. A total of 106 patients consented to this follow-up visit. Presence of tender and swollen joints was assessed. Grip strength was measured. Functional Index for HOA (FIHOA) and Australian/Canadian OA Index questionnaires (AUSCAN) were completed by the patients. Pain was scored on a visual analogue scale from 0-100mm (VAS pain). Radiographs of hands were taken and scored using the anatomical phase scoring system for HOA by Verbruggen and Veys5. Patients were defined as radiographic progressor when two or more joints progressed to another phase within the scoring system, except for N-phase to S-phase. Logistic regression was performed on the clinical data and outcomes such as presence of tenderness (yes or no), soft tissue swelling (yes or no), VAS pain, disease duration, FIHOA and AUSCAN. VAS pain was dichotomized into two groups: VAS ≤33mm and VAS >33mm. Disease duration was dichotomized in ≤5 years and >5 years; p-values and odds ratios (OR) with 95% confidence intervals (95% CI) were calculated.

Results: After a mean follow-up of 9.7 years, 73.3% of the patients showed radiographic progression. The following clinical factors were associated with radiographic progression on patient level (OR [95%CI]): presence of tenderness (4.19 [1.52-11.61]), presence of soft tissue swelling (2.73 [1.08-6.92]) and disease duration > five years (4.00 [1.50-10.66]). Other outcomes were retained as prognostic factors for radiographic progression (OR [95%CI]): VAS pain (1.02 [1.00-1.04], total FIHOA (1.12 [1.03-1.23]), total AUSCAN (1.02 [1.01-1.04] and AUSCAN pain (1.07 [1.02-1.12], AUSCAN function (1.03 [1.01-1.06]) and VAS pain > 33mm (2.87 [1.14-7.24]). The mean number of E and R joints was 1.2 and 1.4 at baseline, and 0.2 and 0.5 after 10 years (p<0.001). The total number of joints that progressed to the E-phase and R-phase over a period of ten years was respectively 20 (1.05%) and 399 (21%).

Conclusion: Clinical presence of pain and soft tissue swelling at baseline remain strong predictors of radiographic progression in HOA after ten years. Tenderness upon pressure, moderate VAS pain and moderate impaired function at baseline are identified as new predictors. After ten years, more remodelling and less erosive joints are seen.

THU0417 – THE SEVERITY OF STRUCTURAL AND INFLAMMATORY FEATURES OF HAND OSTEOARTHRITIS ASSOCIATE WITH PERIPHERAL PAIN SENSITIZATION

Pernille Steen Pettersen1, Tuhina Neogi2, Karin Magnusson1,3, Hilde Berner Hammer1, Tore K. Kvien1, Till Uhlig1, Ida Kristin Haugen1,2, Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway; 1Boston University School of Medicine, Clinical Epidemiology Research and Training Unit, Boston, United States of America; 2Lund University, Faculty of Medicine, Department of Clinical Sciences Lund, Orthopaedics, Clinical Epidemiology, Lund, Sweden

Background: Increased sensitivity to pain in the area around joints with osteoarthritis (OA), i.e., peripheral sensitization, is associated with higher pain severity. The mechanisms underlying peripheral sensitization in hand OA have not been substantially explored in previous studies.

Objectives: We aimed to explore whether the severity of structural or inflammatory OA features in the distal and proximal interphalangeal (DIP/PIP) joints were associated with lower pressure pain thresholds (PPT) at the same joint in a large study sample of persons with hand OA.

Methods: In these cross-sectional analyses we included 277 persons with hand OA from the Nor-Hand cohort. All participants underwent radiographic and ultrasound examination (GE S8, ML 6-15MHz probe) of both hands. Pressure pain threshold (PPT) was tested with a hand-held algometer (FPX025, 1cm² flat rubber probe) in perpendicular position at the dorsal side of the DIP/PIP joint reported to be the most painful. Information about demographics and psychosocial factors was collected with questionnaires. We examined whether increasing radiographic severity (Kellgren-Lawrence 0-4 score) and ultrasound-detected inflammation (grey-scale synovitis 0-3 score and presence of power-Doppler activity) were associated with PPT at the same joint. We conducted separate analyses of linear regression with adjustments for age, sex, BMI, education level, use of analgesics, sleep disturbance, the Pain Catastrophizing Scale and the Hospital Anxiety and Depression Scale.

Results: The majority of the study population were women (89%), median age was 61 (IQR 57-66) years, mean BMI was 26.3 (SD 4.6) kg/m² and mean duration of hand OA symptoms was 6 (IQR 3-13) years. The DIP/PIP joints demonstrated a wide range of PPT (mean [SD] 3.9 [1.9], range 0.6-11.4 kg/cm²) and OA severity (Table). We found that both increasing radiographic severity and inflammation were associated with lower PPTs (Table). When including grey-scale synovitis and power Doppler as confounders in analysis of radiographic severity, the results became weaker but remained significant (Table).

Abstract THU0417 – Table 1. Associations of structural and inflammatory OA features of DIP/PIP joints to pressure pain thresholds at the same joint, n=277.

Adjusted for age, sex, BMI, analgesics, education, sleep disturbance, the Pain Catastrophizing Scale and the Hospital Anxiety and Depression Scale. *Additional adjustments for grey-scale synovitis and power Doppler.

Conclusion: Both structural and inflammatory hand OA features in DIP/PIP joints were associated with lower pressure pain thresholds, i.e. pain sensitization, at the same joint. Our results suggest that peripheral sensitization might be driven by structural and inflammatory features, and that targeting the disease early might prevent peripheral sensitization and reduce pain.

THU0418 NEUROPATHIC-LIKE PAIN IN PERSONS WITH HAND OSTEOARTHRITIS AND ASSOCIATIONS WITH PERIPHERAL AND CENTRAL SENSITIZATION

Pernille Steen Petersen1, Tuhina Neogi2, Marthe Glearsen1, Karin Magnusson1,2, Hilde Bernt Hammer1,2, Tore K. Kviën1,2, Tili Uhlig1, Ida Kristin Haugen,1,2, Tore K. Kvien1,2. 1Department of Clinical Medicine, 2School of Medicine, Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Clinical Epidemiology Research and Training Unit, Boston, United States of America; 1Lund University, Faculty of Medicine, Clinical Sciences Lund, Orthopaedics, Clinical Epidemiology, Lund, Sweden.

Background: Despite no current knowledge of lesions or disease of the sensory nervous system in osteoarthritis (OA), subgroups of knee OA patients report neuropathic-like pain. The neuropathic-like pain component has been suggested to reflect central sensitization.

Objectives: To describe the prevalence of neuropathic-like pain in persons with hand OA and explore whether neuropathic-like pain associate with peripheral and/or central sensitization.

Methods: These cross-sectional analyses included 280 participants with hand OA from the Nor-Hand study. A modified PainDETECT questionnaire was used to characterize neuropathic-like hand pain (mPD-hand, 0-36 scale). We conducted quantitative sensory testing (QST) of pressure pain thresholds (PPT) and temporal summation (TS). Low PPTs at local sites (painful finger joint and non-painful finger joint) indicate peripheral and/or central sensitization, while low PPTs at extra-segmental sites (radionuclar joint, musculus trapezius and tibialis anterior) indicate central sensitization. TS, defined as an increase in pain ≥2 on a numeric rating scale (NRS) at 0-10 during a repetition of ten punctuate stimuli at the wrist, indicates central sensitization. Participants with painful hand OA (NRS of hand pain above the patient acceptable symptom score of >4), were categorized as having either nociceptive pain (mPD-hand ≤12) or neuropathic-like pain (mPD-hand score >12). We examined whether reporting nociceptive or neuropathic-like pain, as compared to no/mild pain (NRS hand pain below 4) was associated with QST results using regression analyses.

Results: In this study sample, 88% were female, median age was 61 (IQR 57-66) years and 94% fulfilled the ACR criteria for hand OA. Median mPD-hand score was 8 (IQR 3, 13). Half of the participants (n=144, 51%) reported NRS pain ≥4, of whom 58% (40%) had neuropathic-like pain. Those with neuropathic-like pain reported higher mean (SD) NRS pain severity than persons with nociceptive pain (5.9 (1.6) vs 5.3 (1.5), p=0.01). We found that neuropathic-like pain was associated to higher pain sensitization reflected by lower PPT at the painful finger joint (Table), non-painful finger joint (β -1.1, 95% CI -2.3, -0.9), radionuclar joint (β -1.1, 95% CI -1.8, -0.4), trapezius (Table) and tibialis anterior (β -1.0, 95% CI -1.8, -0.2) and presence of TS (Table). The associations between neuropathic-like pain and QST were weaker than the association between nociceptive pain and sensitization were weaker than the association between nociceptive pain and sensitization.

Conclusions: In this study, the prevalence of neuropathic-like pain was 51% in hand OA. The presence of neuropathic-like pain was associated with decreased pain thresholds and increased pain sensitization.

THU0419 BIOMARKERS OF BONE AND CARTILAGE TURNOVER CTX-I AND CTX-II PREDICT TOTAL JOINT REPLACEMENTS IN OA

Jonathan Bierne-Bastos1, Anne-Christine Bay-Jensen2, Morte Mandel1, Inger Bjyrjallsen2, Jeppe Ragnar Andersen3, Bente Juel Riis2, Claus Christiansen1, Asger Reinsup Bihlet1. 1Nordic Bioscience, Clinical Development, Herlev, Denmark; 2Nordic Bioscience, Biomarkers and Research, Herlev, Denmark; 3Nordic Bioscience, Herlev, Denmark.

Background: Osteoarthritis (OA) can lead to joint failure and ultimately total joint replacement (TJR). Identifying risk-factors of developing joint failure is of interest for clinicians and researchers. Currently late-stage clinical trial design for new treatments in OA is evolving with the possible utilization of accelerated approval pathways. This may require outcome studies with longer duration, in which joint failures may qualify as an endpoint. However, TJRs are relatively rare events and are known to be biased by doctor/patient interactions as well as local practice guidelines, and consequently, there is a need for objective non-invasive measures, such as soluble biomarkers (BM), to enrich the population for this outcome. BM may act as important tools in investigating the association between biochemical/pathological processes and risk of joint failure. Destruction of collagen types I and II are known to be involved in OA disease progression, and the biomarkers CTX-I (C-telopeptide of crosslinked collagen type I), a marker of bone degradation, and CTX-II (C-telopeptide of crosslinked collagen type II), a marker of cartilage degradation, may reflect disease progression with clinical relevance for the risk of joint failure.

Objectives: To evaluate baseline (BL) BM sCTX-I and uCTX-II as predictors of TJR.

Methods: Data from two clinical trials investigating on salmon calcitonin (SNC) in OA, NCT00486434 and NCT00704847, was analyzed post-hoc. Data was dichotomized by the bottom and top quartile of the respective BM concentration at BL to compare the number TJRs of the knee or hip in groups with high vs. low sCTX-I or uCTX-II, respectively. For means of visualization, plotted in Kaplan-Meier curves. Cox Proportional Hazard Regression was performed to determine the association of BL sCTX-I and uCTX-II to the incidence of TJR while adjusting for co-variates; age, BMI, and gender. Data from both treatment groups were analyzed. Only the first reported incident was included in the analysis for each subject.

Results: A total of 68 TJRs of knee or hip were reported, of which 49 were knees and 18 were hips. One patient underwent two TJRs, resulting in 67 subjects with events.

Results from the Cox Proportional Hazard Regression adjusted for covariates of age, BMI, and sex (table 1), indicate that high BL sCTX-I compared to low was associated with a 3.4 times higher risk of undergoing an arthroplasty of the knee or hip within a two-year period (p=0.04). High BL uCTX-I compared to low was associated with a 3.1 times higher risk of undergoing a TJR of the knee or hip during the study period (p=0.04), and an 8.9-fold increased risk of undergoing a knee replacement during the study period (p=0.02). TJR events over time in groups of high or low uCTX-II through the study are illustrated in figure 1.

1Linear regression, 2logistic regression. Adjusted for age, sex, BMI, use of analgesics, level of education, sleep disturbance, Pain Catastrophizing Scale, the Hospital Anxiety and Depression Scale and radiographic hand OA severity (Kelgren-Lawrence score sum score).

Conclusion: Of persons with painful hand OA, 40% have a neuropathic-like pain component. Reporting neuropathic-like pain is associated with peripheral and central sensitization, indicated by low PPTs and presence of TS. Our results suggest that patients who report neuropathic-like symptoms are more likely to have sensitization and increased pain.

Conclusion: High levels of sCTX-I and uCTX-II at BL were associated with increased risk of undergoing TJR of the knee or hip during the two-year study. Our findings support the role of sCTX-I and uCTX-II as important biomarkers in clinical OA trials evaluating incidence of TJR.

THU0421

EFFECT OF GAME BASED EXERCISE PROGRAMS ON PAIN, FUNCTIONAL MOBILITY AND BALANCE IN PATIENTS WITH KNEE OSTEOARTHRITIS: RANDOMIZED CONTROLLED STUDY

DEMYİR SERAP YILMAZ1, Ali Erdem Bakı2, 2Zonguldak Atatürk Public Hospital, Physical Medicine and Rehabilitation, Zonguldak, Turkey,
2Zonguldak Bulent Ecevit University Faculty of Medicine, Physical Medicine and Rehabilitation, Zonguldak, Turkey

Background: Osteoarthritis is a chronic joint disease affecting the knee, hip and hand joints. Exercise is an integral component of conservative treatment for osteoarthritis. However, virtual reality applications using interactive games for rehabilitation have become a focus of interest in recent years.

Objectives: The aim of this study was to evaluate the effects of virtual reality games on knee pain, functional mobility and balance in patients with knee osteoarthritis.

Methods: Fifty patients who were complaining of knee pain, aged 40-70 years, and were diagnosed with Kellgren-Lawrence stage 2, 3, 4 idiopathic knee osteoarthritis was included. Patients were randomly assigned to two equal groups (n = 25) as the control and the study group. Age, sex, weight, height, duration of illness was recorded for all patients. In to two equal groups (n = 25) as the control and the study group. Age, sex, weight, height, duration of illness was recorded for all patients. In the study group, all patients received virtual reality games on knee pain, functional mobility and balance in patients with knee osteoarthritis.

Results: In both groups, significant change in VAS, WOMAC knee osteoarthritis index, and CB&M score was observed (p<0.05). In the study group, VAS, WOMAC osteoarthritis index, and CB&M scores were significantly different than control group (p<0.05). The differences between baseline scores were significant in the study group.

Conclusion: MetS is predominantly associated with trajectories of localised and generalised pain through central obesity, suggesting that weight management is important in the prevention and therapy of pain over time.

Disclosure of Interests: None declared

THU0420

METABOLIC SYNDROME AND TRAJECTORIES OF LOCALISED PAIN AND GENERALISED PAIN

Fenn Pan1, Jing Tian1, Flavia Cicutini2, Graeme Jones1. 1University of Tasmania, Merseys Institute for Medical Research, Hobart, Australia; 2Monash University Medical School, Department of Epidemiology and Preventive Medicine, Melbourne, Australia

Background: Metabolic syndrome (MetS) has been suggested as having a link to the pathophysiology of pain; however, no study has assessed whether MetS and its components are associated with localised pain and generalised pain and their courses over time.

Objectives: To describe the associations of MetS and its components with trajectories of localised knee pain (pain severity) and generalised pain (number of painful sites (NPS)) in a general older population.

Methods: 1,099 participants from a population-based older adult cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Data were collected on demographic, psychological, lifestyle and comorbidities, blood pressure, glucose, triglycerides, and high-density lipoprotein (HDL) cholesterol. MetS was defined based on the National Cholesterol Education Program-Adult Treatment Panel III criteria. Radiographic knee osteoarthritis (ROA) was assessed by X-ray. Knee pain was measured by Western Ontario and McMaster Universities Osteoarthritis Index pain questionnaire at each time-point. Presence/absence of pain at the neck, back, hands, shoulders, hips, knees and feet was collected by questionnaire at each time-point.

Group-based trajectory modelling was applied to identify pain trajectories. Multi-nominal logistic regression was used for the analyses.

Results: Of 895 participants included in this study, 32% of participants had MetS and 60% had ROA at baseline. Three localised knee pain severity trajectories were identified: ‘Minimal pain’ (52%), ‘Mild pain’ (33%) and ‘Moderate pain’ (15%). Three NPS trajectories were identified: ‘Low NPS’ (12%), ‘Medium NPS’ (38%), and ‘High NPS’ (49%). In multivariable analysis without adjusting for central obesity, central obesity increased risk of belonging to both mild pain and moderate pain trajectories as compared to the ‘Minimal pain’ trajectory group, but MetS, hypertglycemia and low HDL were only associated with ‘Moderate pain’ trajectory [relative risk (RR): 1.67-2.26, all P<0.05]. Similarly, central obesity was also associated with both ‘Medium NPS’ (RR 2.35, 95%CI 1.40–3.92) and ‘High NPS’ trajectories (RR 3.07, 95%CI 1.85–5.08) compared to ‘Low NPS’ trajectory group, whereas MetS was only associated with ‘High NPS’ trajectory (RR 2.60, 95%CI 1.54–4.41). These associations became weak and non-significant after further adjustment for central obesity.

Conclusion: MetS is predominantly associated with trajectories of localised and generalised pain through central obesity, suggesting that weight management is important in the prevention and therapy of pain over time.

Disclosure of Interests: None declared

and final scores of VAS and WOMAC were significantly higher (p<0.05) in study group.

Conclusion: The results of the present study showed that virtual reality game-based exercise programs performed better results than conventional treatment program in patients with knee osteoarthritis.

THU0422
COMPARISON OF PRP DERIVED GROWTH FACTOR
(PRGF) VERSUS HYALURONIC ACID (HA)
IN MODERATE TO MODERATE KNEE OSTEOARTHRITIS; A SINGLE BLIND
ONE YEAR RANDOMIZED CLINICAL TRIAL STUDY

Seyyed Ahmad Raeissadat1, Azadeh Gharooee Ahangar2, Seyyed Mansoor Rayegani, Pegah Yavari1. 1Shahid Beheshti University of medical sciences, physical medicine and rehabilitation, Tehran, Iran (Islamic Republic of); 2Zanjan University of medical sciences, physical medicine and rehabilitation, Zanjan, Iran (Islamic Republic of)

Background: Osteoarthritis (OA) is the most common joint disease with characteristics of progressive loss of joint cartilage.

Objectives: Aim of this study was to evaluate clinical outcomes of intra-articular injection of PRP derived growth factor (PRGF) versus hyaluronic acid (HA) in patients with knee osteoarthritis.

Methods: 102 patients with grade II or grade III knee OA were randomly assigned to 2 intra-articular injections of PRGF 3 weeks apart or 3 weekly injections of HA. Primary outcome was the mean change from baseline until 2, 6 and 12 months post intervention in scores of visual analog scale (VAS), WOMAC and Lequesne index.

Results: The mean age of patients was 57.08±7.3 in PRGF compared to 58.65±7.09 in HA group. In PRGF group, VAS decreased from 7.8±1.5 to 5.4±1.7, and from 7.8±1.1 to 6.1±1.8 in the HA group after 12 months (P<0.0001). Total WOMAC score decreased from 41.96±11.71 to 27.10±12.3 (P<0.001), and from 39.71±10.4 to 32.41±11.8 after 12 months, respectively (P<0.05). In Lequesne index, all scores were significantly decreased after 12 months in PRGF group in comparison to HA group (P<0.001).

Conclusion: Although PRGF and HA were both effective, but PRGF injection resulted in significantly higher satisfaction, lower VAS and WOMAC and Lequesne total at baseline, 2, 6 and 12 months after injection. PRGF indicates plasma rich in growth factor.

THU0423
ANTEROIOR TIBIALATAR FAT PAD MORPHOLOGY AND
IGNAL INTENSITY ON MAGNETIC RESONANCE
AGING ARE CORRELATED WITH PATIENT
CHARACTERISTICS AND JOINT PATHOLOGY

Slijn Arnaert1, Paul Byttebier2, Sam Van Rossum2, Elie Vereecke3, Ilse Jonkers3, Edwin De4, S.M.A. Birma- Zeinstra5, Rik Lories1,6, Marienke Van Miedel1,2, Stefan Clockaerts7,1, 1KU Leuven, Leuven, Belgium; 2AZ Groeninge, Orthopaedic Surgery and Traumatology, Kortrijk, Belgium; 3KU Leuven, Human Movement Biomechanics Research Group, Leuven, Belgium; 4KU Leuven (KULAK), Development and Regeneration, Kortrijk, Belgium; 5Erasmus MC Medical University Rotterdam, Radiology, Rotterdam, Netherlands; 6Erasmus MC Medical University Rotterdam, General Practice, Rotterdam, Netherlands; 7KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium, 8University Hospitals Leuven, Rheumatology, Leuven, Belgium

Background: Ankle sprains are the most frequent form of trauma in the ankle and up to 33% of patients experience ongoing pain 1 year after the initial trauma.1 In the ankle, trauma is the primary etiology of osteoarthritis with an overwhelming proportion of 70-78%.2 Recently, our group completed a small pilot study that suggested that the anterior tibial fat pad (ATFP) should be investigated as a source of inflammation and pain.3

Objectives: In this study, we tried to investigate the innovative concept of the ATFP as missing link in the pathogenesis of persistent complaints and potential source driving inflammation in the development of osteoarthritis.

Methods: The present study is a secondary analysis of an observational case control study by Van Ochten et al.4 We included 106 patients with a Kellgren & Lawrence score of 0 in the tibial joint on x-ray. T1 MRI scans were assessed for the signal intensity and area of the ATFP. T1 MRI scans in the program 'MATHLAB', quantitative values of intensity and area were generated. Those values were statistically tested for correlations with patient characteristics and structural abnormalities by univariate and multivariate linear regression.

Results: MRI signal intensity of the ATFP is associated with BMI (p=0.03), sex (p<0.01) and age (p<0.01). ATFP area is correlated with sex (p<0.01) and presence of pre-OA signs in the subtalar joint (p=0.01). After multivariate analysis, correcting for sex, subtalar pre-OA signs and BMI, persistent complaints were associated with ATFP area (p=0.04).

Conclusion: This study demonstrates the involvement of the ATFP in hindfoot joint pathology. ATFP MRI characteristics were also influenced by patient characteristics. Further research should confirm these findings in a more elaborate population including OA patients, focus on histological validation and determine underlying pathogenic processes that may explain the observed correlations.

THE NEW TREATMENT APPROACH IN KNEE OSTEOARTHRITIS: EFFICACY OF CELLULAR MATRIX COMBINATION OF PLATELET RICH PLASMA WITH HYALURONIC ACID VERSUS TWO DIFFERENT TYPES OF HYALURONIC ACID (HA) (PROSPECTIVE, RANDOMIZED, DOUBLE BLIND CONTROL STUDY)

Blanko Barac, Nemanja Damjanov, Ana Zekovic. Institute of rheumatology, Belgrade, Serbia

Background: Osteoarthritis pathogenesis is a complex process associated with decreased ability to regenerate cartilage mainly due to lack of physiologic vascularization. One of the most commonly affected joints is the knee.

Objectives: The aim of this study was to compare the efficacy of intra-articular (IA) injections of platelet rich plasma (PRP) combined with hyaluronic acid (HA) prepared with the Cellular Matrix device versus IA injections with two different types of hyaluronic acid for treatment of knee osteoarthritis.

Methods: This is a prospective, randomized, double-blind, controlled study on 53 patients (90 knees) suffering from knee osteoarthritis, divided in 3 groups. The first group comprised 19 patients (30 knees) treated with 3 IA injections, one every second week, of Cellular Matrix (CM) PRP-HA combination. The second group of 19 patients (30 knees) was treated with 3 weekly IA injections of 2% non-cross-linked sodium hyaluronate and the third group of 15 patients (30 knees) treated with 3 weekly IA injections of 2% non-cross-linked sodium hyaluronate with mannitol. All groups were homogeneous concerning gender, age and Kellgren Lawrence scale (I to III). For all patients visual analog pain scale (VAS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Knee Injury and Osteoarthritis Outcome Score (KOOS), The International Knee Documentation Committee (IKDC) score (‘well-being’ scale for all 4 regions) were used as outcome measures. Responsiveness was assessed using standardised response means (SRM) (CIs were assessed using the bootstrap method of EFron) and derived the number of patients per arm in a putative trial to demonstrate 50% change, at 80% probability, α=0.05.

Results: 6,945 knees (3,667 subjects, 2,085 female) were included (KL 0: 2,796; KL1: 1,338 knees; KL2: 1,879 knees; KL3: 924 knees). Table 1 provides summary results and Figure 1 shows SRM and putative trial cohort numbers by KL grade for bone shape and cartilage thickness.

Conclusion: The Cellular Matrix PRP-HA combination might be one of the most potent, safe, fast and novel therapeutic option for osteoarthritis of the knee, as well as a useful tool for postponing arthroplasty surgery when it is necessary.

COST-EFFECTIVE OA TRIALS REQUIRE ENROLMENT OF KNEES WITH DEFINITE JOINT SPACE NARROWING (KELLGREN LAWRENCE 3); DATA FROM 6,939 KNEES FROM THE OSTEOARTHRITIS INITIATIVE

Michael Bowes1, Alan Brett1, Philip G. Connaghan2, 1Imorphics Ltd, Manchester, United Kingdom; 2University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: The design of clinical trials for osteoarthritis is challenging; structural changes in tissues are quantitatively small and proceed very slowly. No clear guidance exists on how to optimise recruitment. We have previously shown that the use of radiographic joint space width of 2 to 4.5 mm is of major importance for improving responsiveness in clinical trials using MRI bone and cartilage outcomes. However, it can be technically challenging to screen for joint space width this carefully, so we considered whether Kellgren-Lawrence (KL) grade could be used as an enrichment strategy. As no other commonly used covariates have been shown to reliably increase responsiveness, it would be useful to know the numbers needed using ONLY an expert-read KL grade structural inclusion criterion.

Objectives: To determine responsiveness of change in femur bone shape and cartilage thickness using a large observational dataset and calculate likely trial cohort sizes per arm for each KL grade.

Methods: We used all knees from the Osteoarthritis Initiative which had MR images at baseline, 1 and 2 years, and a baseline KL grade (centrally read and adjudicated by 2 experienced radiologists). Quantitative 3D femur bone shape, and cartilage thickness in the central medial femoral region were used as outcome measures. Responsiveness was assessed using standardised response means “SRM” (CIs were assessed using the bootstrap method of Efron) and derived the number of patients per arm in a putative trial to demonstrate 50% change, at 80% probability, α=0.05.

Results: 6,939 knees (3,667 subjects, 2,085 female) were included (KL 0: 2,796; KL1: 1,338 knees; KL2: 1,879 knees; KL3: 924 knees). Table 1 provides summary results and Figure 1 shows SRM and putative trial cohort numbers by KL grade for bone shape and cartilage thickness.

Conclusion: Expert-read KL3 inclusion, using 2 independent radiologists, with strict attention to standards provides increased responsiveness for common MRI OA outcomes. It is worth noting that 80% of KL3 knees have OARSI JSN grade 3, and 78% of KL3 knees have radiographic JSN of 2 to 4.5 mm, and similar enrichment can be expected using these alternatives. Few clinical studies can afford cohort sizes of greater than 200 knees, and for these studies, using a large proportion of KL3 knees is critical, especially if cartilage thickness is to be used as the outcome.
Abstract THU0425 – Figure 1. SRM and cohort numbers by KL grade for bone shape and cartilage thickness in 6,939 knees. Top row shows SRM values at 1 year (left) and 2 years for femur bone shape and central medial femur cartilage thickness, with 95% confidence limits calculated using a bootstrap method. Bottom row shows numbers needed per cohort arm, assuming 50% change, 80% probability, alpha 0.05. Units are in vector units for bone shape, and mm for cartilage thickness.

Abstract THU0426 – Table 1. Responsiveness of bone shape and cartilage thickness by KL Grade

Detailed breakdown of SRM values, cohort size, mean change, and SD of that change for Figure 1. Units are in vector units for bone shape, and mm for cartilage thickness.

THU0426 EFFECTS OF SODIUM SUCCINATE AND HYALURONIC ACID IN KNEE OSTEOARTHRITIS TREATMENT

Oleksandr Burianov1, Liudmyla Khimion2, Taras Omelchenko1, Halyna Havylyuk2, 1Bogomolets National Medical University, Traumatology and Orthopedic, Kyiv, Ukraine; 2Shupyk National Medical Academy of Postgraduate Education, Family Medicine, Kyiv, Ukraine

Background: At present hyaluronic acid (HA) is rather widely used in treatment of patients with osteoarthritis (OA). HA normalizes the properties of the synovial fluid; has a protective effects; promotes the cartilage nutrition and so improves the signs of OA and function of the joints. Sodium succinate (the salt of the succinic acid) helps to normalize intracellular metabolism and tissue respiration in hypoxic conditions via mitochondrial mechanism of action; normalizes acid – alkaline balance; takes part in K+ and Ca2+ transportation and provides antioxidant defense, - so is a promising compound for cartilage treatment

Objectives: To investigate the clinical efficacy of combination of hyaluronic and sodium succinate in treatment of early OA stages

Methods: The study included 126 patients with knee OA (stages I-II), Kelgren and Lawrence, mean age (54.3 ± 2.7) years, among them - 75 women (60%) and 51 men - (40%). All enrolled patients had OA exacerbation (without clinically evident synovitis) and received standard OA treatment (NSAIDs, exercises, orthopedic devices) for 15 days; Gr.1 patients (58) also got 5 intra-articular injections of 1.1% hyaluronic acid, stabilized with sodium succinate (2 ml, once a week); patients of Gr.2 (68) in addition to standard treatment received 5 intra-articular injections of 1.1% solution of non-stabilized HA (2 ml, once a week). Clinical observation and evaluation of the results were performed at the beginning of the treatment, at 6th, 12th and 24th week after the study beginning

Results: During the treatment period, patients in both groups showed the positive changes in clinical signs and symptoms of OA which led to the lowering of the WOMAC index (from (78.3 ± 4) to (75.4 ± 3.8) in Gr. 2 at the beginning of the study to (27.9 ± 2.6) and (29.8 ± 1.9) accordingly at week 12 (p<0.05 for both groups). The VAS score in both groups indicated a significant pain reduction, but the stability and duration of the clinical effect in the groups was different. In patients of Gr.1, the pain syndrome continued to decrease after 12 weeks till 24th week, whereas in Gr.2 after the treatment course there was no significant changes in further pain regression after 6th week point. The changes in Lisholm score were also significantly better in Gr.1 than in Gr. 2 (before treatment (21.7 ± 4.6) and (22.6 ± 5.3), at week 6 - (86.4 ± 5.7) and (71.3 ± 4.8), at week 12 – (87.6 ± 5.2) and (83.7 ± 5.3), respectively. p<0.05 between groups at week 12th

Conclusion: Combination of the hyaluronic acid and sodium succinate biochemical and physiologic properties in early stages of knee OA (as intra-articular injections) allows to increase the treatment efficacy, achieve better pain control, and more stable remission comparing to use of the hyaluronic acid alone

THU0427 THE LIFETIME RISK OF KNEE AND HIP REPLACEMENT FOLLOWING A GP DIAGNOSIS OF OSTEOARTHRITIS: REAL WORLD COHORT DATA FROM CATALONIA INCLUDING 48,311 PARTICIPANTS WITH UP TO 9 YEARS OF FOLLOW-UP

Edward Burn1, David W Murray2, Gillian A Hawker3,4, 5, Rafael Pinedo-Villanueva1, Daniel Prieto-Alhambra1, 6, 1Centre for Statistics in Medicine, NDOMS, University of Oxford, Oxford, United Kingdom; 2NDOMS, University of Oxford, Oxford, United Kingdom; 3Women’s College Hospital, Women’s College Research Institute, Toronto, Canada; 4Institute for Clinical Evaluative Sciences, Toronto, Canada; 5Department of Medicine, University of Toronto, Toronto, Canada; 6GIREMPAL Research Group, Idiap Jordi Gol and CBERFes, Universitat Autonoma de Barcelona and Instituto de Salud Carlos III, Barcelona, Spain

Background: The lifetime risk of knee and hip replacement following a primary care diagnosis of knee or hip osteoarthritis is unknown and overly negative beliefs about prognosis act as a barrier to implementing recommended management strategies.

Objectives: To estimate lifetime risk of knee and hip replacement following a GP diagnosis of osteoarthritis and assess how this risk varies with patient characteristics.

Methods: Primary care and linked hospital data from Catalonia, covering 2006 to 2015, were used. Study participants had a newly recorded GP diagnosis of knee or hip osteoarthritis. Parametric survival models were specified for risk of knee/hip replacement and death following diagnosis. Survival models were combined and extrapolated using a Markov model and lifetime risk estimated for the average patient profile. The effects of age at diagnosis, sex, comorbidities, socioeconomic status, body mass index (BMI), and smoking on risk were assessed.

Results: 48,311 individuals diagnosed with knee osteoarthritis were included with a median follow-up of 4.3 years (IQR: 2.1 to 6.5) and of whom 2,561 underwent knee replacement. Reference figures for hip osteoarthritis were 15,105 individuals diagnosed with a median follow-up of 3.8 years (IQR: 1.8 to 6.1) and 1,247 hip replacements. The average participants’ lifetime risk for knee replacement was 30% (95% CI: 25% to 36%) and for hip replacement was 14% (10% to 19%). Notable patient characteristics influencing lifetime risk were age at diagnosis for knee and hip replacement, sex for hip replacement, and BMI for knee replacement. BMI increasing from 25 to 35 was associated with lifetime risk of knee replacement increasing from 24% (20% to 28%) to 32% (26% to 37%) for otherwise average patients.

Conclusion: Knee and hip replacement are not bound to happen for most after a GP diagnosis of osteoarthritis, with average lifetime risks of less than a third and a sixth, respectively. Patient characteristics influence lifetime risks with, most notably higher BMI associated with a meaningfully increased risk of knee replacement.

Background: Even though Neuromuscular electrical stimulation (NMES) has been widely used as a non-pharmacological intervention in patients with knee osteoarthritis (OA) to improve muscle strength and function, prior research has shown conflicting results regarding NMES effectiveness in knee OA treatment.

Objectives: The aim of this systematic review and meta-analysis was to investigate the effectiveness of NMES in muscle strengthen, pain, and function in individuals with knee OA.

Methods: Only randomized controlled trials (RCTs) were included in this study. Two authors independently performed the study selection. We used Pubmed, Embase, LILACS, PEDro and Cochrane Central Register of Controlled Trials as data sources. The main outcome evaluated was muscle strength. Function and pain were assessed as secondary outcomes using the Western Ontario Macmaster (WOMAC) questionnaire and Timed up and go (TUG) test. The methodological quality was assessed using PEDro scale.

Results: A total of 23,215 were initially identified. After selection of titles and abstracts, studies were selected for the full-text analysis, ten studies were included with a total sample size of 622 patients. The methodological quality of the selected studies was moderate, with a mean score of 5.5 on a 0-10 scale (PEDro). The following analysis were performed:

Legend: Data homogeneity (Chi² = 5.03; I² = 21%) was identified, with no significant difference in favor of NMES (Z = 0.07, p = 0.95). NMES - Neuromuscular electro stimulation.

Conclusion: NMES increased muscle strength in patients with OA compared to the active control group. However, the evidence to date did not demonstrate effects for pain control nor improvement in physical function.

Table: Results of four separate multiple linear regression models with the WOMAC as the dependent variable. Regression coefficients with 95% confidence intervals are shown.

Discussion: The outcome of the consultation.

Results: No differences between groups were observed on the 3 subscales of the COQ (group difference (95% CI): communication 0.009 (-0.10, 0.12), conduct -0.02 (-0.12, 0.07) and information provision 0.02 (-0.18, 0.21)). Between group differences (95% CI) were in favour of the intervention group for knowledge (1.4 (0.6, 2.2)), negative beliefs regarding physical activity (-0.12 (-0.23, -0.02)) and pain medication (-0.30 (-0.49, -0.01)). We found no differences on other secondary outcomes.

Conclusion: An educational eHealth tool to prepare a first orthopaedic consultation for hip or knee OA does not result in higher patient satisfaction with the consultation, but it does influence cognitions about osteoarthritis.

Preparing an Orthopaedic Consultation Using an EHealth Tool: A Randomized Controlled Trial in Patients with Hip and Knee Osteoarthritis

Aneke Claassen1, Henk J Schers2, Vincent Jf Busch3, Petra Heesterrebeek4, Frank van den Hoogen1,1, Thea Vliet Vlieland2, Cornelia van den Ende1,1, Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands; 2Radboud University Medical Center, Department of Primary and Community Care, Nijmegen, Netherlands; 3Sint Maartenskliniek, Department of Orthopaedic Surgery, Nijmegen, Netherlands; 4Sint Maartenskliniek, Sint Maartenskliniek Research, Nijmegen, Netherlands; 5Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands; 6Leiden University Medical Center (LUMC), Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands

Background: Hip and knee OA patients who are referred to an orthopaedic surgeon often expect action to be taken.1 However, the majority of those patients is not (yet) eligible for a joint replacement.2,3 We hypothesized that a solid preparation using the eHealth tool is likely to streamline patients’ expectations and increase satisfaction, irrespective of the outcome of the consultation.

Objectives: To evaluate the effect of a stand-alone mobile and web-based educational intervention (eHealth tool) compared to usual preparation of a first orthopaedic consultation of patients with hip or knee osteoarthritis (OA) on patients’ satisfaction.

Methods: A two-armed unblinded randomized controlled trial involving 286 patients with (suspicion of) hip or knee OA, randomly allocated to either receiving an educational eHealth tool to prepare their upcoming consultation (n=144) or usual care (n=142). Satisfaction with the consultation on three subscales (range 1-4) of the Consumer Quality Index (CQI - primary outcome) and knowledge (assessed using 22 statements on OA, range 0-22), treatment beliefs (assessed by the Treatment beliefs in OsteoArthritis questionnaire, range 1-5), pain medication use (yes/no), assessment of patient’s involvement in consultation by the surgeon (assessed on a 5-point Likert scale) and patient satisfaction with the outcome of the consultation (numeric rating scale), were assessed.

Results: No differences between groups were observed on the 3 subscales of the COQ (group difference (95% CI): communication 0.009 (-0.10, 0.12), conduct -0.02 (-0.12, 0.07) and information provision 0.02 (-0.18, 0.21)). Between group differences (95% CI) were in favour of the intervention group for knowledge (1.4 (0.6, 2.2)), negative beliefs regarding physical activity (-0.12 (-0.23, -0.02)) and pain medication (-0.30 (-0.49, -0.01)). We found no differences on other secondary outcomes.

Conclusion: An educational eHealth tool to prepare a first orthopaedic consultation for hip or knee OA does not result in higher patient satisfaction with the consultation, but it does influence cognitions about osteoarthritis.

Frequency of Tendon Involvement and Its Effect on Hand Function in Hand Osteoarthritis

Irina Geiss1, Anna Vinatzer1, Gabriela Supp2, Michael Zauner1, Michaela Loikandl3, Martina Durechova1, Valentin Ritsch1, Josef S. Smolen1, Daniel Aletaha1, Peter Mandl1, 1Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria; 2Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria; 3Medical University of Vienna, Section for Outcomes Research, Vienna, Austria

Background: Tenosynovitis and consequent tendon damage are common findings in inflammatory arthritides. In contrast to rheumatoid arthritis (RA) and psoriatic arthritis, little is known about the frequency of tendon involvement in hand osteoarthritis (HOA) and the influence thereof on hand function. Ultrasound has been reported to have a high specificity in diagnosing tenosynovitis and tendon damage.

Objectives: We aimed to appraise the frequency of tendon involvement in HOA and to assess the agreement between ultrasound (US) and clinical diagnosis of tenosynovitis and tendon damage in HOA. In addition, we wanted to assess the influence of tendon involvement on hand function.

Methods: We included 73 patients with HOA in the study. Each patient underwent a clinical as well as a US examination of the 6 extensor tendon compartments and 6 flexor tendons of the hand (fig. 1). They were assessed for US signs of tenosynovitis and tendon damage as well as osteophytes (presence/absence) by a sonographer blinded to clinical information, as well as for clinical tendon involvement (presence/absence) by a biometrician blinded to the US results. Difference in frequency of sonographically detected tendon involvement between flexor and extensor tendons and between right and left hand were calculated by Chi-Square test. Osteophytes were also evaluated on standard radiographs. Agreement between US and clinical examination was calculated by Cohen’s kappa. Hand function was quantified using the Score for the Assessment and Quantification of Chronic Rheumatoid Affections of the Hands (SACRAH) questionnaire as well as the Mobberg pick-up test (MPUT). Correlation between MSACRAH and tendon involvement was calculated by Spearman’s correlation.

Results: In 41 patients (56.2%), at least one tenosynovitis was observed and in 8 (11%) patients, at least one tendon damage was detected by US. Tendon damage was found more often in flexor tendons (0.2% vs. 2.2%, p<0.001), while tenosynovitis was found more often in extensor
Abstract THU0431 – Figure 1.

Conclusion: This study revealed a high frequency of tendon involvement in HOA. The prevalence of tenosynovitis was similar as reported for RA and other inflammatory arthritides. The fact that we could demonstrate marked differences in the distribution of tenosynovitis and tendon damage between and among flexor and extensor tendons as assessed on US, coupled with the overall homogenous clinical involvement, suggests that clinical examination may be less specific for tendon involvement as compared to US. Tendon involvement on US does not seem to have an impact on hand function in HOA.

THE BURDEN OF OSTEOARTHRITIS PAIN FROM THE PATIENT’S PERSPECTIVE IN EUROPE

JamesJackson1, WenHuiWen2, PavinaHubanova3, NathanWilliams3, JenniferMellow1, PaulLee1, Adelephi Real World, Cheshire, United Kingdom; 2Regeneron Pharmaceuticals, Inc, Tarrytown, United States of America; 3Teva Pharmaceutical Industries, Frazer, United States of America

Background: Pain, the primary symptom of osteoarthritis (OA), affects multiple aspects of a patient’s life.

Objectives: To evaluate the burden of OA pain from the patient’s perspective in 5 European countries (France, Germany, Italy, Spain, the United Kingdom; EUS).

THU0432

LUMBAR FACET JOINT OSTEOARTHRITIS IS A RISK FACTOR OF SACROILIAC JOINTS DEGENERATION

Zhi-xiang Huang1, Li Guo-Chao2, Qi Min2, Shi-Yu Wang2, Wei-Ming Deng1, Li Tian-Wang1. Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2Ganzi Tibetan Autonomous Prefecture People’s Hospital, Department of Rheumatology and Immunology, Ganzi Tibetan Autonomous Prefecture, China

Background: Degeneration of sacroiliac joints (SLJ) is common in the general population, which associates with age, gender and body mass index (BMI). This degenerative disease relates to various lumbar disorders. Lumbar facet joint osteoarthritis (LFJOA) is highly prevalent, but relationship between this disease and SLJ degeneration remains poorly evaluated.

Objectives: This study aimed to investigate the relation between LFJOA and SLJ degeneration. We hypothesized that LFJOA patients might suffer more serious SLJ degeneration, thus multiple linear regression was employed to compare the effect of LFJOA and demographic characteristics on degeneration of SLJ.

Methods: We reviewed pelvic and lumbar computed tomography (CT) examinations of LFJOA patient with low back pain (LBP) through a picture archiving and communication system. The controls were age, gender and BMI-matched individuals who were free of LFJOA and LBP, and underwent pelvic and whole abdomen CT scans due to the non-musculoskeletal symptoms. Severity of SLJ degeneration was scored using a quantitative method which has been described by Bäcklund et al [1]. LFJOA was graded using a method which has been mentioned by Weishaupt et al [2]. Briefly, this method concerns facet joint space, osteophytes, hypertrophy of the articular processes, and subarticular bone erosions, which ranges from 0 to 3 for a joint. If there is a discrepancy between 2 joints in the same level, the greater one was used. LFJOA was defined as at least one level ≥2 from L1-2 to L5-S1. Scores of SJU degeneration were compared between LFJOA patients and the controls. Correlation analysis between SJU degeneration score and number of LFJOA levels, number of LFJOA joints, sum of LFJOA grades were performed. Stepwise multiple linear regression model was used to find the most important contributor of SJU degeneration among LFJOA, gender, age and BMI.

Results: (1) CT examinations of 992 LFJOA patients and 399 controls were reviewed. (2) Score of SJU degeneration in LFJOA patients were higher than that of the controls (8.85±2.94 vs. 4.31±2.52, P<0.05). (3) SJU degeneration score positively correlated with number of LFJOA levels (r=0.11, P<0.05), number of LFJOA joints (r=0.09, P<0.05) and sum of grades (r=0.10, P<0.05). (4) Results of multiple linear regression were shown in Table 1. LFJOA had the greatest standardized coefficient in the regression model.

Conclusion: LFJOA patients suffers more significant SJU degeneration, and more severe LFJOA leads to more serious SJU degeneration. Influence of LFJOA on SJU degeneration is stronger than demographic characteristics.

KNEE JOINT DISTRACTION AS STANDARD OF CARE
TREATMENT FOR KNEE OSTEOARTHRITIS: A COMPARISON WITH CLINICAL TRIAL PATIENTS

Mylène Jansen1, Simon Mastberger2, Michelle Van Eijmen2, Esmee Kester2, Farris Latif3, Roel Custers2.1 University Medical Center Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands; 2University Medical Center Utrecht, Orthopedic Surgery, Utrecht, Netherlands

Background: Knee joint distraction (KJD) has been evaluated as joint-preserving treatment for patients with knee osteoarthritis (OA) in 3 clinical trials since 2004. KJD aims to delay a total knee arthroplasty (TKA) in serving treatment for patients with knee osteoarthritis (OA) in 3 clinical trials since 2004. KJD showed cartilage regeneration and clinical improvement. Since 2014, KJD is a standard of care treatment option in several Dutch hospitals for younger (<65 yrs) knee OA patients.

Objectives: Compare baseline characteristics and clinical outcome at 1 year post-treatment between KJD patients treated in regular care vs study conditions.

Methods: In the OPS, patients (n=20; age <60 years) with end-stage OA indicated for TKA were treated with KJD for 8 weeks between 2004 and 2006. In an RCT comparing KJD with TKA, end-stage knee OA patients considered for TKA were treated with KJD (n=19; age <65 years) and completed 1-year follow-up. In an RCT comparing KJD with HTO, medial knee OA patients considered for HTO were treated with KJD (n=22; age <65 years). In both RCTs, patients were treated with KJD for 6 weeks between 2011 and 2014. From 2014-2017, 84 patients were treated with 6-week KJD in regular care and available for 1-year follow-up.

All distraction surgery was performed using two external fixators with built-in springs. The knee was distracted 5 mm and weight-bearing was supported. WOMAC questionnaires were assessed at baseline (0) and 12 months. Only regular care patients completed both questionnaires were included in analyses.

Abstract THU0434 –Table 1.

Baseline patient characteristics were compared between ‘study’ (OPS/ RCT) and ‘regular care’ patients. For each group, the total WOMAC scores and subscales at follow-up were compared to baseline. The influence of different characteristics on the 1-year change in WOMAC scores was analyzed. Characteristics predicting being a responder to KJD treatment were analyzed according to the OMERACT-OARSI responder criteria, defined as an increase of ≥50% and ≥20 points in WOMAC pain or function scales, or a ≥20% and ≥10-point improvement in both scales.

Results: In regular care, 41 patients completed both questionnaires. Base-line characteristics for both groups are shown in table 1, showing a significant, but small difference in distraction duration, which was longer for study patients, but shorter when excluding the OPS patients who received distraction 2 weeks longer. The total WOMAC score and subscales for both groups increased significantly at 1 year compared to baseline (figure 1). The increase in total WOMAC and all subscales was over 15 points and thus clinically significant for both groups. The increase in the WOMAC function subscale was statistically, but not clinically, significantly higher for study patients (6.7 points) than regular care patients, while the total WOMAC, pain and stiffness were not different between groups (figure 1). After 1 year, 69% of patients were responders (60% regular care, 75% study patients, p=0.120). None of the baseline characteristics could significantly predict being a responder or had a significant influence on the increase in total WOMAC.

**Abstract THU0434 – Figure 1**

Conclusion: KJD results in a statistically and clinically significant 1-year improvement in total WOMAC and subscales for most patients. There were no clinically relevant differences between study and regular care patients. Longer follow-up will show whether this is maintained. As such, KJD not only shows good efficacy in study conditions, but also in regular care and can be a joint-preserving treatment of choice for young knee OA patients.

**THU0435 ASSESSING THE EFFECTS OF PULSED ULTRASOUND TREATMENT ON PAIN, FUNCTIONALITY, SYNOVIAL FLUID AND CARTILAGE THICKNESS, IN KNEE OSTEOARTHRITIS**

Ali Karakas1, Muhammed Abdulkerim Şahin2, Hülya Ellidokuz3, Banu Dilek2, Özlem Şenocak2.

1Dokuz Eylül Üniversitesi Hastanesi, Department of Physical Medicine and Rehabilitation, Department of Rheumatology, izmir, Turkey; 2Dokuz Eylül Üniversitesi Hastanesi, Department of Physical Medicine and Rehabilitation, izmir, Turkey; 3Dokuz Eylül Üniversitesi Hastanesi, Institute of Oncology, Department of Preventive Oncology, Izmir, Turkey

**Background:** Osteoarthritis (OA) is a progressive rheumatic disease which is the most common cause of musculoskeletal pain and functional impairment, particularly in the elderly group. Ultrasound therapy is one of the most commonly used physical modalities in the OA treatment. It has deep heating effect and increases tissue regeneration, blood flow and metabolic effects while reducing the inflammation. In addition, it increases the cartilage regeneration according to certain in vivo and in vitro studies (1).

**Objectives:** To research the effect of pulsed ultrasound treatment on pain, functionality, synovial fluid and cartilage thickness in knee osteoarthritis.

**Methods:** This study was a randomised-controlled and parallel group study. 96 patients (79 females and 17 males) were included to study who had knee pain, aged between 45-75 years. They also have diagnosed as knee osteoarthritis according to ACR diagnostic criteria and their Kellgren-Lawrence grades were <3. These patients were divided in two groups randomly: Treatment group (exercise + US), (9 male, 39 female), control group (exercise + Sham US), (8 male, 40 female). The patients in the treatment group were treated with a 1 MHz probe and a density of 1w/cm², 1: 4 for 10 minutes, and 3 sessions a week for 8 weeks. Sham US treatment was applied to each group at the same time. Both groups received a home exercise program including knee range of motion and isometric strengthening exercises. All patients were evaluated by ultrasonographic measurements and quality of life tests; VAS (Visual Analog Scale) rest, VAS walking, Timed Up and Go Test, WOMAC Questionnaire scores (before treatment, after treatment, 3 months after treatment).

**Results:** 9 out of 48 patients in the treatment group and 12 out of 48 patients in the control group were excluded from the study because they did not continue treatment or come to the control. The distribution of groups was similar (Table-1). VAS rest, VAS walking, Timed up and go test, WOMAC questionnaire scores, were improved statistically significant in both groups (P<0.05), but group effect could not be demonstrated (P>0.05) There were no statistically significant results in terms of both synovial fluid and femoral cartilage thickness measurements (P>0.05) (Table 2).

**Conclusion:** Therapeutic ultrasound treatment in addition to home exercise program has not been shown to be effective rest and walking pain, functionality, synovial fluid and femoral cartilage thickness in the treatment of knee osteoarthritis. This is the first study to evaluate the effect of therapeutic intermittent ultrasound on synovial fluid and cartilage thickness by
ultrasound, international collaborative studies and randomized clinical trials will help in clarifying these areas of uncertainty.

THU0436
THE RELATIONSHIP OF BONE MINERAL DENSITY OF THE AXIAL SKELETON ON THE RISK OF PROGRESSION OF OSTEARTHRITIS OF THE KNEE

Natalia Kashevarova, Elena Taskina, Ludmila Alekseeva, Nikolay Demin, Aleksandr Lila. VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: To find the relationship between bone mineral density (BMD) and risk of knee OA progression in a 5-year prospective study.

Methods: 110 females with knee OA were examined twice with 5-year interval. Examination included filling questionnaires, VAS pain assessment, plain knee radiography and axial skeleton densitometry. I stage knee OA was established in 33 (30%) patients, II stage - in 46 (41.8%), III stage - in 26 (23.6%), and IV - in 5 (4.5%). Normal lumbar vertebral densitometry BMD values were found in 45 patients (40.9%), osteopenia-corresponding BMD values - in 33 (30.0%), and osteoporosis - in 32 (29.1%). Normal femoral neck BMD values were identified in 60 (54.5%) patients, osteopenia-level BMD - in 48 (43.7%), osteoporosis - in 2 (1.8%). In all premenopausal patients (n = 15) axial skeleton BMD values were normal.

Results: In 5-year interval radiographic progression was established in 40 patients (Group 2), while in 70 (Group 1) patients no progression occurred. Both groups were comparable in terms of age and disease duration, although, more patients from Group 2 tended to have normal baseline densitometry BMD values - both in lumbar vertebral and femoral neck: 47.5% vs 37.1%, and 62.5% vs 44.3% as compared to Group 1 patients. Patients from Group 1 more often had BMD values corresponding to osteoporosis and osteopenia: 32.9% vs 22.5%, and 55.7% vs 37.5%, respectively, as compared to Group 2 patients, although not achieving statistical significance. These differences were still identifiable after 5-year interval. Absolute BMD values at the second examination in 5 years were indicative of statistically significant increase in femoral neck and total hip BMD in Group 2 patients with knee OA progression: 0.79 ± 0.11 vs 0.73 ± 0.16, p<0.01, and 0.93 ± 0.14 vs 0.84 ± 0.25, p<0.05, respectively.

<tr>
<td>III stage</td>
<td>0.16±0.13</td>
</tr>
<tr>
<td>IV stage</td>
<td>0.15±0.14</td>
</tr>
</tbody>
</table>

Thorough analysis of lumbar vertebrae BMD (g/cm²) relationship with OA stages revealed that in patients with stage IV OA lumbar BMD values were significantly higher than in patients with stages I-II OA (stage I OA - BMD 0.87±0.12 g/cm²; stage II OA - 0.92±0.21 g/cm²; stage III OA - 0.88±0.13 g/cm², stage IV OA - BMD 1.07±0.17 g/cm²) (Table1). Femoral BMD values didn’t show evident correlation with knee OA stage, although there was a trend towards higher BMD values in patients with stage IV OA compared to stage III OA (p = 0.06). Total hip BMD values were quite similar to lumbar BMD values (p = 0.01) (Table 2). BMD values were statistically significantly higher in patients with stage IV OA, than in patients with stages I and III (respectively, IV - 0.98 ± 0.13 g/cm², I - 0.85 ± 0.10 g/cm² and III - 0.86 ± 0.16 g/cm²). Correlation analysis also confirmed direct correlation between knee OA stage and BMD values in all evaluated compartments (p<0.05).

Conclusion: Increasing during the 5-year follow up period femoral neck and total hip BMD values can be interpreted as the predictor of knee PA progression. More advanced OA stages are associated with higher BMD values. Future multicenter prospective studies are deemed to better establish the correlation between BMD and knee OA progression.

THU0437
INCIDENCE OF OSTEOARTROPOIC FRACTURE IN PATIENTS WITH KNEE OSTEOARTHRITIS: CLINICAL IMPACT OF FRAX-BASED OSTEOPOROSIS TREATMENT

Bo Young Kim, Sung-Soo Kim. Gangneung Asan Hospital, Division of Rheumatology, Gangneung-si, Gangwon-do, Korea, Rep. of (South Korea)

Background: The relationship between osteoporosis and osteoarthritis is complex and controversial. Several previous studies have indicated inverse relationship between osteoporosis and osteoarthritis [1-2]. However, the increased bone mineral density in osteoarthritis does not confer a reduce risk for fractures in other studies [3-4]. From the Rotterdam study, although patients with knee osteoarthritis had a higher bone mineral density, their incident fracture risk was increased as compared with those without knee osteoarthritis [5]. Therefore, fracture risk assessment in patients with knee osteoarthritis should not be overlooked.

Objectives: We aimed to evaluate the incidence of high risk group of osteoporotic fracture in patients with knee osteoarthritis comparing the FRAX and WHO criteria. We also examined whether patients with knee OA differ from age, sex, and BMI matched community-based control group without knee OA in terms of the incidence of high risk group of osteoporotic fracture.

Methods: We retrospectively assessed 282 Korean patients with knee OA who visited 5 medical centers between November 2012 and November 2015. For control group, 991 subjects aged of > 50 years-old were enrolled in database of health checkup centers. After matching for age, sex and body mass index, 552 subjects (276 subjects in knee OA group and 276 subjects in control group) included for this study.

Results: Osteoporosis according to WHO criteria was detected 110 (39.86%) subjects in OA group, and 101 (36.59%) subjects in control group; these difference were not significant. However, mean FRAX major osteoporotic fracture probabilities calculated with femur neck T-score were significant different between OA group and control group (7.72% vs 6.10%, p<0.001). Mean FRAX major osteoporotic fracture probabilities calculated without femur neck T-score were also significant different between OA group and control group (8.85% vs 6.86%, p<0.001). Mean FRAX hip fracture probabilities calculated with femur neck T-score were significant different between OA group and control group (2.48% vs 1.73%, p<0.001). Mean FRAX hip fracture probabilities calculated without femur neck T-score were also significant different between OA group and control group (3.50% vs 2.37%, p<0.001). When FRAX calculations without the use of femur neck BMD was adjusted for knee OA group rather than control group, 5.9% more patients would be recommend for osteoporosis treatment. Among the clinical risk factors of FRAX, previous fracture was significant different between knee OA group and control group (15.9% vs 0%, p<0.001).
Conclusion: We demonstrated that knee OA patients have an increased risk of osteoporotic fracture according to FRAX criteria, but not WHO criteria. Our study suggests that FRAX supports clinical decision to reduce the risk of osteoporotic fracture in patients with knee OA.

DO CORTICOSTEROIDS OR HYALURONIC ACID INTRA-ARTICULAR INJECTIONS IMPACT THE RISK OF TOTAL KNEE REPLACEMENT? REAL-LIFE DATA FROM THE KHOALA COHORT

Augustin Latourte1,2, Anne-Christine Rat3,4, Willy Nguyen Sime5, Abdou Omorou6,7, Florent Eymard8,9, Jeremie Sellam10, Christian Roux6,7, Francis Guillemin4,5, Pascal Richette2,9.

1Hopital Lariboisière, Rheumatology, Paris, France; 2Duke-NUS Medical School, Singapore, Singapore; 3CHU Pasteur 2, Nice, France; 4CHU Lariboisiere, Rheumatology department, Paris, France; 5CHRU Nancy, Rheumatology Department, Vandoeuvre les Nancy, France; 6Lomane University, EA 4380, Nancy, France; 7CHRU Nancy, Inserm CIC 1433 Epidémiologie clinique, Vandoeuvre les Nancy, France; 8Henri Mondor Hospital, Créteil, France; 9Saint Antoine Hospital, Rheumatology department, Paris, France; 10CHU Pастeur 2, Nice, France; 9Hopital Lariboisiere, Rheumatology department, Paris, France

Background: Long-term structural outcomes of corticosteroids (CS) or hyaluronic acid (HA) intra-articular injections in knee osteoarthritis (KOA) are unclear. Whether HA injections delay the need for total knee replacement (TKR) remains controversial, and an increased risk of cartilage damage has been reported with repeated CS injections.

Objectives: We conducted this study to compare, in real-life setting, the risk of TKR in patients receiving CS or HA vs. in those who did not receive intra-articular injections.

Methods: Khoala cohort is a French nationwide population-based cohort of 878 patients with symptomatic hip or knee OA (ACR criteria), aged 40-75 years. This study included patients with baseline KOA only. Patients were followed annually by self-reported questionnaires and by clinical examination and radiography at baseline (year 0), years 3 and 5.

The risk of incident TKR was compared between patients who had never received intra-articular injections vs. patients who received at least 1 CS or HA injection during follow-up.

The model allows for adjustment for time-varying confounding factors (i.e. pain, function and mental health scores) in addition to constant confounders (i.e. baseline age, sex, BMI, Kellgren-Lawrence grade).

Results: This study involved 656 patients (mean age 62.2 ± 8.5 years; 70.3% females) of which 91 (13.9%) underwent TKR during follow-up. CS or HA injections were performed in 143 (21.8%) and 191 (29.1%) patients, respectively, and 92 (14.0%) received both treatments. The 5-year relative risk of incident TKR in treated vs. untreated knee was 0.98 (95% CI 0.35 to 2.66; p=0.94) CS-treated knees and 0.38 (95% CI 0.15 to 1.03; p=0.06) in HA-treated knees.

Conclusion: In this study, CS injections for symptomatic KOA did not increase the 5-year risk of incident TKR. There was a non-significant trend for a reduced risk of TKR in HA-treated knees.

THU0440 – THE ASSOCIATION OF PLASMA FATTY ACIDS LEVELS WITH HAND AND KNEE OSTEOARTHRITIS

Mareike Loef1, Andrea Ioan-Facsinay1, Dennis Moock2, Ko Willems van Dijk3, Renée de Mutsert3, Margreet Rospenkrog2,3, Frits Rosendaal3,1, LUMC, Rheumatology, Leiden, Netherlands; 2LUMC, Epidemiology, Leiden, Netherlands; 3LUMC, Human Genetics, Leiden, Netherlands

Background: Obesity is one of the most important risk factors for osteoarthritis (OA). For long the association between obesity and OA was thought to be explained by increased mechanical loading. However, the role of systemic factors is increasingly recognized, especially in non-weightbearing joints. Obesity is strongly associated with increased levels of circulating fatty acids, which may result in lipotoxicity. However, our knowledge about the effect of different fatty acids on OA is sparse.

Objectives: To investigate the association of plasma saturated fatty acids (SFAs), monounsaturated fatty acid (MUFAs), polyunsaturated fatty acids (PUFAs), omega (n-3) and n-6 PUFAs with clinically defined hand and knee OA.

Methods: In the population-based Netherlands Epidemiology of Obesity (NEO) study, a total of 6,671 middle-aged participants were recruited from the greater area of Leiden. Clinical hand and knee OA were defined by the ACR clinical classification criteria. Blood samples were obtained after an overnight fast and 150 minutes after consumption of a standardized liquid mixed meal containing 600kCal, with 16% of energy (En%) derived from protein, 40 En% from carbohydrates and 34 En% from fat. EDTA-plasma samples were used for a high-throughput proton nuclear magnetic resonance (NMR) metabolomics platform (Nightingale Health Ltd., Helsinki, Finland) to quantify 159 lipid and metabolite measures. For the present analyses the concentrations of fasting and postprandial total fatty acids, SFAs, MUFAs, PUFAs, n-6 PUFAs and n-3 PUFAs in mmol/l were used. Since we are in a postprandial state most of the day, these samples were used for the primary analyses. All fatty acid concentrations were standardized (mean 0, SD 1), to ensure a similar interpretation of the estimated effect. We excluded participants who reported to have inflammatory rheumatic disease or fibromyalgia, with missing physical examination, who were non-fasting at baseline, or reported using lipid-lowering medication. Logistic regression analyses were used to investigate the association between fatty acids and clinical OA phenotypes. All analyses were stratified by sex and corrected for age, education, ethnicity and total body fat percentage. Data are presented as odds ratios (OR) with 95% confidence intervals (CI).

Results: In the current analysis 5,328 NEO participants were included, with a mean age of 56 years and 56% were women. Hand OA, knee OA and concurrent hand and knee OA were defined in 8%, 10% and 4% of participants, respectively. After correction for possible confounders, total fatty acids, SFA, total PUFA and omega-3 PUFA levels were positively associated with clinical hand OA in men, with OR (95% CI) of 1.24 (1.01 – 1.50), 1.23 (1.00 – 1.50), 1.26 (1.00 – 1.58) and 1.24 (1.01 – 1.52), respectively. Although not significant, similar effect estimates were observed for men with concurrent hand and knee OA, but not for clinical knee OA alone. In women no associations were seen of any of the fatty acids with clinical hand or knee OA. Analyses of the association between fasting fatty acid levels and clinical hand and knee OA showed rather similar results, with slightly lowered ORs and wider confidence intervals.

Conclusion: Quantitatively measured plasma postprandial SFA and PUFA levels were significantly associated with hand OA in men. In women no associations were found. Intriguingly, although SFA and omega-3 PUFAs are deemed to have opposing effects on inflammation, both were positively associated with hand OA. Future research is warranted to replicate the association and determine whether there is a causal role for plasma fatty acid levels in hand OA.

**THU0441**

**IMPROVED KNEE PHYSICAL FUNCTION CORRELATES SIGNIFICANTLY WITH TIBIOFEMORAL CARTILAGE THICKNESS INCREASE AFTER IA TPX-100: RESULTS OF A POST HOC ANALYSIS**

Dawn McGuire1, Neil Segal2, Samy Metyas3, Richard Barthe4, Meg Miller5, David Rosen6, Yoshinari Kumagai7, OrthoTrophix, Inc., Oakland, United States of America; 2University of Kansas Medical Center, Kansas City, Renabilitation Medicine, Kansas City, United States of America; 3Covina Arthritis Clinic, Covina, United States of America; 4Cottage Health, Santa Barbara, United States of America; 5OrthoTrophix, Inc., Preclinical Research, Oakland, United States of America

**Background:** In new draft guidance for OA drugs, the U.S. FDA notes the “well-recognized discordance” in clinical trials between structural imaging and patient benefit. In a randomized doubleblind, placebo-controlled trial, IA TPX-100 was associated with statistically significant and clinically meaningful improvement in knee functions among subjects (n=93) recruited for mild-moderate (ICRS grades 2-3) bilateral patellofemoral OA. No treatment differences in PF cartilage were detected, consistent with FDA concerns. However, only 14% of knees had measurable PF cartilage change on follow-up MRIs, limiting power for analysis of treatment differences in PF cartilage (ACR/ACHP 2017).

**Objectives:** To conduct a subset analysis of knee function and cartilage thickness correlations among the 73% of subjects (n=68) who had, in addition to PFOA, bilateral tibiofemoral OA (TFOA).

**Methods:** Subjects received 4 weekly injections of IA TPX-100 in one knee and identical saline placebo in the contralateral knee, as randomly assigned. MRIs were obtained at baseline, 6 and 12 months; and patient-reported outcomes (KOOS/WOMAC) were obtained at baseline, 3, 6 and 12 months. Subjects, sites, sponsor and central readers were blind to treatment assignment. All subjects receiving 4 weekly injections of 200 mg TPX-100 with at least one follow-up MRI were included for efficacy. The database was locked prior to all analyses, and clinically meaningful differences in outcome measures were selected a priori, based on the literature (Roos 2003).

**Results:** Of 68 subjects with bilateral TFOA, 47% had ICRS grade 4 (severe) TFOA at baseline, and 43% had ICRS grade 3 (moderate) disease. Demographic data for the cohort were consistent with the U.S. OA population in mean age (60.8 years), BMI (30.6), and gender distribution (60% females). IA TPX-100 was safe and well tolerated, with no drug-related serious adverse events or safety concerns. The mean functional improvement of TPX-100-treated knees was significantly higher than that of placebo-exposed knees at 6 and 12 months (p<0.004 and p<0.02, respectively). Responder knees, defined a priori with ≥8 points increase in KOOS physical function, had mean improvements in function of 20.5 and 22.4 at 6 and 12 months, respectively. Pearson analysis revealed a significant positive 12-month correlation (p=0.05) between degree of functional improvement and cartilage thickness increase/stabilization in TF cartilage in TPX-100-treated knees (Table 1).

**Table 1.**

**Conclusion:** In subjects with bilateral TFOA, statistically significant and clinically meaningful robust functional improvements in TPX-100-treated knees were seen at 6 and 12 months compared with placebo-exposed knees. Formal analysis revealed statistically significant correlations between functional improvement and increase or stabilization of lateral, medial and total TF cartilage thickness. To our knowledge, TPX-100 is the first candidate DMOAD to show improvement in critical knee function concordant with increase/stabilization of cartilage structure compared with placebo-exposed knees.

**THU0442**

**SOCIAL VULNERABILITY AND DISCHARGE DISPOSITION AFTER ELECTIVE TOTAL HIP REPLACEMENT? RISK-ADJUSTED ANALYSIS OF LARGE REGIONAL DATASET**

Bella Mehta1, Susan Goodman1, Kaylee Ho2, Debra D’angelo2, Michael Parks3, Said Ibrahim2, 1Hospital for Special Surgery, Main Campus, New York, United States of America; 2Weill Cornell Medical College, New York, United States of America

**Background:** With the aging of the world population and the rising prevalence of Osteoarthritis (OA), elective joint replacement (JR) has become one of the fastest growing procedures in the management of end-stage OA. There is also increasing evidence that social determinants of health such as where one lives impact healthcare utilization and decision-making. Furthermore, elective JR of the hip and knee is one of the most important cost-centers for Medicare, the largest payer in the US, and has therefore been the subject of ongoing payment reform models that shape discharge destination and risk of readmission.

**Objectives:** In a large regional dataset, we sought to examine how social vulnerability impacts discharge destination after elective THR, and what is the role in this relationship of patient race, another key social determinant of health which has been previously associated with disposition after surgery.

**Methods:** We used the Pennsylvania Health Care Cost Containment Council (PHC4) database to identify all patients who underwent elective THR between 2012 and 2016. Community level Social Vulnerability Index (SVI) was derived from the American Census Survey, which draws 15 different measures of vulnerability including socioeconomic, housing, and disability among others. SVI ranges from 0 (least vulnerable) to 1 (most vulnerable). SVI was dichotomized into low versus high (median) and high (above median). We used binary logistic regression to test the association between community SVI and discharge disposition: Institution (Nursing home or inpatient rehabilitation vs Home). We adjusted for important clinical, demographic, and facility level covariates.

To examine the role race (African American (AA) vs White) in this relationship, we included in the model an interaction term for SVI and race.

**Results:** There were a total 86,215 THR done between Jan 2012 and Dec 2016 that met our inclusion criteria. About 40,881 were ≥65 years of age, and 45,334 were ≥65 years of age. Patients from low SVI community went to high volume hospitals as compared to high SVI in all age groups. Figure 1 shows the geospatial localization and relationship of THR patients in the State of Pennsylvania by community SVI level. Compared to white patients, AA patients were more likely to live in higher SVI communities (median SVI AA 0.66; IQR 0.48-0.83 vs median SVI W 0.42; IQR 0.28-0.55, respectively). Compared to low SVI communities, patients from high SVI communities were more likely to be discharged to an institution (vs home) for age <65, aOR= 1.11, 95% CI: 1.07-1.16, p<0.001). The odds of discharge to an institution (vs Home) for patients living in high SVI communities (vs low SVI) was higher in AA compared to whites in all age groups. [Figure 2].

**Conclusion:** In this large regional dataset of patients who underwent THR, social vulnerability index of the community is associated with discharge disposition after surgery. Moreover, this association was stronger in African-Americans compared to Whites. This association when coupled with ongoing payment reform models may have implications for access to care for socially vulnerable populations.
ASSESSING PAIN CHARACTERISTICS IN PERSONS WITH HAND OSTEOARTHRITIS USING THE MCGILL PAIN QUESTIONNAIRE

Elisabeth Mulrooney,1, Karin Magnusson,2, Hilde Bemer Hammer,2, Hanne Solveig Dagfinруд,2, Tore K. Kvien,1,2, Ida Kristin Haugen1,1. Oslo University Hospital, Department of Rheumatology, Oslo, Norway,2Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway,2Lund University, Department of Orthopedics, Lund, Sweden,1University of Oslo, Department of Interdisciplinary Health Sciences, Oslo, Norway,1University of Oslo, Department of Orthopaedics, Oslo, Norway

Background: Pain in osteoarthritis (OA) causes significant physical, psychological and social limitations. Increased understanding of the pain experience is important for improved patient care.

Objectives: We aimed to assess the pain characteristics of hand OA using the McGill Pain Questionnaire, a multidimensional self-reporting questionnaire that assesses the quality and intensity of the pain. Secondly, the external validity was examined.

Methods: Three-hundred persons with hand OA from the Nor-Hand study completed questionnaires, including a modified McGill questionnaire. The participants are presented with a list of 106 pain descriptors in 18 sections. The questionnaire consists of three subscales: sensory (12 sections, 0-71.3 scale), affective (5 sections, 0-32.9 scale) and evaluative (one section, 0-8.6 scale), and an intensity score (no pain – severe pain). The total scale is rated from 0-112.8. The subscales and total scale were normalized to 0-100 scales. The participants also completed the Numeric Rating Scale (NRS, 0-10 scale) about hand pain, the Australian/Canadian (AUSCAN) hand pain subscale (0-20 scale) and questionnaires about psychological factors; Hospital Depression and Anxiety Scale (HADS, 0-42 scale), Pain Catastrophizing Scale (PCS, 0-52 scale) and the pain subscale of the Arthritis Self Efficacy Scale (ASES, 10-100 scale). For all scales except ASES, high scores indicate poor health. We identified the adjectives in the McGill questionnaire with most frequent responses. To determine the external validity, the McGill questionnaire was correlated to other questionnaires (AUSCAN, NRS, HADS, PCS and ASES) using Spearman correlation coefficients.

Results: The participants (89% women) with median (IQR) age of 61 (57-66) years demonstrated a wide range in pain characteristics and intensity, with a median (IQR) of 34.5 (0-62.3), 14.9 (0-39.2) and 44.2 (34.9-48.8) for the sensory, affective and evaluate subscales, respectively. The median for the total pain sum score was 29.7 (7.0-53.2). A floor effect was detected for the sensory (23.7% with score 0) and affective (40.3% with score 0) subscales. The reported adjectives with highest frequency were “sore” (n=208, 69.3%), “inhibiting” (n=124, 41.3%) and “annoying” (n=97, 32.3%). The participants frequently reported neuropathic-like characteristics such as sticking/stabbing/pricking (n=137, 45.7%), smarting/burning (n=95, 36.6%), smarting/burning (n=137, 45.7%), smarting/burning (n=95, 36.6%), smarting/burning (n=95, 36.6%) and smarting/burning (n=95, 36.6%).

The McGill total scale showed moderate correlations with AUSCAN and NRS pain (Table). Similar strength of correlations was found for all the subscales, and stronger for the intensity score (0.63-0.64). The correlation with HADS was similar for the McGill questionnaire, AUSCAN and NRS pain. The correlations with PCS and ASES were weaker for McGill than for the other pain questionnaires.

Abstract THU0443—Table 1. Correlations between the McGill questionnaire and questionnaires assessing pain and psychological health.

Conclusion: The McGill Pain questionnaire may be a useful tool in research settings for a broad evaluation of pain characteristics in hand OA. Moderate correlations with other pain questionnaires suggest that the McGill questionnaire measures other constructs. For the first time, we have shown that neuropathic-like pain characteristics are frequently reported by persons with hand OA.

THU0444

CROSS-CULTURAL TRANSLATION, ADAPTATION AND VALIDATION OF A JAPANESE VERSION OF THE FUNCTIONAL INDEX FOR HAND OSTEOARTHRITIS (J-FIHOA)
studies concerning Asian countries. To both pursue appropriate clinical courses for patients and to engage in future research, physicians need to discriminate symptomatic HOA. The Functional Index for Hand Osteoarthritis (FIHOA) assesses hand OA-related functional impairment and is accepted as a gold standard with excellent reliability and responsiveness [1,2].

**Objectives:** Our objective was to make a Japanese version of the FIHOA (J-FIHOA) and to validate it among Japanese HOA patients.

**Methods:** J-FIHOA was created following forward/backward translation processes distilled from the established guidelines. A prospective, multi-center study was undertaken for its validation. Seventeen collaborating hospitals recruited hand OA patients from September 2017 to September 2018. Patients who met the ACR classification criteria were included. A medical record review and the following patient-rated questionnaires were collected: J-FIHOA, Japanese Health Assessment Questionnaire (J-HAQ), and the Short Form 36 Health Survey (J-SF-36). As item 7 is a gender-role question, an item total correlation needed to be calculated independently for women and men. The J-FIHOA scores at enrollment were used to assess Cronbach’s alpha coefficient/item-total correlation and compared with the J-HAQ, NRS pain and J-SF-36 yielding respective Spearman’s rank correlation coefficients.

To assess reliability, we used test-retest methods for patients with unchanged symptoms/treatments. The interval was 1-2 weeks and data sets were assessed with the intraclass correlation coefficient (ICC). To evaluate responsiveness, those who started new pharmacological treatments were required to answer the questionnaires and to have a 1-month follow-up visit. Differences between pre- and post-pharmacological treatments were used to calculate the effect size (ES).

**Results:** Twenty-nine male and 145 female HOA patients participated (mean age 65 years). Cronbach’s alpha was 0.91, showing high internal consistency. Each item was well correlated with the total score (all values >0.30; range 0.46 to 0.89). Construct validity between J-FIHOA and other scales was: 0.73 (J-HAQ), 0.56 (NRS pain), -0.31 (J-SF-36 physical component) and -0.21 (J-SF-36 mental component). Although the FIHOA has no pain-related question, previous reports showed moderate correlations between the FIHOA and pain. Our results were concordant with these reports. It was expected that J-SF-36 mental component had the weakest correlation. One hundred fifty-seven longitudinal data sets were pooled and used to evaluate reliability (137 for test-retest) and responsiveness (20 for ES). ICC for test-retest was 0.83 (95% CI, 0.77 to 0.88). The ES were 0.56 for J-FIHOA and 0.44 for J-HAQ. We assumed that this higher ES related on the HOA specificity of J-FIHOA.

**Conclusion:** We created a cross-culturally adapted J-FIHOA. Our results showed its good metric qualities to assess dysfunction in HOA and equivalence with the original FIHOA.

**Background:** Up to 20% of patients are dissatisfied with the outcome of total knee replacement (TKR). Pre-operative expectations may affect patient’s outcomes, including satisfaction after surgery. Better understanding of patient’s expectation could aid the development and improvements of pre-operative education. Pre-operative expectations and post-operative satisfaction may vary across cultures and have not been described in an Asian context.

**Objectives:** We aimed to evaluate the association between patient’s pre-operative expectation and post-operative satisfaction following TKR for osteoarthritis.

**Methods:** Patients listed for TKR because of OA in a tertiary referral centre were recruited. Pre-operatively, participants completed sociodemographic questions, Western Ontario and McMaster Universities Index (WOMAC) pain and function, and the Hospital for Special Surgery (HSS) KR expectation survey. At 6 months after TKR, patients rated their satisfaction with each expectation on the HSS as completely satisfied, partially satisfied or dissatisfied. Overall satisfaction with TKR was assessed with a 4-point Likert scale and dichotomized to satisfied or dissatisfied. Association between overall satisfaction at 6 months and pre-operative expectation was analysed using logistic regression after adjustment for demographic data.

**Results:** Between June 2017 and December 2017, 215 patients were recruited and completed follow up at 6 months after TKR (71% female, 82% Chinese, mean age 65±7 years). The overall satisfaction rate was 92%. The most prevalent pre-operative expectations were improved ability to perform daily activities (85%), participation in recreation (83%), pain relief (81%) and ability to change position (81%) (Figure 1). At 6 months after TKR, the top five fulfilled expectations (defined as ‘completely satisfied’) were improvement in the ability to perform daily activities (82%), walking short distance (66%), improvement in psychological well-being (64%), pain relief (64%) and position change (56%) (Figure 1). For most items on the questionnaire, expectations were high and not fully met; however most patient’s expectations were at least partially met. In the logistic regression model, post-operative HSS total score, but not pre-operative HSS score, was associated with overall satisfaction (P<0.01) after adjusting for demographic data (Table 1).

**Conclusion:** Although most patient’s expectations were at least partially met, they were not fully met. This suggests that many patients have unrealistic expectations of TKR outcome. Fulfillment of expectations, rather than expectation per se, was the most important variable associated with patient’s overall satisfaction.

DIACEREIN PROVEN AS EFFECTIVE AS CELECOXIB IN REDUCING PAIN AND SYMPTOMS IN KNEE OSTEOARTHRITIS PATIENTS IN A MULTICENTRE DOUBLE-BLIND RANDOMISED STUDY (DISSCO)

Jean-Pierre Peletier1, Jean-Pierre Raynaud2, Patrice Patiemn3, Johanne Martel-Pelletier3, Jean-Pierre Pelletier1
1Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada; 2Institut de Rhumatologie de Montreal, Montreal, Canada; 3Arthrolab Inc., Montreal, Canada

Background: There was a need to ascertain in a clinical trial the comparative efficacy of diacerein, an IL-1 inhibitor, vis-à-vis celecoxib, a COX-2 inhibitor, in relieving knee osteoarthritis (OA) symptoms.

Objectives: The primary outcome of this study was to show that diacerein is non-inferior to celecoxib in terms of pain reduction (WOMAC A pain subscale) after 6 months of treatment in moderate-to-severe symptomatic knee OA patients.

Methods: A randomised double-blind multicentre trial was conducted in four European countries (Spain, Belgium, Austria, Czech Republic) and in Canada evaluating treatment with diacerein versus celecoxib in patients with OA diagnosed according to ACR criteria, with KL grade 2-3 knee OA and moderate-to-severe pain (VAS pain score [0-100] while walking on a flat surface > 40 mm). Eligible patients were randomised to treatment for 6 months with either diacerein 50 mg once daily for the first month and twice daily thereafter, or celecoxib 200 mg once daily. The primary outcome was the change from baseline in WOMAC pain subscale (0-50 scale) after 6 months of treatment. Secondary outcomes included WOMAC function and stiffness, VAS pain, presence of joint swelling/effusion, rescue medication consumption, percentage of OMERACT-OARSI responders, and SF-36. A total of 380 patients were randomised in the study. The primary outcome assessment on the per protocol set (PPS) (n=288) was followed by sensitivity analysis on the ITT population (n=370).

Conclusion: This clinical trial showed that in patients with moderate-to-severe knee OA pain, diacerein has comparable efficacy to celecoxib with respect to reducing pain and stiffness and improving function after 6 months in a clinically relevant manner. The drug also demonstrated a good safety profile with positive benefit to risk ratio.

THE RELATIVE EFFICACY OF TOPICAL NON-STEROIDAL ANTI-INFLAMMATORY DRUGS AND CAPSAICIN IN OSTEOARTHRITIS: MOVING FROM AVERAGE TREATMENT EFFECTS TO INDIVIDUAL TREATMENT PREFERENCES

Monica Persson1, Joanne Stocks1, Aliya Sarmanova2, Gwen Fernandes2, Gyula Varadi2, Mohammad Hashem Hashempur2, Robbert van Haselen3, David Walsh4, Michael Doherty4, Weiya Zhang4, University of Nottingham, Nottingham, United Kingdom; University of Bristol, Bristol, United Kingdom; 2Biophysics Pharma, Inc., Beverly, United States of America; 3Fasa University of Medical Sciences, Fasa, Iran (Islamic Republic of); 4International Institute for Integrated Medicine, London, United Kingdom

Background: Pain is an important issue for people with osteoarthritis (OA). Topical non-steroidal anti-inflammatory drugs (tNSAIDs) and capsaicin are recommended treatments, but reduce OA pain by different mechanisms.

Objectives: To [1] determine the relative efficacy of tNSAIDs and capsaicin in OA and [2] identify predictors of response that may allow tailoring of topical therapy to the individual.

Methods: Systematic literature searches were conducted up to 16/11/2015 for randomised controlled trials (RCTs) of tNSAIDs or capsaicin in OA. Placebo-controlled RCTs were pooled in conventional meta-analyses (CMA) for specific (difference between treatment and placebo) and overall (pain reduction in treatment arm) treatment effects. Bayesian network meta-analysis (NMA) compared treatment effects via placebo. RCT discrepancy analyses were conducted and an individual patient data meta-analysis (IPDMA) examined for predictors of response.

A pilot n-of-1 trial series (PNTS) examined treatment effects, patient preferences, and predictors of response. Participants with painful radiographic knee OA were allocated to three treatment cycles, each comprising four weeks treatment with 5% ibuprofen gel and 0.025% capsaicin cream in a random order.

Effect sizes (ES) are Hedges’ g and 95% confidence interval (CI) or credible interval (Crl). Predictors of response were identified in regression modelling for treatment-by-covariate interactions (specific effect) or covariate associations (overall effect). 9 and 25 predictors were examined in IPDMA and PNTS, respectively.

Results: CI 63 tNSAID and 10 capsaicin RCTs identified, CMA and NMA analysed 21 tNSAID (n=6191) and five capsaicin (n=415) RCTs. The quality of evidence was moderate for tNSAIDs and very low for capsaicin. Overall treatment effects were large and likely clinically significant (tNSAIDs ES 1.23, 95%CI 1.06-1.41; capsaicin ES 1.05, 95%CI 0.52-1.57). tNSAIDs (all drugs/doses grouped) were superior to placebo (ES 0.31, 95%CI 0.20-0.41), but capsaicin was only effective at 0.025% concentration (ES 0.41, 95%CI 0.17-0.64; ES of all capsaicin RCTs 0.28, 95%CI -0.04-0.60). On average, tNSAIDs and capsaicin were equally effective (ES 0.04, 95%CI -0.29-0.37).

IPD were provided for 15 (n=3889) tNSAID RCTs, including 11 (n=3140) placebo-controlled RCTs. No IPD were obtained for capsaicin. A significant but small interaction was observed between sex and tNSAID use for pain relief, with women reporting greater effect (11 RCTs, n=2939, p=0.023).

22 participants enrolled in the PNTS and completed 104 treatment periods. Clinically important pain relief (≥1 on 0-10 numeric rating scale) was achieved in 64% of periods, with no difference in efficacy between treatments overall (p=0.271). Individual responses to treatment varied, with 60% of people preferring one treatment over the other, but without clear predictors for the preference.

Conclusion: tNSAIDs and capsaicin may relieve OA pain, but treatment effects from group comparisons do not directly translate to treatment outcomes at an individual level. No baseline characteristics robustly determine which treatment is more likely to benefit an individual. Patients may benefit from trying both treatments to determine which is better for them.

DISEASE BURDEN IN OSTEOARTHRITIS (OA) IS SIMILAR TO RHEUMATOID ARTHRITIS (RA) FROM THE PATIENT’S PERSPECTIVE, SLIGHTLY HIGHER IN RA AT PRESENTATION, SIMILAR ONE YEAR LATER, AND SLIGHTLY HIGHER IN OA TWO YEARS LATER AT ONE PRIVATE PRACTICE SETTING

Martin Bergman1, Mariam Riad2, Theodore Pincus3, 4Drexel University College of Medicine, Philadelphia, United States of America; 5Rush University Medical Center, Chicago, United States of America

Background: Disease burden traditionally has been regarded as considerably greater in rheumatoid arthritis (RA) versus osteoarthritis (OA). However, recent reports of cross-sectional data indicate similar disease burden in OA vs RA according to MDHAQ/RAPID3 (multidimensional health assessment questionnaire/routine assessment of patient index data). One concern is that these findings may reflect only better treatment for RA, and initial disease burden may be considerably higher in RA vs OA.

Objectives: To analyze disease burden in patients with OA vs RA at baseline and 1- and 2-year follow-up according to MDHAQ/RAPID3 scores in routine care at a single rheumatologist private practice site.

Methods: All patients seen in routine care at this site complete an MDHAQ at each visit in the waiting area prior to seeing the rheumatologist. The MDHAQ includes three 0-10 scores for physical function, pain visual analogue scale (VAS), and patient global VAS, compiled into a 0-30 RAPID3, as well as 0-10 fatigue VAS, and 0-48 self-report painful joint count scores. Mean MDHAQ scores were compared in OA versus RA patients at 1st visit and visits 1 and 2 years later, using t tests, adjusted for age and body mass index (BMI) using analysis of variance (ANOVA).

Results: Among 101 OA and 175 patients with RA, at first visit, all MDHAQ scores except pain VAS were statistically significantly higher in RA vs OA, e.g., mean 0-30 RAPID3 was 11.9 in OA and 13.7 in RA. However, none of these differences appear clinically significant (Table). After 1-year, all scores improved, but more in RA vs OA patients (Table), e.g., mean RAPID3 of 11.5 in OA and 10.9 in RA; no differences between OA and RA were statistically or clinically significant. After 2-years, mean RAPID3 was 11.9 in OA vs 9.0 in RA, indicating continued improvement in RA but little change in OA. All scores other than fatigue VAS were higher in OA, including the self-report painful joint count. Differences between OA and RA were explained only minimally by age and BMI.

Conclusion: Most MDHAQ/RAPID3 scores were higher in RA than in OA at the first visit, indicating greater severity of RA, although OA was almost as severe. One year later, scores were similar with no statistically significant differences. Two years later, most scores were higher in OA. These findings are largely independent from better treatment for RA vs OA. At an individual level, patients with primary OA may be better or poorer than other patients with primary RA. Nonetheless, at a group level, the severity of disease burden in OA appears almost as great as in RA, and becomes greater over the next 2 years, likely as a result of better treatment. The severity of OA is understated, suggesting a need for increasing resources for research toward better treatment for OA.

Abstract THU0449 – Figure 1

EFFECT MODERATION OF ANALGESIC TREATMENT OUTCOMES BY DEPRESSION IN PERSONS WITH OR AT-RISK FOR SYMPTOMATIC KNEE OSTEOARTHRITIS

Alan Rathbun1, Michelle Shardell2, Joseph Gallow3, Alice Ryan4, Elizabeth Stuart5, Megan Schuler6, Michelle You7, Marc Hochberg1. 1University of Maryland School of Medicine, Baltimore, United States of America; 2National Institute on Aging, Baltimore, United States of America; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, United States of America; 4RAND Corporation, Boston, United States of America; 5Hinda and Arthur Marcus Institute for Aging Research, Boston, United States of America

Background: Depression often accompanies knee osteoarthritis (OA), exacerbates pain severity, and may negatively affect analgesic treatment outcomes.

Objectives: To determine whether depression moderates the effect of analgesics on pain severity in persons with or at-risk for symptomatic knee OA.

Methods: Participants (n=2059) were from the Osteoarthritis Initiative, with or at-risk for symptomatic knee OA, and had complete data on selected measures at baseline and four annual follow-up visits. Analgesic initiation (acetaminophen, non-steroidal anti-inflammatory drugs, opioids) was assessed at three annual follow-up visits in those who were not analgesic users at baseline. Depression was evaluated concurrent to assessment of analgesic use with the Center for Epidemiological Studies Depression (CES-D) scale using the corresponding CES-D screening threshold (CES-D score ≥ 16). Pain severity at the fourth annual follow-up visit was the outcome and measured with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain scale (rescaled range = 0-100).

Conclusion: The persistent use of analgesics at years one and two (β = -2.17; 95% CI: -4.62, 0.27) or years one, two, and three (β = -1.36; 95% CI: -4.22, 1.50) did not increase the magnitude of the treatment effect in non-depressed participants. In contrast, time-specific associations in depressed participants increased during follow-up from 0.61 (95% CI: -9.17, 10.38) to -9.64 (95% CI: -17.96, -1.33), and the treatment effect of year three analgesic use on year four pain severity was statistically significant. The magnitude of the treatment effect increased from year one with persistent analgesic use at years one and two (β = -5.76; 95% CI: -20.65, 9.15) and years one, two, and three (β = -15.39; 95% CI: -33.99, 3.21). However, effect moderation was only significantly concerning year three analgesic use, where the subsequent difference in treatment effect between depressed and non-depressed participants was -10.46 (95% CI: -18.97, -1.94). Time-varying confounders measured at three annual follow-up visits were: WOMAC pain score, Kellgren-Lawrence grade, body mass index, physical performance, knee injuries, and knee injections. Structural nested mean models appropriate for evaluating time-varying effect moderation of dynamic treatments by evolving effect modifiers were implemented using an inverse-probability-of-treatment-weighting regression with-residuals approach.

Results: In non-depressed participants, analgesic treatment effect at years one, two, and three on pain severity at year four was minimal (Figure 1).
QUALITY OF LIFE OF PATIENTS WITH A COMBINATION OF SARCOPENIA AND OSTEOARTHRITIS OF LOWER EXTREMITY

Yuliya Safonova1, Evgeniy Zotkin2.
1Northwestern State Medical University named after I.I. Mechnikov, St. Petersburg, Russian Federation; 2Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation

Background: In accordance with the updated recommendations of the EWGSOP (2018), sarcopenia is a muscle disease (muscle failure) rooted in adverse muscle changes that accrue across a lifetime [1]. Sarcopenia and osteoarthritis significantly affect the self-esteem quality of life which is associated with a decrease in muscle strength and muscle performance, falls, joint pain [2]. In 2015, the SarQoL® questionnaire (Sarcopenia and Quality of Life, www.sarqol.org) was developed, specific to patients with sarcopenia. Improvement of quality of life should be the priority of any interventions to prevent and treat osteoarthritis and sarcopenia in the ageing population [3].

Methods: Prospective study of 159 women, mean age 74 ± 13.3. Sarcopenia was diagnosed according to the algorithm proposed by the European Working Group on Sarcopenia in Older People (EWGSOP, 2010). Life quality assessment was performed using EQ-5D questionnaires and a specific questionnaire in patients with sarcopenia SarQoL.

Results: 31.45% of people with OA older than 65 years had sarcopenia. The results of the study showed a statistically significant decrease in overall health on the questionnaire EQ-5D in patients with sarcopenia compared with patients without sarcopenia (0.48 ± 0.22 points and 0.74 ± 0.19 points, respectively, p <0.01) and no differences according to the EQ-VAS scale in the studied groups (p = 0.05). The decrease in the general health status of EQ-5D in patients with OA sarcopenic compared with non-sarcopenic is associated with a restriction of the usual daily activities: in 70% (95% CI: 55.4-82.1) and 52.3% (95% CI: 42.5-61.9) respectively, (p <0.01). In patients with OA, reduced global SarQoL in sarcopenic subjects compared to non-sarcopenic ones: 50.65±14.23 vs. 75.10±14.46, p<0.001. Significantly lower scores for all domains were found in patients with OA sarcopenic compared with non-sarcopenic patients (p<0.001).

Conclusion: In patients with OA sarcopenic, the quality of life is worse than that of non-sarcopenic due to a decrease in habitual daily activities, probably associated with low muscle strength.

Disclosure of Interests: None declared

in Spain, including peripheral (hip, knee and hand) and axial (cervical and lumbar spine) OA.

Objectives: To estimate in adult population the prevalence of symptomatic axial OA (cervical and lumbar spine) and associated factors.

Methods: EPISER 2016 study is a cross-sectional, population-based descriptive study. To estimate the OA prevalence, adult population aged 40 or older was selected. The initial recruitment was made through a call center. Participants who met the premises of an initial screening based on symptoms were also identified. In a second phase rheumatologists confirmed the diagnosis. The axial OA diagnostic criteria to confirm new diagnosis were both clinical and radiographic criteria. Clinical criteria: mechanical pain longer than 3 months of evolution and stiffness of less than 30 minutes or absence of it; and radiographic criteria: vertebral osteophytes or reduction of intervertebral space with sclerosis of vertebral plate and sclerosis of interarticular joints. To confirm the diagnosis, it was necessary that both clinical criteria and at least one radiographic criteria were met.

Results: The sample of the EPISER study was 3,336 subjects ≥ 40, of whom 978 had peripheral or axial OA. The mean age was 64.72 years, 730 were women, 62.6% had basic education, 64.8% were overweight or obese and 83.9% were ex-smokers or non-smokers (Figure 1). The prevalence of global OA (peripheral+axial) was 29.35%. Prevalence of peripher- al and axial OA was 19.62% and 19.17% respectively. The characteristics of patients with peripheral and axial OA follow similar patterns. Both types of OA are more frequent in women with basic education levels. Regarding age, there are more patients with axial osteoarthritis between 40-49 years than with peripheral OA. Obesity or overweight are more strongly associated with peripheral OA.

Prevalence of cervical OA was 10.10%. In the multivariate analysis, it was observed that cervical OA is more frequent in women and older subjects, with the prevalence peak between 60-69 years. It is also more frequent in subjects with obesity and in subjects with a basic education level (Figure 2). OA cervical prevalence is lower in subjects from northern Spain than in population from the Mediterranean area (including the Balearic islands) and central Spain. Smoking, living in a rural or urban environment or having been born abroad were not associated with cervical OA.

Prevalence of lumbar OA was 15.52%. Multivariate analysis also showed that lumbar OA is more frequent in women and it increases with age (prevalence peak in ≥ 80 years). Greater association was observed with obesity or overweight and with basic study levels. Lumbar OA prevalence was higher in population from centre of Spain compared with other areas. Tobacco consumption, living in a rural or urban environment or having been born abroad were not associated with lumbar OA.

Conclusion: EPISER2016 study shows similar prevalence of peripheral and axial OA. Lumbar OA is more prevalent than cervical OA. Axial OA in Spain is more frequent in women, increases in women with erosive disease at the third year between 60-69 years for cervical OA and ≥ 80 years for lumbar OA. Both cervical and lumbar OA are more frequent in patients with obesity or overweight and with basic studies.

THU0453

PROGRESSION OF PAIN, NUMBER OF PAINFUL AND SWOLLEN JOINTS AND ULTRASOUND DETECTED CHANGES IN THE GROUP OF 133 PATIENTS WITH HAND OSTEOARTHRITIS OVER THREE YEARS

Olga Slepiova, Olga Růžíková, Karel Pavelka, Ladislav Šenolt. Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic

Background: Hand osteoarthritis (HOA) is a common and frequent cause of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a three years longitudinal study.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined, and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and at the first, second and third year of follow-up.

Results: Altogether, 133 patients (14 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2019. Out of these patients, 72 (6 male) had erosive disease. The disease duration (p<0.01) was significantly higher in patients with erosive compared with non-erosive disease. Pain reported on VAS was significantly higher (p<0.01) in patients with erosive compared with non-erosive disease, however the results are inconsistent.

Objectives: The aim of this study was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a three years longitudinal study.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined, and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and at the first, second and third year of follow-up.

Results: Altogether, 133 patients (14 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2019. Out of these patients, 72 (6 male) had erosive disease. The disease duration (p<0.01) was significantly higher in patients with erosive compared with non-erosive disease. Pain reported on VAS was significantly higher (p<0.01) in patients with erosive compared with non-erosive disease at baseline. Progression of pain after the third year of follow up was significantly higher in patients with erosive disease (p<0.05). The number of painful and clinically swollen joints was significantly higher in patients with erosive compared with non-erosive disease at baseline. The number of painful and clinically swollen joints remained statistically higher (p<0.01) at the third year of follow up in patients with erosive disease. According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain (p<0.05) and stiffness (p<0.01) at baseline. Pain (p<0.01) and function (p<0.01) but not stiffness, worsened in patients with erosive compared with non-erosive disease at the third year of follow up.

US-detected pathologies such as gray-scale synovitis (p<0.001), intensity of PDS (p<0.01) and number of osteophytes (p<0.01) were significantly higher in patients with erosive compared with non-erosive disease at

Abstract THU0452 – Figure 1

Abstract THU0452 – Figure 2
baseine. There were improvements in gray-scale synovitis total score and intensity of PDS in patients with non- erosive disease while patients with erosive disease worsened after the iso third year of follow up. On the other hand, the progression of US-determined osteophyte formation was observed in both groups but were significantly higher in patients with ero- sive compared with non- erosive disease after the third year of follow up.

Conclusion: The findings of this study show that pain and number of painful and clinically swollen joints associated with US-detected synovial changes and osteophyte formation is more severe in patients with erosive HOA than in patients with non- erosive disease. In addition, osteophyte formation is more likely to progress independent of synovial inflammation.

THU0454

CONDITIONED PAIN MODULATION AND TEMPORAL SUMMATION IN PERSONS WITH HAND OSTEOARTHRITIS AND ASSOCIATIONS WITH PAIN SEVERITY

Perrine Steen Peterssen1, Tuhina Neogi2, Karin Magnusson3,1,3, Hilde Berner Hammer1, Tore K. Kvien1, Till Uhlig1, Ida Kristin Haugen1,1, Diakonhjemmet Hospital, Rheumatology, Oslo, Norway, 2Boston University School of Medicine, Clinical Epidemiology Research and Training Unit, Boston, United States of America, 3Lund University, Faculty of Medicine, Clinical Sciences Lund, Orthopaedics, Clinical Epidemiology, Lund, Sweden

Background: Conditioned pain modulation (CPM) assesses adequacy of descending modular pathways. Temporal summation (TS) reflects ascending facilitation of nociceptive signals in the central nervous system (central sensitization). Inadequate CPM and enhanced TS of pain are both known to contribute to pain in chronic pain conditions. Different pain phenotypes may respond to different treatments strategies and may therefore be important to assess in clinical practice. CPM has not previously been explored in persons with hand OA and its relation to pain severity in unknown.

Objectives: To examine the prevalence of CPM and central sensitization alone or in combination in persons with hand OA, and to explore their associations with pain severity.

Methods: These cross-sectional analyses included 248 participants with hand OA from the Nor-Hand study. Participants reported hand pain severity during the last 24 hours on a numeric rating scale (NRS, 0-10), CPM was tested with pressure pain threshold (PPT) at the left wrist before (PPT1) and during (PPT2) a painful ischemic cuff stimulating stimulus at the opposite upper arm. Adequacy of CPM was calculated as CPM-ratio (PPT1/PPT2). CPM-ratio < 1 (increased PPT) indicates adequate CPM, while CPM-ratio ≥ 1 (unchanged/decreased PPT) indicate inadequate CPM. Presence of TS was calculated as TS-index (PPT1/PDT2). The TS-index > 1.5 indicates presence of TS. TS and inadequate CPM were included as covariates in the analysis. Regression analyses adjusted for age, sex, BMI, use of analgesics, education level, sleep disturbance, the Pain Catastrophizing Scale, the Hospital Anxiety and Depression Scale and radiographic hand OA severity (Kellgren Lawrence sum score).

Results: Of the 248 participants included, 90% were women, median age was 61 (IQR 57, 66) years and mean BMI was 26.3 (SD 4.7) kg/m2. CPM-ratio ranged from 0.4 to 1.6 (mean 0.9, SD 0.2), and 32% showed inadequate CPM. Presence of TS was found in 46% of the study population. Overall, 38% had no TS and adequate CPM, 29% had inadequate CPM only, 16% TS only and 16% had both (Table). We found that persons with inadequate CPM only and TS only reported higher pain severity than persons with adequate CPM and no TS (Table). Those with both inadequate CPM and TS reported similar levels of pain as persons with inadequate CPM only and TS only.

Adjusted for age, sex, BMI, analgesics, education, sleep disturbance, Pain Catastrophizing Scale, the Hospital Anxiety and Depression Scale and Kellgren Lawrence sum score.

Conclusion: One third of persons with hand OA had inadequate CPM. Those with inadequate CPM, central sensitization or both reported higher pain severity than persons without any signs of altered central pain processing. Having both inadequate CPM and central sensitization was not associated with higher pain severity than having only one of the features. Our results are the first to demonstrate such a heterogenous variety of clinically relevant pain phenotypes in persons with hand OA.

THU0455

PHARMACOKINETICS (PK) OF A SINGLE INTRA-ARTICULAR (IA) INJECTION OF CNTX-4975 (TRANS- CAPSAICIN) VS TOPICAL 8% CAPSAICIN PATCH

Randall Stevens1, Kimberly Guedes1, Eddie Armas2, Valerie Smith3, Andrew Volosov3, Centrexion Therapeutics Corp, Boston, United States of America, 2Well Pharma Medical Research Corp, Miami, United States of America, 3Premier Research, Durham, United States of America

Background: CNTX-4975 is in phase 3 trials for treatment of moderate to severe pain associated with knee osteoarthritis (OA). PK data from prior studies of CNTX-4975 in subjects with moderate to severe knee OA pain suggest low systemic and short-term exposure, similar to the FDA-approved topical capsaicin 8% patch.

Objectives: We compared single-dose systemic exposure to trans- and cis-capsaicin following IA injection of CNTX-4975 (>99.5% trans-capsaicin, <0.5% total impurities) with 8% capsaicin patch in subjects with moderate to severe knee OA pain.

Methods: This open-label, crossover study enrolled adults aged 50–75 y with moderate to severe knee OA pain in ≥1 knee (most painful knee index knee; nonindex knee, no to mild pain [0–1; NPRS 0–4 scale]). Subjects were randomized 1:1 to 2 sequences: A (CNTX-4975 1 mg IA, index knee) followed by B (topical capsaicin 8% patch, posterior rib cage for 60 min) or BA sequence, with ≥7-day washout between treatments. Plasma samples for trans- and cis-capsaicin concentration assays were taken before and at specified times after study treatment. PK parameters, including maximum observed plasma concentration (Cmax), area under the plasma concentration-time curve from time 0 to last quantifiable plasma concentration (AUCt), and to infinity (AUC∞), time to Cmax (Tmax), and half-life (t1/2), were determined. PK parameters were reported using descriptive statistics. Geometric means ratios of In-transformed AUCt0–∞, AUC∞0–∞, and Cmax, were evaluated using ANOVA.

Results: Sixteen subjects (median age, 62 y; female, 62.5%) were randomized to treatment (PK analysis population). Tmax showed more rapid absorption of trans-capsaicin from IA CNTX-4975 vs the topical patch (Table). AUCt0–∞ and Cmax indicated greater trans-capsaicin exposure

with CNTX-4975 vs the patch; however, exposure was short term, with mean t1/2 0.5 h. Cis-capsaicin concentrations were insufficient for calculating PK.

Conclusion: Trans-capsaicin from CNTX-4975 injection was rapidly absorbed and eliminated. The extent of systemic exposure to trans-capsaicin was significantly higher after CNTX-4975 vs the 8% capsaicin patch.

THU0456 EVALUATION OF THE USE OF ORLISTAT IN THE COMPLEX TREATMENT OF OBESITY IN PATIENTS WITH KNEE OSTEOARTHRITIS

Ekaterina Strebkova, Ludmila Alekseeva. Nasonova research institute of rheumatology, Moscow, Russian Federation

Background: Currently in the world there is a pandemic of obesity, which leads to an increase in diseases associated with obesity. Obesity is an important factor in the development and progression of osteoarthritis (OA). The metabolic phenotype of OA, which is directly associated with obesity, is highlighted. Due to the growing number of patients with obesity and OA, a high level of comorbidity and the lack of effectiveness of non-drug therapy, the problem of the effectiveness and safety of the therapy of obesity is very relevant.

Objectives: To evaluate the efficacy and safety of drug therapy for obesity in patients with OA of the knee.

Methods: 50 female patients (45-65 y.o.) with Kellgren-Lawrence stage II-III KOA and obesity (BMI=30kg/m²). Patients in Group 1 (n = 25) took 120 mg of orlistat 3 times a day in combination with a low-calorie diet and exercise for 6 months. Patients in Group 2 (n = 25) were on a low-calorie diet combined with exercise for 6 months. All patients received a variety of non-steroidal anti-inflammatory drugs (NSAIDs) in tablet form. All patients were assessed for body mass, parameters of the WOMAC index, EQ-SD quality of life index, NSAID consumption, and orlistat therapy safety assessment.

Results: After 6 months of drug therapy for obesity, patients from Group 1 achieved a significant weight loss by 10.07% (p < 0.05). Patients from Group 2 showed the use of non-medical methods of treating obesity reduced body weight by 9.9% (p < 0.05). Patients from Group 1 improved the WOMAC index: pain decreased by 52.5% (p < 0.05), stiffness by 47.98% (p < 0.05), and functional insufficiency by 51.55% (p < 0.05). Patients from Group 2 also showed a decrease in the WOMAC index, but these changes were worse than in patients with greater weight loss. Patients from Group 1 showed a significant improvement in the quality of life for the EQ-SD index by 52.27% (p < 0.05). Patients from Group 2 against the background of insignificant changes in body weight, the quality of life index EQ-SD did not change. The need to take NSAIDs on the background of drug therapy for obesity and weight loss decreased by 4.6 times. On the contrary, in Group 2 of patients on the background of non-pharmacological treatment of obesity after 3 months of observation, the need for NSAIDs was maintained in 76%. The need for NSAIDs in patients of Group 2 decreased 1.3 times. In general, the tolerability of orlistat in patients of Group 1 was good. Adverse reactions were observed in two patients in the form of steatorrhea. The appearance of an undesirable reaction was associated with errors in nutrition (eating food saturated with animal fats), which did not require discontinuation of the drug. After correcting the diet, no adverse reactions were noted in patients.

Conclusion: The results of our study showed a significant decrease in body weight by more than 10% in the group of patients with OA while receiving orlistat. Significant weight loss helps reduce pain intensity, improve joint function, and improves the quality of life of patients with OA. Orlistat reduces the need for NSAIDs, which can help stabilize other comorbid diseases in patients with OA and obesity. The study noted good safety of therapy with orlistat; no serious adverse reactions were reported. Thus, drug therapy for obesity using orlistat can be included in the management of patients with OA and obesity, who cannot achieve weight loss using non-drug methods.

THU0457 EVALUATION OF THE EFFECTIVENESS OF COMPLEX TREATMENT OF OBESITY ON THE CLINICAL MANIFESTATIONS OF KNEE OSTEOARTHRITIS AND THE DYNAMICS OF CYTOKINES, DEPENDING ON THE DEGREE OF WEIGHT LOSS

Ekaterina Strebkova, Ludmila Alekseeva. Nasonova research institute of rheumatology, Moscow, Russian Federation

Background: Obesity is a risk factor and progression of the metabolic phenotype of osteoarthritis (OA). The decrease in body weight is important in the treatment of OA. Non-drug therapy aimed at altering the eating behavior, allows you to achieve a decrease in body weight of only 5%, which does not always contribute to the achievement of the clinical effect in patients with diseases of the joints.

Objectives: Assess the effectiveness of complex treatment of obesity with the use of orlistat (intestinal lipase inhibitor) on the clinical manifestations of the knee OA and the dynamics of cytokines (CRP, IL-6, TNF-α) depending on the degree of weight loss.

Methods: 50 female patients (45-65 y.o.) with Kellgren-Lawrence stage II-III KOA and obesity (BMI=30kg/m²). Patients in Group 1 (n = 25) took 120 mg of orlistat 3 times a day in combination with a low-calorie diet and exercise for 6 months. Patients in Group 2 (n = 25) were recommended non-drug therapy for obesity for 6 months. At baseline and after 6 months, the clinical parameters of the knee OA (WOMAC) were evaluated, the quality of life was assessed (EQ-SD). A laboratory study of peripheral blood was conducted at baseline and after 6 months: CRP, IL-6, TNF-α.

Results: After 6 months of complex treatment of obesity with the use of orlistat, patients in Group 1 achieved a significant weight loss of 10.07% (p = 0.03) and <5% (p = 0.02). Data for statistically significant changes
Efficacy and Safety From a Phase 2b Trial of SM04690, a Novel Intra-articular Wnt Pathway Inhibitor for the Treatment of Osteoarthritis of the Knee

Yusuf Yazici1, Timothy Micalidorn2, Allan Gibofsky3, Nancy Lane4, Christian Lattermann5, Nebojsa Skrepnik6, Christopher Sweerijgen1, Anita DiFrancesco1, Jeyashein Tambian7, Marc Hochberg7.

Background: A phase 2a study of SM04690, a small-molecule, intra-articular (IA) Wnt pathway inhibitor reduced knee pain and improved physical function and medial joint space width (mJSW) at 52 weeks in subgroups of subjects with unilateral symptomatic knee osteoarthritis (OA) compared to placebo (PBO).1

Objectives: A 24-week phase 2b study was conducted to refine patient-reported outcome (PRO) measures, target population, medication dose, and to evaluate safety. PRO results for Weeks 12 and 24 are presented here.

Methods: Study subject inclusion criteria required ACR-defined knee OA, Kellgren-Lawrence (KL) grades 2-3, and Pain Numeric Scale (NRS) ≥4 and ≤8 in the target knee and <4 in the contralateral knee. A single IA injection of 2 mL SM04690 (0.03, 0.07, 0.15, or 0.23 mg), vehicle PBO, or sham (dry needle only) was given in the target knee at baseline. PRO endpoints included change from baseline in weekly average of daily pain in the target knee by NRS diary (NRS) [0-10], Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain [0-100], WOMAC Physical Function, improvements were observed for 0.07 mg (Week 12 [P=0.031]) and 0.23 mg (Week 12 [P=0.010], Week 24 [P=0.033]) dose groups.

Conclusion: SM04690, in development as a potential disease-modifying OA drug, showed in this phase 2b study statistically significant improvements from baseline in both the 0.07 mg and 0.23 mg dose groups compared to vehicle PBO for Pain NRS, WOMAC Pain, WOMAC Physical Function, and PtGA. These data support the continued development of SM04690 as a treatment for knee OA. Phase 3 studies are being planned.

Abstract THU0458 – Figure 1. Dynamics of CRP depending on the degree of weight loss (p <0.05).

Figure. Actual observations over time and ladder plots depicting least squares mean (LSM) improvement of Pain NRS (± 95% CI) in SM04690 compared to vehicle PBO, adjusted for baseline.

Disclosure of Interests: Elena Taskina1, Ludmila Alekseeva1, Natalia Kashchevarova1, Sergey Anikin1, Evgenia Sharapova1, Ekaterina Strebkova1, Lena Zonova2, Tatiana Raskina3, Elvira Otteva4, Irina Vinogradova5, Aleksandr Lil4, Y. A. Nasonov Research Institute of Rheumatology, Moscow, Russian Federation; FSBIE HE Novosibirsk State Medical University, Novosibirsk, Russian Federation; SBIE HE KemSMU MOH, Kemerovo, Russian Federation, Regional SBH CDC MOH Khabarovsk kray, Khabarovsk, Russian Federation, SHI Ulyanovsk regional affiliated hospital, Ulyanovsk, Russian Federation.

Objectives: To identify knee OA rapid progression factors in a multicenter prospective study.

Methods: 185 female patients from 5 RF constituent territories aged 40-75 with confirmed Kellgren-Lawrence grade I-II knee OA were included into prospective study after signing the informed consent form. Mean age was 59.2±7.4 years (42-75), mean BMI=27.1±4.4 kg/m², mean disease duration–12±8.1 years. Individual patient’s medical record included relevant anthropometric data, records from case history and clinical examination, VAS articular pain assessment, WOMAC scores, comorbidities. Instrumental diagnostic methods included plain radiography of knee joints, DEXA of the lumbar spine and femoral neck, MRI examination of knee joints. Stage II knee OA was established in 135 (73%) out of 185 patients, stage III – in 50 (27%).

Abstract THU0459 – PREDICTORS ASSOCIATED WITH RAPID PROGRESSION OF KNEE OSTEOARTHRITIS

Elena Taskina1, Ludmila Alekseeva1, Natalia Kashchevarova1, Sergey Anikin1, Evgenia Sharapova1, Ekaterina Strebkova1, Lena Zonova2, Tatiana Raskina3, Elvira Otteva4, Irina Vinogradova5, Aleksandr Lil4, Y. Objectives: To identify knee OA rapid progression factors in a multicenter prospective study.

Methods: 185 female patients from 5 RF constituent territories aged 40-75 with confirmed Kellgren-Lawrence grade I-II knee OA were included into prospective study after signing the informed consent form. Mean age was 59.2±7.4 years (42-75), mean BMI=27.1±4.4 kg/m², mean disease duration–12±8.1 years. Individual patient’s medical record included relevant anthropometric data, records from case history and clinical examination, VAS articular pain assessment, WOMAC scores, comorbidities. Instrumental diagnostic methods included plain radiography of knee joints, DEXA of the lumbar spine and femoral neck, MRI examination of knee joints. Stage II knee OA was established in 135 (73%) out of 185 patients, stage III – in 50 (27%).
**Results:** Knee OA progression (form radiographic stage II to stage III) within 1 year follow up was documented in 15 patients (Group 2 – with progressed OA), while 170 patients did not show any progression (Group 1 - no progression). Both groups were comparable in terms of age, age at RA onset, and duration of the disease. Although patients who progressed had higher body weight (97.1±14.0 vs 74.2±10.8 kg, p<0.001) and BMI (31.9±5.8 vs 27.3±4.1 kg/m², p<0.001). Patients from Group II had more intense knee pain during walking (VAS - 65.8±11.8 vs 47.5±16.7 mm (p<0.0003), and higher WOMAC pain: 330.5±56.6 vs 237.8±85.4 mm (p<0.0001). A function - 1044±190.4 vs 859.2±243.8 mm, p<0.007. Patients from Group II showed higher rates of varus knee alignment (66.7% vs 35.3%, RR=1.89, 95% CI 1.25-2.85, p=0.02) and H-VA1386 (86.7% vs 61.8%, RR=1.4, 95% CI 1.11-1.77, p=0.04), as well as higher rates of higher arteries hypertension (93.3% vs 71.8%, respectively, RR=1.3, 95% CI 1.1-1.53, p=0.05) and type 2 diabetes mellitus (DM) (33.3% vs 12.9%, RR=2.57, 95% CI 1.14-5.82, p=0.04). MRI showed higher percentage of medial and lateral tibia cartilage defects in Group 2 patients (57.2% vs 18.6%, respectively; RR=3.06, 95% CI 1.74-5.38, p<0.003; 57.2% vs 14%, RR=4.08, 95% CI 2.23-7.46 p=0.0006); bone marrow edema (BME) in medial (71.4% vs 12.2%, RR=5.3, 95% CI 3.38-10.1, p<0.000004) and lateral tibial compartments (21.4% vs 4.1%, RR=5.25, 95% CI 1.47-18.7, p=0.03); subchondral cysts, occupying more than 25% of the area in medial and lateral tibial compartments (respectively, 28.6% vs 7.4%, RR=3.84, 95% CI 1.4-10.5, p<0.03; and 35.7% vs 8.8%, RR=4.06, 95% CI 1.7-9.7, p<0.01). Synovitis (MRI findings) was documented in 100% patients from Group 2 and in 58.4% patients without OA progression (RR=1.71, 95% CI 1.5-2.0, p=0.002). A multivariate (discriminant) analysis showed that the most important risk factors for knee OA progression were: higher body weight, high WOMAC pain score, presence of type 2 DM, BME in medial tibial compartment, and cartilage damage in medial tibial compartment (MRI findings). A model capable of predicting rapid progression of knee OA in an individual patient with high accuracy (area under the ROC-curve 0.925 (95% CI 0.828–0.222)) has been developed based on identified RF and their coefficients.

**Conclusion:** In a prospective multicenter study, using comprehensive instrumental examination the following key predictors of rapid knee OA progression were identified: excessive body weight, high WOMAC pain score, presence of type 2 DM, BME in medial tibial compartment, and cartilage damage in medial tibial compartment (MRI findings).

**IDENTIFICATION OF DEFINITIONS OF POOR OUTCOME AFTER TREATMENT OF KNEE OSTEOARTHRITIS: A LITERATURE REVIEW**

Malou te Molder1, J.M.H. Smolders2, Petra Heesterbeek3, Cornelia van den Ende4, 1Sint Maartenskliniek, Research, Nijmegen, Netherlands; 2Sint Maartenskliniek, Orthopaedic Surgery, Nijmegen, Netherlands; 3Sint Maartenskliniek, Orthopaedic Research, Nijmegen, Netherlands; 4Sint Maartenskliniek, Rheumatology Research, Nijmegen, Netherlands

**Background:** Total knee replacement (TKR) is considered an effective intervention of the treatment of advanced knee osteoarthritis (OA) (Kelg-ren & Lawrence >2). However, a significant proportion of patients could be considered as a poor-responder to TKR (i.e. no or little improvement) in terms of chronic knee pain, functional disability, poor quality of life (QoL), and dissatisfaction after TKR. Both in research and in clinical practice it is challenging to identify those patients with an unfavourable course after TKR. It is difficult though to quantify the proportion of patients with poor response to TKR, as different definitions of, and perspectives (clinician’s and patient’s) on failure are being used.

**Objectives:** The aim of this study was to review the literature and summarize definitions of poor response to TKR.

**Methods:** A systematic search up to 2016 was performed to identify and review previously used definitions of poor response to primary TKR in the literature. Studies were included if dichotomous definitions of outcome after primary TKR were used, if a prospective design was used and in English full text available. The type, amount and combination of domains (i.e. pain and physical function), outcome measures, type of responses (absolute/relative, change/cut-off), values and moments of follow-up used in definitions were summarized.

**Results:** A total of 44 different dichotomous definitions of poor response to TKR, were extracted from 1849 initially identified studies. 34 definitions incorporated one domain, six definitions comprised two domains and four definitions comprised three domains. Eight different domains were used in identified definitions: pain, physical function (mobility), physical functioning

OUTCOME PREDICTION FOR TREATMENT OF KNEE OSTEOARTHRITIS WITH A TOTAL KNEE ARTHROPLASTY. THE INFLUENCE OF DEMOGRAPHIC FACTORS, PAIN, PERSONALITY TRAITS, PHYSICAL AND PSYCHOLOGICAL STATUS

J.J. Toki1, R.P.A. Janssen1, T.M. Haanstra2, M. (Marike) C. van der Steen3, S.M. A. Bierma-Za\end{document}
Highest expectations were scored for pain relief and improvement of the ability to walk of short and medium distances. Patients had the lowest expectations for improvement of mobility, in knee and thigh, psychological well-being, sexual activity and the ability to have paid work.

Female sex, higher age, higher depression score and duration of complaints > 50 months showed to be significant predictors of lower expectations for the treatment outcome after TKA. Baseline pain and function scores were not related to the level of pre-operative expectations.

Conclusion: In conclusion, young, male patients with a short duration of complaints might be at risk of having too high expectations of the treatment result. On the contrary patients with depressive symptoms are more likely to have low expectations, with a potential negative influence on their treatment result. The present study aids in identifying patients at risk for having either too high or too low expectations. This knowledge can be utilized in individualized expectation management interventions.

THU0464 PHASE 2 CLINICAL TRIAL OF THE GI SAFETY OF A HYDROGEN SULFIDE-RELEASEING ANTI-INFLAMMATORY DRUG (ATB-346)

John Wallace1, André Buret2, Peter Nagy3, Marcelo Muscara4, Gilberto de Nucci5
1University of Calgary, Calgary, Canada; 2National Institute of Oncology, Budapest, Hungary; 3University of Sao Paulo, Sao Paulo, Brazil; 4University of Campinas, Campinas, Brazil

Background: Hydrogen sulfide (H2S) is a naturally occurring gaseous mediator produced by intestinal bacteria and various eukaryotic cells. H2S exerts anti-inflammatory, pro-resolution and cytoprotective effects in vivo. ATB-346 is an H2S-releasing derivative of naproxen, which in animals was shown to produce negligible gastrointestinal (GI) damage and bleeding. In human studies, ATB-346 was found to be much more potent and long-lasting than naproxen. A phase 2 open-label efficacy study demonstrated that ATB-346 (250 mg daily) significantly reduced pain in patients with osteoarthritis of the knee, and markedly suppressed cyclooxygenase (COX) activity. The aim of the present study was to determine if ATB-346 would induce less gastrointestinal ulceration than standard dose naproxen.

Objectives: To determine if healthy subjects taking ATB-346 for 14 days would develop significantly less gastrointestinal ulcers (<3 mm diameter with depth) than subjects taking an equi-effective dose of naproxen.

Methods: This was a double-blind, active control, endoscopic study. 244 healthy volunteers completed the study. Upper GI endoscopy was performed prior to and on day 14 after commencing treatment with naproxen (550 mg twice daily) or ATB-346 (250 mg) once daily in the morning and placebo once daily in the evening. Whole blood thrombocyte synthesis was measured on days 0, 7 and 14. Plasma H2S levels were also measured.

Results: 53 subjects taking naproxen (42.2%) developed at least one ulcer, while only 3 subjects (2.5%) treated with ATB-346 developed at least one ulcer (p = 0.0001). The two drugs suppressed COX activity to the same extent (>95%). Affected subjects in the naproxen group developed more ulcers (an average of 4 per subject) than in the ATB-346 group (an average of 1.3), and there was a much greater incidence of larger ulcers (>5 mm diameter) in the naproxen group than in the ATB-346 group (125 vs 0, respectively). The incidence of gastro-esophageal reflux was higher in patients and nausea was lower with ATB-346 than with naproxen. Plasma H2S levels were significantly elevated (by 50%; p=0.001) in the ATB-346 group.

Conclusion: Consistent with the pre-clinical studies, this phase 2 clinical trial demonstrated a dramatic reduction of upper GI ulcer formation in subjects treated with equi-effective doses of ATB-346 versus naproxen. The COX inhibition observed in this trial was consistent with a previous phase 2A trial that demonstrated significant pain relief with ATB-346 in patients with osteoarthritis of the knee. ATB-346 appears to be an effective and much safer alternative to existing NSAIDs.

THU0464B IS THERE AN ASSOCIATION BETWEEN METABOLIC SYNDROME AND SEVERITY OF HAND OSTEOARTHRITIS? RESULTS FROM A NATIONWIDE STUDY

Margarida Cruz1, Alexandre Sepriano2, Sara Dias3, Ana Maria Rodrigues4, Helena Canhão5, Nélia Gouveia6, Mónica Eusebio7, Sofia Ramiro7, Jaime Branco2, 1Nova Medical School – Lisboa, Lisboa, Portugal; 2Faculdade de Ciências Médicas, CEDOC, Lisboa, Portugal; 3Faculdade de Ciências Médicas, CEDOC, EpiDoc, Lisboa, Portugal; 4Faculdade de Ciências Médicas, Lisboa, Portugal; 5Sociedade Portuguesa de Reumatologia, Lisboa, Portugal; 6Leiden University Medical Center, Leiden, Netherlands; 7Nova Medical School, CEDOC, Lisboa, Portugal

Background: Hand osteoarthritis (HOA) is a highly prevalent rheumatic disease that predominates in females and causes pain, joint deformities and loss of functional capacity. Overweight and metabolic syndrome have been previously suggested to associate with the severity of HOA, but clarity on these associations is yet to be achieved.

Objectives: To test the possible association between body mass index (BMI) and other individual components of metabolic syndrome with severity of HOA in females from a nationwide epidemiological study.

Methods: EpiReumaPt was a three-stage national health survey where, in the first phase, 10,661 adult participants were randomly selected and interviewed using a structured face-to-face questionnaire that included screening for rheumatic diseases, such as HOA. In the second phase, positive screeners for ≥1 rheumatic complaint plus 20% of the negative screeners were invited for an assessment by rheumatologists. Finally, 3 rheumatologists revised all the information and defined the final diagnosis by consensus. Female patients with a final clinical diagnosis of primary HOA were included in this analysis. Hand functional status as assed by the Cochin questionnaire was the outcome of interest. The explanatory variables of interest were: BMI evaluated as a categorical variable (Normal: 18-24.99; overweight: > 25-29.99; obesity: ≥ 30), diabetes mellitus, hypertension and hypercholesterolemia (all self-reported and as binary variables: yes/no). The possible associations between BMI and the individual components of the metabolic syndrome with the Cochin score were tested in a multivariable linear regression model. Only significant variables (p<0.05) were kept in the final model. Potential confounders of the associations of interest and the outcome were defined a priori on clinical grounds and included age and symptoms of depression (HADS score).

Results: Out of the 3,877 participants evaluated by Rheumatologists, 473 women had primary HOA (national prevalence: 6.6%). In this population, 40% were overweight and 29% were obese. Ninety-three (20%) participants had diabetes, 261 (56%) had hypertension and 261 (56%) had hypercholesterolemia. In the multiple regression model, BMI and diabetes were found to significantly associate with HOA severity, whereas hypertension and hypercholesterolemia did not, thus not being selected in the final model (table).

Abstract THU0464 – Table 1. Association between individual components of the metabolic syndrome and HOA severity (Cochin score). Multivariable linear regression model

Conclusion: In this study, higher BMI and the presence of diabetes mellitus associated with a worse functional capacity on women with primary HOA. These data add to the body of evidence suggesting a possible role of metabolic factors in the severity of HOA.

The evaluation of the effectiveness of intra-articular steroid, tenoxicam and combined steroid-tenoxicam injections in the treatment of patients with knee osteoarthritis

VILMAZ Ebru , Korfez Government Hospital, Physical Therapy and Rehabilitation, Kocaeli, Turkey.

Background: Intra-articular corticosteroid injections are widely applied in the treatment of symptomatic knee osteoarthritis (OA). There is an evidence of short-term effects of intra-articular corticosteroid injection (up to 3-4 weeks), however there is no consensus for the long-term benefit of this treatment yet (1). Tenoxicam is an effective analgesic and anti-inflammatory drug for symptomatic treatment of OA. Additionally, apart from oral use, tenoxicam is also applied as an intra-articular treatment option to minimize gastrointestinal side effects of NSAIDs (2). Clinical evidence suggests that the combined use of NSAIDs and corticosteroids is synergistic (especially macular edema after cataract surgery in ophthalmology) (3).

Objectives: The aim of this study is to compare the effectiveness of intra-articular administration of these treatments and their combination and determine whether the combination of intra-articular steroid and tenoxicam was more effective for a long period rather than only tenoxicam and steroid injection alone in OA treatment.

Methods: In 90 patients (56 female, 34 male) with diagnosis of knee osteoarthritis, patients with knee osteoarthritis were randomly divided into three groups (30 patients per group): Group 1 were treated by intra-articular injection of triamcinolone hexacetonide. Group 2 were treated by intra-articular injection of triamcinolone hexacetonide combined with tenoxicam. The estimation of the severity of pain by the visual analog scale (VAS) were enrolled at baseline and 1, 3, 6 months post-injection. Additionally, the Western Ontario and McMaster Universities Index (WOMAC) was used to determine the outcome measures of pain, stiffness and physical functioning at baseline and 1, 3, 6 months post-injection.

Conclusion: The combination of triamcinolone hexacetonide and tenoxicam was more effective for a long period rather than only tenoxicam and steroid injection alone in OA treatment.

THU0465 PHARMACOKINETICS AND TOXICOKINETICS STUDIES OF A SUSTAINED RELEASE LIPOSOMAL FORMULATION OF DEXAMETHASONE SODIUM PHOSPHATE (TLC599) FOLLOWING INTRA-ARTICULAR INJECTION IN DOGS

Background: Osteoarthritis (OA) is a degenerative joint disorder with limited long-lasting treatment options. Various steroid formulations on the market are effective but required frequent intra-articular (IA) injections due to short-term symptomatic relief. IA steroids have been shown to increase cartilage loss in knee and the rapid absorption into systemic circulation could cause adverse side effects, limiting their effectiveness (1). To circumvent these issues, TLC599, a novel sustained-release liposome formulation of dexamethasone sodium phosphate (DSP) was developed to provide a sustained OA pain management over an extended period with reduced side effects and toxicity. TLC599 resulted in sustained presence in the synovial fluid without significant local and systemic side effects from OA treatments following IA injection.

Objectives: To evaluate pharmacokinetics (PK) and toxicokinetics (TK) of TLC599 following IA injection in dogs.

Methods: In two studies, the dexamethasone phosphate (DP) and dexamethasone (DEX) concentration was quantified and the PK/TK profile of TLC599 following IA injection in dogs.

Results: Study #8351851: Following a single-dose IA injection of TLC599, DP concentration declined after 15 days but remained at similar level from 30 days to 120 days post-dose. Overall, the prolonged 120-day residence time of TLC599 in synovial joint was observed (Figure 2).

Conclusion: TLC599, a novel extended-release liposome formulation of DSP, showed a long-lasting-profile up to 120 days in synovial joint after a single IA injection in a preclinical dog study. In addition, no significant systemic exposure and accumulation of DP and DEX in dog plasma was observed following multiple-dose administration of TLC599. Animal studies indicate that TLC599 may be an effective and superior chronic treatment for OA.

Acknowledgement: The authors thank Yingfang Li, Jiunmin Lai, Ruixue Chen, Ph.D. and Carl Brown Ph.D. for reviewing support.

Results: The mean age of patients was 65.97±9.29 years. In tenoxicam group, median pre- and post-treatment (at 1, 3 and 6 months) VAS/ WOMAC scores were 8.00/34.00, 0.00/8.00 and 8.00/34.00, respectively. In steroid group, median pre- and post-treatment (at 1, 3 and 6 months) VAS/WOMAC scores were 8.00/34.00, 1.00/8.00, 8.00/ 34.00 and 8.00/34.00, respectively. In steroid plus tenoxicam group, median pre- and post-treatment (at 1, 3 and 6 months) VAS/WOMAC scores were 7.00/34.00, 0.00/6.00, 1.00/8.00 and 2.00/10.00, respectively. VAS and WOMAC scores in 1 month after the injection significantly decreased in both groups compared to baseline (p<0.01). However, there was a pronounced improvement in only steroid plus tenoxicam group at 3 and 6 months post-injection (p<0.01). Steroid plus tenoxicam group showed significantly improved VAS and WOMAC scores when compared to only steroid and tenoxicam group at follow-up 3 and 6 months (p<0.01).

Conclusion: The combination of corticosteroids and tenoxicam seems to produce a more effective result than alone therapy in reducing pain and improving functional recovery.

OBJECTIVES: To examine the possible role of genetic susceptibility for fatigue in southern Spanish women with fibromyalgia, by looking at the possible associations of fatigue and single nucleotide polymorphisms in 34 fibromyalgia candidate-genes, at the interactions between genes, and at the associations between gene-physical activity.

METHODS: In this cross-sectional study participated 276 women with fibromyalgia. We extracted DNA from saliva in order to analyse gene-polymorphisms related to fibromyalgia susceptibility, symptoms, or potential neurological impacts. Accelerometers registered the participants' physical activity and sedentary time. Five dimensions of fatigue were assessed with the Multidimensional Fatigue Inventory. Age, body fat (%), and analgesics and antidepressants consumption were considered as confounders in all analyses. Based on the Bonferroni’s and False Discovery Rate (FDR) values, the statistical significance was interpreted.

RESULTS: AT carriers of the rs4435709 polymorphism (sodium channel protein type 9 subunit alpha, SCN9A, gene) showed the highest scores on fatigue. Carriers of the heterozygous genotype of the rs1801133 (methylene tetrahydrofolate reductase, MTHFR, gene) or rs4597545 (SCN9A gene) polymorphisms who were physically active reported lower fatigue compared to their inactive counterparts. Highly sedentary carriers of the homozygous genotype of the rs7607967 polymorphism (AA/AG genotype; SCN9A gene) presented higher fatigue than those with lower levels of sedentary time.

CONCLUSION: Physical (in)activity behaviours and the SCN9A and MTHFR genes were jointly related to fatigue. Thereby, the potential benefits of following an active lifestyle might be observed more clearly in women with fibromyalgia genetically predisposed to higher levels of fatigue.

Results: Replacing 30 minutes of ST with LPA was associated with better strength in upper limb (B=0.19), handgrip strength (B=0.02) and aerobic fitness (B=0.22); all p<0.02). Replacing 30 minutes of LPA with MPA was related to better strength and flexibility in lower and upper limb (B ranging from 0.43 to 1.97; all p<0.02). Finally, replacing 30 minutes of LPA with MPA was associated with better strength and flexibility in lower and upper limb, aerobic fitness and balance (B ranging from 0.15 to 8.54; all p<0.04).

Conclusion: Replacing short time periods (30 min) of ST by PA (especially of moderate intensity) was related to better physical fitness. Moreover, to replace 30 min of LPA by MPA was related to better physical fitness. Our findings support the implementation of experimental research to better understand the extent to which replacing sedentary time (by LPA or MPA) or replacing LPA (by MPA) might enhance difference components of physical fitness in fibromyalgia. Such findings would have direct clinical implications.

THU0471
THE EFFECT OF VIRTUAL REALITY EXERCISES ON PAIN, FUNCTIONALITY, CARDIOPULMONARY CAPACITY AND QUALITY OF LIFE IN FIBROMYALGIA SYNDROME: A RANDOMIZED, SINGLE-BLIND, CONTROLLED STUDY

Musa Polat1, Abdulkahar Kalveci2, Zafir Gürmen2, Gülçin Kaymak Karatas2.
1Niğde University, Niğde, Turkey; 2Gazi University Faculty of Medicine, Ankara, Turkey

Background: Fibromyalgia Syndrome (FMS) is a clinical condition with many symptoms such as chronic generalized pain, fatigue, sleep disorder, cognitive dysfunction and depressive mood. Management of FMS is difficult and the most important component is regular exercise. In this syndrome, patients generally have compliance and motivation problems in maintenance of exercises. In recent years, exercises, with fun and game components, have been prescribed to increase patient compliance.1 Motion-controlled video games targeting virtual reality are examples of these exercises.2

Objectives: To investigate the effect of motion controlled video games on pain, functionality, cardiopulmonary capacity and quality of life in fibromyalgia women.

Methods: Forty women (> 18 years) who have FMS were included in study. Patients were randomized into study and control groups. Control group performed aerobic exercise (cycling, 3 days/week, 20 minutes/day) for 4 weeks. Study group performed virtual reality exercise (Volleyball, Microsoft Xbox Kinect®, 3 days/week, 15 minutes/day) together with cycling exercise. After the four week supervised exercise program, both groups received the same home exercise program for four weeks. All patients were evaluated at baseline, 4th and 8th weeks. Primary outcome measure was Fibromyalgia Impact Questionnaire, Visual Analogue Scale (VAS), Hospital Anxiety and Depression Scale, Fatigue Severity Scale (FSS), Symptom Severity Scale, EuroQoL-Quality of Life/Visual Analogue Scale (EQ5D-QoL/VAS) and 6 Minute Walk Test (6MWT) were used as secondary outcome measures. Positive and Negative Affect Schedule (PANAS) was used for patient satisfaction. T-test was used to compare demographic data between two groups. Repeated measures ANOVA was used in evaluation of intra-group efficiency of treatment. Treatment group and time interaction was evaluated by two-way analysis of variance. We calculated 20 patients per group, in order to find 14% minimal clinical difference in Fibromyalgia Impact Questionnaire with 80% power and 0.05 error rate (Tip 1 error).3

Results: All patients completed supervised exercise program (4 weeks), 34 patients (17 study group, 17 control group) were evaluated at the 8th week. Age, body mass index, education status, comorbidities and drug use were similar in both groups (p > 0.05). After four weeks, all outcome measures improved significantly in both groups (p<0.05). However, there was no statistically significant difference in all outcome measures between 4th and 8th weeks. Group and time interactions for 6MWT (F (1,21, 46.33) = 4.04, p = 0.043), FSS (F (1,61, 61.24) = 4.21, p = 0.026), EQ5D-QoL Scale (F (2, 76) = 4.55, p = 0.014) and EQ5D-VAS Scale (F (1, 4, 53.55) = 3.59, p = 0.049) were significant only for the study group. In addition, PANAS score was significantly higher in study group (p <0.001).

Conclusion: Virtual reality exercises along with aerobic exercise increase cardiopulmonary capacity and quality of life in FMS. In addition, they increase patient satisfaction and may improve patient compliance to exercise.

THU0472
FIBROMYALGIA SYNDROME IN WEST AFRICA: ACR 1990 IS NOT SENSITIVE FOR THE UNDER-DIAGNOSED AND WIDELY MISUNDERSTOOD DISORDER

1University of Ilorin Teaching Hospital, Ilorin, Orthopaedic Surgery, Ilorin, Nigeria; 2University of Ilorin Teaching Hospital, Ilorin, Rheumatology, Ilorin, Nigeria; 3University of Ilorin Teaching Hospital, Family Medicine, Ilorin, Nigeria; 4Ladoke Akintola University of Technology Teaching Hospital, Family Medicine, Ogbomoso, Nigeria

Background: Like most poorly understood rheumatic conditions, Fibromyalgia is thought to be rare in West Africa. Many clinicians rely on the various ACR classification criteria to make a diagnosis of Fibromyalgia despite the unknown performance of these criteria among patients of sub-Saharan African origin.

Objectives: To describe the characteristics of fibromyalgia in Nigerian patients and determine the sensitivities of four ACR criteria sets.

Methods: Consecutive patients diagnosed with fibromyalgia for the first time by a rheumatologist were evaluated using ACR 1990, ACR 2010, 2011 modification of ACR 2010 (ACR 2011) and ACR 2016 classification criteria for fibromyalgia. Sleep quality was assessed with the Pittsburgh Sleep Quality Index (PSQI), fatigue with the Fatigue Severity Scale (FSS) and severity of fibromyalgia with the Revised Fibromyalgia Impact Questionnaire (FIQR). The overall characteristics and the beliefs of these patients regarding their disease were analysed.

Results: Of the one hundred and fourteen (114) patients, ninety six (96) were females; male-to-female ratio is 1:5.3. The median duration of symptoms before diagnosis is 54 months (3 to 273 months) and the mean age is 44.6±15.6 years. Mild, moderate, and severe fibromyalgia were found in 32(28.1%), 53(46.5%) and 29(25.4%) patients respectively. Sensitivities of ACR 1990, ACR 2010, ACR 2011, and ACR 2016 were 38.5%, 68.2%, 76.7% and 76.7%, respectively. Poor sleep was found in 83 (72.8%) patients. Patients in functional classes I, II, and III were 71 (62.3%), 19 (16.7%) and 24 (21.1%), respectively. There was none in class IV. There was positive history of widespread pain in at least one first degree relative of 56 (49.1%) patients. Twenty-one (18.4%) patients had changed or quit their job due to the disease and there was
significant association between job loss and number of tender points as well as disease severity. The Mean FFS score is 4.48±1.3 and 73 (64.0%) patients believed their problem is a spiritual attack while 43 (37.7%) had done one form of ritual or the other in search of cure.

**Conclusion:** Fibromyalgia syndrome exists in West Africa. It is poorly understood among the sufferers and ACR 1990 is not sensitive as a diagnostic tool for the condition.

**THU0473**  
**MINDFULNESS IN FIBROMYALGIA: MEAN LEVELS AND CORRELATION WITH DISEASE BURDEN**

**Marco Antivalle, Federica Rigamonti, Michele Agostì, Piercarlo Sarzi Puttini. L. Sacco University Hospital, Rheumatology, Milano, Italy**

**Background:** Limited evidence suggests that mindfulness-based interventions can have a role in the management of fibromyalgia (FMS) [1], with positive effects on quality of life, pain perception [2] and sleep problems [3]. However, there is little data on the levels of mindfulness in FMS and its relationship with the impact of disease.

**Objectives:** To evaluate the levels of mindfulness and its correlation with disease burden in FMS.

**Methods:** Mindfulness was assessed in 112 FMS patients (mean age 45.9±11.36 yrs, 86.5% females) and in 128 (43.60±14.35 yrs, 75% females) healthy control subjects by the Mindful Attention Awareness Scale (MAAS) questionnaire [4]. The MAAS, a 15-item scale developed to assess individual differences in the frequency of mindful states over time, is the most popular scale measuring mindfulness. Each item can be scored on a Likert scale from 1 to 6, lower scores indicating a greater tendency towards mindfulness. FMS patients were further evaluated by Widespread Pain Index (WPI) and Symptom Severity Scale Score as per 2016 criteria, by the revised FIQ score, and by the Facit-Fatigue scale. Data analysis, including ANOVA and Pearson correlations, was performed with the SPSS software.

**Results:** In the whole population, mean MAAS score was 4.17±0.72, a value comparable to literature data in different populations, and was correlated to age (r=-0.175, p= 0.008) but not significantly different in males vs females (4.28±0.67 vs 4.16± 0.72). FMS patients and control subjects showed similar values (4.12±0.80 and 4.22±0.63, p=0.291). In FMS patients, the MAAS score showed a significant direct correlation with FACIT-fatigue scores, and a significant inverse correlation with overall impact of disease, as assessed by the burden of somatic symptoms and FIQR score. MAAS score showed no significant correlations with variables directly related to pain domain (WPI, tender points), nor with disease duration (Table 1).

**Conclusion:** Mindfulness levels, as assessed by MAAS questionnaire, are not significantly different in FMS patients as compared to unselected healthy control subjects. However, levels of mindfulness are higher in patients reporting a higher disease burden, but lower in patients reporting lower levels of fatigue, and are not significantly correlated to pain. Mindfulness in FMS shows complex interactions with the different domains of the disease, and needs to be further investigated, in order to clarify its relationship with disease features, and eventually to establish guidelines for mindfulness-based interventions.

PREVALENCE OF THYROIDIAN DISORDERS IN A POPULATION WITH FIBROMYALGIA

Marco Antonio G Pontes Filho, DOMICIANO DIOGO SOUZA, Rafael Pontes Andreussi, Leonardo Rodrigues Da Silva. Hospital Das Clínicas, Rheumatology, São Paulo, Brazil

Background: Fibromyalgia (FM) is a clinical syndrome characterized by diffuse pain associated with other symptoms such as fatigue, sleep disturbance and mood. It presents a series of differential diagnoses such as thyroid disorders, hypoparathyroidism, systemic inflammatory diseases and myopathies. Hypothyroidism is a disease with a prevalence of 4-6% of the population, having many symptoms in common with FM, such as fatigue, mood changes, constipation, and diffuse pain in some cases.

Objectives: The purpose is to evaluate the association between FM and thyroid disorders.

Methods: A retrospective monocentric case-control study in a tertiary hospital, with patients and controls having regular follow-up. The cases were composed of women over 40 years old, diagnosed with FM by the criteria ACR 1990 and ACR 2010, without autoimmune disease or other confounding diseases for pain. The control consisted of women over 40 years old, without autoimmune diseases. Laboratory tests included TSH and free T4 in all patients. Evaluation by ANA, anti-TPO and anti-thyroglobulin antibodies, only when appropriate. The sample was classified into euthyroid, clinical and subclinical hyperthyroid, clinical and subclinical hypothyroid. Statistical analysis included Fischer’s T-tests and others where appropriate. The p value was significant when ≤ 0.05.

Results: The sample consisted of 142 patients, (median age of 58 years) and controls with 136 patients (median age of 67 years). Patients with FM had a greater number of thyroid disorders (31.7%) than controls (14.7%) (p = 0.001). FM patients had a TSH higher than the controls (mean 9.06 vs 2.96; p = 0.0026), with a lower free T4 (mean 1.06 vs 1.31; p = 0.0001), ANA, anti-TPO and anti-thyroglobulin antibodies analysis showed no differences between both groups (p = 1; p = 0.08, p = 1; respectively), when performed. Because of the small difference in median age between the two groups, a sub analysis was performed separating patients between the ages of 40 to 60 years and over 60 years. The same results previously seen were found.

Conclusion: Patients with FM had a greater association with clinical hypothyroidism. However, we did not find any association with autoantibodies in our casistic.

THU0475 THE EFFECT OF SUPERVISED DYNAMIC EXERCISE PROGRAM ON SOMATOSENSORY TEMPORAL DISCRIMINATION IN PATIENTS WITH FIBROMYALGIA SYNDROME

Tugce Ayyıldız1, İliknur Onurulu2, Alperen Korucu2, Zater Günel1, 1 Gaziantep University Faculty of Medicine, Ankara, Turkey; 2 Gaziantep University Hospital, Ankara, Turkey; 3 Numune Research and Training Hospital, Ankara, Turkey

Background: Somatosensory temporal discrimination (STD) is the detection of two separate stimuli applied to the body over a short period of time (1). It is thought that STD provides information about the central processing of sensory stimuli. It has recently been reported that STD is impaired in fibromyalgia syndrome (FMS), which is considered to be the prototype of central sensitization syndromes (2).

Objectives: To evaluate the effect of dynamic exercise program on STD in patients with FMS.

Methods: The study included 48 female FMS patients diagnosed according to the ACR 2010 classification criteria who applied to outpatient clinics of Physical Medicine and Rehabilitation Department. Patients with inflammatory rheumatic disease, peripheral and central neurological diseases, history of malignancy and cardiode problems, and those who started a new medical therapy or exercise program related to FMS in the last 3 months were excluded. Before the study, local ethics committee approval was obtained. The study was designed as a prospective, randomized, single blind and controlled study. The patients were divided into two groups. Those included in the supervised exercise group (SEG) were given an exercise program that consisted of submaximal aerobic exercise (treadmill) and low-medium resistant isometric exercises under the supervision of a physiotherapist, 1-hour per day, 3 days in a week for 4-weeks. Those included in the home exercise group (HEG) were given a home exercise program that consisted of low-to-medium resistance isometric exercises and aerobic exercises 1-hour per day, 3 days in a week for 4-weeks. All patients were evaluated at baseline and after 4 weeks of treatment. Visual analogue scale (VAS) for pain, hospital anxiety and depression scales (anxiety: HADA, depression: HADD), fibromyalgia effect questionnaire (FIO), symptom severity scale (SSS) were used for clinical assessment. Additionally somatosensory temporal discrimination threshold (STDT) was measured by a blinded investigator. In order to achieve a difference of 25ms in STDTs between two groups, we calculated 20 FMS patients per group (power: 80%, alpha: 0.05 two sided) (2). However, 24 patients were included in the study because of the 20% chance of discontinuation. For the demographic, basal clinical and neurophysiological comparisons between the two groups, the independent sample-T test was used for the normally distributed data, and the Mann Whitney U test was used for the non-normally distributed data. In order to assess the effect of treatment on outcome measures, 2-way repeated measures of variance analysis (Treatment group x time) was used. Intention to treat analysis was performed.

Results: There were statistically significant changes in the VAS, HADA, HADD, FIO and SSS scores and STDTs in both groups after treatment programs (p <0.001). In the 2-way repeated measures of variance analysis, the treatment group x time interactions for VAS, HADA, HADD, FIO and SSS scores were found to be significant in favor of the supervised exercise group (p <0.05). However, no statistically significant interaction (treatment group x time) was found for STDT (p: 0.18).

Conclusion: We demonstrated that STD improves with exercise in patients with fibromyalgia for 4 weeks. However, this change was similar in both groups. Additionally, we showed that dynamic exercise program ameliorates pain, psychological status, function and other symptoms related to fibromyalgia syndrome.

THU0476 NEW PARADIGMS IN FIBROMYALGIA RESEARCH: INFLAMMATORY CELLS-TO-LIPOPROTEINS RATIOS AS PREDICTIVE AND DISCRIMINATOR MARKERS

Marwan Alnimer1, Talar Merzca1, Ayin Marco2, 1 Hawer Medical University, College of Pharmacy, Erbil, Iraq; 2Rizgany Teaching Hospital, Rheumatology, Erbil, Iraq

Background: Fibromyalgia (FM) is a chronic idiopathic disease characterized by diffuse pain, fatigue, sleep disturbances, stiffness, anxiety and depression. Compared to healthy subjects. FM patients have significant high ratios of mean platelet volume, Neutrophil-to-lymphocyte, and platelet to lymphocyte. Fibromyalgia showed a significant abnormal lipid profile characterized by higher levels of fasting serum triglyceride and cholesterol.

Objectives: This study aimed to derive ratios from the circulating inflammatory cells and serum lipoprotein levels as markers of disease-severity in newly diagnosed fibromyalgia.

Methods: We carried out a cross-sectional study with 90 newly-diagnosed fibromyalgia patients and 25 aged-matched healthy subjects to determine the haematological indices and serum lipoprotein profile. Revised
fibromyalgia impact questionnaire (FIQR), Tender points (TPs), fatigue severity scale, insomnia severity index, and the Hamilton’s scale for depression were used to assess the disease severity.

Results: Monocyte-to-high density lipoprotein ratio (MHDR) correlated significantly and inversely with tender points and FIQR scores while lymphocyte-to-high density lipoprotein ratio (LNHDLR) and lymphocyte-to-apo lipoprotein-B100 (LAPOR) ratio correlated significantly and directly with FIQR. None of the circulating inflammatory cells-to-lipoprotein ratios correlated with fatigue, insomnia, and depression-related symptoms.

Multi-variable regression analysis revealed a significant mean score of FIQR-symptoms equal to 63.2 with prediction of 11.9% (R=0.346, F=5.903, p=0.004, β coefficients for MHLDR=−0.257, and for LNHDLR=−3.789). The area under the curve and 95% confidence intervals of LNHDL is 0.658 (0.545–0.771) at the cut-off score of the FIQR-related symptoms at 63.2.

Conclusion: Circulating inflammatory cell-to-lipoprotein ratios can serve as prognostic markers in the assessment of disease-severity in fibromyalgia patients.

THU0477
A FIBROMYALGIA ASSESSMENT SCREENING TOOL ON A MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE (MDHAQ) WHICH DOES NOT INCLUDE A SELF-REPORT PAINFUL JOINT COUNT (PAINFUL JC), FAST3nJC, RECOGNIZES FIBROMYALGIA SIMILARLY TO OTHER FAST3 INDICES WHICH INCLUDE A PAINFUL JC

Theodore Pincus, Isabel Castrejon. Rush University Medical Center, Chicago, United States of America

Background: Fibromyalgia (FM) generally is easily recognized, but a diagnosis may be difficult, particularly in patients with secondary FM who have other primary diagnoses. Criteria for FM initially were reported in 2000, and revised in 2011 and 2016, based entirely on a patient self-report questionnaire. However, FM criteria are not collected in most routine clinical care, as it is not feasible to use multiple patient questionnaires in busy clinical settings. MDHAQ/RAPID3 (multidimensional health assessment questionnaire/routine assessment of patient index data) has been found informative in all diseases in which it has been studied. Cumulative indices based on MDHAQ scales known as FAST3 (fibromyalgia assessment screening tool) recognize FM at levels of agreement with revised FM criteria of >80% and correlations of >0.80, p<0.001. Pragmatic recognition of FM in non-rheumatic diseases based on MDHAQ may be possible, as most components of the MDHAQ (as well as the HAQ) appear generic rather than disease-specific. One component of MDHAQ/FAST indices, a self-report painful joint count (painful JC), is rheumatology-specific. Therefore, a FAST3-nJC (no painful JC) index was analyzed vs revised FM criteria as gold standards for possible use in non-rheumatology patients to recognize FM.

Objectives: To analyze FAST3-nJC versus 2011 and 2016 FM criteria, and compared to other FAST3 indices which include a painful JC, to recognize FM.

Methods: All patients with all diagnoses complete an MDHAQ at all visits in routine care at one setting. The self-report questionnaire to recognize the 2011 and 2016 FM Criteria was added over a 6-month period to be completed by consecutive patients. The MDHAQ includes 0–10 scores for physical function, pain and patient global visual analog scales (VAS), compiled into 0–30 RAPID3, as well as a 0–10 fatigue VAS, 0–5 self-report painful joint count, and 0–60 symptom checklist. All MDHAQ scales were analyzed for agreement with FM Criteria according to receiver-operator-characteristic (ROC) curves for area under the curve (AUC). Optimal cut points for each measure were identified, based on specificity and sensitivity, to develop optimal cumulative indices for clues to FM versus the 2011 and 2016 Criteria as gold standards.

Results: Among 502 patients with complete data, primary ICD-10 diagnoses were FM in 49, OA in 74, RA in 78, SLE 88 and other rheumatic diseases in 213. Primary or secondary FM was identified in 131 (26%) who met 2011 FM criteria, and 112 (22%) who met 2016 FM criteria. The 4 MDHAQ scales with the highest AUC vs FM Criteria (0.829–0.889) were symptom checklist, painful JC, fatigue, and pain. Three cumulative FAST3 measures were: FAST3-P with symptom checklist, painful JC and pain VAS; FAST3-F with symptom checklist, painful JC and fatigue VAS; FAST3nJC with symptom checklist, pain and fatigue VAS, but no painful JC. All FAST3 indices agreed with FM Criteria >79% and kappas were >0.52, indicating good agreement (Table). As expected, lowest agreement was seen for FAST3nJC, since the FM criteria include a self-report painful joint count, but differences are quite small.

Abstract THU0477 – Table 1. Percent agreement and kappa of 3 FAST3 (fibromyalgia assessment screening tool) indices vs 2011 and 2016 FM Criteria

<td>0.60 (0.51–0.68)</td>
<td>0.52 (0.44–0.60)</td>
</tr>
</tbody>
</table>

Conclusion: FAST3nJC had slightly lesser agreement with 2011 and 2016 FM criteria than FAST3-P and FAST3-F but would appear
satisfactorily as a candidate for clues to recognize FM in patients with non-rheumatic diseases, as a diagnosis of FM ultimately is made by a physician.

THU0478 IS FIBROMYALGIA ASSOCIATED WITH STRUCTURAL OR FUNCTIONAL ABNORMALITIES IN SKELETAL MUSCLE?

Carlos Pineda1, Héctor García1, Gabriela Pineda2, Ángelica Peña3, Laura Aline Martínez2, Jaime Mendoza Torres1, Luis Carlos Rodriguez Delgado1, Mariana Moreno1, Jessica Gutierrez1, Araceli Bernal1, Marwin Gutierrez1, Manuel Martínez-Lavin1, Instituto Nacional de Rehabilitación Luis Guillermo Ibarra Ibarra, Mexico City, Mexico; IMSS Hospital General Regional No. 1, Queretaro, Mexico; Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico; ISSSTE Hospital General Zona Fernando Quiroz, Mexico City, Mexico.

Background: Fibromyalgia (FM) is a chronic nonarticular pain syndrome of unknown etiology characterized by diffuse muscular pain, fatigue and mood disturbances. Previous studies have shown absence of skeletal muscle degeneration, regeneration or inflammation. Altered muscle fiber size distribution and decreased capillary density were the only abnormalities reported. From the clinical point of view some FM symptoms (fatigue, pain, myalgias, trigger points, stiffness) suggest skeletal muscle involvement. Objectives: The objective of this study is to determine if there are structural and functional abnormalities in the skeletal muscle in patients with primary FM assessed by means of a non-invasive, low-cost multimodality approach.

Methods: Female patients > 18 years, with FM diagnosis (ACR 2010 criteria) and healthy controls matched by age. Skeletal muscle morpho-structure and function were assessed by: body mass index (BMI), total fat mass and total muscle mass calculated by direct segmental multi-frequency bioelectrical impedance analysis. Cross-sectional measurements of rectus femoris muscle area and tissue echogenicity were evaluated by ultrasound and pixel analysis. Maximum handgrip strength by digital dynamometry, gait speed (6-meter time walk test), and FM Health Assessment Questionnaire (FAHQ).

Results: A total of 94 FM patients and 140 healthy controls were included, mean age was 51.6 years +/- 10.8 vs 50.2 +/- 11.3, respectively (p = 0.27). FM patients compared with controls had similar BMI (27.9 kg/m2 +/- 4.9 vs 26.8 +/- 4.5, p = 0.14), higher total body fat mass (27.8 kg +/- 9.2 vs 25.1 +/- 7.6, p = 0.04), rectus femoris muscle area was also higher for FM patients (44.6 cm2 +/- 11.4 vs 41.7 +/- 13.9, p = 0.05); regarding ultrasound tissue echogenicity, FM patients demonstrated higher mean brightness in rectus femoris (157.2 pixels +/- 19.4 vs 149.8 +/- 22.4, p = 0.01); lesser handgrip strength (22.0 kg +/- 6.6 vs 26.2 +/- 5.4 p = 0.0001); slower gait speed (1.14 m/s +/- 0.2 vs 1.3 +/- 0.2 p = 0.0001); and major impairment in daily activities by FFAQ (47% vs 2.90% p = 0.0001).

Conclusion: This non-invasive multimodal evaluation of the skeletal muscle showed the presence of structural and functional abnormalities in women with FM. These changes can be attributed to sedentary and hyperactive lifestyle with consequent higher total body fat mass, skeletal muscle fat infiltration, and functional impairment of activities of daily living. Alternatively, these abnormalities may also be an expression of a small-fiber neuropathy (myoneuropastic deregulation). Further studies are required to elucidate its underlying pathological process.

THU0479 SAFETY AND Efficacy of MedicaL CANnaBiS in FIBROMYALGIA

Ittch Sagyi1, Lihi Bar-Lev Schleider2, Mahmoud Abu-Shakra2,3, Victor Novack1.

1Soroka Medical Center, Rheumatology, Beersheba, Israel; 2Soroka Medical Center, Beersheba, Israel

Background: Although chronic pain is a well established indication for medical cannabis therapy, there is scarce evidence to support the role of medical cannabis in the treatment of fibromyalgia.

Objectives: The aim of this study was to investigate the characteristics, safety and effectiveness of medical cannabis therapy for fibromyalgia.

Methods: A prospective study with 6 months follow-up period based on fibromyalgia patients who were willing to answer questionnaire in a specialized medical cannabis clinic between 2015 and 2017.

Results: Among the 367 fibromyalgia patients the mean age was 52.9 +/-15.1, of whom 301 (82.0%) were women, 28 patients (7.6%) stopped the treatment prior to the six months follow-up. The six months response rate was 70.8%. Pain intensity (scale 0-10) reduced from a median of 9.0 at baseline to 5.0 (p<0.001), and 194 patients (81.1%) achieved treatment response. In a multivariate analysis age above 60 years (Odds ratio [OR] 0.34, 95% C.I 0.16-0.72), concerns about cannabis treatment (OR 0.36, 95% C.I 0.16-0.80), spasticity (OR 2.26, 95% C.I 1.08-4.72) and previous use of cannabis (OR 2.46 95% C.I 1.06-5.74) were associated with treatment outcome. The most common adverse effects were mild and included dizziness (7.9%), dry mouth (6.7%) and gastrointestinal symptoms (5.4%).

Conclusion: Medical cannabis appears to be safe and effective alternative for the treatment of fibromyalgia symptoms. Standardization of treatment compounds and regimens are required.

THU0480 IS PROLONGED SEDENTARY TIME ASSOCIATED WITH THE IMPACT OF THE DISEASE IN WOMEN WITH FIBROMYALGIA? THE AL-ANDALUS PROJECT

Víctor Segura-Jiménez1, Blanca Gaviñán Carrera2, Pedro Acosta-Manzano2, Alberto Soriano Maldonado3,4, Inmaculada C Alvarez-Gallardo5, Fernando Estevez-Lopez6,7,8, Faculty of Education Sciences, University of Cádiz, Department of Physical Education, Cádiz, Spain; 6Faculty of Sport Sciences, University of Granada, Department of Physical Education and Sports, Granada, Spain; 7Faculty of Education Sciences, University of Almería, Department of Education, Almería, Spain; 8CERNEP Research Center, University of Almería, Sport Research Group, CTS-1024, Almería, Spain; 9Faculty of Education Sciences, University of Cádiz, Department of Physical Education, Cádiz, Spain; 10Faculty of Sport Sciences, University of Granada, Department of Physical Education and Sports, Granada, Spain; 11University of Ulster, Belfast, United Kingdom

Background: Spending time seated has previously shown to be associated with worse symptomatology in fibromyalgia. In addition, to accumulate sedentary time (ST) in prolonged, unbroken periods (bouts) has shown to be particularly harmful in the general population.

Objectives: To examine the association of prolonged ST with the impact of the disease in women with fibromyalgia.

Methods: Four-hundred-and-seven (51.4±7.6 years old) fibromyalgia women participated in this cross-sectional study. Sedentary time accumulated in bouts of ≥10, ≥20, ≥30 and ≥60 minutes, and moderate-to-vigorous physical activity (MVPA) were measured with triaxial accelerometer (GT3X+). To control for total ST, the percentage of ST spent in different bout categories were calculated (e.g., time spent in bouts ≥30 min/ total ST) ×100. We assessed different domains of fibromyalgia impact (function, overall, symptoms) and the global impact of fibromyalgia (total score) with the Revised Fibromyalgia Impact Questionnaire (FIQ). Separate linear regression models were built to assess the association of percentage of ST spent in different bout categories (independent variables) with the domains of fibromyalgia impact and the global impact of the disease (dependent variable) while controlling for age, fat percentage, medication for fibromyalgia and depression, and total accelerometer wear time.

Results: Greater percentage of ST spent in bouts ≥10 min (β=0.171, p<0.001), ≥20 min (β=0.163, p<0.001), ≥30 min (β=0.169, p<0.001), and ≥60 min (β=0.161, p<0.001) was associated with greater global impact of the disease. In model 2, greater percentage of ST spent in bouts ≥10 min (β=0.145, p<0.003), ≥20 min (β=0.138, p<0.004), ≥30 min (β=0.148, p<0.001) was associated with greater impact of the disease.

SLEEP DISTURBANCES IN FIBROMYALGIA – AN AUSTRALIAN TERTIARY HOSPITAL EXPERIENCE

Kevin Su1, Krishna Bajee Sriram1, Parham Afsaraby1. 1Gold Coast University Hospital, Rheumatology, Southport, Australia; 2Gold Coast University Hospital, Respiratory, Southport, Australia

Background: Fibromyalgia (FM) is a central pain disorder with an estimated population prevalence of 2-7% and six times as common in women than men. Obstructive sleep apnoea (OSA) is a structural sleep disorder, with an estimated incidence of 14% of males and 5% females. Incidence of OSA in FM has been variably reported but estimated at 25-40% disorder, with an estimated incidence of 14% of males and 5% females.

Conclusion: Female predominance and 3% population incidence of FM was congruent with literature. We note the mean age was nearing expected upper limits for FM. Increased age as a risk factor for OSA may have led this selection bias. Unexpectedly, overall severity of OSA as per AHI and number of desaturating events as per ODI3 was less in FM. We hypothesise that this is due to a higher proportion of females in the FM group compared to males, confirmation would require a larger study cohort, a limitation of this study. It was beyond the scope of this study to explore concomitant medication use and comorbidities and its effect on sleep. Another significant finding was in males, where sleep efficiency (SE) was lower in both matched and random groups. Furthermore, when matched for age, gender and BMI, males FM have reduced total sleep time. Suggesting that males with FM may have additional impediments to good sleep efficiency which may not be readily recognised during clinical evaluation. Similarly to Prados et al, we found females with FM (fig. 3) had a trend for better sleep quality and less sleep disturbance. However, no domain reached statistical significance, which again reflects low study power. This study emphasises the contribution of OSA as a comorbidity for patients with FM and its effect on sleep quality. Importantly, also the differences in gender.

**HUMAN LUMBAR SPINE FACET JOINT OSTEOARTHRITIS DISPLAYS PREDOMINANT NGF EXPRESSION AND SIGNALING IN CAPSULAR SYNOVIOUM AND SUBCONDYRAL BONE MARROW TISSUES INDEPENDENT OF OSTEOARTHRITIS GRADE**

Matthias Seidel1, Nathalie Busso2, Veronique Chobaz2, Cordula Netzer3, Thomas Huegiele2, Jeroen Geurts3, Matthias Seidel1, Nathalie Busso2, Veronique Chobaz2, Cordula Netzer3, Thomas Huegiele2, Jeroen Geurts3.

**Background:** Increased nerve growth factor (NGF) levels are associated with chronic pain conditions, including low back pain and osteoarthritis (OA). NGF signalling through its receptor TrkA regulates pro-inflammatory neurotransmitters such as substance P (SP). Inhibition of NGF has shown therapeutic efficacy in knee OA [1] and chronic back pain [2], but trials have revealed rare cases of rapidly progressive OA of peripheral joints.

**Objectives:** To describe the tissue distribution of NGF, TrkA, SP and macrophages in facet joint osteoarthritis (FJOA) of the lumbar spine and their association with FJOA grade.

**Methods:** FJOA specimens were obtained by facetectomy from patients undergoing intervertebral fusion (n=10, average age 69 years, 5 males). FJOA severity and presence of synovial hypertrophy was graded using preoperative magnetic resonance imaging (MRI). Relative abundance of NGF, CD68 (macrophages), TrkA and SP in capsular synovium (SY), cartilage (CL), subchondral bone (SB) and subchondral bone marrow (BM) was evaluated semi-quantitatively on a scale ranging from 0-3 using immunohistochemistry. Association between imaging parameters and tissue expression was determined using Pearson correlation analysis.

**Results:** Synovial hypertrophy as determined by MRI was present in six cases (60%) and median Weishaupt grade of FJOA was 2 (1.5-3) corresponding with moderate to severe OA. NGF was abundantly expressed in SY (3 [0.5-3]) and to a lesser extent in BM tissues (2 [1-3], whereas TrkA expression was detected in BM exclusively. NGF abundance in SY and BM showed a strong correlation (r=0.94), but did not associate with synovial hypertrophy or FJOA severity. CD68+ macrophages were highly abundant in BM (3 [1.5-3]) and sparse in SY tissues (0.5 [0-1]). The relative abundance of macrophages and NGF was strongly correlated in SY tissue only (r = 0.78). SP as a downstream mediator of NGF signalling was also abundantly expressed in SY, CL and BM tissues. Tissue distributions of CD68, NGF and SP are summarized in the figure.

**Conclusion:** NGF expression and signalling is evident in lumbar spine FJOA specimens, but not strongly associated with synovial hypertrophy or disease severity. These results are in agreement with recent studies of human knee OA, which have shown osteochondral NGF expression as a hallmark of symptomatic OA independently of chondropathy or synovitis [3].

**DEMOGRAPHICS AND CLINICAL CHARACTERISTICS OF A NATIONAL COHORT OF 290 PATIENTS WITH JOINT HYPERMOBILITY SYNDROME, THEIR SOCIOECONOMIC BURDEN AND THE PERFORMANCE OF THE 2017 INTERNATIONAL CLASSIFICATION CRITERIA OF THE EHLERS DANLOS SYNDROMES**

Mirjana Dociovska, Royal National Orthopaedic Hospital, Rheumatology, Stanmore, United Kingdom

**Background:** Joint hypermobility syndromes (JHS) encompass a spectrum ranging from asymptomatic joint hypermobility through to Ehlers Danlos syndromes (EDS) including hypermobile EDS (equivalent to the former diagnosis of EDS type 3). Many EDS patients have significant musculoskeletal pain and other systemic comorbidities including autonomic, bowel and bladder dysfunction. We present data from a cohort of patients with JHS referred to our tertiary centre from December 2015 to May 2017.

**Objectives:** To increase the awareness of the hypermobility syndrome among general rheumatologists and other health professionals. To assess the impact of this condition on the patient general health and their work disability.

**Methods:** We undertook a retrospective analysis of medical records. Statistical analysis utilised non parametric Chi squared analysis for between group comparisons.

**Results:** There were 280 patients: 253 patients (90%) were female and 27 were male (10%) with a female to male ratio of 9:1. The age distribution was from 18 to 66 (mean age 42 years). The age at which they were first diagnosed ranged from 4 to 55 (mean age 29 years); 279 (96%) had Ehlers Danlos Syndrome type 3, one patient had Marfan’s, one Kyphoscoliotic EDS, and two patients had Tenascin X deficiency.

Family history of hypermobility was reported among 185 patients (86%). In relation to the autonomic dysfunction, 185 patients (86%) had orthostatic intolerance, 126 (45%) had gastrointestinal problems; 109 (39%) had bladder dysfunction with 2.5% of them requiring catheterisation. Chronic joint and muscle pain was reported in 91%; 49.6% of these used opioid analgesia long term. One hundred and twenty patients (43%) had work disability.

**Conclusion:** Treatment of JHS is likely to have work disability; 54% vs. 34% (p<0.001). Bladder problems were more common in the group taking opioids (46% vs 32%; p<0.02). A significant association between orthostatic intolerance and bowel problems was observed. Almost half (47%) of those with orthostatic hypotension had bowel problems, compared to only 19% without (p<0.001). Patients with bowel problems were more likely to have bladder problems compared to those without bowel problems (P <0.001).

**ESTIMATION OF PATIENT ACCEPTABLE SYMPTOM STATE FOR PATIENT-REPORTED OUTCOMES BETWEEN 2 POPULATIONS OF PATIENTS WITH NON-SPECIFIC CHRONIC LOW BACK PAIN**

Camille Daste1, Frantz Foisac2, Hendy Abdoul2, Marie-Martine Lefere-Colau1, François Rannou1, Serge Poiraudeau3, Christelle Nguyen4. Hôpitaux Universitaires Paris Centre – Groupe Hospitalier Cochin, Service de Rééducation et de Réadaptation de l’Appareil Lomoteur et des Pathologies du Rachis, Paris, France; 1Centre d’Investigation Clinique Paris Descartes Necker/Cochin, Hôpital Tarnier, Unité de recherche clinique, Paris, France

**Background:** Clinical relevance of commonly used patient-reported outcomes (PROs) is unclear in people with non-specific chronic low back pain (cLBP). Our aim is to determine whether baseline variables contribute to an acceptable symptom state at 1 month.

**Objectives:** To estimate and compare patient acceptable symptom state (PASS) at 1 month post-intervention for 4 PROs between 2 populations of patients with non-specific cLBP and to determine which baseline variables contribute to having an acceptable symptom state at 1 month.

**Methods:** Overall, we included 256 patients: 135 patients with cLBP and active discopathy participated in a randomized controlled trial assessing the efficacy on pain at 1 month of a single glucocorticoid intradicinal injection compared to contrast alone (2), and 121 patients with cLBP and without active discopathy participated in a randomized controlled trial assessing the efficacy on pain at 4 months of 12 sessions of immersive virtual reality (VR) compared to usual care (3). Using an anchor-based method, PASS estimates for PROs were obtained using the 75th percentile method (4). Logistic regression was used to determine baseline variables contributing to achieving PASS at 1 month.

**Results:** At 1 month, 137/256 (53.52%) participants self-rated their health as acceptable. In the whole population, PASS (95% IC) was 47.50 (40.00 to 55.00) for the lumbar-pain VAS, 30.50 (30.00 to 40.00) for the radicular-pain VAS, 39.27 (33.60 to 45.26) for the QUEBEC score, 9.95 (9.16 to 10.00) for the HAD anxiety subscale and 6.70 (6.00 to 8.00) for the HAD depression subscale. The PASS estimates did not differ between the 2 populations of cLBP patients for any of the PRO. The only baseline variable contributing to having an acceptable symptom state at 1 month was symptom intensity.

**Conclusion:** PASS estimates at 1 month did not vary across 2 independent samples of people with cLBP and 2 distinct nociceptive sources of cLBP. The main contributor of the PASS was symptom intensity at baseline. Our findings can be useful in interpreting the clinical relevance of PROs values.

**EFFICACY OF EXTRACORPOREAL SHOCK-WAVE THERAPY IN THE TREATMENT OF SHOULDER CALCIFIC TENDINITIS IN INSUFFICIENT RESPONDERS TO LOCAL STEROID INJECTION THERAPY: A RETROSPECTIVE ANALYSIS**

Meryem Yılmaz Kayşin, Feyza Ünlü Ozkan, Aktas Ilknur, Pinar Akpinar. University of Health Sciences, Faith Sultan Mehmet Training and Research Hospital, Physical Medicine and Rehabilitation, Istanbul, Turkey

**Background:** Calcific tendinitis (CT) results from the deposit of calcium hydroxyapatite crystals in periacellar muscular attachments, and most commonly affects the tendons of the shoulder (1). Extracorporeal shock wave therapy (ESWT) is based on the use of shock waves, and used for pain reduction and tissue healing (2).

**Objectives:** The aim of this analysis is to demonstrate the effects of ESWT in patients with shoulder CT with inefficient response to local steroid injection.

**Methods:** Two-year data of shoulder outpatient clinic were scanned. 10 patients with shoulder calcific tendinitis without satisfying response to local steroid injection (less than 50% decrease in pain-visual analog scale (VAS) score) who were treated with ESWT were reviewed.

**Results:** 10 patients (9 women, 1 man) fulfilled the inclusion criteria. The mean patient age was 51.3 years (range, 32-70 years) and body mass index was 26.2 kg/m2. The affected shoulder was left in 6 (60%) patients and right in 4 (40%). The calcific tendinitis involved the dominant side in 5 (50%) patients and non-dominant side in other 5 (50%). All patients had one peritendinous local steroid injection-2 ml 2% prilocain and 1 ml steroid (5 mg of betamethasone dipropionate + 2 mg betamethasone sodium phosphate). Mean time from symptom onset to the ESWT treatment was 3.5 weeks (range, 2-6 weeks). Mean VAS score was 9 and Shoulder Disability Index (SDI) score was 84.4 before ESWT treatment. ESWT system Elmed-Vibrolith ver3.0 was used in the treatment, each treatment consisted 2000 shocks with a frequency of 150 shocks a minute with maximum tolerable energy density (range, 3.2-3.4 bar). Mean ESWT session was 3.3 (3 patients had 3, 1 patient had 4 and 1 patient had 5 sessions of treatment). Mean post-treatment VAS score was 4.2 (53.3% decrease) and SDI score was 43.8 (48.1% decrease) which were evaluated after the last ESWT session.

**Conclusion:** With its good tolerance and safety, ESWT might be an alternative treatment method for calcific tendinitis of the shoulder. Although limited number of patients, we hope that this study might give rise to future randomized-controlled studies about the efficacy of ESWT in acute-subacute shoulder calcific tendinitis.

**PREGBALFIN EFFICACY IN THE TREATMENT OF CHRONIC PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Ekaterina Filatova, Shandor Erdes. Federal State Budgetary Scientific Research Institute Rheumatology named after V A Nasonova, Moscow, Russian Federation

**Background:** Objectives: To study the efficacy of Pregabal in the treatment of chronic pain in patients with rheumatoid arthritis.

Methods: We enrolled 80 patients with rheumatoid arthritis. Screening with the DN4 neuropathic pain questionnaire showed that 31% of patients (n=25) had a neuropathic pain component (NCP+), DN4-4 points. Mean age was 57.0 ±7.49 years, disease duration - 9.87 ± 9.5 years, DAS28 disease activity - 5.5 ± 1.3, VAS pain intensity - 73.1 ± 17.4. All patients were randomized into two groups: group I received pregabalin in combination with DMARDs; group II received DMARDs only. All patients underwent a clinical and neurological examination, disease activity was assessed with the DAS28 index, the effect of treatment on neuropathic pain was assessed with the DN4 and Pain DETECT questionnaires, pain intensity at rest – with the VAS scale.

**Results:** There were no significant differences between groups before the start of the study (Table 1)

Positive dynamics of VAS pain intensity was observed in both groups [Fig. 1] (77.0 ± 13.5 vs 75.2 ± 14.7, at week 2 48.8 ± 14.2 vs 72.9 ± 14.7).
PERINEURAL INJECTION THERAPY; A NEW MODALITY IN MANAGEMENT OF MECHANICAL LOW BACK PAIN; A COMPARATIVE STUDY

Mohammed Hassan Abu-Zaid, Samar Abd Alhamed Tabra. Faculty of Medicine Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt

Background: Chronic mechanical low back pain represents the second leading cause of disability worldwide being a major welfare and economic problem².

Subcutaneous prolotherapy treats prolonged pathological peripheral neurogenic inflammation for several painful conditions. As it induces apoptosis of proliferating peptidergic nociceptors and neovessels by reducing vascular endothelial growth factor.²

Objectives: To assess the effectiveness of subcutaneous perineural injection therapy in management of pain, physical function, disability and psychological status in mechanical low back pain

Methods: Ninety patients with non-radiating non-specific chronic mechanical low back pain (LBP) that persisted for 12 weeks or more were selected in this study. (Patients with inflammatory LBP, radiating, or LBP due to specific cause, pregnant women or Patients with implanted pacemaker or spinal cord stimulator were excluded from this study). After giving written consent; the patients were randomly divided into 3 groups 30 patients in each. Group I received 8 weekly subcutaneous injections of 1 ml of buffered dextrose 5% in each chronic constriction injury points and tender points in back and buttock. Group II treated by using pulsed electromagnetic field stimulation (PEMFs) for 30 minutes over the lower lumbar region with frequency of 10 Hz and intensity of 2 millitesla every other day for 8 weeks. Group III received sham PEMFs. All patients will be instructed to follow an exercise program in the form of stretching for bar region with frequency of 10 Hz and intensity of 2 millitesla every day for 8 weeks.

Results: The mean age of patients in the 3 groups was 40.2±10.5, 38.3 ±9.9, and 43.1±10.8 respectively. The mean VAS was 7.9±1.4, 8.2±0.6, and 7.6±1.1 respectively. No baseline differences existed between all groups in all parameters. There was significant improvement in VAS, WOMAC and HDAS in group I & II (p<0.05) after treatment, and 4 months later (figure 1). While the improvement in group III was non-significant (p>0.05). The improvement in group I was better than in group II with significant difference between the two groups (p<0.05) after treatment and 4 months follow up.

Conclusion: This preliminary data shows greater effectiveness of Pregabalin in comparison with NSAID and DMARD treatment, both in terms of pain intensity and the neuropathic pain component, which is of practical importance.

ACHILLES TENDON RUPTURE ASSOCIATED WITH THE USE OF FLUOROQUINOLONES IN PATIENTS OLDER THAN 60 YEARS

Andrea Briones-Figueroa, Walter Alberto Silientes-Giraldo, Jose Luis Morell Hita, Mónica Vázquez Díaz. University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: Fluoroquinolones (FQ) are a class of broad-spectrum antibiotics whose use has spread as they are considered safe and well tolerated drugs. Among its musculoskeletal side effects, Achilles tendon rupture (ATR) is a well-known complication that can be disabling, arising recent interest from the pharmacovigilance system after evaluating the reported side effects.

Objectives: To describe the epidemiological and clinical features of patients diagnosed with FQ-associated ATR in a Spanish tertiary hospital.

Methods: A retrospective observational study was performed, which included all patients older than 60 years who were diagnosed of ATR in our center during the period 2000-2017, identifying patients who had been previously treated with FQ. The demographic, clinical and outcome data were obtained from their medical records.

Results: During the study period, 44 patients with ATR were identified, 8 (14.6%) of them previously treated with FQ. In this group of patients, the mean age at diagnosis of ATR was 77.3±9.54 years, being male 6 (75%). Four of them (50%) received concomitant treatment with corticosteroids (CS) and one patient had undergone kidney transplantation due to nephroangiosclerosis. Seven patients (87.5%) were treated with Levofloxacin and one case received Ciprofloxacin, all of them orally. The indication for FQ treatment in half of the cases was acute bronchitis and in the other half exacerbations of underlying respiratory pathology (chronic obstructive pulmonary disease and diffuse interstitial lung disease). The mean duration of treatment with FQ was 6.16 ± 2.4 days, while the mean time from the start of treatment to the diagnosis of ATR was 19.25 ± 14.83 days. In seven patients (87.5%) the rupture was spontaneous, while one patient presented traumatic rupture (low impact traumatism). 87.5% of the ruptures were total ruptures and all cases required surgical treatment, without recurrence reported. The comparison of the characteristics of patients with ATR who had or not received treatment with FQ is shown in the table, identifying significant differences in favor of a higher percentage of patients who were smokers, received concomitant treatment with CS and had spontaneous rupture in the group of patients who had received FQ.

Disclosure of Interests: None declared

References:
Fluoroquinolones Non-Fluoroquinolones p-value

| Age (years) | 77.37 ± 9.54 | 70.13 ± 8.3 | 0.48 |
| Sex | Male 6 (75%) | 25 (69.4%) | 0.75 |
| | Female 2 (25%) | 11 (30.6%) |
| Smoking | 5 (62.5%) | 1 (2.8%) | 0.00 |
| Treatment with CS | 4 (50%) | 2 (5.6%) | 0.01 |
| Treatment with | 0 (0%) | 5 (13.9%) | 0.26 |

Type of rupture

Spontaneous 7 (87.5%) 8 (25.8%) 0.01

Traumatic 1 (12.5%) 23 (74.2%)

Conclusion: The Achilles tendon is the most frequent location of tendinopathy associated with FQ, being affected in 95% of cases. The risk factors associated to an increased risk to develop FQ-associated ATR includes age over 60 years, male gender, chronic treatment with CS and organ transplantation, all these being present in our cases. Despite being a relatively frequent adverse event, it is underdiagnosed and the risk of ATR is not usually assessed when indicating FQ treatment. It is important to perform a risk/benefit assessment, specially in patients with associated risk factors, because most ruptures are complete and require surgical treatment, and may be a potential cause of disability.

THU0489 REAL-WORLD EFFECTIVENESS OF FIXED-SITE HIGH-FREQUENCY TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION IN CHRONIC LOW BACK PAIN

Xuan Kong, M, Dawn Chesser, M, NeuroMetrix, Inc., Waltham, United States of America; GlaxoSmithKline Consumer Healthcare, Weybridge, Surrey, United Kingdom

Background: Fixed-site high-frequency transcutaneous electrical nerve stimulation (FS-TENS) is a form of TENS in which the stimulator is designed for a predetermined location rather than for co-localization with the patient’s pain. A small wearable device for localized application while active and sleeping facilitates adequate dosing.

Objectives: To evaluate the effectiveness of regular FS-TENS use in a large, real-world chronic low back pain (CLBP) population.

Methods: This retrospective, observational study evaluated use of FS-TENS (worn on upper calf; providing semi-continuous stimulation of sensor nerves) to treat CLBP across a 10-week period using previously collected therapy utilization, demographic, and clinical (pain characteristics, ratings) data. Data collected by the device and companion smartphone app are stored in a cloud database. Device usage was significantly different between groups

Results: A total of 834 device users met the inclusion criteria and were assigned to the treatment (671, 80%) or reference (163, 20%) groups. With few exceptions, the two groups had similar demographic and pain characteristics at baseline: the treatment group was older (58±13 vs 56 ±14, P=0.035), had lower body mass index (30.5±8.8 vs 31.9±7.9 kg/m2, P=0.043), was more likely to have hip pain (P=0.037), and less likely to have diabetes (P=0.002) or prior neck injury (P=0.006). There was no difference in baseline composite pain (6.3±2.1, treatment; 6.5±1.9, reference; P=0.364). Device usage was significantly different between groups (86±15%, treatment; 31±13%, reference; P<0.001), as was duration of therapy per week (46±22 hrs/week, treatment; 11±7 hrs/week, reference; P<0.001), median stimulation intensity (ratio of stimulation to sensation level expressed in decibels) (5.3 dB, treatment; 6.0 dB, reference; P=0.045). Of the 163 participants in the original reference group, 143 (88%) served as matches for the treatment group. The baseline to 10-week follow-up change in composite pain was −0.89±2.30 for the treatment group and −0.01±2.3 for the matched reference group, with a standardized mean difference between the groups of 0.38 (95% confidence interval, 0.27–0.49; P<0.001).

Conclusion: This study demonstrated that 10 weeks of regular FS-TENS use improved pain outcomes in a real-world sample of CLBP patients compared with a reference group with low FS-TENS use. This study suggests that regular FS-TENS use may be effective in improving pain outcomes in CLBP patients.

THU0490 PREDICTORS OF CHRONIC PAIN RELIEF BY FIXED-SITE HIGH-FREQUENCY TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION

Xuan Kong, M, Dawn Chesser, M, NeuroMetrix, Inc., Waltham, United States of America; GlaxoSmithKline Consumer Healthcare, Weybridge, Surrey, United Kingdom

Background: Fixed-site high-frequency transcutaneous electrical nerve stimulation (FS-TENS) is a form of TENS in which the stimulator is designed for a predetermined location rather than for co-localization with the patient’s pain. Previous studies in individuals with chronic pain have demonstrated the efficacy and real-world effectiveness of a small wearable FS-TENS device designed for localized application to a single placement site to ensure comfort while both active and sleeping. Results demonstrated that 50–80% of FS-TENS users with chronic lower extremity or low back pain experience clinically meaningful pain relief, and daily use of the device was associated with greater pain relief relative to intermittent use.

Objectives: To determine predictors of a positive FS-TENS response.

Methods: This retrospective, observational study evaluated users of a FS-TENS device to treat chronic pain over a 10-week period. The device and companion smartphone app collected dosage data, demographics, pain characteristics, and pain ratings and all data were stored in a cloud database. The primary study outcome was the baseline to week 10 change in composite pain (average of pain intensity and pain interference with sleep, activity, and mood). Device users were included if they provided demographic data, pain characteristics indicative of chronic pain, and baseline and week 10 pain ratings. Participants were defined as a responder or comparator based on their change in composite pain (responder: ≥15% decrease; comparator: ≥15% increase). Stepwise forward probit regression was used to determine independent predictors.

Results: There were 451 responders and 263 comparators. Independent predictors (Table) that were associated with greater response to FS-TENS included age, baseline composite pain, adherence/utilization rate (defined as the percentage of days with at least 30 minutes of stimulation), and stimulation intensity (defined as the ratio of therapeutic stimulation to sensation threshold, expressed in decibels). Negative predictors (associated with lower response) included history of headache/migraine and diabetes.

A MULTICENTRE RANDOMISED CONTROLLED FOLLOW-UP STUDY OF EFFECTS OF THE UNDERRIGHTER TRACTION THERAPY IN CHRONIC LOW BACK PAIN

Tamas Gati1, Agota Kulisch2, Eva Czimer2, Györgyi Cserhát3, Judit Feher4, Mihály Oláh5, Zuzsanna Mándó2, Tamas Bender1.

1Polyclinic of The Hospitalier Brothers of St John of God, Budapest, Hungary; 2St. Andrew Hospital for Rheumatic Diseases, Hévíz, Hungary; 3Sóstógyógyfőkút, Nyíregyháza, Hungary; 4Kenézy Gyula Hospital and Clinic (Debrecent), Debrecen, Hungary; 5Hungarospor Hajdúszoboszló Private Limited Company, Hajdúszoboszló, Hungary

Background: Chronic low back pain established for more than 3 months is one of the most common problems in the world. The prevalence could reach the 33%.

Objectives: To investigate the effects of underwater traction therapy on chronic low back pain.

The primary objective was to prove the hypothesis that underwater traction therapy has favourable effect of LBP using the change in the clinical parameters. Our secondary objective was to evaluate whether it also leads to the improvement in the quality of life.

Methods: A prospective, multicenter, comparative (intervention arm vs. control arm), randomized follow-up study. Participants aged between 18 and 85 years with more than 3 months low back pain and selected from outpatient clinics.

The participants were randomized to three groups: underwater weight bath traction therapy, weight bath and non-steroidal anti-inflammatory drugs (NSAIDs) medication and only non-steroidal anti-inflammatory drugs (NSAIDs) medication.

During the traction therapy ankle weights were used. The following parameters were measured before, right after, and nine weeks after the three-week therapy: level of low back pain in rest, level during activity tested using the Visual Analog Scale (VAS); specific questionnaire on back pain (Oswestry); questionnaire on quality of life (EuroQ-ual-SD) and clinical parameters.

Results: 141 participants aged 57.67 (±13.04) years. All of the investigated parameters improved significantly (p<0.001) in the underwater weight bath traction therapy groups by the end of the treatment compared to the base period, and this improvement was persistent during the follow-up period. There were no significant changes in the measured parameters in the control group except for the Oswestry Disability Index, which may also be the result of that group receiving pain-relieving drug therapy.

Conclusion: Based on our results, underwater weight bath traction therapy, might have favourable impact on the clinical parameters and quality of life of patients suffering from chronic low back pain.

ROLE OF PLATELET RICH PLASMA IN TREATMENT OF ROTATOR CUFF TENDINOPATHY AND PARTIAL THICKNESS TEAR: FOLLOW UP BY ULTRASOUND

Yasmin Khairy. Mona Nasr, Fatma Ali, Rashaa Ali, Mohammed Abdelhakem, Adham Khalil. Faculty of Medicine, Minia University, Egypt., Rheumatology and Rehabilitation Department, Minia, Egypt

Background: Shoulder pain is the third most common musculoskeletal reason for seeking medical care. The diagnosis of Rotator Cuff Tendinopathy (RCT), with supraspinatus partial thickness tendon tears and tendinosis, constitutes more than 50% of adult cases presenting with shoulder pains at any time. Platelet rich plasma (PRP) injections are nowadays being used as an alternative for treating the tendinopathies, who have failed to be managed by conservative management.

Objectives: This work aimed to asses the effect of PRP injection under musculoskeletal ultrasound (MSUS) guidance in patients with rotator cuff tendinopathy, and partial thickness tear in comparison with those who received a rehabilitation program only. Baseline assessment and after three months was done using clinical, functional and ultrasonographic evaluation.

Methods: Our study included 60 patients with RCT diagnosed both clinically and by MSUS. Patients were divided into two groups (gl, gii); group I included 30 patients who received a Supervised Rehabilitation Program and group II included 30 patients who received PRP injection. Patients in both groups were assessed clinically, functionally (VAS) and (SPADI) and sonographically at baseline and after 3 months. Rehabilitation Program included: hot packs, (TENS), and (therapeutic ultrasound). The Exercise Programs (supervised and home-based) were applied, including: (ROM, stretching and strengthening exercises of the rotator cuff and scapular muscles). PRP injection was prepared under complete sterile conditions by whole blood centrifugation with specific

THU0494

RELATIONSHIP BETWEEN THE AREA OF THE MEDIAN NERVE CROSS SECTION AND THE CIRCUMFERENCE OF THE CARPUS AS A DIAGNOSTIC TOOL FOR CARPAL TUNNEL SYNDROME

Carlos Guillen-Astete, Patricia García-Casado. Hospital Ramón Y Cajal, MADRID, Spain

Background: The diagnosis of carpal tunnel syndrome (CTS) is fundamentally electrophysiological, however, on diagnostic suspicion ultrasonography has been shown to correlate satisfactorily with the electromyogram. The limitations of the ultrasonography study of the median nerve in patients with STC are due to the fact that the intervals of normality of the area of the median nerve cross section (ACTNM) are variable according to the sources consulted, the sex and the anthropometry of the individual.

Objectives: The purpose of this study is to determine whether NMTA can be correlated with a simple measurement such as wrist circumference length (MCL) in patients with electrophysiological diagnosis of TCEs and healthy subjects and used to discriminate them better than with the simple measurement of NMTA.

Methods: We included 50 patients with electrophysiological diagnosis of CTS and 43 healthy subjects of white ethnicity, older and with different anthropometric characteristics. The patients came from the Rheumatology consultations of three different centres. Healthy volunteers were subjects without CTS clinic, thyroid alterations, diabetes or known autoimmune rheumatological diseases whose data were obtained from a previous study. Circumference was measured with a flexible tape measure around the carpus immediately distal to the interstyloid line. The ultrasound measurements were made at the height of the escoid and pisiform bones using three different ultrasound scanners according to the head-quarters: Toshiba Nemio XG, 13Mhz linear probe, Siemens HM70a 14 Mhz and Logiq e GE 12 MHz. All the measured images were captured for analysis and correction of circumference lengths by an observer not linked to the identity of the subjects nor to their character of patient or control. An association study between wrist circumference and ACTNM was performed for both groups and a correlation index was submitted to a validation test for the determination of sensitivity and specificity.

Results: ACTNM was 11.11 SD 1.18mm2 in the control group and 12.73 SD 1.50mm2 in the patient group (p<0.05). The LCM was 18.81 DE 1.50cm and 18.72 DE 1.85 (p=0.803). In healthy subjects, the correlation between ACTNM and carpal circumference showed a satisfactory correlation (Coef Pearson 0.809, p<0.01, bilateral) as well as in patients (Coef Pearson 0.876, p<0.01, bilateral). The ACTNM/LCM index in the control group was 0.590 and for the patient group 0.679 (p<0.01). The area under the ACTNM curve was 0.808 EE 0.049 while in the case of the ACTNM/LCM index was 0.954 EE 0.019. The area under the ACTNM curve was 0.808 EE 0.049 while in the case of the ACTNM/LCM index was 0.954 EE 0.019. With an index of 0.62 or a sensitivity of 93% and specificity of 78% are obtained for the diagnosis of CTS.

Conclusion: LCM correlates well with ACTNM in healthy patients. It could be considered as a good anthropometric marker for further studies of normal ultrasound ranges of the median nerve. The LCM/ACTNM index is a useful measure to discriminate controls of patients with electrophysiological diagnosis of JTS. In our series, this index exceeds the discriminatory capacity of the ACTNM as an individual measure.

Disclosure of Interests: None declared

protocol; blood was centrifuged firstly at 1000 rpm for 10 minutes. The plasma was then transferred to a new glass tube and centrifuged at 3000 rpm for 15 minutes. Platelets will form a pellet at the bottom of the tube. Finally, a pure platelet rich plasma was obtained with a concentration 4 times greater than baseline. Ca gluconate was mixed with PRP (in a ratio of 0.3 ml ca gluconate/ml PRP) immediately before the injection. Under ultrasound guidance, 3ml PRP was injected slowly into the bursa without usage of local anesthetics prior to injection. Post injection, patients were advised to rest, use cold packs and were allowed to do light range of motion exercises 2-5 days post injection. Acetaminophen was allowed for tolerable post injection pain.

Results: Statistical analysis was made to 60 patients. Intragroup analysis showed statistical significant difference in both groups at follow up compared to baseline regarding clinical, functional and radiological data. Inter-group analysis showed more significant results in PRP group regarding clinical improvement (p <0.001), functional assessment (SPADI, PS, DS and total) and WORC score (p <0.0001) and sonographic assessment in (subscapularis tendinopathy, supraspinatus tendinopathy, supraspinatus fibrillar tendon disruption and supraspinatus tendon thickness) (p <0.0001) and sonographic subacromial subdeltoid bursitis (p > 0.001).

Conclusion: Single PRP injection is an effective mean of treatment of RCT as it improves patients’ quality of life clinically, functionally and structurally, better than traditional physical therapy program.

THU0496 THE EFFECT OF ADDITION OF BUFFERED DEXTROSE SOLUTION ON PAIN OCCURRING DURING LOCAL STEROID INJECTION FOR PLANTAR FASCIITIS

Abo alhazen Mosthir1, Mohamed Elwan2, “Al Azhar University, Rheumatology, Assiut, Egypt; “Al Azhar University, Rheumatology, Assiut, Egypt

Background: 5% dextrose water (D5W) has been previously reported to decrease pain when co-administered with noxious agents as chemotherapeutics and micropherses1,2. It has also been reported to have an immediate analgesic effect on low back pain and radiculopathy when injected epidurally3.

Objectives: To evaluate the potential immediate analgesic effect of D5W when added to the injectate during local steroid injection for treatment of plantar fasciitis.

Methods: In this single blind study, a total of 122 patients with plantar fasciitis were randomly assigned to receive either 40 mg triamcinolone acetonide/1ml + 0.5ml lidocaine 2% (group A: 61 patients; 73 heels) or 40mg triamcinolone acetonide/1ml+0.5ml lidocaine2%+ 0.5ml buffered D5W (group B: 61 patients; 69 heels) as a local injection using the medial approach. Clinical assessment including disease duration, BMI, history of previous injection and post-injection complications and 2-week recurrence rate was performed. Plain X-ray lateral view on the painful heel was obtained for diagnosis of associated calcaneal spur. Visual analogue scale (VAS 0-10) was used to assess the degree of pain intensity during injection.

Results: There were no significant difference between both groups regarding age, sex or BMI where the mean for age was 42.56 years in group A and 43.39 years in group B (P = 0.86), the male to female ratio was 16:45 in both groups and the mean for BMI was 31.49 in group A and 30.86 in group B (P=0.51). The mean disease duration was 6.02 months in group A and 10.77 months in group B (P=0.005). Calcaneal spur was diagnosed in 60 patients (82%) in group A and in 47 patients (68%) in group B. A highly significant difference in VAS was observed as the mean was 8.26±2.00 in group A and 4.25±2.05 in group B (P <0.0001) with a confidence interval (95% CI) of 7.78 -8.74 for group A.

Conclusion: Early intervention by rheumatologists in patients with TD due to musculoskeletal disorders reduces the duration of the processes, saving costs to the health system.

THU0498 RISK FACTORS FOR SHOULDER PAIN PERSISTENCE IN ROTATOR CUFF DISORDERS

Sandica Albina1, Ana-Maria Ramazan2, 1Rehabilitation Clinical Hospital, Rehabilitation Clinic, Eforie Nord, Romania; 2Emergency County Clinical Hospital “St Apostol Andrei”, Rheumatology, Constansta, Romania

Background: A large proportion of patients with atraumatic painful shoulder have an unfavorable outcome with long-term disability (1). Predictors of no recovery in patients with shoulder disorders were identified previously: repetitive overhead activity in sport and work (2) duration of complaints, somatization, low social support, older age, unemployment, musculoskeletal comorbidity, recurrent complaint (3,4).

Objectives: To identify the risk factors for over 6 month pain persistence in patients with rotator cuff disorders

Methods: Our prospective study included 51 hospitalized patients with atraumatic shoulder pain. The assessment was clinical and shoulder MRI for confirmation of rotator cuff disorders. We have studied the influence of the patient’s characteristics and the influence of the condition’s characteristics for pain persistence. Statistical analysis was performed in SPSS-18, p<0.05 was significant.

Results: No significant correlations were found between pain persistence and age, gender, smoking status, occupational overuse, physical demands before the onset of pain, marital status, continuous pain, lesions on shoulder MRI. The association with the following elements is statistically significant for pain persistence: opposite shoulder previously affected (p=0.01), diabetes mellitus (p=0.04), insidious onset (p=0.004), the high educational level (p=0.02), physical therapy (p=0.03), local injection (p=0.08).

Using multinominal regression we observed only acute onset of the pain shoulder (RR=7.1) and physiotherapy treatment (RR=0.1) with p=0.026.

Conclusion: The factors that determine the shoulder pain persistence are non-specific and can be sometimes psychosocial, local, physical or other comorbidities like diabetes.

THU0500 PELVIC CONGESTION SYNDROME, UNCOMMON CAUSE OF LOW BACK PAIN

José Luis TANAIPAN JAIME1, Mireia Castil1lo Viella2, Laura Berbel Ancobe1, Georgina Salvador Alarcon3, Nuria Gimenez Gomez3, Lluis Moga Donadeu4, Josep Royo Serrand4, Elena Riera Alonso3, Silvia Martinez Pardo3, 1Rheumatology Hospital Universitari Mutua Terrassa. 2Hospital Universitari Mutua de Terrassa, Rheumatology, Terrassa, Spain; 3Hospital Universitari Sagrat Cor, Rheumatology, Barcelona, Spain; 4Hospital Universitari Mutua de Terrassa, Epidemiology, Terrassa, Spain; 5Hospital Universitari Mutua de Terrassa, Vascular Surgery, Terrassa, Spain

Background: The pelvic congestion syndrome (PCS) is an under and often misdiagnosed entity that appears more frequently in premenopausal age and multiparous women. The pathophysiology consists of a sum of phenomena including venous stasis and inversion of the pelvic venous flow that cause varicose veins and congestion. The left ovarian vein is usually the most affected. Typically it presents as a dull, chronic abdomi nal-pelvic (AP) pain, which worsens with menstruation and prolonged comparing a standard dose with a very low dose: Mature results after 12 months’ follow-up. Int J Radiat Oncol Biol Phys 2012;84:e455-462.

Disclosure of Interests: None declared
standing, and lasts longer than six months. Pain is associated with dyspareunia and varicosities in lower limbs (LL) and genitals. It is a challenging and important to consider typical clinical presentations that simulate osteoarthritic (OA) pathologies. It is usually diagnosed by Angio-CT, and a safe, definitive and successful treatment is the embolization of the affected vein.

Objectives: The objective of this study was to evaluate the characteristics of those patients diagnosed with PCS in our University hospital from January 2014 to May 2018, paying close attention to the atypical forms of presentation that simulate OA pathology.

Methods: We included all patients from our center who were operated by embolization due to a PCS from January 2014 to May 2018. Socio-demographic variables, forms of presentation, pain characteristics, associated symptoms, patient management and outcome data were collected.

Results: Sixty women were included with a mean age of 43 years at diagnosis, 87% (n=52) were multiparous, with a mean of 2 previous pregnancies. In 95% (57) of all cases the duration of symptoms until the diagnosis exceeded 6 months. Patients were classified according to presence and location of pain in 4 groups: 1. Women with AP pain, 23% (14); 2. Women with OA pain 5% (3); 3. Women with mixed AP and OA pain, 59% (35); and 4. Women with other symptoms 13% (8). Regarding patients from groups 2 and 3 (only OA pain or mixed pain) (38), 90% (34) of them presented low back pain, 53% (20) hip pain and 40% (15) sciatic pain. Only 5% (3) of all patients were evaluated by a rheumatologist.

As for the pain characteristics from groups 1, 2 and 3 (52), in 72% (37) of patients it was diurnal, in 48% (26) it worsened with menstruation, in 62% (32) it worsened with prolonged standing and in 35% (18) it worsened at rest. Among the associated manifestations, stand out the presence of LL varicose veins in 74% (38) of patients, genital varicosities in 58% (30), dyspareunia in 42% (22), dysmenorrhea in 40% (21), hemorroids in 37% (19) and dysuria in 18% (9). All patients underwent embolization of the affected vein, with an initial Visual Analogue Scale (VAS) mean of 7.38 over 10, and final VAS mean of 2.63. The mean recovery time was 36 days. The evolution was good or very good in 84% (32) of patients with mixed (AP and OA) pain and in 57% (8) of those who only had AP pain. Less than 2% (1) had a recurrence without the need for reoperation.

Conclusion: PCS is a rare entity, typically associated with long lasting AP pain, but, in more than half the cases, is accompanied with OA symptoms, mainly low back pain. It is important and challenging for the rheumatologist to identify these patients, since treatment is usually safe and effective, and diagnostic delay worsens their quality of life.

27. BACK PAIN, MECHANICAL MUSCULOSKELETAL PROBLEMS, LOCAL SOFT TISSUE DISORDERS

THU0501 MUSCULOSKELETAL DISORDERS IN TYPE 1 AND 2 DIABETIC PATIENTS: PREVALENCE AND ASSOCIATION WITH MICROVASCULAR COMPLICATIONS OF DIABETE

Emraza Toufik, Mohamed A.Ghassem, Julien Dossou, Najlae El Ouardi, Abderrahim Majd, Abdellah El Saleh, Mohammed El Magraoui. Mohammed V Military Academic Hospital, Faculty of Medicine and Pharmacy, Mohammed V University, Rheumatology Department, Rabat, Morocco

Background: Diabetes mellitus (DM), a worldwide high prevalence disease, is associated with a large variety of musculoskeletal (MS) disorders. They are poorly treated, as compared to microvascular complications. However, they are a common source of disability.

Objectives: We designed this study to assess the prevalence of MS disorders among diabetic patients and their relation to microvascular complications of diabetes.

Methods: A cross-sectional study enrolled consecutive subjects with diabetes seen in the Endocrinology department. We recorded age of patients, sex, body mass index, type and duration of diabetes, Long-term glycemic control assessed by hemoglobin A1c levels, and lipid profile. Musculoskeletal and microvascular disorders assessment was done by detailed history with clinical examinations and investigations if needed.

Results: A total of 376 subjects were studied, (84.6% had type 2 diabetes). The mean age was 52.5±13.9 years, 41% had one or more microvascular complications, among which retinopathy was present in 28.2%, nephropathy in 16.1% and neuropathy in 12.8%. Moreover, 23.4% of the patients had one or more musculoskeletal disorders. Shoulder cap- sulitis was present in 12.5%; carpal tunnel syndrome in 8.8%; trigger finger in 5.9%; and 2.9% had diabetic cheiroarthropathy. Dupuytren’s contracture and Charcot foot, were found in 0.5% and 0.3% of the cases respectively. Symptomatic osteoarthritis was found in 19.4%. Musculoskeletal disorders prevalence increased with age, diabetes duration, presence of dyslipidemia and various microvascular complications.

THU0502 DIFFERENTIAL DIAGNOSIS OF MONOARTHRITIS: THREE CASES WITH PIGMENTED VILLONODULAR SYNOVITIS

Serkan Turucu, Ceyhun Acarı, Hatice Adıgüzel Dundar, Erbil Unsal. Doçuk Eylul University, Faculty of Medicine, Department of Pediatric Rheumatology, İzmir, Turkey

Background: Pigmented Villonodular Synovitis (PVNS) is a proliferative disorder of synovium that affects synovial joints, tendon sheaths and bursas. The estimated incidence is around 1.8 cases per million people in a population. PVNS is usually found in adults aged 20-50 years, but it may occur also in children. As it is a rare pathology in children, diagnosis is often delayed, and it is difficult to distinguish from Juvenile Idiopathic Arthritis (JIA), hemophilic arthropathy, tuberculosis, and other neoplastic processes.

Objectives: The aim of this case series is to emphasize PVNS in the differential diagnosis of monoarthritis, and the importance of interpretation of imaging, i.e. MRI.

Methods: Three pediatric PVNS cases who were misdiagnosed as monoarticular JIA and familial Mediterranean fever (FMF) are presented as case series.

Results: Case-1: A 14-year-old male had swelling and pain on his left knee for one year. An MRI of knee was reported as joint effusion in suprapatellar bursa, and he was referred to our clinic as monoarticular JIA. He was on methotrexate (MTX) 15 mg/m²/wk. SC, and despite effective treatment there was no improvement. MRI was performed by a pediatric radiologist who was an expert on musculoskeletal diseases. Joint effusion and a lesion compatible with PVNS were observed in left suprapatellar recess (Figure-A). Arthroscopic synovectomy was performed and histopathological result was PVNS.

Case-2: A one year-old female had swelling on her right knee for three months after a minor trauma. On physical examination, she had effusion of the right knee which was confirmed on USG. She was diagnosed as monoarticular JIA and intraarticular triamcinolone injection was performed. She was unresponsive to adequate non-steroid drug therapy, and MTX was started. Despite intensive therapy, there was no change. MRI showed focal lesions with high signal in T2 weighted images in suprapatellar and intraarticular areas, and findings were evaluated as compatible with PVNS (Figure-B). Total synovectomy was performed and PVNS was confirmed in pathological evaluation (Figure-C). She is in complete remission without treatment.
The purpose of this study is to determine the ultrasound characteristics of the coxofemoral joint of patients who consult for acute inguinal pain, correlate it with its clinical presentation and propose a reasoned strategy for its management.

Methods: We reviewed the clinical records of patients under the age of 50 who consulted for direct non-traumatic hip joint pain. Only cases with less than one week of evolution were included. Patients who consulted on weekends or in the afternoon were not included in this register because of the lack of immediate ultrasound study during these periods of time. We excluded those patients who, during the consultation, acknowledged having used anti-inflammatory drugs in the last 24 hours and those whose records are incomplete. The ultrasounds were performed with a portable Logiq e ultrasound machine, equipped with a linear probe of up to 12MHz.

Results: Between 2014 and 2017, 211 patients under 50 years of age consulted for non-traumatic mechanical groin pain. Excluding patients who consulted outside of the immediate ultrasound study access hours, who had recently taken NSAIDs and whose clinical records were incomplete, we reviewed 116 clinical and image records. The mean age of the patients whose records were included was 37.8 SD 8.5. The mean time in days, between the consultation and the onset of symptoms according to history constancy was 4 SD 2. 59 subjects were male (50.9%). In the physical examinations described in the reports, 29 patients (25%) presented painful passive manoeuvres, 38 (32.8%) presented painful active manoeuvres, and 22 (19%) could not maintain standing due to the impossibility of loading due to coxofemoral pain. Regarding the ultrasound findings, 5 patients presented unequivocal capsular distension at the level of the upper anterior labrum (4.3%) and 32 (27.6%) presented distension of the anterior recess. One patient with capsular distension was finally diagnosed with ONA and another with APso.

Conclusion: Our results show that in the studied population (<50 years old, non-traumatic coxofemoral pain of sufficient intensity to be consulted in the emergency department in less than 7 days of evolution) synovitis is a finding present in a quarter of patients and that it is severe in approximately 4%. Its strong association with incapacity for load and passive joint dysfunction would condition the incorporation of these findings in therapeutic decision making, including -in these cases- rest in unload- ing. On the other hand, the absence of synovitis in ¾ parts of the patients strongly suggests a muscular etiology that with proper treatment will respond positively only to NSAIDs. The incorporation of ultrasound, in our opinion, plays a role of diagnostic clearance when the semiological exploration is doubtful.

THU0504 ROTATOR CUFF CALCIFICATION AND SHOULDER PAIN: A CLINICAL AND ECHOGRAPHIC STUDY OF 465 PATIENTS

Ottil Luisa1, Alexander So1, Faron Aliant2, Pascal Zufferey2 1RHU, DAL/CHUV, Lausanne, Switzerland; 2OTR, DAL/CHUV, Lausanne, Switzerland

Background: Shoulder pain is a common cause for medical consultation and is commonly linked to lesions of the rotator cuff. Rotator cuff calcification (due to BCP crystal deposition) is also a common finding and can give rise to chronic pain as well as acute inflammatory episodes

Objectives: The goal of the study was to compare the clinical and the echographic characteristics of patients with BCP calcification in the rotator cuff and shoulder pain to those with no signs of calcification

Methods: A retrospective case-control study of 465 patients whose primary complaint was shoulder pain presenting between 1997 and 2011 and seen by one rheumatologist. 125 patients who had rotator cuff calcification (RCC) were identified and constituted the study group. We compared the patients with RCC with 125 patients without calcification who were randomly extracted from the same registry which constituted the control group. All had detailed demographic and clinical documentation as well as a precise description of the echographic findings. Subgroups
were defined according to the type and the duration of symptoms (Hyper-
acute painful shoulder, subacute inflammatory symptoms and chronic
mechanical pain). Short-term response (up to 6 weeks) to treatment was
also analyzed for the two first subgroups.

Results: 25% of the patients consulting for shoulder pain had evidence of
RCC as demonstrated by ultrasound. Hyperacute and subacute inflam-
matory symptoms were not linked to calcification (Hyperacute: 16 pts
with 13pts without (p value : ns), subacute: 32 pts in both groups). The
mean age (54 years) and female predominance (60%) were also similar
in patients with or without calcification. However, patients with hyperacute
painful shoulder with RCC were younger (mean years: 49 against 58
years; p: 0.007). None were <35 or > 60 years old and 75% of them
were females. In 60% of cases of hyperacute painful shoulder linked to
calcification, the acute flare was the first shoulder complaint compared to
<30% in the over 60 years group. More than a 1/3 of the patients with RCC
(35% in chronic and 43% in acute symptom groups) had no other echographic lesion compared to < 5% of patients without RCC. Calculifications were rarely associated with
partial or total rotator cuff rupture (<10% against 25%, p: 0.007).

Steroid infiltrations were mostly performed with rapid short-term response in
the acute and subacute groups linked to calcification: 15/16, 24/34
against 4/13 p=0.001, 10/34 p=0.001 without calcification. Surgery was
necessary in 7/101 pts with chronic symptoms without calcification against
only 1/95 when calcifications were present (p=0.03).

Conclusion: Clinical and demographic data cannot clearly predict the
presence of RCC in patients presenting with shoulder pain. However, acute
symptomatic (54 years) is found preferentially in middle aged women,
often with no degenerative or traumatic echographic lesions. Steroid infil-
tration appears to be the treatment of choice when acute inflammatory
symptoms linked to RCC are present.

Background: DADA2 Deficiency is an autoinflammatory disease character-
ized by systemic vasculopathy, strokes and mild immunodeficiency.
The defect is due to a mutation in ADA2 gene. It regulates the catabolism of
extracellular adenine, which is an important regulator of Class Switch
Recombination in B lymphocytes.

Objectives: We addressed if ADA2 mutation affects directly B-cell function
and the capacity of helper T cells to support B cells.

Methods: 14 patients carrying LOF mutations in ADA2 were examined. We analyzed immunophenotype by flow cytometry. B cells isolated from
DADA patients or HD have been cultured alone or in co-culture with
CD4+ T cells and in vitro B cell proliferation has been evaluated by
CFSE dilution, whereas B cell differentiation to Immunoglobulins secreting
cells in response to TLR9 agonist and T cell help has been evaluated by
ELISA assay.

Results: Flow-cytometric analysis showed a significant reduction of
switched memory B cells and of CD4+/CD8+ T cells. We identified an
significant expansion of circulating Tfh cells in DADA2. Then we investig-
gated a role of ADA2 in B cells: we found that it is expressed, secreted
but the activity is strongly impaired in DADA2. We also addressed the
interaction between B and T cells; we found that proliferation and differ-
entiation of patients' B cells were not sustained from patient's T cells.

Moreover DADA2 T cells showed an impairment in the IL21 production and
a downregulation of CD40L.

Conclusion: Our findings suggest that ADA2 mutation could affects
indirectly B cell function and T cell help functions.

MAST CELL DEFICIENCY AMPLIFIES INFLAMMATORY RESPONSE IN A MOUSE MODEL OF KAWASAKI’S DISEASE

Jason Springer1, Mingcai Zhang1, Ryan Funk2, Ossama Tawfik3, Naohito Ohno4, Noriko Miura4, Mehrdad Maz1, Kottarappat Dileepan1.
1University of Kansas, School of Pharmacy, Kansas City, United States of America; 2University of Kansas, School of Pharmacy, Kansas City, United States of America; 3University of Kansas, School of Pharmacy, Kansas City, United States of America; 4Tokyo University of Pharmacy and Life Sciences, Department of Immunopharmacology of Microbial Products, Tokyo, Japan

Background: Kawasaki’s disease is a pediatric medium vessel vasculitis
causing coronary arteritis and potentially coronary artery aneurysms.
Higher systemic levels of Interleukin-6 (IL-6) in the first week of disease
has been shown to be associated with a higher risk of coronary artery
aneurysms (1, 2). Mice injected with Candida albicans water-soluble frac-
tion (CAWS) develop coronary and aortic arteritis like that seen in Kawa-
saki’s disease. Our prior work has demonstrated that mast cell
degranulation can inhibit lipopolysaccharide (LPS)-induced IL-6 gene
expression in the aorta and systemic IL-6 production (3).

Objectives: The objective of this study was to determine if mast cells
play a role in the IL-6 homeostasis in an established mouse model of
Kawasaki’s disease (CAWS) model.

Methods: 8-10-week-old male wild type controls (WT) and kitw-sh-w-sh-w mice (mast cell deficient, MCD) of C57Bl/6 background were randomly
distributed into four groups (WT-PBS, WT-CAWS, MCD-PBS, MCD-
CAWS). They were either injected intraperitoneally with PBS or CAWS (2
mg/mouse) daily for a period of 5 days. Eight animals from each group

Scientific Abstracts
were sacrificed at either 7, 14 or 30 days after the last injection and blood, aorta and heart specimens were harvested. A pathologist (OT), blinded to treatment groups, examined aortic root and adjacent myocardium specimens and assigned a score for the degree of inflammation (0-6).

Results: Seven MCD-CAWS mice died unexpectedly within 24 hours of the first CAWS injection. Autopsies reviewed marked liver sinusoidal dilation in all and patchy necrosis of the liver in 4. Similar, liver findings were seen in 75% of MCD-CAWS after 7 days, but not in other groups. MCD-CAWS mice had higher systemic IL-6 compared to WT-CAWS at both 7 days (208 ± 21 vs 152 ± 12 pg/ml; p<0.001) and 14 days (226 ± 49 vs 169 ± 19 pg/ml; p<0.004), but not at 30 days. By 14 days mice in MCD-CAWS had significantly higher serum INFγ compared to WT-CAWS mice (97 ± 4 vs 87 ± 7 pg/ml; p=0.0086) which remained persistently elevated even at 30 days (103 ± 8 vs 91 ± 4 pg/ml; p=0.002). TNFα was higher in MCD-CAWS compared to WT-CAWS at 7 days (258 ± 8 vs 243 ± 6.5 pg/ml; p=0.0016), 14 days (266 ± 14 vs 239 ± 66 pg/ml; p<0.001) and 30 days (328 ± 52 vs 256 ± 8 pg/ml; p=0.002). The average aortic root inflammatory score was non-significantly higher in the MCD-CAWS group compared to WT-CAWS at both 7 days (1.5 ± 1.3) and 14 days (3.7 ± 2.4).

Conclusion: Mast cell deficiency resulted in higher systemic levels of IL-6, TNFα and INFγ in the CAWS mouse model of Kawasaki’s disease. Similarly, mast cell deficiency resulted in more intense inflammation at the root of the aorta in this model. These results support the novel concept that mast cells play a protective role in reducing the initial systemic inflammatory response in Kawasaki’s disease.

THU0507

TYPE I INTERFERON SCORE AND INTERFERON INDUCED MEDIATORS CXL10 and NEOPTERIN ARE CORRELATED WITH DISEASE ACTIVITY IN JUVENILE DERMATOMYOSITIS

Rebecca Nicolai1, Ivan Caiello1, Lucilla Rava1, Luisa Bracci-Laudiero2,3, Francesco Liciardi3, Angelo Ravelli1, Fabrizio De Benedetti1, Gian Marco Moneta1,2,3, Silvia Rosina1,2
1Ospedale Pediatrico Bambino Gesù, IRCCS, Division of Rheumatology, Roma, Italy; 2Ospedale Pediatrico Bambino Gesù, IRCCS, Clinical Epidemiology Unit, Roma, Italy; 3Istituto Giannina Gaslini, IRCCS, Clinica Pediatrica e Reumatologia, Genova, Italy; 4Institute of Translational Pharmacology, CNR, Roma, Italy; 5Ospedale Pediatrico Regina Margherita, Immunoreumatologia, SCDU Pediatría 2, Torino, Italy

Background: Interferons (IFNs) seem to play an important role in the pathogenesis of juvenile dermatomyositis (JDM). Our group previously reported that expression of both type I and type II IFN related genes is increased in muscle biopsies of JDM patients and correlates with histological and clinical features of the disease.

Objectives: The aim of this study was to investigate expression of interferon regulated genes (IRGs), as well as serum levels of type II and type I IFN induced chemokines (CXCL9, CXCL10) and neopterin in peripheral blood of JDM patients and to assess their correlations with clinical and laboratory findings.

Methods: We collected 189 blood samples from 39 JDM patients at different time points during follow-up. In 11 patients we obtained the first blood sample at time of muscle biopsy. We measured expression of type I IRGs (IFI27, IFI144L, IFI1, ISG15, RASD2, SIGLEC1), IFNγ and type II IRGs (CXCL9, CIITA, IDO1) by quantitative PCR (qPCR) and calculated a type I and type II IFN score for muscle and blood samples; serum levels of CXCL9, CXCL10 and neopterin were analyzed by ELISA. Ten healthy subjects were used as controls (HC). At each visit, the following clinical and laboratory data were recorded: physician’s global assessment (PGA) of disease activity VAS (Visual Analogue Scale), cutaneous VAS, Cutaneous Assessment Tool (CAT) activity score, Childhood Myositis Assessment Score (CMAS), serum levels of creatine phosphokinase (CK, IU/l), presence of myositis specific or myositis associated antibodies (MMAA), prednisone (or equivalent) dose (mg/kg/daily), ongoing immunosuppressive medications.

Results: Serum levels of CXCL9 where significantly correlated with muscle expression of IFNg and type II IFN score. The correlation of CXCL10 levels with muscle type I and type II IFN score was weaker. Muscle expression of CXCL9 and CXCL10 correlated with serum levels of these chemokines. Type I IFN score in blood of JDM patients was increased compared to HC and significantly correlated with PGA, cutaneous VAS, CAT activity score. Serum levels of CXCL9 and CXCL10 were significantly higher in JDM patients compared to HC. MSA positive JDM patients showed higher levels of CXCL9 and CXCL10 compared to MSA negative patients. CXCL10 levels correlated with PGA and CMAS, but not with cutaneous disease activity. CXCL9 showed no significant association with the evaluated clinical features. Neopterin levels significantly correlated with PGA, cutaneous VAS, CAT activity score and CMAS.

Conclusion: Our findings indicate that expression of IRGs, measured as type I IFN score, and serum levels of CXCL10 and neopterin reflect specific features of disease activity in JDM, supporting their role as valuable disease biomarkers.

THU0508

CHANGES IN MIR-17–92 CLUSTER EXPRESSION LINK SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS, MONOCYTE-TO-MACROPHAGE DIFFERENTIATION, AND INTERFERON REGULATION

Divya Takkeilapati1, Xiaoliing Niu2, Thuy Do3, Grant Schuler2,3, 1University of Cincinnati, Cincinnati, United States of America; 2Cincinnati Children’s Hospital Medical Center, Rheumatology, Cincinnati, United States of America; 3University of Cincinnati, Pediatrics, Cincinnati, United States of America

Background: MicroRNAs (miRNAs) are small noncoding RNAs which post-transcriptionally regulate gene expression. The miR-17-92 cluster is well studied in cancer biology and cellular differentiation; its overexpression has been found to serve a major oncogenic role in the targeting and downregulation of tumor-suppressive pathways, such as PTEN or TGFB. Our previous work identified several members of the cluster – miR-18, miR-19a/b, miR-20a, and miR-92a – with significantly higher levels in monocytes from patients with active Systemic Juvenile Idiopathic Arthritis (SJIA). SJIA is a chronic inflammatory disease of childhood with features of autoinflammation, and innate immune cells including monocytes have important roles in disease pathogenesis. Children with SJIA are at risk for life-threatening complications including Macrophage Activation Syndrome (MAS), an episode of overwhelming inflammation characterized by macrophage proliferation and driven by IFN signaling.

Objectives: Characterize the regulation of the miR-17-92 cluster, define key targets, and determine the cluster’s role in inflammation and SJIA.
Methods: miRNA levels were examined in THP-1 cells, as well as primary human monocytes isolated from healthy donors over the course of the monocyte to monocyte-derived macrophage (M/M) transition. miR-17, miR-19a, and miR-20a were overexpressed via transfection in CD14+ monocytes for 2 days. Transcriptional profiles were performed using Ampliseq Transcriptome and the Ion Torrent S5 system and analyzed using AltaAnalyze. Potential targets of the miR-17-92 cluster determined from sequencing analysis were then validated via dual-lucerase reporter assay.

Results: Neither blood monocytes nor fully differentiated THP-1 cells showed significant changes in miR-17-92 levels under standard polarization conditions, including M1, M2a, and M2b conditions, or IL-6 and IL-10 stimulation. The most sizable changes in miR-17-92 levels were found during monocyte to macrophage transition. Interestingly, primary monocytes showed miR-17-92 clusters within the first 48 hours of differentiation towards MDM, variable by miRNA and experiment, similar to that seen in SJIA monocytes. In contrast, both PMA-differentiated THP1 cells and fully differentiated MDMs showed decreased miR-17-92 compared to undifferentiated monocyte cells. MiR-17-92 was overexpressed in vitro in primary monocytes to model these early transition changes. Genome-wide transcriptional profiling showed an upregulation of genes involved in Type I and II interferon pathways, including response to interferon-alpha (adjusted p=2.71x10^-10) and interferon-gamma (adjusted p=7.81x10^-5). Analysis of genes significantly downregulated by miR-17, miR-19a, or miR-20a identified several putative and previously validated miR-17-92 cluster targets, including ATG5, IFRD2, JAK1, PPARG, and PTEN2 which have interferon-regulatory functions. Dual-lucerase reporter assays experiments support that these genes are direct targets of miR-17, miR-19a, and/or miR-20a.

Conclusion: MiR-17-92 cluster members demonstrate initial increase followed by subsequent decrease in expression during 2-week human monocyte to macrophage differentiation. Overexpression of miR-17-92 miRNAs upregulates Type I and II interferon pathway genes, and these miRNAs target multiple genes involved in regulating interferon signaling and/or inflammatory response. Taken together, miR-17-92 cluster overexpression in SJIA monocytes may suggest a more differentiated phenotype, and contribute to IFN sensitivity and risk for MAS.

THU0509 MONOCYTES PROTEOMIC PROFILE OF PATIENTS WITH DIFFERENT AUTOINFLAMMATORY DISEASES: A NEW APPROACH TO CHARACTERIZE THESE DISEASES

Federica Penco1, Andrea Petetto2, Chiara Lavarello2, Ilaria Guelli3, Anna Berton4, Alessia Omenetti5, Claudia Pastorino5, Marco Gattorno5. 1F.C.C.S. Instituto Giannina Gaslini, UOSD Centro Malattie Autoinfiammatorie ed Immunodeficienze, Genova, Italy; 2I.R.C.C.S. Instituto Giannina Gaslini, Laboratorio Core Facilities – Proteomica e Metabolomica, Genova, Italy; 3I.R.C.C.S. Instituto Giannina Gaslini, Clinica Pediatrica e Reumatologica, Genova, Italy

Background: Autoinflammatory diseases are a group of inherited diseases characterized by early onset and systemic inflammation. These pathologies are caused by mutations in genes involved in the regulation of innate immune response with a consequent inflammatory phenotype. The most common genetically defined periodic fever are Familial Mediterranean Fever (FMF), Cryopyrin-associated periodic syndromes (CAPS), TNF receptor-associated periodic syndrome (TRAPS) and mevalonate kinase deficiency (MKD/HIDS).

Some patients show clinical features similar to autoinflammatory diseases, but no genetic mutation has been found.

Objectives: Our aim is to evaluate the differences in the expression of proteins or pathway in monocytes, and plasma metabolites in patients with autoinflammatory diseases compared with healthy subjects to clusterize and better understand the mechanisms underlying different genetically defined disorders and try to characterize the genetically undefined pathologies.

Methods: Monocytes, purified from peripheral blood and incubated with or without LPS, were collected from patients and healthy donors; samples have been processed by IAT protocol. Each digested sample was analyzed by high-resolution liquid chromatography and tandem mass spectrometry (LC-MS/MS) based on Orbitrap technology. The quantification strategy is a label-free approach (LFQ) available in MaxQuant suite.

Results: Here we identified a median of about 5000 proteins from the monocyte samples of each 4000 are quantified by LFQ approach. PCA analysis and Person’s correlation show good reproducibility of data and a good separation between the different groups. The data were then submitted to an appropriate statistic. T-Tests highlighted differentially expressed proteins and through Cytoscape with the ClueGo app we obtained the differently regulated pathways in the different conditions. It has also been constructed, starting from significative proteins, a network, related to disease using the information of String Disease db. We observed that the expression of proteins is differently enriched according to the different conditions. For each autoinflammatory disease, a list of significantly modulated proteins was obtained: some of which are already known to be related to the disease, while others have not yet been described. In FMF, MEFV, RhoA and some related proteins were significantly up-regulated together with genes linked to the interferon pathway.

TRAPS relevant proteins turn up related to the maintenance of Golgi and cellular trafficking. The bioinformatics analysis allows us to better understand the functional interaction between these monocytes proteins and give a new explanation of the disease.

Conclusion: Here, we addressed how a high-resolution proteomics approach could be used to better understand the biology of autoinflammatory diseases. The characterization of a broad spectrum of proteins and their interaction network will allow us to identify new biomarkers for the different pathologies and better comprehend and recognize the genetically undefined disorders.

THU0510 NEUTROPHIL FUNCTION IN PEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Rakesh Kumar1, 2, Amit Rawat1, Jitendra Shandilya1, Kanika Arora1, Biman Saikia2, Anju Gupta2, Surjit Singh3, 1Post Graduate Institute of Medical Education and Research, Chandigarh, Allergy Immunology Unit, Department of Pediatrics, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Immunopathology, Chandigarh, India

Background: While the role of adaptive immune system in pathogenesis of systemic lupus erythematosus (SLE) has been well characterized, there is paucity of literature on innate immunity in these patients. There are limited data on neutrophil function in pediatric lupus. In this study we analyzed neutrophil functions in a cohort of pediatric lupus from North India.

Objectives: To evaluate phagocytic and oxidative burst activity of neutrophils in patients with pediatric-onset SLE

Methods: This prospective study was carried out at a tertiary care center in North India in patients with SLE during the period July 2017 to December 2018. Diagnosis of lupus was based on SLICC 2012 criteria and patients who had disease onset below 18 years were included. Controls were age matched children attending the outpatient clinic of department. Disease activity was measured by SELENA-SLEDAI score. Phagocytic activity was estimating using the pH Rhodamine Escherichia coli BioParticles kit by flow cytometry. Phagocytic activity is normalized as% phagocytic activity of neutrophils, delta mean fluorescent intensity (%MFI), and stimulation index (SI). Oxidative burst activity was performed by Dihydroorhodamine (DHR) flow cytometry assay and% positivity of neutrophils, %MFI, and SI were calculated.

Results: Eighty-seven children with lupus (83 girls; 24 boys) comprised the study group. 44 healthy controls were also enrolled. Disease onset was 8.5±2.95 years whereas age at enrolment was 12.3±4.57 years. Phagocytic activity in neutrophils SLE and controls were 76.59±20.70% and 91.90±4.47% p<0.001 respectively. %MFI phagocytosis in patients with SLE and control were 0.09 (0.05-0.16), 0.18 (0.15, 0.22); (p.< 0.002) respectively. SI of phagocytosis in patients with SLE and controls were 2.79 (1.92, 3.79), 5.00 (4.50, 6.12); p<0.001. SLEDAI score was negatively correlated with phagocytic function in neutrophils in patients with SLE. Oxidative burst activity of neutrophils in patients with SLE and controls in form of positivity on neutrophils were 84.03±17.36%, 92.26±20.70% respectively.
5.49; p<0.001 respectively. ΔMFI and SI on DHR between patients and healthy controls were comparable. There was no difference in oxidative burst activity between active and inactive SLE patients. Two patients showed a double peak in DHR flow cytometry consistent with mosaic burst activity between active and inactive SLE patients. Two patients healthy controls were comparable. There was no difference in oxidative dysfunction and disease activity. The E.coli based phagocytic functions of neutrophils were significantly reduced in pediatric SLE patients compared to healthy controls. Phagocytic activity of neutrophil was significantly lower in patients with disease activity and coexistent infection in patients with pediatric SLE. Oxidative burst activity was reduced in patients with pediatric SLE compared to healthy controls. However, there was no significant correlation of oxidative burst activity to the age, disease activity and coexistent infections.

THU0511 COMPARISON OF PAXGENE AND TEMPUS WHOLE BLOOD RNA COLLECTION AND ISOLATION SYSTEMS FOR THE QUANTIFICATION OF TYPE I INTERFERON-STIMULATED GENE EXPRESSION

Lovro Lamot1, Iwona Niemietz2, Kelly Brown3, 4 The University of British Columbia and British Columbia Children’s Hospital Research Institute, Department of Pediatrics, Division of Pediatric Rheumatology, Vancouver, Canada. 2The University of British Columbia and British Columbia Children’s Hospital Research Institute, Department of Microbiology and Immunology, Vancouver, Canada

Background: Type I interferons (IFN) have important roles in many pediatric and adult rheumatic diseases and are a new therapeutic target for which several “anti-interferon (anti-IFN)” treatments are currently in use or in development. Since the direct detection of these proteins in biological samples has proved challenging, indirect methods are often used to infer the presence of type I IFN. Most commonly this involves quantification of the relative expression of interferon-stimulated genes (ISGs) that are used to calculate an interferon score (IS) (1). This score has been used for example to assess type I IFN activity in pediatric patients with type I interferonopathies, systemic lupus erythematosus, dermatomyositis and systemic juvenile idiopathic arthritis (2). Both qPCR and Nanostring technology have similar sensitivity and reproducibility for IS determination (3). The use of different whole blood RNA collection systems on the IS have not been evaluated however despite evidence of method-dependent changes in gene expression (4).

Objectives: The aim of the study was to compare expression of six common ISGs (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1) and the corresponding IS in RNA derived from two commonly used whole blood RNA collection systems (PAXgene and Tempus).

Methods: Whole blood was collected from ten healthy individuals (median age 25.5 years) in sodium heparin tubes and incubated without or with recombinant human interferon alpha 2b (rhIFNa, 2 IU/ml, 4 hrs, 37°C, 5% CO2). Next, samples were divided between PAXgene (PreAnalytiX, Becton Dickinson) and Tempus (Applied Biosystems) tubes and RNA was isolated according to the manufacturer’s protocols. cDNA was synthesized (500ng input RNA; qScript cDNA synthesis kit) and ISG expression measured on a QuantStudio 6 Real-Time PCR instrument using a TaqMan Fast Advanced Assay. For each ISG, expression was normalized against the geometric mean of two housekeeping genes (18s rRNA and HPRT1) and calculated using the formula 2-ΔΔCt. Relative gene expression is reported as the normalized expression of each ISG divided by the median of normalized expression of the same ISG in unstimulated samples. The median relative expression of all six ISGs was used to calculate the IFN score for each sample.

Results: There was no statistically significant difference in the normalized expression of any of the six ISGs in either the rhIFNa-stimulated or unstimulated samples derived from PAXgene or Tempus tubes. The greatest difference in mean normalized expression in both unstimulated and stimulated samples was observed for ISG15 (difference in mean normalized expression was 0.0034 and 0.11, respectively). Overall there was a strong correlation of the IFN score between PAXgene and Tempus tubes for both the unstimulated (R2 = 0.9117, p<0.0001) and rhIFNa-stimulated samples (R2 = 0.8529, p<0.0001).

Conclusion: Despite reported differences in gene expression patterns associated with samples collected in PAXgene versus Tempus tubes, our results demonstrate that 6-gene interferon scores do not differ significantly between RNA samples obtained with these two systems. These results suggest that health care and research centres can use either tubes for IFN score determination using these 6 ISGs and results can be directly compared irrelevant of the RNA collection system employed.

WHAT IS HIDDEN BEHIND SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS, ADULT ONSET STILL’S DISEASE, AND SECONDARY MACROPHAGIC ACTIVATION SYNDROME. THE UTILITY OF THE BIOMARKERS

Alina Boteanu1, Carlota García-Hoz2, Andrea Briones-Figueroa2, Daniel Clemente3, Juan Carlos Nieto González4, Martina Steiné5, Concepción Morado Quiroga6, Antía García Fernández6, María Luz Gámir Gám6, Monica Vazquez Diaz4, 1University Hospital Ramón y Cajal, Rheumatology and Pediatric Rheumatology Unit, Madrid, Spain; 2University Hospital Ramón y Cajal, Madrid, Spain; 3University Hospital Niño Jesus, Madrid, Spain; 4University Hospital Gregorio Marañón, Madrid, Spain; 5University Hospital Infanta Sofía, Madrid, Spain; 6University Hospital Clínico San Carlos, Madrid, Spain

Background: Systemic Juvenile Idiopathic Arthritis (SJIA) and adult onset Still’s disease are rare diseases of unknown etiology that share several clinical and laboratory features. The pathogenesis of these two diseases is complex and multifactorial, with an important role of innate immunity: activation of neutrophils and macrophages and increased levels of cytokines dependent on the activation of the inflammasome. A proportion of these patients will develop a Macrophage activation syndrome (MAS), a serious and life-threatening complication.

Objectives: To identify immunological markers that allow a differential diagnosis between patients with inactive SJIA, active SJIA or MAS. To evaluate if there are differences between biomarkers in SJIA and adult onset Still’s disease.

Methods: Observational, prospective and multicenter study, inclusion criteria: patients with SJIA or adult onset Still’s disease, followed in Paediatric or Adult Rheumatology Department from 5 Madrid hospitals. Group 1: Patients with active SJIA or adult onset Still’s disease: diagnosis of secondary MAS at the first visit, have been followed-up performing a second clinical and analytical visit at 3 months. Group 2: Patients with reactive SJIA or adult onset Still’s. Clinical and analytical data were collected. PBMCs were obtained before and after treatment, and several leukocyte subtypes were evaluated by flow cytometry (FACS). The intracytoplasmic expression of TNF-α, IL-1b and IL-6 in monocytes was determined by flow cytometry before and after stimulation with lipopolysaccharides (LPS) in the presence of monensin ( Golgi inhibitor). In addition, IL-18 levels were determined by ELISA in all visits.

Results: A total of 25 patients were included (18 SJIA and 7 adult onset Still’s disease), 2 of them being excluded from the analysis because exclusions criteria. 30.4% patients presented MAS at the first visit (5 SJIA and 2 adult onset Still’s disease) and other 2 at some time during the disease. The median of IL-18 was 296.1 (CI 108.3-346.0) in patients who have never had MAS and 899.85 (CI: 397.32-1095.6) in the other group. Patients with active MAS had a CD4/CDC8 ratio close to the lower limit (1.1 +/- 0.1 SD) reflecting a decrease in the CD4 + population and an increase in CD8 +. On the other hand, the rest of the groups presented a CD4/CDC8 ratio of 2.6 +/- 0.5 SD in patients without disease activity and 2.0 +/- 0.7 SD in patients with active SJIA or adult onset Still’s disease but without MAS. No significant differences were found between patients with SJIA or adult onset Still’s disease.

Conclusion: The results of this study show that the analysis of three determinations: %CD4,%CD8 and the CD4/CD8 ratio can help in the early detection of patients with MAS secondary to SJIA or adult onset Still’s disease. The determination of IL-18 has been in our study a marker of MAS, similar to several published studies. No significant differences were found in the immunological tests between patients with SJIA and adult onset Still’s disease with active or inactive disease.

WHOLE BLOOD CELLS FROM PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (SJIA) IN CLINICAL INACTIVE DISEASE DISPLAY A DYSREGULATED RESPONSE TO TLR-4 STIMULATION

Antonia Pascarella, Manuela Pardeo, Ivan Caioeli, Claudia Bracaglia, Marianna Rossi, Giulia Marucci, Emanuela Sacco, Fabrizio De Benedetti, Giusi Principe, Bambino Gesù Children’s Hospital, IRCSS, Rome, Italy

Background: Systemic juvenile idiopathic arthritis (sJIA) is a polygenic autoimmune inflammatory disease. Innate immune mechanisms appear to play a central role in the pathogenesis of the disease. Nevertheless, a better understanding of the pathophysiology of sJIA is still needed to identify patients responsive to IL-1 or IL-6 targeted therapies.

Objectives: In this study, we evaluated the production of IL-1β, IL-6 and TNF-α by fresh whole blood cells isolated from sJIA patients in disease remission, after stimulation with the TLR-4 ligand lipopolysaccharide (LPS), and we investigated whether sJIA patients that respond or not respond to treatment with the IL-1 receptor antagonist anakinra show a different response.

Methods: We collected fresh whole blood samples from sJIA patients during clinical inactive disease (inactive sJIA, n=19) and sJIA patients during active disease (active sJIA n=4). Active and inactive disease was defined at time of sampling. As controls, fresh whole blood samples from healthy subjects (HS, n=10) were used. Whole blood cells were left unstimulated or stimulated with 10ug/mL of LPS for 24 hours. Cytokine levels (IL-1β, IL-6 and TNF-α) released in the supernatants were measured by ELISA. Response to anakinra was defined as achievement of clinical inactive disease off glucocorticoids at 6 months after initiation of anakinra treatment.

Results: We found that LPS-stimulated cells from inactive sJIA patients released significantly higher amounts of all the inflammatory cytokines tested, compared to HS (p<0.01). In addition, cells from inactive sJIA patients produced significantly higher levels of IL-1β also compared to active sJIA patients (p<0.05). When we divided inactive sJIA patients in two groups (responders and non-responders), depending on the clinical response to anakinra treatment, we observed that in both groups of patients IL-1β, IL-6 and TNF-α levels were significantly higher than those observed in HS. In addition, we found that LPS-stimulated whole blood cells from non-responder inactive sJIA patients released significantly higher levels of IL-1β and TNF-α compared to responder inactive sJIA patients. The CD4+ CD107a+ SJIA patients displayed significantly lower levels of IL-1β and TNF-α compared to the CD4+ CD107a+ SJIA patients.

Conclusion: Our preliminary results show a dysregulated production of inflammatory cytokines by whole blood cells from sJIA patients in remission disease, when stimulated with a TLR-4 agonist.

ROLE OF THE ORAL MICROBIOME IN CHRONIC NON-BACTERIAL OSTEOMYELITIS IN CHILDREN

Mona Zeus, Stefan Janssen, Ute Fischer, Hans Jürgen Laws, Arndt Borkhardt, Prasad Commen. University Duesseldorf, Duesseldorf, Germany

Background: Chronic non-bacterial osteomyelitis (CNO) is a rare autoinflammatory disease of the bone and bone marrow. The presentation of the disease is broad, but pain and osteodema on MRI are the hallmark of CNO. While the activation of inflammasomes and the subsequent release of IL-18 seems to play a central role, the exact molecular pathophysiology of CNO is largely unexplained. In respect of the potential role of the microbiome to date only experimental data on mice are available, indicating that the manipulation of the microbiome through dietary modulation might alter the course of the disease and also plays a role in the release of IL-18 from innate immune cells.1

Disclosure of Interests: None declared

**Objectives:** To identify the impact of the oral microbiome on CNO in children and adolescents. Dysbiosis as a state of pathological alteration of the microbiome has been discussed as an environmental factor in rheumatic diseases in adults and in children. Human data in CNO are lacking.

**Methods:** 20 patients (12 male and 8 female, aged 3 to 13 years) with a median of 10.3 years were examined. Two different sites of the oral cavity (central and left part of the tongue) were swabbed. In total, 143 individual samples were retrieved and subjected to 16s r-RNA amplification sequencing; DNA was extracted using the QIAamp® DNA Microbiome Kit. The V4 region of the 16S ribosomal RNA gene was amplified by PCR with V4 specific primers. A limited cycle amplification step was performed. Libraries were normalized and pooled, and sequenced on a MiSeq system (Illumina). Raw sequence reads were demultiplexed and clustered into sub-OTUs (operational taxonomic units) via Deblur in QIIME. Qiime2 was used to calculate alpha- and beta- diversity for multiple alternative metrics. Statistical significance was calculated with non-parametric tests (Mann-Whitney and Permanova).

**Results:** The administration of medication in general (mostly NSAIDs) had a significant impact on the microbiome (p-value < 0.02). With limited statistical power of the small cohort, gender, age and disease activity do not significantly influence the microbiome. There is a significant difference between the variable swab sites at the 1% level (p<0.01). Whereas swabs from the center of the tongue exhibit more Streptococci salivarius, the left outer part of the tongue shows more Haemophilus parainfluenzae.

**Conclusion:** To the best of our knowledge, this is the first study of the oral microbiome in children and adolescents in CNO. Our data suggest that administration of medication to CNO patients alters the microbiome. It is also influenced by a change of the swab site. Limited patient numbers did not allow to show an effect on disease activity, but enrollment will continue.

**PAIN IS THE MAIN DETERMINANT OF WELL-BEING IN OLIGO- AND POLYARTICULAR JIA: EVIDENCE FROM THE PHARMACHILD REGISTRY**

**Alessandra Alongi**, Alessandro Consolaro2, Gabriella Giancane1, Maria Greca Magnolia2, Giovanni Filocamo3, Esther Hoppenreij3, Angelo Ravelli2, Nicolina Ruperto1.1 IRCSS G. GASLINI, Genoa, Italy; 2IRCSS G. GASLINI, Clinica Pediatrica e Reumatologia, Genoa, Italy; 3Centro Storico della Stella Hospital, Pediatrics, Orvieto, Italy; 4Fondazione IRCSS Ca' Grande-Ospedale Maggiore Policlinico, Clinica Pediatrica De Marchi, Milano, Italy; 5Radboud UMC, Paediatric Rheumatology, Nijmegen, Netherlands

**Background:** Juvenile idiopathic arthritis (JIA) affects patients’ well-being as the result of a complex interplay of multiple factors, including disease activity, symptoms, physical and emotional quality of life, and treatment burden. Little evidence exists about the relative contribution of these elements to disease impact.

**Objectives:** 1) To identify direct and indirect determinants of well-being, expressed by VAS-measured parent/patient global assessment of well-being (PGW), in children with oligo- and polyarthritis. 2) To assess whether the impact of the major determinants varies with level of disease activity.

**Methods:** We analyzed data of 1873 patients evaluated in 4464 prospective visits from the international JIA pharmacovigilance registry Pharmachild. Patient-reported outcomes were collected through the Juvenile Arthritis Multidimensional Assessment Report (JAMAR). Evaluated predictors of PGW included VAS-measured physician global assessment, inflammatory markers, active joint count, VAS-measured pain, morning stiffness duration, Juvenile Arthritis Functional Score (JAFS), Physical (PhHS) and Psychosocial (PsHS) subscales of the Pediatric Rheumatology Quality of Life (PRQL) scale, disease damage measured through the Juvenile Arthritis Damage Index (JADI) and adverse events (AE). We used path analysis to assess direct and indirect effects of variables on PGW. We repeated the analysis on subsets of visits stratified by disease activity, measured with JADAS10, to test differences across activity states.

**Results:** Pain severity proved the strongest direct determinant of PGW (b 0.521, p<0.001), followed by Psychosocial (b 0.191, p<0.001) and Physical Health (b 0.158, p<0.001). Stiffness (f2 0.041, p<0.001) and joint damage by the JADI (f2 0.032, p<0.001) were also indirectly associated with PGW, through their effects on function and PhHS. Patient-reported adverse events (AE) had a small effect on PGW (f2 0.025, p<0.001) through their impact on PsHS. Relations among variables and relative coefficients are depicted in the graph. Multi-group comparison between Remission, Low (LDA), Moderate (MDA) and High Disease Activity (HDA) groups revealed that for subjects in Remission, pain had a lower impact on function and physical health compared to those with LDA, while remaining the strongest predictor of PGW. Among the HDA group, the direct effect of pain on well-being and the impact of physical health on psychosocial health was greater than in other activity states (table). The effect of AE remained significant across all activity categories.

**Conclusion:** Pain was the main determinant of PGW in all disease activity states. The level of PGW also reflected other aspects of disease impact, particularly physical and psychosocial distress, and, to a lesser extent, treatment adverse events. The impact of pain and physical functioning on psychosocial health and well-being varies with disease activity, being greater in patients with higher disease activity.

Background: Tocilizumab (TCZ) administered intravenously (IV) was effective for the treatment of polyarticular (pJIA) and systemic (sJIA)1,2 Objectives: To evaluate the long-term safety and efficacy of subcutaneous (SC) TCZ in patients (pts) with pJIA or sJIA enrolled in a long-term extension (LTE) phase of two 52-week, open-label studies. Methods: Pts aged 1-17 years received body weight (BW)-based TCZ SC: pJIA pts who failed or could not tolerate MTX received TCZ 162 mg every 3 weeks for BW <30 kg or every 2 weeks (Q2W) for BW <30 kg; sJIA pts received a standard response to NSAIDs and glucocorticoids recibed TCZ 162 mg Q2W for BW <30 kg or every 2 weeks for BW ≥30 kg. All pts discontinued biologic DMARDs (approximately 50% switched from TCZ IV to TCZ SC). After 52 weeks, pts continued BW-based TCZ in a separate LTE study; safety data (adverse events [AEs], serious AEs [SAEs]) in the LTE study to clinical cutoffs December 1, 2017 (pJIA), and February 28, 2018 (sJIA), are reported for all pts who received ≥1 dose of TCZ SC and had >1 postdose safety assessment.

Results: Most pJIA (n=44) and sJIA (n=38) pts were female (72.7% and 55.3%) and white (88.6% and 84.2%); median (range) age was 9.0 (2-18) years. AE rates (Table) were similar regardless of BW. Most AEs were grade 1 or 2; grade ≥3 AEs were reported by 10.4% (20.8%) pJIA pts and 4/38 (10.5%) sJIA pts, most commonly nasopharyngitis (pJIA, 17/ 44 [38.6%]; sJIA, 11/38 [28.9%]). Other AEs reported in ≥15% of pts included arthralgia, gastroenteritis, cough, vomiting, diarrhea, pyrexia, headache, and oropharyngeal pain (pJIA) and upper respiratory tract infection, cough, pyrexia, arthralgia, and rash (sJIA). No opportunistic infections developed. Neutropenia AEs were reported by 6/44 (13.6%) pJIA pts and 7/38 (18.4%) sJIA pts. SAEs occurred in 5/44 (11.4%) pJIA pts (furuncle, appendicitis, pneumonia, eye pain/headache, infectious mononucleosis) and 2/38 (5.3%) sJIA pts (pneumonia, cranioencebral injury from a fall); only pneumonia (pJIA) was considered treatment related. Neutralizing anti-TCZ antibodies developed in 2 (4.7%) pJIA pts and no sJIA patients. No deaths were reported in the LTE study.

Conclusion: In this LTE study in children with pJIA or sJIA, SC TCZ continues to have an acceptable tolerability profile with no new safety concerns.

Background: In 2008 the Paediatric Rheumatology European Society (PReS) promoted an International Project for the study of Autoinflammato-ry Diseases (AIDs) named Eurofever, whose main purpose is to create a web-based registry for the collection of information in AIDs patients.

Methods: The data were extracted from the Eurofever registry, which is hosted in the PRINTO website (http://www.printo.it). From February 2015 we started the longitudinal collection of follow-up data with particular focus on treatment, modification of the clinical picture, onset of complica-tion/adverse events. We have enrolled patients included in the registry up to 28 September 2018.

Results: Up to date 4175 patients have been enrolled (3843 of them with complete demographic information, 1903 M e 1940 F) from 62 coun-tries. For 3356 (87%) patients also clinical data from onset to diagnosis, with complete demographic information, were collected during the first visit performed at referred pediatric or adult cen-ter, are available. For each disease the number of enrolled patients is: FMF 1086 pts (951 with complete clinical data); TRAPS 273 pts (256 complete); CAPS 298 pts (279 complete); MKD 205 pts (190 complete); Blau’s disease 49 pts (26 complete); PAPA 42 pts (41 complete); NLRP12 mediated periodic fever 13 pts (11 complete); DADA2 14 pts (9 complete); DIFA 3 pts (all complete); SAVI 3 pts (all complete); CANDLE 1 pt (complete) and Majeed 4 pts (all complete). Among multifactorial autoinflammatory diseases: PFAPA 676 pts (551 complete); CNO 581 pts (540 complete); Behcet 214 pts (186 complete), undefined periodic fever 368 pts (292 complete) and Schnitzler 13 pts (all complete). The median onset age is 36 months (range 1 month – 75 years), the median diagnosis age is 8 years (range 1 month – 78 years). Most of patients (3509 /91%) presented disease onset during pediatric age (<16 years), 334% (9) during adult age (81 FMF, 31 CAPS, 53 TRAPS, 40 CRMO, 12 Schnitzler syndrome e 90 unknown fever), 405 of 3509 (12%) patients with pediatric onset received diagnosis during adult age. The median diagnos-tic delay is 5 years; diseases with longer diagnostic delay are: NLRP12 (24 years, range 4-76), CAPS (15 years, range 0-77), PAPA (14 years, range 2-57), TRAPS (12 years, range 0-77). 396 patients have been treated with at least one biologic drug, 1031 with DMARDs, 427 with systemic steroid and 686 with others drugs. The most frequent diseases treated with biologic drugs are: CAPS (38%), multifactorial diseases (28%), FMF (22%), MKD (11%), rare monogenic (8%: 1 CANDLE, 2 DIFA, 2 NLRP12, 3 Majeed, 8 DADA2 and 14 PAPA), and FMF (7%). Since February 2015, longitudinal visits have been inserted for 477 (12%) patients, with detailed data on treatment and safety.

Conclusion: The enrollment in Eurofever Registry is still ongoing. The analysis of data will improve our knowledge both on the natural history of the single disease and on the efficacy/safety of treatment commonly used in the clinical practice.

EARLY IDENTIFICATION OF VENTRICULAR DYSFUNCTION IN JUVENILE SYSTEMIC SCLEROSIS BY SPECKLE TRACKING ECHOCARDIOGRAPHY

Giovanni Civieri1, Biagio Castaldi1, Giorria Martini1, Omella Milanesi1, Francesco Zulian1, 1Pediatric Rheumatology, Department of Woman’s and Child’s Health, University of Padova, Padova, Italy; 2Pediatric Cardiology, Department of Woman’s and Child’s Health, University of Padova, Padova, Italy

Background: Juvenile Systemic Sclerosis (JSSc) is a rare multisystemic connective tissue disease, with onset before the age of 16. Cardiac involvement, recognized in 8-24% of the patients [1], begins in early stages of JSSc and has a poor prognosis. The classical cardiac US imaging, including the left ventricular ejection fraction (EF), evaluates the global function of the heart, thus being inappropriate to assess the subclinical course of the disease. A new echocardiographic technique, the speckle tracking echocardiography (STE), has been shown to be able to identify regional ventricular dysfunctions also in early stages of adult-onset SSc[2,3].

Objectives: Aim of our study was to assess the longitudinal strain of right and left ventricle in JSSc patients, in order to identify ventricular dysfunctions earlier and more effectively than with traditional echocardiography. Furthermore, we investigated the evolution of cardiac involvement during follow-up, in order to establish a possible correlation between age and overall disease severity, measured by the Juvenile Systemic Sclerosis Severity Score (J4S)[4].

Methods: Consecutive patients with JSSc underwent clinical and cardiological evaluation. This included traditional echocardiography (such as M-Mode, EF, Pulsed- and Tissue-Doppler), 3D-Echocardiography and STE, measuring the global longitudinal strain of left ventricle (GLS) and the longitudinal strain of right ventricle free-wall (RVLS). Each patient was assessed several times by pediatric rheumatologists for J4S and by cardiologists with STE and standard echo.

Results: 18 JSSc patients (12 F, 6 M), mean age 12.3 years, disease duration 4.5 years, entered the study. At baseline evaluation, EF was abnormal in 1 patient, whereas GLS and RVLS were normal in 5. The diagnostic sensitivity of cardiac involvement of STE increased, with a prevalence rising from 22.2% to 38.8%. During the follow-up, last mean 30 months (range 17-43), the mean GLS values gradually worsened (-21.2; -20.1; -19.4%) while there was no significant variations of EF. The strong correlation between GLS and J4S, found at baseline, vanished during the follow-up. Speckle tracking echocardiography is a useful technique to evaluate the cardiac involvement in patients with JSSc. In comparison with traditional EKG or echocardiography, it allows to increase the diagnostic sensitivity of cardiac involvement. Over time, we observed a gradual worsening of GLS, sign of a progressive left ventricular dysfunction, that was not identified by EF. It is possible that the coronary microvascular damage compromises the subendocardial fibers function which are more sensitive to ischemia and whose contractility is well assessed by GLS [5]. Finally, the initial correlation between strain and J4S disappeared during the follow-up, maybe because of the pharmacological therapy, which was effective on several aspects of the disease but had low impact on the ventricular function.

Clinical manifestations and comparison of subtypes of juvenile idiopathic inflammatory myopathies: data from the REMICAM registry

Jesús Loarce-Martos1, Carmen Larena1, M. Ángeles Blázquez2, Beatriz Joven-Ibáñez3, Patricia Carrera3, Francisco J López-Longo3, Julia Martínez-Barrio3, J. C. López Robledillo4, Raquel Almodóvar3, María Jesús García de Yébenes3, Laura Nuño2, REMICAM5, HU Ramón y Cajal, Madrid, Spain; 6HU 12 de Octubre, Madrid, Spain; 7HU Gregorio Marañón, Madrid, Spain; 8HU Niño Jesús, Madrid, Spain; 9HU Fundación Alcorcón, Madrid, Spain; 10Instituto Salud Musculoesquelética Innmus, Madrid, Spain; 11HU La Paz, Madrid, Spain

Background: Juvenile idiopathic inflammatory myopathies (JIIM) are a heterogeneous group of autoimmune diseases affecting children, characterized by symmetric muscular weakness, cutaneous rash and systemic organ involvement. Given its low incidence, there are few studies describing the characteristics of this disease and its subtypes in Spanish patients.

Objectives: To describe the demographic, clinical and analytical characteristics of patients with JIIM from the registry of inflammatory myopathies in Madrid community (REMICAM), and to compare those measures with polyomysitis (PM) and juvenile dermatomyositis (JDM) subgroups.

Methods: A multicentre retrospective study from the REMICAM registry was performed. Patients were selected if they were 18 years or younger at onset of JIIM and met definite or probable criteria for JIIM by the modified Bohan and Peter criteria. We included patients with JDM or PM subgroups, overlap myositis patients were excluded.

Results: 86 patients were included, 12 classified as PM and 74 as JDM. 70% were women and 96% were Caucasian. Mean age at diagnosis was 11.8 years in PM group vs 7.2 years in JDM group. 44% presented arthritis and 93% presented muscular weakness. Gottron sign was present in 76% of the patients, and calcinosis was present in 31.4%. Cardiac and pulmonary manifestations were rare (<5%). There were no cases of neoplastic disease. Clinical features and complementary analysis are shown in table 1 and table 2.

Conclusion: JDM was the most frequent form of MIU in our study (86%). The most frequent manifestations were the muscular and dermatological ones, but an important group also presented arthritis and fever. There was no statistical difference between both groups, regardless, myalgias and dysphagia were more common in JDM group, and they had higher CPK and aldolase values. PM patients were older, had more fever and arthritis, also, cytoptenia and ANA positivity were more common.

Obesity is associated with severe renal involvement, persistent purpura and longer joint symptoms in children with Henoch Shölein purpura

Hatice Adığüzeli Dundar1,2, Mehmet Pektanoğlu3, Meral Torun Bayram4, Alişer Soyulu4, Salih Kavukçu5, 1Dokuz Eylül University Faculty of Medicine, Department of Pediatrics, Pediatric Rheumatology Unit, izmir, Turkey; 2Dokuz Eylül University Faculty of Medicine, Department of Pediatrics, izmir, Turkey; 3Dokuz Eylül University Faculty of Medicine, Department of Pediatrics, Pediatric Nephrology Unit, izmir, Turkey; 4Dokuz Eylül University Faculty of Medicine, Department of Medicine, Pediatric Nephrology and Rheumatology Unit, izmir, Turkey

Background: Over the last 20 years, the prevalence of obesity is increased in the developed and developing countries. Adipose tissue has an effect on inflammatory processes and immune system besides metabolic and appetite regulating mechanisms. On this basis, it is now of major interest to clarify the relationship between obesity and autoimmune/inflammatory diseases (1,2).

Objectives: We aimed to evaluate the role of obesity on the clinical course and response to treatment in patients with Henoch Shölein Purpura (HSP).

Methods: Data charts of children with HSP followed in Dokuz Eylül University Children’s Hospital were reviewed retrospectively. Obesity was defined as BMI >95 percentile in conformity with Centers for Disease Control and Prevention (CDC) (3). Persistent purpura was defined as skin involvement persisting for >30 days. Mild nephropathy was defined by the presence of microscopic hematuria and/or nonnephrotic proteinuria, and severe nephropathy by nephrotic syndrome and/or acute nephritic syndrome and/or renal insufficiency (4). Patients were grouped as obese and non-obese depending on BMI. Two groups were compared for demographic, clinical and laboratory parameters.

Results: There were 199 patients [M:F=104:95; presenting age 7.1 years (range 5.0-9.2); follow-up period 17.5 months (range 3-50)]. Obesity was associated with severe renal involvement and persistent purpura.
ARE CHILDREN AND ADULTS HAVING DIFFERENT PHENOTYPE AND GENOTYPE OF FMF?

Nuray Aktay Ayva1, Cemal Besı2, Hatice Ermine Sormez1, Ayaş Tanatar1, Şerife Gül Karadağ1, Nilüfer Aliyaz Kanıtı2, Selda Celik1, Özcan Cemal Içaparı1, Mustafa Çakın1, Figen Çakmak1, 1University of Health Science, Kanuni Sultan Süleyman Research and Training Hospital, Pediatric Rheumatology, Istanbul, Turkey; 2University of Health Sciences, Bakırköy Sadi Konuk Research and Training Hospital, Rheumatology, Istanbul, Turkey; 3Istanbul University Faculty of Medicine, Pediatric Rheumatology, Istanbul, Turkey

Background: Familial Mediterranean fever (FMF) is an autosomal recessively inherited autoinflammatory disease and begins in childhood. In nearly 60% of patients, the first attack occurs before the age of 10, and in 94% of the before the age of 20 years. There is a prospective study designed for comparing childhood onset and adult onset FMF.

Objectives: To compare the demographic data, clinical features, genetic analysis, laboratory values and severity scores of both childhood and adult onset FMF. Compliance and resistance to colchicine, presence of accompanying diseases and complications due to FMF were also analyzed and reviewed.

Methods: The patients were divided into two groups; group I: children with FMF (symptoms begin before 18 years of age) and group II: adults with FMF (symptoms begin after 18 years of age). A questionnaire for collecting age at disease onset, sex, age at diagnosis, delay at diagnosis and duration of the disease, family history of FMF, consanguinity and accompanying diseases were filled. The questions were asked by an adult and pediatric rheumatologist to both groups by face to face interviews. Genetic analysis results and treatment protocols were taken from patient’s charts. Laboratory data concerning complete blood count, ratio of urine protein to creatinine, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), serum amyloid A (SAA) levels were obtained during their routine follow-up at attack-free period.

Results: There were 178 (60.3%) children with the diagnosis of FMF; 73 female and 104 male and 117 (39.7%) adults diagnosed as FMF after 18 years of age; 69 female and 48 male. The mean±SD age at symptom onset, at the diagnosis and current age was 12.9±3.03, 6.4±5.61, 11.9±4.38 for group I and was 18.35±10.34, 32.23±11.62, 38±11.64 for group II, respectively. Consanguinity was significantly more frequent among children with FMF (36.1%). A positive family history of FMF was similarly present in 102 (57.6%) of group I and 66 (56.4%) of group II. Twelve (10.2%) adult patient have FMF at their children. Family history of amyloidosis was equally distributed between groups; 6.2% in group I and 6.8% in group II. The median number of FMF attacks per year was 18 in children and 15 in adults. While children were having significantly more frequent attacks, the duration of attacks were longer in adults compared to children (p<0.001). The most frequent symptom was fever (91.5%) in children and abdominal pain (96.5%) in adults. Arthritis, chest pain and erysipelas like rash were seen similarly in both cohorts. Sacroiliitis (10.2%), amyloidosis (5.1%) and chronic renal insufficiency (5.1%) were significantly more common in patients with FMF diagnosed after 18 years of age. Colchicine resistance and compliance were evenly distributed among groups. In genotypic evaluation, groups were compared for homozygotes, compound heterozygotes and heterozygotes and had put forth similar results. Attack free acute phase reactants like CRP; median 2.8 mg/dl and SAA; median 3.86 mg/dl were significantly higher in group I.

Conclusion: Both clinical features and acute phase response in FMF were less pronounced in patients diagnosed at adulthood. Children were having more frequent attacks, but accompanying diseases were more common in adults. While following patients taking age of the patient in account will help to better understand the disease course.

THU0524B EXTRA-OCULAR MANIFESTATIONS OF CHILDREN WITH SACROID-LIKE UVEITIS

Abhay Shivpuri1, Emily Kalms2, Ameenat Lola Solebo2, Harry Petrushkin2, Dhanes Thomas3, Elizabeth Graham4, Clive Edelsten5, Sandrine Compeyrot-Lacassagne6, 1Great Ormond Street Hospital, Paediatric Rheumatology, London, United Kingdom; 2Great Ormond Street Hospital, Ophthalmology, London, United Kingdom; 3Moorefield’s Eye Hospital, Ophthalmology, London, United Kingdom

Background: Paediatric sarcoidosis may represent a spectrum of disease. Early onset sarcoidosis & its genetically defined counterpart Blau syndrome associated with NOD2 mutations are characterized by fever, rash, arthiritis and organomegaly. Later onset sarcoidosis has wider organ involvement including lungs, kidneys, lachrymal and extra-ocular glands. Both presentations may lead to long term complications due to end-stage organ damage. Although similar disease manifestations can be seen in adults and children, some entities are essentially pediatric at onset, namely Blau syndrome and most forms of immunodeficiency associated granulomatous diseases. Ocular sarcoidosis has a well described uveitis phenotype (1). We created a retrospective cohort of patients currently followed at GOSH with likely ocular manifestation of sarcoidosis (1)

Objectives: To describe a retrospective cohort of children with sarcoid-like uveitis. To describe their extra-ocular manifestations at the time of the study. To describe their management.

Methods: Retrospective case review of children currently followed at GOSH with a phenotype of ocular sarcoidosis with uveitis (ophthalmologist define (5, 6)), or a diagnosis of idiopathic uveitis (anterior, posterior, intermediate or panuveitis) with raised ACE level at least once. We collected demographics and all extra-ocular involvement described in the study.

Results: 52 patients. 27/52 males. Median age onset of uveitis 4.20 yrs (1.41-15.16). 30/52 had onset <8 yrs. Median ACE 73 and mean ACE 77 at presentation (9-90UL normal). Median max ACE79% max mean ACE 88.2 (14.420).NOD2 done in 12 patients: 6+, 6-. Only 4/6 patients Blau phenotype.

Ethnicity: black 13, asian 10, caucasian 13, unknown 16.52. 49/52 had bilateral uveitis. Uveitis anterior 17/52, intermediate 5/52, posterior 2/52, panuveitis 25/52, unknown 1/52. ANA+15/47(32%). Extra-ocular (n=52): Lymphadenopathy: 15 (29%) clinically Liver: 16 (31%) - transaminitis 9, ultrasound(US)/USG abnormality (hepaticomegaly, calcification, increased echogenicity) 5 & both abnormal USS & blood 2 (glycogen 15%, 29%) large joints of lower limbs & joints hands. Tenosynovitis 4 (7.7%) Renal: 15 (29%) (USS or Blood/urine tests – raised serum creatinine,
raised urinary ca creat ratio, raised urinary NAG/RBP) — 4/15 on USS and 9/15 in blood/urine tests, 2/15 on both USS and blood/urine tests. Lungs: 7 (12.5%): 6 abnormal lung function test, 1 abnormal CXR, lung function & CT chest - severe interstitial lung disease & presented- progressive shortness of breath. Skin: 10 (19.2%), eczema-like/non-specific skin Pariod/plandulair: 1 (1.9%) on USS Spleonomegaly: 4 (7.7%) on USS Sensorineural hearing loss: 2 (3.8%).

Medications to treat uveitis and/or extra-ocular manifestations were: Methotrexate 13 (25%), Methotrexate + Adalimumab 11 (21.2%), MMF 6 (11.5%), topical steroids 6 (15.4%), systemic steroids 2 (3.8%). 10 patients no medication

Conclusion: Most of the sarcoid-like uveitis patients had at least one extra-ocular involvement. ACE does not appear to be a sensitive biomarker. Some patients (19.2%) have a mild phenotype and require no treatment. Our data demonstrate the importance of close monitoring for extra-ocular manifestations and highlight good clinical response to steroids, MTX, MMF and anti-TNF.

THU0525 DEVELOPMENT OF A PREDICTIVE TOOL FOR RESPONSE TO ANTI-TNF-ALPHA THERAPY IN JIA USING GENE EXPRESSION PROFILES IN PERIPHERAL DERIVED MONONUCLEAR CELLS
Jedidja Baaji1, Rianne Scholman1, Rae Yeung2, Trang Duong3, Nico Wulfraat1, Joost F. Swart1, Sebastian Vaster1, Sytze De Roock1, 1UMC Utrecht, Department of Pediatric Rheumatology, Utrecht, Netherlands; 2Hospital for Sick Children, Department of Paediatrics, Toronto, Canada

Background: Heterogeneity in response to biological medication is a major challenge in the management of Juvenile Idiopathic Arthritis (JIA) (1). Biomarkers such as cytokines or whole blood RNA expression profiles that predict therapy efficacy prior to treatment pose a solution and could enable precision medicine. It was previously demonstrated that whole blood gene expression profiles can predict response to anti-TNF-α therapy in patients with JIA (2). These findings currently await validation in a multicenter prospective cohort study. Harmonization of data from different cohorts, however, is often hampered by site-dependent differences in biological sample collection and processing (3). For instance, the biological material that is retrospectively available from biobanks depends on what is stored exactly, e.g. whole blood versus peripheral blood mononuclear cells (PBMC). Furthermore, different blood collection tubes containing different additives can affect sample quality at an early stage and make interchangeability or comparability of data impossible.

Objectives: We evaluated the comparability of gene expression profiles when whole blood from patients with JIA is collected in different RNA collection tubes and processed accordingly. Next, we will investigate the predictive capacity for therapy response of RNA expression profiles from frozen PBMC of 63 JIA patients.

Methods: Peripheral blood from 11 children with non-systemic JIA with active disease was collected in PAXgene (PreAnalytX) and Tempus (Applied Biosystems) tubes. All tubes were subsequently stored in the freezer at ~80 °C. After thawing, RNA from the PAXgene tubes was extracted with use of the PAXgene Blood RNA Kit and RNA from the Tempus tubes was isolated by using the Tempus Preserved Blood RNA Purification Kit I; Gene expression of CSNK1D, C1D, ASAP2, SRRR, PPP1R3B, HLA-DOA1, PDZK1P1 and MZB1 was determined with qPCR. For our next experiment, frozen PBMC derived from patients with non-systemic JIA who are included in our longitudinal Pharmacology biobank will be used. Of the 63 patients, 28 (44.4%) children were diagnosed with oligo articular JIA, 19 (30.2%) with poly articular JIA, 9 (14.3%) with enthesis-related JIA, 4 (6.3%) with psoriatic JIA and 3 (4.8%) with undifferentiated JIA. The average age at sampling was 11.5 years ± 4.0 and 65% of the patients was female. These samples will be run on a 96-analyte NanoString panel and associated with clinical response at time points 3 and 6 months after start of TNF-α blockade.

Results: Both RNA blood collection systems yielded high-quality RNA, with overall higher RNA concentrations for blood collected in Tempus tubes in comparison to PAXgene tubes. qPCR data showed that gene expression of all measured genes is affected by the method of blood collection and processing. However, the inter-individual variation was similar between both collection tubes, indicating that similar RNA profiles were observed.

Conclusion: Gene expression profiles derived from whole blood collected in PAXgene or Tempus tubes are comparable, but are not interchangeable.

THU0526 LONG-TERM OUTCOME IN JUVENILE IDIOPATHIC ARTHRITIS – A POPULATION-BASED STUDY FROM SWEDEN
Elisabet Berthold1, Bengt Månsson1, Robin Kahn1, 2Clinical science Lund, Lund University, Department of Rheumatology, Lund, Sweden; 2Clinical science Lund, Lund University, Department of Pediatrics, Lund, Sweden

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children. The incidence rate among Caucasians is reported to be 8-15/100 000/year (1, 2). The long-term prognosis is insufficiently studied in JIA, although it is known that the disease often proceeds into adulthood and may cause joint damage leading to significant morbidity and physical disability. There are many challenges in elucidating the long-term prognosis. Amongst others, frequent occurrence of disease misclassification in diagnostic registers and the heterogeneity of JIA have made it difficult to interpret results (3, 4).

Objectives: To study the epidemiology, incidence and long-term outcome of JIA in southern Sweden using a population-based cohort of children with a validated diagnosis of JIA collected over nine years.

Methods: Potential cases of JIA, diagnosed between 2002 and 2010 were collected from a local search at the Department of Rheumatology in Lund and at the National Board for Health and Welfare, using the ICD-codes M08-M09. The study area is Skåne, the southernmost county of Sweden (population 1.24 million; 19.1% aged < 16 years) and the median follow-up time was eight years. The JIA-diagnosis was validated and subcategorised through medical record review based on criteria defined by The International League of Associations for Rheumatism. Parameters on disease activity and pharmacologic treatment were recorded annually until the end of the study period.

Results: 251 cases of JIA were confirmed. The mean annual incidence rate for JIA was estimated to be 12.8/100 000/year. The highest age specific annual incidence is at the age of two years (36/100 000/year). This peak is consistent in the female group, but the incidence peak among males is at 12 years of age. Almost all patients are at some point during their disease course prescribed non-steroidal anti-inflammatory drugs (98%). Intra-articular steroid injections are also frequently used (78.9% in the total cohort). Methotrexate is the most common disease modifying anti-rheumatic drug prescribed (60.8%). Tumor necrosis factor alpha-inhibitors are used as treatment in 23.9% of the children.

Oligoarthritis was the largest subgroup (44.7%), followed by undifferentiated JIA (16.3%), polyarticular rheumatoid factor negative JIA (13.9%), enthesitis-related arthritis (8.8%), polyarticular rheumatoid factor positive JIA (6.8%), juvenile psoriatic arthritis (6.8%) and systemic JIA as the smallest subgroup (2.8%).
Uveitis, both acute and chronic, was seen in 10.8% of the children. Permanent joint affection was seen in 20.7% of the children and 8.8% have been treated with joint corrective orthopedic surgery. At five-year follow-up, 57% of the children had disease activity, defined as arthritis and/or uveitis (2.1% with uveitis as active disease).

**Conclusion:** This is a well-defined, population-based and validated cohort of children diagnosed with JIA investigating long-term outcome in the era of biologics. We found that a considerable part of the children still develop uveitis, permanent joint affection and need joint corrective surgery occasionally. More than 50% of the cohort has active disease five years after diagnosis. In conclusion, we still have long-term challenges in children with JIA, in spite of state-of-the-art treatment.

**THU0527 RISK SCORE OF MACROPHAGE ACTIVATION SYNDROME IN PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS**

Simone Carbogno1, Denise Pires Marafon2, Giulia Manucci3, Manuela Pardeo4, Antonella Insalaco5, Virginia Messi6, Emanuela Sacco7, Fehrat Derm8, Betul Sözen8, Alenka Gagro9, Nastasia Kifer10, Marija Jelusic11, Francesca Minoia12, Mikhail Kostik13, Olga Vougiouka14, Roberta Simoni15, Francesca Minoia16, Mikhail Kostik17, Olga Vougiouka18, Fabrizio De Benedetti19, Claudia Bracaglia20, 21

**Background:** Macrophage Activation Syndrome (MAS) is a severe, life-threatening, complication of rheumatic diseases in childhood, particularly of systemic Juvenile Idiopathic Arthritis (sJIA), occurring in approximately 25% of the patients with sJIA. A score that identifies sJIA patients who are at high risk to develop MAS would be useful in clinical practice.

**Objectives:** To evaluate whether routine laboratory parameters at disease onset may predict the development of MAS in patients with active sJIA. To define a risk score of MAS for sJIA patients using these parameters.

**Methods:** Laboratory parameters of disease activity and severity (WBC, N, PLT, Hb, ferritin, AST, ALT, gGT, LDH, TGL, fibrinogen, D-dimer and CRP), were retrospectively evaluated in 86 sJIA patients referred to our Division of Rheumatology from 1998 to 2017 with at least one year of follow-up. Laboratory parameters were evaluated during active sJIA, without MAS, at time of hospitalization (T1) and before treatment for sJIA was started (T2). Patients were divided in two groups: group 1 (patients without history of MAS), group 2 (patients with at least one MAS episode during disease course). To calculate a MAS risk score, laboratory parameters, collected at T2, with a statistical significant difference between the two groups of patients were selected.

**Results:** Thirty-three patients, who fulfilled the 2016 classification criteria for MAS [1] at time of sampling, were excluded from the analysis. Therefore, we analysed laboratory parameters of 53 patients with sJIA, 33 of whom without history of MAS (group 1) and 20 who developed at least one episode of MAS during disease course (group 2). Levels of ferritin, AST, ALT, gGT and TGL, collected at T2, were statistically significant higher in patients with a history of MAS compared to those without a history of MAS. For each of these parameters an arbitrary cut-off was defined. In order to define the final score an arbitrary rate was attributed to each parameter. Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated to define the most scoring system. The scoring system with the best sensitivity was chosen (Table 1). A MAS risk score >3 identified 19 out of 20 sJIA patients with a history of MAS and 4 out of 33 sJIA patients without history of MAS.

**Conclusion:** In conclusion we developed a MAS risk score based on routine laboratory parameters that are available worldwide, that can help clinicians to identify patients at higher risk to develop MAS. A validation on a larger population is necessary.

**THU0528 DISCONTINUATION OF COLCHICINE THERAPY IN CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER**

Yonatan Butbul1, Rawan Sliman2, Shade Fahoun3, Yackov Berkun4, 5, Rappaport Children’s Hospital, Rambam Medical Center, Haifa, Israel, Pediatric Rheumatology Service, Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Department of Pediatrics B, Haifa, Israel; 4 Rappaport Children’s Hospital, Rambam Medical Center, Haifa, Israel, Pediatric Rheumatology Service, Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel; 3 Hadassah-Hebrew University Medical Center Mount Scopus, Jerusalem, Israel, Department of Pediatrics and FMF clinic, Haifa, Israel

**Background:** Clinical phenotype of FMF exists in some carriers of MEFV mutation. These patients tend to have a mild disease. Prolonged colchicine free remission was reported in a small group of FMF patients.

**Objectives:** To describe and characterize a group of children with FMF in whom colchicine was discontinued.

**Methods:** The study cohort consisted of all children with FMF followed at 2 referral centers in Israel. In conclusion, we still have long-term challenges in children with JIA investigating long-term outcome in the era of biologics.

**Results:** In order to validate the MAS risk score on a different population, we applied it on 53 patients from other paediatric Rheumatologic centres. Thirty-seven of these patients without history of MAS while 16 with at least one episode of MAS. Sensitivity and specificity were 0.750 and 0.784 respectively.

**Conclusion:** In conclusion we developed a MAS risk score based on routine laboratory parameters that are available worldwide, that can help clinicians to identify patients at higher risk to develop MAS. A validation on a larger population is necessary.

Whole-body magnetic resonance imaging in juvenile dermatomyositis: a longitudinal study

**Objectives:** To compare whole-body MRI (WB-MRI) with clinical examination. Correlations between WB-MRI muscle score and disease activity is a challenge in clinical practice.

**Methods:** We included consecutive JDM patients followed in the rheumatology unit. All patients were submitted to clinical and laboratory evaluation. WB-MRI images were obtained using a 1.5 T MRI scanner and short T inversion recovery sequences (STIR). Muscle, peripheral inflammation and subcutaneous inflammations signal abnormalities were scored in 42 muscular groups. Muscle inflammation was classified as: 0 = absent; 1 = Mild to moderate/involvement less than 50% of muscle extension and 2 = Accentuated/greater than 50%. Peripheral and subcutaneous inflammations were classified as: 0 = absent; 1 = present; and on proximal and distal extremities. WB-MRI and clinical assessments were performed concurrently and results compared. Evaluation was repeated after 12 months. Statistics was performed according to the nature of the variable.

**Results:** WB-MRI revealed muscle inflammation in 6 (31.6%) at study entry. We observed grade 2 muscle inflammation of the right and left scapular girdle (1/19 patients), right and left pelvic girdle (2/19 patients) and right and left thigh (1/19 patients). Grade 1 inflammation was observed in peripheral right and left arm (2/19 patients), peripheral right and left thigh (1/19 patients). Grade 1 subcutaneous inflammation was observed in right and left thigh (1/19 patients) and left leg (1/19 patients). Additionally we observed sacroiliitis (1/19 patients), spinal cord infarction (21%), and osteonecrosis (5.2%). All patients were treated with standardized treatment. After 12 months 13/19 (68.4%) patients repeated the WB-MRI. Five (38.4%) patients had new/worsening of muscle and subcutaneous inflammation, one (7.7%) patient had tibial medullary infarction. Correlations between WB-MRI muscle score and disease activity measures were excellent (Manual Muscle Test: r = 0.88, Childhood Myositis Assessment Scale: r = 0.81). Patients with subcutaneous inflammation developed clinically evident subcutaneous calcifications during follow-up.

**Conclusion:** WB-MRI provides additional information to clinical evaluation and represents a promising tool to determine the grade of muscle inflammation to additional peripheral and subcutaneous tissue inflammation.

**DOI:** 10.1136/annrheumdis-2019-eular.2380
Background: Childhood uveitis is a group of heterogenous, potentially blinding inflammatory disorders. Management is complex. There is growing recognition of the importance of actively involving affected children and their families in their own care. Co-designed interventions, developed through active involvement of staff and patients, can provide effective solutions to problems identified by those affected.

Objectives: To use findings from a patient and family discussion group to inform the co-designed development of health care processes and interventions.

Participants: Five children/young people with uveitis (age ranges 8 to 17), seven parent/carers of children with uveitis and four health care professionals attended a 90 minute discussion group. Main discussion topic was the identification of areas in need of interventions or support structures. Sub-topics were determined a priori using previous PPI and existent research (REFS). They comprised: Direct health care; Impact on families; School, education and peers. Responses were collated. Consent was taken for use of direct quotes from participants.

Results: We outline the areas identified by children and families:

Direct health care: Four interconnected areas were identified: (1) Transitioning to adult services, (2) peer support (health care services being a valuable site for identifying peers), (3) communication between care structures to adult services, (2) peer support (health care services being a valuable site for identifying peers), (3) communication between care structures and (4) education for families. With regards to family education, there was identification of the need for specific services or interventions around the communication of (4a) diagnosis, (4b) treatment, (4c) likely long term outcomes/prognosis, (4d) and the child’s progress. There was also discussion on (4e) the formats used to communicate with families.

Impact on families: Participants discussed support around (1) family relationships, (2) the impact of systemic medication, They also discussed (3) a need for recognition of the changing nature of their lived experience as affected families over the disease course and the need for on-going psychologic support especially at presentation to help with acceptance.

School, education and peers: Participants discussed the need for support around: (1) the impact of treatment on school life, (2) communication with school professionals and peers, (3) impact of visual impairments, (4) education for families, With regards to family education, there was identification of the need for specific services or interventions around the communication of (4a) diagnosis, (4b) treatment, (4c) likely long term outcomes/prognosis, (4d) and the child’s progress. There was also discussion on (4e) the formats used to communicate with families.

Conclusion: Through the above approach, we have identified a range of issues affecting our patients and their families. Our findings are similar to those of other groups (1, 2) These lived experiences will be used to inform the co-design of supportive services (patient leaflets, videos, website, psychology intervention) and research on the effectiveness of these interventions in improving the management of affected children and their families.

NEW CLASSIFICATION CRITERIA FOR RECURRENT AUTOINFLAMMATORY DISEASES APPLIED TO AN INDEPENDENT COHORT: EXPERIENCE FROM THE JIR COHORT DATABASE

Glory DINGULU1, Sophie Georgin-Lavialle2, Isabelle Koné-Paut2, Pascal Pillet2, Anne Pagnier3, Étienne Merlin4, Daniela Kayser4, Alexandre Belot4, Michael Hofer5, Helene Hempten6, Reference Center for Autoinflammatory Diseases-CEREMAIA, Le Chesnay, France; Reference Center for Autoinflammatory Diseases-CEREMAIA, Paris, France; Reference Center for Autoinflammatory Diseases-CEREMAIA, Kremlin-Bicêtre, France; Hospital Pellegrin, Bordeaux, France; Centre Hospitalier Universitaire de Grenoble, La Tronche, France; Chu Estaing, Clermont-Ferrand, France; Luzerner Kantons Spital Wolhusen, Wolhusen, Switzerland; Hospital Woman Mère Enfant – Hôl, Bron, France; CHUV Centre hospitalier universitaire vaudois, Lausanne, Switzerland

Background: New classification criteria for the inherited periodic fever syndromes (TRAPS, FMF, MKD and CAPS) have recently been developed during a Consensus Conference held in Genoa in March 2017.

Objectives: The aim of our study was to compare these new classification criteria for monogenic recurrent fever syndromes with the diagnoses of clinicians. For this purpose we used the JIR cohort database, an international platform gathering data of patients with pediatric inflammatory disease.

Methods: The Genoa classification criteria were applied to all the patients, then compared to the clinical diagnosis of the treating physician. As patient diagnosis could be confirmed or suspected, the patients could have up to two diagnoses. Classification criteria relied on genetical HRF pathogenicity classification. Finally, criteria performance were assessed by firstly determining sensitivity and specificity and secondly analyzing true positive, false positive and false negative patients.

Results: 455 patients included in the JIR cohort database with a recurrent fever syndrome were enrolled to the study.

CAPS: The analysis of the performance of the CAPS criteria showed sensitivity of 60% and specificity of 98%. 14 patients fulfilled Genoa CAPS classification criteria, with 6 true positive and 8 false positive patients. Patients with confirmatory genotype always fulfilled classification criteria. 4 patients, who carried heterozygous mutations, were false negative.

TRAPS: The analysis of the performance of the TRAPS criteria showed sensitivity of 100% and specificity of 98%. 22 patients fulfilled Genoa TRAPS classification criteria, all true positive patients with confirmatory and non-confirmatory genotype. 5 were false negative with 4 patients with contramatory genotype.

FMF: The analysis of the performance of the FMF criteria showed sensitivity of 96% and specificity of 89%. 118 patients were true positive while 35 were false positive patients. True positive patients were all patients with confirmatory genotype, patients with non-confirmatory genotype and no mutation. 37 were false positive patients. 5 patients were false negative with 3 patients with non-confirmatory genotype.

MKD: The analysis of the performance of the CAPS criteria showed sensitivity of 64% and specificity of 66%. 7 patients with confirmatory genotype were true positive patients. 148 were false positive patients with 44 patients diagnosed TRAPS, FMF, CAPS while the rest were SURF. 4 were false negative including 3 patients with non-confirmatory genotype.

Conclusion: This study confirms that classification was undertaken on a cohort of patients seen with recurrent fever. This descriptive study shows tremendous performance Genoa criteria for patients with confirmatory genotype and help classifying patients with non-confirmatory genotype. On the other hand, those classification criteria were less performant when patients did not display at least one gene mutation. Therefore, Genoa classification criteria for TRAPS outperformed the others, because mandatory genetic screening. This study also highlights permissive criteria for clinical CAPS, FMF and MKD. The implementation of biological criteria in MKD would improve MKD criteria.

NATURE AND IMPACT OF THE FRENCH NETWORK RESRIP ON SCHOOLING, FOR CHILDREN WITH CHRONIC INFLAMMATORY RHEMATISM

Perrine Dusselier1, Christelle Hascoët2, Isabelle Koné-Paut3, Linda Rossi-Semerano4, Bioclin Hospital, Paediatric Rheumatology, reference center for auto-inflammatory disease and amyloidosis, French network RESRIP, Le Kremlin Bioclin, France;2French network RESRIP, Le Kremlin Bioclin, France

Background: Pediatric chronic inflammatory rheumatism (CIR) has a significant impact on daily life, especially on schooling, that can lead to child’s drop-out. In this context, a French paediatric health network, RESRIP (Réseau pour les Rhumatismes Inflammatoires Pédiatriques), has been created in 2014 for children with CIR and living in the Ile-de-France region. Patients are included in this network if they meet certain criteria such as the need to find trained health professionals close to their home or for support because of adverse social conditions or difficulties with their schooling. If the criteria are fulfilled, the patient and his family participate in an intake interview which allows RESRIP to understand the patient’s need and to set up targeted actions.

Objectives: In our study, we aim to describe and evaluate RESRIP’s role on improving school attendance and tackling absenteeism.

Methods: A descriptive retrospective study was performed regarding the support provided by RESRIP with respect to patients’ schooling and education professionals. Rates of non-attendance were collected at inclusion
and every 6 months from 2014 to 2017, through a standardized auto-questionnaire.

Results: 278 patients (M/F: 0.29) aged 12.7 years on average (± 4.9 range 2-21) were taken care of between 2014 and 2017 by RESRIP. Juvenile idiopathic arthritis (JIA) (n = 142), connective tissue disease (n = 49) and auto-inflammatory disease (AID) (n = 32) are the 3 main pathologies covered. Among the 278 patients, twenty-one percent of patients needed academic support when entering the network, including: 37% in the JIA group, 34% in the connective tissue group and 18% in the AID group. Educational assistance was set up for all patients with school difficulties at inclusion but also for all the patients during their follow-up. Patient Support: 178 Individual Action Plan (IAP) were implemented by RESRIP. Twelve patients benefited from additional time for their school exams and 10 were allowed to pass the baccalaureat (French final college exam) only two years instead of a year. In thirty patients, sports education has been adapted. Forty-one MDPH files (Departmental Houses for the Disabled) were produced to enable the establishment of a school life assistant (AVS), teaching materials and/or technical aids. Finally, 8 patients received home school assistance through Home Learning Assistance Services (SAPAD).

Education professional support: RESRIP established partnerships with the French National Education (FNE) and the SAPAD (home tuition service for ill children). For the FNE, RESRIP provided school doctors or nurses with: 8 continuing medical training and 25 personal interviews to explain the pathologies. In addition, 5 multidisciplinary meetings, within the institutions were organized, for 5 patients with social integration difficulties and school educational exemptions, has added a significant decrease in school absenteeism between 2014 and 2017: 3.2 days per year on average at age 1 to 0.5 days per year on average (p <0.05) at 42 months. Conclusion: Over time, a better understanding of the impact of chronic illness on school and education professionals, has allowed RESRIP to improve its support. The result is a notable decline in school absenteeism and in unjustified physical education exemptions. Several projects are underway: The development of a standard IAP available for doctors, the set-up of a partnership with school hospital, willing to help for the implementation of home school support courses in addition to SAPAD.

Disclosure of Interests: Perrine Dusser: None declared, Chrystelle Has-coet: None declared, Isabelle Kéna-Paut Grant/research support from: SOBI, support of a product (anakinra) for the presented study, Consultant for: SOBI, Novartis, Pfizer, Abbvie, UCB, CHUGAL, ROCHE, Linda Rossi-Semerano Grant/research support from: Roche DOI: 10.1136/annrheumdis-2019-eular.7122

THU0537 ANGIOMATOID FIBROUS HISTIOCYTOMA MIMICKING SYSTEMIC JIA VIA MUTATION-DRIVEN IL-6 PRODUCTION

Mark Fisswell1, Stephen Owens2, Gail Halliday3, 1Great North Children’s Hospital, Paediatric Rheumatology, Newcastle upon Tyne, United Kingdom; 2Great North Children’s Hospital, Paediatric Immunology, Newcastle upon Tyne, United Kingdom; 3Great North Children’s Hospital, Paediatric Oncology, Newcastle upon Tyne, United Kingdom

Background: Angiomatoid Fibrous Histiocytoma mimicking Systemic JIA via mutation-driven IL-6 production: Angiomatoid Fibrous Histiocytoma (AFH) is a rare tumour associated with mutation-driven production of Interleukin-6 (IL-6) which causes a systemic inflammatory picture similar to Systemic Juvenile Idiopathic Arthritis (sJIA). Objectives: A previously well 6-year old girl was referred with 6 weeks of abdominal pain, nausea, weight loss, night sweats, & lethargy. Examination was unremarkable apart from a 2cm lump in the right popliteal fossa. This had been reported on USS 2 months earlier, at an external hospital, to be a Sebaceous cyst. There was no rash, organomegaly, lymphadenopathy, or synovitis. She had persistent recurrent fevers of >39C, but not in the classical coutidial pattern of sJIA. Methods: Bloods showed persistent Hb <70, platelets >600, ESR >100 & CRP >200. Autoantibody & full infection screens were negative. Urine HMMA:creatinine ratio was minimally raised at 7.2 (normal 1.8 - 5). Faecal calprotectin, upper & lower GI endoscopy were normal. Bone-Marrow Aspiration was reported as being highly reactive but with no malignancy seen. Whole-body STIR MRI was reported as normal, but repeat localised USS of the knee showed a 27x18x21mm well circumscribed, mixed cystic/solid lesion with marked vascularity. The lesion was then biopsied, and subsequently excised Plasma IL-6 levels were significantly elevated at 46.7pg/ml (normal range: 0-2), but normalised after excision. TNF and IL1b levels were normal Results: Initial biopsy and FISH analysis confirmed the diagnosis of AFH via mutation-driven IL-6 production. Angiomatoid Fibrous Histiocytoma (AFH) is a rare tumour associated with mutation-driven production of Interleukin-6 (IL-6) which causes a systemic inflammatory picture similar to Systemic Juvenile Idiopathic Arthritis (sJIA).

Conclusion: No statistical differences were detected, although the scarce number of control subjects might have influenced this result. There is a trend towards a lower antibody persistence anti-Hb in patients compared to healthy children. The response to life virus vaccine and tetanus seem to be as good as in healthy children.

González-Fernández: None declared, B Lopez-Montesinos: None declared, Inmaculada Calvo Grant/research support from: received research grants from Pfizer, Roche, Novartis, Clementia, Sanofi, MSD, BMS and GSK, Consultant for: Advisory boards: Novartis, AbbVie, Speakers bureau: AbbVie, Roche, Novartis, SOBI DOI: 10.1136/annrheumdis-2019-eular.6378

THU0536 LONG TERM IMMUNITY IN A PAEDIATRIC COHORT OF PATIENTS WITH RHEUMATIC DISEASES FROM A TERTIARY HOSPITAL IN SPAIN

Laura Fernández Silveira1, M.J. Gimenez2, E Andreu-Alapont2, Patricia Falomir-Salcedo2, E Serrano-Poveda2, M.I. González-Fernández2, B Lopez-Montesinos3, Inmaculada Calvo2, Hospital Virgen del Rocío, Sevilla, Spain; 3Hospital la Fe, Valencia, Spain; 2Centro de salud Campanar, Valencia, Spain; 3Centro de Salud Miguel Servet, Valencia, Spain

Background: Pediatric patients with rheumatic diseases (RD) are at increased risk of infections. Vaccines have been proved to be very effective to prevent them. Nevertheless the long-term immunity after vaccination remains quite unknown in this group.

Objectives: To compare the long term seroprotection in pediatric patients with rheumatic diseases who received measles, rubella, mumps, tetanus, diphtheria, hepatitis B, Hib and meningococcus C vaccination according to the routine immunization schedule in Spain, and healthy children.

Methods: We designed a cross-sectional study including consecutive pediatric patients with RD who attended the rheumatology clinic and healthy children older than 10 y.o. The administered vaccines, treatment and pathology of each patient will be recorded. Their antibodies titers against each antigen were quantified and compared to healthy children.

Results: 60 patients (median age 13 y.o IQR 10.2-17) and 15 healthy children (mean age 11.3 y.o. IQR 11.3-12.7) were included. In the patients group 62% were female, and 35% in healthy. Diagnosis: 85% Idiopathic juvenile arthritis, 16% Lupus or juvenile dermatomyositis. 46% had received biologic treatment sometime. Seroprotection rate was (patient vs control): measles 89%/ vs 81%, rubella 78.8% vs 73.3%, parotiditis 84.7% vs 66.7%, VHB 27% vs 10.5%, diphtheria 89.5% vs 81%, tetanos 64.9% vs 61.1%. Hib 42% vs 53%, pneumococco 92.4% vs 100%, meningococcus C 12% vs 11%. p>0.05

Conclusion: No statistical differences were detected, although the scarce number of control subjects might have influenced this result. There is a trend towards a lower antibody persistence anti-Hb in patients compared to healthy children. The response to life virus vaccine and tetanus seem to be as good as in healthy children.

THU0539

SERUM SOLUBLE CD25: AN USEFUL BIOMARKER OF MACROPHAGE ACTIVATION SYNDROME IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

Sandesh Galeria1, Anju Gupta1, Amit Rawat1, Prateek Bhatia2, 1Post Graduate Institute of Medical Education and Research, Chandigarh, Allergy Immunology unit, department of Pediatrics, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatric hematopoietology unit, department of pediatrics, Chandigarh, India

Background: Systemic juvenile idiopathic arthritis (SJIA) is an auto-inflammatory disorder secondary to innate immune dysfunction with a propensity to develop macrophage activation syndrome (MAS), a life-threatening condition (1). sCD25 has been used as a sensitive biomarker for the diagnosis of Hemophagocytic lymphohistiocytosis which has similarities in clinical features and pathogenesis to MAS (2).

Objectives: To assay serum soluble CD25 in children with systemic juvenile idiopathic arthritis (SJIA) and to compare levels of sCD25 in children with inactive disease, active disease and those with macrophage activation syndrome (MAS).

Methods: This prospective study was conducted in a tertiary care referral centre in North India from January 2017 to June 2018. All patients fulfilling the International League of Associations for Rheumatology (ILAR) 2001 criteria for SJIA were eligible for enrolment. At enrolment, all patients were examined clinically for signs of disease activity. Appropriate investigations were carried out and sCD25 was analyzed by using commercially available sCD25/IL-2R ELISA kit.

Results: A total of 35 children (1-18 years) with 43 events were included in the study. Mean age at enrolment in the study was 7.3±3.59 years with male to female ratio of 2.5. Based on clinical features and investigations, events were categorized into 3 groups; SJIA with inactive disease (15; 34.9%), SJIA with active disease (15; 34.9%) and SJIA with MAS (13; 30.2%). Mean sCD25 levels in the study population were 10,966.02 ± 10,854.93 pg/ml. Children with inactive disease, active disease and disease with MAS had mean ± SD serum sCD25 levels of 4710.6 ± 1817.04 pg/ml, 7604 ± 2376.24 pg/ml, and 22062.9 ± 14335.97 pg/ml respectively. Although, Mean level of sCD25 in children with active disease was higher than those with inactive disease, but no significant difference could be found. sCD25 levels significantly (p value 0.0001) varied between MAS and other 2 groups. sCD25 cut off level of 10,385 pg/ml was found to have sensitivity of 100% and specificity of 96.7% in differentiating MAS in SJIA from disease flare and inactive disease. There was no significant correlation of sCD25 with demographic parameters. Total leucocyte count, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), platelet counts, urea, creatinine, prothrombin time, activated partial prothrombin time and fibrinogen levels. A correlation of sCD25 was found with levels of haemoglobin (p-value .01), ferritin (p-value .001), aspartate aminotransferase (AST) (p-value .00), alanine aminotransferase (ALT) (p-value .00), alkaline phosphatase (ALP) (p-value .005) and triglycerides (p-value .001). Higher sCD25 levels were found in patients who had low Hb, elevated ferritin, elevated AST, ALT, ALP and serum triglyceride levels.

Conclusion: sCD25 is a useful biomarker in differentiating MAS in SJIA from disease flare and inactive disease with sensitivity and specificity of 100% and 96.7% respectively at a cut off level of 10,385 pg/ml. Coupling sCD25 with other laboratory parameters may be useful for early diagnosis of MAS in SJIA.

SYSTEMATIC REVIEW OF BIOLOGICAL TREATMENT OF DEFICIENCY OF INTERLEUKIN-36 RECEPTOR ANTAGONIST (DIRTA) IN CHILDREN AND ADOLESCENTS

Toni Hospach1, Fabian Glowatzki2, Friederike Blankenburg3, Dennis Conzelmann1, Christian Strinkorb1, Chris Sandra Muellerschoen2, Peter Driesch von den2, Lisa Koehler2, Meino Rohfils3, Christoph Klein2, Fabian Hauck3, 1Klinikum Stuttgart Olghospital, Pediatric Rheumatology, Stuttgart, Germany; 2Klinikum Stuttgart Bad Cannstatt, Stuttgart, Germany; 3Dr. von Hauner Children’s Hospital, University Hospital, LMU, Munich, Germany

Background: Deficiency of interleukin-36 receptor antagonist (DIRTA) is a life threatening autoinflammatory disease caused by autosomal recessive mutations of the IL36RN gene leading to recurrent episodes of generalized purpuric psoriasis with systemic inflammation and fever. The disease is rare and no standardized treatment guidelines exist.

Objectives: To systematically review and analyze the literature on biologically treated pediatric DITRA patients.

Methods: A NCBI pubmed database research was performed to identify all relevant articles on pediatric DITRA patients treated with biologicals. According to defined response criteria therapeutic efficacy was analyzed.

Results: Our literature research revealed 13 pediatric patients with DITRA and biotreatment. Ten patients were homozygous including six with the p.Leu27Pro, three with the p.Arg10Argfs* and one with the p.Thr123Met mutation and three were compound heterozygous. We add an unreported DITRA patient with a compound heterozygous IL36RN p.Pro76Leu/pSer113Leu mutation. In total 29 flares in 14 patients were treated with biological agents-targeting IL-1/IL-17, IL-12/23 and TNF-α. Complete response was achieved in 15 (52%), partial in 4 (14%), and no response in 10 (34%) of the flares. Response rates were heterogeneous among the different agents. While complete/partial/no response with inhibition of TNF-alpha could be achieved in 6 (46%)/3 (23%)/4 (31%), the inhibition of IL-17 and of IL-12/23 led in each 4 flares to a 100% complete response. IL-1/3R inhibition led to complete/partial response in each 1 (13%) and was not effective in 6 (75%) flares. Of note, the unreported patient was successfully treated with weekly dosed adalimumab.

Conclusion: DITRA is a rare disease that has to be considered in patients with generalized purpuric psoriasis with systemic inflammation and fever. It can be effectively treated with specific biological inhibition of TNF-alpha, IL-12/23 and IL-17, while anti-IL-1/3R treatment seems less effective. Weekly dosed adalimumab appears to be a novel treatment option for pediatric patients. Further reports and studies of biological treated pediatric DITRA patients are warranted for evaluation of optimal treatment.

ANTI-VACCINE ANTIBODY LEVELS IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS: PRELIMINARY DATA IN 90 PATIENTS

Natalia Lubinová1, Olga Golèva2, Irina Fridman2, Lubov Sorokina2, Rena Idrisova1, Susanna Khan1, Mikhail Kostik1, Christine Nang'Sia2, 1Children’s City Hospital # 2 na Saint Mary Magdalene, Saint-Petersburg, Russian Federation; 2Pediatric Research and Clinical Center for Infection Diseases, Saint-Petersburg, Russian Federation; 3Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation; 4Children’s City Hospital # 1, Saint-Petersburg, Russian Federation

Background: Patients with juvenile idiopathic arthritis (JIA) may have lower protective levels of anti-vaccine antibodies (AVA) due to high inflammatory activity, interrupted or incomplete vaccination schedule, using of immune-modulating drugs, e.g. systemic corticosteroids (CS), methotrexate (MTX) and biologics [1].

Objectives: The aim of our study was to evaluate levels of AVA in the patients with JIA.

Disclosure of Interests: None declared

Methods: We included data about 90 JIA (26 M and 64 F) aged from 2 to 17 years, who received scheduled vaccination before the age of 2 years and before JIA onset. In all patients the Ig G anti-measles (AM), anti-parotitis (AP), anti-hepatitis B (AHB), anti-diphtheria (AD) and anti-rubella (AR)AVA levels were detected with ELISA. In each patient we evaluate the type of the JIA (oligoarthritis – OA (n=38), polyarthritis – PA (n=36), systemic-SA (n=7) and enthesitis-related arthritis – ERA (n=10), routine disease activity and treatment. In healthy controls were measured anti-measles (n=40) and anti-parotitis (n=30) antibodies (AB) for comparison with JIA.

Results: The main demographic characteristics: age of inclusion in the study 11 (8-15) years, disease onset – 6 (4-8) years, JIA duration – 2 (7-2) years. The AM AB in JIA patients were 0.2 (0.0-0.5) IU/ml and in HC 0.3 (0.2-1.1) IU/ml (p=0.00002), despite the higher age of JIA patients than HC (p=0.0000001); AP AB were 2.6 (1.0-5.1) IU/ml vs 1.1 (0.0-4.9) IU/ml in JIA and HC, respectively (p=0.04). Protective levels of AM AB was detected in 50% of all JIA population, vs. HC – 87.5% (p=0.00005), AP – 67.7% vs. 60% in HC (p=0.076), AHB – 54.4%, AD – 50%, AR – 97.8%. The main data related to vaccination status in the table. We have found correlation between JIA duration and levels AM AB (r=-0.27, p=0.01). Differences in the study between studies can be explained by differences in the study populations (age, disease duration and disease state) and differences in the study methods (1-3). Depression and anxiety are the most common disorders, but most studies were based on questionnaires to investigate incidence of only these two diseases (1,3).

Objectives: To explore mental and behavioral disorders in JIA patients compared to the control population.

Methods: All incidents patients with JIA during 2000-2014 were collected from the nationwide register, maintained by the Social Insurance Institution of Finland (4). The National Population Registry identified three controls (similar regarding age, sex and residence) for each case. They were followed up together until 31Dec 2015. ICD-10 codes of psychiatric diagnosis (F10-F99) were picked up from the Care Register for Health Care of the National Institute for Health and Welfare.

Results: During 28,941 follow-up years, 974 (23%) JIA patients were diagnosed with mental or behavioral disorders, whereas the number in the control group was 1,807 (15%), (p<0.001). Neurotic, stress-related and somatoform disorders (F40-48) and mood (affective) disorders (F30-39) were the most common psychiatric diagnoses in the JIA (10.41% and 8.18%) and in the control group (5.44% and 5.13%). The odds ratio for neurotic disorders (F40-48) was 2.02 (95% CI 1.78-2.29) and for mood disorders (F30-39) 1.65 (95% CI 1.44-1.89). Additionally, JIA statistically significantly associated with behavioral and emotional disorders and disorders of psychological development (Table). Female patients with JIA had higher odds ratios than males for all mental and behavioral disorders except behavioral syndromes (F50-59), for which males with JIA had higher odds ratio.

Conclusion: The risk of psychiatric disorders in JIA patients is increased.

THU0543
LATENT TUBERCULOSIS INFECTION IN CHILDREN WITH PEDIATRIC RHEUMATOLOGIC DISEASES TREATED WITH CANAKINUMAB
Bhalan Makay1, Özge Altug Guçmen2, İker Çalıfaz1, Süleyman Nuri Bayram2, Nesliş Gülec3, İlker Devrim2, Dr. Behyet Uz Children’s Hospital, Department of Pediatric Rheumatology, İzmir, Turkey, 2Dr. Behyet Uz Children’s Hospital, Department of Pediatric Infectious Diseases, İzmir, Turkey

Background: Little is known about the long-term safety of canakinumab treatment (Table). In this study, we report the follow-up data of children with pediatric rheumatologic diseases treated with canakinumab (THU0543).

Disclosure of Interests: None declared

Objectives: To determine the incidence of latent tuberculosis infection and evaluate the follow-up protocol of the patients treated with canakinumab in a single pediatric rheumatology center from a TB-medium burden country.

Methods: The hospital charts of patients treated with canakinumab between 2012 and 2019 were retrospectively reviewed. The patients were screened for TB using tuberculin skin test (TST) and/or Quantiferon-TB Gold (QFT-G) test. They had no history of active TB prior to screening and no signs or symptoms of active TB. None of the patients had recent close contact with a person diagnosed as active TB. At initial evaluation, in patients who had never been given immunosuppressive therapy, TST ≥ 15 mm (if BCG vaccinated) and TST ≥ 10 mm (if BCG unvaccinated) were considered as positive. In the case of prior immunosuppressive drug use TST cut-off limit was accepted as 5 mm. Patients with either a positive TST or QFT-G result, in whom previous TB ruled out, were to receive appropriate treatment for latent TB one month prior to the first dose of canakinumab and continue throughout 9 months. Chest radiographs were performed prior to therapy and every 6 months. In case TST was anergic, both chest X-ray and TST were repeated after 3 months. Patients were evaluated for signs and symptoms of active TB by an infectious disease specialist every 3 months while on canakinumab therapy according to the guidelines of Ministry of Health for use of biologic agents\(^1\). The TST conversion was considered as a variation ≥ 5 mm between the two TSTs performed within an interval at least 3 months. If TB was suspected during the study, repeat TB testing (TST, QFT-G, and chest radiograph) was recommended.

Results: Twenty-six of 344 children had received a diagnosis of juvenile idiopathic arthritis, 1 TRAPS and 1 hyper Ig D syndrome patients were evaluated. The mean age at canakinumab onset was 12.4 ± 4.3 years (min: 2, max: 17 years). The average duration of canakinumab use was 2.3 ± 1.4 years (min: 1 max: 6.5 years). Among 37 patients, 5 patients had positive TST and one had positive QFT-G with normal chest X-ray prior to therapy. They were given isoniazid prophylaxis for latent TB. QFT-G was checked in 6 patients prior to canakinumab, 5 were negative. Seven patients had TST conversion during follow-up. Their chest X-rays were normal. None of them had active TB symptoms, such as; cough, fever, night sweats and weight loss. The mycobacterial cultures, mycobacterium tuberculosis PCR of induced sputum (via hypertonc saline nebulization) or morning gastric aspirates were negative in these patients. QFT-G was checked in 10 patients during follow-up and all were negative. None of the patients experienced active TB during follow-up.

Conclusion: To the best of our knowledge, this is the first study investigating the frequency of latent tuberculosis infection among patients treated with canakinumab. The results of this study suggest that although frequency of latent TB infection in children treated with canakinumab may not be low in a TB-medium burden country, canakinumab seems to be a safe treatment option in terms of active tuberculosis risk. Close follow-up of children on canakinumab treatment with respect to TB by the pediatric infectious disease department is important to prevent possible complications.

(CNO) in short term. Little is known about long-term outcome in CNO after IV-PAM.

Objectives: To describe a consecutive series of pediatric CNO (pCNO) patients who were prospectively followed after treatment with IV-PAM between 2003-2018 at a single center regarding: 1) The effect of IV-PAM on pain and Whole Body Magnetic Resonance Imaging (WBMRI) documented inflammation initially and after flare; 2) Relapse rate and; 3) Spinal CNO and 4) Urine N-telopeptide/creatinine ratio (UNtx/Cr) (a product of collagen I breakdown).

Methods: Patients: All consecutive pCNO patients <18 years at diagnosis, with WBMRI confirmed active disease who required IV-PAM between 2003-2018. IV-PAM: First dose 0.5 mg/kg; subsequent doses 1 mg/kg (maximum annual dose 11.5 mg/kg). IV-PAM was administered once monthly x 9. With confirmed flare IV-PAM was repeated (max 9 doses/year). Pain response: Visual analogue scale for pain (VAS) with “0” indicating no pain and “10” maximum pain was administered at baseline, at each IV-PAM treatment, and at suspected flare. Imaging: WBMRI before 1st IV-PAM, at 6 and 12 months, at suspected flare and after retreatment. CNO resolution was documented as complete (CR) if there was 95% improvement in the WBMRI signal. Spinal x-rays were performed at baseline and annually. UNtx/Cr was measured at baseline, after each IV-PAM and with suspected flare.

Results: 17 patients (9F, 8M) were included. The median [range] age at CNO diagnosis was 10.3[4-15] years, and at first IV-PAM 11.6[4-20] years. The median [range] follow-up was 9.2[1-15] years. Six patients had unifocal CNO, 4 had spinal CNO (2 with baseline vertebral fractures) and 6 had multifocal non-spinal CNO. VAS was uniformly 10/10 at baseline and decreased to 0-1/10 first month after IV-PAM. CR was achieved by all at 6 months, which persisted at 12 months. Four patients, 3 unifocal and one multifocal, had no further flares. Twelve patients had WBMRI confirmed flare at previously active sites at 9-36 months and 11 received 1-9 further doses of IV-PAM. With flare, VAS ranged from 4-9/10 and decreased to 0-3/10 within first month after re-initiation of IV-PAM. On final WBMRI, 12/17 (70%) had CR and 5/17 (30%) stable mild increased signal but no clinical symptoms. No further spinal compression fractures occurred. One patient required a third course of IV-PAM. Regarding UNtx/Cr, each patient had appropriate reduction after first IV-PAM. No patients flared while UNtx/Cr remained suppressed. Three patients developed arthritis and one acne. At last follow-up, 10/17 (59%) patients were on no medications, 4/17 (24%) required prn Naproxen for CNO and 3/17 (18%) were on Naproxen and/or disease modifying medications for arthritis.

Conclusion: Long-term follow-up of pCNO patients treated with IV-PAM confirms that while several patients eventually flare, the flares are less painful and have an excellent response to IV-PAM retreatment. No further spinal fractures occurred. No flares occurred while UNtx/Cr remained suppressed, suggesting a role of osteoclasts in CNO. Further prospective multicenter studies are now required to define the long-term clinical and imaging response to IV-PAM.

Disclosure of Interests: None declared

Methods: This was a retrospective study which looked at JIA patients who had been treated at the Children’s Hospital in Glasgow and had tibial or subtalar or midfoot involvement (TT, ST and MF respectively). 680 patients with JIA were identified from clinic lists from 2002 until 2018, inclusive. The clinic lists from 2008-2010 were inaccessible meaning that anyone who was seen exclusively within those two years has not been identified. Children with systemic arthritis were excluded. Of the 680 who were identified to have JIA; 123 have been found to have TT, ST or MF involvement. Of these; 104 were included in this study and the results of 19 patients were not available for analysis. For each of the 104 patients with ankle involvement their notes were reviewed and information about their JIA disease course was noted; specifically looking at any ankle involvement or potential risk factors for a adverse outcome. Poor ankle outcomes was defined as ankle arthritis having a significant impact on the child’s quality of life, persistently limited joint movement for more than 12 months or damage on imaging.

Results: Barriers to treatment was defined as anything which prevented a child from getting their medication as prescribed. Figure 1 shows the outcomes of children who had barriers to treatment compared to the children who did not. The difference between the two groups is stark with 67% of children who faced barriers to treatment having poor ankle outcomes compared to only 25% in the group which did not experience barriers to treatment. Furthermore, children with poor ankle outcomes are almost three times more likely to need surgery if they have experienced barriers to treatment compared to those who have not. This shows that children who experience barriers to treatment are more likely to have severe long-term damage to their ankle resulting in pain and limited functionality.

Figure 1: Outcomes in Children who experienced Barriers to Treatment

Abstract THU0546 – Figure 1

Five children declined any treatment at one point in their care against the advice of their healthcare team and of these five; four (80%) had severe ankle involvement with one requiring surgery and another's ankle auto-fused.

Conclusion: Experiencing barriers to treatment has been shown to increase the risk of poor ankle outcomes. Identified barriers to treatment ranged from concerns about adherence to needle phobias in addition to side effects and medication being with-held or taken incorrectly. This study demonstrates the need for further work to explore how these barriers can be effectively minimised.

THU0547
FIBRODYSPLASIA OSSIFICANS PROGRESSIVA IN PEDIATRIC RHEUMATOLOGY PRACTICE: LARGE SERIES EXPERIENCE OF THE SINGLE CENTER
Irina Nikishina, Alia Latypova, Maria Kaleda, Svetlana Arsenyeva, Dmitri Alexseev, Nizanov Research Institute of Rheumatology, Moscow, Russian Federation, Pediatric, Moscow, Russian Federation

Background: Fibrodysplasia Ossificans Progressiva (FOP), also known as a “second skeleton disease” is extremely rare (1: 2000000) and disabling genetic disorder, caused by mutation of ACVR1 gene, a bone morphogenetic protein receptor. Among medical specialties there are no certain, capable to provide not only diagnostics, but also all medical maintenance (assessment and monitoring of extent of damages, the differentiated drug treatment, rehabilitation, contact with adjacent experts). It would be reasonable if the rheumatologist carried out a role of the main attending physician for the patient with FOP. It seems to be a lot of similarities between rheumatic diseases, especially spondyloarthritids (SpA) and FOP in the pathophysiology, clinical manifestation and the therapy approach.

Objectives: to present the single-center experience of the FOP patients and to identify similar symptoms in FOP and rheumatic disease.

Methods: The analysis of the large series of patients with FOP, who observed in the rheumatologic clinic.

Results: Our single center experience includes 26 patients with FOP. All 26 patients (13 male and 13 female) had 3 basic FOP clinical manifestations. In 23 patients molecular-genetic tests were performed and typical mutation (Arginine 206) occurred in 22 cases and one had an extremely rare mutation (Glicine 328). 22 (85%) patients had common for FOP massive heterotopic ossifications. 3 of them had formed heterotopic ossification through the X-ray negative stage to visible changes. Among typical phenotypic stigmas were: great toe malformation; thumbs malformation; peripheral osteochondromas; cervical spine abnormalities. Majority of the cases presented some similarities to SpA manifestations: ankylosis of the apophysial joints and vertebral bodies mostly in cervical spine; X-ray/CT evidence of the sacroiliitis in all patients, who were examined (n=8). Because of severe body deformity or metal details after previous surgery intervention there were no possibility to perform MRI in most patients, but we confirm typical sacroiliitis with extended bone edema on MRI in 3 patients. Recurrent episodes of the large joints synoviitis were present in 5 patients. 4 patients demonstrated gradual formation of great toe ankylosis during the follow-up observation. The involution and decreasing of new FOP nodes associated with non-steroidal anti-inflammatory drug intake and/or glucocorticoids therapy were occurred in all patients.

Conclusion: Appearance of the similarities in FOP and SpA manifestation and the therapy approach could identify FOP as a potential rheumatic disease. Clinical observation of FOP patients could provide the important information for rheumatologist about insufficiently explored process of new bone formation.

THU0548
ASSOCIATIONS BETWEEN: MARKERS OF BONE TURNOVER AND RADIOLOGICAL FINDINGS IN CHILDREN DIAGNOSED WITH JUVENILE IDIOPATHIC ARTHRITIS
Marta Janicka-Szczepaniak, Krzysztof Orczyk, Elzbieta Smolewska, Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland

Background: Although many children attending pediatric rheumatology departments are diagnosed with low bone mineral density on the basis of clinical imaging, it is difficult to determine which patients have the higher risk of developing osteoporosis as the secondary disease. Recently performed studies involving rheumatological patients have proposed numerous serological indicators for better evaluation of the disease activity. These include markers of bone turnover, among others: bone alkaline phosphatase and osteoprotegerin (which are more specific for bone formation) and also beta isomerized carboxy terminal telopeptide of type I collagen, also known as Beta-Crosslaps (which is considered as an indicator of bone resorption).

Objectives: The main objective of the study was to evaluate the clinical usefulness of measuring serum concentrations of the selected markers of bone turnover in juvenile idiopathic arthritis (JIA) patients and assess their potential significance in prevention of osteoporosis in these children.

Methods: Study involved 59 children previously diagnosed with JIA (mean age at diagnosis: 9.0±4.3 years, mean age at study baseline: 12.7±3.9 years). All patients underwent Dual X-Ray Absorptiometry (DXA) examinations in order to assess bone mineral density. Wrist radiographs were also taken for evaluation according to the Steinbrocker classification. The presence of abnormalities in these tests was chosen as the criterion to divide patients into subgroups to perform group comparisons for the serum levels of markers of bone turnover: bone alkaline phosphatase, osteoprotegerin and Beta-Crosslaps.

Results: According to the Steinbrocker classification, 10 (16.9%) patients were staged as class I or higher. These children had significantly lower serum levels of bone alkaline phosphatase (p=0.0333) than patients with no radiological changes on wrist radiographs. The non-zero Steinbrocker subgroup had also lower Total Body Less Head Z-Score results (p=0.010) than the remaining patients. The DXA results, expressed as Total Body Less Head and Lumbar Spine Z-Score, disclosed low bone mineral density in 10 (16.9%) and 12 (20.3%) patients, respectively. There were no significant correlations between serum levels of markers of bone turnover and bone mineral density measurements. However, bone alkaline phosphatase and osteoprotegerin were negatively correlated with DXA muscle mass (p=0.359 p=0.040 for bone alkaline phosphatase, r=-0.372 p=0.0392 for osteoprotegerin). Similar correlation was found for bone alkaline phosphatase and DXA fat mass (r=-0.418 p<0.01).

Although Beta-Crosslaps appeared to be the only marker of bone turnover significantly (p=0.0410) associated with Juvenile Arthritis Disease Activity Score 27-Joint Count (JADAS27), it was independent from radiological findings involved in the analysis. However, serum levels of Beta-Crosslaps were higher in patients subsequently diagnosed with osteoporosis, than in those assessed in winter (p=0.064). Radiological findings were not season-variable.

Conclusion: Low serum concentration of bone alkaline phosphatase seems to be a risk factor for low bone mineral density and, by extension, for osteoporosis. Therefore it should be considered as an important laboratory test in JIA patients suspected of secondary osteoporosis. Clinical significance of osteoprotegerin and Beta-Crosslaps needs to be further investigated.

Disclosure of Interests: None declared

THU0549
SURGICAL MANAGEMENT IN JUVENILE IDIOPATHIC ARTHRITIS: A MONOCENTRIC EXPERIENCE OF 257 PROSTHESIS
Inne Pontiakal1, Carolina Artua2, Marco Di Marco3, Alessandro Sinelli2
1ASST Pini – CTO, Unit Of Pediatric Rheumatology-Department Of Rheumatology, Milan, Italy; 2ASST Pini – CTO, Unit Of Rheumatology, Milan, Italy; 3ASST Pini – CTO, Unit of Rheuma Surgery, Milan, Italy

Background: Juvenile idiopathic arthritis (JIA) includes all forms of inflammatory arthritis, with onset before the 16th birthday, lasting more than 6 weeks. Although conservative management with nonsteroidal anti-inflammatory drugs and disease-modifying antirheumatic drugs can be effective, a significant number of young adults affected by JIA requires a major surgical procedure, including different types of prosthetic devices.

Objectives: This article presents a monocentric experience of an interdisciplinary team of rheumatologists and orthopedic surgeons for JIA and the outcome of patients subjected to prosthesis implantation.

Methods: Data were collected through a retrospective analysis of 583 patients attending to our transitional care center for JIA between 1998 and 2018, in the context of a once-weekly rheumatologic counseling with the orthopedic surgeons. Descriptive statistics were used to evaluate the baseline and follow-up data.

Results: On a total of 257 prosthesis implantations, 137 were total hip prosthesis, 101 total knee prosthesis and 19 total ankle prosthesis. The 10-year implant survival rate was 97%, with good results in term of function and comfort for the patients. Complications were observed in 9% of
patients, including intraoperative fractures, periprosthetic joint infections and wound dehiscence. The majority of patients were treated with biologic therapy before surgery.

**Conclusion:** Prosthesis implantation in JIA patients is a complicated and difficult procedure, related to the management of the biologic therapy, the low quality of bone, the remarkable stiffness and deformity of the joints. Long-term results were good, even in patients with severe arthritis, showing drastic reduction of joint pain and an improvement of functionality. The risk of complications results to be modest compared to a great survival rate and a valid recovery of joint range of motion. The interdiscipli- nary team composed by rheumatologists and orthopedic surgeons for the all follow-up of these patients is a cornerstone to obtain the perfect schedule for prosthetic implantation.

**MYCOPHENOLATE MOFETIL (MMF) IN DEFINED AND UNDEFINED INTERFERONOPATHIES**

Carmela Gerarda Luana Raffaele, Gian Marco Moneta, Silvia Federici, Manuela Pardeo, Claudia Bracaglia, Fabrizio De Benedetti, Antonella Insalaco. IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy

**Background:** Type I interferonopathies are genetic disorders characterized by an up-regulation of type I interferon (IFN) activity. An increased expression of type I IFN regulated genes, IFN signature (IS), is described in these conditions. They are characterized by autoinflammation and varying degrees of autoimmunity or immunodeficiency. Some patients with a phenotype strongly suggestive for type I interferonopathy with a high IS, do not show any mutations in known type I interferonopathies related genes, being classified as undefined

**Objectives:** To evaluate the effect of mycophenolate mofetil (MMF) in patients with defined and undefined type I interferonopathy

**Methods:** 7 patients with type I interferonopathy followed at a Pediatric Rheumatology center, were included. Leucocyte (WBC) and platelet count, hemoglobin (Hb), CRP, ESR, serum amyloid A (SAA), autoantibodies, complement levels and IS, were assessed before and after 5-7 months of MMF treatment (600 mg/m² BID). IS was determined by qPCR (high scores >1.42).

**Results:** Patient 1 and 2 presented respectively with SAVI and Aicardi-Goutieres syndrome. The others were classified as undefined. In patient 1(table), treated with JAK1/2 inhibitor, MMF was followed by decrease of inflammatory markers and resolution of lung involvement; in patient 2 to an increase in Hb and normalization of inflammatory markers. Among patients with an undefined phenotype the addition of MMF to low dose prednisone led to complete resolution of inflammation. A reduction of the antinuclear antibodies titre was observed in patients 2, 3 and 7 and a normalization of complement level in patients 3, 4 and 7. Patient 5 had normal inflammatory markers already before the beginning of MMF possibly due to previously administered immunosuppressive treatment. Despite all patients presented a significant improvement of clinical picture after 5 months of MMF treatment, the IS decreased only in 4/7 patients while it remain stable or increased in the others

**Conclusion:** Our data suggest that mycophenolate mofetil might be an effective therapy in patients with type I interferonopathy leading to improvement of clinical and laboratory features thus allowing a glucocorticoid sparing

**VACCINATION COVERAGE IN FRENCH CHILDREN WITH AUTO-INFLAMMATORY DISEASES : PRELIMINARY DATA FROM THE JIRCOHORTE**

Virginie Rollet-Cohen1, Justine Miret1, Glöy Dingulu1,2, Andreas Wömer3, Marie-Alette Dommergues1, Véronique Hentgen1,2, Versailles Hospital, Department of General Pediatrics, Le Chesnay, France; 3University of Basel Children’s Hospital, Department of pediatrics, Basel, Switzerland

**Background:** Autoinflammatory diseases (AID) comprise a large number of rare diseases that manifest as recurrent sterile inflammation or disproportionate infection-induced inflammatory symptoms. Vaccine relation to AID is complex: on one hand the susceptibility to infections vary with the treatment options of the patient, on the other hand the disease activity may be triggered by vaccination. Nevertheless, effective immunization is crucial in this population. Up to know very little is known about vaccina- tion coverage in AID children.

**Objectives:** To determine vaccination coverage in French children with an autoinflammatory disease.

**Methods:** Patients between 2 and 18 years with autoinflammatory diseases followed at the French Reference Center for Auto-Inflammatory Diseases-Versailles Hospital and included to the Juvenile Inflammatory Rheumatism cohort (JIRcohort) network - an international multicenter prospective cohort for children with inflammatory and rheumatological diseases - were included in this retrospective monocentric observational study. Vaccination coverage of each disease and complete status of vaccination was assessed at the last out-patient visit, according to the national immunization program. Detail of every vaccine received (number of doses and date of administration) were collected by a pediatrician from written immunization record (vaccination card). Demographic data, disease and medications used since diagnosis were also assessed. Patients with no available immunization record were excluded.

**Results:** 128 patients met the inclusion criteria. Sex ratio was 1.2 (70/58). Median age at the last out-patient visit was 8.4 years (2.5-17.9 years). 53 children (41%) presented periodic fever with aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome, 30 familial mediterranean
fever, 29 unexplained autoinflammatory recurrent fevers, 8 TNF receptor associated periodic syndrome (TRAPS), 8 other autoinflammatory diseases. 68 patients (53%) were treated by on-demand corticosteroids, nine patients (7%) by biological agents, the other patients did not receive any immunosuppressive treatment. 

At the last clinic visit, only 49% (n=63) of our entire cohort had a complete vaccination status (human papilloma virus and tuberculosis excluded). Coverage rates were superior to 85% for diphtheria/tetanus/ poliomyelitis (89%), pertussis (95%), haemophilus influenza type B (94%) and measles/mumps/rubella (86%). 84% of the children were well-vacci- nated against pneumococcus. Lowest individual vaccination coverage rates were observed for hepatitis B at 77% and for meningococcus C at 77%. Only one girl received complete vaccination against human papilloma virus.

Conclusion: Vaccine coverage in children with autoinflammatory dis- eases appears suboptimal. Measures to optimize vaccination coverage in these children should be implemented.

THU0553 THE IMPACT OF BACKGROUND BIOLOGICAL THERAPY ON SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS-ASSOCIATED MACROPHAGE ACTIVATION SYNDROME: A SINGLE CENTER STUDY

Riccardo Russo1, Maria Katsikas2,3, Garrahan Pediatric Hospital, Immunology/ Rheumatology, Buenos Aires, Argentina; 2Garrahan Pediatric Hospital, Immunology/Rheumatology, Buenos Aires, Argentina

Background: Macrophage activation syndrome (MAS) is a severe compli- cation of Systemic juvenile idiopathic arthritis (SJIA). Biological therapy of SJIA may modify the clinical expression of MAS (1). Objectives: to assess and compare the clinical, biochemical, and haema- tolological features of SJIA-associated MAS in patients treated with biologic (B) or non-biologic (NB) agents.

Methods: retrospective analysis of data from dedicated medical records and databases. Inclusion criteria included: diagnosis of SJIA according to the ILAR criteria, diagnosis of MAS according to the expert’s opinion, and prescription of corresponding therapy. Patients were followed and treated at a tertiary center from 2006 to 2018. Demographical, clinical, haematological, biochemical and treatment-related features were recorded. The worst recorded values (e.g. highest ferritin levels) during each MAS episode were included for analysis. Outcomes (complete or partial recover- y, death) and fulfillment of current classification criteria (2) were also recorded. Comparisons between groups (patients developing MAS during B therapy vs. NB therapy) were performed by chi square or Wilcoxon rank sum tests.

Results: Twenty-four (14 F, 10 M) patients who developed 31 MAS epi- sodes were included. Age at SJIA onset 4 years, age at MAS onset 6 years; 10 episodes occurred during the initial (0-3 months) stage of SJIA course. Patients were receiving biological agents (canakinumab 4, tocilizumab 4, anakinra 1, etanercept 1) in 10 (32%) MAS episodes. Frequency of cardinal clinical features was similar in both groups. During MAS course, ferritin (1,408 vs 26,574 ng/mL, p < 0.001), LDH (922 vs 3308 IU/L, p = 0.04), SGOT (66.5 vs 389 IU/L, p = 0.02), and triglyceride levels (259 vs 352 IU/L, p = 0.03) were lower in B than in NB treated patients, while platelet count (215 vs 66 n/mL, p < 0.01), and hemoglobin (104 vs 79 g/dL, p < 0.01) were higher in the B than in the NB treated patients. No significant differences were found in GGT, fibronectin, SQPT levels or neutrophil count. Duration of admission during MAS tended to be longer in the NB treated group (31 days) than in the B group (16 days). Treatment of MAS included high dose steroids, cyclosporin, and/or biological agents. Five patients, all belonging to the B group (p < 0.001), did not fulfill current SJIA MAS classification criteria. There were 4 deaths recorded, all belonging to the NB group.

Conclusion: SJIA patients treated with biological agents exhibit similar clinical features than those treated with non-biologic therapy. However,
different haematological and biochemical variables are significantly milder in patients on biological therapy, which may limit the utility of classification criteria in this group. Assessment of these findings in larger cohorts is needed.

THU0554  THE CLINICAL UTILITY OF TWO VASCULITIS ACTIVITY SCORES(BVAS AND BDCF) IN BEHÇET’S SYNDROME: A PROSPECTIVE COHORT STUDY

Casandra Buzatu1,2, Stephen Duffield2, Laura Chadwick2,3, Robert J Moots2,3. 1Research Center of Rheumatic Diseases, Sf Maria Hospital, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; 2Liverpool Behçet’s Centre of Excellence, Liverpool, United Kingdom; 3Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, United Kingdom

Background: Behçet Disease(BD) is a rare chronic autoinflammatory condition that can lead to irreversible organ damage. The potential for multi-organ involvement and fluctuating activity highlights the need to perform a careful and systematic assessment of disease activity that is sensitive to change. Several disease activity tools have been used in both daily practice and clinical trials, yet the published data comparing the clinical utility of different tools in informing changes to therapy is needed.

Objectives: To compare the utility of two major activity scores: BD Current Activity Form (BDCF2006)1 and Birmingham Vasculitis Activity Score (BVAS)2 in predicting physician’s decision to adjust treatment (step-up/step-down) in patients with BD.

Methods: A 6-month prospective observational study was performed in a cohort of patients meeting the International Criteria for Behçet’s Disease (ICBD),at the National Centre for BD in Liverpool, UK. Participants were described for their demographics, clinical manifestations and treatment plan. BVAS and BDCF2006 activity scores were completed for each patient at evaluation. The outcome of interest was treatment change which was classified as ‘step-up’ or ‘step-down’, reflecting escalation or de-escalation in treatment (dosage adjustment or adding new immunosuppressant), respectively. We assessed the association between BVAS and BDCF scores and step-up/step-down treatment using Spearman rank correlation and multivariate logistic regressions, adjusting for gender, age and patient’s perception of disease activity on visual analogue scale (VAS), Odds ratios(OR) and 95% confidence intervals were calculated. Data analysis was conducted in Microsoft Excel, SPSS 2.0 and STATA.

Results: Ninety-five patients met inclusion criteria: 25 males (26.3%) and 70 females (73.7%) with a mean age at diagnosis of 32.7 years (±11.3 SD). HLAB1 was positive in 11/51 cases (11.6%). The most frequent clinical manifestations were oral ulcerations (100%), genital ulcerations (94.7%) followed by papulo-pustular skin lesions (37.8%) arthralgia (31.6%) and headache (30.5%). Mean BVAS score (range 0-6) was 2.14 (±1.8 SD) and mean BDCF score (range 0-8) was 3.04 (±1.72 SD). Both BVAS and BDCF correlated with decision to step-up treatment (r=0.752; r=0.370, respectively). Furthermore, BVAS was more strongly associated with decision to step-up treatment than BDCF (OR 4.25 95%CI 2.37 to 7.61; 1.51 95%CI 0.91 to 2.54). Adjusting for gender, a stronger association was observed in male participants across BVAS and BDCF scores (OR 5.89 95%CI 1.17 to 29.63; 3.48 95%CI 1.20 to 10.09, respectively). Following adjustment for patient’s perception of their disease (VAS), BVAS remained significantly associated with treatment step-up (OR 3.87 95%CI 2.08 to 7.19) but not BDCF (OR 1.30 95%CI 0.91 to 1.84).

Regarding different clinical manifestations, the BVAS mucocutaneous and ocular activity showed a significant odds ratio for step-up therapy (OR=5.78, CI 1.49-22.15; and OR-4.2 CI: 2.26-7.83).

Conclusion: BVAS can be a useful tool to assess BD activity. In this study, BVAS correlated better with clinical treatment decisions than BDCF, particularly in male participants. It also appears to be less influenced by patient’s subjective perception of disease activity, and therefore may be a more objective measure of BD activity.

THU0555 10 YEAR PROGNOSIS OF PATIENTS DIAGNOSED WITH FAMILIAL MEDITERRANEAN FEVER

Ruqiu Han Efevi, Asli Ece Soykut, Bilgesu Ergezen, Serdal Uguçu. University of Istanbul-Cerrahpasa, Istanbul, Turkey

Background: In Familial Mediterranean Fever (FMF), other than amyloidosis factors affecting mortality are being debated. In our previous study, we did not observe any atherosclerotic plaque formation in carotid or femoral artery. We thought that the risk of atherosclerosis did not increase in patients diagnosed with FMF.

Objectives: The aim of this study was to assess the 10 year prognosis and comorbidity of patients diagnosed with FMF who have been treated in our rheumatology clinic.

Methods: The sample group is a subset of 2009 study. In 2009, the patients who already had myocardial infarction or cancer diagnosis were excluded. The patients were interviewed with polar questions of whether they were diagnosed with acute myocardial infarction (AMI), cerebrovascular events, cancer, diabetes, and hypertension.

Results: We studied 71 patients (37 males, 34 females; mean age: 49.66±9.91) with FMF, and 59 patients (24 males, 35 females) in healthy control (HC) group. The gender and age difference between two groups was not found significant.

During 10 year follow-up, 8% of FMF patients had either a cardiovascular or cerebrovascular event comparing to 5% in HC (p=0.05). 3% of FMF patients had a cancer diagnosis comparing to 3% in HC (p=0.05). Even though diabetes mellitus diagnosis rate was higher in FMF patients (15% to 10%), results were still not significant (p=0.05). Hypertension diagnosis was 5% higher in FMF group (p=0.05)

Table. Prognostic Factors of FMF patients compared with Healthy Controls

<table>
<thead>
<tr>
<th></th>

ARTERIAL AND VENOUS THROMBOTIC EVENTS IN IGG4-RELATED DISEASE: A NATIONAL OBSERVATIONAL RETROSPECTIVE STUDY

Blindane Gutierrez1, Aurélie Grados2, Sylvain Patal1, Emmanuel Ribeiro2, Noémie Le Gouellec1, Julien Haroche1, Thomas Papo1, Jean-Robert Harlé1, Kim Ly Nicolas Schleinitz1, Mikael Ebbo3, GEFMA4 (French IgG4-Related Disease Study Group), 1Limosoge University Hospital, Internal Medicine, Limoges, France; 2CH de Niort, Internal Medicine, Niort, France; 3Hôpital Saint-André, Internal Medicine and Clinical Immunology, Bordeaux, France; 4CH de Valenciennes, Nephrology, Valenciennes, France; 5Sorbonne Université, AP-HP, Hôpital Pitéı́s-Salpétrière, Internal Medicine, Paris, France; 6Université Paris-Diderot, Internal Medicine, Hôpital Bichat, Paris, France; 7Hôpital de la Timone, AP-HM, Aix-Marseille Université, Internal Medicine, Marseille, France

Background: IgG4-related disease (IgG4-RD) is a fibro-inflammatory disorder that can affect virtually every organ. Although arterial involvements have been reported, no studies have examined the occurrence of arterial or venous thrombotic events in these patients.

Objectives: To explore the frequency, the characteristics, and risk factors of arterial and venous thrombotic events in IgG4-related disease patients.

Methods: An observational, descriptive, retrospective study was conducted from a multicentric national case registry for IgG4-RD. Patients fulfilled the Comprehensive Diagnostic Criteria (CDC) for IgG4-RD, and all patients with arterial or venous thrombotic events confirmed by imaging during follow-up were analyzed. Clinical, radiological, biological, histological and therapeutic characteristics were retrospectively collected using a standardized online data sheet. Results obtained in patients with thrombosis were compared to those without thrombosis.

Results: One hundred eighty-nine patients with IgG4-RD (135 men/54 women, median age 61 years) were included. During a 12-months median follow-up, one or more arterial thrombotic events occurred in 10 patients and venous thrombotic events in 16 (5.3 and 8.5 events/100 patient-years, respectively). Arterial complications (coronary artery disease n=5, lower limb peripheral arterial disease n=2, mesenteric ischemia, transient ischemic attack, and carotid thrombosis: n=1) occurred on average 30 months [0-140] after the first symptoms of IgG4-RD. They were in 2 patients without any cardiovascular risk factor, and associated with IgG4-RD arterial involvement in 3 (coronary aneurysms n=2, leg arteritis n=1). Among patients with arterial thrombosis, 60% had systemic involvement (>3 organs involved), 89% elevated serum IgG4 (> 3N in 56%), and 57% CRP >10 mg/l. Only 5/10 were treated with steroids at the time of arterial complication, and 4 had never been exposed to steroid therapy.

Conclusion: Arterial complications associated with the occurrence of an arterial thrombotic event (p = 0.03).

Venous thromboembolic complications (deep venous thrombosis (DVT) n=12, pulmonary embolism n=4) occurred on average 24 months [0-164] after the first symptoms of IgG4-RD, but were inaugural in 6 patients. Usual venous thrombosis risk factors were found in only 3/16. Seven patients had retroperitoneal fibrosis (RPF), 2 had mediastinal fibrosis, 60% had localized IgG4-RD (<2 organs involved), serum IgG4 level was normal in 67% and CRP <10 mg/l in 79%. Nine patients were on steroids at the time of venous thrombosis. RPF was more frequent in the group of IgG4-RD patients with a venous thrombotic event (p = 0.05), and largely associated with DVT in a multivariate analysis (OR=8.36 [2.25-35.90], p = 0.002).

THU0558

NERVE GROWTH FACTOR, SCLEROSTIN AND DKK-1 SERUM LEVELS IN COMPLEX REGIONAL PAIN SYNDROME (CRPS)-1: A PILOT STUDY ON 41 PATIENTS

Chiara Crott1, Maria Marana1, Francesca Zucchi1, Davide Gatti2, Maurizio Rossini2, Massimo Varenna1. 1ASST-Gaetano Pini-CTO, Division of Rheumatology, Milan, Italy; 2University of Verona, Department of Medicine, Rheumatology Unit, Verona, Italy

Background: Pain is the hallmark of Complex Regional Pain Syndrome (CRPS). Nerve growth factor (NGF), widely known as pain mediator, is increased in the affected skin and in tibia bone of rat models of CRPS, while is lowered by administration of anti-NGF antibodies. CRPS usually occurs after limb trauma or injury: significantly more often after limb fractures. Some reports considered bone as a main player in CRPS pathogenesis, hypothesizing that sclerostin (SOST) and Dickkopf-related protein-1 (DKK-1) may be involved in CRPS pathogenesis.

Objectives: To evaluate NGF, SOST, and DKK-1 serum levels from affected arm of CRPS patients and compare them with unaffected one and healthy controls (HCs).

Methods: Adults patients affected by CRPS diagnosed according to IASP criteria at upper limb were consecutively enrolled from April 2017 to August 2018. Patients with prior treatment with bisphosphonates, and history of disorders of mineral metabolism were excluded. Sera from the basilica vein of affected and unaffected arm of CRPS patients were collected, as well as sera from HCs paired for age and sex. NGF, SOST, and DKK-1 concentrations were determined by ELISA kit. Comparisons between patients and HCs were performed by Student test, while comparison between affected and unaffected arms were performed with Wilcoxon test for paired data. Pearson correlation was used to correlate NGF, SOST, and DKK-1 levels with demographic and clinical variables.

Results: The overall population included 41 patients: males (M) 21.9%, mean age at diagnosis [± standard deviation, SD] 61.9±8.4 yrs, mean disease duration 67 days (inter quartile range (IQR) 14.0; 22.5), 39 (95.2%) experienced a fracture as an inciting event, mean VAS pain score (0-100) 54.8±18.6 mm. Mean NGF levels (pg/ml) were 12.0±2.8 and 11.4±3.5 in the affected and unaffected side, respectively, and 13.5±5.5 in HCs. NGF was undetectable in most patients; no statistical significant differences of NGF levels were found between patients and HCs. Mean SOST levels (pmol/L) were 32.6±16.1, 29.8±17.7, and 34.0±13.3 in affected, unaffected arm, and in HCs, respectively. No statistical significantly differences of SOST levels were found between patients and HCs, while a significant difference was found between affected and unaffected arms (p=0.03). Mean DKK-1 levels (pmol/L) were higher in affected arm (31.2±22.9) than in unaffected one (29.3±28.6) or in HCs (27.5±18.2) without reaching statistical significance. NGF was significantly correlated with VAS pain score (p=0.04).

Conclusion: To our best knowledge, this is the first study to evaluate NGF, SOST, and DKK-1 levels in adults affected by CRPS-1. SOST levels were significantly higher in affected arms compared to unaffected ones, suggesting a possible role of this bone mediator in CRPS pathogenesis. NGF was consistent with the expression of pain, trough VAS pain score. Further studies need to clarify these preliminary findings.

comparisons. To establish the relationship between its value and the AOSD-related mortality.

Methods: Retrospective study realized in two University Hospitals. Clinical, laboratory, AOSD-related complications data, administered biologic treatments and number of deaths (AOSD related or not) were recorded. Each patient was characterized for the presence of AOSD-related complications such as macrophage activation syndrome (MAS), myocardiitis, lung involvement (pulmonary hypertension, interstitial infiltrate), renal involvement (tubulointerstitial nephritis, acute renal failure), secondary amyloidosis and AOSD-related death. SSS was applied at the onset of the disease development, assigning a point to each of the next 12 variables: fever, exanthema, pleuritis, pneumonitis, pericarditis, alteration of liver tests or hepatomegaly, splenomegaly, lymphadenopathy, odynophagia, leukocytosis >15,000/mm³, myalgia and abdominal pain. A > 7 score has been validated on other populations as the one which identifies the patients with high risk of complications. The relationship between SSS value and the next parameters was determined: clinical course, complications, biologic treatments administered and AOSD-related mortality.

Results: Data from 64 patients was analyzed (40,6% men, mean age 37 years). SSS values of < 7 were obtained in 50 patients (78,3%) and of ≥ 7 in 14 patients (21,7%). MAS and renal involvement were significantly related with a score of ≥ 7 (Table 1). Lung involvement, myocardiitis and secondary amyloidosis were not significantly associated with a high SSS value. Even so, analyzing each case, it was found that individually they had a score of ≥7 (except for lung involvement). Biologic treatment requirement along the disease course was related to SSS ≥7. Moreover, SSS value was not related to the different clinical patterns or the not-related-AOSD deaths. It was not possible to determine the relationship between the score and the AOSD complications-related deaths due to having only two registered cases. Despite this, it was found that individually both had a SSS of ≥7.

Conclusion: The prognosis score described by Pouchot et al could be useful to identify those patients with high risk of developing clinical complications and those who will need biologic treatment along the course of their disease. It is necessary a higher number of patients to determine if the score could be useful to estimate the death risk related to AOSD complications.

THU0559 PSYCHOLOGICAL EFFECTS OF A BEHÇET’S DIAGNOSIS ON DISEASE ACTIVITY PERCEPTION– A PROSPECTIVE OBSERVATIONAL STUDY

Casandra Buzatu 1,2, Hannah Nicholson 2, Roisin Cunningham 3,4, Robert J Moots 3,4, Liverpool Behçet’s Centre of Excellence, Liverpool, United Kingdom; University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; University of Liverpool, Liverpool, United Kingdom; Institute of Ageing and Chronic Disease, Liverpool, United Kingdom

Background: There is a pressing need to understand more about the psychological experience in patients with Behçet’s Disease (BD). The presence of poor wellbeing, low mood and anxiety may affect the ability to both manage and cope with this complex disorder and also impact upon the perception and experience of disease activity1,2,3.

Objectives: Our aim was to investigate the relationship between patient rating of disease activity and their psychological experience (anxiety, low mood, illness perception and coping style) in a UK Centre of Excellence for BD.

Methods: This study had full UK research ethics approval. A 12-month prospective observational study of a cohort of patients diagnosed with BD according to the International Criteria for BD(ICBD) under surveillance in the BD Centre of Excellence Liverpool, UK. All patients that agreed to a psychological evaluation were included. Participants were described for demographics and clinical presentation. BD Current Activity Form 2006 and a clinician’s and patient’s visual analogue scale (VAS) were recorded. Participants completed validated self-reported measures: Brief COPE, IPO-R, PHQ-9, GAD-7 and WEMWBS. Spearman Rank correlations, multivariate regression analysis and mediation analysis were used to investigate the relationship between patient perception of disease activity, coping mechanisms and mood. For data analysis Excel and SPSS were used.

Results: 86 patients were selected (24 males, 68 females; mean age at time of evaluation 43.58 years ±11.8 SD; mean disease duration 9.76 years ±10.01). The correlation between Clinician’s BAS and Patient’s VAS was strong 0.754 (p<0.005). Strong correlations were also observed between Patient’s VAS and low mood (PHQ-9) r=0.533 (p<0.005), anxiety (GAD-7) r=0.433(p<0.05), illness perception- emotional representation (IPO-R) r=0.377 p<0.05 and emotion-focused coping (COPE) r=0.320 (p<0.05).

The results of the mediation analysis indicated that patient’s perception of disease activity was a significant predictor for Dysfunctional Coping Strategies (b=1.5.5e+0.57, p<0.05). Dysfunctional Coping Strategies had a mediating impact on the relationship between patient perception of disease activity (VAS) and mood 0.645(CE: 0.68±1.389).

Conclusion: Psychological experience plays an important part in the patient evaluation and experience of disease activity. Patient coping strategies and psychological representation of illness experience influence their perception of disease activity and their mood. This highlights the need for patients for psychological support and for improving coping mechanisms in order to obtain a better disease control and a higher quality of life.

Disclosure of Interests: Casandra Buzatu: None declared, Hannah Nicholson: None declared, Roisin Cunningham: None declared, Robert J Moots: Grant/research support from: Biogen, Bristol-Myers Squibb, Chugai, Novartis, Pfizer Inc, Roche, Sandoz, and UCB, Consultant for: Biogen, Bristol-Myers Squibb, Chugai, Novartis, Pfizer Inc, Roche, Sandoz, and UCB, Speakers bureau: Biogen, Bristol-Myers Squibb, Chugai, Novartis, Pfizer Inc, Roche, Sandoz, and UCB

Background: IgG4-related ophthalmic disease (IgG4-ROD) may present as a cause of orbital myositis leading to proptosis and diplopia. This clinical scenario can be mistakenly diagnosed as Graves' orbitopathy (GO), preventing a timely and adequate treatment.

Objectives: To elucidate if there are specific radiological features that might differentiate between IgG4-ROD and GO by imaging.

Methods: We included 19 patients with diagnosis of IgG4-related disease (IgG4-RD) according to the Comprehensive Diagnostic Criteria for IgG4-RD, who regularly attended a tertiary referral center in Mexico City. All the patients had ophthalmic involvement and available computed tomography (CT) and/or magnetic resonance imaging (MRI) of the orbits. The patients had ophthalmic involvement and available computed tomography (CT) and/or MRI of the orbits. Imaging studies were evaluated by a blinded head and neck radiologist for the following features: exophthalmos, extraocular muscles (EOM) size and morphology, lacrimal gland enlargement, orbital fat involvement, stretching of the optic nerve (ON), ON sheath thickening and orbital bone changes.

Results: Both groups were similar in age (49.1±15.8 vs. 51.6±14.7, p=0.58) and gender (men 58.9% vs. 40.6%, p=0.23). In addition to ophthalmic involvement, 18 (94.7%) IgG4-RD patients had extra-ocular involvement with a median number of organs involved of 7 (1-12), mainly submandibular glands (73.7%), lymph nodes (68.4%), parotid glands (63.2%) and pancreas (47.4%). Three patients were misdiagnosed as GO before IgG4-RD diagnosis. Graves’ disease was the underlying thyroid disorder in 28 (87.5%) GO patients. Hashimoto’s thyroiditis in 2 (6.3%), papillary thyroid carcinoma in 2 (3.1%) and one patient was euthyroid with positive thyroid stimulating immunoglobulin. The prevalence of EOM and orbital fat involvement was protective (OR 0.05, 95% CI 0.005-0.61, p=0.001) and a tendency for the lateral rectus to be the most frequently involved EOM (22.2% vs. 0%, p=0.07); conversely they had a lower prevalence for the inferior rectus to be the most frequently involved EOM, (33.3% vs. 72.7%, p=0.04), orbital fat involvement (47.4% vs. 81.3%, p=0.01), ON stretching (57.9% vs. 87.5%, p=0.02) and orbital bone changes (0% vs. 25%, p=0.02), EOM bellies were involved in all the IgG4-ROD and GO cases, whereas EOM tendon involvement was present in 9% of GO and in none of the IgG4-RD group. Patients with IgG4-RD had more frequently the combination of lacrimal gland and lateral rectus (31.6% vs. 3.1%, p=0.008) and less frequently the combination EOM and orbital fat involvement (21.2% vs. 59.4%, p=0.008).

At the logistic regression analysis we found an association of lacrimal gland involvement (OR 64.4, 95% CI 6.8-609.5, p=0.001) with IgG4-RD. In a second model including combined variables, the combination of lacrimal gland and lateral rectus involvement was associated with IgG4-RD (OR 62.5, 95% CI 3.31-1000, P=0.006), whereas the presence of EOM and orbital fat involvement was protective (OR 0.06, 95% CI 0.006-0.48, p=0.009).

Conclusion: Imaging features may reliably differentiate between IgG4-ROD and GO. The presence of both lacrimal gland and lateral rectus enlargement must alert clinicians to consider IgG4-RD diagnosis.

REFERENCES:
Familial Mediterranean Fever (FMF) is the most frequent auto-inflammatory disease characterized by recurrent, self-limiting attacks of fever, peritonitis, pleuritis, synovitis, myalgia, and erysipelas-like erythema (ELE). Attacks have a robust inflammatory response which completely normalizes when attacks subside. However, substantial number of FMF patients possess chronic persistent inflammation even in between attacks. Clinical significance of persistent inflammation and its contribution to damage accrual are yet to be determined.

**Objectives:** We aimed to determine the prevalence and underlying factors of chronic persistent inflammation and its association with the domains of Auto-inflammatory disease damage index (ADDI) in a large cross-sectional multicenter cohort.

**Methods:** All patients recruited from FMF in Central Anatolia (FICA) cohort, which is a duplication disabled, internal and externally controlled, cross-sectional, multicenter accessible web-based cohort. Demographic data, disease characteristic, attack features (ever presented) were meticulously questioned. Genotype data (if available) and laboratory features including inflammatory markers were recorded. FMF related damage scores was assessed by auto-inflammatory disease damage index (ADDI), which is recently validated. Patients were stratified according to their antecedent acute phase responses as having persistent inflammation (PI group) or not, both groups compared in terms of disease characteristics, attack features, inflammatory comorbidities and damage domains.

**Results:** Study is comprised 970 adult patients (mean age 35.3±12.1, 61% female). 54 of them were excluded for their first inclusion. 15% of patients had persistent inflammation. PI group had significantly younger age of diagnosis, male dominance, homozygous M694V, more frequent attacks it the last year, more pleuritis, arthritis, myalgia and ELE and more severe disease according to ISSF than other patients (Table-1). Moreover, colchicine resistance and ADDI damage scores were remarkably higher in PI group.

In multi-variate analyzes colchicine resistance OR=2.71 [95%CI 1.38-5.33], ISSF OR=11.06 [95%CI 5.23-23.39], male gender OR= 2.38 [95%CI 1.51-3.76], homozygous M694V mutation OR= 2.31 [95%CI 1.41-3.78] and ELE OR= 1.72 [95%CI 1.04-2.857] found as independent predictors of persistent inflammation. PI group had more damage in multiple domains like joint restriction, musculoskeletal pain, proteinuria, amyloidosis, renal insufficiency and developmental delay. Same variables and persistent inflammation further analyzed in in terms of predicting the damage. Persistent inflammation found to be an independent predictor of proteinuria OR=2.02 [95%CI 1.05-3.90], amyloidosis OR=2.71 [95%CI 1.34-5.48], and renal insufficiency OR=4.36 [95%CI 1.84-10.32].

**Conclusion:** Persistent inflammation is relatively common in FMF patients particularly in those harboring M694V homozygous mutation and is associated with major complications of disease indicating poor prognosis.

COMPARISON BETWEEN PATIENTS WITH IDIOPATHIC PULMONARY FIBROSIS AND INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES: A PROSPECTIVE COHORT

Gianluca Sambataro1,2, Domenico Sambataro2,3, Sebastiano Emanuele Torrisi1, Vancheri Ada1, Mauro Pavone1, Francesca Pignataro4, Nicoletta Del Papa5, Stefano Palmucci6, Carlo Vanchieri1, Lorenzo Malatino3, 1Teaching Hospital – Vittorio Emanuele II, 2Teaching Hospital – Policlinico, Catania, Italy, 3Department of Medical Surgical Sciences – Cannizzaro, 4Day Hospital of Rheumatology, 5Hospital “G. Pini” – CTO, Department of Rheumatology, Milan, Italy, 6Teaching Hospital – Policlinico, Catania, Italy

Background: The term “Interstitial Pneumonia with Autoimmune Features (IPAF)” is used to describe patients with Interstitial Lung Disease in combination to clinical, serological and/or pulmonary features that are suggestive, but insufficient to satisfy classification criteria of a specific Connective Tissue Disease (CTD). Some retrospective studies available in literature described patient cohorts with IPAF heterogeneous in terms of clinical, serological, and radiographic manifestations.

Objectives: To prospectively recruit a cohort of consecutive ILD patients classified as IPAF or as affected by Idiopathic Pulmonary Fibrosis (IPF); to describe their clinical, serological, and radiological features by a multidisciplinary team composed by Pulmonologists, Radiologists, and Rheumatologists, comparing IPAF and IPF patients.

Methods: In the lasts 2 years, they were enrolled 45 patients with IPAF and 143 with IPF among a total of 506 patients with Interstitial Lung Disease (ILD). All patients were evaluated clinically by both rheumatologists and pulmonologists, also by means of chest high resolution computed tomography (hrCT), pulmonary function tests (PFT), and nailfold videocapillaroscopy.

Results: In IPAF cohort the most common characteristics from the clinical, serological and morphological domain were Raynaud’s phenomenon (31.1%), antinuclear antibodies positivity with titre ≥1:320 or any titre for centromeric or nucleolar pattern (17.7%) and nonspecific interstitial pneumonia (88.8%) respectively. The majority of patient (89.8%) had the minimum of 2 criteria at the recruitment. Female gender was more common in IPAF compared to IPF (62.2% vs 23%, p<0.0001) and the mean age of onset was lower in patient with IPAF (66 vs 73, p <0.0001). HRCT results positive in 2 patients, both without RP. Patients with IPAF showed better performances in PFT than patients with IPF than those with IPF (mean forced vital capacity 83% vs 74%, p =0.01; mean diffusing lung capacity for carbon monoxide 64% vs. 52%, p=0.01). Patients with IPAF less commonly than patients with IPF needed oxygen therapy (44.4% vs 77.6%, p <0.0001) and more commonly showed at frCT NSIP (68.8% vs 6.9%, p <0.0001) than UIP pattern (0% vs 86%, p <0.0001).

Conclusion: IPAF criteria recruit a rare cohort of patients with a disease probably less severe than IPF, even though clinically relevant. Further prospective studies may better define the long-term prognosis of ILD in IPAF. The follow-up of these patients by a multi-disciplinary team may be useful in order to early recognize and treat the new cases of CTD. IPAF classification can recruit incomplete form or early onset of CTD that can allow a timely treatment in patients without a structured damage.

THU0564

COULD A PROBABLISTIC REASONING AI ACCELERATE RARE DISEASE DIAGNOSIS? EVALUATING THE POTENTIAL IMPACT OF A DIAGNOSTIC DECISION SUPPORT SYSTEM IN A RETROSPECTIVE STUDY

Simon Ronke1,2, Martin C. Hirsch2, Ewelina Türk2, Katharina Larirov1, Daphne Tientcheu1, Annette D. Wagner1, 1Outpatient clinic for rare inflammatory systemic diseases, Department of Nephrology, Hannover Medical School, Hannover, Germany; 2Ada Health GmbH, Berlin, Germany

Background: The diagnosis of rare diseases is often delayed by years [1]. The main factor for this delay is believed to be the lack of knowledge and awareness regarding rare diseases [2]. Probabilistic diagnostic decision support systems (DDSS) have the potential to accelerate rare disease diagnosis by highlighting differential diagnoses for physicians [3, 4]. DDSS’s are based on case input and incorporated medical knowledge.

Objectives: We examine a probabilistic DDSS prototype and assess its potential to provide accurate rare disease suggestions early in the course of rare disease cases.

Methods: Retrospectively, information from the medical records of 93 patients was transferred to the DDSS. Each of these patients had a confirmed rare inflammatory systemic disease. The accuracy of the DDSS disease suggestions was assessed for all documented visits over time. Time to correct top fit (TF) and top five fit (TSF) disease suggestion was assessed, as was the original time to clinical diagnosis (TD), TD/TD as well as TSF/TD were calculated to allow for comparison of TF respective TSF normalized to TD. Wilcoxon signed-rank test was conducted for TD-TF and TD-TSF.

Results: The DDSS suggested the correct disease at a time earlier than the time of clinical diagnosis among the top five fit disease suggestions in 53.8% of cases (50 of 93), and as the top fit disease suggestion in 37.6% of cases (35 of 93). Median advantage of correct disease suggestions compared to the time point of clinical diagnosis was 3 months or 50% for top fit respective 1 month or 21% for top fit. The correct diagnosis was suggested at the first documented patient visit among the top five fit disease suggestions in 33.3% (top five fit), respective 16.1% of cases (top fit). Wilcoxon signed-rank test shows a significant difference between the time to clinical diagnosis and the time to correct disease suggestion for both top five fit and top fit (z-score -6.68, respectively -5.71, p<0.05, p-value <0.001). The DDSS suggested the correct rare disease at the time of diagnosis in 89% of cases (83 of 93)

Conclusion: The DDSS was capable of providing accurate rare disease suggestions in most of the rare disease cases. In many cases it provided correct rare disease suggestions early in the course of the disease, sometimes in the very beginning of a patient’s journey. The interpretation of these results suggests that DDSS’s have the potential to highlight the possibility of a rare disease to physicians early in the course of a case. Limitations of this study derive from its retrospective and unblinded design, data input by a single user, and the optimization of the knowledge base during the course of the study. Whether the use of this DDSS leads to a reduced time to rare disease diagnosis in a clinical setting should be validated in prospective studies.
To describe the follow-up results of patients investigated for FUO and had a certain diagnosis.

**Objectives:**
To describe the follow-up results of patients investigated for FUO and had a certain diagnosis.

**Methods:**
Data from patients who admitted to Hacettepe University Hospitals, inpatients sections of the internal medicine with the complaint of FUO collected prospectively from January 2015 to October 2017. Patients with an uncertain diagnosis after all diagnostic procedures were excluded. Patients were divided into 3 main subgroups: rheumatologic (n=49, 46.2%), infectious (n=28, 26.4%) and malignant (n=29, 27.4%) groups. We compared Kaplan-Meier curves for all diagnosis-to-death time frames with the standart log-rank test. $p<0.05$ was considered as statistically significant.

**Results:**
Total 106 patients were included, 58 (55%) of them were female. Median age was 48 (18-81) years. Patients were also divided into three subgroups: rheumatologic, infectious and malignant groups. We compared Kaplan-Meier curves for all diagnosis-to-death time frames with the standart log-rank test. $p<0.05$ was considered as statistically significant.

**Discussion of Interests:**

**THU0565**

**COMPARISON OF SURVIVAL RATES AMONG SUBGROUPS OF PATIENTS EVALUATED FOR FEVER OF UNKNOWN ORIGIN**

**Hacettepe University Medical School Internal Medicine, Rheumatology, Ankara, Turkey**

**Background:** Fever of unknown origin (FUO) is one of the most challenging clinical situations. Although several studies showed a relatively benign course of patients remained undiagnosed, long-term outcome of patients with a certain diagnosis remain non-established (1).

**Objectives:** To describe the follow-up results of patients investigated for FUO and had a certain diagnosis.

**Methods:** Data from patients who admitted to Hacettepe University Hospitals, inpatients sections of the internal medicine with the complaint of FUO collected prospectively from January 2015 to October 2017. Patients with an uncertain diagnosis after all diagnostic procedures were excluded. Patients were divided into 3 main subgroups: rheumatologic, infectious and malignant groups. We compared Kaplan-Meier curves for all diagnosis-to-death time frames with the standart log-rank test. $p<0.05$ was considered as statistically significant.

**Results:**
Total 106 patients were included, 58 (55%) of them were female. Median age was 48 (18-81) years. Patients were also divided into three subgroups: rheumatologic (n=49, 46.2%), infectious (n=28, 26.4%) and malignant (n=29, 27.4%) groups. We compared Kaplan-Meier curves for all diagnosis-to-death time frames with the standart log-rank test. $p<0.05$ was considered as statistically significant.

**Conclusion:** Among patients evaluated for FUO, survival rate was higher in patients who had a rheumatological diagnosis. Further diagnostic algorithms are needed to identify these subgroups, because of the higher mortality among INF and MLG groups.

**THU0566**

**OCULAR FEATURES IN 381 PATIENTS WITH SYSTEMIC SARCOIDOSIS AND ITS CORRELATION WITH THE IWOS CRITERIA. STUDY IN A UNIVERSITY HOSPITAL**

Belén Atienza-Mateo, José Luis Martín-Varillas, Rosalia Demetrio-Pable, Vanesa Calvo-Rio, Raúl Fernández Ramón, D. Prieto-Peña, Monica Calderón-Goerreke, Lara Sánchez Bilbao, Iñigo González-Mazón, Miguel A. González-Gay, Ricardo Blanco. Hospital Universitario Marqués de Valdecilla, Rheumatology and Ophthalmology. Santander, Spain

**Background:** Sarcoïdosis is a multisystemic inflammatory disease characterised by non-caseating epitheloid granulomas that can affect any organ system. The three most frequency affected organs are lung, skin and eyes. Ocular involvement is the presenting symptom in approximately 20-30% and can involve any part of the eye and its aneal tissues. Sarcoïdosis may cause uveitis, conjunctivitis, episcleritis/scleritis, optical nerve disease and orbital inflammation.

**Objectives:** To analyze the prevalence of ocular involvement is systemic sarcoïdosis, the clinical patterns and their correlation with the International Workshop on Ocular Sarcoïdosis (iWOS) criteria. These criteria classify ocular sarcoïdosis as definite, presumed, probable and possible, according to some ophthalmological and analytical findings. They are especially useful if a biopsy is not obtained or it is negative.

**Methods:** Retrospective study of patients admitted to a single reference University Hospital between 1999 and 2019 with diagnosis of sarcoïdosis. Clinical findings, demographics features, anatomic location and iWOS intraocular signs were recorded. We also collected serum angiotensin
converting enzyme (ACE), liver enzyme test, chest radiography, chest computed tomography scan, treatment and biopsy if performed.

| TABLE: Demographic and clinical features of the 50 patients with ocular sarcoidosis. |
|---------------------------------|---------------------------------|
| **Patients (n=50)**              | **Patients (n=50)**              |
| **Ages, median (SD) years**      | 45.6 (16.7)                      |
| **Sex, n(%)**                    | Male, 32 (64)                    |
| **Affected organs, n (%)**       | Lung 30 (60), Skin 14 (28), Liver 4 (8), Kidney 3 (6), Musculoskeletal system 3 (6), Central nervous system 3 (6), Heart 2 (4) |
| **Ocular signs, n (%)**          | Bilaterality 22 (44), Snowball/tangle of pears 19 (38), Multifocal/retinal 15 (30), Multiple choroidal peripheral lesions 7 (14), Periphlebitis 5 (10), Anterior synchiae 1 (2), Uveitis disc granulomas 1 (2) |
| **IOWS criteria, n (%)**         | Definite 22 (44), Presumed 13 (26), Possible 4 (8) |

**Abbreviations:** ADA: adalimumab; AZA: azathioprine; CoA: cyclosporine A; GLM, glabelumab; IFX, infliximab; IS, immunosuppressors; KPs, keratic precipitates; MMF, mycophenolate mofetil; MTX, methotrexate; SD, standard deviation.

Results: We selected patients with ocular inflammation from a cohort of 381 patients with sarcoidosis (n=50, 13%). Most of the cases were women (54%) and median age was 45.5±16.7 years. In these 50 cases, the most affected organ was lung (60%), followed by skin (28%). Forty patients had uveitis, 32 of them with ocular symptoms. Thirty-nine out of 50 patients (78%) met one of the 4 IOWS diagnostic categories: 22 with definite (44%), 13 presumed (26%) and 4 with possible (8%) sarcoidosis. Eleven patients did not meet IOWS criteria. The most common ocular signs were bilaterality (44%), snowball or strings of pears (38%), mutton-fat KPs (24%), multiple choroidal peripheral lesions (14%) and periphlebitis (10%). The median value of ACE was 69 U/l. Forty-four patients (88%) received oral corticosteroids, 21 (42%) received methotrexate, 11 (22%) received another conventional immunosuppressor and 11 (22%) a biological treatment. TABLE shows demographic and clinical features.

Conclusion: In our population the IOWS Criteria had a sensitivity of 78%. Even though there is no gold standard for diagnosing ocular sarcoidosis yet, IOWS signs can help clinicians suspect it.

**THU0567 POLYMYALGIA RHEUMATICA-LIKE SYNDROME FROM CHECKPOINT INHIBITOR THERAPY: CASE SERIES AND SYSTEMATIC REVIEW OF THE LITERATURE**

cassandra calabrese1, Laura Cappelli2, Marie Kostine3, Elizabeth Kirchner1, Tawnie Braaten2, Leonard Calabrese1, Cleveland Clinic Foundation, Rheumatic and Immunologic Disease, Cleveland, United States of America; 2Johns Hopkins University, Rheumatology, Baltimore, United States of America; 3Centre Hospitalier Universitaire de Bordeaux, Rheumatology, Bordeaux, France

**Background:** Checkpoint inhibitor therapy has caused a paradigm shift in the field of oncology, producing significant survival benefits in patients with an ever-growing list of malignancies, but their use is attended by a spectrum of immune related adverse events (irAEs). Many rheumatic irAEs have been described. A critical and presently unanswered question is what proportion of these rheumatic irAEs represent appearances of classic rheumatic diseases or, alternatively, represent new clinical variants with potentially different pathogenesis, clinical course and treatment responsiveness. Little is known about the PMR-like entity that has been described in the setting of ICI therapy.

**Objectives:** To assess whether the polymyalgia rheumatica (PMR)-like syndrome reported as an irAE from checkpoint inhibitor therapy is consistent with the 2012 EULAR/ACR provisional criteria for PMR1.

**Methods:** The cases were derived from two sources. Group 1 represents reported cases from three contributing centers. Group 2 was derived from a systematic review of the literature searching for all cases reported as PMR or PMR-like illness associated with checkpoint inhibitor therapy. Cases were assessed for the quality of reporting and then analyzed to determine whether they fulfilled the 2012 EULAR/ACR provisional criteria for PMR.

**Results:** A total of 49 patients were included for analysis, including 9 cases from Cleveland Clinic (Table 1), 4 cases from Johns Hopkins University, and 7 cases from University Hospital of Bordeaux, in addition to the 29 separate cases found by systematic review. Among the entire group, 37 (75%) were designated “complete” indicating that they had sufficient data to reliably apply the 2012 EULAR/ACR criteria of which 28 (75%) cases fulfilled complete criteria for PMR. A number of cases also demonstrated some clinical features unusual for idiopathic PMR.

**Conclusion:** This study suggests a high proportion of reported cases of checkpoint inhibitor-related PMR fulfill preliminary criteria for PMR yet in one quarter clinical details were incomplete making verification problematic. Furthermore, in the absence of a gold standard for the diagnosis of PMR, the relationship of checkpoint inhibitor-related PMR to the idiopathic form remains unclear.

**THU0568 CLINICAL CHARACTERISTICS OF SEVEN RELAPSING POLYCHONDritis CASES MISDIAGNOSED AS ARTHRITIS**

Xiaoyu Cao, Ji-Liang Zhao, Dona Xu, Yong Hou, Xiaofeng Zeng, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Graduate School of Peking Union Medical College, Beijing, China

**Background:** Relapsing polychondritis (RPC) is a rare autoimmune disease. It mainly affects the tissue abundant of cartilage, such as ear, nose, and tracheoles. The multiple systems including eye, joint, mucocutaneous, and kidney could be involved. As the presentation of arthritis was nonspecific and could appear in several connective tissue diseases,
it was easily misdiagnosed. The delay in establishing the diagnosis of RPC was common. A survey from the United Kingdom found a median length of 1.9 years from the first disease attack to diagnosis\(^2\). One recent research reported 64% of RPC patients had a diagnostic delay with more than five years\(^3\).

**Objectives:** We made a retrospective study to explore distinct characteristics of relapsing polychondritis with arthritis as the first attack. By comprehending the nature of disease fully, misdiagnosis at the early phase of illness could be avoided.

**Methods:** The clinical features and prognosis of 7 RPC patients in Peking Union Medical College Hospital between October 2012 and October 2018, presenting as arthritis at onset, were retrospectively analyzed.

**Results:** There were five female patients. The female to male ratio of the case series was 5:2. The age of 7 patients was 43.43±9.86 years. The number of affected joints was 20.14±10.92. The joint involvement was most common in the bilateral proximal interphalangeal joints (PIP\(\alpha\)) and interphalangeal joints of the thumb. Recent arthritis occurred in 5 patients. There was no accompanying enthesitis. The specific serum indexes of RA, such as rheumatoid factor (RF), anti-cyclic citrullinated peptide (CCP) antibody, were negative. There were three patients administered with conventional synthetic disease modifying anti- rheumatic drugs firstly, and they did not respond well. The median delay time from onset to diagnosis of RPC was ten month (Figure 1). The deformity and destruction of the joint were not observed in all patients, by clinical and radiological assessment. The average duration from arthritis to the occurrence of other involved system was 8.3 months. Four patients were misdiagnosed as rheumatoid arthritis at first. One patient was considered as ankylosing spondylitis at first. Two patients were diagnosed as arthritis at the beginning. As regards to treatment, glucocorticoids (GCs), cyclophosphamide and mycophenolate mofetil were used. Two patient was complicated with palmoplantar pustulosis and Kikuchi-Fujimoto disease. During follow up, myelodysplastic syndrome occurred in one patient. After following up for 35.43±30.92 months, all patients survived and were not with the recurrence of arthritis.

\(^3\) University of Ferrara, Cona, Italy;

\(^4\) ASL3 – Azienda Sanitaria Genovese, Genoa, Italy;

\(^5\) University of siena, Siena, Italy;

\(^6\) University of Palermo, Palermo, Italy;

\(^7\) San Raffaele Scientific Institute, Milan, Italy;

\(^8\) University of Pavia, Pavia, Italy;

\(^9\) Istituto Giannini Gaslini, Genoa, Italy;

\(^10\) University of Padua, Padua, Italy

**Background:** Still’s disease is a rare autoinflammatory disease, presenting in both pediatric (systemic juvenile idiopathic arthritis [SJIA]) and adult patients [adult-onset Still’s disease (AOSD)]. Due to the rarity of the disease, clinical trials are limited and treatment guidelines are not available. In patients refractory to the classical therapy with NSAIDs, corticosteroids and DMARDs, the introduction of drugs targeting IL-1 has greatly expanded treatment options. Among these, canakinumab, a human monoclonal anti-IL-1\(\beta\) antibody, and anakinra, a human recombinant IL-1RA, have been recently approved for the treatment of refractory patients.

**Objectives:** To produce recommendations, based on evidence and expert consensus, that can help clinicians in choosing the most appropriate treatment of AOSD, with particular attention to anti-IL-1 therapies, in order to achieve disease remission before the development of complications.

**Methods:** The recommendations development process took place from April to October 2018 and consisted of three steps. The first step was dedicated to a comprehensive literature review and development of statements. Two separate literature searches were performed: a) similarities and differences between SJIA and AOSD; b) efficacy and safety of IL-1 blockade in AOSD. The issue related to the treatment of AOSD with anti-IL1 therapies was specified into 4 questions: 1) efficacy and safety; 2) comparison among IL-1 inhibitors; 3) early versus late treatment; 4) systemic versus chronic articular pattern of the disease. In the second step, the statements were submitted in a Delphi process to a panel of 87 rheumatologists. Consensus threshold was set at 66%: positive, > 66% of voters selected scores 3 to 5; negative, > 66% of voters selected scores 1 or 2. At the third step of the consensus process, the voting results were analyzed, and the statements were finalized.

**Results:** In the two literature searches, 332 and 358 publications were identified; 30 and 25 publications, respectively, were selected according to the inclusion criteria. Based on the review of the literature and personal clinical experience, 11 statements were developed. Positive consensus was reached after the first round of voting and was full (> 95%) on the majority of statements. A large consensus was achieved in considering AOSD and SJIA as the same disease. The use of anti-IL1 therapies in refractory patients was considered quite safe and effective both as first and as subsequent line of biologic treatment, especially in systemic patients. Because of the lack of head-to-head comparisons, a different profile of efficacy among IL-1 inhibitors could not be established. There was a large consensus that failure of the first IL-1 inhibitor does not preclude a therapeutic response with another one. The lack of studies comparing early versus late treatment in AOSD patients did not allow to draw conclusions, however data from SJIA suggest a better response in early treated patients.

**Conclusion:** The Delphi method was used to develop recommendations that we hope will help clinicians in the management of patients with AOSD refractory to conventional therapies.

**Acknowledgement:** Editorial support was provided by Springer Healthcare Communications and funded by Novartis Farma, Italy.

**Disclosure of Interests:** Serena Colafrancesco: None declared, Maria Manara: None declared, Alessandra Bortoluzzi: None declared, Teodora Serban: None declared.
Efficacy and Safety of Anakinra in the Treatment of Autoimmune Myocarditis

Giacomo De Luca, Corrado Campochiaro, Giulio Cavalli, Silvia Sartorelli, Lorenzo Dagna. Myocarditis Clinic - Cardiovascular Immunopathology Unit at IRCCS San Raffaele Hospital and Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: Virus-negative or “autoimmune” myocarditis (VNM) is a severe, inflammatory heart disease with a poor prognosis, and is a leading cause of inflammatory dilated cardiomyopathy (IDCM). Therapies are limited. Preliminary data indicate that interleukin-1 (IL-1) plays a key role in the initiation and maintenance of the inflammatory heart response, sustaining an auto-inflammatory cycle [1,2]. Objectives: to evaluate the efficacy and safety of anakinra (ANK) in idiopathic left ventricular dysfunction (LV-F) on transthoracic echocardiography (TTE) in patients with VNM.

Methods: Biopsy-proven VNM patients were enrolled and treated with ANK 100 mg daily subcutaneously. All patients received treatment with the maximum tolerated dose of any beta blockers and ACE-inhibitors, according to current guidelines. At baseline and 8±4 weeks after ANK therapy, all patients underwent a full evaluation with assessment of conduction status (New York Heart Association [NYHA]), measurement of high-sensitivity troponin T (hs-TnT) and NT-proBNP serum levels, electrocardiography (ECG), 24h-ECG-Holter, TTE and cardiac magnetic resonance (CMR).

Any myocarditis-related complication, cardiovascular deaths and adverse events (AEs) was recorded during follow-up. Continuous variables were assessed with the Wilcoxon signed-rank test for non-parametric tests and a p-value <0.05 was considered statistically significant.

Results: Eleven patients (6M, 5F, mean age 46.2±12.2 years) diagnosed with EBM-proven VNM were enrolled. Nine patients received ANK as first line therapy, and in 5 cases ANK was used as monotherapy: ANK was combined with prednisone (mean dose 31.7±16.7 mg daily) in 6 patients, 5 of them were concomitantly treated with azathioprine. On EMB, 8 patients were classified as i-DCM, 3 with acute VNM e 1 with active and chronic VNM [3,4]. Clinical onset was characterized by congestive heart failure in the most cases (72.7%). The majority of patients (72.7%) was in NYHA class III-IV. Mean LV-EF on TTE at baseline was 38.7% ±19.6, with comparable findings on CMR (36.45%±18.0), and 8 patients (72.7%) and 6 patients (54.5%) were treated with ANK therapy. At baseline, mean levels of hs-TnT and NT-proBNP were 150.0±153.9 ng/L and 6968.8±10788.4 pg/ml respectively. Hs-TnT and NT-proBNP levels were elevated in 10 (90.9%) patients. The LV-EF increase was >10% in 5 patients (45.5%) and 9 patients (81.8%) respectively. At 8 weeks, LV-EF improved in 10 patients (90.9%). The LV-EF increase was >10% in 5 patients (45.5%) and between 5-10% in 5 cases (45.5%); only 1 patient showed a <10% LV-EF decrease. Mean LV-EF at the end of follow-up improved to 49.4% ±10.8 (p=0.039). When evaluating the 8 patients with baseline reduced LV-EF, the LV-EF improvement was statistically significant (baseline 29.2±12.9; after ANK 45.2±9.2, p=0.025). The LV-EF amelioration was paralleled by clinical improvements in all patients, since the majority of them (90.9%) were in NYHA class I-II at the end of follow-up. Consistently, hs-TnT declined after 8 weeks (64.6±100.7 ng/L, p=0.028), and a similar trend was observed for NT-proBNP, even though not statistically significant (2582.6±5048.1 pg/ml, p=0.06). We did not observe any myocarditis-related death or complications, nor any ANK-related AEs.

Conclusion: Our pilot study supports the efficacy and safety of ANK in the treatment of inflammatory heart failure in VNM and provides the first clinical evidence to support the therapeutic blockade of IL-1 in myocarditis.

The Impact of Aging on Familial Mediterranean Fever Patients

Okan Aydin, Serdal Uğurlu, Bugra Han Eekl, Asli Ece Soykut, Deniz Demir, Huri Ozdogan. University of Istanbul- Cerrahpasa, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF) is a monogenic auto-inflammatory disorder with innate immune activation with an onset before age 20 in approximately 90% of the patients. There is scarce data on the effect of aging on FMF patients over 50 years of age.

Objectives: This study aims to collect data on FMF patients who have survived over 40 years of age. Here we report our preliminary data on disease course and treatment status and comorbidities of our patients with FMF.

Methods: Among the FMF patients who have been followed in our FMF outpatient clinic with a pool of approximately 5000 patients, those who have aged 40 and over are being included to the study. As by today 180 patients are considered for evaluation. The files of patients were reviewed and a standard questionnaire was used to interview the patients. Here we report the results of 100 of these patients (56%) who were contacted for this purpose. These patients were questioned on their demographic characteristics, comorbid conditions, colchicine treatment details, and attack information. In order to see the trend of the change in the parameters assessed, the patients were divided into two groups based on their present age (Group 1: 40-50 years, Group 2: ≥50 years).

Results: A total of 100 (78 F, 22 M) patients were evaluated. There were 61(64%, 15M) patients aged between 40-50 years and 39 (32F, 7M) over 50. The demographic characteristics and clinical features of these patients are given in Table 1. Besides 3, all patients were still on colchicine regularly. Ninety-six percent of the patients declared overall benefit from colchicine therapy; however 38% experienced a side effect related to this treatment. Over 88% of the patients reported decrease in severity and frequency of FMF attacks. The mean daily colchicine dose was lower in the age 50 and over group (1,750,77 mg versus 1,35±0,58 mg). There were no patients with AA amyloidosis in neither age group. The mean duration from the last attack increased from 15.3±19.7 months to 35.6±52 months in the older patients. One or more additional disease was present in 75% of this patient group. Among the comorbidities hypertension was the most frequent, diagnosed in 25% of the patients, followed by hypothyroidism (16%), diabetes mellitus (10%) and cardiac disease (5%). Sixty-five of the patients were receiving other medications in addition to colchicine.

</tr>
</tbody>
</table>
Conclusion: According to our preliminary data the majority of the patients continue to take colchicine after age of 40. However the frequency of FMF attacks as well as daily colchicine dose decrease as the patients get older. With well designed trials stopping colchicine treatment may be considered in a subgroup of patients after 50 years of age. Approximately 1/3 of the FMF population over 40 years of age has a comorbidity that necessitates additional medications which underlines the need for special attention.

THU0572 RHEUMATOLOGICAL ASPECTS OF FORMS AND VARIANTS OF PANNICULITIS

Olga Espinosa1, Boris Belov1, Svetlana Glukhova1, S. Radenkova-Lopovok2, I.V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2FSBEIH EIM, Sechenov Moscow State Medical University, Moscow, Russian Federation

Background: Panniculitis (Pn) is a set of heterogeneous inflammatory diseases characterized by lesions of subcutaneous fat (SCF) and often accompanied with the defeat of the musculoskeletal system and internal organs. Depending on the etiology and histomorphological picture, Pn is divided into two forms: septal (SPn) and lobular panniculitis (LPn) with and without signs of vasculitis, which is reflected in the clinical picture of the disease. Often Pn is one of the symptoms of rheumatic diseases (Rd), it can lead to late diagnosis of the underlying disease.

Objectives: to study the frequency of occurrence of forms and variants of Pn in rheumatological practice on the basis of long-term prospective observation.

Methods: We examined 687 patients with Pn (613 women and 74 men, mean age 39.7±11.31 and 41.2±12.57 years, respectively) with the referral diagnosis of “Erythema Nodosum” (EN) or “Panniculitis”, who were observed in the rheumatologic clinic in 2007-2017. In addition to general clinical examination, we determined serum concentrations of α1 antitrypsin, amylose, lipase, ferritin, creatine phosphokinase, conducted a CT scan of the chest organs, immunological, TB tests and pathological study of skin biopsy from the node.

Results: As a result of application of the developed diagnostic algorithm; 430 patients (62.6%) were diagnosed with SPn and 249 patients (36.2%) - with LPn. In 9 cases (1%) (3 patients with SPn and 4 with LPn), it was not possible to confirm the variant of Pn, despite the comprehensive examination. In 8 patients (1.1%) no Pn data were revealed, the following diagnoses were verified: 2 patients (25%) — discoid lupus and lipo-dystrophy; 1 (12.5%) — erysipelis, lichen, fixed erythema and keratoacanthoma. SPn in 94% of cases (400 patients) was presented by EN, in 4% (18) — by superficial migrating thrombophlebitis, in single cases (1-0%) — by eosinophilic fasciitis, skin nodular polyarteritis and scleroderma-Pn (2, 6 and 1 patients, respectively). In 28% of cases LPn was associated with systemic connective tissue lesions, in 27% with idiopathic lobular Pn (Weber — Christian panniculitis) (p<0.002), in 32.92% with lipodermatosclerosis and in 14.28% with subcutaneous sarcoid. In a few cases LPn was caused by lymphoproliferative (2.88%) and cancer (2.49%) diseases, calciphylaxis (2.05%), erythema Bazin (1.64%), cold Pn (0.02%) and alpha-1 antitrypsine failure (0.41%).

Conclusion: the results confirm that patients with SPn were found twice as often as with LPn. Prenosological Pn was mainly associated with sarcoidosis, EN and RD, which confirms the relevance of further research of Pn.

THU0573 COMPLICATIONS AND ACTIVITY OF UVEITIS IN A MULTIDISCIPLINARY REFERENCE UNIT IN THE NORTH OF SPAIN

Patricia Fanlo1, Henar Heras1, Alfredo Adan2, Gerard Espinosa3, 1Complejo Hospitalario de Navarra, Multidisciplinary Uveitis Unit, Pamplona, Spain; 2Hospital Clinic, Ophthalmology, Barcelona, Spain; 3Hospital Clinic, Autoimmune Systemic Disease Unit, Barcelona, Spain

Background: Uveitis, an intraocular inflammatory disease, is a significant cause of visual impairment. It is not known how many patients with uveitis will retain visual acuity and how many develop visual impairment or even blindness. The activity of uveitis, the use of topic and oral steroids could produce ocular complications.

Objectives: To describe the complications and the activity of the uveitis in a cohort of 500 patients diagnosed in one unit of reference in the north of Spain.

Methods: A prospective study of complications and the activity of the 500 adults with uveitis were evaluated in the multidisciplinary Uveitis Unit of Complejo Hospitalario de Navarra from January of 2010 to March of 2015. Uveitis activity and the type of complication to the year of follow-up were analysed. The variables were collected according to the terminology of the activity of the SUN (inactive, worsening, improvement and remission). To facilitate statistical analysis variables inactive and remission were grouped in a same term. A study of characterization of the evolution and worsening of the activity to the year of follow-up with sex, foreign, type of uveitis, etiology, laterality, treatments and complications. The characterization was carried out through the SPAD 8 program and was carried out by contrast Chi square.

Results: We collected a total of 500 patients, 54.4% of patients remained inactive or in remission after 1 year of follow-up, 13.2% presented worsening of their activity and 32.45% had improved. A bivariate analysis was performed between the variable evolution per year and other variables. We did not observe relationship between the evolution per year and sex, foreign, type of uveitis, etiology, laterality, topical treatment, intravitreal treatment, biological treatment or surgical treatment. Relationship was found statistically significant between the evolution with the existence of complications (p = 0, 0) and oral immunosuppressive treatment (p = 0, 008). There was statistically significant relationship between the existence of complications (p = 0, 0) and oral immunosuppressive treatment (p = 0, 011), and not relationship with age was found (p = 0, 8), sex (p=0,35), foreign (p = 0, 27), type of uveitis (p = 0, 65), laterality (p = 0, 6) etiology (p = 0, 1), periciliar treatment (p = 0, 5), intravitreal (0.56) and biologic treatment (p=0,182). 65% of the patients did not show any complication a year of follow-up and the most frequent complications were cataract (10%), synecchia (8%), macular edema (5%), glaucoma (3%), detachment of retina (3%), epiretinal membrane (2%) and other (5%).

Conclusion: 87% of the patients were in remission or improvement to the year of follow-up. The worsening of the uveitis is related with the existence of complications and oral immunosuppressive treatment.

**THU0574**

**DOES THE USE OF CHOLCHICINE EFFECT COGNITIVE FUNCTIONS IN FAMILIAL MEDITERRANEAN FEVER?**

**PRELIMINARY STUDY**

Halise Hande Gaozu1, Ozge Devezer Uslu2, Didem Erdem1, Sevap Acer Kasman1, Mehmet Tuncay Duruöz2, 1Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Rheumatology Division, Istanbul, Turkey; 2Institution of Clinical and Forensic Psychology, Clinical Psychology, Istanbul, Turkey

**Background:** In Familial Mediterranean Fever (FMF), although cognitive functions have been shown to be impaired in children and adolescents, it has been shown that colchicine can be preservative on the cognitive functions in patients who are on long term colchicine treatment.

**Objectives:** This study aimed to evaluate cognitive functions in adult patients with FMF and cognitive effects of colchicine use.

**Methods:** The study included patients who were diagnosed with FMF according to Tel-Hashomer criteria. The control group included patients with no other inflammatory or systemic disease. Clinical features such as disease duration, comorbid diseases, colchicine treatment duration and dosage, amyloidosis and chronic renal failure (CRF), FMD gene mutations and PRAS scoring for evaluation of disease activity were recorded. Pittsburgh Sleep Quality Index (PSQI), Fatigue Severity Scale, FMF Quality of Life Scale and Beck Depression Scale were used to assess patents clinical situations. Cognitive measurements were evaluated under executive-propellent skills. KAS test was used for information processing and fluency skills; fruit-name test was used for the evaluation of focusing, concentration, and attention skills; animal counting test and The Montreal Cognitive Rating Scale (MOCA) which can evaluate different subunits (visuospatial/executive, naming, memory, attention, language, abstraction, delayed recall, and orientation) were used for the fluency and maintenance of attention. Different attention parameters were evaluated for patients and healthy individuals. These attention parameters were; focusing, elaborate, sustainability, ability to pay attention to two information at the same time.

Descriptive analysis was performed for all parameters. Mann-Whitney U-test and Spearman correlation coefficient were used to compare parameters. P <0.05 was accepted as statistically significant.

**Results:** The study included 24 (21 women, 3 men) patients with FMF and 10 (7 female, 3 male) age, sex and BMI matched healthy controls. The mean age of the patients and controls were 36.83 (SD:10.9) and 39.3(SD:8.6), respectively. No significant difference was found between FMF and healthy control groups regarding animal counting, KAS test, MOCA test, and subgroups. Only fruit-name counting test was decreased in the FMF group compared to the healthy controls (p <0.05). As the duration of colchicine treatment was prolonged, a moderate positive correlation was found in KAS scores (r=0.511) and MOCA naming scores (r=0.445). In the FMF group, the number of attacks in the last three months and the sleep scores of Pittsburgh and depression scores had a moderately positive correlation (r = 0.496). Depression scores and quality of life scores were highly correlated (r = 0.631).

**Conclusion:** FMF patients attention parameters are impaired compared to the healthy controls. Information processing and fluency performance is increased in FMF patients with the duration of colchicine treatment that demonstrate the ability to categorize and fluent use of the information. Number of attacks are correlated with poor sleep quality and depression.

**THU0575**

**HYPERCOAGULABILITY AS A CAUSE OF THROMBOSIS IN BEHÇET’S SYNDROME: A SYSTEMATIC REVIEW AND META ANALYSIS**

Gül Gürela Koksoy, Berna Yurttas, Sinem Nihat Esatoglu, Vedat Hamuryudan, Hasan Yaricio, Gülen Hatemi, Istanbul University-Cerrahpasa, Medical Faculty of Cerrahpasa, Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** While thrombosis in Behçet’s Syndrome (BS) is considered to be mainly caused by inflammation in the vessel wall, several prothrombotic factors have been studied with inconsistent results.

**Objectives:** We aimed to perform a systematic review of clinical studies investigating the thrombophilic factors in BS.

**Methods:** The online database of PubMed was searched with the keyword “Behcet” in four languages (English, German, French and Turkish) from inception up to May 2018. Titles and/or abstracts of all studies were screened independently by two reviewers (GG and BY) for studies reporting on thrombosis, fibrinolysis, endothelial factors and comparing BS patients with and without thrombosis. Conflicts were solved by a third reviewer (GH). The pooled odds ratios (OR) with 95%CI were calculated for binary outcomes and standardized mean differences (MD) were calculated for continuous outcomes by using RevMan 5.3.

**Results:** Of 9937 articles, 9373 were excluded due to repetition and inappropriate study design after reviewing titles and abstracts. Full text review of the remaining 564 articles yielded 86 papers meeting our predetermined inclusion criteria. Several factors such as protein C, protein S, active protein C resistance, anti-thrombin III, plasminogen, plasminogen activator inhibitor, fibrinogen, factor 7, factor 12, thrombin activatable fibrinolytic inhibitor, anticoagulation antibodies, antiβ2 Glycoprotein1 antibodies and methylenetetrahydrofolate reductase gene C677T mutation were not different in BS patients with thrombosis compared to those without thrombosis. On the other hand, vascular endothelial growth factor levels, P-selectin glycoprotein ligand-1, platelet-activating factor seemed to be more frequent in BS patients with thrombosis in the few studies reporting on these, including a small number of patients.

Among the 11 parameters with controversial results across studies, meta-analysis showed significantly higher homocysteine levels, higher factor VIII levels, more frequent Factor V Leiden mutations and higher von Willebrand factor levels in BS patients with thrombosis, whereas the pooled difference was not significant for mean platelet volume, tissue plasminogen activator, thrombin gene mutations, lupus anticoagulant, P-selectin level, erythrocyte aggregation and thrombomodulin level (Table).

**Conclusion:** Among the several prothrombotic factors that were studied in BS patients, factor V Leiden mutation, high homocysteine levels, factor 8 levels and von Willebrand factor levels may be associated with thrombosis in BS. Studies investigating these factors together in a large number of patients together with appropriate controls are needed to confirm these results.

**Table. Meta-analysis of studies with controversial results**

THU0576  PROGNOSTIC FACTORS PREDICTING THE SURVIVAL OF PATIENTS WITH MACROPHAGE ACTIVATION SYNDROME

Seungmin Jung, Sungsoo Ahn, Sangwon Lee, Jason Jungik Song, Yongbeom Park, Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Macrophage activation syndrome (MAS) is a hyperinflammatory condition, which can lead to death in patients with rheumatologic disease. However, the prognosis of adult patients with MAS is largely unknown.

Objectives: We aimed to investigate the mortality in patients with MAS accompanied Adult-onset Still’s disease (AOSD) or systemic lupus erythematosus (SLE) and to evaluate the prognostic factors predicting the mortality in patients with MAS.

Methods: We retrospectively reviewed febrile patients with AOSD or SLE admitted to Severance Hospital between 2005 and 2018. Patients who satisfied the classification criteria of MAS was included in the analysis. Cox-regression analysis was performed to evaluate the clinical factors associated with the overall mortality in patients with MAS.

Results: Of the total 123 patients, 48 (39%) patients and 75 (61%) patients were diagnosed with AOSD and SLE, respectively. Forty-three patients (35%) were died from MAS during hospitalization. There was no significant difference in mortality between AOSD and SLE (P = 0.675). In multivariate analysis, cytopenia, and insufficient reduction of ferritin and P-selectin 2 33 75 MD: 0.85 (-0.62, -0.15) were independently associated with death in patients with MAS (P = 0.019, < 0.001, and 0.011, respectively).

Conclusion: The presence of cytopenia, and treatment response after glucocorticoid treatment was closely related with death in patients with MAS. More intensive treatment should be considered in high-risk patients with poor prognostic factors.

THU0577  EFFICACY OF RADIOSYNOVIOGRAPHY IN PIGMENTED VILLONODULAR SYNOVITIS OF THE KNEE

Background: Pigmented villonodular synovitis (PVNS) is a rare disorder with the benign tumoral proliferation of the synovium. The surgical treatment of PVNS alone in most cases is unsatisfactory, because if a few cells have not been removed, the disease will recur.1 Post-synovectomy adjuvant treatment with intra-articular injection of Yttrium-90 (90Y) or Holmium-166 (166Ho) yielded better results. The radiosynoviorthesis (RSO) is an effective way of treating the chronic synovitis, with this method we are eliminate the inflammation in 75 percent of the cases.2

Objectives: To study efficacy of radiosynoviorthesis after the surgical synovectomy in pigmented villonodular synovitis of the knee.

Methods: Between May 1996 and August 2018, 17 patients (seven men and ten women aged 14–68 years) with diffuse PVNS were treated. All patients had monoarticular arthritis of the knee with histologically proved PVNS. The patients underwent 33 operations, two patients had four surgical procedures, one patient underwent three surgeries, eight patients had two surgeries and six patients had one surgical procedure (Table 1). The radiosynoviorthesis was performed according to the method accepted in the national protocol.Yttrium-citrate injectable suspension marked by 185 MBq 90Y-citrate injectable suspension, and 40 mg of 1 ml trimcinolone acetonide and 1 ml of lidocaine 1%.3 Holmium-phytate injectable suspension marked by 600 MBq 166Ho-phytate injectable suspension, and 40 mg of 1 ml trimcinolone acetonide and 1 ml of lidocaine 1%.3 Evaluation was based on the criteria as described by Müller, Rau and Schütte the score system was developed by the authors.4 The circumference of joint-swelling, the joint function, the measure of flexio-contracture, pain in state of rest and load on a pain analogue scale 1-10, joint warmth, walking capacity, the numbers of joint-junctions after the treatment, whether operation was necessary or not after the treatment were examined.

Results: Mean follow-up time was 56 months (range from 4 to 144 months). All patients were followed up using clinical assessment. After the first injection excellent and good results were recorded in 41%. After the second radiosynoviorthesis thirteen patients (76%) showed excellent and good results were recorded in 41%. The mean functional evaluation score of 17 patients was 28 (range 16-34). Most of the ratings were excellent or good, in four cases moderate (24%). No complications were noticed after surgery or after the radiosynoviorthesis.

THU0578

COMMON VARIABLE IMMUNODEFICIENCY IN PATIENTS WITH SARCOIDOSIS

Isabel Madroñal García, Clara Aguileras Crost, Maria Dolores Arcila Duran, Lara Mendez, Marina Gomez Vargas, Alberto Ruiz Roman, Noemi Patricia Garrido Puñal, Ricardo Juan Gil Velez, Jose Antonio Rodriguez Portal, Esteban Rubio Romero. Hospital Universitario Virgen del Rocio, Reumatología, Sevilla, Spain

Background: Common variable immunodeficiency (CVID) is a primary immunodeficiency characterized by hypogammaglobulinemia and a deficient production of specific antibodies. Almost 30% of patients with CVID develop autoimmune and granulomatous disease, similar to clinical and histological sarcoidosis (S), it affects the lung fundamentally. This can lead to a misdiagnosis of S in a patient with CVID, this leads to inadequate treatment and increases the morbidity and mortality of the disease.

Objectives: Describe the clinical and radiological characteristics of a cohort of patients diagnosed with S with predominant pulmonary involvement. Make a study of immunoglobulin (IG) levels to see the frequency of CVID in these patients.

Methods: Retrospective descriptive study of patients treated in our Hospital (2008-2018), with diagnosis of S. The data was obtained by reviewing medical records. The delay in the diagnosis of S was defined as the difference in months between the initial diagnostic suspicion and the final diagnosis of S.

Results: 55 patients (31 women) were included, with a mean age of 52 ±12 years. The initial diagnosis was: 85% S, 10% lymphoma and 4% tuberculosis. The median of months from the start of the clinic to the diagnosis of S was 5.5 months.

Regarding the clinical, 21% patients present fever at the beginning of the disease, and 65% extrathoracic localization (cutaneous was the most frequent in 27%, and renal was the least frequent 5%). Simple x-ray and high resolution tomography of chest were done in all patients. Pulmonary stage 2 was the most frequent (51%), followed by stage 3 (16%), stage 0 (14%) and stage 4 (9%).

In 90% of the patients, histological confirmation was obtained by transbronchial (47%), cutaneous (11%) or lymph node biopsy (29%). Igs were normal in 87% of patients, only 4 patients had low IG levels (lg G in 3 patients and Ig M in 1). An extended ID study was performed in these 4 patients, being diagnosed with CVID 3 patients.

Results of the 4 patients and the differential characteristics between CVID and S in table 1.

Conclusion: Although their clinical presentation and histological appearance may be identical, the management of these two conditions is very different. The difficulties in the differential diagnosis between S and CVID, shows the importance of a history of screening for recurrent infections and the measurement of IG levels before the diagnosis of possible S.

Disclosure of Interests: None declared
Background: Inhibitors of CTLA-4 and PD-1 have shown improvements in survival in multiple advanced cancers. Immune-mediated effects such as arthralgias and arthritis have been described, but their prevalence and characteristics have not been well defined.

Objectives: The objective of the study is to describe the prevalence of immunemediated joint manifestations (IJM), their characteristics and evolution in patients who received immunotherapy (nivolumab NV, pembrolizumab PB) from January 1, 2016 to December 31, 2018 in our center.

Methods: Data collection was performed at through the RPIST (Registre Pacients Tractats) database of the CatSalut, and the patients referred to the monographic medical office of inflammatory joint diseases of our center. In all cases, the variables: age, sex, neoplasia, drug, number of doses, were recorded. In patients with joint involvement: other autoimmunemanifestations, joint affection prior to treatment, delay rheumatology derivation, joint affection type, swollen and tender joint counts, ESR, CRP, RF, ACPR, ANA, HLA B 27, Hb, leukocytes, neutrophils, lymphocytes, treatment and evolution, were recorded. The statistical analysis was carried out with the SPSS 15.0 computer package.

Results: 126 patients received treatment (TTO) with immunotherapy (71 NV, 35 BP) for neoplasia (81 lung, 10 renal, 8 melanoma, 2 oropharynx). The mean age was 67.93 ± 10.7 years (21.7% women, 78.3% men). There were 11 events catalogued as IJM. The overall prevalence was 10.3% (5.6% NV, 14.3% PB). Patients with UVM received a greater number of doses (17.67 ± 9.3 vs 9.24 ± 10.1 p = 0.018). No patient with melanoma presented UVM. All UIM suspicions cases were assessed by a rheumatologist. When studying their characteristics (Table 1), 3 patients were added from the database of the rheumatology service (14 cases). They received in a clinical trial BP295411 (rectal cancer), Atezolizumab (lung cancer) and Durvalumab (lung cancer). 42.9% of the patients presented inflammatory arthralgias (IAT) and 57.1% arthritis (AT). In reference to their previous history, 2 patients had a history of hyperuricemia and arthritis. One patient concomitantly presented lymphocytic colitis confirmed by biopsy. The delay time for assessment by rheumatology was 18.1 ± 22.1 days. Patients with AT were older (p = 0.014), had higher ESR (p = 0.947) than those with IAT. No differences were found in other variables (table1). With reference to the analytical study, 1 patient was RF +, 2 ANA + at mean titters (1/160-1/320), none ACPR or HLA B 27 +. After assessment by rheumatology, two patients with IAT were diagnosed with bone M1 and two AT were categorized as gouty arthritis. The rest of the IAT responded to NSAIDs and were resolved. 6 cases of AT received prednisone, 3 required treatment dose 1 mg/kg weight and subsequently MTX in 2 of them, with evolution to low disease activity at present. One only patient met RA classification criteria.

Conclusion: The prevalence of IJM was higher than 10%, depending on the number of doses. Patients with arthritis had higher age and higher ESR. No patient presented ACPR and HLA B 27 +, so to include them in the initial analytical could be not necessary. In these patients, it is important the assessment by a rheumatologist to make a correct differentiated diagnosis, as well as establish referral criteria to avoid delay of care.

Background: Non ischaemic optic neuritis (NION) is a severe inflammation of the optic nerve that may lead to blindness. It can be primary or associated to immune mediated inflammatory diseases (IMIDs). The treatment of the NION is based on systemic corticosteroids and conventional immunosuppressive drugs.

Objectives: To assess the efficacy of the biological treatment in refractory NION to conventional treatment.

Methods: Multicenter study of 12 patients diagnosed with NION refractory to systemic corticosteroids and at least one conventional immunosuppressive drug. The main outcomes were visual acuity (VA) and optical coherence tomography (OCT) of the optic nerve and the ganglion cells. Comparisons were made between baseline and the 1st week, 1st and 6th month and 1st year. (STATISTICA, StatSoft Inc. Tulsa, Oklahoma, USA).

Results: We studied 12 patients (19 affected eyes) (5 men/women); mean age of 29.8 ± 12.9 years. The underlying diseases were systemic lupus erythematosus (n=1), neurofibromatosis optica (n=1), neuroretinitis (n=1), relapsing polychondritis (n=1), pars planitis (n=1), Behçet’s disease (n=2) and idiopathic (n=6). Before biological treatment and besides oral corticosteroids, patients had received intravenous (IV) methylprednisolone boluses (n=9), cyclophosphamide (n=2), mycophenolate (n=2), hydroxychloroquine (n=1), methotrexate (n=8) and azathioprine (n=5). Biological treatment was bases on rituximab (n=2) (2 IV, doses of 1 g/week 2 weeks and every 6 moths), adalimumab (n=5) (40 mg/1-2 week), tocilizumab (n=4) (8 mg/kg/2-4 weeks) and infliximab (n=3) (5 mg/kg at 0, 2 and 6 week and then every 8 weeks). The characteristics of the 12 patients are shown in the TABLE.

After biological treatment we observed an improvement in the ocular parameters: VA [0.66±0.32 to 0.84±0.29; p= 0.03] of the OCT of the nerve [123.20±58.28 to 190.54±175.38; p= 0.11] and OCT of the ganglion cells [269.55±137.37 to 270.67±23.21; p= 0.03] at one year. After a mean follow-up of 29.09±19.23 months, there were no severe adverse effects.

Conclusion: Biological therapy in NION idiopathic or associated to IMIDs, refractory to conventional treatment, seems to be effective.
THU0582
THE TNF RECEPTOR-ASSOCIATED PERIODIC SYNDROME (TRAPS): CLINICAL AND GENETIC CHARACTERIZATION OF A COHORT OF ADULTS DIAGNOSED OF TRAPS SYNDROME

Alberto Ruiz Romagún1, Salvador García Morillo2, Marco Montes Cano2, Clara Aguilara Cres1, Manuel Leon Luque1, Maria Jose Valenzuela Porcel1, Maria Arcila Duran1, Lara Mendez1, Isabel Madroñal García1. 1HOSPITAL VIRGEN DEL ROCIO, Rheumatology, Seville, Spain; 2HOSPITAL VIRGEN DEL ROCIO, Internal Medicine, Seville, Spain; 3HOSPITAL VIRGEN DEL ROCIO, Immunology, Seville, Spain

Background: Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a disease that is included within hereditary syndromes of periodic fever. It presents an autosomal dominant pattern of inheritance. It’s due to mutations of TNFRSF1A gene. It is usually present in childhood; although it can also appear in adulthood and it tends to cause high levels of acute phase reactants, fever, musculoskeletal symptoms (myalgias, arthralgias, arthritis), rash, abdominal pain, etc.

Objectives: To describe the clinical characteristics and genetic variants of patients diagnosed with TRAPS syndrome in a cohort of patients with auto-inflammatory syndromes with follow-up in a tertiary hospital from 2013 to the present

Methods: Retrospective descriptive study of adult patients diagnosed with autoinflammatory syndrome since 2013 (year of introduction of genetic tests in the hospital laboratory) until now. The data was obtained from the review of medical records. All patients with mutations in TNFRSF1A gene and clinically compatible with this diagnosis were reviewed

Results: Of a total of 44 adult patients diagnosed with hereditary syndromes of periodic fever (FMF, TRAPS, cryopyrinopathies, HIDS) and compatible genetic mutations (excluding polymorphisms), 13 (29.5%) presented mutations in the TNFRSF1A gene. Of those 13 patients, 9 (69.2%) were women. The most frequent mutations were the mutation in MEFV gene (92.3%) and one case (7.6%) with mutation in heterozygosis in exon 4 (p.R92Q) with 12 cases (92.3%) and one case (7.6%) with mutation in heterozygosis in exon 3 (p.P461L).

Conclusion: The TRAPS syndrome is a clinical entity to consider when making a differential diagnosis in patients with suspected autoinflammatory syndrome, that present fever, acute phase reactants elevation, arthromyalgia and its confirmation diagnosis is with genetic test

THU0583
EXPERIENCE OF ANAKINRA AND CANAKINUMAB IN PATIENTS WITH COLCHICINE-RESISTANT FAMILIAL MEDITERRANEAN FEVER AND COMPLICATED WITH AMYLOIDOSIS

All Sahin1, Mehmet Emin Derin2, Fahit Albayrak2, Burak Karakaya2. 1Sivas Cumhuriyet University, Rheumatology-Internal Medicine, sivas, Turkey; 2Sivas Cumhuriyet University, sivas, Turkey

Background: Familial Mediterranean Fever (FMF) is a hereditary auto-inflammatory disease characterized by recurrent fever and serosal inflammation (1). The goal of FMF treatment is to prevent the attacks and to minimize subclinical inflammation between attacks, and in attacks-free period. Colchicine is a major drug that sinue qua non in the treatment of FMF. However, anti-interleukin-1 agents are recommended in colchicine resistant and/or intolerant FMF patients (2).

Objectives: The aim of this study is to evaluate the efficacy of anti-interleukin-1 (anti-IL-1) agents in 54 FMF patients with resistant/intolerated to colchicine or complicated with amyloidosis.

Methods: Between January 2014 and December 2018, fifty four patients who were diagnosed as FMF according to the criteria of Tel-Hashomer following-up at Sivas Cumhuriyet University Medical Faculty, Rheumatology-Internal Medicine Department were included in to the study.

Results: 25 (46.3%) male and 29 (53.7%) female were included in the study. The mean age at diagnosis of 18 (min:15-max: 46) years and the median age at diagnosis was 18 (min: 3-max: 46) years. Anakinra was used in 34 (63%) FMF patients (100 mg/day), and canakinumab was used in 20 (37%) patients (150mg/2weeks). 37 cases were resistant to colchicine, 8 were intolerant to colchicine, 9 (20%) cases were complicated with amyloidosis. 8 patients had renal transplantation. MEFV gene mutations were shown in Table 1. Median duration of anti-IL-1 agent use was 12 months (min:2-max:40). 5 patients were resistant to anakinra, 4 patients had side effects which anakinra related. After a median follow up 12 months overall clinical response was95% (frequency of attacks <1/6months). Median proteinuria decreased from 3850 mg/day to median 1600 mg/day (p< 0.04) (Table 2). IL-6 treatment was started in 3 patients because of ineffectiveness of canakinumab. One pregnant patient was followed up with anakinra during pregnancy and there were no problems.

Conclusion: Anti-interleukin-1 agents can be used effectively and safely in the treatment of FMF patients. These agents are especially effective in the treatment of proteinuria due to amyloidosis. Large and long-lasting follow-up studies are needed to evaluate long-term effects of these drugs.

THU0584
RHEUMATOLOGICAL IMMUNE-RELATED ADVERSE EVENTS ASSOCIATED WITH IMMUNOTHERAPY IN SOLID ORGAN TUMOR, STUDY OF 102 CASES FROM A REFERRAL SINGLE CENTER FOR LAST 4 YEARS

Lara Sánchez Bilbao1, Ilígo González-Mazón1, Rosalía Demetro-Pabó2, José Luis Martín-Varillas1, Marina Delgado Ruiz2, Isabel Bernat Piña2, Belén Alenza-Mateo1, Monica Calderón-Goercke1, D. Prieto-Pería1, Almudena García Castaño2, Miguel A González-Gay1, Ricardo Blanco1, 1Maquers de Valdecilla University Hospital, Rheumatology, Santander, Spain; 2Maquers de Valdecilla University Hospital, Oncology, Santander, Spain

Background: Immune checkpoint blockade therapy (ICBT) currently is one of the most used therapies against cancer. The activation of the immune system can lead to different immune-related adverse events (irAEs), being the rheumatological side effects among the most common.

Objectives: Our aim was to assess the rheumatological irAEs in patients who received immunotherapy.

Methods: We set up an observational study of patients treated with Nivolumab and Pembrolizumab (anti-PD1), Atezolizumab (anti-PD-L1) and Ipilimumab (antiCTLA-4) for solid organ tumors. All these patients were followed in a single reference University Hospital from March-2015 up to December-2018. The main outcome was to determinate the incidence of rheumatological irAEs.

Results: We studied 102 patients (63%/39%) with a mean age of 60.6 ±9.7 with different solid organ tumors. Only 7 patients (6.8%) had previous diagnosis of an immune-mediated disease: psoriasis (n=2), psoriatic arthritis (n=2), rheumatoid arthritis (1), spondyloarthritis (1), psoriatic arthropathy (1), and skin lupus (1).
Rheumatological side effects were observed in 15 patients (14.7%): inflammatory arthralgia (8), arthritis (6), myositis (2) and aortitis (1). The time of appearance of the rheumatological irAEs was of 6.36 months (+2.81). From the 7 patients with previous diagnosis of an immune-mediated disease, only 1 patient with psoriasis suffered a worsening of skin symptoms and another one with psoriatic arthropathy had a monarticular episode.

Among the 14 patients who suffered from arthralgia/arthritis, the most frequent pattern was oligoarticular (40%), followed by poly (30%) and monarticular (30%). The most affected joint was the knee (n=4), followed by wrist (3), hands (3), ankle (2), shoulder (2) and foot (1). Apart from the articular disease, 2 patients suffered from myositis in lower limbs, with weakness of legs and arthralgia in their knees. A patient was diagnosed of aortitis through a PET, although the patient did not have any symptom.

Immunology tests such as RF, ACCP and ANA were done in 8 out of the 15 patients with musculoskeletal irAEs, being negative in all cases. Interviewing 40 of the patients who received ICBT, 7 of them (17.5%) referred xerophthalmia. 6 of them (15%) had a positive Schirmer test, and 3 (7.5%) had a reduced tear break-up time. None patient met Sjögren criteria.

In 6 out of the 15 patients with rheumatological irAEs (all of them with arthralgia/arthritis) the ICBT was removed, temporary in all cases, and could be reintroduced after a mean of 33 ± 18.9 days. 6 patients were treated with NSAIDs and 5 with oral prednisone (2 of them also required intra-articular corticoids).

Conclusion: Rheumatological irAEs are common in clinical practice. Arthralgia-Arthritis and dry-syndrome are the most frequent adverse events.

**THU0585 LYMPHADENOPATHY IN IG4-RELATED DISEASE IS ASSOCIATED WITH DISEASE ACTIVITY AND EOSINOPHILIA**

Satoshi Takanashi1,2, Jun Kikuchi1, Takarori Sasaki1, Mitsuhito Akiyama1, Yuko Kaneko1, Hidekko Yashouka1, Katsuya Suzuki1, Kunio Sugahara1, Tsutomu Takeuchi1,2

1Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan; 2Fujita Health University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Aichi, Japan; 3Mitsubishi Tanabe Pharma Corporation, Research Unit/Immunology and Inflammation, Tokyo, Japan

**Background:** IgG4-related disease (IgG4-RD) is an immune-mediated systemic disease characterized by the enlargement of multiple organs. IgG4-RD frequently involves the pancreas, lachrymal glands, salivary glands, bile duct, kidneys, lungs, and retroperitoneum, but can potentially affect any organ. Lymphadenopathy is often seen in patients with IgG4-RD along with other organ involvements, but the significance of the exist of lymphadenopathy in IgG4-RD is unclear.

**Objectives:** The aim of this study is to clarify the characteristics of patients with IgG4-RD who have lymphadenopathy.

**Methods:** We conducted cluster analysis with clinical data in consecutive 85 patients with untreated active IgG4-RD in our institute. We divided the patients into two groups who had lymphadenopathy or not (lymph group and non-lymph group), and compared clinical characteristics between the two groups. We counted the areas of swollen lymph nodes and performed correlation analysis with clinical characteristics. We also comprehensively screened serum protein concentrations in IgG4-RD patients (n=15) and healthy controls (n=5) by using high-throughput proteomics analysis, and differentially expressed proteins were extracted. We compared the concentrations of serum proteins which were extracted between lymph group and non-lymph group.

**Results:** Among 85 patients with IgG4-RD, 44 (52%) were male. Median age was 63 years old. Forty-seven (55%) patients were lymph group. Clusters analysis revealed that lymphadenopathy was in a cluster with serum IgG4, IgG4/IgG, IgG4-RD responder index (IgG4-RD RI), soluble interleukin-2 receptor (sIL-2R), eosinophilia, erythrocyte sedimentation rate (ESR), lung involvement, hemoglobin, albumin, C3 and C4. In lymph group, serum IgG4, IgG4/IgG, IgG4-RD RI, eosinophilia, sIL-2R and ESR were significantly higher than non-lymph group (Figure). Spearman’s correlation analysis revealed that areas of the swollen lymph nodes were positively correlated with serum IgG4, IgG4/IgG, sIL-2R, eosinophilia. Proteomics analysis revealed that 68 proteins were significantly higher in IgG4-RD (p<0.05). Among them, proteins related to adhesion of immune cells, fibrosis, formation of lymph node and eosinophil activation such as integrin/β1, CCL18, CCL19 and eotaxin3 were higher in lymph group (p<0.05, p<0.003, p<0.006 and p<0.006, respectively).

**Conclusion:** Lymphadenopathy in IgG4-RD is associated with disease activity and eosinophilia. Proteomics analysis can provide some clues for elucidating the significance of lymphadenopathy in IgG4-RD.

THU0587

COMPARING OF TWO DISTINCT SEVERITY SCORES FOR EVALUATING DISEASE SEVERITY IN FAMILIAL MEDITERRANEAN FEVER

Emre Tekgoz1, Seda Colak1, Fatma Ikknur Cinar2, Sedat Yilmaz1, Muhummet Çınar1, 1University of Health Sciences, Gulhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, 2University of Health Sciences, Gulhane Faculty of Nursing, Department of Internal Medicine Nursing, Ankara, Turkey

Background: Familial Mediterranean Fever (FMF) is a chronic hereditary disease which is characterized by recurrent attacks of fever accompanied by serositis. Severity of disease is related with morbidities such as amyloidoses and chronic renal failure.

Objectives: The aim of this study was to evaluate disease severity with two disease severity scores in FMF patients, and compare them.

Methods: The study included 160 patients with FMF. Demographic and clinical data were recorded in the patients' form. The patients' disease severity were evaluated with International Severity Scoring System for FMF (ISSF) and The Second Set of FMF severity score (F-SS-2).

Results: A total of 160 patients, comprising of 106 males (66.3%) and 54 (33.8%) females with a mean age of 33.5 ± 12.2 years were evaluated. Mean disease duration was 16.6 ± 10.3 years. Other demographic and clinical characteristics of the patients were shown in Table 1. According to ISSF, 67 (41.9%) patients were classified as having mild disease, 80 (50.0%) patients as intermediate disease and 13 (8.1%) patients as severe disease. On the other hand, 59 (36.9%) patients were classified as having mild disease, 41 (25.6%) patients as intermediate disease and 60 (37.5%) patients as severe disease according to F-SS-2 score. Higher rates of patients were found having severe disease according to F-SS-2 compared with ISSF (p<0.001). Also, lower rates of patients were scored as having intermediate disease with F-SS-2 compared with ISSF (p<0.001) (Table 2).

Clinical phenotypes of IgG4-related disease

A literature review and meta-analysis of different clinical phenotypes were described in a multinational and ethnically variable cohort. The review aimed to identify how the clinical presentation of IgG4-related disease (IgG4-RD) may help clinicians improve disease management.

**Background:** Knowing the regional phenotypes of IgG4-RD is crucial. The influence of race could modify the clinical presentation of IgG4-RD. Knowing the regional phenotypes of IgG4-RD may help clinicians improve disease management.

**Methods:** A systematic review and meta-analysis of 160 English-speaking studies including 95 retrospective case series, 14 prospective case series, and 3 systematic reviews were included. The patients were from three continents: Africa, Asia, and Europe.

**Results:** Among the 160 included studies, the majority was retrospective (80.6%). The representation of each clinical phenotype was: HBP 14%, RA 25%, HNL 19%, MIK 6%, and systemic 7%. Forty-two patients (42%) had elevated serum IgG4. The most commonly involved tissues were: retroperitoneum (35%), lymph nodes (19%), head and neck (18%), salivary glands (16%), and pancreas (14%).

**Conclusion:** The Spanish IgG4-RD population was mainly ethnically Caucasian (86%), followed by African/Middle Eastern (5%). Men were predominant in all groups (71, 84, 70, and 70%). The representation of each clinical phenotype was: HBP 14%, RA 25%, HNL 19%, MIK 6%, and systemic 7%.

**FREQUENCY, CHARACTERISTICS AND CLINICAL DETERMINANTS OF “PRODROME” IN FAMILIAL MEDITERRANEAN FEVER PATIENTS**

Hakan Babaoglu, Nuh Atas, Ozkan Varan, Hasan Satıç, Reyyhan Bilici Salman, Aslıhan Avanoglu Güler, Hasan Karadeniz, Beran Goker, Seminur Hazez Daroglu, Mehmet Akıl Oztürk, Abdukhrameh Tufan, Gazi University Faculty of Medicine, Department of Internal Medicine Rheumatology, Ankara, Turkey.

**Background:** Prodrome was defined by the presence of manifestations that precede an FMF attack and predict its emergence. This period might be turned to a window of the opportunity for the prompt treatment of impending attacks with fast-acting IL-1 inhibitors.

**Objectives:** To determine the frequency, characteristics and clinical determinants of prodrome in patients with FMF.

**Methods:** 401 FMF patients were enrolled in this cross-sectional study. We applied a questionnaire to the FMF patients about attack types, prodrome manifestations and latent time. Four hours was accepted as the cutoff point for prodrome as described in the literature, which is compatible with the pharmacokinetics of anakinra.

**Results:** The mean age was 37.7 ±11.0 years, and the disease duration was 20 years (3-58). 248 of the patients (61.8%) were female. MEFV gene mutations were achieved in 364 (90.8%) patients, of these 121 (30.2%) patients harbored homozygous exon 10 mutations. Patients with a latent time over four hours considered as prodrome positive (PP) patients (n=141). Male gender, homozygous MEFV mutations, peritonitis, pleuritis, and ELE were more pronounced in PP group. 25.9% of patients with peritonitis, 14.7% of patients with pleuritis, 13.2% with arthritis, and 5.5% with ELE had prodrome with variable latent time durations (median, 6.7-42), (6-48), (6-472), and 7.7 (4-30) hours, respectively.

Prodrome was found to be more common in those with peritonitis. Male gender, having peritonitis or arthritis were found to be the independent clinical determinants of having prodrome (RR 1.72 (1.07-2.76), P=0.02, 4.27 (1.80-10.1), P<0.001, 1.77 (1.04-3.04), P=0.04, respectively). Age, MEFV mutations, pleuritis and ELE were not found as clinical determinants of prodrome.

**Conclusion:** Especially male patients with peritonitis or arthritis tend to have prodrome more than other patients, and should be questioned. Prodrome positive patients are candidates for prevention of the impending attacks with on-demand treatments.

**CLINICAL PHENOTYPES OF IG4-RELATED DISEASE IN SPAIN**

María Toledano-Macías1, Andreu Fernandez-Codina2, Igor Carballo2, Borja De Miguel-Campo2, Luis Sáez-Comet5, José Hernández-Rodríguez5, María Álvarez-Morillo4, Blanca Pinilla1, Fernando Martínez-Vallés2, Registro Español de Enfermedad Relacionada con la IgG4 (REERIGG4) GEAS/SEMI. 1Gregorio Marañón Hospital, Internal Medicine, Madrid, Spain; 2Western University, Rheumatology and Internal Medicine, London, Canada; 3Hospital Clínico Universitario de Santiago, Medicina Interna, Santiago de Compostela, Spain; 4Hospital 12 de Octubre, Internal Medicine, Madrid, Spain; 5Hospital Universitario Miguel Servet, Internal Medicine, Zaragoza, Spain; 6Hospital Clinic, Autoimmune Diseases, Barcelona, Spain;

**Background:** Recently, several clinical phenotypes in IgG4-related disease have been described in a multinational and ethnically vary cohort. The objective of this study was to assess the clinical presentation of IgG4-related disease (IgG4-RD) in Spanish patients and assess the distribution among different clinical phenotypes.

**Methods:** Clinical data were obtained from the Spanish IgG4-RD registry (REERIGG4) from October 2013 to December 2018, including 9 centers. We reviewed demographic data and organ involvement. The assignment of clinical phenotypes was done by 2 experts, based on organ involvement and clinical manifestations, following Wallace et al. subsets. The phenotypes were: pancreatico-hepato-biliary (HPB), retropertioneum and aorta (RA), head and neck limited (HNL) and Misulciz and systemic (MS).

**Results:** The representation of each clinical phenotype was: HNL, followed by RA. The HBP phenotype was less frequent than in previous reports. The influence of region could modify the clinical expression of IgG4-RD. Knowing the regional phenotypes of IgG4-RD may help clinicians improve disease management.

Background: Familial Mediterranean fever (FMF) is a disease with an onset before 20 years of age in 90% of the patients. However, late onset FMF defined as age of onset over 40 years is being recognised more frequently.

Objectives: To better define patients with FMF who had their first attack before age 40 and compare them with early onset patient group in Turkish population.

Methods: The files of 2180 FMF patients followed in a single center between 2008-2017 who have fulfilled Tel-Hashomer criteria, were reviewed with regard to age of onset 40 years and over (index patients, Group 1). For control purposes files before and after the index patients were browsed and first patients with an onset before age 20 years (Group 2) were included. The demographic, clinical and genetic characteristics are compared between these 2 subgroups.

Results: Patients with an onset after 40 years consisted 2.7% of our FMF population. 50 of the 59 patients with an onset 40 years or over were re-evaluated and compared with early onset group consisting of 100 patients (Table 1). The delay in diagnosis, and disease duration were significantly longer and number of patients with M694V homozygosity and M694V allele frequency were significantly more frequent among group 2. In general, phenotypes of both onset groups were similar, the only significant differences being the frequency of fever and myositis which were less common among group 1. Also response to colchicine was more pronounced in group 1. One other interesting observation was the low incidence of amyloidosis in a group with such a significant delay in diagnosis and thus treatment.

Conclusion: FMF should be included among the differential diagnosis of patients over 40 years of age with recurrent autoinflammatory manifestations. Less than 3% of FMF patients experience their first attacks after 40 years of age. The frequency of M694V is significantly less in the late onset group, pointing out a milder disease.

Disclosure of Interests: None declared

Objectives: To identify predictors of relapse of IgG4-RD after induction therapy.

Methods: We retrospectively reviewed 57 patients diagnosed with IgG4-RD and treated with GC in our hospital between January 2004 and November 2018. Clinical features at baseline, including organ involvement and blood markers (total hemolytic complement [CH50], its fractions [C3 and C4], IgG4, IgG, IgE, anti-nuclear antibody, rheumatoid factor, C-reactive protein, soluble interleukin-2 receptor, eosinophil) were collected. We divided patients into 2 groups on the basis of clinical features and examined whether they relapsed. In this study, hypocomplementemia was defined as decreased serum C3, C4, or CH50 less than the lower limit of normal. A relapse was defined as any new or worsened state of disease activity that required an escalation in treatment (immunosuppressants and/or GC). The follow-up period was defined as 182 days.

Results: Forty-three men and 14 women (mean age 68.1 ± 10.9 years) were included. Both serum IgG4 and IgG were measured at baseline in all patients (mean IgG4 798.8 ± 873.1 mg/dL and mean Ig 2874.0 ± 1934.1 mg/dL, respectively). All of the serum C3, C4, and CH50 were measured at baseline in 34/57 patients (mean C3 75.7 ± 33.3 mg/dL; mean C4 14.8 ± 11.5 mg/dL; and mean CH50 37.0 ± 23.1 U/mL). Fifteen patients had at least one episode of hypocomplementemia, and 19 patients did not. Most patients had multiple organ lesions. The details of dominant lesions were as follows: Dacryoadenitis and/or sialadenitis (Mikulicz disease), 36/57 patients (63.2%); biliary or pancreatic lesion, 29/57 (50.1%); retroperitoneal fibrosis, 22/57 (38.6%); and renal lesion 16/57 (28.1%). All patients were given prednisolone and gradually reduced (mean induction dose 31.7 ± 9.8 mg/day). No patients received immunosuppressive agents. The follow-up period was defined as 182 days. Relapsed lesions were as follows: Mikulicz disease, 3/6 patients (50.0%); biliary or pancreatic lesion, 1/6 (16.7%); retroperitoneal fibrosis 1/6 (16.7%); and pulmonary lesion 1/6 (16.7%). Patients with hypocomplementemia had significantly shorter relapse-free survival than those without (p=0.039, Figure 1). Patients with decreased serum C4 or CH50 (less than the lower limit of normal) also had significantly shorter relapse-free survival than those without, but those with decreased serum C3 did not. Such a tendency was not seen in other blood markers (IgG4, IgG, IgE, anti-nuclear antibody, rheumatoid factor, C-reactive protein, soluble interleukin-2 receptor, eosinophil).

Conclusion: Hypocomplementemia at baseline in patients with decreased serum C4 or CH50 may predict relapse of IgG4-RD after prednisolone therapy.

CLINICAL AND GENETIC FEATURES OF CHINESE ADULT PATIENTS WITH TUMOR NECROSIS FACTOR RECEPTOR-ASSOCIATED PERIODIC SYNDROME

Mengzhu Zhao, Yi Luo, Min Shen, Di Wu, Wen Zhang, Xiaofeng Zeng. Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Key Laboratory of Rheumatology and Clinical Immunology, Ministry of Education, Beijing, China

Background: Tumor Necrosis Factor Receptor-Associated Periodic Syndrome (TRAPS) is an autosomal dominant autoinflammatory disease, associated with the mutation of tumor necrosis factor superfamily member 1A (TNFRSF1A) gene, located on chromosome 12p13. TRAPS is usually diagnosed during pediatric age. However, adult-onset disease or diagnosis during adulthood has been occasionally described. Moreover, TRAPS has been hardly reported in the Chinese population. Herein, we aimed to characterize the clinical and genetic features of Chinese adult patients with TRAPS.

Objectives: Adult patients (≥16 years) suspected monogenic autoinflammatory diseases during the period April 2015 to October 2018, at the adult autoinflammatory disease center, Department of Rheumatology, Peking Union Medical College Hospital (PUMCH).

Methods: Clinical data were evaluated. Gene sequencing was performed in each patient to support the diagnosis and exclude other monogenic autoinflammatory diseases. Finally we compared the data with those from Japan and Europe.

Results: During the study period, 8 patients with TRAPS were diagnosed and followed-up. The ratio of male to female was 3:1. The median age of disease onset was 4 (0.5–38.5), and adult-onset was observed in 2 (25%) patients. The median time of diagnosis delay was 17.8 (1.5-50.5) years. There were seven Chinese Han and one Manchu patients. One patient had a family history of TRAPS. The most frequent symptom was fever (8, 100%). The attacks of 5 (62.5%) patients lasted more than 1 week, and the intervals of 7 (87.5%) patients were longer than 2 weeks. Skin involvement occurred in 6 (75%) patients, with maculopapular mentioned in 6 and erythema annulare presented in 3. Four (50%) patients had articulargia, while one had polyarthritis. 4 (50%) patients complained respectively of myalgia or headache. 4 (50%) patients experienced abdominal pain and one (12.5%) had vomiting. One (12.5%) patient had periorbital edema, while 3 (37.5%) had conjunctivitis. Up to 5 (62.5%) patients got nonspecific pharyngitis. No patient suffered from chest pain or amyloidosis. Eight gene variants were detected in TNFRSF1A gene. Heterozygous gene variants were found in 7 Chinese Han patients, and homozygous (c.769-23, T>C) happened to the Manchu patient. The variants included C58 (exon 2), G65E (exon 3), F298L (exon 3), C99G (exon 3), V202G (exon 6), c.769-23T>C (IVS8), S290I (exon 9) and m.1735A>G (non-coding region). NSAIDs were given to 2 patients, glucocorticoid or immunosuppressive agents given to 3 patients respectively, and etanercept to 5 patients. A complete response was found in all the 5 patients received etanercept. The effectiveness of other drugs were 50% in NSAIDs, 66.7% in glucocorticoid and immunosuppressive agents.

Conclusion: This is the first and largest case series of TRAPS in Chinese adult patients. It highlights the importance of screening TNFRSF1A gene in patients with unexplained periodic fever syndrome. Four novel TNFRSF1A variants, S290I, F298L, V202G and m.1735A>G in non-coding region, have been identified. The atypical clinical manifestations of our patients compared to those from Europe might be related to their low-incidence in the Chinese population.
Diagnostics and imaging procedures

Marta Mazzoni1,2, Silvia Merlo1, Angela Pistorio2, Stefania Viola2, Alessandro Consolaro1,2, Angelo Revelli1,2, Clara Malattia1,2. 1Università degli studi di Genova, Genova, Italy; 2IRCCS Istituto Giannina Gaslini, Clinica Pediatrica e Reumatologia, Genova, Italy; 3IRCCS Istituto Giannina Gaslini, Epidemiologia e Biostatistica, Genova, Italy.

Background: remission is becoming a realistic target in JIA, but clinical remission (CR) may not accurately reflect real absence of synovitis. It would be desirable to have instruments to predict the risk of relapse in patients in CR in order to establish the most appropriate therapeutic strategy. Despite in RA the role of imaging to predict disease flare is established, this field has remained almost unexplored in JIA.

Objectives: 1) to investigate the prevalence of musculoskeletal ultrasound (MSUS)-detected subclinical synovitis in JIA patients in CR; 2) to establish which and how many joints should be scanned to reliably assess remission; 3) to evaluate the persistence of subclinical synovitis over the time; 4) to investigate whether subclinical synovitis entails a risk of disease flare; 5) MSUS data will be integrated with serum levels of inflammatory biomarkers to develop a multidimensional measure of remission.

Methods: it is a longitudinal prospective 4 years study started on November 2017. So far we have enrolled 99 consecutive JIA patients who met the Wallace criteria for CR. For each patient 46 joints were scanned for synovial hyperplasia/joint effusion and PD signal, all graded semiquantitatively on a 0–3 scale independently by 2 expert ultrasonographers. Subclinical synovitis was defined when total synovitis score for each joint was ≥2. MSUS was performed at baseline and at 6 month follow up visit. At inclusion serum assays have been stored to determine levels of inflammatory biomarkers (S100A8/9-A12, bFGF, IL-6, IL-10, CXCL9-10, VEGF, YKL40). A flare of synovitis was defined as a recurrence of clinically active arthritis.

Results: 99 patients (79.8% F; median age 11.3 y; median disease duration 5.3 y; median CR duration 1.6 y) were included. Thirty-eight/99 (38.4%) patients had persistent oligoarthiritis; 34/99 (34.3%) extended oligoarthiritis; 22/99 (22.2%) polyarthiritis; 5/99 (5.1%) systemic arthritis. Fifty-nine/99 (59.6%) patients were in CR on medication. Subclinical synovitis was detected in 54/99 (54.5%; 95% CI: 45.2–65.5%) patients, PD in 18/99 (18.2%; 95% CI: 11.1–27.2%) patients; subclinical tenosynovitis in 7/99 (7.1%; 95% CI: 2.9–14%) patients. Subclinical synovitis was found more frequently in the ankle [31/54 (57.4%) patients] and wrist joints [17/54 (31.5%) patients]. No patients had subclinical synovitis in the hip. A 14-joint reduced count including bilateral knee, ankle (tibiotalar, subtalar and talonavicular joints), wrist (radiocarpal and intercarpal joints) and elbow joints, detected 92.6% of children with subclinical synovitis. Twenty-five/99 (25.2%) patients in persistent CR were reassessed with MSUS at a follow up visit (median follow up duration 7 months): 82.3% of patients showed persistent subclinical synovitis. Sixty-four/99 (64.6%) patients had a clinically follow up of at least 6 months and 9/64 (14%) patients experienced a disease flare (median time to flare 6.6 months). Six/9 (66.7%) patients who experienced a relapse had subclinical synovitis at baseline.

Conclusion: our preliminary results confirm the discrepancy between clinical and imaging remission and that clinical evaluation may not sensitive to detect an inflammation-free state. Bilateral US assessment of the elbow, wrist, knee and ankle joints is reliable to detect subclinical synovitis. So far, patients who have relapsed are a small percentage, but to extend follow up is crucial to test predictive value of MSUS. Imaging findings will be combined with serum biomarkers leading to the construction of a predictive model.
Background: The evaluation of structural damage with plain radiography is important to clinicians and patients. Standard scoring methods include the Sharp-van der Heijde (SVdH) and Ratingen methods [1] however these systems are time-consuming. Therefore, it is difficult to perform large cohort studies. We set out to develop an automated algorithm to identify bones on plain radiographs as a step towards developing automated quantification of structural damage for use on large datasets.

Objectives: To develop a novel algorithm to segment outlines of finger bones in hand radiographs.

Methods: 101 hand radiographs were gathered from the Bath longitudinal cohort (UK). All patients fulfilled the CASPAR criteria for Psoriatic Arthritis (PSA). None of the patients had damage on SVdH and Ratingen scoring (blinded). The metacarpal (MC), proximal phalanx (PP), middle phalanx (MP), and distal phalanx (DP) in the right index finger were delineated by a rheumatologist. These outlines were used to build a statistical model of the shape using a Gaussian Process Latent Variable Model (GPLVM) [2]. Bones are segmented by matching the shape on a radiograph to the statistical model.

Results: The performance of the matching algorithm was compared with a traditional algorithm (snakes) using the Adjusted Rand Score (ARND). The ARND score measures the similarity of the segmentation with the ground truth. A perfect segmentation has a score close to 1. We tested the algorithm on 9 PP, 9 MP and 8 DP and 6 MC bones in the right hand. The results are reported in Table 1. We report a mean improvement in ARAND of 0.19, 0.87, 0.43 and 0.30 for the PP, MP, DP and MC respectively.

Conclusion: We report a reliable algorithm for the identification of metacarpal, proximal, middle and distal phalanx bones of the hand. Future work will focus on using the output of the segmentation algorithm to track damage progression over time.

Key: Adjusted Rand Score (ARND) score measures the similarity of the segmentation with the ground truth. A perfect segmentation has a score close to 1. Metacarpal (MC), proximal phalanx (PP), middle phalanx (MP), and distal phalanx (DP)

Figure 1. Shape matching algorithm output demonstrating segmented outlines of the DP, MP, PP and MC in red, green, orange, and blue respectively.

THU0596

DEVELOPMENT OF AN AUTOMATED SEGMENTATION ALGORITHM TO IDENTIFY BONES OF THE HAND

Background: The evaluation of structural damage with plain radiography is important to clinicians and patients. Standard scoring methods include the Sharp-van der Heijde (SVdH) and Ratingen methods [1] however these systems are time-consuming. Therefore, it is difficult to perform large cohort studies. We set out to develop an automated algorithm to identify bones on plain radiographs as a step towards developing automated quantification of structural damage for use on large datasets.

Objectives: To develop a novel algorithm to segment outlines of finger bones in hand radiographs.

Methods: 101 hand radiographs were gathered from the Bath longitudinal cohort (UK). All patients fulfilled the CASPAR criteria for Psoriatic Arthritis (PSA). None of the patients had damage on SVdH and Ratingen scoring (blinded). The metacarpal (MC), proximal phalanx (PP), middle phalanx (MP), and distal phalanx (DP) in the right index finger were delineated by a rheumatologist. These outlines were used to build a statistical model of the shape using a Gaussian Process Latent Variable Model (GPLVM) [2]. Bones are segmented by matching the shape on a radiograph to the statistical model.

Results: The performance of the matching algorithm was compared with a traditional algorithm (snakes) using the Adjusted Rand Score (ARND). The ARND score measures the similarity of the segmentation with the ground truth. A perfect segmentation has a score close to 1. We tested the algorithm on 9 PP, 9 MP and 8 DP and 6 MC bones in the right hand. The results are reported in Table 1. We report a mean improvement in ARAND of 0.19, 0.87, 0.43 and 0.30 for the PP, MP, DP and MC respectively.

Conclusion: We report a reliable algorithm for the identification of metacarpal, proximal, middle and distal phalanx bones of the hand. Future work will focus on using the output of the segmentation algorithm to track damage progression over time.

DIAGNOSTIC VALUE OF ULTRASOUND AND DUAL ENERGY COMPUTED TOMOGRAPHY TO ACHIEVE ACR-EULAR GOUT CLASSIFICATION CRITERIA IN REAL LIFE CLINICAL PRACTICE

André Raman1, Marie Schmitt1, Romaric Ne2, Pierre Emmanuel Berthod3, Hervé Devilliers3, Jean Francis Maillefert3, Paul Ornetti3, André Ramon1, Marie Schmitt1, Romaric Ne2, Pierre Emmanuel Berthod3, Hervé Devilliers3, Jean Francis Maillefert3, Paul Ornetti3. DOI: 10.1136/annrheumdis-2019-eular.589

Background: 2015 ACR/EULAR gout classification criteria (1) include ultrasound with double contour (DC) sign as key ultrasound features and dual energy computed tomography (DECT) with evidence of urate deposition. The positivity of either DECT or ultrasound allows 4 points in addition to others clinical and biological criteria to classify as gout is ≥8/23. However, in routine care, the imaging modality that should be promoted remains unclear between ultrasound or DECT.

Objectives: To validate a possible diagnostic algorithm for the clinical use of DECT and ultrasound in suspected gouty arthritis.

Methods: We conducted a single-center prospective study in the Rheumatology Department of Dijon University Hospital from July 2016 to December 2018, including all patients hospitalized for suspected gouty arthritis. Each patient received joint aspiration if possible, an ultrasound assessment (DC sign and/or tophus) and DECT scanning of symptomatic joints. All these examinations were performed blind of the clinical data and results of joint aspiration. The gold standard used for this study was the 2015 ACR/EULAR gout classification criteria. We have established two
US examinations of the IMT at both common carotids were performed by a rheumatologist expert in US, using a linear probe and an automatic method (cIMT) based on the radio-frequency technology. For the IMT, a cut-off point of 0.8 mm was adopted, according Mannheim cIMT Consensus.

Results: A total of 684 common carotids were assessed. In 65 (47.10%) out of the 138 patients with gout and 50 (47.62%) out of the 105 patients with asymptomatic hyperuricemia, US detected an increased cIMT and only 9 (0.09%) of the control group patients had an increased cIMT (p=0.0001). The regression analysis found a significant positive correlation between increased cIMT and disease duration in gout group (p<0.001) and between the level of uric acid and increased cIMT in asymptomatic hyperuricemic patients (p=0.009). No significant correlation was found with the other clinical and laboratory parameters. There was a significant difference in cIMT between in gout and control groups (p=0.0001) and between asymptomatic hyperuricemia and control group (p=0.0001).

Conclusion: Our results demonstrate that patients with gout and hyperuricemia without clinically evident cardiovascular disease have a high prevalence of atherosclerosis represented by the increased cIMT.

Disclosure of Interests: None declared

age and sex group). DECT has high sensitivity, specificity and diagnostic accuracy in detection of MSU coronary deposits and can be used as a feasible, quick, low dose and low risk screening tool to detect coronary gout. DECT cardiac scans should be included in the routine CT gout protocol. Performing CT Calcium score using dual-energy has the added value of coronary gout detection as part of cardiovascular risk assessment and workup.

THU0599

RESOLUTION OF VASCULAR INFLAMMATION IN PATIENTS WITH GIANT CELL ARTERITIS RECEIVING GLUCOCORTOICOIDS, METHOTREXATE OR TOCILIZUMAB TREATMENT-DATA FROM THE ITALIAN/GERMAN RIGA STUDY

Verena Schönau1, Jessica Roth1, Koray Tasciilar1, Jürgen Rech1, Daniela Schmidt1, Torsten Kuwert1, Filippo Crescentini2, Luigi Boiardi2, Massim Iliano Casali2, Annibale Versari2, Georg Schett1, Carlo Salvarani2, Francesco Muratore2.

1Friedrich Alexander University Erlangen-Nuremberg, Erlangen, Germany; 2Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy.

Background: 18F-FDG-PET/CT is a sensitive and comprehensive technique to diagnose giant cell arteritis (GCA) (1). This technique may be also very useful to test whether vascular inflammation in GCA has disappeared or not, judging effectiveness of anti-inflammatory treatment. However, the role of 18F-FDG-PET/CT in monitoring disease activity and judging disease remission is less well-established to date.

Objectives: RIGA is an observational 2-center study that addresses the resolution of vascular inflammation in patients with new-onset GCA that are treated with either glucocorticoid monotherapy (GLC), GLC/methotrexate (MTX) or GLC/tocilizumab (TOC).

Methods: Patients with newly diagnosed GCA with large vessel involvement were clinically documented, subjected to sequential 18F-FDG-PET/CT scanning and received treatment with GLC, MTX or TOC upon physicians’ decision. Images were graded as active, questionable active and inactive according to nuclear medicine physician opinion and additionally graded by PETVAS score proposed by Grayson et al. (0-27) (2). We performed a mixed effects linear regression analysis to estimate the change in the PETVAS score adjusted by baseline CRP level and tested for treatment group interactions. We compared the proportion of radiologic activity states according to the activity tracer uptake in the follow up 18F-FDG-PET/CT scan in three treatment groups with a chi-squared test.

Results: We included 48 patients (n=20 from Germany, n=28 from Italy) with a mean age of 66 years. At baseline 18F-FDG-PET/CT scan was graded active in 46 patients while it was graded as questionable active in the remaining 2 patients. The mean CRP level was 66.8 mg/L (min 1.2; max 233.2 mg/l) and the mean PETVAS score was 21.1 (min=10 max=27). 12 patients received GLC, 27 MTX and 9 TOC as primary treatment. Follow-up PET/CT scans were graded as active in 11, questionable in 16 and inactive in 21 patients. The mean CRP level at follow up was 12.4 mg/l (min 0.2; max 76.0) and the mean PETVAS score was 9.1 (min 0, max 27) with significant decreases in all 3 groups. The mean adjusted improvement in the PETVAS score (95%CI) was 13.0 (8.7 – 17.3) in GLC, 11.7 (8.9 – 14.6) in MTX and 11.8 (6.8 – 16.7) in TOC groups and interaction terms for treatment effect were not significant. However, only 17% of patients who received GLC showed no vascular activity in their follow up PET-CT compared to 53% of patients who received MTX or TOC (figure 1).

Conclusion: GLC, MTX and TOC significantly reduced vascular inflammation in GCA, but no significant differences between the three treatment strategies was found in this yet small population. However, when looking at complete resolution of vascular inflammation, MTX and TOC appear as being superior to GLC monotherapy, suggesting that addition of these agents right from the beginning of treatment of GCA may be beneficial to achieve complete control of vascular inflammation.

QUANTITATIVE INDEXES TO ASSESS THE INTERSTITIAL LUNG DISEASE, AND ITS EXTENSION, IN SJÖGREN’S SYNDROME

Pablo Guijado-Vargas1,2, Mario Silva2, Miguel Angel Duarte-Millán2, Gianlucia Sambatoni2, Chiara Bertolazzi2, Mauro Pavone2, Isabel Martin-Garrido2, Oriol Martin-Segarra1, José Manuel Luque-Pirulla1, Daniele Santilli3, Domenico Sambataro4, Sebastiano Emanuele Torrisi4, Vancheri Ada4, Irene Cecchi, Massimo Radin, Elena Rubini, Silvia Grazietta Foddai, Daniela Rossi, Savino Sciascia, Dario Roccatello.

Background: Intersitial lung disease (ILD) is the most frequent pulmonary impairment in Sjögren’s syndrome (SS). The diagnosis is challenging, as there are no standard tests (i.e. autoantibodies or pulmonary function tests) or symptoms. Chest CT is the gold standard. Semiquantitative visual scores (SQCT) estimate ILD extent, though burdened by relevant intra-, inter-rater variability. Quantitative chest CT (QCT) is a promising method to assess ILD severity.

Methods: in this multi-center, cross-sectional, and retrospective study, sub-intra-, inter-rater variability. Quantitative chest CT (QCT) is a promising method to assess ILD severity.

Results: 102 consecutive SS patients were enrolled. ILD prevalence was 36% (36/102). There was a difference in QCT indexes’ distribution in SS-ILD versus SS without ILD (p < 0.001). Moreover, SS-ILD patients with an ILD >20% (according to Goh score) had QCT indexes statistically different from those with a limited ILD extension (p<0.001). QCT indexes have a moderate to good correlation with Goh and Taouli scores (from 0.78-0.95) but size of vacuoles did not reveal significant differences in QCT indexes distribution were analyzed using non-parametric tests.

Conclusion: Different image parameters had different significance for representing the gland conditions. For parotid glands, fibrosis bands and hetero-ergenic structure were main parameters. For submandibular glands, fibrosis bands and size of vacuoles accounted for the change of glands. SQUS correlated with final pathology result.

THE ROLE OF INFRARED THERMOGRAPHY IN THE ASSESSMENT OF PERIPHERAL VASCULOPATHY AND IN THE THERAPEUTIC MANAGEMENT OF SYSTEMIC SCLEROSIS PATIENTS TREATED WITH SYNTHETIC PROSTANOIDS

Irene Cecchi, Massimo Radin, Elena Rubini, Silvia Grazietta Foddai, Danietta Rossi, Savino Sciascia, Dario Roccatello. University of Turin, Turin, Italy

Background: Skin lesions represent the leading feature of systemic sclerosis (SSc), with Raynaud’s phenomenon (RP) the most frequent and early clinical manifestation of the disease. Digital vasculopathy severely affects SSc patients, lowering their quality of life and negatively impacting on their daily functions. Digital ulcers is associated with poor cardiovascular prognosis and decreased survival rate [1]. Nevertheless, standardized treatment strategies and non-invasive tools for the management of RP and SSc skin manifestations are badly needed.

Objectives: The aim of this study was a) to evaluate the efficacy of infrared thermography in the assessment of peripheral vasculopathy in a cohort of SSc patients treated with cyclic intravenous infusions with synthetic prostanoids b) to identify those patients who might benefit from an intensified infusional treatment protocol with prostanoids.

Methods: Twenty-six SSc patients [2], attending our Department for their routinely 28-days apart intravenous therapy with prostanoids (iloprost) based on the presence of severe secondary RP and/or digital ulcers, were enrolled in this study. Thermographic evaluation of both hands were made at baseline (T0), and at days 14 and 28 after the first prostanoid infusion (named T1 and T2, respectively). Statistical analyses have been performed and a p-value <0.05 was considered statistically significant.

DISCLOSURE OF INTERESTS: None declared
The thermographic assessment showed a substantial stability of the temperature values when comparing T0 and T1 (mean differences of the right hands 0.4 ± 5.6; mean differences of the left hands 1.2 ± 4.5), while they were significantly reduced when comparing T1 and T2 (mean differences of the right hands -3.1 ± 9.3, p=0.049; mean differences of the left hands -3.4 ± 8.5, p=0.012 respectively) (Figure 1A). When stratifying according to clinical manifestation, a higher differences in temperature variations were observed between T1 and T2 in SSc patients with systemic involvement, when compared to those with limited cutaneous SSc (mean of the differences of the right hands -5.0 ± 11; mean of left-hands differences -4.9 ± 11.5 Vs. mean right-hands differences -2.5 ± 11; mean left-hands differences -3.2 ± 8.6; p=0.035 respectively) (Figure 1B).

Conclusion: Thermography could represent a reliable, non-invasive, manageable and cost-effective method for the assessment and monitoring of peripheral vasculopathy in patients with SSc. These data also show that SSc patients with systemic involvement could benefit more from an intensified infusion protocol with prostanoids compared to SSc patients with a limited skin form of the disease. Thermography has shown excellent potential to be a reliable and objective outcome measures to facilitate clinical trials of novel treatments SSc-related RP.

THU0603 SUITABILITY OF PET-CT IN REFRACTORY POLYMYALGIA RHEUMATICA

Maria Emilia Corica1, Patricia Moya2, Alejandro Fernandez2, Berta Magallanes2, Ignasi Gich1, Ana Milena Milan Arceiniegas, Hyesang Park2, Monica Paola Sarmiento2, Ana Laiz2, Cesar Diaz-Tomze, Josep Maria Llobet2, Ivan Castellvi2, Hector Corominas1, Hospital José N. Lencinas, Mendoza, Argentina; 2Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; 3Colmédica, Bogotá, Colombia

Background: Polymyalgia rheumatica (PMR) is characterized by pain in the shoulders and hips, elevation of acute phase reactants and a rapid response to treatment with corticosteroids. Currently, there is no specific test for its diagnosis, and it presents a wide differential diagnosis. Positron Emission Tomography - Computed tomography (PET-CT) is a non-invasive technique, capable of measuring metabolic activity by locating and quantifying glucose consumption. The use of PET-CT in the study of neoplastic, infectious or inflammatory processes suggests that it may be a suitable technique for the study of the differential diagnosis of patients with PMR. It is unknown if there are differences in the result of the technique in patients with debut PMR vs. patients with cortico-resistant PMR.

Objectives: To describe the findings of PET-CT in patients with PMR. To analyze if there are significant differences between the results of patients with onset PMR and those of cortico-resistant PMR patients.

Methods: This is a cross-sectional prospective study performed in a cohort of patients with PMR. Out of all patients with PMR who do follow up treatment in our centre, the patients selected for this study included those who underwent a PET scan at the time of diagnosis and those who presented corticosteroid resistance (patients who did not respond to conventional therapy with corticosteroids or with a relapse with doses <7.5mg/day of prednisone or equivalent). Demographic, epidemiological data of the disease, treatment, as well as analytical parameters (CRP, ESR, Hematological and Biochemical) were collected from all the patients at the time the PET-CT was performed.

For the categorical variables, the chi-square test or Fisher’s exact test were used, as appropriate. In the case of quantitative variables, we used the comparison of the mean values, by means of a “t” test. The level of statistical significance was established for those values of p <0.05.

Results: 163 patients with a PMR diagnosis who had undergone a PET-TC were included, out of the total number of patients that we visited in our service. 52 (50.4%) patients had an onset PMR and 51 (49.9%) had PMR refractory to treatment. The demographic, clinical and serological characteristics of the patients at the time of PET-CT are shown in Table 1.

The PET-CT showed a distribution of uptake compatible with the diagnosis of PMR in 73 (70.9%) patients, vasculitis of large vessels in 16
was completed, along with visual analog scale (VAS). Ultrasound assessment was carried out by a rheumatology physician who was blinded to any other information. CSA of the median nerve was measured at the level of the proximal third of the pronator quadratus muscle and the largest CSA within the carpal tunnel. The presence or absence of tenosynovitis, Doppler signal and a bifid median nerve were noted. Steroid injection was carried out under indirect ultrasound guidance with 20mg depomedrone. Follow-up assessment was carried out 12 weeks post-injection. Repeat ultrasound scan was performed to measure the CSA of the median nerve, as before. Repeat Boston Questionnaire and VAS were recorded. After the second assessment those who had not responded adequately were referred on for consideration of surgical release.

Results: 52 patients attended for initial assessment, with 47 patients reattending for follow up. 53% of patients were discharged at follow up; the remainder were referred for consideration of surgery. 78.9% of patients met the criteria for defining CTS with a median nerve CSA 0.1cm², with 77% meeting this at the entrance to the carpal tunnel, and 55.8% at the level of the pronator quadratus muscle. A bifid nerve was noted in 12 patients.

There was no statistically significant relationship between the initial size of the median nerve on ultrasound and the change in Boston score. There was a statistically significant correlation between a decrease in the size of the median nerve at the entrance to the carpal tunnel and an improvement in the Boston score (r=0.42, p-value 0.003). There was no correlation between change in median nerve measurement and final outcome (discharged or referred to surgery). There was no relationship between the degree of entrapment on NCS and pre-test Boston score. There was a significant change in the Boston score of 0.944 post-injection (95% CI 0.41-1.48, p-value 0.001). There was a statistically significant change in the VAS score of 9.87 post-injection (95% CI 0.78-18.95, p-value 0.03). No patients demonstrated evidence of surrounding tenosynovitis or positive power doppler signal.

Conclusion: There is an overall improvement in symptoms of CTS, based on the Boston questionnaire, following corticosteroid injection. There is a clear role for the use of ultrasound to confirm diagnosis of CTS in symptomatic patients by measuring the CSA of the median nerve at the entrance to the carpal tunnel. There are no definite ultrasound or clinical prognostic indicators of response to injection. References:

THU0605

SHEAR WAVE ELASTOGRAPHY MUSCLE STIFFNESS MAY DIMINISH AFTER CORTICOSTEROID TREATMENT

Abdulrahman M. Aljunied1,2, Allyn Tan2,3, Philip O’Connor2, Paul Emery2,3, Richard Wakefield2,3

1Princess Margaret Cancer Foundation, University of Toronto, ON, Canada; 2Rheumatology and Medical Imaging, Khar, Saudi Arabia; 3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: The use of corticosteroids is associated with several adverse effects including corticosteroid-induced myopathy (CIM). CIM may cause structural alterations to the myofibres, which support the hypothesis of altered muscle stiffness as seen in histological and preclinical studies. There is a significant change in the Boston score of 0.944 post-injection (95% CI 0.41-1.48, p-value 0.001). There was a statistically significant change in the VAS score of 9.87 post-injection (95% CI 0.78-18.95, p-value 0.03). No patients demonstrated evidence of surrounding tenosynovitis or positive power doppler signal.

Conclusion: There is an overall improvement in symptoms of CTS, based on the Boston questionnaire, following corticosteroid injection. There is a clear role for the use of ultrasound to confirm diagnosis of CTS in symptomatic patients by measuring the CSA of the median nerve at the entrance to the carpal tunnel. There are no definite ultrasound or clinical prognostic indicators of response to injection. References:

THU0604

CARPAL TUNNEL SYNDROME: CAN ULTRASOUND PREDICT RESPONSE TO STEROID INJECTION?

Cathy Donaghy1, Ashley Elliott1, Adrian Pendleton1, Claire Benson1, Kerry Aston1, Aidan O’Neill1, Mark Leith: None declared, Roger Stewart: None declared, Mark Leith: None declared, Colette Beattie: None declared

Background: Carpal tunnel syndrome (CTS) is the commonest nerve entrapment disorder of the upper limb. Diagnosis is often clinical, based on a suggestive history and physical examination. Neurophysiological studies correlate closely with clinical evaluation. The use of ultrasound has been evaluated, and a feature which consistently supports a clinical diagnosis of CTS is increased cross sectional area (CSA) of the median nerve within the carpal tunnel. Local injection with corticosteroid is generally accepted as the next step in those who remain symptomatic after conservative treatment with splinting and nonsteroidal anti-inflammatory drugs. If this is unsuccessful referral for consideration of surgery should be considered.

Objectives: To evaluate the utility of ultrasound in the assessment of CTS and identify predictors of response to injection.

Methods: Patients were recruited via primary care referrals to the rheumatology department. Inclusion criteria were age over 18 years, appropriate symptoms in the distribution of the median nerve for at least 3 months, and positive nerve conduction studies (NCS). Patients with evidence of tenar atrophy were excluded. At initial review a full symptom and medical history was taken. A Boston Carpal Tunnel Questionnaire

respectively (p<0.001). Muscle strength was generally preserved at follow-up. However, there were moderate to strong correlations (r= 0.54–0.96) between weaker muscle strength at follow-up and greater reduction in SWV.

**Conclusion:** The GCA patients showed a significant loss of muscle stiffness after 3 and 6 months of corticosteroid treatment. With further validation in larger samples, shear wave elastography may be useful for detecting subclinical CIM.

**CORRELATION BETWEEN ULTRASOUND AND STANDARD RADIOGRAPHY AND BETWEEN ULTRASOUND AND CLINICAL DATA IN RHEUMATOID ARTHRITIS**

**THU0607**

**PROLIFERATIVE GLOBULAR SYNOVITIS, A CHARACTERISTIC ULTRASONOGRAPHIC PATTERN OF SEROPOSITIVE RHEUMATOID ARTHRITIS**

Ana Belén Azuaga-Piríango, Beatriz Frade-Sosa, Roberto Gumucio, Katherine Cajiao, Stanislava Mandelikova, Raul Castellanos-Moreira, Virginia Ruiz, Raimón Sanmartí, Juan D. Cañete, Julio Ramirez. Hospital Clinic, Rheumatology, Barcelona, Spain

**Background:** Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) have a different ultrasound (US) patterns. Synovial changes are characteristic of RA patients and soft tissue changes are more frequently found in PsA. However, no previous studies have analysed if US findings differ between seropositive and seronegative RA patients.

**Objectives:** To analyse differences in the ultrasound pattern among patients with seropositive and seronegative RA. To assess if proliferative globular synovitis is characteristic of seropositive RA patients.

**Methods:** Retrospective Analysis. We collected clinical, epidemiological and ultrasound images of patients with RA who met American College of Rheumatology/European League Against Rheumatism 2010 criteria with bilateral carpal and hand ultrasonography carried out during the last five years. Synovial hyperechogenicity (SH) and Power Doppler signal (PD) in wrist and hand (1-5 metacarpophalangeal [MCP]) were evaluated. We calculated the SH score (sum of the SH degrees of each joint), PD (sum of the PD degrees of each joint) and the total score (sum of the score of SH and PD) for each patient. We also evaluated the presence of proliferative globular synovitis, defined as big synovial hyperechogenicity with exophytic growth and a convex upper limit.

**Results:** 145 RA patients were collected. 80% were women. Mean age was 59.06 (14.8) years and the mean time of disease evolution was 114.6 (112.8) months. 68.3% were RF positive and 74.5% ACPA positive. Overall, 115 of the 145 (79.3%) patients were seropositive for RF/ACPA. 53.1% had radiographic erosions. 73.1% used conventional synthetic Disease-modifying drugs (DMARDs), 29.7% biological therapy, and 57.2% low doses of corticosteroids (<5 mg prednisone). The mean DAS28 was 2.81 (1.14), the number of swollen joints was 3 (3.4), and the C reactive protein (CRP) was 0.99 mg/dl (1.6).

No significant differences between seropositive and seronegative patients in terms of disease activity (swollen joints count [SJC], tender joint count [TJC], CRP, DAS28), treatment (use of corticosteroids, DMARDs, biological), time of evolution or US scores (SH, PD and total scores) were found. Globular synovitis was present in 62% and 13.7% of seropositive and seronegative RA patients, respectively (p<0.0001). Globally, 75 (51.7%) out of 145 patients had “globular” synovitis by US (Figure 1). 71 out of 75 patients were FR/ACPA positive (94.6%). Only four patients with seronegative RA had this US pattern (p<0.0001). Furthermore, patients with “globular” synovitis had more erosions (72% vs 33%, p <0.0001), higher SJC (3.3 vs 2.5, p = 0.013) and higher SH and PD scores (p=0.0001).

**Conclusion:** The presence of proliferative globular synovitis was significantly associated with the presence of RF/ACPA in patients with RA. This US pattern identified a subgroup of RA patients with poor prognosis: more erosions and greater inflammatory activity both at clinical and ultrasound level.

CAPILLAROSCOPIC DIFFERENCES IN PRIMARY BILARY CHOLANGITIS WITH OR WITHOUT SCLERODERMA AND RAYNAUD’S PHENOMENON, A PRELIMINARY STUDY

Mayka Freire1, Sandra Martínez2, Bernardo Sopera3, Jago Carballo1, Esteban Otero1, Nestor Vazquez-Agra1, Ana-Teresa Marques1, Arturo González-Quintela1, 1Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain; 2Universidad de Santiago de Compostela, Santiago de Compostela, Spain; 3Hospital of Sun Yat-sen University, Guangzhou, China

Background: A high proportion of capillaroscopic alterations have been reported in patients with Primary Biliary Cholangitis (PBC) (1). Association with Raynaud’s phenomenon (RP) and/or scleroderma has been described in patients with PBC and Raynaud’s phenomenon (RP), possibility for antitopomerase antibodies (ACA) and overlap with another systemic autoimmune disease, the most frequent being Systemic Sclerosis (SSc) (association with a prevalence up to 17% of PBC patients called Reynolds Syndrome) (2). However, studies are scarce and not very detailed in terms of the differential capillaroscopic findings between patients with PBC with/without SSc and without RP.

Objectives: To analyze the differences between clinical, serological and capillary morphological alterations observed in three different groups of patients with PBC: patients with PBC alone (PBC-A), patients with PBC and RP (PBC-RP) and patients with Reynolds Syndrome (PBC-RS).

Methods: Pentagonal capillaroscopy was performed on 12 patients with PBC-A, 10 with PBC-RP and 13 with PBC-RS, who received follow-up in our systemic diseases and hematology monographic outpatient. Capillaroscopy was made with USB Digital Microscope Dino-Lite ® epiluminiscence video. The capillaroscopic alterations were according to a semiquantitative method. All patients were given a detailed clinical evaluation. Variables related to clinical, serological and capillaroscopic parameters were collected. A comparative study was done.

Results: Of the 36 patients analyzed, 32 (88.9%) were women, with no sex differences between the three groups. The median age at PBC diagnosis was 50 + -12.8 years in PBC-A group, 60.5 + -15 years in PBC-RP and 62 years in PBC-RS, showing significant difference between the first group and the other two (p = 0.012), 14 patients had other systemic diseases: 1 hemolytic anemia, 1 SLE, 2 Psoriasis, 1 PVI and 9 Sicca. The only clinical parameter with significant difference between the three groups was association with Sicca: 3 (25%) PBC-A, 5 (50%) PBC-RP and 12 (85.7%) PBC-RS, p 0.002. Twenty five (73.5%) patients had positive AMA, with no differences between the groups. All 11 patients who had ACA, were from the PBC-RS group. Statistically significant differences were observed between the capillaroscopic parameters were the presence of capillary dilatations [5 (41.7%) PBC-A, 5 (50%) PBC-RP, 11 (84.6%) PBC-RS, p 0.03] and pathological hemorrhages [1 (8.3%) in PBC-A, 2 (22.2%) PBC-RP, 11 (78.6%) PBC-RS, p <0.001] as well as the presence of a different capillaroscopic pattern (p <0.001): normal or nonspecific in 9 (75%) of PBC-A, 4 (44.4%) PBC-RP and 2 (15.4%) PBC-RS; connective tissue disease suggestive pattern in 3 (25%) of PBC-A, 5 (55.6%) of PBC-RP and 1 (7.7%) of PBC-RS; sclerodermiform pattern in 10 (76.9%) PBC-RS, and none of the other two groups. We did not find significant differences in the presence of simple tortuositities, complex tortuosities, branched capillaries or capillary loss. No capillaroscopic parameters correlated with other systemic diseases.

Conclusion: This preliminary study shows an evolutionary trend in some clinical (age at PBC diagnosis, sicca association) and capillaroscopic parameters (capillary dilatation, hemorrhages, general capillaroscopic pattern) in patients with PBC-A, PBC-RP and PBC-RS, which may suggest three different phenotypic expressions of the same pathogenic process.

ULTRASOUND AS A USEFUL TOOL IN THE DIAGNOSIS OF RHEUMATOID ARTHRITIS IN PATIENTS WITH UNDIFFERENTIATED ARTHRITIS

Marwin Gutierrez1, Chiara Bertolazzi2, Edwin Castillo3, Denise Clavijo Cornejo4, Luis Carlos Rodriguez Delgado5, Jaime Mendoza Torres6, Carlos Pineda6, Pedro Santos-Moreno6, 1Instituto Nacional de Rehabilitación Luis Guillermo Ibarra Ibarra, Division of Musculoskeletal and Rheumatic Diseases, Tiahapan, Mexico; 2Center of Rheumatoid Arthritis BIOMAB, Rheumatology, Bogota, Colombia; 3Instituto Nacional de Rehabilitación Luis Guillermo Ibarra Ibarra, Division of Musculoskeletal and Rheumatic Diseases, Mexico City, Mexico; 4Center of Rheumatoid Arthritis BIOMAB, Bogota, Colombia

Background: Nowadays, rheumatologists face challenges in finding an effective method to classify and treat patients with undifferentiated arthritis (UA). There is a need for new tools that could ensure accurate characterization of inflammatory processes in these patients.

Objectives: To investigate if a characterization of UA patients using US may help to fulfill the 2010 ACR/EULAR RA classification criteria in a real-life cohort.

Methods: We conducted a cross sectional study in two rheumatology care clinics. Patients not fulfilling the 2010 ACR/EULAR RA criteria were included. On the examination day, all patients underwent a physical examination, radiographs and US. The 7-joint US score (US 7) was adopted to scan all patients. US was performed according to EULAR criteria and interpreted by OMERACT definitions. Greyscale and power Doppler synovitis and tenosynovitis were scored. Bone erosions were also evaluated during the US examination.

Results: A total of 204 patients were included. The diagnosis was modified from UA to RA in 86 (42.1%) patients. The greater proportion of synovitis detected by US was the main parameter that allowed changing the diagnosis from UA to RA, and modified the final score of the 2010 ACR/EULAR classification criteria, from a mean (±SD) of 4.6 (0.5), by clinical examination, to 6.5 (0.6) by US. The changes in the score of the 2010 ACR/EULAR classification criteria were from score 4 to score 6 in 7% patients; from 4 to 7 in 24 (27.9%) patients; from 5 to 6 in 42 (48.8%) patients; from 5 to 7 in 5 (5.8%) patients and from 5 to 8 in 5 (5.8%) patients.

In addition to synovitis, a wide range of tenosynovitis and bone erosions were detected by US. Synovitis was more frequently detected in 2ndMCP followed by 2ndMTP and 5thMTP. The tendons of the wrist, 2nd and 3rd finger were the most affected. In relation to bone erosions, 2ndMCP and 5thMTP where the joints with more proportion of anatomical damage.

Conclusion: US demonstrated to be useful to help accurately classify UA patients previously diagnosed with UA.

ANALYSIS OF ANTINUCLEAR ANTIBODY ANTIBODIES POSITIVITY AND THEIR MAJOR KARYOTYPES IN PATIENTS WITH AUTOIMMUNE DISEASES AND HEALTHY SUBJECTS

Qiujing Wei1, Yutong Jiang, Jiwen Xie, Jun Qi, Jianguo Gu, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Autoantibodies, especially antinuclear antibodies (ANA), play an important role in the diagnosis and differential diagnosis of autoimmune disease (AID); disease monitoring, efficacy observation and pathogenesis research.

Objectives: Our aim was to investigate the rate of ANA positivity and their major karyotypes in different AIDs and healthy controls.

Methods: The distribution and positive rate of Antinuclear antibody (ANA) karyotypes detected by indirect immunofluorescence in 3704 patients with AID and 1073 healthy subjects were retrospectively analyzed.

Results: The positive rate of ANA in different AID groups was 90.7% (1845/2034) in SLE, 54% (525/973) in RA, 86.4% (267/309) in SS,
SERUM HIGHLY-SENSITIVE CARDIAC TROPONIN-I AND KNEE JOINT PAIN IN AN ELDERLY, HEALTHY
Arnd Kleyer1, Antonella Adinolfi2, Johann Williet3, Stefan Kiechl3, John Todd2, Matthew Budoff3.

We recently reported that serum levels of highly-sensitive cardiac troponin-I (hs-cTnI)- a specific structural myocardial biomarker- and independently predicted CAC progression in patients with RA. We here explored whether baseline evaluation of both hs-cTnI and a-b2GPI-IgA presence, high hs-cTnI independently predicts significant increase in coronary atherosclerosis burden.

Methods: Ninety five participants with a baseline plaque evaluation by coronary computed tomography angiography (CCTA) underwent follow-up assessment within 6.9±0.3 years. Coronary artery calcium (CAC) was demonstrated that presence of IgA antibodies against beta2-glycoprotein-1 (a-b2GPI-IgA, an apolipoprotein readily expressed in human atherosclerotic plaque) associated with baseline coronary artery calcium (CAC) scores and independently predicted CAC progression in patients with RA.

Objectives: We here explored whether baseline evaluation of both hs-cTnI and a-b2GPI-IgA better predicts CAC progression than either of them in isolation.

Methods: Ninety five participants with a baseline plaque evaluation by coronary computed tomography angiography (CCTA) underwent follow-up assessment within 6.9±0.3 years. Coronary artery calcium (CAC) was quantified by the Agatston method. Hs-cTnI and a-b2GPI IgA Ab were assessed on the day of baseline CCTA; the latter were reconfirmed 12 weeks later, if positive. CAC change was evaluated by the MESA method as the natural logarithm plus 25 difference [(ln CAC (follow-up)+25) – (ln CAC(baseline)+25)]. Generalized linear models evaluated the effect of hs-cTnI, a-b2GPI-IgA and their interaction on CAC change. Models were adjusted for age, hypertension, waist-to-height ratio (obesity indicator), cumulative inflammatory burden (time-averaged C-Reactive protein), total prednisone dose and duration of statin exposure from baseline to follow-up scan.

Results: Baseline cTnI was higher in a-b2GPI-IgA positive compared to negative patients [median (IQR) of 1.9 (1.3-1.7) vs. 1.4 (1.3-1.7) respectively, p=0.043]. Hs-cTnI alone did not independently predict CAC change (β=0.214, p=0.132) in the multivariable model whereas a-b2GPI-IgA presence did (β=0.454, p=0.003). There was a significant interaction between hs-cTnI and a-b2GPI-IgA on CAC progression (Wald Chi-square=4.19, p=0.041); high hs-cTnI (>1.5pg/ml) predicted significantly greater CAC change in a-b2GPI-IgA positive patients but not in negative ones [estimated marginal mean difference (IQR)=0.36 (0.12-0.59), p=0.03 and figure 1].

Conclusion: Baseline hs-cTnI in isolation is not predictive of CAC progression in patients with RA; however, in the context of a-b2GPI-IgA presence, high hs-cTnI independently predicts significant increase in coronary atherosclerosis burden.

THU0611

ERYTHROCYTE ANIONIC MEMBRANE PROTEINS ARE ASSOCIATED WITH AGING AND AGING-ASSOCIATED PATHOLOGY IN THE KNEE JOINTS

George Karpouzas1, Sarah Ormseth1, Elizabeth Hernandez2, Joel Estis2, John Todd1, Matthew Budoff2, 1Harbor UCLA Medical Center, Rheumatology, West Carson, United States of America; 2Singulex, Inc., Alameda, United States of America

Background: Aging is associated with decreased muscle strength and diminished quality of life. As aging occurs, knee pain may increase due to OA. The knee is the most commonly involved joint in OA, and it is the primary location for aging-associated pathology which is related to OA pain.

Objectives: To determine the relationship between erythrocyte anionic membrane proteins and knee pain in older individuals.

Methods: 55 volunteers ages 65-84 years were divided into two groups; (1) individuals with knee pain and (2) individuals without knee pain. Erythrocyte anionic membrane proteins were measured using a multiplex immunoassay system.

Results: Individuals with knee pain had significantly higher levels of erythrocyte anionic membrane proteins compared to individuals without knee pain.

Conclusion: Erythrocyte anionic membrane proteins may be a potential biomarker for knee pain in older individuals.

Disclosure of Interests: None declared.

THU0612

KNEE JOINT PAIN IN AN ELDERLY, HEALTHY POPULATION IS ASSOCIATED WITH INFLAMMATORY ARTICULAR AND ENTHESEAL CHANGES DETECTED BY ULTRASOUND

David Simon1, Arnd Kleyer1, Antonella Adinolfi2, Johann Willeit2, Stefan Kiechl2, Nina Gasperi3, Georg Schett4, Christian Dejaoc5, Annamaria Iagnocco5, Maria-Antoinetta D’Agostino6, Friedrich-Alexander University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany; 7University of Siena, Department of Rheumatology, Policlinico Le Scotte, Siena, Italy; 8Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria; 9Department of Rheumatology, Hospital of Bruneck, Bruneck, Italy; 10Department of Rheumatology and Immunology, Medical University Graz, Graz, Austria; 11Department of Rheumatology, Hospital of Bruneck, Bruneck, Italy; 12Department of Rheumatology, Hospital of Innsbruck, Department of Neurology, Innsbruck, Austria

Background: Knee pain is highly prevalent in elderly and influences quality of life. Pathogenesis of knee pain in such population is commonly related to osteoarthritis (OA). It is yet unclear however, which pathological lesions in the knee contribute most to symptomatic disease.

Objectives: To define the articular and enthesal inflammatory and structural changes that contribute to knee pain in an elderly healthy population using Power Doppler ultrasound (PDUS).

Methods: All subjects (≥65 years) were part of the prospective long-term population-based Bruneck Study (1) and received a clinical and ultrasound investigation of both knees. Ultrasound was performed by an independent investigator unaware of clinical symptoms. Knee entheses (quadiceps insertion, proximal and distal patella insertion) and joint cavity were assessed. Demographic variables were recorded in all individuals. Pain sensation during knee palpation was collected and participants were asked to complete a standardized pain questionnaire for knee joints (Knee injury and osteoarthritis outcome score [KOOS], question P1-P9). Joint changes (synovial hypertrophy, power doppler [PD] signal, joint effusion, baker cysts, osteophytes) were assessed using a GE Logic E

Disclosure of Interests: None declared.

MRI AND ULTRASOUND (US) ASSESSMENT OF both TMJ inflammation and damage 3 but US is a widely used diagnostic tool in rheumatic patients as well as hypoechogenecity were also recorded. All ultrasound abnormalities were scored using validated OMERACT scores. The prevalence of observed changes was compared between subjects without palpation and patients with pain. By summing up the articular and enthesal changes a total score was calculated and correlated with the KOOS pain values.

Results: A total of 303 (Male 154; Female 149) aged participants (age: 75.3±6.9 years) underwent ultrasound examination of both knees. Knee tenderness was found by 30/149 (20.1%) women and 15/154 (9.7%) men. Ultrasound effusion (p=0.010), synovial hypertrophy (p=0.001), PD synovial activity (p=0.003) and osteophytes (p=0.001) were more prevalent in women with knee tenderness than without. In men, knee tenderness was associated PD synovial activity (p=0.0014), and enthesal calcification (p=0.0002). Presence of more than 1 ultrasound pathology was associated with lower KOOS pain values, indicating higher impact on symptoms. This was observed in both women (r=-0.285, p=0.021) and men (r=-0.298, p=0.008).

Conclusion: In an elderly healthy population, knee pain is associated with the presence of joint and enthesal inflammatory lesions.

Table 4: There was agreement between MRI and US regarding joint effusion and metatarsophalangeal (MTP) joints (2-5) and MCP (1-5) joints.

Conclusion: The concordance between MRI and ultrasound is not optimal, and existing TMJ US protocols are based on children. Further studies are needed to develop a suitable US protocol to detect TMJ involvement in adult patients as a screening tool.
Results: Sixty-two consecutive ERA patients and 34 CTR were included in this study. Mean age and gender distribution were comparable between ERA and CTR (47.3±14.5 vs. 43.4±12.5). ACPA were present in 61%, rheumatoid factor in 54%, and bone erosions in 27% of ERA patients. 57% of ERA patients presented with FET and 0% of CTR (p<0.001). The delay between the first symptom and diagnosis, the DAS28CRP, SDAI, CDAI, CRP level, 44TJC, 44SJC, HAQ did not differ significantly between patients with FET involvement and those without. In univariate analysis, the presence of FET involvement was significantly associated with the presence of bone erosions (p=0.02), ACPA (p=0.002), rheumatoid factor (p=0.02) and tobacco use (p=0.02). In multivariate analysis, the presence of FET involvement was significantly associated with the presence of bone erosions (p=0.01), ACPA (p=0.001), RF (p=0.01).

Conclusion: FET is relatively frequent in ERA patients and it is not present in asymptomatic subjects. Our results show that FET involvement is associated with the presence of ACPA, rheumatoid factor and bone erosions, thus identifying patients with possibly more aggressive or severe disease at baseline.

THU0615

POSITIVE MRI OF THE SPINE AS IMAGING CRITERION IN THE ASAS CLASSIFICATION CRITERIA FOR AXIAL SPONDYLOARTHRITIS

Mauricio Ochoa1, Daniel Rios2, Annelise Goecke3, Julio Cruz3, 1HOSPITAL SAN JOSE, RHEUMATOLOGY, SANTIAGO, Chile, 2HOSPITAL CLINICO UNIVERSIDAD DE CHILE, RADIOLOGY, SANTIAGO, Chile, 3HOSPITAL CLINICO UNIVERSIDAD DE CHILE, RHEUMATOLOGY, SANTIAGO, Chile

Background: MRI is a useful tool for the evaluation of patients with chronic back pain suspected of axial spondyloarthritis. As defined by ASAS classification criteria, MRI suggestive of axial spondyloarthritis is based on the presence of inflammatory lesions in the sacroiliac joints. However, inflammatory lesions in the spine may also occur. A consensus definition for a positive MRI-spine was developed by OMERACT MRI working group. In this consensus a positive MRI-spine is described as the presence of ≥ 3 inflammatory lesions in the corner of the vertebrae (bone marrow edema lesions), whereas each lesion needs to be present on ≥2 consecutive slices.

Objectives: The purpose of this study was to evaluate the presence of spinal inflammatory lesions on MRI performed between January, 2015 and December, 2015 in the Universidad de Chile Clinical Hospital.

Methods: Data from MRI performed between January, 2015 and December, 2015 in the Universidad de Chile Clinical Hospital was collected. The patients were derived by a physician as part of the study of chronic back pain.

Results: A total of 118 MRI were performed in this period, from which 8 showed evidence of spinal involvement without sacroilitis. The finding in MRI were: 3 patients with enthesitis of spinal ligaments, 2 patients with spondylodiscitis and 3 patients with bone marrow edema in the corner of the vertebrae. However, no patients fulfilled the OMERACT criteria for a positive MRI-spine (≥ 3 corner based inflammatory lesions). Patients with inflammatory lesions in the corner of vertebrae only showed 1 or 2 bone marrow edema sites. When we hypothetically added this criteria (assuming 2 bone marrow edema sites as a positive MRI-spine) to the ASAS criteria for axial spondyloarthritis, only one patient could be classified via the imaging arm.

Conclusion: Adding a positive MRI-spine as an imaging criterion to the ASAS-criteria for axial spondyloarthritis did not resulted in newly classified patients in this cohort. A combination of MRI-spine and MRI-SI had no incremental value compared with MRI-SI alone.

THU0616

WHOLE-BODY MRI OF PSORIATIC ARTHRITIS AND RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY CONTROLS – INTERSCAN, INTRAREADER AND INTERREADER AGREEMENT AND DISTRIBUTION OF FINDINGS

Anna Enevold Floestrup Poulsen1, Mette Bjerrum Dalhusen1, René Panduro Poggenborg1, Iris Eshedi1, Simon Krabbe1, Daniel Gilintza2, Jakob Mollenbach Möller1, Mikelí Østergaard1, 1COPECARE, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; 2Department of Diagnostic Imaging, Sheba Medical Center, Tel Aviv University, Tel Aviv, Israel; 3Department of Radiology, Herlev Hospital, University of Copenhagen, Herlev, Denmark

Background: Whole-body MRI (WBMRI) is a promising tool for monitoring disease activity in inflammatory joint diseases. Earlier studies have shown good correlation with conventional MRI and scoring systems for WBMRI have been developed [1,2]. However, the validation of WBMRI is limited; no studies have evaluated the agreement between repeated scans (inter-scan agreement) and only few studies have evaluated the intra- and interreader agreement.

Objectives: To validate WBMRI by evaluating the interscan agreement in patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA) and healthy controls (HC) and to evaluate the intra- and interreader agreement and determine the distribution of pathologies in the subjects.

Methods: WBMRI was performed twice with a one-week interval in 14 patients with PsA, 10 with RA and 16 HC. Coronal images of shoulders, hips, hands and ankles/feet, and sagittal images of knees, ankles, feet and spine were obtained (STIR and pre- and post-contrast T1 weighted spin echo images). Images were anonymized and read in pairs with unknown chronological order by experienced readers (peripheral: IE; spine: SK). WBMRI was scored for 83 peripheral joints and for 33 peripheral entheses according to the OMERACT WBMRI scoring system [1] and according to the CarDen MRI spine scoring system [2]. Two image sets were re-analyzed for assessment of intra- and interreader agreement (Peripheral and spine: MO). Agreement was calculated on lesion level by percentage exact agreement (PEA) and Cohen’s kappa with squared weights, and for sum scores by absolute agreement single-measure intraclass correlation coefficient (ICC).

Results: The age in the PsA/RA/HC was median (range) 48/31-68/49/26-58/35-54 years and the symptom duration 10/0-24/7-23/4-24/NA years. WBMRI of the spine and peripheral joints and entheses generally showed moderate to almost perfect interscan agreement with a PEA ranging from 95-100%, kappa ranging from 0.71-1.00 and ICC ranging from 0.95-1.00 (Table 1). Intra- and interreader agreement showed moderate to almost perfect agreement with few exceptions (Table 2).

Conclusion: WBMRI of the spine and peripheral joints and entheses showed very good interscan agreement, implying that repositioning between examinations does not markedly affect scoring of lesions. Intra- and interreader agreement showed moderate to almost perfect agreement. The distribution of findings in PsA, RA and HC was determined.

WRIST ULTRASOUND (US) PATHOLOGY IN EARLY RHEUMATOID ARTHRITIS (RA): OBSERVATIONS FROM AN EARLY INFLAMMATORY ARTHRITIS (EIA) DIAGNOSTIC SERVICE

Rowan Raja1, Momina Zaman2, Tim Jones2, Fazal Sheikh3, Mohammed Sharif4,  
1Croydon Health Services NHS Trust, Rheumatology, Croydon, United Kingdom;  
2St George’s University Hospital NHS Trust, Rheumatology, Tooting, United Kingdom;  
3Epsom and St Helier’s NHS Trust, Rheumatology, Carshalton, United Kingdom;  
4King’s College Hospital NHS Foundation Trust, Rheumatology, Orpington, United Kingdom

Background: To ensure a timely diagnosis of RA, diagnostic US is increasingly being utilized to detect subclinical pathology in order to implement treatment plans rapidly. There are several optimal synovitis scoring protocols in the literature but a consensus regarding a definitive system still eludes us. There are few studies that have focussed specifically on wrist US pathology in early RA. Hence, we assessed what the common wrist US pathologies are in patients diagnosed with early RA.

Objectives: To identify the patterns of wrist US abnormalities seen in patients diagnosed with early RA from our EIA service in a large urban London hospital.

Methods: Retrospective service review of patients seen in the EIA US diagnostic service at Croydon Health Services in South London. Patients diagnosed with RA (EULAR/ACR 2010 criteria) with wrist US synovitis/tenosynovitis (EULAR-OMERACT definitions) between Jan2017-Dec2018 were included. The US protocol in the EIA diagnostic service includes lateral and dorsal (long axis & short axis views) of the ulnarcapral(UCJ) & radiocarpal(RCJ) joints with views covering the radioulnar joints & ulnar-styloids and views of the extensor & flexor tendons. Images and reports were reviewed and correlations with rheumatoid factor(RhF), anti-CCP antibodies(CCP), CRP & ESR were also assessed.

Results: 86 patients with RA (meeting EULAR-ACR criteria) were found to have wrist pathologies on US. The commonest finding (36%) was moderate (grade 2) greyscale(GSUS) synovitis in the UCJ with almost all having moderate (grade 2) power Doppler(PDUS) synovitis (32%). Only a few (5/86) had more severe pathology with GSUS/PDUS (grade 3). 22% (19/86) had milder changes GSUS grade 1 with three quarters of these patients having concomitant PDUS signal. Just under 10% had RCJ US synovitis and 3 cases had radioulnar joint synovitis. Only 6% of the cohort had whole wrist joint involvement. Erosions were very uncommon (2/86). In total just under 25%(21/86) had tendon disease with roughly 70% affecting 1 tendon compartment and the others affecting 2 or more. Of those with tendon pathology, the two most commonly affected tendons were the 2nd [46%(10/21)] and 4th [38%(8/21)] extensor compartments. Extensor tenosynovitis was more common than flexor(46 v 4 cases). US synovitis ‘only’ was seen in 76%, US tendon disease ‘only’ in 7% and concomitant pathology in 17%. Correlation with inflammatory markers was not seen with only 3 patients presenting with significantly elevated CRP (>15) and ESR (>20). Though CCP was more commonly seen compared to RhF(32% vs 17%), just over half did not have positive antibodies.

Conclusion: Our observational study found that in early RA, mild-to-moderate GSUS and PDUS in the UCJ is the commonest wrist US pathology with tenosynovitis of the 2nd and 4th extensor compartments. Severe disease and erosions were very uncommon. The pattern of these US wrist pathologies are likely to reflect the initial disease course of these patients that present to our EIA service (i.e. early RA patients). Furthermore, biochemical markers do not seem to be useful in these patients and serology may not be present in over 50%. Therefore, clinicians who are running EIA diagnostic services with US should be expectant of milder-to-moderate US findings when diagnosing early RA and not be misled by the absence of more severe findings. Our understanding of US pathologies in the RA disease course therefore needs to be more nuanced and further work in other specific joint areas may help to elabo rate what US pathology is most common in early RA.

CLINICAL COMPARISON BETWEEN MAGNETIC RESONANCE TOMOGRAPHY AND X-RAY IN DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS

Mariljon Salokhiddinov, Muborak Salieva. Tashkent Medical Academy, Tashkent, Uzbekistan

Background: For decades, X-ray images have been used to help detect rheumatoid arthritis (RA) and to monitor for the progression of bone damage. In early RA, however, X-rays may appear normal although the
disease is active – making the films useful as a baseline but not much help in getting a timely diagnosis and treatment. Modern imaging techniques, including ultrasound and magnetic resonance imaging (MRI), which can reveal early, non-bony signs of RA that are invisible on X-ray

**Objectives:** To conduct a comparative analysis of the possibility of MRI in RA patients in the early diagnosis of the disease with the data X-ray of hands and feet

**Methods:** The study included 56 patients with a reliable diagnosis of RA aged from 17 to 66 years, with disease duration from 4 months to 1 year. Verification of the diagnosis of RA was carried out in accordance with the diagnostic APA criteria (1987). The criteria for the selection of patients was the presence of disease activity. Patients were mainly with the II degree of disease activity. All patients underwent radiography of the small joints of the hands and feet, and 28 patients underwent MRI with dominant hand.

**Results:** The study showed certain changes in the structures of the joint based on MRI in the early stages of RA. So, according to MRI of the brushes, it was revealed: thickening of the synovial membrane - in 23 (86%) patients; marginal erosion and subchondral cysts - in 21 (75%) patients; bone erosions - in 25 (90%) patients; phenomena of destruction of the articular cartilage (thinning, ulceration and destruction) - in 16 (57%) patients; effusion to the joints - in 19 (68%) patients and tenosynovitis in 18 (64%) patients. In turn, the radiological data of the hands and feet showed that erosive arthritis was found in 23 (41%) patients and marginal erosions in 22 (39%) patients.

**Conclusion:** Thus, MRI of the hands plays an important role in the early diagnosis of RA, since it allows visualizing the characteristic changes in all joint structures in RA. MRI is a highly effective diagnostic method in diagnosis of RA, which in combination with other methods of research helps to establish the diagnosis at an early stage diseases and timely appointment of adequate basic treatment unlike radiography

**THU0620 THE PHYSIOLOGICAL FINGER JOINT ARCHITECTURE – AGE-RELATED INCREASE OF EROSIONS AND OSTEOPHYTES IN THE JOINTS OF HEALTHY INDIVIDUALS**

David Simon1, Andreas Berlin1,2, Koray Tasca1, Sara Bayat1, Klaus Engelke1, Jürgen Reich1, Camille Figueiredo1, Axel Hueber1, Georg Schett1, Am Kleyer1, Friedrich-Alexander University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany; 2University Hospital Würzburg, Würzburg, Germany; 3School of Medicine from São Paulo University (FMUSP), Sao Paolo, Brazil

**Background:** The “normal” finger joint architecture has not yet been defined and could change in the course of life. Therefore the objective was to assess the physiological finger joint architecture of healthy individuals and the relation of structural changes to age and sex using high-resolution quantitative computed tomography (HR-pQCT) of the hands.

**Methods:** Healthy individuals without rheumatic diseases and other comorbidities were recruited through a field campaign and received HR-pQCT examination of the Metacarpophalangeal 2/3 and Proximal Interphalangeal 2/3 joints of one hand. The number of erosions and osteophytes was quantified across different sexes and age decades (6 decades within the age range of 21-80 years).

**Results:** 120 healthy individuals (10 women and 10 men in each decade) were recruited. Bone erosions [median (Q1-Q3), 1 (0-2)] and osteophytes (2 (1-4)) were found in both sexes without significant differences. However, structural changes increased with age: the overall incidence rate (IRR) for the number of erosions and osteophytes per age were 1.04 (95% CI 1.03-1.06, 95% CI 1.03-1.05), which indicates a 4% increase in the number of erosions and osteophytes per year. The use of the 3rd decade as the reference demonstrated that healthy individuals in the age decades from 50 years had higher IRR for erosion number (6th, 7th, 8th decade: 4.87 (2.20-11.75), 6.81 (3.08-16.46) and 6.92 (3.11-16.79)) compared to younger subjects (4th, 5th decade: 1.80 (0.69-4.87), 1.53 (0.59-4.10)). The IRRs of osteophytes also indicate a progressive increase after the fifth decade, with IRRs of 2.32 (1.32-4.17), 4.17 (2.38-7.49) and 6.86 (3.97-12.20) for the 6th, 7th and 8th decades, respectively.

**Conclusion:** Structural changes in the finger joints of healthy individuals are age-related. While being rare under 50 years of age, erosions and osteophytes accumulate above the age of 50, suggesting that the threshold between “normal” and “pathological” shifts with increasing age.

**THU0619 THE VALUE OF MORPHOLOGICAL AND BIOCHEMICAL MAGNETIC RESONANCE IMAGING (MRI) OF RADIOCARPAL CARTILAGE FOR THE DIFFERENTIATION OF RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS**

Philipp Sewerin, Lino Sawicki, Christoph Schleich, Daniel Abbar, Matthias Schneider, Stefan Vordenbäumen, Benedikt Ostendorf. Universitätsklinikum Düsseldorf, Düsseldorf, Germany

**Background:** Using high-field MRI to differ morphologically between OA and RA.

**Objectives:** To evaluate the value of morphological and biochemical, contrast-agent free high-field (3 Tesla) MRI of the radiocarpal cartilage to differ between osteoarthritis (OA) and rheumatoid arthritis (RA).

**Methods:** The group consisted of 47 subjects, who were examined during the period from October 2016 to December 2017. The clinical dominant hand of 11 patients suffering from early rheumatoid arthritis (RA) (German Arthromark cohort, Ø 52.8years; min: 32; max 74) was compared with 120 healthy (OA) (Ø 48.55 ± 15.23 years, min: 34 years, max: 68 years, disease duration Ø 6 years ± 8.29) and 26 healthy volunteers (Ø 46.55 ± 17.55 years, min: 20 years, max: 79 years) were examined with a 3T MRI scanner, prospectively. Morphological and biochemical assessment of radiocarpal cartilage was performed using DESS, TrueFISP and T2* images.

**Results:** Morphological sequences demonstrated significantly higher cartilage damage in RA and OA compared to healthy controls (DESS: p = 0.01, p = 0.0004; TrueFISP: p = 0.02, p = 0.0001), while there was no significant difference between RA and OA patients. With biochemical MRI using T2* imaging, patients with OA showed higher cartilage integrity compared to patients with RA (p = 0.01).

**Conclusion:** Morphological and biochemical MRI of radiocarpal cartilage could be helpful to differentiate between RA and OA patients. Both, RA and OA, are associated with cartilage damage measured by morphological MRI of the hand. Hence, OA was associated with more loss of cartilage integrity compared to RA using biochemical MRI, whereby only early RA patients were analyzed in this first evaluation. Non-contrast-agent morphological and biochemical MRI could be a non-invasive tool to investigate cartilage integrity in RA and OA patients and could help to differ disease pattern in the future.

**Acknowledgement:** We would like to thank Erika Rädisch for the assistance in receiving the MRI scans.

Background: Tendon tenosynovitis (TS) is a common, often clinically undetectable finding in Rheumatoid Arthritis (RA). Recent data showed TS on ultrasound (US) has a role in predicting outcome in early disease and flare in clinical remission. However data is limited on US TS measured in healthy subjects (HS), none specifically encompassing the older age range when RA commonly presents.

Objectives: This OMERACT study aimed to determine prevalence of US TS and particularly PD abnormalities in HS throughout the age range.

Methods: Adult HS without: joint pain (VAS <10/100), hand osteoarthritis and PD of grade ≥1 was more common than DF grade ≥1 (p=0.001).

Conclusions: Low prevalence of TS or PD abnormalities in tendons of HS even in old age suggests US determined TS will be a robust tool in clinically managing RA.

THU0622

MRI OF THE CRANIO-CERVICAL JUNCTION IN RHEUMATOID ARTHRITIS – DEFINITION OF NORMAL AND PATHOLOGICAL FINDINGS

Katharina Ziegele1, Christoph Korsing2, Matthias Bollow2, Kay Geert A. Hermann2, Tübingen: University medicine Tübingen, Tübingen, Germany; 2University-Hospital Aachen, Aachen, Germany

Background: In rheumatoid arthritis (RA), disease involvement at the cervical spine is common and may lead to malposition of the dens axis, resulting in severe neurological impairment. To date, malalignment is mostly described by X-rays.

Objectives: The aim of this investigation was to systematically define ossous and ligamentous MRI-findings in cranio-cervical RA in comparison to a control group without the disease.

Methods: MRI datasets of patients with cranio-cervical RA were identified retrospectively from the institutional image database and matched regarding age and gender with control patients. All image datasets were systematically reviewed for: position and morphology of dens axis (including erosions and osteitis); width and angle of the cranio-cervical joints; length, angle and visibility of peridental ligaments; vascularization of peridental

Results: Data from 999 HS and 144 RA patients were included.

DF 1-5 TSH (g) >1 (%)

| DF 1-5 PD (g) | 3 | 2 | 0 | 2 | <0.001 | 0.06 |

ECU TSH grade >1 (%)

| ECU PD grade >1 (%)

| RA had 66/68 joint count |

Prevalence of TSH and particularly PD abnormalities in HS was very low at all ages, and was all grade 1 except in one individual ECU tendon. US TSH grade >1 was more common than DF grade >1 in the older HS groups, and less common in the 18-39 age group (p=0.011). TSH and PD of grade >1 were common in RA patients, with DF PD abnormalities more common in early disease (p=0.02).

Conclusion: Low prevalence of TSH or PD abnormalities in tendons of HS even in old age suggests US determined TS will be a robust tool in clinically managing RA.

Disclosure of Interests: Esperanza Naredo Consultant for: Abbvie, Speakerv, Puebulo: Abbvie, Roche, Bristol-Myers Squibb, Pfizer, UCB, Lilly, Novartis, Janssen, and Celgene GmbH, Florentin Ananu Vejo Consultant for: abbbie and novartis, Speakers bureau: abbbie, novartis, pfizer, san-do, eli lilly, ucb pharma, Garifallia Sakellariou: None declared, George Bruyn: None declared, Georgios Filipouf Speakers bureau: Laborest, Abbovie, BMS, Novartis, Ga La Paglia: None declared, Gustavo Leon: None declared, Helen Keen: None declared, Hilde Berner Hammer Grant/research support from: Abbvie, Pfizer and Roche, Paid instructor for: Abbvie, Pfizer, UCB, Novartis, Roche, Speakers bureau: Abbvie, Pfizer, UCB, Novartis, Roche, Ilaria Tinazzi: None declared, Irene Azziolin: None declared, Jacek Fliczinski: None declared, James Wilton: None declared, Kei Ikeda: None declared, Lene Terslev: None declared, Lea von Weender: None declared, Mohammad A Mortada: None declared, Philippe Carron: None declared, Sarah Ohrndorf: None declared, Takeshi Suzuki: None declared, Teodora Serban: None declared, Maria-Antonietta d’Agostino: None declared, Andrew Filer: None declared
RESULTS: A total of 40 patients were included in this retrospective case-control study, 20 in each group (RA and control). Position of dens was significantly more cranial in the RA group (dens to McGregor line: -1.62 mm for RA vs. 2.15 mm for controls, p<0.002; dens to McRae line: 3.20 mm for RA vs. 5.36 for controls, p<0.001). Visibility of alar ligaments was significantly lower in RA patients (fully visible in 10% of RA and 35% of control patients, p=0.012). Similarly, signal of transverse ligaments was normal in 5% of RA vs. 35% of control patients (p<0.001). There was no difference in length of the aforementioned ligaments (p<0.056).

Conclusion: With this case control study, MRI data on the position of the osseous and ligamentous structures of the cranio-cervical junction in patients with rheumatoid arthritis are available for the first time. Cranialization of the dens axis and signal changes of the transverse ligament and the alar ligaments are the most obvious findings. In a next step, the diagnostic value of the cervical spine in RA should be prospectively investigated and the available scoring system developed into an internationally established outcome measure.

Disclosure of Interests: [2] Katharina Ziegeler: None declared, Christoph Korsing: None declared, Mattias Bollow: None declared, Kay Geert A. Hermann: None declared, Katharina Ziegeler: None declared, Christoph Korsing: None declared, Mattias Bollow: None declared, Kay Geert A. Hermann

Methods: A retrospective cohort study was conducted using the National Health Information Database of Korea between 2008 and 2017. The enrollee had at least two claims with the RA diagnosis code, and had at least one prescription for TNFi since 2009 when national insurance of Korea started to cover the expense of IGRA. Exclusion criteria were organ transplantation, HIV infection, or active TB infection within 1 year prior to enrollment. The follow up was initiated on the day of the first prescription for TNFi, and ended on the date of the first claim on active TB, the date of death or December 31, 2017 whichever came first. The utilization of IGRA test method was confirmed by the codes of tuberculin skin test (TST) and IGRA claimed within 2 months prior to the initiation of the TNFi. Patients were categorized into 3 groups; no-test, TST only, IGRA (IGRA only or IGRA and TST). The incidence of active TB was defined as the presence of claims with diagnosis code for TB and the start of standard 3-drug or 4-drug first line anti-TB medication combination therapy.

Descriptive statistics on baseline characteristics of participants in each group were presented before and after application of weighting method using standardized mortality rate weight (SMRW). The incidence of active TB in each group was presented as event per 1000 person-year (PY). We treated death as competing event to the occurrence of TB. Therefore TB in each group was presented as event per 1000 person-year (PY).

We treated death as competing event to the occurrence of TB. Therefore TB in each group was presented as event per 1000 person-year (PY).

UNDERSTANDING ETHNIC DIFFERENCES IN THE UTILIZATION OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS FOR OSTEOARTHRITIS

Ernest Vina1, Michael Hannon2, Jazmin Dagnino3, C. Kent Kwoh1. 1University of Arizona, Rheumatology, Tucson, United States of America; 2Pinney Associates, Pittsburgh, United States of America

Background: The prevalence of arthritis-attributable activity limitation, work limitation and severe pain are significantly higher among Hispanics than among non-Hispanic Whites (NHWs) in the US. While Hispanics are less likely to report regular use of nonsteroidal anti-inflammatory drugs (NSAIDs), reasons for this decreased NSAID use are unknown. It is also unclear whether there are ethnic differences in the use of both over-the-counter (OTC) and prescription NSAIDs.

Objectives: To determine: 1) if there are ethnic differences in the use of OTC and prescription oral NSAIDs for knee/hip osteoarthritis (OA); 2) if there are differences in familiarity with and perceptions of efficacy and risk of NSAIDs between Hispanics and NHWs; and 3) if patient attitudes/ beliefs about NSAIDs mediate observed ethnic differences in the use of NSAIDs for OA.

Methods: Participants ≥50 years of age with chronic frequent pain due to knee/hip OA completed structured interviews. Data on sociodemographic characteristics, clinical information, actual use of oral NSAIDs for OA treatment (last 6 months), and familiarity with NSAIDs (3 items, yes/ no response) were collected. Perceptions of efficacy (4 items) and risk (3 items) of NSAIDs were evaluated using five-category ordinal response scale questions. Responses were averaged, with higher values indicating higher perception of efficacy/risk. Fisher’s exact or Wilcoxon-Mann-Whitney tests were conducted to determine if knowledge and perceptions about NSAIDs differed by ethnicity. Multivariable logistic regression models were built to determine if ethnic differences in NSAID use were mediated by knowledge and perceptions about the medication.

Results: Among knee/hip OA patients, Hispanics (n=130), in comparison to NHWs (n=204), were younger (mean age 61.8 vs. 65.7) and less likely to have an annual income >$40K (21.6% vs. 56.5%). Hispanics, compared to NHWs, had lower odds of using an OTC NSAID (OR 0.57, 95% CI 0.36-0.90) but greater odds of using a prescription NSAID (OR 1.66, 95% CI 1.04-2.64) for OA. Hispanics, compared to NHWs, were also less likely to ever hear about OTC and prescription oral NSAID to treat OA or have a good understanding of either oral NSAID type as a treatment for OA (Table 1). Mean [SD] perceived efficacy of OTC and prescription oral NSAIDs were slightly lower among Hispanics than NHWs (2.91 [0.98] vs. 3.12 [0.88], p=0.0565; 3.03 [1.02] vs. 3.34 [0.87], p=0.0462; respectively). Mean [SD] perceived risk of prescription NSAIDs were lower among Hispanics than NHWs (2.44 [1.03] vs. 2.82 [1.01], p=0.0012). After adjustment for all familiarity with OTC NSAIDs questions, the association between prescription NSAID use and ethnicity remained significant (OR 2.62, 95% CI 1.51-4.54).

Conclusion: Among patients with knee or hip OA, Hispanics were less likely than NHWs to utilize an OTC oral NSAID as treatment for arthritis. They were also less familiar with the use of NSAIDs for OA treatment and less likely to believe in their efficacy. Patient familiarity and perceptions of OTC oral NSAIDs may mediate ethnic differences in the use of NSAIDs for knee/hip OA.

CAN WE IMPROVE INPATIENT REFERRALS TO RHEUMATOLOGY IN A TEACHING HOSPITAL IN THE UK?

Arani Vivekananthan, Zenab Sarwar Mateen, Roseanna Wheatley, Rachael Myers, Pippa Watson, Jayne Litte. Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: Inpatient referrals to rheumatology vary nationally from paper/electronic methods to phone conversations with the rheumatology registrar. In our Trust, which includes two large teaching hospitals in the UK, rheumatology referrals were hand written, faxed to secretaries and then given to the rheumatology registrar. This method was time consuming and referrals often lacked vital information. The referrer would also not know when the registrar had received the referral. A quality improvement project (QIP) in another UK hospital has shown an electronic referral system to be more efficient and safer for patients [1].

Objectives: This QIP aimed to evaluate the current system for inpatient referrals to two rheumatology departments within one large UK NHS trust and to identify aspects for improvement.

Methods: Two hundred and ten inpatient rheumatology referrals received between January 2018 - January 2019 were analysed retrospectively for inclusion of important information such as, patient location and referrer’s contact details.

Results: The review of current referrals identified several areas for improvement. The results are summarised in Table 1. The reasons for referrals ranged from swollen, painful joints to new rashes and medication reviews.

Table 1. Inclusion of important items in inpatient rheumatology referrals.

A process mapping session was undertaken to identify how the referral system could be improved. An electronic referral system, via the local electronic patient record (EPR), was created. As well as ensuring that there is an audit trail and referrals are received in a timely manner, referers are provided with a proforma to direct them to supply the
relevant information. There is also functionality for the rheumatology team to reply to the referral with advice, which creates a new permanent document in the patient’s EPR. The Orthopaedic team, who are the first point of call for hot joints in our Trust, were consulted to ensure that there were not any unintended consequences as a result of this change. The form included the following sentence to avoid delays in patient care: “If gout is suspected, the referrer will be linked to guidelines and patient information sheets to assist best management whilst awaiting review. We would encourage others to consider their referral systems—could you improve yours?"

THU0626 SOCIAL NETWORKS AS A SOURCE OF INFORMATION FOR PATIENTS WITH RHEUMATIC DISEASES
Daniel G. Fernández-Ávila1, Julián Barahona-Correa2, Diana Romero-Alvernia3, Angel García4, Oscar Muñoz5, 1Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine – Rheumatology, Bogotá, Colombia; 2Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine, Cra 7 No. 40-62, Colombia; 3Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine, Bogotá, Colombia

Background: Internet is an informative source for patients with different diseases. False information in social networks about health issues is a growing problem. Rheumatology is no stranger to this problem and there is a lot of false information regarding rheumatic diseases.

Methods: We create accounts on Facebook (FB) and Google unique for networks available to Spanish-speaking rheumatic patients

Results: Of the first 50 videos with more reproductions, 39 are of natural or home remedies such as vinegar, "morning", etc. and 35 videos indicate that they can cure RA. With the term "lupus", the most reproduced video is titled "God's tea, cure chronic tiredness, thyroid, arthritis, lupus and vertigo" (1.4 million reproductions). Of the first 50 videos with more reproductions, 31 correspond to natural or home remedies such as celery, thyme, diets among others and 29 videos indicate that they can cure lupus. With the term "fibromyalgia", the most reproduced video is entitled "I am 61 years old and this cured my arthritis, vertigo, fibromyalgia, lupus, chronic fatigue and the thyroid" (1.1 million reproductions).

Conclusion: YT and FB are social networks with a high content of false information. The majority of available videos promise to cure different rheumatic diseases (even several simultaneously). This is the first work of a line of research that seeks to highlight the high degree of misinformation. We will continue to analyze other diseases and social networks, to make publications and communications in different media and to alert local regulatory entities.

THU0627 VACCINATIONS IN PATIENTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES: STILL ROOM FOR IMPROVEMENT
Delphine Bertrand1, Solie Coenen2, Sofia Pazmino1, Veerle Stouten1, Diederik De Cock1, Kristen Van der Elst3, Rene Westhoven1,2,3, Marc Ferrante, Patrick Verschueren2, 1KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 2UZ Leuven, Gastroenterology and Hepatology, Leuven, Belgium; 3UZ Leuven, Rheumatology, Leuven, Belgium

Background: Patients with autoimmune inflammatory rheumatic diseases (AIRD) have an increased risk for acquiring infections. Vaccines were developed to diminish the prevalence of vaccine-preventable infections. The EULAR recommendations for vaccination in adult patients with AIRD emphasise the importance of assessing the vaccination status of patients with AIRD.

Objectives: To determine the vaccination status of patients with AIRD, the reason for non-vaccination and the proportion of patients that are vaccinated according to the EULAR recommendations.

Methods: The single-centre cross-sectional COLOSSeUM study was conducted in a tertiary referral centre. Between August and December 2018, all consecutive patients with AIRD including Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA), Ankylosing Spondylitis (AS) and Juvenile idiopathic Arthritis (JIA) who visited the outpatient clinic were included. The vaccination status (influenza winter season 2017-2018, pneumococcal, tetanus toxoid and hepatitis B vaccine) and history of varicella zoster virus infection was determined using a one-page questionnaire which was completed by the treating rheumatologist after discussion with the patient.
The patients’ reason for non-vaccination was registered if applicable. Patients were classified as vaccinated according to the EULAR recommendations if they had a yearly influenza, an every-five-year pneumococcal and a decennial tetanus toxoid vaccine, the latter as recommended in the general population.

Table 1: The vaccination status of all patients

</tr>
</tbody>
</table>
| Vaccination status with JIA with a mean ± standard deviation age of 59.8 ± 13.6, 55.8 ± 14.3, and 35.0 ± 13.9 respectively. Of all included patients with AIIRD, 69.2% were vaccinated for influenza, followed by vaccination rates of 55.0%, 32.1% and 30.5% for tetanus toxoid, pneumococcal and hepatitis B vaccination, respectively (Table 1). In addition, 70.6% of patients with AIIRD had a history of varicella zoster virus infection. Various reasons for non-vaccination were reported, of which ‘No specific reason’ was the most common, closely followed by non-awareness of the need for pneumococcal vaccination. The compliance with EULAR recommendations was 18.5%. Of the 429 patients with AIIRD not vaccinated according to the EULAR recommendations, 68 (15.9%) patients were not compliant with all three of the vaccines, 136 (31.7%) were not compliant with 2 vaccines (1: pneumococcal and 2: influenza or tetanus toxoid vaccine), 148 (34.5%) were not compliant with 1 vaccine (103 pneumococcal, 41 tetanus toxoid and 4 influenza vaccine) and 77 (17.9%) patients were unaware of their vaccination status for at least 1 vaccine.

Conclusion: In our patients with AIIRD, the highest vaccination rate for recommended vaccines was observed for influenza (nearly 70%). Not being vaccinated for pneumococcosis was the main reason why patients did not comply with the EULAR recommendations. More attention is needed to determine and optimise the vaccination status of AIIRD patients and to increase the awareness regarding the pneumococcal vaccine.

Methods: Incident IA cases were identified between January 1, 2007 and December 31, 2015, in patients enrolled in the Veteran Health Administration, using International Classification of Diseases codes and natural language processing. Patterns of treatment initiation and non-treatment with disease modifying anti-rheumatic drugs (DMARDs) were assessed in the 12-month follow-up period after the incident diagnosis.

Results: The population consisted of 12, 118 IA patients (9,711 RA, 1,472 PsA, 935 AS), with 91.3% males and a mean age of 63.7. In total, 58.2% of patients initiated a DMARD within 12 months after diagnosis (RA 60.0%, PsA 64.3%, AS 29.6%) (Figure). A DMARD was dispensed ≤30 days after IA diagnosis in 41.2% of patients and ≤90 days in 90.0% of patients. Rheumatology specialty care was accessed during the study period, prior to DMARD dispensation, by 82.7% of patients exposed to a non-biologic DMARD and 90.0% of patients exposed to a biologic DMARD. The percentage of IA patients with DMARD exposure during the 12-month follow-up period increased from 48.8% in 2008 to 66.4% in 2015.

Conclusion: Approximately one-half of patients received treatment with a DMARD within 90 days after their initial IA diagnosis. DMARD treatment rates during the initial 12 months after diagnosis increased between 2007 and 2015, but non-treatment remained common, particularly in patients with AS. Timely access to a rheumatologist is likely important for early DMARD treatment.

THU0629 TREATMENT PATTERNS WITH DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN UNITED STATES VETERANS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, OR ANKYLOSING SPONDYLITIS

Jessica A. Walsh1, Shaobo Pei1, Gopi Penmetsa1, Brian Sauer1, Vikas Patil1, Jodi Walker2, Jerry Clewell2, Kevin Douglas2, Daniel Clegg1, Grant Cannon2, Ahmad Halwani2,1, Salt Lake City Veteran Affairs and University of Utah Medical Centers, Salt Lake City, United States of America;2AbbVie, Inc, North Chicago, United States of America

Background: Delays in treatment for inflammatory arthritis (IA) are associated with unfavorable outcomes, including impaired quality of life, irreversible joint damage, and disability.

Objectives: To characterize treatment initiation patterns in patients with newly diagnosed rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS).

Methods: Incident IA cases were identified between January 1, 2007 and December 31, 2015, in patients enrolled in the Veteran Health Administration, using International Classification of Diseases codes and natural language processing. Patterns of treatment initiation and non-treatment with disease modifying anti-rheumatic drugs (DMARDs) were assessed in the 12-month follow-up period after the incident diagnosis.

608 Thursday, 13 June 2019
Background: The ACR’s Rheumatoid Informatics Informatics System for Effectiveness (RISE) is a national, EHR-enabled registry that passively collects data on all patients seen by participating practices, thus reducing the selection bias present in single-insurer claims databases. Launched in 2014, RISE is designed to help practices improve their quality of care.

Objectives: The objectives of our study were to a) examine changes in practice-level performance on selected quality measures for patients with rheumatoid arthritis (RA) in 2016 and 2017 and b) assess variations in performance over time between practices.

Methods: We analyzed data collected on all patients with a diagnosis of RA who had at least one clinic visit between January 1, 2016 and December 31, 2017. Six quality measures in the areas of RA management (disease activity measurement and tuberculosis (TB) screening), and cardiovascular risk reduction (body mass index (BMI) screening in 18-64 years, BMI screening in >64 years, tobacco use screening and cessation, and blood pressure (BP) control) were examined. Performance on quality measures, defined as the percentage of eligible patients receiving recommended care, was examined at the practice level. We used a hierarchi- cal linear model to predict change in practice-level measure performance per quarter, accounting for clustering by practice. We also assessed variations in within-practice performance changes over time by calculating the range for each measure.

Results: Data from 150,099 patients from 135 practices was examined. Mean age was 63±14 years, 77% were female, 72% were Caucasian. The most common practice structure was a single-specialty group practice (65%), followed by solo (20%) and multi-specialty group practice (10%). From January 2016 to December 2017 there was an improvement in quarterly performance on disease activity measurement (+2.9%, p<0.001), TB screening (+1.9%, p<0.001), BMI screening in 18-64 years (+2.4%, p<0.001), and tobacco use screening and cessation (+1.2%, p<0.001), and a decline in quarterly performance on BMI screening in >64 years (-0.4%, p<0.001) and BP control (-0.6%, p<0.001). Improvements in performance on RA management measures were steady from Q1 2016 to Q4 2017 (Figure). Within-practice change in performance varied signif- icantly across practices (Table). For example, from 2016 to 2017 within-practice change in performance on blood pressure control varied from a decrease by 66.7% to an increase by 100%.

Conclusion: Among practices participating in RISE, from 2016 to 2017 average performance on most measures for individuals with RA improved. We found significant variations in performance over time between practices, suggesting that future work to identify workflow patterns leading to high performance or to dramatic improvements in quality are warranted. Disclaimer: This data was supported by the ACR’s RISE Registry. How- ever, the views expressed represent those of the authors, not necessarily those of the ACR.
A POPULATION-BASED STUDY OF TUBERCULOSIS INCIDENCE AMONG RHEUMATIC DISEASE PATIENTS UNDER ANTI-TNF TREATMENT

Natalia Sarot1, Rafael Chakr2, Anfonio Papke2, Paulo Piccon,1 Jeruzsa Neyloff1,2
1Hospital de Clínicas de Porto Alegre, Department of Rheumatology, Porto Alegre, Brazil; 2Hospital de Clínicas de Porto Alegre, Department of Rheumatology, Porto Alegre, Brazil; 3Hospital de Clínicas de Porto Alegre, Department of Internal Medicine, Porto Alegre, Brazil; 4Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

Background: Tuberculosis (TB) is an infectious disease caused by Mycobacterium tuberculosis, with a high incidence in the general population of Brazil. The advent of antituberculosis agents is associated with significant reductions in the incidence of TB, as well as in the population at risk. However, the incidence of TB among patients receiving anti-TNF agents for treatment of rheumatic diseases, despite achieving substantial efficacy in controlling disease activity, has been associated with a significant increase in incident cases of tuberculosis in this population due to blockade of TNF, which is responsible for maintenance of granuloma structure.

Objectives: Estimate the incidence of tuberculosis in Public Health System patients receiving anti-TNF therapy for rheumatic diseases. As secondary objectives, we sought to evaluate mortality and the influence of screening for latent tuberculosis infection on clinical outcomes in this population.

Methods: This retrospective cohort study included all Public Health System patients from the Brazilian state of Rio Grande do Sul (RS) who received prescriptions of anti-TNF agents for treatment of rheumatic diseases between 2006 and 2016. All data were obtained from official government records (drug dispensing, tuberculosis reporting, and mortality) where notification was mandatory. For a subset of patients, latent tuberculosis screening data were obtained through a review of medical records.

Results: A total of 5853 patients were included from 2006 to 2016, of which 3653 (62.4%) had rheumatoid arthritis, 1150 (19.7%) had ankylosing spondylitis, 872 (14.9%) had psoriatic arthritis, and 123 (2.1%) had juvenile idiopathic arthritis. Overall, 43 cases of TB were found, with an incidence of 734.7 cases per 100,000 exposed, which corresponds to 2.86 per 1000 person-years exposed. Two hundred and fifty deaths occurred in this cohort. In a subgroup of patients recruited from the outpatient rheumatology clinic of Hospital de Clínicas de Porto Alegre (n = 268), screening for latent tuberculosis infection (LTBI) was performed in 86% of patients before initiation of anti-TNF therapy; 30.1% had a positive tuberculin skin test. LTBI treatment was administered to 74 patients. In this subgroup of patients, 5 cases of TB were diagnosed, 2 in patients who had previously completed LTBI treatment.

Conclusion: In this population-based study, a high incidence of tuberculosis among patients with rheumatic diseases exposed to anti-TNF agents was found, reinforcing the need for screening and treatment of LTBI to reduce the risk of reactivation of granulomatous disease. No significant impact on mortality was demonstrated.

REFERENCES:
Conclusion: AS-related work disability and healthcare resource utilization have an enormous economic impact in Portugal. Investment in strategies that encourage early referral, diagnosis and treatment is fundamental to mitigate such burden.

THU0634 PHYSICIAN PERCEPTIONS OF BIOLOGICS VERSUS THEIR BIOSIMILAR COUNTERPARTS IN RHEUMATOLOGY: A MULTICOUNTRY STUDY IN EUROPE

Casey Zhang1, Denise Baldock2, Elizabeth Baynton2. *Ipsos, New York, United States of America; 1Ipsos, London, United Kingdom

Background: Following LOE for the originator brand of etanercept in 2016 and the subsequent launch of its first biosimilar version, several other biosimilars have arrived in the rheumatoid arthritis treatment space. Due to their potential for reducing healthcare spend and their supposed equivalence, biosimilars are expected to be of rising relevance and impact in the following years. 12 biosimilar brands of biologic originator treatments are now available in Europe to treat rheumatoid arthritis; it will be crucial to understand physician perceptions of biosimilars relative to branded products and the impact such views have on potential prescribing decisions.

Objectives: The objective of the study was to assess perceptions of efficacy and safety for biosimilars relative to branded biologic originator products among treating Rheumatologists in the EU5 countries (United Kingdom (UK), France (FR), Italy (IT), Spain (SP) and Germany (DE)).

Methods: A cross-sectional survey was conducted in Q3 2018 in the EU5 among national, regional and hospital physicians who had been practicing between 3-30 years. Respondents completed a Physician Perceptual Questionnaire online, which assessed the overall perception of biologic brands and anti-TNF biosimilars, important attributes for treatments, and specific barriers to prescribing them. Data were analyzed using descriptive statistics.

Results: A total of 261 rheumatologists in the EU5 were recruited as part of the study (with almost equal numbers of rheumatologists representing each EU5 country). Treating rheumatologists were practicing for an average of 17.4 years, mainly in teaching hospitals (50.2%) and urban hospitals (20.7%)1. Physicians consistently expressed greater satisfaction for branded products, with 73.9% (range: 63.5% DE to 90.6% FR) of physicians having rated satisfaction with the originator brand of etanercept as a 6 or 7 (on a 7-point scale where 7 corresponded to highest satisfaction), compared to only 37.5% for biosimilar etanercept (range: 26.6% IT to 51.9% DE)2. When asked about specific attributes related to RA treatments, 64.4% of our sampled rheumatologists associated the originator brand of rituximab with ‘Inhibition of radiographic progression’ (range: 55.1% IT to 81.1% FR)1 – versus 47.5% association for biosimilar rituximab (range: 32.7% IT to 62.3% FR)1. 73.2% of physicians associated the originator brand of infliximab with ‘helps maintain or improve physical function’ (range: 55.8% DE to 87.0% ES) compared to 58.6% of biosimilar infliximab (range: 44.9% IT to 67.9% FR)1. For ‘reduction in morning stiffness’, 78.5% of our rheumatologists associated it with originator etanercept (range: 65.4% DE to 88.7% FR) versus only 66.7% for biosimilar etanercept (range: 55.1% IT to 81.1% FR)1.

Conclusion: Biosimilars score lower on overall satisfaction and are less frequently associated with specific efficacy attributes relative to branded products. This is possibly due to their relatively short time in clinical practice, and the resulting lack of experience and supporting data compared to the older branded equivalents. Proof of concept may be essential to close the perceptual gap that still exists between branded products and biosimilars.

THU0635 REAL WORLD PHYSICIAN SATISFACTION WITH SECUKINUMAB IN PSORIATIC ARTHRITIS AND ANKYLOSING SPONDYLITIS IN EUROPE

Elizabeth Holdsworth1, Nicola Booth1, Steve Lobosco1, Olivia Massey1, Amie Scott2, Haijun Tian3, Dorothy Keininger1. 1Adelphi Real World, Manchester, United Kingdom; 2KMK Consulting Inc, Morrisstown, United States of America; 3Novartis Pharmaceuticals Corporation, East Hanover, United States of America; 4Novartis Pharma AG, Basel, Switzerland

Background: Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) can lead to reduced physical functioning and quality of life. Secukinumab has demonstrated clinical benefits in PsA and AS, however little is known about physician satisfaction with its ability to control disease in the real world.

Objectives: Assess physician satisfaction with secukinumab’s ability to control disease in a real-world setting.

Methods: This was a cross-sectional survey of rheumatologists and dermatologists (PsA only) in France, Germany, Italy, Spain, and UK. Data were collected from Jun-Aug 2016 via physician-completed patient record forms. Patients receiving any treatment were included in the survey. Patients receiving secukinumab >1 month were included in this analysis. Physicians rated satisfaction on a 5-point scale (Very satisfied to very dissatisfied), a binary variable of satisfied/not satisfied was created by grouping “Very satisfied” and “Satisfied” responses as satisfied and “Neutral”, “Dissatisfied”, and “Very dissatisfied” as not satisfied. Data were reported by disease, then stratified by overall physician-rated disease severity (mild/moderate/severe) at initiation of secukinumab, prior biologic use, treatment duration, and concomitant medication.

Results: 438 PsA and 277 AS patients were receiving secukinumab >1month at time of data collection. Patient mean age was 46.9 years (9.2 PsA; 8.2 AS). At secukinumab initiation, 44.2% of patients were rated by their physician as severe vs. 3.5% at the current consultation (39.3% vs. 2.7% PsA; 52.0% vs. 4.7% AS).

Overall, 87.6% of physicians were satisfied with the ability of secukinumab to control disease (87.9% PsA; 86.3% AS). Physicians report high satisfaction across each stratification (Table 1).
Table 1. Population characteristics, and physician reported satisfaction with secukinumab

<table>
<thead>
<tr>
<th>Population characteristics</th>
<th>Satisfaction level</th>
</tr>
</thead>
<tbody>
<tr>
<td>N (%) PsA patients in each category (n=438)</td>
<td>N (%) AS patients in each category (n=277)</td>
</tr>
<tr>
<td>N (%) PsA physicians satisfied (n=438)</td>
<td>N (%) AS physicians satisfied (n=277)</td>
</tr>
</tbody>
</table>

Overall satisfaction 385 (87.9) 239 (86.3) 28 (6.4) 4 (80.0)

Severely at initiation* 128 (46.2) 105 (50.6) 5 (1.8) 2 (40.0)

Mild 210 (89.0) 155 (59.6) 18 (64.3) 4 (80.0)

Overall satisfaction 239 (86.3) 126 (87.5)

*PsA base size=435

Conclusion: This study provides insight into physician satisfaction with secukinumab in a real-world clinical setting. Physicians reported being highly satisfied with the ability of secukinumab to control PsA and AS disease, regardless of patient population subgroups.

THU0636

HIGHER SOCIAL MEDIA USER STICKINESS ON SELF-MANAGEMENT SYSTEM MAY IMPROVE THE REMISSION RATE OF PATIENTS WITH ANKYLOSING SPONDYLITIS

Xiaojian Ji, Jian Zhu, Jiangan Zhang, Feng Huang. SpAMS co-authors. Chinese PLA General Hospital, Department of Rheumatology, Beijing, China

Background: With the advancement of mobile health technologies, it is possible to set up economic management systems to improve health care. By using a Smart-phone Spondyloarthritis Management System (SpAMS), the Chinese Ankylosing Spondylitis (AS)/Spondyloarthritis Prospective Imaging Cohort (CASPIC) was launched.

Objectives: To explore the improvement of disease management and cost-effectiveness of SpAMS for Chinese patients with AS.

Methods: Patients enrolled in the CASPIC cohort who fulfilled the 1984 modified New York criteria and who at least 2 evaluations of Ankylosing Spondylitis Disease Activity Score (ASDAS) were included in this analysis. All physician-reported assessments were collected at the Chinese People’s Liberation Army General Hospital using SpAMS in Beijing. The disease activity states were defined according to ASDAS1, which separated inactive disease (ID) from low disease activity (LDA) by 1.3, LDA from high disease activity (HDA) by 2.1, and HDA from very high disease activity (VHDA) by 3.5. According to ASDAS at the baseline visits and final visits, patients were divided into four groups (Figure 1): maintainer of ID/LDA, patients with relapse, maintainer of active disease, and new achiever of ID/LDA.

Results: From April 2016 to April 2018, 1201 patients with AS were enrolled in CASPIC. 4659 patient self-assessments were completed, including 3304 pre-visit assessments and 1355 assessments during the follow-up interval. After online consultation, 29.1% of clinic visits to a tertiary hospital were considered unnecessary and could be solved in the primary care hospital. The time and cost of each patient’s journey to Beijing were calculated based on the location of each patient. For the 1037 (86.3%) patients who lived outside the vicinity of Beijing, at least an average of 5.3 hours and 327.4 RMB for each person (USD: RMB = 1:6.418) for traffic time and expenses were saved, which equaled to 16% of the Chinese monthly disposable personal income (data in 2016).

Table 1. Characteristics of disease activity

<table>
<thead>

Smoker, %
NSAIDs at baseline, %
TNFi at baseline, %
DMARDs at baseline, %
TNFi during follow-up period, %

<0.001*
P < 0.05.

Of these patients enrolled in CASPIC, 777 patients had at least 2 evaluations of ASDAS. The rate of patients with ID/LDA was 57.2% at baseline and increased significantly to 79.2% with a mean (SD) follow-up of 13.3 (5.9) months (Table 1). Compared with patients who relapsed, those that maintained the ID/LDA had more patient assessments [5.0 (2.7) vs 3.3 (1.8), P < 0.001]. The new achievers of ID/LDA also completed online patient assessments more frequent [5.6 (3.1) vs 4.5 (2.5), P < 0.001] compared to patients who maintained active disease.

Conclusion: Higher social media user stickiness on self-management system may improve the remission rate of AS patients. SpAMS could serve as a cost- and time-saving specialty care online platform for patients with AS.

ACADEMIC ACHIEVEMENT, EMPLOYMENT STATUS, WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA): DETERMINANTS AND CONSEQUENCES

Chennappa Kavadichanda, Karunya Ravi, Niru Negi. Jawaharlal Institute of Postgraduate Medical Education and Research, Clinical Immunology, Puducherry, India

Background: Changes occurring in childhood due to JIA leads to academic and work impairment during their transition to adulthood. The factors impairing work and overall activity among adults with JIA need to be explored to formulate policy decisions and rehabilitation measures.

Objectives: To assess the level of academic achievement, employment, work productivity and activity impairment among adults suffering from JIA. To identify factors determining activity impairment among adults with JIA

Methods: Consecutive adults classified as JIA (1) were included. Consent was defined as ever remission:

Remission was assessed by Wallace criteria. Remission was done and remission was assessed by Wallace criteria. Remission was defined as ever remission: ≥3 months and sustained remission: ≥ 6 months of disease control. Appropriate statistical tests to assess association and correlation of various factors with WPAI were used.

Results: Demography (n=51) is depicted in table 1. Never attaining remission resulted in significantly higher college dropouts (8 vs 17, p<0.05), functional impairment (mean iHAQ 1.08 vs 0.5, p<0.05) and arthritic damage (mean JADI A 3 vs 8, p<0.01). Disease duration, JADI A and iHAQ correlated well (r² >.400, p<.05) with measures of WPAI (table 2). Assessment of patient variables like gender, occupation, disease activity and remission status (figure 1) showed that women, especially the homemakers and individuals with moderate to high disease activity had significant activity impairment (P<0.05).

Conclusion: Early effective treatment directly impacts employment levels and activity in adults with JIA. Homemakers in middle- and low-income countries have the most impairment in activity as they cannot alter their work. Replacement costs for homemakers would be an added financial burden to the family and is seldom captured by studies. Our study highlights the need to look further into the indirect and intangible costs involving women that will help policy makers formulate effective economic policies for individuals with JIA.

THU0639

Figure 5: Correlation between various disease associated factors and WPAI measures.

Figure 6: Association of patient and disease characteristics with activity/impairment

Acknowledgments: The study was supported by the EULAR-SERNECRA Research Grant. The authors acknowledge the support of the countries where patients are living with RA and their country’s disease activity scores used in this study.
with RA have an increased risk of comorbidities e.g. interstitial lung (IL) disease (7.7% incidence\(^5\)), up to 60% IL abnormalities in early RA\(^5\), depression (up to 200%\(^4\), 18.8%\(^3\)), cardiovascular disease (40-70%\(^6\), 5-12.9%\(^7\)) and diabetes (IR of 8.6 per 1000 person-years\(^8\); 20%\(^9\)). Yet, there are few comprehensive recommendations on the management of RA-related comorbidities.

**Objectives:** This study aimed to identify models of good quality care for patients with RA and their associated comorbidities in Europe and understand how these practices can be widely implemented.

**Methods:** Existing published recommendations across Europe on good practice in RA care including screening/managing selected comorbidities were reviewed. Team members of 12 specialist centres across Europe were interviewed. The interventions identified were reviewed and prioritised to form a selection of considerations by a consensus process involving 18 experts including rheumatologists, a patient rep., a nurse and also RA comorbidity specialists: cardiologist, psychologist, pulmonologist and diabetologist.

**Results:** The interventions were prioritised for each patient profile:

1. suspected RA:
   1. rapid access to care (online referral, triage, ultrasound guided diagnosis)
   2. enhanced communication with primary care (hotline, education sessions)
   3. early arthritis clinic (timely clinical assessment and diagnosis)

2. recently diagnosed:
   1. enabling self-management (self-monitoring and disease activity management support)
   2. early arthritis clinic
   3. comprehensive comorbidity assessment (standalone or in conjunction with RA appointment)

3. established disease:
   1. dedicated comorbidity specialist
   2. integrating patient registries into daily clinical practice
   3. enabling self-management

Eleven other interventions were identified including task-shifting to non-physician healthcare professionals, tailored education to patients and family members, and developing care networks.

**Conclusion:** Despite limited European recommendations on management of RA comorbidities, a range of good practice care model interventions across Europe were identified which are non-complex, high-impact and meaningful. Next step will be to assess how these care models can be implemented in different healthcare systems for the benefit of patients with RA.

**THU0639 AUTOMATED CAPTURE AND HIGH UPTAKE RATES OF PATIENT REPORTED OUTCOME MEASURES IN ROUTINE RHEUMATOLOGY PRACTICE**

Manjari Lahiri\(^1\), James Yip\(^3\), \(^1\)Yong Loo Lin School of Medicine, National University of Singapore, Department of Medicine, Singapore, Singapore; \(^2\)National University Hospital, Division of Rheumatology, University Medicine Cluster, Singapore, Singapore; \(^3\)National University Hospital, Department of Cardiology, Singapore, Singapore

**Background:** Patient reported Outcome Measures (PROMs) are an integral part of value based healthcare and outcomes that matter to patients; however resource and time constraints are often barriers for routine collection in clinic.

**Objectives:** We piloted an automated, electronic collection of PROMs for patients attending an outpatient specialist rheumatology clinic.

**Methods:** All patients with a clinic appointment were sent an automated message, one day before their scheduled doctor’s appointment, with a hyperlink to fill in the Routine Assessment of Patient Index Data (RAPID3) [0-30, 30 being worst, calculated as the sum of physical function measured using the 10-item multidimensional health assessment questionnaire (mDH AQ), pain visual analogue scale (VAS), and patient global VAS questionnaire]. The text message was personalised with the attending physician’s name and thumbnail photograph and the questionnaire was presented in the patient’s preferred language (English or simplified Chinese) by detecting their phone configuration. RAPID3 responses flowed back to the electronic medical record and were available for the attending clinician to view during the clinic consult the next day. Patients who did not fill in the questionnaire within 6 hours were sent a reminder, and those still remaining were encouraged to fill it in the clinic waiting room. Hardcopy flyers were distributed to inform patients of the initiative and clinicians were encouraged to discuss the responses at the clinic visit. Patients were sent the survey only once during the study period. Weekly usage reports were sent to the clinicians (Figure 1).

**Results:** 4078 patients [mean (SD) age 55.8 (16.3) years, 67.9% female, 70.6% Chinese] were sent the text message invitation over 6 months, of which 64.4% responded. Diagnosis data from SNOMED codes were available for 2262 patients. The most common primary diagnoses were rheumatoid arthritis (653, 29.5%), Spondyloarthritides (SpA), including psoriatic arthritis (318, 14.4%) and lupus (310, 14%). Data on disease duration, clinical features and medications were not available for this study. The mean (SD) mDH AQ score (range 0-3, 3 being the worst) was 0.3 (0.5), mean (SD) pain-VAS (0-10, 10 being worst) was 2.4 (2.3), patient global was 2.6 (2.2) and RAPID3 was 6.1 (5.2). On multivariable logistic regression, age (OR = 0.38, 95% CI 0.32, 0.44 for the top tertile), gender (OR 1.22, 95% CI 1.06, 1.4 for females), race (OR = 0.79, 95% CI 0.64, 0.98 for Indian vs. Chinese race) and treating physician (OR 0.7, 95% CI 0.61, 0.8 for junior vs. senior doctor) were independent predictors of survey response, while primary rheumatic disease was not (Figure 2). Ten of 11 clinicians (from 13 surveyed) found the information from PROMs useful, and 8/11 supported expansion of the pilot project to include more PROMs. Lack of time was cited as the biggest challenge to implementing PROMs routinely.

**Conclusion:** Automated collection of PROMs in routine clinical care is feasible with high uptake rates and minimal clinician burden.

**[1] Figure 1: Weekly usage reports**
Early retirement due to RA translated into 6.5 years of active work lost, compared to retirement due to other causes. Patients who retired due to RA are more likely to be younger at diagnosis of 49.6 ± 9.0 vs. 56.1 ± 8.6 years-old; p<0.01, female (82.6% vs. 68.9%, p<0.01), have longer disease duration (23.2 ± 10.7 vs. 18.3 ± 9.9 years, p<0.01) and lower educational level (4.5 ± 2.3 vs. 6.0 ± 4.1 school years, p<0.01). In the multivariate analysis, disease-related predictors for early retirement were: disease duration (OR: 1.11; 95% CI 1.08-1.13/year), erosive disease (OR: 4.45; 95% CI 2.37-8.35) and the need for biologic therapy switching (OR:1.37; 95%CI 1.02-1.83). Work-related predictors were: educational level (OR: 0.75; 95%CI 0.68-0.81/year) and heavy manual type of work (OR: 1.62; 95%CI 1.16-2.26).

Conclusion: Early retirement is still common among patients with RA; 60% in this cohort. The main reasons for early retirement are associated with the disease itself, but work-related factors also play a relevant role.

THU0640 EARLY RETIREMENT ATTRIBUTED TO RHEUMATOID ARTHRITIS AND ITS PREDICTORS IN PORTUGAL

Mariana Luís1, Ana Rita Cunha2, Helena Assunção1, Ana Rita Prata1, Luisa Brites1, Flávio Costa1, João Dinis de Freitas1, Stephanie Silva1, Anaabela Barcelos1, Célia Duarte1, José Antonio P. Da Silva1, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; 2Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

Background: Work disability is a common consequence of Rheumatoid Arthritis (RA) with economic implications for both the patient and society. Scarcely information is available on work and disease-related factors associated with early retirement in Portugal.

Objectives: To evaluate the rate of early retirement due to RA. Secondary aim consists in the identification of its main predictors, both work and disease-related.

Methods: Retrospective cohort study involving two national rheumatology centers, including patients with RA according the ACR/EULAR 2010 or the 1987 ACR Classification Criteria for RA. Patients retired prior to RA diagnosis, never-employed or with missing information on current work status were excluded. Type of work was independently classified as non-manual/white collar/manual/heavy manual by two authors based on patient occupation with excellent inter-agreement (Cohen’s kappa coefficient 0.91). Retirement due to RA versus retirement for other reasons were compared using T-test and Chi2 test as adequate. Variables with p<0.05 in univariate analysis and other potential predictors selected on clinical and epidemiological grounds were included in multivariable binary logistic regression.

Results: 492 patients were included (80.3% female, aged 60.9 ±13.1 years-old, mean disease duration 15.9 ±10.5 years). Until the present time, 45.1% (n=222) of the patients retired, this being due to RA in 59.5% of the cases. Early retirement due to RA translated into 6.5 years of active work lost, compared to retirement due to other causes. Patients who retired due to RA are more likely to be younger at diagnosis (49.6 ± 9.0 vs. 56.1 ± 8.6 years-old; p<0.01), female (82.6% vs. 68.9%, p<0.01), have longer disease duration (23.2 ± 10.7 vs. 18.3 ± 9.9 years, p<0.01) and lower educational level (4.5 ± 2.3 vs. 6.0 ± 4.1 school years, p<0.01). In the multivariate analysis, disease-related predictors for early retirement were: disease duration (OR: 1.11; 95% CI 1.08-1.13/ year), erosive disease (OR: 4.45; 95% CI 2.37-8.35) and the need for biologic therapy switching (OR:1.37; 95%CI 1.02-1.83). Work-related predictors were: educational level (OR: 0.75; 95%CI 0.68-0.81/year) and heavy manual type of work (OR: 1.62; 95%CI 1.16-2.26).

Conclusion: Early retirement is still common among patients with RA; 60% in this cohort. The main reasons for early retirement are associated with the disease itself, but work-related factors also play a relevant role.

THU0641 USE OF A WEB-BASED RHEUMATOLOGY PATIENT MANAGEMENT PORTAL

Tin Aung1, Robert Sharp2, Roopa Manhas1, Stuart Kyle2, Northern Devon Healthcare NHS trust, Rheumatology, Barnstaple, United Kingdom; 2Medimetric, Barnstaple, United Kingdom

Background: The benefit of incorporating tele-rheumatology into standard care is increasingly recognised. In January 2017, we introduced a web-based Rheumatology Patient Management Portal (RPMP), developed by MedMet, to our rheumatology patients at the North Devon District Hospital. In 2018 the portal service was fully operational. Suitable patients included undifferentiated inflammatory arthritis, rheumatoid arthritis, psoriatic arthritis and spondyloarthritides. Patients were consented to collected data such as diagnosis, treatment and disease activity onto the RPMP. For a selected group of patients who agreed to their email use, we set up schedules in the form of email reminders for them to complete PROMs (patient reported outcome measures) such as Health Assessment Questionnaire, Spinal Pain, Bath Ankylosing Spondylitis Disease Activity Index and Work Productivity and Activity Impairment. Patients can also report disease flares electronically, which is acknowledged by a health care professional who will contact them with advice as necessary.

Objectives: To understand patient participation in the use of the RPMP, between 01.01.18 and 31.12.18. To develop a cohort of clinically stable patients who can self-manage via RPMP use and scheduled PROMs. The potential to remotely manage these patients has the advantage of reducing the number of face-to-face clinic appointments and eventually will lead to setting up a virtual clinic. To examine patient perception on the RPMP use. To examine whether tele-rheumatology is a useful adjunct to standard care.

Methods: The data was collected from interrogating the web-based RPMP database. Specific data was reviewed including; total number of patients on the portal, number of patients consenting to use their email, number of PROMs completed on the RPMP, number of flares reported and time to acknowledgment. In order to gain further understanding of user experience, a survey questionnaire (figure 1) was sent on 14.01.19.

Results: In total we have 883 patients recruited to the RPMP. During the study period of one year, 289 patients have consented to share their emails and set up schedules. Thirty-three percent of patients on the RPMP are using their emails through 2018. 310 patients responded to their portal request to complete a schedule. 758 PROMs were completed as part of the schedule response. 1744 PROMs were completed face to face whilst in standard clinic review. Therefore, 30% of PROMs were completed through a scheduled response. 55 patients contacted us through the RPMP to report a flare. The average time to acknowledging a flare is 37 hours. 78% of flare reports were acknowledged within 3 days. Results from the survey of patient experience as follow: number of patients responding to the survey was 99 and respond rate was 34%.
Among them, 94% reported the RPMP as easy to use, 54% found that the RPMP helped them in understanding their rheumatology condition and 25% reported a flare through the RPMP.

### Conclusions

A large number of our rheumatology patients have consented to use the RPMP and their email. Uptake of the RPMP use is increasing (figure 2).

We have identified a significant proportion of 289 patients using the portal and email that could be targeted for virtual clinic use. Our data showed that use of tele-rheumatology in conjunction with standard care has potential to reduce number of standard clinic appointments however further work is required to investigate this.

Feedback from clinical staff is that having PROMs completed prior to consultation gives more time to discuss key issues whilst facilitating appropriate monitoring. The survey showed that a majority of patients found the RPMP easy to use and helpful in understanding their rheumatology condition. The RPMP is an effective monitoring system for selected patients and has improved patient understanding in monitoring their disease activity, with a larger group of health professionals, patients and app developers are being involved.

**EULAR POINTS TO CONSIDER FOR THE DEVELOPMENT, EVALUATION AND IMPLEMENTATION OF MOBILE HEALTH APPLICATIONS FOR SELF-MANAGEMENT IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES**

Aurélie Najm1,2, Elena Nikphorou1, Marie Kostine3, Christophe Richez4, John Pauling5, Axel Finckh6, Valentin Ritschl7, Yeliz Prior8, Petra Balazova9, Simon Stones10, Zoltán Szekanecz11, AnnaMaria Iagnocco12, Sofia Ramiro13, Francisca Sivera14, Maxime Dougados15, Loreto Carmona16, Gerd Rüdiger Burmester17, Laura Gossec18, Francis Berenbaum19, Nantes University Hospital, Rheumatology, Nantes, France; INSERM UMRS 1238 University of Medicine Nantes, Nantes, France; King’s College London, Rheumatology, London, United Kingdom;* Bordeaux University Hospital, Rheumatology, Bordeaux, France; Royal National Hospital for Rheumatic Diseases, Bath; and Department of Pharmacy and Pharmacology, University of Bath, United Kingdom, Bath, United Kingdom; Service de Rhumatologie Hôpital Beau-Séjour, Hôpitaux Universitaires de Genève, Geneva, Switzerland; Medical University of Vienna, Section for Outcomes Research, Vienna, Austria; Centre for Health Sciences Research, University of Salford, Salford and Mid Cheshire NHS Foundation Trust Hospitals, Crewe, United Kingdom;* EULAR Young PARE, Zurich, Switzerland; University of Leeds, Leeds, United Kingdom; University of Debrecen, Debrecen, Hungary; Academic Rheumatology Centre, Università degli Studi di Torino, Italy, Torino, Italy;* Leiden University Medical Centre, Leiden, Netherlands; Hospital General Universitario de Elche, Elche, Spain;* Hospital Cochin, Paris, France;* Instituto de Salud Musculosquelética, Madrid, Spain;* Charité University Clinic, Berlin, Germany;* Sorbonne Université, Pitié Salpêtrière Hospital, Paris, France;* Sorbonne Université, Saint Antoine Hospital, Paris, France.

**Background:** In the expanding era of e-health, a wide range of mobile health applications (apps) have become available to enable people with rheumatic and musculoskeletal diseases (RMDs) to better self-manage their health. However, guidance on the development and evaluation of such apps is lacking.

**Objectives:** The objective of this EULAR task force was to establish points to consider (PtC) for the development, evaluation and implementation of apps for self-management of RMDs.

**Methods:** A systematic literature review of app content and development strategies was conducted, followed by a qualitative study with six patients and an online survey of people living with RMDs (n=394). Based on these data and expert opinion, the PtC were formulated in a face-to-face meeting in November 2018 by a multidisciplinary TF panel of experts, including patients, from 10 countries. The level of agreement among the panel in regard to each PtC was established by anonymous online voting.

**Results:** Three overarching principles and 10 PtC were formulated (Table), Out of the 10 PtC, three were related to patient safety (1,5,6), considered as a critical issue by the panel, along with accuracy of information provided by apps. Three were related to relevance of the content and functionalities (2,7,9) and the importance of apps being tailored to the individual needs of people with RMDs. The requirement for transparency around app developers and funding sources (3,4), along with involvement of relevant health professionals were also raised. Ease of app access across ages and abilities was highlighted (8), in addition to considering the cost-benefit of apps from the outset (10). The level of agreement was high (Table).

**Conclusion:** These PtC provide guidance on important areas that should be considered for the development of new apps, the quality assessment of existing apps, as well as for further development of existing apps. As part of the dissemination phase, these PtC will be shared with a larger group of health professionals, patients and app developers and for wider consensus.

**Table 1. The 10 Points to Consider.**

<table>
<thead>
<tr>
<th>Points to consider</th>
<th>Level of agreement mean (SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. The information content in self-management Apps should be up-to-date, scientifically justifiable, user-accessible and evidence-based where applicable</td>
<td>9.8 (0.4)</td>
</tr>
<tr>
<td>2. Apps should be relevant and tailored to the individual needs of people with RMDs.</td>
<td>9.7 (0.5)</td>
</tr>
<tr>
<td>3. The design, development and validation of a self-management App should involve people with RMDs and relevant health care providers.</td>
<td>9.8 (0.4)</td>
</tr>
<tr>
<td>4. There should be transparency on an App’s developers, funding source, content validation process, version updates and data security.</td>
<td>9.3 (0.3)</td>
</tr>
<tr>
<td>5. Data collection as part of an App must adhere to all applicable regulatory frameworks, particularly data protection.</td>
<td>9.9 (0.3)</td>
</tr>
<tr>
<td>6. Apps must not result in potential or actual harm to people with RMDs.</td>
<td>9.5 (0.3)</td>
</tr>
<tr>
<td>7. Apps could facilitate patient-health care provider communication and contribute to electronic health records or research.</td>
<td>9.4 (0.9)</td>
</tr>
<tr>
<td>8. App design should consider accessibility of people with RMDs across ages and abilities.</td>
<td>9.4 (0.9)</td>
</tr>
<tr>
<td>9. If a social network is an important component of an App, structures should be put in place to ensure appropriate content moderation.</td>
<td>9.5 (0.6)</td>
</tr>
<tr>
<td>10. The rheumatology community should consider the cost-benefit balance of Apps before its endorsement and/or its promotion.</td>
<td>8.9 (1.3)</td>

ARE PSORIATIC ARTHRITIS OUTCOMES BETTER IN PATIENTS MANAGED IN EARLY ARTHRITIS CENTRES?

Muhammad Khurram Nisar, Luon and Dunstable University Hospital, Luton, United Kingdom

Background: There is good evidence that dedicated early arthritis clinics (EACs) improve referral lag time and reduce delay in establishing disease-modifying therapy. However it remains arguable whether such clinics improve outcomes especially for arthritides other than RA. In the UK, only 57% of units have dedicated EACs. Our early arthritis service won national best practice commendation award for achieving high standards.

Objectives: We analysed our psoriatic arthritis (PsA) population data to ascertain whether this cohort benefits from EACs.

Methods: The department set up an early arthritis service with introduction of six clinics (EACs) every week. An agreed treatment protocol incorporating ultrasound was developed to ensure standardised approach to early initiation of treatment, drug education and timely review. This is a retrospective study of all patients with PsA presenting to the service in the first 3 years.

Results: Our catchment area covers a population of 350,000 with 40% ethnic minorities. Of 1884 patients referred, 482 (25.5%) were triaged into EACs based on set criteria. All were reviewed within 3 weeks. 247 (51%) were confirmed to have early inflammatory arthritis (EIA). Mean age was 52.4 years (17-86y). 157 (63.5%) were women. 177 (71.6%) were White, 58 (23.5%) of Asian and twelve of other background. 159 (63.4%) had RA, 55 (22%) with PsA and 33 had other inflammatory arthritides. There was median 26 days delay (0.0-1043 days) from symptom onset to GP presentation. Median time for GP referral to the department was 4.0 days (0-84 days).

All PsA patients had regular PsARC assessment. Mean tender (TJ) and swollen joint (SJ) counts at first visit were 8.2 (1-35) and 3.5 (0-14) respectively [n=55]. The patient (PtGA) and physician (PhGA) global assessments mean were 3.0 and 2.9 (1-5). 95% commenced their DMARDs within 3 week of initial review. Other 5% who missed the target was owing to patient factors. Target [TJ & SJ ≤2] was achieved for 38 patients (69%) and good PsARC response for a further 4 (7%). Median time to achieve the target or good response was 22 weeks (0-48 weeks). Of 55, only four (7%) patients required escalation to biologic therapy. Final TJ and SJ mean was significantly better at 1.2 (0-4) and 0.3 (0-2) [p <.0001] with similar improvement in PtGA [mean 1.8 (1-4)] and PhGA [mean 1.6 (1-3)]. Only six (11%) patients were true non-responders as the remaining seven declined therapy.

Conclusion: Dedicated EACs help achieve good clinical outcomes in majority of PsA patients. Nearly 76% of our cohort attained the target or good PsARC response in less than six months. This was despite a significant delay in patients presenting to their GPs and moderately-high disease activity. 100% of our patients were treated to target facilitated by protocol driven escalation of therapy in these clinics. This is in contrast to the national audit findings whereby only 68% of patients were treated with disease modifying drugs within 6 weeks of referral and 89% had treatment to target. This study shows that the establishment of dedicated EACs improve the prognosis of psoriatic arthritis in terms of primary clinical outcomes compared to patients managed outside of EACs.

THU0644 PATIENTS’ PERCEPTION AND USE OF MEDICAL MARIJUANA

Kelly Gavigan1, Shilpa Venkatachalum2, Jeffrey Curtis3, Seth Ginsberg1, W. Benjamin Nowell1. 1Global Healthy Living Foundation, Nyack, United States of America; 2University of Alabama at Birmingham, Birmingham, Birmingham, United States of America

Background: Though the introduction of biologics has resulted in significant improvements in their quality of life, people living with rheumatic and musculoskeletal disease (RMD) often seek alternative treatments such as marijuana (THC) and cannabidiol (CBD). As these substances become more widely available, and legal in some jurisdictions, health care providers (HCP) need to understand patients’ THC/CBD perceptions, use and information needs.

Objectives: To examine patient behavior and information needs regarding THC/CBD medical use.

Methods: A 77-item survey was developed in partnership with RMD patient partners and administered online via CreakyJoints and the ArthritisPower research registry. Participants (pts) were eligible if they were ≥19 years of age, resided in the US and reported physician-diagnosed RMD. Pts reported current health status (NIH PROMIS Global Health), use and perceptions of THC/CBD, and related information needs.

Results: To date, 189 pts completed the survey. A majority of pts were female (87%) and white (93%), with mean age of 55(11). More than half of all pts (62%) reported a diagnosis of rheumatoid arthritis. Most pts (78%) reported fair/poor health (PROMIS Global Physical Health <43). Only 30% of all pts were satisfied with their current treatment, and more than half (63%) had been on their current treatment for >1 year. Of those surveyed, a majority of pts (n=168, 89%) reported trying THC and/or CBD for a purpose they perceived as medical and offered various reasons for initiating its use (Table). Half of all pts (n=98, 52%) reported ever using CBD and a third (n=70, 37%) ever using THC for medical reasons, “fifty-one (73%) of whom currently use THC. More than half (53%) of those currently using THC reported using it at least once daily. Top reasons for stopping among the 19 who previously used THC were cost (26%) and illegality (26%). Most pts who had ever used THC reported that THC improved their symptoms (83%) and/or their condition (71%). Pain (100%) and sleep disturbance (73%) were the main symptoms pts sought to relieve with THC. Many pts had used THC in lieu of prescribed (56%) or OTC (73%) medications. Two thirds (67%) reported telling their HCP about their THC use, most of whom (64%) reported that their HCP did not consider it when making treatment changes nor offer advice about mode of administration or dosage. When acquiring THC, 39% of pts used a medical marijuana card issued by the state; the main reason given for not using a card was that THC was not legal for medical use where the pt lived (44%). Whether they had used THC for medical reasons or not, nearly all pts wanted information about THC, including its effectiveness (37%) and its interaction with other medications (34%); a majority preferred to receive information from HCPs (55%) or online educational resources (34%). Two thirds (60%) of all pts expressed interest in THC/CBD trial participation.

Table: Participants’ Reasons for Initiating THC/CBD Use (N=168)

VIRTUAL VISITS IS THE FUTURE COMING? TELEREUMATOLOGY. PILOT PROJECT: REVIR PROGRAM, RHEUMATOLOGY SERVICE. BARCELONA, SPAIN

Fabiola Ojeda1,2, Manel Ciria1, Carolina Perez-Garcia1, Eric Sitjas2, Elena Martinez1, Daniel Martinez-Laguna1, Montserrat Pimienta1, Jordi Montfort1.
1Hospital del Mar, Rheumatology, Barcelona, Spain; 2Hospital del Mar, Dirección, Barcelona, Spain; 3Institut Català de la Salut, CAP Vila Olimpica, Barcelona, Spain; 4Institut Català de la Salut, CAP Sant Marti, Barcelona, Spain; 5Institut Català de la Salut, CAP Ramón Turró, Barcelona, Spain

Background: The prevalence of rheumatic diseases in the Spanish population is estimated at 22.6% according to the EPISER 2000 study. A new epidemiological study is currently underway, EPISER 2016 and its preliminary results point towards a higher prevalence. Within the national health system, primary care is the first level of access to the health system and is provided at primary care centers (CAP). The rheumatology at primary care centers at Spain has been a pioneer in the application from the team at Parc de Salut Mar (Hospital del Mar), with the physical presence of rheumatologists in the 14 centers belonging to the CAP network of the SAP Litoral. The high prevalence of the medical pathology of the musculoskeletal system and the aging of the population, can condition an increase in visit requests in rheumatology, and with it, the increase in the waiting lists of patients.

Objectives: The main objective of this study is to know the resolutive possibility of virtualization, measured in the number of visits resolved telemedically, as well as its impact on the waiting list of the primary care physician and the reduction of the waiting list of first face-to-face visits.

Methods: Prospective experimental study, started on December 1, 2017 and ended on May 31, 2018. Four primary care centers were selected according to population and waiting list: Sant Martí Nord, Sant Martí Sud, Ramón Turró and Villa Olimpica. The REVIR program proposes the creation of a circuit for the assessment of referrals to rheumatology from primary care physicians (MAP).

Results: 726 first visit requests were received during the REVIR program. The most common categorized pathology was mechanical pathology, representing about 70% of the first visits requested. Metabolic bone disease ranked second with 16%, and inflammatory pathology ranked third (SLE, RA, SA, SPA, PsA). Chronic musculoskeletal pain ranked fourth (including fibromyalgia) and lastly soft tissue pathology. The number of first visit requests was multiplied by two in all the participating primary care centers of the project. Despite this increase, the telematic resolution of the visits created was stable, with a value greater than 40%.

Conclusion: The implementation of a system of assessment of the first visits in rheumatology requested from Primary Care is effective in decreasing the waiting list to make face-to-face visits, as well as to detect early serious pathology that requires hospital control. It has been achieved, therefore, that the patient is treated at the level of attention that corresponds to him. Guaranteeing the adequate use of hospital resources and reducing the waiting list for a first in-person visit in rheumatology in primary care is one of the most important goals fulfilled, given that it is directly related to maintaining the accessibility and equity of the public health system.

HIGH LEVELS OF DAMAGE IN INFLAMMATORY RHEUMATIC DISEASES: A CLUE TO LOW RATES OF REMISSION AND LOW DISEASE ACTIVITY

Isabel Castrejon, Sarah Everaekes, Joel Block, Sonali Khandelwal, Alida Nika, Padmanabh Raghu, Theodore Pinus, Rush University Medical Center, Rheumatology, Chicago, United States of America

Background: Despite introduction of powerful biologic medications over the last 2 decades, rates of remission and low disease activity rates in RA remain less than 50%. One possible basis is that measures and indices such as disease activity score 28 (DAS28) and clinical disease activity index (CDAI), while sensitive primarily to disease activity in clinical trial patients selected for high inflammatory activity, may also reflect clinically important joint damage and patient distress in unselected patients in routine care. Similar considerations may pertain to systemic lupus erythematosus disease activity index (SLEDAI), Bath ankylosing spondylitis disease activity index (BASDAI), and other measures and indices initially designed to assess disease activity. Levels of organ damage and patient distress, as well as inflammation, may be quantitated according to 3 physician (0-10) visual analog scales (VAS), in addition to physiological global assessment VAS (DOCGL), scored in fewer than 10 seconds in routine care.

Objectives: To test a hypothesis that damage and distress may be prominent in patients with inflammatory conditions, according to mean VAS for inflammation or reversible findings (DOCINF), damage or irreversible findings (DOCDAM), and distress (DOCDST), e.g., fibromyalgia.

Methods: All patients at one site complete a multidimensional health assessment questionnaire (MDHAQ), which includes patient global VAS (PATGL), at each visit in routine care. Physicians complete four 0–10 (none-highest) VAS for DOCGL, DOCDAM, and DOCDST, and a query to estimate the proportion of clinical decisions (total-100%) attributed to each of the 3 findings. Patients were classified into various diagnostic groups, in which scores were analyzed according to mean and standard deviation.

Results: Analyses included 563 patients (Table). Mean levels of DOCGL ranged from 3.2 to 5.2, and PATGL from 3.6 to 6.5, which might be interpreted to indicate high disease activity. Highest mean DOCINF scores were seen in patients with RA, SLE, vasculitis, polyarthritis rheumatica (PMR), spondyloarthropathy (SpA) and gout (2.2-2.8), while highest mean DOCDAM was seen in OA (4.9) and DOCDFST in FM (6.2) (Table). However, in RA, mean DOCDAM was 3.7 vs 2.4 for DOCDIN. DOCDAM also was almost as high or higher than DOCDINF in SLE, SpA, vasculitis, and gout. Mean estimates of distress were also ≥1.5 in patients with all inflammatory diagnoses.

Conclusion: Rheumatologists estimated high levels of damage in patients with RA and other inflammatory rheumatic diseases, similar or higher than inflammation, as well as recognizable distress which may elevate measures such as tender joint count and PATGL. These findings may explain in part low rates of remission and low disease activity noted in RA and other inflammatory diseases, as index scores used to document improvement are not affected by anti-inflammatory therapy. Most rheumatology clinical quantitative measurement is directed to inflammatory activity. However, an estimate of damage and distress may clarify why many patients may appear to lack inflammatory activity despite aggressive treatment, including treat to target in RA.

Disclosure of Interests: None declared

CHARACTERIZING PERSISTENCE OF IV ABATACEPT AMONG ELDERLY PATIENTS WITH RA IN THE US MEDICARE POPULATION

Tayla Poreta, Dhaval Patil, Ying Bao, Francis Lobo. Bristol-Myers Squibb, Princeton, NJ, United States of America

Background: Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease characterized by inflammation of the joints, which can ultimately lead to cartilage damage and bone destruction. While early and aggressive intervention with biological treatment may alter the course of the disease and improve physical functioning, persistence to these medications varies, ranging from just 30 to 80%. It is important to understand the factors associated with persistence to RA treatment, as non-adherence may incur greater healthcare costs and utilization, disease progression, and the potential requirement for even more aggressive therapy in the future.

Objectives: To describe patient characteristics and baseline healthcare costs that affect persistence to intravenous (IV) abatacept, which may be supportive in evaluating the risk-benefit ratio of abatacept for treatment of RA.

Methods: Patients (aged >65 years) with at least one inpatient or two outpatient medical claims for RA and subsequent treatment of IV abatacept from 01JUL2006 to 31DEC2016 were identified in the Truven MarketScan Medicare Supplemental database. The date of first prescription of IV abatacept was considered the index date; patients with another biologic DMARD claim on the index date were excluded. Patients were required to have 6 months continuous enrollment before and 12 months continuous enrollment following index date. Persistence was defined as the number of days from treatment initiation (index date) to first switch to another biologic DMARD, discontinuation of abatacept, or end of follow-up. Patients with >6 months of treatment were categorized as high persistence and ≤6 months of treatment as low persistence. Patient characteristics were summarized by level of persistency and compared using Wilcoxon’s rank sum test for continuous variables and chi-square test for categorical variables.

Results: Among 1,963 patients meeting inclusion criteria, 1,167 patients (59.4%) were categorized as having high persistence to IV abatacept. Patient characteristics were similar at baseline between cohorts; the mean age was 74 years, 79% were female, and the mean Charlson Comorbidity Index (CCI) score was 2.02. Compared to low persistency cohort, patients with high persistence to IV abatacept had significantly greater prior exposure to methotrexate (44% vs 51%, p=0.001) and infliximab (18% vs 24%, p<0.001). Patients with high persistence to abatacept also had higher, albeit non-significant, prior use of TNFi (39% vs 41%, p=0.304). In addition, higher persistence to abatacept was significantly associated with higher all-cause baseline medical per patient per month (PPPM) costs ($450 vs $475, p=0.005) and higher RA-related baseline medical PPPM costs ($177 vs $231, p<0.0001). Patients with lower all-cause baseline pharmacy PPPM costs ($709 vs $596, p=0.174) and RA-related baseline pharmacy PPPM costs ($375 vs $272, p=0.773) had higher persistence to abatacept, although these associations were not statistically significant.

Conclusion: Among US Medicare patients with RA, surrogate markers of high disease severity, including prior methotrexate and infliximab use and higher baseline medical costs, were significantly associated with higher IV abatacept persistence. These results may assist both physicians and payers in identifying Medicare patients who benefit from abatacept and tailoring their approach accordingly to minimize the risk of non-persistence.

WORK DISABILITY IN A PERUVIAN COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Cristina Reartequi Sokolovs1,2, Claudia Elara Fitzcarrald1,2, Rocío Violeta Gamboa Cárdenas1, Manuela Medina1, Francisco Zevallos Miranda1, PaolaAlejandra Zerpa Huanças1, Víctor Pimentel Quiroz1, Jorge M Cusco-Vélez1, Cesar Pastor Asurza1,3, Zoila Rodríguez Bellido1,4, Risto Perich Campos1,4, Graciela S Alarcón1,5,6, Manuel F. Ugarte-Gi1,3, 1Hospital Nacional Guillermo Almenara Iñiguez, Lima, Peru, 2Unidad para la Generación y Síntesis de Evidencias en Salud, Universidad San Ignacio de Loyola, Lima, Peru, 3Universidad Científica del Sur, Lima, Peru, 4Universidad Nacional Mayor de San Marcos, Lima, Peru, 5University of Alabama at Birmingham, Birmingham, United States of America, 6Universidad Peruana Cayetano Heredia, Lima, Peru

Background: Work disability in patients with systemic lupus erythematosus (SLE) is common but the factors associated with it in Low and Middle Income Countries have been scarcely evaluated.

Objectives: To determine the prevalence of and the factors associated with work disability in SLE patients.

Methods: We studied 239 consecutive (1997 American College of Rheumatology (ACR) criteria) patients from a Peruvian SLE cohort from October 2017 to December 2018. Work disability was measured from a single self-report questionnaire. Data were collected and included sociodemographic information, clinical lupus features including disease activity [Systemic Lupus Erythematosus Disease Activity Index 2000 update (SLEDAI-2K)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDII)], as well as Health-Related Quality of Life (LupusQoL), and medication use. Work disability was defined by patients’ self-report of not being able to work because of SLE. Univariable analysis comparing those patients with work disability and those who remained working were performed with the Mann Whitney U test for continuous variables and the Chi-square test for dichotomous variables. For the multivariable analyses, binary logistic regression with backward elimination was used to determine which factors remained associated with work disability.

Results: Of 239 patients, 194 patients were working at least for at least some time since diagnosis, 181 (93.0%) were female, they had a mean age at diagnosis of 34.5 (12.3) years, and a mean disease duration of 11.5 (7.4) years, their mean SLEDAI was 2.53 (3.7) and their mean SDI was 1.2 (1.5). Twenty-eight patients changed their activities at work due to SLE and 51 (26.6%) stopped working after their diagnosis; 21 of them (41.1%) stopped working because of SLE. One hundred and forty-three were working at the time of the evaluation. In the multivariate analyses, those work-disabled due to SLE were more likely to have higher SLEDAI-2K (p=0.009), and lower HRQoL in two domains, planning: OR=0.975 (CI 95%: 0.954-0.998) p=0.020 and body image OR=0.977 (CI95%: 0.956, 0.998), p=0.032.

Conclusion: Work disability due to SLE is associated with higher damage accrual and a poorer HRQoL.

Rheumatic/systemic irAEs can be divided into 5 phenotypic clusters: articular, muscular, granulomatous, vasculitic and systemic. These findings must be confirmed in real-life patients, and an international data-sharing ICIR registry is planned to be launched.

**COMPLEMENTARY AND ALTERNATIVE MEDICINE IN RHEUMATOLOGY: A SURVEY OF ITS USE FOR COMMON RHEUMATOLOGICAL CONDITIONS AMONG MULTI-ETHNIC PATIENTS IN LEICESTERSHIRE**

Chris Sabu Tharakan1, Nutchaya Ungcharoen2, Jessy Sabu3, Anumugam Moorthy4. 1University of Nottingham, School of Medicine, Nottingham, United Kingdom; 2University Hospitals of Leicester NHS Trust, Rheumatology, Leicester, United Kingdom

**Background:** The use of complementary and alternative medicine (CAM) is common in patients with chronic disease. However, the usage of CAMs among patients with rheumatological conditions has been understudied. A significant portion of primary care trusts are now providing therapies such as acupuncture and osteopathy to some of the 9 million users of CAMs in the United Kingdom (UK). As the NHS serves a varied patient populace, it is important to appreciate the perceptions and utilisation of CAM amongst multi-ethnic groups.

**Objectives:**
1. To identify the different types CAMs utilised by Rheumatology patients.
2. To identify Rheumatology patients' views towards the role and use of CAMs in managing their condition(s).
3. To identify locations where patients receive CAM and to determine patient's spending practices.

**Methods:** A cross-sectional survey on CAMs, and its use for common rheumatological conditions was conducted among multi-ethnic patients in Leicestershire, UK, through convenience sampling. The initial questionnaire was created by a multi-disciplinary input, with a patient-centred focus. Thereafter, 12 questionnaires were piloted and revised accordingly. The data subsequently underwent statistical analyses.

**Results:** A total of 107 patients completed the survey over a 3-month period with a response rate of 90%. Most of the respondents (91.8%) were over the age of 35 (age range 19 to 78 years, mean age 50.512 (SD)). Among the respondents, 66% were women and 34% were men. 72.9% were of white British or European ethnicity and 20.6% of South Asian ethnicity (17.8% Indian and 2.8% Pakistani). Majority of the patients (66.4%) had rheumatoid arthritis (RA), followed by psoriatic arthritis (11.2%) and ankylosing spondylitis (4.7%). The respondent demographics were consistent with known epidemiology of common rheumatological conditions, with a higher prevalence among women than men (female-to-male ratio of 3:1 in RA), 31.8% used CAM for managing symptoms related to their condition(s). Almost half of these respondents (41.2%) used CAM products and/or practices daily, with up to 64.7% spending between £10–£100. The majority of respondents (82.4%) received CAM therapy within the UK, following a phased approach (6.7%) and ankylosing spondylitis (4.7%). The patient demographics were consistent with known epidemiology of common rheumatological conditions, with a higher prevalence among women than men (female-to-male ratio of 3:1 in RA).

**Conclusion:** In our local multi-ethnic population, it is evident that a notable proportion of patients have utilised CAM to supplement the management of their condition. Healthcare professionals need to be aware of the CAMs available, particularly when informing and treating their patients. Effective communication is required in this area to maintain patient's confidence and safety. Further qualitative research should consider the reasons for the use of CAMs.

**AN INDIVIDUALIZED DECISION-AID FOR DIVERSE WOMEN WITH LUPUS NEPHRITIS (IDEA-WON): A RANDOMIZED CONTROLLED TRIAL**

Javvinder Singh1, Liana Fraenkel2; Candace Green3, Graciela S Alarcon4, Jennifer Barton1, Kenneth Saag1, Leslie Hanahan2, Sandra Raymond3, Robert Kimberly1, Amye Leong4, Elyse Reyes5, Richard Street6, María Suarez-Almazor6, Guy Eakin7, Laura Marrow8, Charity Morgan9, Brenda Cara10, Jeffrey Sloan11, Bochra Jandal12, Salvador Garcia12, Jennifer Grossman13, Kevin Winthrop13, Laura Trupin13, Maria Dallera14, Alexia Mezari15, Tara Rizvi16, Winn Chatham16, Jinoo Yazzdany16. 1University of Alabama in Birmingham, Birmingham, United States of America; 2Yale University, New Haven, CT, United States of America; 3Oregon Health Science University, Portland, OR, United States of America; 4Lupus Foundation of America, Washington DC, United States of America; 5Healthy Motivation Inc., Los Angeles CA, United States of America; 6Elyse Reyes Consulting, Los Angeles CA, United States of America; 7Texas A&M University, College Station TX, United States of America; 8University of Texas MD Anderson Cancer Center, Houston TX, United States of America; 9Arthritis Foundation, Atlanta GA, United States of America; 10Georgia State University, Atlanta GA, United States of America; 11Mayo Clinic School of Medicine, Rochester, MN, United States of America; 12Baylor College of Medicine, Houston TX, United States of America; 13University of California, Los Angeles CA, United States of America; 14Ohio State University, Columbus OH, United States of America

**Background:** Medication decision-making is challenging in lupus. No validated, effective decision-aids are available to assist patients with medication decision-making.

**Objectives:** Our objective was to assess the effectiveness of an individualized, culturally-tailored, computerized decision-aid for immunosuppressive medications for lupus nephritis.

**Methods:** In a multicenter, randomized controlled trial, diverse adult women with lupus nephritis, largely racial/ethnic minorities with low socioeconomic status, were randomized to decision-aid vs. American College of Rheumatology lupus pamphlet (1:1 ratio). Co-primary outcomes were change in decisional conflict and informed choice regarding immunosuppressive medications.

**Results:** Of 301 randomized women, 47% were African-American, 26% were Hispanic, and 15% White. Mean age (standard deviation [SD]) was 37 (12) years, 57% had annual income of <$40,000, and 36% had a high-school education or less. Compared to the pamphlet (n=147), participants randomized to the decision-aid (n=151) had: (1) a clinically meaningful and statistically significant larger decrease in decisional conflict, 21.8 (standard error [SE], 2.5) vs. 12.7 (SE, 2.0; p=0.005); and (2) a clinically meaningful difference in informed choice, statistically non-significant in the main analysis, 41% vs. 31% (p=0.08), but significant in sensitivity analysis (net values for immunosuppressives positive [in favor] vs. negative [against]), 50% vs 35% (p = 0.006). Respectively, unResolved decisional conflict post-intervention was significantly lower, 22% vs. 44% (p=0.01). In delayed group, participants randomized to decision-aid had greater interest in obtaining patient-rated information to be excellent for understanding lupus nephritis (49% vs. 33%), risk factors (43% vs. 27%), medication options (50% vs. 33%; p<0.003 for all); and the ease of use of materials higher (51% vs. 38% p=0.006).

**Conclusion:** An individualized decision-aid was effective in reducing decisional conflict for immunosuppressive medications in diverse women with lupus nephritis.

THE ECONOMIC BURDEN OF ANCA-ASSOCIATED VASCULITIS IN GERMANY – A CLAIMS DATA STUDY

Philip Spearpoint1, Dieter Götte2, Angelika Deichmann3, Marc Wengler4, Matthias Schoenemark3, Peter Rutherford2, Viforpharma, Global Pricing and Market Access, Glattbrugg, Switzerland; Viforpharma, Global Medical Affairs, Glattbrugg, Switzerland; SKC Beratungsgesellschaft, Hannover, Germany

Background: ANCA-associated vasculitis AAV is a rare systemic disease, characterized by recurrent episodes of systemic inflammation. It is a severe disease associated with hospitalization, risk of renal failure and a therapy inducing serious side effects. The economic impact of AAV to the German health care system is currently not well understood.

Objectives: The aim of this study was to better understand and quantify the economic burden of AAV in Germany. Therefore, selected aspects, such as prevalence and incidence, frequency of hospitalization, frequency of intensive care unit (ICU) stays and treatments costs, were systematically assessed in a claims data study.

Methods: Longitudinal data from years 2013 to 2016, provided by German statutory health insurance (SHI) companies from the InGef database have been analyzed representing an age- and gender stratified cohort of approx. 4 million insured persons representative for the German population.

Results: Prevalence and incidence data show that, in accordance with the previously published literature (1, 2), Granulomatosis with Polyangiitis (GPA) was more frequent than Microscopic Polyangiitis (MPA). On average, a combined prevalence of 256 : 1 000 000 (210 : 1 000 000 for GPA and 46 : 1 000 000 for MPA) was identified within the data set over the observed time period of 4 years (2013-2016). Incidence rates were found to be 46 : 1 000 000 (34 : 1 000 000 for GPA and 13 : 1 000 000 for MPA) within the same time period. Over the observed time period, prevalence and incidence rates remained stable.

The majority of GPA and MPA diagnoses were made in hospitals (61%), another 24% were diagnosed in the outpatient sector and 15% were diagnosed in both within one quarter. In total, 97% of newly diagnosed patients (GPA and MPA) were hospitalized within 4 years post diagnosis. Especially during the induction period (quarter of diagnosis and the following 2 quarters) 91% (GPA) to 95% (MPA) of the patients were hospitalized. Of these patients, approx. 60% were hospitalized due to GPA and MPA disease, showing the high rate of severe co-morbidities.

Patients diagnosed with GPA and MPA were frequently treated at ICUs (in average 1 stay per quarter); in particular severe infections and renal involvements increased the likelihood of ICU stays.

Treatment costs were highest during the induction period; within this period hospitalization represented the largest cost factor. Severe kidney disease, which occurred in 11.6% of GPA and 24.3% of MPA patients, induced total costs ranging between 131.521€ (GPA) to 145.472 € (MPA) over four years post diagnosis, with the induction period being most expensive (approx. 58.826 € to 50.339 € for GPA and MPA during the induction period). In the following years total treatment and hospital costs decreased, however remained high.

Conclusion: AAV represents an underestimated financial burden to the German healthcare system, especially during induction therapy. The high level of hospitalizations amongst AAV patients also represents a high usage of healthcare resources. Thus, AAV represents an underestimated cost factor for the German health care system, and better treatment options are desperately needed.

SOCIOECONOMIC ANALYSIS OF GOLIMUMAB TREATMENT IN PATIENTS WITH RA, PSA, AND AS – NON-INTEVENTIONAL STUDY GO-NICE

Klaus Krueger1, Gerd Rüdiger Burmester2, Siegfried Wassenberg3, Astrid Thiele4, Matthias Thomas5, 1Rheumatologisches Praxiszentrum St. Bonifatius, München, Germany; 2Charité - Universitätsmedizin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 3Rheumazentrum Ratingen, Ratingen, Germany, 4Krankenhaus St. Josel, Wuppertal, Germany, 5Msd Sharp and Dohme GmbH, Medical Affairs, Haar, Germany

Background: Rheumatic diseases are associated with pain, loss of functionality, fatigue, hospitalization, sick leave, and work disability. This results in high economic burden for patients and society.

Objectives: Golimumab (GLM) is an effective but costly treatment option for patients (pts.) with moderate to severe, active rheumatic diseases. The aim of this analysis of the GO-NICE study was to investigate the direct and indirect costs of healthcare utilization and sick leave after starting a treatment with GLM.

Methods: Data of outpatients collected in the non-observational study GO-NICE in 1,483 pts. with RA (n = 474), PsA (n=501), and AS (n=483) in 158 sites (2010-2015) in Germany were analysed. Details on the study design, pts., characteristics, the clinical and patient-reported outcomes, and safety data have been reported earlier [1,2]. Direct medical and indirect costs per patient and year were calculated for consultations, physiotherapy, massages, hospitalisations and inpatient reha- bilitation, medication (DMARDs, Glucocorticoids, NSAIDs, and biologics) as well as sick leave days. Findings were shown for RA-, PsA- and AS-pts. and categorised by biological-naïve pts. and pts. with a pre-treatment with a biologic. The 6-month periods prior baseline (BL)/start of a GLM therapy vs. month 24 (M24) were compared.

For this calculation the standardized evaluation rates were used (Bock et al. (2015), AG MEG of the DGSMMP (2005)). Costs for prescribed and documented medication were calculated by the mean cost per defined daily dose (detailed use 2010-2015). Indirect costs were estimated through the human capital approach (HCA).

Results: Data of 758 biologic-naive pts. (n = 265 RA, 247 PsA and 246 AS) and 694 pts. with biologics as pre-therapy (n = 208 RA, 252 PsA and 234 AS) were included in the analysis. Direct medical costs (excl. medication) decreased in all 6 groups, min. 765€ (PsA pre-treatment group) and max. 2,426€ (AS pre-treatment) as well as the costs due to work disability/sicknessism, min. 855€ (PsA pre-treatment) and max. 2,564€ (RA pre-treatment, table). Total costs in biological-naive pts. increased due to the additional expense of the biologic agent.

Absolute changes in costs totalled 15,685€ (RA-, table), 15,799€ (PsA-) and 14,764€ (AS-patients) per patient and year when comparing the BL vs. M24 periods.

Total savings of 6,289€ (RA-, table), 2,617€ (PsA-), and 5,555€ (AS-patients) per patient and year were generated in the group of biologic-pre-treated patients.

RA pts. biologic-naive (n=265) RA pts. with biologics as pre- treatment (n=208)

Table 1. Costs per patient and year (Subgroup patients with RA)

Conclusion: Costs of healthcare utilization, as well as work disability decreased after starting GLM within an observation period of 24 months, for pts. with RA, PsA, and AS, respectively. Due to the high costs of TNFi therapy, drug costs in the group of biologic-naive pts. rose markedly. Savings were generated in the group of pts. pre-treated with biologics.

THU0654 INFLUENCE OF THE NEW PHARMACOLOGICAL AND NON-PHARMACOLOGICAL APPROACHES IN RHEUMATOID ARTHRITIS ON WORK PARTICIPATION: A SYSTEMATIC LITERATURE REVIEW

Famke Wildeemersch1, Peggy Jacques2,3, Philippe Carron1, Xavier Janssens1.
1University of Ghent, Ghent, Belgium; 2University of Ghent, Rheumatology, Ghent, Belgium; 3Inflammation Research Center, Flanders Institute of Biotecnology, Ghent, Belgium

Background: Rheumatoid arthritis (RA) is a chronic and progressive autoimmune disease that frequently has a negative impact on work participation among patients. Even more, patients with RA are at greater risk to become work disabled, have a reduced work productivity (presenteeism) or increased sick leave (absenteeism) compared to the general population. This outcome can be related to the World Health Organization International Classification of Functioning, Disability and Health (the WHO ICF framework), that is useful in understanding the impact of RA regarding functioning. Since 2000, the management of RA has made significant progress. With the establishment of the new ACR/ EULAR criteria and the treat-to-target (T2T) strategies, patients are nowadays diagnosed and treated earlier. Furthermore, the improvement of the management of RA has led to much better results regarding disease activity and joint destruction. However, many of these patients are confronted with additional fees when contracting private insurances, since the risk assessment by insurances is mainly based on historical data.

Objectives: This systematic literature review was performed to study the influence of new pharmacological and non-pharmacological approaches on work participation among patients with RA with the objective to improve the risk assessment of RA patients when contracting private insurances.

Methods: A systematic literature review from January 1990 until January 2018 was performed using Pubmed, Embase and Web of Science. Different search terms were used in each database: employment, workplace, sick leave, absenteeism, work capacity and international classification of functioning, disability and health. All studies assessing one of the search terms were analysed.

Results: Finally, 49 relevant articles were selected. The selected studies were subdivided according to study design (RCT versus cohort studies and disease duration of the studied patients. Studies that examined the value of an adequate early intervention were grouped separately. Overall, studies on the impact of the non-pharmacological approach were limited and very heterogeneous. Positive results of pharmacological agents (combination of DMARDs or biologic therapy) on work participation could be demonstrated in patients with recent-onset RA. Long-term observational studies showed an association between initiation of new therapeutic strategies and a reduction in work disability among patients with RA. However a causal relation was difficult to confirm because of the study design. Moreover, some studies pointed out other contextual factors that also influence work disability such as political policy, demographic changes in age distribution or educational level.

Conclusion: The large heterogeneity in terms of patient population, study design and outcome measures limits interpretation of the data. However, this systematic literature review could demonstrate that the effect of a treatment is of utmost importance and not the treatment itself. This emphasizes also the importance of early intervention with pharmacological agents regarding work productivity outcomes in RA. In addition, the impact of personal and environmental factors on work participation may not be neglected.

Epidemiology, risk factors for disease or disease progression

THU0655 LONG-TERM OUTCOME OF JUVENILE IDIOPATHIC ARTHRITIS: COMPARISON OF BIOLOGIC AND METHOTREXATE ERAS

Gabriella Giancane1,2, Valentina Muratore3, Valentina Mazzeri3, Neus Quíllis Maris3, Beatríz Serrano Benavente1, Francesca Bagnasco1, Alessandra Alongi1, Adele Cinvio1, Lorenzo Quarulli3, Alessandro Consolaro1,2, Angelo Ravelli1,2,1, I.R.C.S. Gianna Giagni, Clinica Pediatrica e Reumatologica, Genova, Italy; 3Università degli Studi di Genova, Genoa, Italy; 4RCCS Fondazione Policlinico San Matteo, Clinica Pediatrica, Pavia, Italy; 5Ospedale Generale Provinciale, Padania, Macerata, Italy; 6Ospedale Vito Fazzi, Lecce, Italy; 7Azienda Ospedaliero Cardinale G. Panico, Tricase, Italy

Background: After nearly two decades from the start of the Biologic era, systematic analyses of patients with juvenile idiopathic arthritis (JIA) have shown a high frequency of attainment of inactive disease (ID) and satisfactory levels of physical function and quality of life. However, whether and to what extent the disease prognosis has improved in comparison with the methotrexate (MTX) era is still uncertain.

Objectives: To compare the long-term disease state, in terms of activity and damage, of children with JIA who had their disease onset in MTX or Biologic eras.

Methods: Patients were included in MTX or Biologic era cohorts depending on whether their disease presentation occurred before or after January 2000. Patients in the MTX era cohort and part of the patients in the Biologic era cohort were taken from a previous cross-sectional study published by our group, which enrolled 310 patients with disease onset between December 1986 and December 2002. An additional sample of patients with onset in the Biologic era was enrolled in a subsequent prospective cross-sectional study, which included all consecutive patients meeting the ILAR criteria for JIA, who were seen consecutively at the Istituto Gaslini of Genoa, Italy, between January 2015 and June 2017. All patients had disease duration ≥ 5 years and underwent a prospective cross-sectional assessment, which included measurement of disease activity and damage. ID and low disease activity (LDA) states were defined according to Wallace, JADAS10 and cJADAS10 criteria. Articular and extra-articular damage was assessed with the Juvenile Arthritis Damage Index (JADI).

Results: MTX and Biologic era cohorts included 239 and 269 patients, respectively. Patients were divided in the “functional phenotypes” of oligoarthritis and polyarthritis. At cross-sectional visit, patients in the Biologic era cohort with either oligoarthritis or polyarthritis had consistently higher frequencies of ID and LDA than patients in the MTX era cohort. The measurement of disease damage at cross-sectional visit revealed that the frequency of impairment of > 1 JADI-Articular items was higher in MTX than in Biologic era cohort (17.6% versus 11% in oligoarthritis and 52.6% versus 21.8% in polyarthritis). Likewise, frequency of involvement of > 1 JADI-Extraarticular item was higher in MTX than in Biologic era cohort (26.5% versus 16.2% in oligoarthritis and 31.4% versus 13.5% in polyarthritis). The sole JADI items that were detected in more than 5% of patients in the Biologic era cohort were temporomandibular damage in oligoarthritis and polyarthritis, ankle damage in polyarthritics and leg-length inequality in oligoarthritis. The analysis of the temporal trend of damage development over the 25 years of our analysis (1986-2011) highlighted
the marked decrease in damage over time and the more pronounced decline in the Biologic era (Figure 1).

Conclusion: Our study provides evidence of the remarkable prognostic improvement obtained with the recent therapeutic advance in JIA.

THU0656 IMMUNE CHECKPOINT INHIBITORS IN PATIENTS WITH CANCER AND RHEUMATOLOGIC DISEASES: A SYSTEMATIC REVIEW OF THE LITERATURE

Noha Abdel-Wahab1,2, Houssein Safa3, Maria A. Lopez-Olivo4, Adi Diab3, Maria Suarez-Almanzor1. 1University of Texas MD Anderson Cancer Center, Section of Rheumatology and Clinical Immunology, houston, United States of America; 2Faculty of Medicine, Assiut University Hospital, Department of Rheumatology and Rehabilitation, Assiut, Egypt; 3University of Texas MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, United States of America; 4University of Texas MD Anderson Cancer Center, Section of Rheumatology and Clinical Immunology, Houston, United States of America

Background: Immune checkpoint inhibitors (ICI) have resulted in unprecedented advancements in the treatment of cancer, with remarkable survival benefits, unseen with traditional treatment. While the benefits of ICI have been clearly documented, a myriad of immune-related-adverse events (irAEs) have been recognized in multiple organs and systems, secondary to persistent activation of the immune system.

Objectives: To systematically review the literature and provide an updated summary on adverse events associated with the use of ICI therapy in patients with cancer and rheumatologic diseases.

Methods: Five electronic databases were searched through 2018 with no restrictions. Articles were screened and selected by two independent investigators using a 2-step approach. Case reports, series, and observational studies describing patients diagnosed with rheumatologic disease prior to initiation of ICI for treatment of concomitant cancer were included.

Results: A total of 69 patients in 27 publications were identified. Median age was 65 (38-87) years; 50% were female; 90% had metastatic melanoma; and 64% were receiving anti-cytotoxic T-lymphocyte-associated protein 4 (anti-CTLA-4) antibody. Rheumatoid arthritis was the most common underlying disease, and 55% (n=38) had de novo irAEs. Patients with active diseases at ICI initiation seemed to have more disease flare than those with inactive disease (61% vs. 29%; p = 0.03), while no differences were observed in de novo irAEs (36% vs. 39%). Patients with rheumatoid arthritis were reported to have more flares with anti-CTLA-4 antibody (63% vs. 33%), while those with spondyloarthropathy reported more flares with anti-programmed cell death 1 agents (63% vs. 29%); however numbers were small. Patients receiving immunosuppressive therapy at ICI initiation had fewer adverse events than those not receiving treatment (26% vs. 44%). Most flares and irAEs were managed with corticosteroids, and 13% required additional disease modifying anti-rheumatic drugs. Adverse events improved in 64% and did not require discontinuation of ICI therapy. In melanoma patients, disease control rate was 44%. In all patients, no treatment related mortality was reported.

Conclusion: About one third of patients with pre-existing rheumatologic autoimmune disease flared after receiving ICI therapy for treatment of cancer. However, flares and irAEs can often be managed and may not require discontinuation of cancer therapy. Prospective longitudinal studies are needed to evaluate potential differences among diseases and to determine optimal toxicity therapy while conserving antitumor immunity.

THU0657 ASSOCIATION OF DIET AND SPICES WITH TREATMENT OUTCOME IN ASIAN INDIAN PATIENTS WITH RHEUMATOID ARTHRITIS — A CROSS SECTIONAL STUDY

Harshini Aiy Shaikumari1, Ramya Aithala1, L. Jayaseelan2, Debashish Danda1.
1Christian Medical College, Clinical Immunology and Rheumatology, Vellore, India; 2Christian Medical College, Biostatistics, Vellore, India

Background: Influence of diet on inflammation, especially foods like fish oil, spices like turmeric, capsaicin, garlic etc. are reported in published literature. However, a well-designed study on this subject amongst Asian Indian patients is lacking.

Objectives: To analyze whether the type and quantity of intake of various food constituents, with particular reference to Indian spices, makes an impact on the control of disease activity in patients with Rheumatoid arthritis(RA)

Methods: Patients diagnosed as RA by the ACR 2010 criteria and receiving standard triple drug therapy in our clinic between June 2017 and June 2018, for at least one year were enrolled. Disease activity was assessed during the routine OPD visit. They were administered a food frequency questionnaire [1] pertaining to the quality as well as quantity of food and spice intake. Analysis was done using multivariate logistic regression

Results: A total of 400 patients were included with 86.75% females. 67.75% patients were in disease remission, 10% had mild disease activity and 22.25% moderate to high disease activity; only 18.09% were vegetarians and the rest consumed non-vegetarian food. Median age was 47.98years(SD 10.67);median duration of illness prior to presentation to our clinic was 7years(IQR 4.10), median ESR was 37mm/hr(IQR 23.52), median CRP was5.34mg/L(IQR 2.04,12.4), and median DAS28CRP was 2.07(IQR 1.64,2.97).

Patients with DAS28CRP of ≤2.6 were compared with those >3.2. Statistically higher consumption of ginger, garlic, turmeric and coriander were noted amongst patients in remission. Similar results were obtained when patients with DAS28CRP of ≤1.4 were compared with DAS28CRP >5.1. Significant numerical differences were noted for intake of food constituents like wheat, total pulse, vegetables, fruit, milk and fish

Conclusion: Higher consumption of Indian spices like ginger, garlic, turmeric and coriander were found to be associated with better control of disease activity and hence the inflammation, as evidenced by DAS28CRP in patients with Rheumatoid arthritis, receiving standard triple therapy.

Catastrophizing in Rheumatology

CHARACTERIZATION OF SCLERODERMA PATIENTS

Background: Rheumatic disorders (RD) provide chronic pain. Catastrophizing in RD patients is suspected to be involved in persistence and amplification of chronic pain.

Objectives: To assess catastrophizing level in RD and to evaluate the association between catastrophizing and physical pain intensity, disease activity, disability, depression and quality of life.

Methods: We performed a systematic review of literature and search in the following databases: MEDLINE, COCHRANE and EMBASE until April 2018. All observational, cross-sectional and randomized control studies investigating catastrophizing in patients with RD (rheumatoid arthritis (RA), low back pain (LBP), osteoarthritis) were included. Statistical analysis defined pooled mean catastrophizing level by using the Pain Catastrophizing Scale (PCS), the latter ranging from 0 to 52. To assess the association between catastrophizing and disease activity (DAS28), pain (Numerical Rating Scale NRS), disability (ODI) and quality of life (SF36, WOMAC) we collected correlation coefficients and pooled them in a meta-analysis using the Fisher’s z transformation with MedCalc v18.11.3.

Results: From 1494 articles concerning catastrophizing and RD, 51 were selected for a meta-analysis:

- 601 RA patients (mean age 57.4 years, 67.7% female, mean pooled DAS 28 = 3.4 and mean pooled NRS = 3.8) included in 7 studies. The mean pooled catastrophizing level at baseline was 14.7 (SD = 11.4) in RA patients vs 2.7 (SD = 3.0) in control group patients (n= 82 in 2 studies). In one study, a RA sample identified 22% of high catastrophizing (defined by PCS ≥ 40).
- 3251 LBP patients (mean age 43.6 years, 57% female, mean pooled NRS = 4.5 and mean pooled ODI = 30.3) included in 27 studies. The mean pooled catastrophizing level at baseline was 19.9 (SD = 11.3).
- 3388 osteoarthritis patients (knee and hip, mean age 67.7 years, 65% female, mean pooled NRS = 5.0) included in 17 studies. The mean pooled catastrophizing level at baseline was 21.2 (SD = 10).

In RA, a significant positive correlation between catastrophizing and DAS 28 was observed: pooled r=0.278 p<0.001 (3 studies) (Figure 1). Pain level was strongly associated with catastrophizing (r=0.71 p<0.01). Higher PCS scores were significantly associated with higher levels of distress i. e. lower SF-36 Mental Health score (r= -0.52 p<0.01) and significantly associated with reduced physical function (r= -0.35 p<0.01) for SF36 Physical Function.

In LBP, higher PCS scores were significantly associated with higher levels of pain and disability : pooled r=0.486 p<0.001 (NRS) and r=0.465 p<0.001 (ODI), respectively. The association between catastrophizing and depression was significant (r=0.538 p<0.01).

Catastrophizing in osteoarthritis was strongly associated with an increase in functional limitations and pain (i.e. higher WOMAC total score, correlation coefficient: rs 0.641 p<0.001).

Conclusion: Catastrophizing is a common psychological trait clearly associated with disease activity, pain, mental health and physical function. Nevertheless catastrophizing is rarely measured. It might be relevant to detect it earlier in order to adapt pharmacologic and non-pharmacologic treatment in at-risk patients.

CHARACTERIZATION OF SCLERODERMA PATIENTS ACCORDING TO ROS2 AND KU ANTIBODIES

Background: Systemic Sclerosis (SSc) is an autoimmune disease that is characterized by progressive and severe fibrosis with cutaneous and visceral involvement, fibroproliferative vasculopathy and alterations of cellular and humoral immunity, very heterogenous from the clinical and immunological point of view. There are many types of antibodies related to the disease that are used in the diagnosis and characterization. Antibodies anti-Ku and anti-Ro52 have been found, although they are not specific to the disease, that could play an important role in the prognosis and clinical expression.

Objectives: To evaluate the clinical pattern and prognosis of SSc patients who carry antibodies Anti-Ku and Anti-Ro52.

Methods: A retrospective, multicentric study of SSc patients included in the Spanish Registry of Scleroderma (RESCLE). Clinical, demographic, prevalence, serological, and survival data were analyzed.

Results: A total of 401 samples were analyzed for anti-Ku with 12 positive results (3%). For anti-Ro52, 1724 sampled were analyzed with 246 positive results (14%). It is observed, from the multivariant analysis, that patients with anti-Ro52 presented, in higher frequency, an association with Sscas syndrome (p<0.001) and its coexistence with the antibody anti-La (OR 4.49 with 95% CI 11.2 p<0.01). Regarding patients with anti-Ku, no clinical association was found with statistical significance.

Conclusion: As opposed to finding SSc specific antibodies such as anti-centromere (ACA), anti-topoisomerase I (ATA), and anti-RNA polymerase III (ARA), the presence of anti-Ku or anti-Ro52 is not conclusive of any distinct clinical profile.

REFERENCES:

Background: A recent study showed that the risk of ankylosing spondylitis (AS) was increased in patients with uveitis.1 Objectives: The study aimed to test the risk of psoriasis (PsO), Crohn’s disease (CD), ulcerative colitis (UC) and AS in uveitis patients.

Methods: The data source of this study was the 2003–2012 claims data from the Taiwanese National Health Insurance Research Database. We identified 4,943 incident patients with uveitis defined as having ≥ 2 ambulatory or inpatient visits with a diagnosis of ICD-9-CM 360.12, 364.00–364.02, 364.04–364.05 or 364.43 made by an ophthalmologist from 2006 to 2012 after excluding those having prior PsO (ICD-9-CM 696.1), PsA (ICD-9-CM 696.0), CD (ICD-9-CM 555), UC (ICD-9-CM 556) or AS (ICD-9-CM 720) and randomly selected 49,430 non-uveitis individuals as controls. We estimated the incidence rates of PsO (diagnosed by dermatologists), CD, UC and AS for the uveitis and non-uveitis cohorts, and the incidence rate ratios (IRR) and hazard ratios (HRs) after adjusting for sex, age, Charlson comorbidity index and concomitant medications.

Results: No incident case of CD was identified in uveitis patients and patients with uveitis had significantly higher incidence rates of PsO (IRR, 8.82; 95% CI, 6.80–11.43), CD (IRR, 7.23; 95% CI, 5.12–10.28) and AS (IRR, 171.69; 95% CI, 143.15–205.93). However, after adjusting for potential confounders, uveitis patients had a significantly higher risk of developing PsO and AS, but not CD.

Conclusion: This nationwide, population-based cohort study revealed that uveitis patients had an increased risk of PsO and AS, but not CD.

The absolute risk of clinically diagnosed gout by clusters of gout associated comorbidities and lifestyle factors – results from 30 years follow-up of the Malmö preventive project cohort in southern Sweden

Taheez Fatima1, Peter Nilsson2, Carl Turesson3, Mats Dehlin1, Nicola Dalbeth3, Lennart T.H. Jacobsson1, Melita C Kapetanovic1. 1University of Gothenburg, Dept of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2Lund University, Dept of Clinical Sciences, Malmö, Sweden; 3University of Auckland, Dept of Medicine, Auckland, New Zealand

Background: Clinical gout is predicted by a number of factors. Several of these (comorbidities and lifestyle) have been shown to cluster in gout patients1,2 indicating several different pathophysiological pathways, but it is not known if and to what extent such clusters predict gout.

Objectives: To examine: 1) the prevalence of comorbidity clusters in the population and 2) the long-term absolute and relative risks for developing gout in these clusters defined at baseline in subjects of Malmö Preventive Project (MPP).

Methods: The MPP is a screening program for cardiovascular risk factors, alcohol abuse and breast cancer in Malmö, Sweden. A total of 33,346 individuals (67% male, age=45.7 years, mean follow-up=28.2 years) screened between 1974 and 1992, participated. Date of gout diagnosis was defined as the first visit with gout (using ICD-codes) to physicians within primary or specialized care, through linkage of the MPP cohort with regional and national health care registers. End of follow-up was defined as the date of first gout diagnosis, death, moving from the area or December 31st, 2014. Hierarchical clustering was performed in a subset of 22,057 individuals (screening period: 1975-1992) to group observations. Variables clustered included obesity, renal dysfunction, diabetes mellitus (DM), hypertension, cardiovascular disease (CVD), dyslipidemia, pulmonary dysfunction (PD), smoking and use of diuretics. For the five identified clusters, their population prevalence as well as the incidence and hazard ratio (HR) for gout were computed using cox-proportional hazard analysis in Rv3.5.2.

Results: Cluster-1 (C1) with “few comorbidities” was by far the most common in the population (73%), followed by cluster-4 (C4) characterized by “obesity and hyperlipidaemia” (17%). These two pathways included 86% of incident gout cases during the follow-up. The four clusters (C2-5) identified by different comorbidity patterns all resulted in a 2-3 fold increased risk for incident gout. The highest incidence for gout was seen for cluster-2 (C2) characterized by “renal dysfunction” and cluster-3 (C3) characterized by “cardiovascular disease” (Table).

Table: Incidence and hazard ratios for gout in observation-clusters of MPP cohort

*Incidence per 100,000 person-years at risk. **Adjusted for age, sex

Conclusion: In a population-based study, we identified five clusters based on gout-related comorbidities. Most gout cases occurred in the cluster characterized by few comorbidities. Such cases may have predisposing factors not captured by comorbidity patterns, e.g. genetics related to serum urate. In addition, we identified four pathways each defined by different comorbidity patterns and contributing to increased risk for gout, pathways that may require partly individual interventional strategies.

PREVALENCE OF RHEUMATIC DISEASES IN COLOMBIA: AN APPROACH FROM MINISTRY OF HEALTH AND SOCIAL PROTECTION DATA (SISPRO)

Daniela G. Fernández-Ávila, Santiago Bernal-Macias, Diana Rincón, Juan Gutiérrez, Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine – Rheumatology, Cra 7 No. 40-62, Colombia; Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine, Bogotá, Colombia; Universidad Militar Nueva Granada – Hospital Militar Central, Rheumatology, Carrera 5 No 49-00, Colombia

Background: The ministry of health and social protection of Colombia uses a system named SISPRO as a tool to establish the basic information of the health system. This information is public and available for anyone to search. We analyze the prevalence and specific characteristics of patients with rheumatic diseases registered in a colombian health system between 2012 to 2016.

Objectives: To establish the prevalence and basic epidemiological characteristics of the main rheumatic diseases in Colombia.

Methods: This is a descriptive epidemiological study using the International Statistical Classification of Diseases and Related Health Problem (ICD-10) as keywords for each rheumatic disease during the analysis of SISPRO data and National Statistical System (DANE) populations projections, as from the last census in Colombia to estimated prevalence of each disease.

Results: Colombia is a middle-income country with an estimated population of 49.834.240 inhabitants to 2018 according to 2005 census projections. Despite some limitations of SISPRO data, actually is the only official database of the government. We calculate the estimated prevalence and number of patients with some rheumatic diseases (table 1), confirming that autoimmune diseases are more frequent in women, and surprisingly, spondyloarthritides (ankylosing, psoriatic and inflammatory bowel disease) are also discreetly more frequent in woman population.

Total cases Prevalence (%) Ratio woman:man
Rheumatoid arthritis 248.995 0.520 4.71 : 1
Ankylosing spondylitis 64.356 0.177 2.71 : 1
Gout 70.881 0.149 0.25 : 1
Sjögren syndrome 58.680 0.123 4.63 : 1
Systemic lupus erythematosus 41.804 0.088 4.17 : 1
Polymyalgia rheumatic 35.331 0.070 6.69 : 1
Sjögren syndrome 10.473 0.022 3.22 : 1
Inflammatory miopathy 8.498 0.018 1.76 : 1
Psoriatic arthritis 1.670 0.004 1.32 : 1
Gouty arthritis with polyarthritis 750 0.014 7.44 : 1
Bechet Disease 523 0.001 2.15 : 1
Churg Strauss disease (EGPA) 186 0.001 2.24 : 1

Conclusion: Epidemiological and prevalence information of rheumatic diseases in Colombia is presented. The data found in the study are concordant with epidemiological studies in other countries.

SERIOUS/AT LEAST MODERATE INFECTIONS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS ON SYNTHETIC AND BIOLOGIC DRUGS FROM THE PHARMACHILD REGISTRY

Gabriella Giancane, Joost F. Swart, Nikolay Tzaribachev, Nadina Rubio, Ruben Cuttica, Ingrida Rumba-Rozenfelde, Wafa Mohammed Saad Suwairi, Calin Lazar, Yosef Uziel, Albenia Telchavara, Tadej Avcin, Angela Minaiči, Emilia Len, Stella Maris Garay, Alina Boteneu, Angela Pistorio, Nico Wulffraat, Nicola Ruperto, Gabriella Giancane: None declared, Joost F. Swart: None declared, Nikolay Tzaribachev: None declared, Nadina Rubio: None declared, Ruben Cuttica Grant/research support from: Roche, Pfizer, Lilly, Bristol Myers Squibb, Novartis, Sanofi, Sanofi Aventis, UCB, Janssen, Janssen, Novartis, Sanofi Aventis, UCB, Janssen, Ingrida Rumba-Rozenfelde: None declared, Wafa Mohammed Saad Suwairi: None declared, Calin Lazar: None declared, Yosef Uziel: None declared, Albenia Telchavara: None declared, Tadej Avcin: None declared, Gabriella Giancane: None declared, Joost F. Swart: None declared, Nikolay Tzaribachev: None declared, Nadina Rubio: None declared, Ruben Cuttica Grant/research support from: Roche, Pfizer, Lilly, Bristol Myers Squibb, Novartis, Sanofi, Sanofi Aventis, UCB, Janssen, Janssen, Ingrida Rumba-Rozenfelde: None declared, Wafa Mohammed Saad Suwairi: None declared, Calin Lazar: None declared, Yosef Uziel: None declared, Albenia Telchavara: None declared, Tadej Avcin: None declared.

Methods: Serious and at least moderate infections were analysed in JIA patients, enrolled in the Pharmachild registry at September 30th, 2018, with more than 6 months of follow up. We divided patients in 3 treatment groups: “MTX alone”, in which patients had received MTX as the only drug over all their history; “MTX Start”, in which patients had received MTX as first drug; “MTX+TNFi” for those patients who received a TNF in addition to MTX after a period of “MTX Start”. All the 3 groups were considered as endpoints for each infecion. We considered serious infections as those that occurred in the drug period stopped as soon as the second drug was introduced. For the group “MTX+TNFi”, we considered all the possible correlations between start and end dates of the two drugs, including the time lag of 90 days after any treatment stop. If the interval between two drugs was shorter than 90 days, treatment was considered continuous. Crude rates (number of infections divided by drug exposure, excluding off-drug periods) and true incidence rates (number of first infections divided by the time lag between first drug administration and the date of the infection if the patient experienced the infection, the last Pharmachild visit if the patient didn’t experience the event) were calculated.

Results: We enrolled in Pharmachild a total of 8061 patients who experienced 1686 infections. We excluded 41 patients who had infections before any treatment start. Of the final number of 8020 patients, we considered: 1226 patients in the group “MTX alone”, 3128 in the group “MTX start” and 1026 in the group “MTX+TNFi”. 7.7% of the patients in the “MTX alone” group, 2.7% of the patients in the “MTX Start” group and 7.0% of the patients in the “MTX+TNFi” group experienced at least one infection. Crude rates of infections per 1000 person-years resulted: 48.0 for the group “MTX alone”, 22.0 for “MTX Start”, 74.0 for “MTX+TNFi”. Incidence rates per 1000 person-years were: 32.0 for the group “MTX alone”, 17.0 for “MTX Start”, 59.5 for “MTX+TNFi”. The percentage of drug exposure on the patient follow-up was variable among the 3 treatment groups (from 15.6% for the “MTX+TNFi” group to 51.5% for the “MTX alone” group).

Conclusion: Pharmachild showed, through the analysis of pure treatment groups, that the addion of the anti-TNF biologic to MTX even triples the incidence rate of infections.

OVERALL INFECTION RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ABATACEPT, RITUXIMAB AND TOCILIZUMAB: AN OBSERVATIONAL COHORT STUDY

Kathrine Gram1, Berete Glintborg1, Frank Mehnert2, Mikkel Østergaard3, Lene Dreyer2, Mette Nergaard2, Niels Steen Krogh4, Merete L. Hetland1, The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark; 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; 3Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark

Background: Most infections in patients with rheumatoid arthritis (RA) are treated in primary care with a prescription of antibiotics. Only a small fraction requires hospitalization. Existing studies of infection risk in patients with RA, who receive non-tumor-necrosis-factor-inhibitor biologic (non-TNFi) therapy, however, have focused primarily on hospitalized infections. (1)

Objectives: In Danish RA patients treated in routine care with the three non-TNFi abatacept, rituximab and tocilizumab 1) to compare adjusted incidence rates (IR) of infections overall, and 2) to estimate the relative risk (RR) of infections across the drugs during the first year of non-TNFi treatment.

Methods: We conducted an observational cohort study including all RA patients in DANBIO who started a non-TNFi treatment between January 2010 and December 2017. Clinical characteristics at baseline were described. We defined infections as either a prescription of antibiotics or a hospitalization due to infection. Baseline comorbidities, antibiotic prescriptions and hospitalized infections were identified through linkage to national registries. We calculated IRs of infections per 100 person-years (age and gender adjusted) and rate ratios (as estimates of RRs, adjusted for additional covariates) during the first year of treatment (Poisson regression).

Results: We identified 3,696 treatment series of non-TNFi (abatacept 1,115/rituximab 1,071/tocilizumab 1,564). Patients receiving rituximab tended to be older, had longer disease duration and more previous malignancies. During the first year of treatment, 1,747 infections were identified. Age and gender adjusted IRs per 100 person-years were (abatacept/rituximab/tocilizumab): 76.1(69.3; 83.6)/87.3(79.3; 96.1)/77.4(71.4; 83.9). Adjusted RRs (Table) were 0.88(0.76; 1.02) for abatacept and 0.87 (0.75; 1.00) for tocilizumab compared to rituximab. For abatacept vs. tocilizumab it was 1.02 (0.89; 1.16).

THE ASSOCIATION BETWEEN ANTI-CCP TITRE LEVEL AND DISEASEACTIVITY AND DISABILITY OVER ONE YEAR FOLLOWING THE INITIATION OF METHOTREXATE OR BIOLOGIC THERAPY FOR ANTI-CCP+ RHEUMATOID ARTHRITIS

James Gwinnutt1, Kimmy Hyrich1,2, Mark Lunt1, Darren Platts3, Nisha Nar3, Anne Barton1,2, Suzanne Verstappen1,2, RAMS and BRAGGS co-investigators. 1Arthritis Research United Kingdom Centre for Epidemiology, Centre for Musculoskeletal Research, Faculty of Medicine, Biology and Health, University of Manchester, Manchester, United Kingdom; 2NIHR Manchester Biomedical Research Centre, Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; 3Arthritis Research United Kingdom Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom

Background: Whilst anti-cyclic citrullinated peptide antibody (anti-CCP) positivity in associated with poor outcomes in patients with rheumatoid arthritis (RA), it is unclear whether titre level over time is associated with outcome.

Objectives: Whilst anti-cyclic citrullinated peptide antibody (anti-CCP) positivity in associated with poor outcomes in patients with rheumatoid arthritis (RA), it is unclear whether titre level over time is associated with outcome.

Methods: Patients were recruited to one of two, UK-based, multi-centre prospective cohort studies: MTX-starters = Rheumatoid Arthritis Medication Study (RAMS); biologic-starters = Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGS). Anti-CCP titre (Axis-Shield Anti-CCP test; U/ml; anti-CCP titre >5 U/ml = anti-CCP+ ) was measured at the co-ordinating centre from blood samples taken at baseline, 6 months and 12 months. Patients who were anti-CCP+ at baseline and had titre measured at one other assessment were included in the analysis. Patients completed the Health Assessment Questionnaire (HAQ) and the Disease Activity Score (DAS28) was calculated at each assessment.

The association between anti-CCP titre and DAS28 and HAQ was assessed using linear random effects models, controlling for age, gender and disease duration (months). Anti-CCP titre was natural log-transformed. Missing data resulting from anti-CCP assay failure were imputed using multiple imputation.

Results: In total, 686 MTX-starters and 346 biologic-starters were included. Biologic-starters had worse disease at baseline compared to MTX-starters (Table). Median [IQR] titre decreased slightly over follow-up for MTX-starters (baseline = 147 [48, 416]; 6 months = 133 [47, 454]; 12 months = 124 [44, 421]; p=0.63) and biologic-starters (baseline = 138 [37, 492]; 6 months = 112 [30, 468]; 12 months = 103 [30, 451]; p=0.36) but this was not significant. For MTX-starters, anti-CCP titre was statistically significantly associated with DAS28 and HAQ, but the effect sizes were small (mean difference [95% CI] per unit increase in log anti-CCP: DAS28 = 0.07 [0.02, 0.11]; HAQ = 0.06 [0.03, 0.08]). There was no significant association between anti-CCP titre and DAS28 and HAQ for biologic-starters (mean difference [95% CI] per unit increase in log anti-CCP: DAS28 = 0.03 [0.05, 0.10]; HAQ = 0.02 [0.01, 0.05]).

Conclusion: Time-varying anti-CCP titre level was not strongly associated with disease activity or disability over one year in either MTX-starters or biologic-starters who were anti-CCP+ at baseline, indicating repeat testing of anti-CCP level may not be necessary.

Disclosure of Interests: James Gwinnutt: None declared, Kimme Hyrich: None declared, Pieta Näsänen-Gilmore: None declared, Anne Barton: None declared, Suzanne Verstappen: None declared, Mark Lunt: None declared, Darren Plant: None declared, Nisha Nair: None declared, Eero Kajantie: None declared, Thomas Bo Jensen: None declared, Mikkel Bring Christensen: None declared, Nicole Tsao: None declared, Seoyoung Kim: None declared, Jon Trærup Andersen: None declared, Copenhagen University Hospital Bispebjerg, Department of Clinical Pharmacology, Copenhagen, Denmark; Brigham and Women’s Hospital, Division of Pharmacoepidemiology and Pharmacoeconomics, Boston, United States of America; University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark; Harvard Medical School, Boston, United States of America.

Background: Maternal exposure to methotrexate (MTX) during pregnancy is known to be teratogenic, but less is known about the risk due to paternal MTX exposure. Because of a theoretical teratogenic risk from paternal exposure, treatment recommendations advocate that men should discontinue MTX three months before conception and continue discontinuation during the partners’ pregnancy. This may lead to suboptimal adherence to treatment, fear among the future parents and pregnancy termination.

Objective: The aim was to systematically review and meta-analyse the collective data on paternal MTX exposure and the risk of congenital malformations.

Methods: We performed a systematic search in the databases – PubMed, Embase, Cochrane Central, and Cinahl – on March 1, 2018. We included studies with an English abstract that assessed major or all (both major and minor) malformations following any paternal exposure to MTX. Studies that included a control group were included in the meta-analysis. No time restriction was applied. Review Manager Version 5.3 was used for the meta-analysis.

Results: We identified 36 studies assessing the risk of congenital malformations following paternal exposure to MTX of which 20 contained original data. Five studies met the inclusion criteria for the meta-analysis. Three studies from Denmark had a major overlap in study populations, one study from Norway, and one German study. All studies were cohort studies using national registries except the German that used structured interviews and phone interviews. Because of the overlapping Danish studies, only the largest Danish study for each of the outcomes were included. We included a total of 265 fathers exposed to MTX and 1,004,834 controls in the meta-analysis investigating risk of major congenital malformations. Among the offspring of the MTX-exposed 7 (2.64%) had a major malformation compared to 33,816 (3.37%) among the unexposed. Pooled odds ratios were 1.02 (95% confidence interval [CI] 0.48-2.20) for major malformations and 1.02 (CI 0.62-1.66) for all malformations.

Conclusion(s): In this systematic review and meta-analysis, we found no association between preconceptions paternal MTX use and major or all congenital malformations. The current recommendations to avoid paternal MTX use before conception do not appear to be supported by evidence and paternal treatment with MTX could be continued when planning pregnancy.

THU0670 PATERNAL USE OF METHOTREXATE AND CONGENITAL MALFORMATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Thomas Bo Jensen1,2, Mikkeli Bring Christensen1,3, Nicole Tsao4,5, Seoyoung Kim4,6, Jon Trærup Andersen1,3,1, Copenhagen University Hospital Bispebjerg, Department of Clinical Pharmacology, Copenhagen, Denmark; Brigham and Women’s Hospital, Division of Pharmacoepidemiology and Pharmacoeconomics, Boston, United States of America; University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark; Harvard Medical School, Boston, United States of America.

Background: Maternal exposure to methotrexate (MTX) during pregnancy is known to be teratogenic, but less is known about the risk due to paternal MTX exposure. Because of a theoretical teratogenic risk from paternal exposure, treatment recommendations advocate that men should discontinue MTX three months before conception and continue discontinuation during the partners’ pregnancy. Objectives: To evaluate the frequency of pulmonary involvement in RA patients followed-up in a 15-years period.

Methods: 549 RA patients were diagnosed according to the ACR/EULAR classification criteria since 2003. A full clinical examination as well as a detailed laboratory and immunological evaluation has been carried-out at baseline. Furthermore, chest, hand and wrist but also feet radiographs had been obtained. All patients were followed-up at predefined times and were treated appropriately with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and/or biologic (b)DMARDs. Any laboratory abnormalities or comorbidities were recorded and investigated appropriately at every visit. In addition, the disease activity score (DAS) using the 28-joints count (DAS-28) was recorded.

Results: Initial evaluation revealed 15 patients as having pulmonary abnormalities. Thus, these patients were excluded. From the rest, 37 (6.7%) patients manifested lung involvement. There were 26 males and 11 females, with mean age of 62.9 ± 5.4 years and disease duration of 8.5 ±2.2 years. 14 were smokers and 10 ex-smokers. Dry cough and dyspnea on exertion were the main pulmonary symptoms. High resolution computed tomography (HRCT) scan of the chest revealed interstitial lung disease (ILD). More specifically, 23 patients showed usual interstitial pneumonia (UIP), 10 patients had nonspecific interstitial pneumonia (NSIP), while 4 had a mixed pattern. Six patients died 4 years after ILD development. ILD was associated with high DAS-28, seropositivity and male gender.

Conclusion: ILD is not a frequent EAM in patients with RA, but it carries a poor prognosis with high morbidity and mortality and it is associated with RA disease activity and male gender. UIP is the most prevalent pattern of ILD in RA patients.

Disclosure of Interests: None declared

Objectives: To examine the risk of developing RA in persons who have had CVD, defined as acute myocardial infarction (AMI) or ischaemic stroke while controlling for established shared risk factors.

Methods: We conducted a population-based cohort study within the Danish Diet, Cancer and Health (DCH) cohort. The cohort was recruited 1993-97 and included individuals aged 50 to 64 years, born in Denmark and living in geographically defined parts of Denmark. Data on lifestyle factors and anthropometric measurements were collected at enrolment into the DCH. Information on incident AMI (ICD-10 code: I21), ischemic stroke (ICD-10 code: I63) and RA (ICD-10 codes: M05, M06 combined with ATC codes for DMARDs) was obtained from nationwide administrative registers. Participants were followed until development of RA, death, loss to follow-up or October 2016, whichever came first. Data were analyzed using Cox’s proportional hazards regression models with delayed entry and age as the underlying time scale and cardiovascular disease (CVD) as a time-varying exposure variable, stratifying by gender. Established shared risk factors - smoking, body mass index and waist circumference - were included in the multivariable analyses.

Results: Complete data were available on 53287 subjects (52% female) without a AMI, stroke or RA diagnosis prior to their enrolment into the DCH. Median age at entry into DCH was 56 years. During follow-up (median 21 years), 4,627 participants developed CVD (37% female) and 516 participants developed RA (69% female). The risk for developing RA was 30% higher in women with CVD than in women without CVD (adjusted hazard ratio (HR) 1.30 (95% CI 0.70-2.38) (Table 1). In men, there was no clear association between CVD and development of RA (adjusted HR 0.73 (95% CI 0.34-1.58)).

Disclosure of Interests: None declared

THU0674 CLINICAL PRESENTATION AND MANAGEMENT OF MONO- AND BILATERAL KNEE ARTHRITIS: RESULTS FROM THE LEIDEN EARLY ARTHRITIS CLINIC COHORT
Johanna M. Maassen, Xanthe Matthijssen, Syske Anne Bergstra, Cornelia Allaart. LUMC, Leiden, Netherlands

Background: Patients presenting with arthritis in one or both knees pose a challenge regarding diagnosis, prognosis and treatment decisions. Objectives: To characterize the patients with knee arthritis who presented to the Leiden Early Arthritis Clinic (EAC) and to evaluate the disease course and initial treatment decisions.

Methods: All patients with arthritis confined to the knee(s) were selected from all patients included in the EAC between 1993 and 2015. The EAC captures patients with arthritis and symptom duration < 2 years, excluding arthritis diagnosed at presentation as definite infectious, gouty or osteoarthritis. EAC follow up is at 2 weeks, 3 months and thereafter yearly. Medical files were reviewed for information on treatment and clinical outcomes. Baseline characteristics were summarized, treatment and outcome was evaluated over time up to 12 months. Patients were stratified over 3 groups: 1. Early remission (at 3 months no clinical synovitis and no flare proceeded) was evaluated over time up to 12 months. Patients were stratified over 3 groups: 1. Early remission (at 3 months no clinical synovitis and no flare proceeded); 2. Persistent gonarthritis at 3 months (improving or stable); 3. Progression to oligo-/polyarthritis at the last available visit). RF and ACPA positivity and high ESR at baseline were predictive for progression (group 3), but did not differ between patients in groups 1 and 2. There was a trend for longer symptom duration at presentation in group 3 (76.5 days, IQR 25.5-175.5, p=0.040 vs. group 1) (table 1).

Results: Of the 206 patients identified, 174 (85%) had mono- and 32 (15%) bilateral gonarthritis. Early remission was observed in 67/206 patients (32.5%, group 1), gonarthritis persisted in 109/206 patients (53.0%) in group 2 and 3/206 patients (<1%) subsequently received a bDMARD. Prednisone was prescribed in 11/206 patients (5.4%). DMARD therapy was prescribed in 14/206 patients (<1%). No differences in initial treatment were observed between groups 1, 2 and 3.

During the first year, in 62/206 patients (30.1%) treatment remained limited to NSAIDs, most often in group 1 (p <0.01). IACs were (also) prescribed in 23/206 patients (11.2%), when a diagnosis of Borrelia or other bacterial arthritis was made or suspected, and 6/206 patients (3.0%) received with colchicine and/or allopurinol (NS between the groups) (2). Disclosure of Interests: None declared.

THU0675

ASSOCIATION OF GLUCOSE HOMEOSTASIS MEASURES AND METABOLIC SYNDROME WITH KNEE CARTILAGE DEFECTS AND CARTILAGE VOLUME IN YOUNG ADULTS

Tao Meng1, Alison Venn2, Flavia Cicutari2, Lyn March3, Marita Cross4, Terence Dwyer1,4, Graeme Jones4, Laura Laslett5, Benny Antony1, Changhai Ding1,5.1. Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; 2. Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia; 3. Institute of Bone and Joint Research, University of Sydney, Sydney, Australia; 4. The George Institute for Global Health, Neild Department of Obstetrics and Gynaecology, University of Oxford, Oxford, United Kingdom; 5. Clinical Research Centre, Zhijiang Hospital, Southern Medical University, Guangzhou, China

Background: Diabetes mellitus and knee osteoarthritis (OA) are commonly coexisting, and metabolic syndrome (MetS) shared many pathways with knee OA. However, the effects of glucose homeostasis and MetS on knee cartilage in young adults were unknown.

Objectives: To describe the associations of glucose homeostasis measures and MetS measures with knee cartilage defects and cartilage volume in young adults.

Methods: Australian young adults from the Childhood Determinants of Adult Health Study were selected to undergo knee magnetic resonance imaging (MRI) scans during 2008-2010 (aged 31-41 years). Fasting blood samples, waist circumference and blood pressure were measured during 2004-2006 (aged 16-26 years). Glucose, insulin, triglyceride and high-density lipoprotein cholesterol (HDL-C) were measured using serum samples. Homeostatic model assessment-2 insulin resistance (HOMA2-IR), HOMA2-beta cell function (HOMA2-b), HOMA2-insulin sensitivity (HOMA-S) were calculated using HOMA2 calculator (version 2.2.3 available from http://www.dtu.ox.ac.uk/homacalculator) according to fasting glucose and fasting insulin. MetS was defined when at least three of the following five components were present: high waist circumference (male >102 cm; female >88 cm), high fasting glucose (>5.6 mmol/L), high serum triglycerides (>1.7 mmol/L), low HDL-C (male <1.03 mmol/L; female <1.3 mmol/L), and high blood pressure (>130/85 mmHg). Cartilage defects and cartilage volume were measured from MRI scans. Data were analysed using log binomial or linear regressions and were adjusted for age, gender, body mass index and physical activity.

Results: Among 328 participants (47.3% were females), 40 (12.7%) had hyperglycaemia and 21 (6.7%) had MetS. Glucose homeostasis measures (except fasting glucose) were associated with tibiofemoral cartilage defects (Fasting insulin: relative risk (RR) 1.05/mU/L, 95% confidence interval (CI) 1.01 to 1.08; HOMA2-IR: 1.44, 1.08 to 1.92; HOMA2-β: 2.59, 1.93 to 3.57; HOMA2-S: 0.36, 0.18 to 0.72), but not patellar cartilage defects. There were no associations between glucose homeostasis measures and knee cartilage volume. MetS measures were not associated with either cartilage defects or cartilage volume, except the associations between high waist circumference and tibiofemoral cartilage defects (RR 2.32, 95% CI 1.18 to 4.54) and between low HDL-C and tibiofemoral cartilage defects (RR 2.32, 95% CI 1.08 to 4.69).

Conclusion: Insulin resistance was associated with higher risk of tibiofemoral cartilage defects amongst young adults. MetS was not associated with neither cartilage defects nor cartilage volume. These suggest that glucose homeostasis, but not MetS, may play a role in cartilage damage in young adults and may lead to knee OA in later life.

Disclosure of Interests: None declared

THU0676

HEPATITIS B VIRUS REACTIVATION IN A COHORT OF PATIENTS TREATED WITH BIOLOGICS – DATA FROM THE ROMANIAN REGISTRY OF RHEUMATIC DISEASES

Corina Mogoșan1, Catalin Codea1,1, Denisa Predeteanu2, Simona Rednic3, Magda Panu2, Elena Rezus2, Ruxandra Ionescu2, Romanian Registry of Rheumatic Diseases. 1. Clinical Center of Rheumatic Diseases “Dr. Ion Stoia”, Rheumatology, Bucharest, Romania; 2. “Sfanta Maria” Hospital, Rheumatology, Bucharest, Romania; 3. “Sfanta Maria” Hospital, Rheumatology, Bucharest, Romania; 4. Clinical Rehabilitation Hospital, Rheumatology, Iasi, Romania

Background: Accompanying the increased use of biological and non-biological antirheumatic drugs, a greater number of cases of hepatitis B virus (HBV) reactivation have been reported in inactive hepatitis B surface antigen (HBsAg) carriers and also in HBsAg-negative patients (pts) who have resolved HBV infection (1). Romania has a high prevalence for HBV infection. According to a national epidemiological study conducted in 2013, 27.9% from the Romanian population has serological markers of resolved HBV infection, while 4.2% of inactive carriers of HBsAg (2). Objectives: To estimate the rate of HBV reactivation in a cohort of patients treated with biologics, in Romania.

Methods: Data were gathered from the Romanian Registry of Rheumatic Diseases (RRBR) for rheumatoid arthritis (RA), ankyllosing spondylitis (AS) and psoriatic arthritis (PsA). The cohort included patients previously exposed to HBV: HBsAg inactive carriers or resolved HBV infection. HBV reactivation was considered as the presence of DNA-HBV or positivity of HBsAg in a previously negative patient. The collected data included exposure to biologics in person-years (PY) and serological markers of HBV.

Results: The cohort included 1744pts (5505.95 PY): 936 RA pts (2762.97 PY), 640 AS pts (2037.64 PY) and 168 PsA pts (705.34 PY). The mean age was 58.72yrs (65yrs for RA, 49.58yrs for AS: 61.58yrs for PsA); 1058 (60.6%) women; 786 (74.2%) RA pts, 175 (16.5%) AS pts and 97 (9.1%) PsA pts. Mean disease duration was 14.5yrs for RA, 10.7yrs for AS and 10.5yrs for PsA. The prevalence of HBsAg inactive carriers were 44 (4.7%) in RA group, 53 (8.28%) in AS group and 6 (3.57%) in PsA. The frequency of resolved HBV infection was 892 (95.3%) in RA group, 587 (91.7%) in AS and 162 (96.4%) in PsA. The total number of observed HBV reactivation cases was 16 (0.9%). In RA, 9 (0.9%) cases of HBV reactivation (0.31/100 PY) were observed, all cases on resolved HBV infection state; 7 pts were treated with rituximab (RTX), 2 pts with TNFα blockers. 8 cases (0.28/100PY) of HBV reactivation were observed in those without antiviral prophylaxis, compared to a single reactivation case (0.03/100PY) when antiviral prophylaxis was used. In AS cohort occurred 6 (0.9%) cases of HBV reactivation (0.29/100 PY), all patients being treated with TNFα blockers (3 etanercept, 1 adalimumab, 1 infliximab, 1 golimumab): 4 cases of HBV reactivation developed in inactive carriers of HBsAg and 2 in resolved HBV infection. 5 cases (0.24/100PY) of HBV reactivation were observed in those without antiviral prophylaxis, compared to a single reactivation case (0.04/100PY) when antiviral prophylaxis was used. In PsA group, only 1 case of HBV reactivation (0.14/100PY), on inactive carrier of HBsAg state, during TNFα blocking agent (golimumab).

Conclusion: HBV reactivation appeared more often on a resolved infection state, especially without antiviral prophylaxis. No cases of fulminant hepatitis were noted. Most cases developed in RTX exposed RA patients, while in AS group all HBV reactivation appeared with TNFα blockers exposure.

IDENTIFICATION OF PROLIFERATION, PROGNOSTIC FACTORS, AND OUTCOMES OF PATIENTS WITH INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES: A SINGLE CENTER LARGE-SCALE OBSERVATIONAL COHORT STUDY

Okinori Murata1,2, Katsuya Suzuki1, Nobuhiro Sasaki3, Makoto Maemondo2, 1. Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 2. Iwate Medical University School of Medicine, Division of Pulmonary medicine, Allergy, and Rheumatology, Department of Internal Medicine, Morioka, Japan

Background: Patients with idiopathic interstitial pneumonia (IIP) may have features of connective tissue diseases (CTDs). The term interstitial pneumonia with autoimmune features (IPAF) has been recently proposed for such patients. A few studies have been reported in prevalence of IPAF which was varied from 7.3% to 34.1% [1, 2]. Factors reported to indicate such patients. A few studies have been reported in prevalence of IPAF

Objectives: To identify of prevalence of IPAF in patients with interstitial lung disease, prognostic factors for exacerbation in patients with IPAF, and compared outcomes among patients with IPAF, iip, and CTD-IILD.

Methods: Six hundreds- and seventy-two patients who visited our department between April 2009 and March 2018 and were evaluated by chest
HRCT scan. Then, they were clinically and radiologically diagnosed as having interstitial lung disease (ILD), IIP or connective tissue diseases associated ILD were enrolled. We applied IPAF criteria to these patients. Then, we purified 68 patients. The prognostic factors for exacerbation were prospectively calculated and statistically analyzed using clinical, laboratory and imaging data collected from medical records.

**Results:** Prevalence of IPAF was 10.1%. Of 68 patients with IPAF, 60% were women and mean age at diagnosis was 64.2 ± 13.8 years old. Mean observation period was 27.1 ± 29.6 months. Smoking history was 42.6% (n=29). Treatment including oral glucocorticoid or/and immunosuppressant use were 44.1% (n=30). Exacerbation rate was 25% (n=17). Overall death rate was 5.9% (n=4) and respiratory death rate was 2.9% (n=2). Comparison of characteristics at diagnosis between the exacerbation group and non-exacerbation group showed that the exacerbation group had a significantly elevated rate of smoking history, KL-6, and SP-D (P=0.01, 0.005, and 0.03, respectively). We then analyzed transition of KL-6 in patients with IPAF, IIP, or CTD-ILD. KL-6 at baseline in patients with IPAF (1212 ± 1626 U/mL) was higher than those with IIP and significantly higher than those with CTD-ILD (1030 ± 1027 U/mL(P=0.69) and 829.5 ± 1002 U/mL(P=0.024)), while exacerbation rate in patients with IPAF (25%) was significantly lower than those in IIP patients (40%) and CTD-ILD patients (41%) (P=0.03). Furthermore, KL-6 in IPAF patients gradually decreased during course and was lower than IIP or CTD-ILD patients at 84 months from diagnosis.

**Conclusion:** Our large-scale observational cohort study revealed prevalence of IPAF in patients with ILD and identified three baseline factors associated with exacerbation in the patients with IPAF and suggested that IPAF might have a better prognosis than IIP or CTD-ILD.

**THU0678**

**MALIGANCY RISK IN MALE PATIENTS WITH ANKYLOSING SPONDYLITIS**

Bora Nam1, HyoYoungKim1, Eun Jin Jiang2, Soo-Kyung Cho1, Yoon-Kyoun Sung1, Tae-Hwan Kim1. 1Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Andong National University, Department of Information Statistics, Andong, Korea, Rep. of (South Korea)

**Background:** In recent studies, the association between autoimmune disease and malignancy has been reported. However in Ankylosing spondylitis (AS), a chronic inflammatory rheumatic disease with marked male predominance, the evidence of this relationship is scarce and inconsistent.

**Objectives:** To determine the overall cancer and site-specific cancer risk in male patients with AS.

**Methods:** Using the claims database of Health Insurance and Review Assessment (HIRA), male patients with AS without prior cancer history between 2012 and 2014 were enrolled (n=21,780). For the control group, male general population, stratified random samples of claims data were used (n=342,361). All individual was observed up to the development of any cancer, or end of the study period (December 31, 2015). Incidence rates (IR) of overall and site-specific cancer were presented as the number of event per 10,000 person-years. To make fair comparison between AS patients and general population, we calculated age adjusted incidence ratio by dividing cancer event of general population with corresponding age. The standard incidence ratio (SIR) was used to represent the association between AS and cancer, accounting for person-years at risk.

**Results:** During 71,046 person-year, total 552 cases of cancer occurred in male AS group. Prostate cancer was the leading type of cancer in male AS patients (101 cases, IR 14.22, 95% CI 11.44-16.99). And it was followed by liver cancer (70 cases, IR 9.9, 95% CI 7.5-12.2), lung cancer (48 cases, IR 6.8, 95% CI 4.9-8.7), colorectal cancer (45 cases, IR 6.3, 95% CI 4.5-8.2) and stomach cancer (43 cases, IR 6.1, 95% CI 4.2-7.9). Compared to general population, the overall incidence of cancer was increased in male patients with AS (SIR 1.25, 95% CI 1.14-1.36).

At a specific malignancy type, the risk of pancreas cancer (SIR 1.75, 95% CI 1.12-2.37) and malignancy of male reproductive system were increased (SIR 1.97, 95% CI 1.59-2.35).

**Table 1. The standardized incidence ratio of overall malignancy.**

ADHERENCE TO THE MEDITERRANEAN DIET AND RISK OF RHEUMATOID ARTHRITIS IN THE FRENCH PROSPECTIVE E3N COHORT STUDY

Vann Nguyen1,2, Carine Salliot1,3, Amandine Gelot1, Juliette Gambaretti1, Xavier Marette4, Marie-Christine Bouthon-Vruwink1, Raphaëlle Sere2,4,6. 1Center for Research in Epidemiology and Population Health – INSERM U1018 – Université Paris Saclay – Université Paris Sud, Villejuif, France; 2AP-HP Hôpital Bicêtre, Rheumatology, Le Kremlin-Bicêtre, France; 3Centre Hospitalier Régional d’Orléans, Rheumatology, Orléans, France; 4Université Paris-Sud, Center for Immunology of Viral Infections and Auto-immune Diseases (IMVA), INSERM UMR 1184, Université Paris-Saclay, Le Kremlin-Bicêtre, France

Background: The Mediterranean diet (MD), widespread in Southern European countries, mainly consists of olive oil, cereal products, fresh or dried fruits and vegetables, nuts, a moderate amount of dairy and meat, and many condiments and spices. It has been associated with significant reduction of overall mortality, cardiovascular diseases, and neoplastic diseases. It has been suggested to have a beneficial effect on rheumatoid arthritis (RA) activity due to its richness in antioxidants and unsaturated fatty acids. However, data on MD as a prevention of RA are limited.

Objectives: To assess the association between adherence to MD and risk of RA in a general population cohort.

Methods: The E3N cohort study (Étude Épidémiologique auprès des femmes de la Mutuelle générale de l’Education Nationale) is a French prospective cohort of 98,995 healthy women included in 1990-91 and followed since then (median follow-up of 28 years). Among women who completed a food-frequency questionnaire, we calculated the modified MD score (from 0 to 9) according to the consumption status of nine food components. Incident RA cases were detected using a validation process using a specific validation questionnaire and a drug reimbursement database. Hazard ratios (HRs) and 95% confidence intervals (CIs) for incident RA were estimated using Cox proportional-hazards analysis with an age adjustment. High adherence to MD was associated with a decreased risk of RA (HR for a 6-9 vs. 0-3 score = 0.78, 95% CI: 0.58-1.04) in ever-smoking women (current or past smokers), high adherence to MD could reduce RA risk in ever-smoking women. Further studies are needed to confirm our findings.

Conclusion: High adherence to a MD could reduce RA risk in ever-smoking women. Further studies are needed to confirm our findings.

Disclosure of Interests: Yann Nguyen: None declared, Carine Salliot: None declared, Amandine Gelot: None declared, Juliette Gambaretti: None declared, Xavier Marette Grant/Research support from: Servier, Consultant for: AstraZeneca, Bristol-Myers Squibb, GlaxoSmithKline, Janssen, Pfizer, UCB Pharma, Marie-Christine Bouthon-Vruwink: None declared, Raphaëlle Sere: None declared.

ANTIPePTIDYL-ARGININE DEIMINASE 3 AND 4 AUTOANTIBODIES IN A COHORT OF RHEUMATOID ARTHRITIS WITH INTERSTITIAL LUNG DISEASE

Boaz Palterer1, Gianfranco Vitallo1, Bernardo D’Onofrio1, Emanuele Vivarelli1, Daniele Cammelli2, Maria Grazia Giudizi2, Laura Martinez-Prat3, Silvia Casas2, Chelsea Bentow2, Michael Mahler2, Paola Parronchi1,3,1

1University of Florence, Department of Clinical and Experimental Medicine, Firenze, Italy; 2Inova Diagnostics, Inc., San Diego, United States of America

Background: Interstitial lung disease (ILD) affects up to 30% of patients with rheumatoid arthritis (RA). Peptidyl-arginine deiminases (PAD) are key enzymes in RA pathogenesis as they are involved in the citrullination of proteins, targets of anti-citrullinated protein antibodies (ACPA). Although RA-ILD significantly contributes to disease burden including mortality, diagnostic and prognostic biomarkers are still lacking.

Objectives: To measure anti-PAD3 and anti-PAD4 antibodies in a cohort of RA and compare their prevalence in patients with and without ILD. To assess the associations of anti-PAD3, anti-PAD4 and ACPA with disease activity, joint erosions, lung involvement and smoking history.

Methods: A total of 71 patients fulfilling the 2010 ACR/EULAR RA Classification Criteria were recruited; the mean age was 63±12.4 and 87% of them were females, 11 (15.5%) of them had been diagnosed with ILD. Demographic, clinical as well as radiological data were retrospectively collected. ILD was defined as usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP) or indeterminate patterns on chest high-resolution computed tomography, according to ATS/ERS guidelines. Particle-based Multi-System Technology (PMAT) (Inova Diagnostics, USA, research use only) was used to measure anti-PAD3 and anti-PAD4 autoantibodies. ACPA IgG were measured by chemiluminescence (QUANTA Flash CCP3, Inova Diagnostics, USA).

Results: Anti-PAD4 levels were correlated with erosive disease (p=0.043) and morning stiffness (p=0.031). Anti-PAD3 and anti-PAD4 levels were associated to DAS28-ESR at the time of sampling (anti-PAD3, r=0.34, p<0.004; anti-PAD4, r=0.34, p=0.004). Anti-PAD4 antibodies were significantly lower in patients with ILD (p=0.043). There was no association between anti-PAD4 and smoking, while anti-PAD3 antibodies were higher in non-smokers (p=0.004). A strong correlation was found between anti-PAD3 and anti-PAD3 antibodies as a biomarker for erosive disease. Further studies that take into account relevant confounders like therapy and larger RA-ILD cohorts are needed.

SEXUAL FUNCTION AND REPRODUCTION CAN BE IMPAIRED IN MEN WITH RHEUMATIC DISEASES: A SYSTEMATIC REVIEW

Luis Fernando Perez1, Bernike Te Winkel2, Juan Pablo Carrazales-Luna3, Wichor Bramer1, Saskia Vorstenbosch2, Eugène van Puijvelde2,3, Johanna Hazes1, Radboud Dolhain1, Erasmus Medical Center, Rotterdam, Netherlands; 2Netherlands Pharmacovigilance Centre Lareb, s, Hertogenbosch, Netherlands; 3Hospital Universitario Dr José Eleuterio Gonzalez, Rheumatology, Monterrey, Mexico; 4Erasmus Medical Center, Library, Rotterdam, Netherlands; 5Groningen Research Institute of Pharmacy, University of Groningen, PharmacoTherapy -Epidemiology and-economics, Groningen, Netherlands

Background: Sexual function and reproduction are important aspects of quality of life for the majority of men (1,2). In the last decade inflammation has been associated with male factor infertility and sexual dysfunction (3,4). Because many patients with rheumatic diseases have a
chronic state of inflammation, it is reasonable to believe that this can result in impaired sexual function and reproduction. Previous research on this topic in Rheumatology mainly focused on the effect of drugs on fertility parameters.

Objectives: Our objective is to summarize the information on the influence of rheumatic diseases on male sexual function and reproduction.

Methods: A systematic search of Embase, Medline, Web of science and Cochrane Central was carried out in May 2018 to find relevant papers. The search strategy was extensive and included a complete list of immune mediated diseases from Rheumatology, Dermatology and Gastroenterology and several keywords for our outcomes (sexuality function, fertility and pregnancy outcome). This review was registered in PROSPERO (5).

The search yielded 6588 articles. Titles and abstracts were screened independently by LP and JC, resulting in 177 papers selected for full text review. Methodological quality of the studies was assessed with the Newcastle Ottawa Scale (6).

Results: Regarding rheumatic diseases a total of 104 papers were included in the final analysis. 4 diseases (Spondyloarthropathies (SpA), Rheumatoid Arthritis (RA), Systemic Lupus Erythematosus (SLE) and Systemic Sclerosis (SSc)) represented 60% of the articles. The overall quality of the studies was low to moderate.

Sexual dysfunction (SD) is a common problem for patients with rheumatic diseases and it is usually undiagnosed. It was reported in approximately half of men with RA, SLE and SpA and in almost all the men diagnosed with SSc. It should be noted that, although in several studies increasing age was correlated with a higher prevalence and severity of SD, young patients with SpA or SLE can also be affected.

Regarding fertility and reproduction, different results per disease were found. Hypogonadism might be a common problem in men with RA and SLE. Many men with SLE and RA have endocrine axis abnormalities. Interestingly, these disturbances were not detected in SpA patients (See Table 1). Semen quality abnormalities are frequent in SLE patients and this was found to be associated not only with medication toxicities but also with disease activity. The number of children of male patients diagnosed with SLE and SSc was lower than healthy controls.

A brief summary of our findings per disease are presented in Figure 1.

Conclusion: Our findings suggest that not only medication can have detrimental effects on sexual function and reproduction of men with rheumatic disease but also the disease itself. Therefore, clinicians should be aware of a high prevalence of sexual and reproduction problems in this population and take this into account when counseling them. More research focusing on this association is needed.

ThU0682 UNDERDIAGNOSIS OF TRADITIONAL CARDIOVASCULAR RISK FACTORS IN RHEUMATIC DISEASES

Jeeva Cecilia Reynosa-Silva1, Dionicio Ángel Galarza-Delgado1, Iris Jazmin Colunga-Pedraza1, José Ramón Azpiroz-López1, Iván de Jesús Hernández-Galarza2, Karla Paola Cuéllar-Calderón3, Marielva Castro-González1, Carolina Marlene Martinez-Flores4. 1Hospital Universitario “Dr. José Eleuterio González”; 2UANL, Rheumatology, Monterrey, Mexico; 3Hospital Universitario “Dr. José Eleuterio González”; 4UANL, Cardiology, Monterrey, Mexico

Background: Patients with rheumatic diseases (RD) have a higher cardiovascular risk (CVR), compared to the general population (1). The increased risk in this population, tends to be associated with the chronic inflammation generated by RD. Another contributor is the coexistence of traditional CVR factors, such as diabetes, hypertension, obesity, smoking, and dyslipidemia (2). It is known that adequate control of this factors can reduce the overall CVR. Due to the increased CVR burden, there’s a growing awareness of cardiovascular assessment in rheumatic patients. Therefore, the 2016 EULAR guidelines recommend making this assessment every 5 years, in order to decrease their morbidity and mortality by early treatment.

Objectives: To determine the prevalence of underdiagnosis and inefficient treatment of traditional cardiovascular risk factors in RD patients.

Methods: A cross-sectional, observational study of patients between 30 and 75 years with rheumatoid arthritis (RA), psoriatic arthritis (PsA), systemic lupus erythematosus (SLE) and ankylosing spondylitis (AS) recruited at the rheumatology clinic at a University Hospital in northeastern Mexico. Exclusion criteria: previous cardiovascular disease, overlap syndromes, diabetes, or pregnancy. Evaluation included history of lifestyle, comorbidities, medications, blood pressure, anthropometry and fasting glucose measures. Framingham-BMI (FRS-BMI) was used to calculate their predicted CVR to 10 years.

Results: A total of 382 patients were recruited, 90.6% were women (n=346), with a median age of 53 years (45-59). In this population, 87.4% of the patients (n=334) had at least one CVR factor; the presence of traditional CVR factors according to RD is shown in Figure 1. Other population characteristics are in Table 1. Around half of the patients were not in their ideal weight, 32% being diagnosed as overweight and 31.4% with obesity. Out of the patients with no previous diagnosis of hypertension (n=350, 91.5%), 36.1% had elevated or high blood pressure levels. The patients that did have previous diagnosis, 68.7% didn’t have an adequate control of their blood pressure, even though they’re on pharmacological treatment. History of dyslipidemia was found in 5.2% of patients. Half of them arrived at consultation with a recent lipid profile, having a median LDL of 133.5 (109-158) mg/dL, not meeting target levels. Even though no diabetic patients were included, 20.8% of the patients had hyperglycemia. According to FRS-BMI, 80.4% of the patients had a low CVR, 14.9% moderate risk, and 4.7% had a high CVR.

Figure 1. Traditional cardiovascular risk factors.

REFERENCES:
Conclusions: In this study, an underdiagnosis and insufficient treatment of traditional CVR factors in rheumatic patients was found. Besides having a RD and at least one traditional CVR factor, 19.6% of the patients had a moderate or high CVR according to FRS-BMI. The observed burden of CVR factors in RD is significant. Therefore, rheumatologists must improve the CV assessment made to each of their patients.

THU0684 HOW MANY OF YOUR PATIENTS HAVE DEPRESSIVE SYMPTOMS? HOW TO ASSESS DURING ROUTINE CLINICAL PRACTICE?

Stefan Kleinert1, Florian Schuch1, Praxedis Rapp1, Monika Ronneberger1, Joerg Wendler1, Matthias Englbrecht2, 1Praxigemeinschaft Rheumatologie – Nephrologie (PGRN.de), Erlangen, Germany; 2Haelhest DataScientist, Eckental, Germany

Background: Patients with rheumatic diseases have a high prevalence of depressive symptoms that affect the patients’ self-assessment, adherence to medication [1], and mortality [2].

Objectives: To evaluate patients with rheumatic diseases regarding depressive symptoms by using the PHQ-2 (Patient Health Questionnaire with 2 items) and assess its feasibility during routine clinical practice.

Methods: 485 consecutive patients with rheumatic diseases attending a rheumatology practice that is part of the public health care system in Erlangen, Germany underwent a routine clinical assessment by different rheumatologists. In addition to disease-specific assessments and questionnaires, every patient answered two questions regarding depressive symptoms which form the PHQ-2 (range of 0[best] to 6[worst]). All questionnaires were answered digitally by touchscreen and Software RheumaDok and RheumaDokM (Nils Körber und Joachim Elgas G.b.R).
A PHQ-2 score $\geq 3$ points has a sensitivity of 87% and a specificity of 78% for detecting a major depressive disorder compared to a structured clinical interview. [3] A positive screening year was thus addressed during subsequent medical consultation or by notifying the patient's general practitioner. The PHQ-2 is a short form of the PHQ-9 which previously had been validated in rheumatoid arthritis. [4]

**Results:** Overall, 26% of patients stated depressive symptoms (PHQ score $\geq 3$). Table 1 shows the prevalence of depressive symptoms by disease entity which was not significantly different among the subgroups ($\chi^2=8.6$, $p=0.3$). However, given our results indicating depressiveness to be common across subgroups, all of these patients merit further evaluation. The PHQ-2 was widely accepted by patients, and seemed very feasible due to its concise form.

**Conclusion:** The PHQ-2 questionnaire is a highly feasible and well accepted tool in routine clinical practice, helping to screen for depressive symptoms as a highly prevalent condition across rheumatic diseases. Real world evidence of depressive symptoms may improve healthcare by shedding light on the patients' mental well-being and comorbidity.

treating and other reproductive factors, and RA risk with conflicting results [2, 3].

Objectives: To assess the relationships between endogenous and exogenous female hormonal exposures and the risk of RA in women involved in the E3N cohort.

Methods: E3N is an ongoing French prospective cohort that included 98,995 women aged 40-65 years in 1990. Women completed mailed questionnaires every 2-3 years on lifestyle, reproductive factors, and health-related information. Female endogenous hormonal exposures were assessed using age at menarche, age at menopause, and the duration of reproductive life. Exogenous hormonal exposures included oral contraception and menopausal hormonal treatment (MHT). Hazard ratios (HRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using Cox proportional hazards regression models with age as the time scale, first applied to the overall population, then stratified for smoking exposure.

Results: A total of 698 incident RA cases were validated among and 78,452 women over 1,865,213 women-years. Multivariate models for age at menopause and cumulative duration of MHT appear in Table. After stratification for smoking exposure, early age at menopause was associated with a somewhat stronger RA risk in women exposed to smoking (HR=1.6, 95% CI: 1.1-2.2; P trend =0.0270) than in those with no smoking exposure (HR=1.3, 95% CI: 0.8-2.2; P trend =0.1811). However when adjusting for cumulative duration of MHT, early age at menopause was no longer associated with incident RA, even in women exposed to smoking (HR=1.3, 95% CI: 0.8-2.2; P trend =0.7973); while a cumulative duration of MHT > 4 years was borderline associated with RA in women exposed to smoking [HR=1.3, 95%CI: 1.0-1.7; P trend =0.09] in comparison with women who did not receive MHT. Age at menopause and duration of THM were strongly correlated: in women with an age at menopause duration of MHT was significantly longer: 7.01 (7.3) years versus 4.8 (5.0) years (p<0.001). There was no evidence of an association between oral contraception use, age at menarche and duration of reproductive life with the risk of RA.

Conclusion: Early age at menopause and/or duration of MHT > 4 years use may increase the risk of RA. Further studies are requested to disentangle the effect of early menopause to that of long-term MHT.

Background: Several autoimmune diseases have been associated with schizophrenia and epilepsy, however little is known about putative links with the auto-inflammatory conditions.

Objectives: We investigated the association between familial Mediterranean fever (FMF), a paradigmatic auto-inflammatory disease, schizophrenia and epilepsy, and assessed the impact of the latter disorders on the survival of FMF patients utilizing a large sample database.

Methods: A case-control study was performed by utilizing the database of Clalit Health Services. FMF patients were compared to age- and sex-matched counterparts in terms of prevalence of schizophrenia and epilepsy. The chi-squared test was used to assess the distribution of categorical variables, while the t-test were applied for continuous variables. Analysis regarding survival were performed using Kaplan-Meier curves, log rank test and multivariate Cox proportional-hazards method.

Results: The study included 7,747 FMF patients, and 10,080 age- and sex-matched controls. At the univariate analysis, schizophrenia and epilepsy as co-morbidities, 50 FMF patients (0.8%) and 89 controls (0.9%) had schizophrenia, respectively. Multiple logistic regression model, FMF was inversely associated with schizophrenia (OR 0.64 [95%CI 0.43-0.90], p=0.0173), while there was no association between FMF and epilepsy. Subjects having either FMF [HR 1.43 [95%CI 1.23-1.66]], schizophrenia (HR 3.97 [95%CI 1.47-10.70]) or epilepsy (HR 2.54 [95%CI 1.72-3.75]) were independently associated with all-cause mortality. However, schizophrenia as co-morbidity in FMF subjects did not worsen their prognosis [HR 2.17 [95%CI 0.60-7.86]].

Conclusion: FMF patients have a significantly lower proportion of schizophrenia than controls. Patients with either FMF, schizophrenia or epilepsy are at higher risk of all-cause mortality, a finding that calls for assessment of better medical management on mortality outcome.

ASSESSMENT OF THE QRISK2, QRISK3, SLE CARDIOVASCULAR RISK EQUATION, FRAMINGHAM AND MODIFIED FRAMINGHAM RISK CALCULATORS AS PREDICTORS OF CARDIOVASCULAR DISEASE EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Jagan Sivakumaran1,2, Paula Harvey2, Jiandong Su2, Ahmed Omar3, Nicole Anderson4, Dafna D Gladman4, Murray B Urowitz2,4, Zahi Touma4,2
1University of Toronto, Medicine, Toronto, Canada; 2Centre for Prognosis Studies in the Rheumatic Diseases, Rheumatology, Toronto, Canada; 3University of Toronto, Cardiology, Toronto, Canada; 4University of Toronto, Rheumatology, Toronto, Canada

Background: Systemic lupus erythematosus (SLE) is recognized as an independent risk factor for cardiovascular disease (CVD), and patients with SLE are at an elevated risk of CVD compared to the general population1. The complex interplay between conventional CVD risk factors, the inflammation caused by SLE and the pharmacological treatment of SLE contributes toward CVD risk1. Despite knowledge of this increased risk, there is no agreement on the use of risk assessment tools in the prediction of CVD in SLE. The Modified Framingham Risk Score (mFRS), QRISK3 and SLE Cardiovascular Risk Equation (SLECRE) have been introduced as promising CVD risk assessment tools considering SLE in prospective patients.

Objectives: To determine which cardiovascular risk assessment tool amongst the QRISK2, QRISK3, SLECRE, Framingham (FRS) and mFRS best predicts CVD events in SLE.

Methods: Single-centre analyses on prospectively collected data of 1887 SLE patients were performed to compute 10-year CVD risk scores for each tool. Tools’ scores were evaluated against CVD events at or within ten years for cases (CVD events) and controls (no CVD events). For cases, the index date for risk score calculation was chosen 10 years, or as close to 10 years as possible prior to the CVD event. For controls, risk scores were calculated as close to 10 years as possible prior to the most recent clinic appointment. Proportions of patients classified as low (<10%), median (10-20%) and high risk (>20%) of developing CVD according to each tool were determined. Sensitivity, specificity, positive/negative predictive values and c-statistics of these tools were analysed.

Results: 232 total CVD events were identified in the cohort including myocardial infarction, stroke, transient ischemic attack, heart failure and CVD death. QRISK2 and FRS risk-stratification was similar, while QRISK3 and mFRS risk-stratification was similar (Figure 1). The SLECRE classified the highest number of patients as median-high risk (Figure 1). The sensitivities and specificities are as follows for each tool: QRISK2 (19%, 93%), FRS (22%, 93%), mFRS (46%, 83%), QRISK3 (47%, 78%), SLECRE (61%, 63%). The tools were similar in negative predictive value, ranging from 89% (QRISK2) to 92% (SLECRE). The FRS and mFRS had the greatest c-statistics, both equaling 0.73, demonstrating the greatest predictive accuracy amongst the tools, while the QRISK3 had the lowest (0.67).

Background: Systemic lupus erythematosus (SLE) is recognized as an independent risk factor for cardiovascular disease (CVD), and patients with SLE are at an elevated risk of CVD compared to the general population1. The complex interplay between conventional CVD risk factors, the inflammation caused by SLE and the pharmacological treatment of SLE contributes toward CVD risk1. Despite knowledge of this increased risk, there is no agreement on the use of risk assessment tools in the prediction of CVD in SLE. The Modified Framingham Risk Score (mFRS), QRISK3 and SLE Cardiovascular Risk Equation (SLECRE) have been introduced as promising CVD risk assessment tools considering SLE in prospective patients.

Objectives: To determine which cardiovascular risk assessment tool amongst the QRISK2, QRISK3, SLECRE, Framingham (FRS) and mFRS best predicts CVD events in SLE.

Methods: Single-centre analyses on prospectively collected data of 1887 SLE patients were performed to compute 10-year CVD risk scores for each tool. Tools’ scores were evaluated against CVD events at or within ten years for cases (CVD events) and controls (no CVD events). For cases, the index date for risk score calculation was chosen 10 years, or as close to 10 years as possible prior to the CVD event. For controls, risk scores were calculated as close to 10 years as possible prior to the most recent clinic appointment. Proportions of patients classified as low (<10%), median (10-20%) and high risk (>20%) of developing CVD according to each tool were determined. Sensitivity, specificity, positive/negative predictive values and c-statistics of these tools were analysed.

Results: 232 total CVD events were identified in the cohort including myocardial infarction, stroke, transient ischemic attack, heart failure and CVD death. QRISK2 and FRS risk-stratification was similar, while QRISK3 and mFRS risk-stratification was similar (Figure 1). The SLECRE classified the highest number of patients as median-high risk (Figure 1). The sensitivities and specificities are as follows for each tool: QRISK2 (19%, 93%), FRS (22%, 93%), mFRS (46%, 83%), QRISK3 (47%, 78%), SLECRE (61%, 63%). The tools were similar in negative predictive value, ranging from 89% (QRISK2) to 92% (SLECRE). The FRS and mFRS had the greatest c-statistics, both equaling 0.73, demonstrating the greatest predictive accuracy amongst the tools, while the QRISK3 had the lowest (0.67).

Figure 1. Percentage of patients considered low (<10%), median (10-20%) and high risk (>20%) between cases (CVD, n=232) and controls (no-CVD, n=1655) according to the FRS, mFRS, QRISK2, QRISK3 and SLE CRE.

Conclusion: While the mFRS performance was superior to the FRS, the QRISK3 did not outperform the FRS. Although the SLECRE had the highest sensitivity, it had the lowest specificity, demonstrated by grouping the most cases and controls in the median-high risk category. Several factors are important to consider when deciding which risk assessment tools to utilize: ease of use/computation, sensitivity/specificity, and laboratory data accessibility. Of the tools currently available, the mFRS is a practical tool with a simple, intuitive scoring system appropriate for the ambulatory clinic setting based on the initial weighting of the FRS while adjusting for SLE. However, much room for improvement exists in predicting CVD in SLE.

ASTHMA AND ELEVATION OF ANTI-CITRULLINATED PROTEIN ANTIBODIES PRIOR TO THE ONSET OF RHEUMATOID ARTHRITIS

Alessandra Zaccardelli1, Xinyi Liu1, Julia Ford1,2, Sara Tedeschi1,2, Jing Cui1,2, Bing Lu1,2, Su Chu1,2, Peter Schur1,2, Cameron Speyer1,2, William Kaldenberg3, Jeremy Sokolove4,2, Carlos Camargo, Jr.1,2, Jeffrey Sparks1,2,1, Brigham and Women’s Hospital, Boston, United States of America; 2Harvard Medical School, Boston, United States of America; 3Stanford University School of Medicine, Palo Alto, United States of America; 4VA Palo Alto Health Care System, Palo Alto, United States of America; 5AbbVie, Redwood City, United States of America; 6Massachusetts General Hospital, Boston, United States of America

Background: Anti-citrullinated protein antibodies (ACPA) are central to RA pathogenesis, with serum ACPA titers elevated years prior to clinical RA onset. ACPA may occur in patients with asthma, forming neoantigens producing ACPA before articular involvement. Thus, individuals with inflammatory airway diseases, such as asthma, may be susceptible to RA-related autoimmunity.

Objectives: To investigate asthma as a risk factor for ACPA+ in serum prior to clinical RA onset.

Methods: We performed a cross-sectional analysis among women in the Nurses’ Health Studies to examine whether asthma was associated with pre-RA ACPA+. Incident RA cases occurring after blood draw met research criteria and were each matched to 3 controls by age and menopausal status. Presence of self-reported asthma and potential confounders, including smoking pack-years, were assessed using questionnaires. The specific (secondary) definition for ACPA+ was: >3 units on CCP2 or elevation >99th percentile of control distribution on the research ACPA assay.

The specific (secondary) definition for ACPA+ was: >3 units on CCP2 or elevation >99th percentile of control distribution on the research ACPA assay. The sensitive (primary) definition for ACPA+ was: >5 units on CCP2 or >99th percentile of control distribution on the research ACPA assay.

Results: We measured ACPA on 1,135 women, including 286 pre-RA cases and pre-RA controls. Serum was banked a mean of 9.7 years (SD 5.8) prior to RA diagnosis, mean age of 51.9 years (SD 7.9). Overall, 12% of pre-RA cases were current smokers (OR 3.11, 95%CI 1.29-7.47) and only pre-RA cases (OR 2.22, 95%CI 1.00-4.88). In the secondary analyses, we found similar associations among all cases (OR 2.32, 95%CI 1.19-4.51).

Conclusion: Asthma may be a novel risk factor for elevation of ACPA prior to RA onset, independent of smoking. These findings encourage further research on the contribution of airway inflammation to RA pathogenesis.

DISEASE ACTIVITY CORRELATES WITH INSULIN RESISTANCE AND ADIPOCYTOKINES IN PATIENTS WITH DMARD-NAIVE RHEUMATOID ARTHRITIS

Ali Taytaz1, Burak Toprak2, Baris Acinci2, Merih Birlik4, Fatma Demet Arslan5, Baris Gundogdu2, Ayler Colak2,1, SBU Tepek Egitim ve Arastirma Hastanesi, Istanbul, Turkey; 2Dokuz Elyaf University School of Medicine, Department of Internal Medicine, Endocrinology, Istanbul, Turkey; 3Dokuz Elyaf University School of Medicine, Department of Internal Medicine, Rheumatology, Istanbul, Turkey; 4Medeniyet University Department of Internal Medicine, Rheumatology, Istanbul, Turkey

Background: Cardiovascular events such as myocardial infarction and stroke are frequent comorbidities in rheumatic diseases [1]. In relation, components of the metabolic syndrome (MS) including insulin resistance (IR), central obesity, high blood pressure, high triglycerides, and low high-density lipoprotein (HDL) are related to a high rate of endothelial dysfunction and atherosclerosis in patients with RA [2].

Objectives: We aimed to investigate the relationship between disease activity and insulin resistance (IR) and the levels of adipoctyokines in non-diabetic patients with newly diagnosed rheumatoid arthritis (RA) who are naïve to disease modifying anti-rheumatic drugs (DMARDs).

Methods: Forty-seven DMARD-naïve patients with RA and 25 age-, gender-, and BMI-matched controls were included. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), 28-point-count disease activity score (DAS28), serum lipids, glucose, HbA1c, insulin, leptin, resistin, visfatin, and RBP4 levels were measured. Homeostasis model assessment for insulin resistance (HOMA-IR) was calculated. Patients were studied before and 3 months after treatment with DMARDs.

Results: Levels of adipokines were similar in patients with RA and controls (p > 0.05 for all). However, RA patients with active disease (DAS28 > 3.2) had numerically higher levels of leptin (9.3 (3.7-14.7) vs. 7.6 (3.7-11.0), p = 0.289), insulin (8.0 (5.2-12.7) vs. 5.9 (4.2-8.7), p = 0.285), and HOMA-IR (1.9 (1.1-3.0) vs. 1.3 (1.0-1.9), p = 0.209). DAS28 was correlated with HOMA-IR (r = 0.356, p = 0.016), insulin (r = 0.323, p = 0.02), and leptin (r = 0.399, p = 0.005) in the study group (Figure-1).

Conclusion: Disease activity is associated with IR and correlates with circulating levels of adipokines in patients with RA. Treatment with DMARDs reduces leptin and improves IR.

CLINICAL, RADIOLOGICAL, THERAPEUTIC ASPECT AND PROGNOSTIC OF INFECTIOUS SPONDYLODYSITIS WITHOUT BACTERIOLOGICAL EVIDENCE

Rawdha Tekaya, Lorna Ben Ammar, Aicha Ben Tekaya, Khadoua Zouaoui, Olfa Sadane, Ines Mahmoud, Leila Abdelmoula. Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia

Background: Early microbiological diagnosis and multidisciplinary management are the main predictive factor for successful treatment in septic spondylodiscitis. However, the therapeutic management of spondylodiscitis without bacteriological diagnosis is not well codified.

Objectives: To evaluate whether there is clinical, biological or significant imaging between patients with infectious spondylodiscitis as they had or not a microbiological diagnosis.

Methods: Retrospective study including 107 patients hospitalized in our department between 1999 and 2018. The diagnosis was based on clinical, biological, radiological and bacteriological data.

Results: This study involved 107 patients, including 58 men (54.2%) and 49 women (45.8%) with a mean age of 55 years [16–86]. Spinal pain was observed in all cases and the lumbar spine was most affected (54.2%). A neurological deficit was noted in 16.62% of cases. The inflammatory syndrome was present in 90.6% of cases. Radiographs of the spine were abnormal in 83.1% of cases. CT and Spinal MRI were performed respectively in 60% and 78.8% of cases. Discal vertebral biopsy was performed in 73 patients and was contributory in 46.5% of cases.

We divided patients into two groups: patients with a confirmed biological diagnosis (group 1: 45.3%) versus patients in whom the diagnosis had been held on presumptive criteria (group 2: 54.7%). There was no statically significant difference in the age (p=0.5), sex (p=0.3), risk factors such as diabetes (p=0.8), the start mode (p=0.4), the presence of an impaired general condition (p=0.3), night sweats (p=0.1) and a neurological deficit (p=0.8), biological parameters (p=0.3) and the occurrence of complications (p=0.09) between the two groups. Vertebral condensation in radiographs of the spine was higher in group 2 and this was statically significant (p=0.03). In addition, the consumption of unpasteurized milk and positivity of wright serology was higher in the first group (p=0.001 and p=0.001; respectively). Similarly, contributive histological result of vertebral biopsy was more frequent in group 1 (p=0.007).

Conclusion: Diagnosing infectious spondylodiscitis is facilitated by improved access to MRI testing. However, microbiological diagnosis is the main key to a successful management of this life threatening infection.

OCULAR MANIFESTATIONS IN BEHCET’S DISEASE MAY BE MORE COMMON IN CHILDREN THAN ADULTS: RESULTS OF A SYSTEMATIC REVIEW

Matthew Turk1, Jacqueline Hayworth2, Tatiana Novskaya3, Janet Pope1.

1University of Western Ontario, Rheumatology, London, Canada; 2University of Toronto, Toronto, Canada

Background: Behcet’s disease (BD) can develop in both children and adults, but they may have different clinical features. Ocular involvement is common in BD and causes substantial impairment. The frequency of ocular involvement in BD has a wide range (5 to 89%).

OBJECTIVES: This study determined the frequency and type of ocular manifestations in childhood and adult BD and compared prevalence of ocular manifestations by geographic location in those with BD.

Methods: The protocol of ocular conditions in rheumatic conditions was registered at clinitrials.gov (NCT03753893). Search terms were: conjunctivitis, keratoconjunctivitis sicca, xerophthalmia, uveitis, eye hemorrhage, optic neuritis, papilledema, orbital disease, retinal artery/vein occlusion, macular edema, retinitis, choriorretinitis, scleritis, iridocyclitis, choroid hemorrhage, blindness and amaurosis fugax in patients with BD. The search was performed with the assistance of an information specialist. Medline, Cochrane and Web of Science were used searching papers that spanned from their inception (1966, 1991 and 1990 respectively) to October 5, 2018. Studies were included if they had a minimum of twenty patients and reported the frequency of ocular manifestations within BD. Random effects models were used to combine the prevalence of ocular manifestations using Revman 5.3. Heterogeneity was evaluated using I² and funnel plots.

Results: The search resulted in 3129 articles, of which 33 were included for meta-analysis. Eye manifestations were more frequent in childhood onset BD with the mean [95% Confidence Interval] frequency of 50 [38-63]% compared to 34 [25-43]% in adults. In both children and adults, posterior uveitis (children 27% vs. adults 25%) was the most common ocular manifestation, followed by anterior uveitis (children 18% vs. adults 23%). When comparing the distribution of ocular manifestations in Behcet’s in adults, there was geographic variation higher along the ancient Silk Road with ocular manifestations occurring in 40% of patients from Turkey and the Middle East. Ocular manifestations were similar in Europe (36%) and North America (36%), but less frequent in North Africa (26%), and East Asia (20%).

Conclusion: The frequency of ocular involvement is higher in children when compared to adults with BD. The most common manifestation in the eyes is posterior and then anterior uveitis. Ocular involvement also presents regional differences.

INPATIENT PREVALENCE, EXPENDITURES AND COMORBITIES OF TAKAYASU’S ARTERITIS: A PROPENSITY-MATCHED COHORT STUDY

Patpongong Ungprasert1, Kam Wijampreecha2, Wisth Cheunprasitporn1, Charat Thongprayoon1, 2Faculty of Medicine Siriraj Hospital, Mahidol University, Clinical Epidemiology Unit, Department of Research and Development, Bangkok, Thailand 3Mayo Clinic Florida, Medicine, Jacksonville, United States of America; 4University of Mississippi Medical Center, Medicine, Jackson, United States of America; 5Mayo Clinic Rochester, Medicine, Rochester, United States of America

Background: Takayasu’s arteritis (TAK) was first described in Japan. Since then, the disease has been extensively studied in Japan and other Asian countries [1]. However, little is known about the characteristics, inpatient burden, expenditures and comorbidities of TAK in the United States (US).

Objectives: To investigate the inpatient prevalence, expenditures and comorbidities of patients with TAK in the US.

Methods: Patients with TAK were identified within the Nationwide Inpatient Sample (NIS) database of the years 2013-2014 using ICD-9 diagnostic code. NIS is a publicly available inpatient database that contained data of over 7 million hospital stays, which are a 20% stratified sample of over 4,000 non-federal acute care hospitals from more than 40 states of the US. Data on patient characteristics, comorbidities, resource utilization and expenditures was collected. A propensity-matched cohort of patients without TAK was also created from the same database to serve as comparators for the analysis of comorbidities. Inpatient prevalence of TAK was calculated using all admissions in the NIS database as denominator. Odds ratios (OR) comparing the prevalence of comorbidities between cases with TAK and propensity-matched controls without TAK were calculated.

Results: A total of 2,840 patients with TAK were identified from the database, corresponding to an inpatient prevalence of 4.6 cases per 100,000 admissions. The main reasons for admission in patients with TAK were as follows: chest pain (17%), acute myocardial infarction (16%), stroke (14%), sepsis (14%) and pneumonia (11%). Compared to the propensity-matched cohort of patients without TAK, patients with TAK were found to have significantly increased odds of stroke, aortic aneurysm, aortic valvulopathy and peripheral vascular disease. TAK was also associated with increased use of some procedures (Table 1). However, the mortality was not significantly different (adjusted OR: 1.44, 95% CI: 0.58 – 3.61, p<0.43). After adjusting for confounders, patients with TAK displayed a mean additional $11,275 (95% CI, $4,946 - $17,603) for total hospitalization charges (the amount of money that each hospital billed for providing its service on each case) when compared to patients without TAK.

Conclusion: The inpatient prevalence of TAK was higher than what would be expected from the overall incidence. The mean total hospital costs and total hospitalization charges for patients with TAK were higher than patients without TAK. Analysis of comorbidities found significantly higher odds of several vascular comorbidities compared to a propensity-matched cohort of patients without TAK.

BRAZILIAN SJÖGREN’S SYNDROME REGISTRY (BRASS): A LARGE BRAZILIAN MULTICENTRIC COHORT OF PRIMARY SJÖGREN’S SYNDROME

Valeria Valim1, Samira Tatayama Myamoto1, Maria Lúcia Lemos Lopes2, Aysa Cesar Pinheiro3, Aysa Cesar Pinheiro4, Leandro Augusto Tanure5, Fabiola Reis Oliveira1, Vanessa Hax6, Aiesa Zanchett Fedrigo7, Henrique Pereira Sampaio8, Roberto de Almeida Pernambuco9, Érica Vieira Serrano1, Sabrina Zanardi Machado1, Virginia Fernandes Moça Trevisani1, Brazilian Committee on Sjögren’s syndrome of Brazilian Society of Rheumatology

1University Federal do Espírito Santo, Vitória, Brazil; 2Universidade Federal do Porto Alegre, Porto Alegre, Brazil; 3Universidade Federal de Pernambuco, Pernambuco, Brazil; 4Universidade Federal de Uberlândia, Uberlândia, Brazil; 5Hospital das Crianças da Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; 6Hospital das Clínicas de Ribeirão Preto, Ribeirão Preto, Brazil; 7Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 8Hospital Evangélico de Curitiba, Curitiba, Brazil; 9Faculdade de Medicina de Botucatu – UNESP, Botucatu, Brazil; 10Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo, Brazil; 11Universidade Federal de São Paulo and Universidade de Santo Amaro., São Paulo, Brazil

Background: Primary Sjögren’s syndrome (pSS) is an orphan systemic autoimmune disease with no treatment based on evidence1. There is an international effort for multicentric registries for getting information about phenotypes, complication, response of treatment, and biobank consortium.

Objectives: To describe the creation of the Brazilian Sjögren’s Syndrome Registry (BRASS) and present the preliminary data.

Methods: BRASS is supported by Brazilian Society of Rheumatology (SBR) and is including patients from all regions of the country. Recruitment started in 2018 and is due to be completed in 2024. We are including patients with pSS according to AECG 2002 or ACR-EULAR 2016 classification criteria. All patients are being assessed for disease activity (ESSDAI), disease damage (SSDDI), symptoms assessment (ESSPRI), fatigue (FACIT-Fatigue), anxiety and depression (HADS), sleepiness (Epworth Sleepiness Scale), physical activity (IPAQ-SF) and quality of life (EQ-5D). In addition, demographics, immunological tests, unstimulated whole salivary flow (UWSF), salivary gland biopsy (SGB), comorbidities, treatment and complications such as cancer and cardiovascular risk assessment are being collected.

Results: There are currently 10 centers across the Brazil and 248 patients were evaluated until now. Most patients were female, white (45%) or mixed (36.3%), with the mean of the disease duration of 8.2 years. ESSDAI at baseline was 6.62±6.37 and currently is 4.2±1.56 (p<0.05). The mean of the SSDDI was 2.1±1.60 and ESSPRI 8.38±6.88. SGB was positive in 81.5% and focus score mean was 1.58±1.30. Schirmer test I was positive in 72.6%, van Bijsterveld in 70.9% and UWSF in 84.8%. About classification criteria, 91.9% fulfilled AECG 2002 and 94% ACR-EULAR 2016. Anti-Ro/SS-A and anti-La were positive in 70.8% and 35.5%, respectively. Forty three percent had positive RF, 88.5% ANA, 6.9% low C3, 10.2% low C4, 34.9% high IgG. Nineteen percent were using prednisone, 40.4% immunosuppressant, 53.6% antimarialar and 17.6% biological therapy. Prevalence of cardiovascular event was 7.5%, hypertension 43.3%, diabetes 13.3%, dyslipidemia 31.5%, smoking 5.8% and cancer 7.5%.

Conclusion: ESSDAI has decreased over time and more than half of patients are on hydroxychloroquine, immunosuppressant or biological therapy. Further analysis is needed to understand whether the reduction in ESSDAI reflects the natural course of the disease or greater access to

Disclosure of Interests: None declared
treatment. BRASS Registry will be important to enhance research and to develop public health planning.

Disclosure of Interests: None declared

Background: Previous reports indicated the strong association between smoking and onset of rheumatoid arthritis (RA), and relation between some of lifestyle habit and disease activity of RA.

Objectives: In this study, we compared differences in habits of smoking, alcohol consumption, coffee and Japanese tea intake between RA patients and healthy volunteers (Vo) in the same study population.

Methods: This study was conducted based on baseline data from ongoing 10-years prospective cohort project TOMORROW study (UMIN000003876), which includes age and sex matched RA patients (n=208) and Vo (n=205).

Data on smoking history and alcohol (Alc), coffee and Japanese tea intake were collected by self-reported questionnaires. Alc intake was categorized into 3 groups by calculating the amount per day using Alc unit (pure Alc 20 mg/Alc unit). We also categorized frequency of Alc intake per week into 3 groups, numbers of cup of coffee and Japanese tea intake per day into 4 groups each. The data of RA patients included anthropometric, blood test data, disease activity score28-ESR (DAS28-ESR), together with baseline characteristics. Using logistic multivariate regression lifestyle habits were compared between RA and Vo.

Results: We analyzed 191 Vo and 198 RA with complete data about lifestyle habits. Demographic data and lifestyle habits of RA and Vo were shown in the Table 1 and 2. In RA patients, the average disease activity showed in the Table 1 and 2. In RA patients, the average disease activity

Conclusion: As shown in previous reports, the smoking history was significantly higher in RA patients with an odds ratio of 5.03. And moderate intake of Alc and caffeinated coffee seems to be low in RA patients.

HPR Service developments, innovation and economics in healthcare
duration of disease at 1st assessment was 7.0 years (IQR 5.5-8.8); 24 patients were transited successfully. Only 60% of our youths felt that transition preparatory is important and had confidence to be prepared for change to adult healthcare system (AHCS). Among the less confident group (scores <7), MKHU, MM, AM and HT domains scored significantly less than those from confident youths (p<0.001-0.021), but only transition importance MKHU scores were <7. Disease duration at first TRAT assessment and diagnoses did not predict confidence level. With further targeted education and counselling (median 8.3 months (IQR 5.7-9.6)), confidence and MKHU was significantly improved (p<0.001).

Conclusion: TRAT enables our PRPT team to learn and understand our youths’ perception and readiness of adult transition process. More than one-half of them did not aware of the importance of the transition process and had less confidence to do so. With further targeted counselling and preparation, all improved their perception and MKHU significantly. TRAT was able to guide individualized counselling to our cohort youths who are ready to be transited.

THU0697-HPR CONTENT OF AND RHEUMATOLOGISTS’ AND NURSES’ OPINIONS ON A NURSE-LED TELEPHONE HELPLINE

Mehmet Elmacioglu1,2, Natalia Westerman3, Debby Vosse4, Annelies Boonen1, Yvonne van Eijk-Hustings1,1 Maastricht University Medical Centre, Maastricht, Netherlands; 2Maastricht University Medical Centre, Maastricht, Netherlands; 3Maastricht University, Maastricht, Netherlands

Background: To improve timely response to patients’ questions and to support that care is provided by the appropriate professional, a nurse-led rheumatology telephone helpline was introduced in May 2015. Different organisational approaches have been tried out to ensure an effective as well as efficient service. Currently a voicemail system is used. A selection menu allows patients to select whether he/she needs 1) advice regarding disease complaints, 2) drug prescriptions, 3) (change in) appointment at the clinic, 4) laboratory forms. Although the menu differentiates between requests, organising timely responses by the appropriate professional remains a challenge. Clear and joint definitions by the rheumatologists and nurses on what questions to what extent should be addressed by whom, are necessary.

Objectives: To facilitate further improvement of the helpline we explored 1) number and content of questions that were registered; 2) experiences of rheumatologists and nurses with the helpline; 3) opinions of rheumatologists and nurses on which questions should be answered via the helpline.

Methods: A file research explored the number of questions and reasons for contacting the helpline. Data were analysed descriptively. In semi-structured interviews among all rheumatologists (n=8) and nurses involved in manning the helpline service (n=6), experiences and opinions were explored. System Engineering Initiative Patient Safety (SEIPS) model, that focuses on system design and it’s interaction with processes, and outcomes for patients, employees and organisation was used to structure thematic coding of the transcripts.

Results: In 37 months, the helpline registered 3389 calls (see Table 1). A majority of the questions was about disease complaints (28.6%) or other related problems such as pain management, and exercise (27.8%). The proportion of requests for prescriptions was 21.8%. The interviews revealed that both rheumatologists and nurses considered the helpline valuable in providing easy access to care for patients with disease related questions. This should be the primary aim. The rheumatologists also valued their reduced workload, which occurred most if the knowledge of the nurse was sufficient to take care of the responses independently. Moreover, they valued if requests, such as prescriptions, were clustered by the nurses. The nurses experienced an increased workload. Sufficient knowledge on and training in rheumatology, and being familiar with the patient were considered pivotal in providing appropriate and for the patient acceptable care. As nurses cannot prescribe medication, the requests for prescriptions were considered inappropriate. Availability of protocols and guidelines were considered prerequisites by all for responding to patients’ requests appropriately.

Conclusion: The helpline is used frequently and the selection menu has helped to gain insight in why the helpline is used by patients. There is consensus on the primary aim of the helpline and on prerequisites for nurse-led responses to patients’ disease related questions. Rheumatologists and nurses have different opinions on some issues, such as the organisation of prescriptions. Our study findings can help in jointly improving consensus on the content of nursing care within the helpline.

THU0698-HPR MORE EFFICIENT DMOAD TRIALS THROUGH INNOVATIVE SCREENING STRATEGIES

Thibault Helleputte1, Anne-Christine Hick2,3, Yves Henrotin2,3, 1DNAlytics, Louvain-la-Neuve, Belgium; 2Artialis SA, Luik, Belgium; 3CHU Liège, UROC, Liège, Belgium

Background: In randomized Clinical Trials (RCT), the number of patients to recruit for assessing effectiveness of disease-modifying OA drug (DMOAD) depends on the proportion of progressors in the population. The higher this proportion, the smaller the cohort to be recruited. In the general OA population, this proportion is quite low (10-30%) [1] requiring large cohorts, hence long and expensive trials.

Objectives: We study how predictive modeling based on early cartilage degradation biomarkers can be used to screen patients, make individual predictions about the likelihood of future progression, and recruit on this basis a progressor-enriched cohort. By doing so, DMOAD RCTs could achieve same or better success rates based on smaller cohorts and lower budgets, even taking into account the extra cost of this innovative screening.

Methods: Two biomarkers (Coll2-1 & Coll2-1-NO2, Artialis, Belgium) have been measured at baseline on 182 OA patients from the placebo arm of a previous RCT. For this cohort, progression at 30M is defined as in [2]. We developed two predictive models of the progression of the patients over 30 months through regularized logistic regressions: one based on Coll2-1 only, the other on Coll2-1 and Coll2-1-NO2. Based on these models, we design a strategy to produce cohorts of patients with a higher rate of progressors than the natural proportion. To do so, we make hypotheses on the expected drug effect (from 30% to 50%), on the costs generated by this innovative screening strategy (a.o. nb patients screened, referrals for devices.

Available online: 1,767,260 of such a study, 554 patients have to be recruited, with a cost of per patient, OR, and R). In the modified version, only patients for which inclusion criteria are met and the tuned biomarker-based model turns positive are enrolled. In the standard version of such a study, 554 patients have to be recruited, with a cost of 1,767,260€. Through the optimized strategy, 1,190 patients are screened,

Calcium deficiency (Ca²⁺) and vitamin D deficiency (25(OH)D³) are important among patients with osteoarthritis (OA). In the standard version of such a study, 554 patients have to be recruited, with a cost of 1,767,260€. Through the optimized strategy, 1,190 patients are screened,
but among them only 344 are recruited in the study, showing a progression rate of about 35% instead of 20%, for a total cost of 1,229,280 €.

**Conclusion:** This work demonstrates the interest for biomarker-based OA-progressors cohort enrichment in DMOAD RCTs. It simulates the gains it could represent for the conduct of such RCTs. The cohorts used in this work (for biomarker measurement and predictive modeling) have a high proportion of women with very large BMI, with K&L grade II-III. The work (for biomarker measurement and predictive modeling) have a high associated with actually using the RD-app (p<0.001).

**IS A SMARTPHONE APPLICATION USEFUL FOR SELF-MANAGEMENT SUPPORT IN PATIENTS WITH A RHEUMATIC DISEASE?**

**Methods:** We performed a prospective before-after study among patients with a RD. The primary outcome was patients' self-management behavior measured with the Partners in Health scale (PH), a generic validated 12 item self-rated scale, which indicates higher scores for better self-management behavior. A paired t-test was used to evaluate changes in the PH-scale score after three months. To measure the user-experience with the app, survey questions addressed whether the RD-app had contributed to get more grip (or not) on the disease and how (why not). Logistic regression analyses served to investigate variables that are important for using the RD-app.

**Results:** Of the 1511 eligible patients, 397 completed both the baseline and the follow-up surveys. Participants who completed both questionnaires were most frequently diagnosed with RA, 65% was female and the mean age was 52.0 (SD 15.6) years. Hundred-fourteen participants used the RD-app. Self-management behavior did not improve according to the PIH-scale score after three months. To measure the user-experience with the RD-app, survey questions addressed whether the RD-app had contributed to get more grip (or not) on the disease and how (why not). Logistic regression analyses served to investigate variables that are important for using the RD-app.

**PHYSIOTHERAPISTS COULD REPLACE PHYSICIANS AS PRIMARY ASSESSORS FOR PATIENTS WITH KNEE OSTEOARTHRITIS IN PRIMARY CARE—A RANDOMISED CONTROLLED STUDY**

**Methods:** Patients seeking primary care with suspected KOA were randomised to either a physiotherapist or a physician for assessment, diagnose and treatment. Inclusion criteria were knee pain and > 38 years old. Exclusion criteria: knee pain due to traumatic cause, other systemic, somatic, mental or rheumatic diseases, pregnancy, or already been diagnosed or assessed by another healthcare giver due to current knee pain. HrQol (Euroqol - EQ5D-3L index, EQ5D-3L VAS), pain intensity (visual analogue scale) and physical function (30 seconds chair stand test) were measured before randomisation, and at 3-, 6- and 12 months. Mann-Whitney’s U test and Chi2 test for independence were used with a significance level of p<0.05.

**Results:** 69 patients with suspected KOA were randomised to either a physiotherapist (n=35) or a physician (n=34). Both groups improved their HrQol, pain and physical function at all follow ups. Patients rated significantly better HrQol (EQ5D-3L VAS) one year after physiotherapy assessment (84 (SD 11) vs 74 (SD 15), p=0.018). No other significant differences were found between the groups.

**Conclusion:** Physiotherapy assessment could replace physician assessment without having negative impact on patient reported outcomes after treatment for patients with suspected KOA. This may play a role in selecting other patients with KOA who could represent for the conduct of these RCTs. In order to achieve yet stronger cohort enrichment and cost reductions, additional markers and/or clinical factors could be considered for the models.

**CArina A Thorstenson1, Lena Nordeman1, 2. Institute of Neuroscience and Physiology, Health and Rehabilitation, Gothenburg, Sweden; 2Närhälsan, Primary Health Care Region Västra Götaland, Närhälsan Lidköping, Rehabomottagning, Lidköping, Sweden, 3Närhälsan, Research and Development Primary Health Care Region Västra Götaland, Research and Development Center Södra Älvsborg, Borås, Sweden

**Background:** It has been estimated that consultations to healthcare will increase with 30-50% among patients with osteoarthritis (OA) over the next 20 years [1]. Patients with knee OA (KOA) report among the lowest health-related quality of life (HrQoL) compared with other chronic diseases [2]. Most patients are assessed by a physician who claims unnecessary healthcare resources since physiotherapists also are primary assessors for patients with KOA and provide recommended treatments. However, it is unclear if physiotherapists could be the first option as primary assessor for this patient group. We hypothesise that all patients with suspected KOA in primary care could be assessed by a physiotherapist first and be referred to physician only when it is required, without having a negative impact on HrQol.

**Objectives:** The aim of this study was to explore differences in HrQol, pain and physical function in patients with suspected KOA after being assessed, diagnosed and treated by physiotherapist first compared with being assessed by a physician in primary care.

**Methods:** Patients seeking primary care with suspected KOA were randomised to either a physiotherapist or a physician for assessment, diagnose and treatment. Inclusion criteria were knee pain and > 38 years old. Exclusion criteria: knee pain due to traumatic cause, other systemic, somatic, mental or rheumatic diseases, pregnancy, or already been diagnosed or assessed by another healthcare giver due to current knee pain. HrQol (Euroqol - EQ5D-3L index, EQ5D-3L VAS), pain intensity (visual analogue scale) and physical function (30 seconds chair stand test) were measured before randomisation, and at 3-, 6- and 12 months. Mann-Whitney’s U test and Chi2 test for independence were used with a significance level of p<0.05.

**Results:** 69 patients with suspected KOA were randomised to either a physiotherapist (n=35) or a physician (n=34). Both groups improved their HrQol, pain and physical function at all follow ups. Patients rated significantly better HrQol (EQ5D-3L VAS) one year after physiotherapy assessment (84 (SD 11) vs 74 (SD 15), p=0.018). No other significant differences were found between the groups.

**Conclusion:** Physiotherapy assessment could replace physician assessment without having negative impact on patient reported outcomes after treatment for patients with suspected KOA. This may play a role in selecting other patients with KOA who could represent for the conduct of these RCTs. In order to achieve yet stronger cohort enrichment and cost reductions, additional markers and/or clinical factors could be considered for the models.

**THU0701-HPR**

**“TO REGAIN ONE’S HEALTH” – PATIENTS’ PREFERENCES OF TREATMENT OUTCOMES IN EARLY RHEUMATOID ARTHRITIS – A QUALITATIVE STUDY**

Ellen Landgren1,2, Ann Bremander1,2,3,4, Elisabet Lindqvist1, Kristien Van der Elst1,6, Ingrid Larsson1,7, LUND University, Skåne University Hospital, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden, Lund, Sweden; RandD Spenshult, Halmstad, Sweden, Halmstad, Sweden; Department of Regional Health Research, University of Southern Denmark, Odense, Denmark; Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sonderborg, Denmark, Sonderborg, Denmark; Department of Rheumatology, University Hospitals Leuven, Leuven, Belgium, Leuven, Belgium; Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven–University of Leuven, Leuven, Belgium; School of Health and Welfare, Halmstad University, Halmstad, Sweden, Halmstad, Sweden

**Background:** Rheumatology care strives to identify and meet the needs of the patients, and to understand disease and treatment impact from the patients’ perspective. A better understanding of patients’ expectations from the treatment is needed to enable a patient centered approach in clinical practice and a shared-decision making as recommended in the EULAR treatment recommendations for rheumatoid arthritis (RA). Understanding of patients’ expectations in the early stage of the RA disease may facilitate adherence to treatment, patient independency and prevent unmet needs in the future.

**Objectives:** To explore patients’ preferred treatment outcomes in early rheumatoid arthritis (eRA).

**Methods:** A qualitative, explorative study. Individual interviews were conducted with 31 patients with eRA, defined as disease duration of ≤ 6 months. Interviews were analyzed using a constant comparison method according to the Qualitative Analysis Guide of Leuven (QUAGOL) and lasted in a core category and four related concepts.

**Results:** The patient-preferred treatment outcomes in eRA were described in the core category “to regain one’s health” and the four related concepts: to experience external control of the disease, to experience independence, to regain identity and to experience joy in everyday life. The patients expected to experience external control of the disease by the given treatment to regain one’s health. It was perceived as controlling the symptoms and as absence of disease. Independence was perceived as regaining former activity levels, experiencing autonomy and using active coping strategies. Patients wanted to regain identity through participation, empowerment and their self-image. Joy in everyday life was perceived as vitality and believing in the future.

**Conclusion:** Patients’ preferred treatment outcomes in eRA were to regain one’s health including both external and internal control. External control as disease control and independence as well as internal control as identity and joy in everyday life. The results from this study can assist healthcare professionals to better understand patients’ preferred treatment outcomes early in the disease process and to tailor the interventions accordingly to improve long term treatment outcome.

**PATIENT UNDERSTANDING OF RISKS OF METHOTREXATE AND ANTI-TNF THERAPY: A CROSS-SECTIONAL STUDY**

Lauren Jackson1, Natalie Murray2, Zoe Pilgrim3, Robert Marshall2,3, Mwamidi Njobi4,1 University of Bristol, School of Clinical Sciences, Bristol, United Kingdom; University of the West of England, Department of Nursing and Midwifery, Bristol, United Kingdom; University Hospitals Bristol NHS Foundation Trust, Department of Rheumatology, Bristol, United Kingdom

**Background:** Disease-modifying anti-rheumatic drugs (DMARDs) have revolutionised the management and long-term prognosis of rheumatoid arthritis (RA). Side-effects of DMARDs include, but are not limited to: immunosuppression, gastro-intestinal upset, skin reactions and headaches. Despite the significant potential side-effects of DMARDs, there have been limited attempts to evaluate patient understanding of the side-effects of methotrexate (MTX) and to our knowledge no studies with regards to anti-tumour necrosis factor (anti-TNF) therapy.

**Objectives:** To evaluate the extent to which each of the known side-effects of MTX and anti-TNF therapy can be identified by patients receiving single or combination therapy for RA.

**Methods:** This was a cross-sectional study conducted in a rheumatology centre in the West of England. Patients with RA, seen in the outpatient clinic within the previous 18 months were invited to participate. Participants had to belong to one of the following treatment groups: (i) MTX only (ii) anti-TNF only or (iii) combined treatment with MTX and an anti-TNF. A postal questionnaire designed by the research team was used to obtain the data. Each participant was asked to (a) select side-effects they considered to be possible from their treatment, (b) tick if they had experienced this side-effect, and (c) select whether they believed this side-effect to be common or not. Descriptive analyses were used to determine the proportion (percentage) of patients who correctly identified the possible side-effects, correctly identified them as common, and had experienced them. Summary results are presented as ranges (minimum to maximum) and their corresponding percentages.

**Results:** Of the 300 patients invited, 119 returned a completed questionnaire; 48 (40%) on MTX only, 25 (21%) on anti-TNF only and 46 (39%) on combined MTX and anti-TNF. Their mean (SD) age was 62.5 (12.8) years, disease duration 13.5 (12.4) years, 111 (93%) had completed compulsory education and 94 (79%) were female. Most participants (115, 97%) spoke English as their first language. Correct identification of each possible side-effect ranged from 29% to 63% of participants in the MTX only group, 15% to 41% of patients in the anti-TNF only group and 8% to 64% of participants in the combined MTX and anti-TNF group. Their mean (SD) age was 62.5 (12.8) years, disease duration 13.5 (12.4) years, 111 (93%) had completed compulsory education and 94 (79%) were female. Most participants (115, 97%) spoke English as their first language. Correct identification of each possible side-effect ranged from 29% to 63% of participants in the MTX only group, 15% to 41% of patients in the anti-TNF only group and 8% to 64% of participants in the combined MTX and anti-TNF group. Correctly recognising these as common ranged from 13% to 52% of participants in the MTX only group, 4% to 35% of participants in the anti-TNF only group and 8% to 64% of participants in the combined MTX and anti-TNF group. Of those correctly identifying possible side-effects, 22% to 55% of participants in the MTX only group, 1% to 25% of participants in the anti-TNF only group and 8% to 56% of participants in the combined MTX and anti-TNF group reported experiencing them.

**Conclusion:** Our data suggests that a considerable number of patients are unable to correctly identify the most common side-effects of DMARDs used in RA management. Effective patient education and involvement in treatment decision-making will allow patients to be more aware of potentially serious side-effects of DMARDs.

A SANCTUARY FROM EVERYDAY LIFE: A QUALITATIVE STUDY OF THE EXPERIENCE OF IN-PATIENT MULTIDISCIPLINARY REHABILITATION, FOR PATIENTS WITH RHEUMATIC DISEASES

Maria Stauning, Jette Primdahl, 1, 2 1Clinical institute, Odense, Denmark; 2University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 3Hospital of Southern Jutland, Aabenraa, Denmark; 4King Christian Xth Hospital for Rheumatic Diseases, Gråsten, Denmark

Background: In Denmark, patients with rheumatic diseases can receive inpatient multidisciplinary rehabilitation at a hospital for rheumatic diseases or at rehabilitation centers. Quantitative studies indicate that it is difficult to detect a general and lasting effect of 1-4 weeks of inpatient multidisciplinary rehabilitation, but few studies have explored patients’ experience of in-patient multidisciplinary rheumatology rehabilitation.

Objectives: To explore how patients, experience the process and personal impact of an inpatient rehabilitation stay.

Methods: An exploratory qualitative phenomenological-hermeneutic study was planned. Adult rheumatic patients admitted for a two-week inpatient rehabilitation stay were invited to participate. Individual semi-structured interviews were conducted in the patients’ home shortly after discharge or at the ward one of the last days of admission. The interviews were audio recorded and transcribed verbatim. The analysis was inspired by Paul Ricour’s interpretative philosophy (1).

Results: Fifteen interviews were conducted, 11(73%) female, age 28-89. The analysis derived a core theme, “A sanctuary”, reflecting that the patients experienced to have sufficient time and mental resources to provide self-care. In addition, the analysis derived five subthemes: 1) “Being seen, heard and acknowledged as an equal and whole person”. To feel acknowledged was vital for the patients’ experience of quality and benefit. 2) “Professional care and compassion”; which were considered by the patients as the most fundamental contextual factors to facilitate their self-care. 3) “Social relations and interactions between patients”, reflecting the patients experience of feeling recognized by other patients and to experience common understanding. 4) “An individually planned rehabilitation stay, but challenges regarding shared decision making”. The patients felt the rehabilitation was individually planned, but with room for improvement in relation to awareness of shared decision-making. 5) “Rehabilitation as a personal process but problems with transferability to everyday life”. The patients experienced the rehabilitation stay as a part of a personal rehabilitation process, but expressed concerns about whether they were able to transfer new learning and habits to everyday life.

Conclusion: Patients with rheumatic diseases experience in-patient rehabilitation as a sanctuary, with rehabilitation at three levels; through multidisciplinary rehabilitation interventions at the hospital; through recognition from the multidisciplinary staff and through recognition, social relationships and interactions with fellow patients. There is a need for improved coordination of rehabilitation across primary and secondary health care, in order to ease transferal to the patients’ everyday life.

PATIENT ACTIVATION AND ADHERENCE TO BIOLOGICAL THERAPY AND TARGETED SYNTHETIC DMARD: PRELIMINARY RESULTS:

A Sendra-Garcia, 1, 2 P Lopis-Salvia, Marta Hermengildo-Cauedvilla, Marta Aguilar-Zamora, L Montolvo-Chiva, Ana Victoria Orenes Vera, I Vazquez-Gomez, A Martinez-Ferres, D Ybañez-García, Elia Valls-Pascual, V Núñez-Morje, I J Turner-Hernández, Mónica Climente-Martí, Juanjo J Alegre-Sancho, University Hospital of Bellvitge, Rheumatology and Pharmacy Department, Valencia, Spain; 2Fisitabo, Valencia, Spain; 3Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain; 4Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain; 5Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain; 6Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain; 7Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain; 8Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain; 9Dr. Peset University Hospital, Pharmacy Department, Valencia, Spain

Background: Medication non-adherence has been associated with treatment failure in chronic inflammatory conditions. A positive relationship between patient activation and adherence to treatment and between activation and improved clinical outcomes has been shown for chronic conditions.

Objectives: To measure adherence to biological therapies and targeted synthetic DMARD (tsDMARD), and their relationship with the Patient Activation Measure (PAM) and with patient and therapy related factors, for chronic inflammatory arthropathies.

Methods: Cross-sectional observational descriptive study in a general tertiary university hospital.

Patients: A total of 68 patients (57% women) participated. The patients were in treatment with the same biological drug (subcutaneous; phase 1) or tsDMARD (oral; phase 2); >6 months were included in order of arrival and those with mental disability, which prevented understanding of the study, were excluded.

Demographic variables (sex, age, living environment, educational level), diagnosis and treatment were collected. Adherence was measured using the Simplified Medication Compliance Questionnaire (SMAC) for biological therapies, the Compliance Questionnaire Rheumatology (CQR-19) for tsDMARD, and the medication possession ratio (MPR). Patients were considered adherent if MPR≥80% and COR-19≥80% or adherent SMAQ. To measure activation, PAM questionnaire, was used. Patients were classified as activated or not activated.

Statistical analysis: relationship between adherence to treatment and PAM was analyzed using chi-square, considering significance level p<0.05. Statistical analysis was performed with spss v17.0.

Results: A total of 58 patients (57% women) were included. Mean age was 54 years (95% CI: 50 to 57), 86% lived in urban areas, 40% had completed elementary education, 31% high-school and 24% university schooling. Distribution by diagnostic: rheumatoid arthritis (81%), anklylosing spondylitis (14%) and psoriatic arthritis (5%). Distribution by treatment was: baricitinib (31%), tocafacitin (18%), adalimumab (16%), tocilizumab (14%), etanercept (12%), secukinumab (7%) and golimumab (3%). Median time of disease duration was 9 years (IQR 13) and time on treatment with the drug was 8 months (IQR 20), with significant differences between groups (27 biological therapy) vs 7 months (tsDMARD).

The proportion of adherent patients was 43%, being higher among tsDMARD (57%) vs biological treated ones (30%), with significant differences. 72% of patients were being more activated biological (80%) than tsDMARD (67%) treated patients. A higher adherent proportion of patients was found among the activated patients (48%) compared to the non-activated ones (27%) in all measures, even though the differences were not statistically significant.

Conclusion: Patients treated with biological therapies and tsDMARD have a high degree of activation for the self-management of their disease and its treatment. Adherence to treatment may be influenced by route of administration, type of drug (oral/tsDMARD 57% vs. subcutaneous/biological 30%) and time on treatment (longer time on treatment, lesser adherence).

The greater proportion of adherence found among patients with a higher degree of activation could indicate a positive relationship between activation and adherence, so analyzing and promoting patient activation seems important in order to improve adherence to drugs.

PELVIC FLOOR AND SEXUAL DYSFUNCTION IN WOMEN WITH SJOGREN SYNDROME

Alime Buyuk Gonen1, S. Yaprak Cetin1, Ayse Aydan2, 1Akdeniz University, Deartment of Physiotherapy, ANTALYA/TURKEY, Turkey; 2Antalya Education and Research Hospital, Department of Rheumatology, ANTALYA/TURKEY, Turkey

Background: Sjögren syndrome (SS) is a systemic autoimmune disease causing secretory gland dysfunction. This leads to dryness of the mainly salivary and lacrimal glands such as the mouth, eyes, nose, larynx, and vagina. The disease overwhelmingly affects middle aged women. These women have symptoms of decreased lacrimal and salivary gland function which usually precede involvement of other exocrine glands such as the upper airway, the gastrointestinal tract and the external genitalia (dyspareunia). Although genital tract symptoms are common in patients with sjögren, such as vulvar and vaginal dryness, dyspareunia, and pruritus, their pelvic floor health and functions have been rarely evaluated.

Objectives: The aim of study was investigation of pelvic floor and sexual dysfunction in patients with SS.

Methods: 23 patients with SS with an average age of 49.00±8.71 were included in the study. Pelvic floor dysfunction of patients with SS were evaluated by the Pelvic Floor Impact Questionnaire-7 (PFIQ-7) and Pelvic
THERE IS ASSOCIATION BETWEEN THE LEVEL OF

The sample consisted of a greater proportion of women aged 40 and 49 years (37.9%). There was a higher proportion of women with pelvic floor dysfunction and sexual dysfunction. This study showed that pelvic floor and sexual functions of patients with SS have been negatively affected. Therefore these functions need to be routinely assessed by health professionals. Further studies need to recommend pelvic health physiotherapy and educational programme about pelvic floor dysfunction.

FOLLOW-UP CARE FOR PATIENTS WITH ESTABLISHED INFLAMMATORY JOINT DISEASES – A FOCUS GROUP STUDY ON PATIENTS’ EXPERIENCES FROM REFRAIMING THE ORGANIZATIONAL SUPPORT FOR INCREASED PATIENT INVOLVEMENT

Bianca Bech1, Jens Jørgen Løykjegaard3, Tine Lundbæk1, Line Mette Birkeland1, Mette Lund Schlyter1, Lotte Hanne Hansen1, Lillian Dalsgaard1, Bente Aapel Ebensene1,2,1 Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Rigshospitalet, Denmark, Glotstrup, Denmark; 2University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Background: Internationally, a Treat-to-Target strategy for proactive manage- 
ment of inflammatory joint diseases (IJD) is recommended.1,2 This includes continuous monitoring of the arthritis, which covers symptoms and the significance of the disease for everyday life.1,2 Control of disease activity has traditionally been ensured with fixed outpatient visits to rheu- 
matologists. However, in general there is a growing interest to involve patients in the control and treatment of their own disease. Open Assess in our outpatient clinic was implemented during October 2016 to respond to fluctuating needs among the patients with established IJD. Patient participation in Open Assess were primarily patient-initiated. They were expected to respond to symptoms and other disease- and treatment-related needs. In addition, two half-yearly planned visits were offered patients: 1) An annual traditional medical consultation with a rheu- 
matologist and a rheumatology nurse in a focused dialogue to involve 

methods: We conducted a qualitative study based on four semi-structured focus group interviews among patients with established inflammatory joint disease (Psoriasis arthritis (PsA)) participating in the Open Access set-up. The analysis of the transcribed interviews was based on content analysis. A patient research partner was involved in all phases of the study.

results: In total 25 patients with IJD participated (20 female (80%), mean age 61.8 (range 28-79)) with RA (n=20), PsA (n=3), axSpA (n=1) and polyarthitis (n=1) participated. We identified three themes. Changes in follow-up care do not affect patients’ perceived support in disease control, referring to patient’s perception of more time available to both themselves and health professionals, as well as trust in access to profes- 
sional support whenever needed. Adequate information to act within a new patient role, reflecting patients’ uncertainty in the transition to Open Access combined with confusion about distribution of responsibilities in the new set-up. Arthritis In a broader perspective, expanding patients understanding of their illness by interaction over time with both a rheu- 
matologist and a rheumatology nurse in a focused dialogue to involve the patient in managing their own health.
CONCLUSION: Patients following Open-Access welcome the flexibility and involvement in disease control. However, patients need relevant information to be able to act adequately to the new role patient. Interacting with both rheumatologists and nurses, combined with sufficient time for dialogue, broadens patients’ perspective, makes opportunities for action visible, and contribute to patient’s ability to participate in the managing of their own condition.

THUU0708-HPR CORRELATIONS BETWEEN FATIGUE AND PATIENT REPORTED OUTCOME IN PEOPLE WITH INFLAMMATORY ARTHRITIS
Bente Appel Esbensen1, Sandra Elkjær Stallknecht2, Maria Madsen2, Lise Hagelund3, Trine Pilgaard3, 1Copenhagen Centre for Arthritis Research, Centre for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, Rigshospitalet, Glostrup, Denmark, 2Incentive, Holte, Denmark, 3Pfizer, Ballerup, Denmark

Background: Fatigue is one of the most common symptoms of people with inflammatory arthritis (IA) and often rated as high as or higher than pain. However, it remains unexplored how fatigue is associated with patient related outcomes (PROs) such as work impairment, as quality of life, sleep, depression, physical functioning and pain.

Objectives: To explore fatigue and to analyze possible correlations between fatigue and PROs in people with rheumatoid arthritis (RA), psoriatic arthritis (PsaA) and axial spondyloarthritis (axSpA).

Methods: A cross-sectional study. People ≥18 years with a confirmed diagnosis of RA, PsA or axSpA were consecutively recruited for the study over a 6-month period via routine visits to outpatient rheumatology clinics in two hospitals departments. Trained study nurses collected information on informed consent, diagnosis, medical treatment and disease activity status. Fatigue was evaluated by a self-completed questionnaire using the FACTIT-Fatigue sub-scale. The questionnaire also included the following PRO scales: Work Productivity and Activity Impairment scale (WPAI), EuroQol (EQ-5D), Medical Outcomes Study Sleep Scale (MOS), Major Depression Inventory (MDI), and Health Assessment Questionnaire (HAQ) on quality of life and pain. Data was analyzed in SAS. Correlations were assessed by a) Pearson correlation coefficients and b) raw and adjusted linear regressions.

Results: In total 633 persons were invited and 487 (77%) (mean age=53.5, SD 14.5) were included (62% women). The mean fatigue score (range 0-52; lower = more fatigued) was 34.3 (SD 11.1) and there was no statistically significant difference between mean fatigue in the three diagnostic groups (p=0.08). Altogether 61% expressed that they were suffering from fatigue (i.e. had a FACIT-Fatigue sub-scale <39). Women generally had a lower overall fatigue score (mean=33.3, SD 11.1) than men (mean=36.0, SD 11.0). Fatigue did not differ between age groups (p=0.33). Those who had changed medical treatment within 0-12 months (21.1%) suffered more from fatigue than those with unchanged treatment (mean=30.1, SD 11.7 vs. mean=35.4, SD 10.7, p<0.0001). The average disease activity as indicated by DAS28, BASDAI and BASFI showed low disease activity in the cohort. Current medical treatment (csDMARDs and/or bDMARDs or none) was not associated with severity of fatigue (p=0.85). Fatigue correlated with all PROs (Pearson correlation coefficients, all p-values <0.0001) (Table 1). Increased work impairment, sleep problems, depression and pain were all associated with increased fatigue, whereas decreased quality of life and physical functioning were associated with increased fatigue (raw and adjusted linear regressions). The associations did not change significantly after additional adjustment for socioeconomic factors. Analyses stratified on type of disease did not differ significantly from the primary non-stratified analysis.

Conclusion: Despite the study cohort represents a stable group with low disease activity, fatigue was a frequently expressed symptom across diagnoses. There was a significant correlation between fatigue and the other PROs why fatigue cannot be seen as a single problem, but rather a symptom that broadly affects people living with inflammatory arthritis.

THUU0709-HPR PERSONS WITH POLYMYSITIS AND DERMATOMYSITIS EXPERIENCE REDUCED WORK ABILITY AND QUALITY OF LIFE
Karin Åström1, Malin Regardt1,2, 1Karolinska University Hospital, Function area Occupational Therapy and Physiotherapy, Stockholm, Sweden, 2Karolinska Institute, LIME, Stockholm, Sweden

Background: A recent study have described that persons with Polymyositis (PM) and Dermatomyositis (DM) experience reduced work ability (1). Information about whether the reduced work ability affect quality of life is lacking.

Objectives: To describe self-rated work ability with two different assessment and quality of life in persons with PM and DM. To investigate correlations between self-rated work ability and quality of life

Methods: Participants were identified through the Swedish Myositis Network registry (SweMyoNet). Of 78 possible participants, 48 agreed to participate in this study. The median (IQR) age were 57 (45-61) years with a median disease duration of 6 (2-14) years. Fifty-three percent of the participants were women. Seventy-seven percent were working, and the remaining were on sick-leave.

Self-rated work ability was measured by the questionnaire Work Ability Index (WAI) and the Work Ability Score (WAS) which is a single item question. Quality of life by the SF-36.

Results: Self-rated work ability measured by WAI in persons with PM and DM varied between poor work ability and good work ability. The median value of the group was 34 which indicates less good work ability.

Self-rated work ability measured by WAS varied between poor work ability and good work ability. The median of the total group indicates less good work ability.

There was a strong correlation between self-rated work ability measured by WAI and WAS (rs 0.879 p<0.01).

Quality of life measured by SF-36 were rated lower in persons with PM and DM when compared to the general population in dimensions; Physical Function, Role-Physical, General Health, Vitality and Social function (p<0.02).

There were moderate to high correlations between self-rated work ability measured by both WAI and WAS, and all dimensions of SF-36 (p<0.01)

Conclusion: Persons with PM and DM self-rated their work ability as poor and the quality of life were significantly reduced when compared to the general population. The measures WAI and WAS correlates highly with each other and revealed comparable results indicating that WAS may work as well as WAI as a screening tool to identify reduced work ability. The WAS may also be more feasible with just one single question to use in clinical practice. Our results indicate the importance to measure self-rated work ability in persons with PM and DM in clinical practice.
BACKGROUND: Spondyloarthritis (SA) is a chronic inflammatory disease that could significantly affect the patient’s quality of life and alter the social activities and relationship.

OBJECTIVES: Here, we aimed to investigate the impact of spondyloarthritis on quality of the social and family life in Tunisian patients.

METHODS: This is a cross sectional study including patients with SA (ASAS criteria). A survey comprising questions about family and social relations and the impact of flare on it, were applied between November 2018 and January 2019. Demographic data, marital status, the disease activity (BASDAI and ASDAS) and the function index (BASFI) were obtained. For statistical analysis, we used Kruskal-Wallis test for qualitative variables and Student-test for quantitative variables. A p value ≤0.05 was considered significant.

RESULTS: We included forty patients. The average age was 41 years-old (±12.9) and the sex ratio was 12.3. 60% of patients were married. The SA was axial in 25%, peripheral in 20% and both in 55%, 17.5% had psoriatic arthritis, 55% had ankylosing spondylitis and 27.5% had inflammatory bowel disease spondyloarthritis. coxitis was found in 47.4% of patients. Most patients had a moderate activity (29.4%) and the mean activity scores were (BASDAI =2.75±2.3, ASDAScrp=2.24±1.07), and the mean function index (BASFI) was 2.57±2.5. 57.5% of patients were on biologics (25% Adalimumab, 22.5% infliximab, 10% Etanercept).

67.5% of patients declared having difficulty in accepting their illnesses. Social relationship were deteriorated after the diagnosis of SA in: 27.5% with partners and 20% family members, 15% with friends and 20% with colleagues in work. Moreover, SA reduced the frequency of social activities like sport in 62.5%, traveling in 62.5%, cultural activities in 77.5% and professional practices in 37.5%.

The impact of flares was also evaluated, the patients declared having difficulties in: crossing the street (57.5%), corporal hygiene (30%), sleeping (70%), private life (32.5%) and doing daily tasks (77.5%) and professional activity (81.8%).

No significant relationship was found between social relationship and activities regarding biologic treatment (p=0.74, p=0.68). However presence of coxitis was significantly associated with a lack of friends (p=0.05), and a bad impact in the professional activities (absenteeism and drop job performance) (p=0.05) and the self-esteem (p=0.06).

Conclusion: Our results suggest that family and social relations are deteriorated in Tunisian SA patients due to their illness. Moreover, coxitis has substantial impact on the self-esteem and the social life.

In the intragroup analyses, comparing pre and post-HSCT scores, there was general improvement in both disease groups, especially in G2. The intergroup comparisons indicate that before HSCT patients in G1 had better FP than those in G2 (p = 0.03). The other aspects were not significantly different between groups. After HSCT, patients in G2 had a better QoL scores in P (p = 0.0338), GHP (p = 0.0001) and MH (p = 0.0049).

Conclusion: These results may be interpreted as positive outcomes of HSCT for MS and SSc. However, our data indicate that HSCT may benefit patients with MS (G2) more than those with SSc (G1).

LINKING THE PATIENT EXPERIENCE OF FOOT INVOLVEMENT RELATED TO PSORIATIC ARTHRITIS TO THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH

Kate Carter,1 Caterina Tannous,2 Steven Walmsey,2 Keith Rome,3 Deborah E. Tumer1.1 Western Sydney University, Podiatry, School of Science and Health, Sydney, Australia; 2Western Sydney University, Occupational Therapy, School of Science and Health, Sydney, Australia; 3Auckland University of Technology, Health and Rehabilitation Research Institute, Auckland, New Zealand

Background: Previous research has shown merit in linking domains of impact in psoriatic arthritis (PsA) to the International Classification of Functioning, Disability and Health (ICF) to categorise the effect of global disease [1, 2]. Localised disease predominance and persistence in the foot in PsA is well recognised [3], but limited foot-specific research exists and there are no outcome measures to comprehensively assess foot involvement and its impact in PsA. To date little is known about the patient experience of foot involvement and how this may link to the ICF to capture disease impact.

Objectives: To categorise the patient experience of PsA-related foot problems by linking it to the ICF.

Methods: Participants were recruited from rheumatology outpatient clinics in Sydney, Australia and Auckland, New Zealand. People with PsA were interviewed about their foot problems and the impact they have on daily living until qualitative data saturation. Three multi-disciplinary focus groups were undertaken with clinicians to explore their understanding of the patient experience. All interviews were audio-recorded and transcribed. Codes, representing concepts obtained from the interviews, were linked to the most appropriate ICF category according to established linking rules. All codes were independently linked to the ICF by 2 investigators and a third investigator for adjudication. Investigator professional backgrounds included occupational therapy and podiatry.

Results: Twenty-one people with PsA-related foot problems and 17 experienced clinicians participated. Over 100 distinct ICF categories were linked to the interview and focus group codes. The most represented ICF category was environmental factors (33%) followed by body functions (26%), activities and participation (25%) and body structure (16%). Environmental factors relevant to patients were shoes and assistive devices, healthcare access and climate. Clinicians identified a greater proportion of body functions and fewer activity and participation categories compared with patients, indicating a possible mismatch of key concerns. Concepts that could not be precisely linked to the ICF were related to coping, aspects of time and knowledge, consistent with previous work. Difficulties in linking highly specific information to categories such as sensations of pain, sensations of skin and emotional functions revealed a limitation in the ICF’s ability to discriminate between various effects of the disease, a shortfall previously noted. Toenail changes were frequently cited by patients and linked to domains of body image and social relationships. Interdisciplinary group analysis demonstrated merit as differences between the predominantly medical approach by podiatry and psychosocial approach by occupational therapist in clinical practice led to additional ICF categories being identified between clinicians, which mostly related to cognitive functions.

Conclusion: Despite the localised anatomical focus of this study, the effect of foot problems in PsA was linked to all components of the ICF, confirming the profound impact on functioning and daily life. Difficulties with linking psychological concepts reflect deficiencies in the ICF and is a major limitation in defining foot disease burden. These findings offer new knowledge using patient and clinician perspectives that could inform the development of an instrument to measure the impact of foot involvement in PsA.

RELATIONSHIP BETWEEN TRUNK POSITION SENSE, TRUNK MUSCLE ENDURANCE AND BALANCE IN WOMEN WITH FIBROMYALGIA SYNDROME

Özge Çoban1, Seyda Toprak Celenay1, Ögužhan Mete1, Deran Oskay2. 1Ankara Yıldırım Beyazıt University, Ankara, Turkey; 2Gazi University, Ankara, Turkey

Background: Position sense plays a fundamental role in human movement which is crucial for daily activities, exercise and sports [1]. Trunk endurance and balance were also integrated part of normal functional movements. Decreased balance and trunk muscle endurance were reported in women with fibromyalgia syndrome (FMS) [2]. However, to our knowledge, the relationship between trunk position sense, trunk muscle endurance and balance has not been studied in women with FMS.

Objectives: This study aimed to determine the relationship between trunk position sense, trunk muscle endurance and balance in women with FMS.

Methods: Women with FMS (n: 25, age: 42.88±11,66 years, body mass index: 25.69±3.48 kg/m²) were recruited. Trunk position sense was assessed with digital inclinometer by trunk reposition errors in which higher scores indicate poor trunk position sense [3]. Trunk flexor, extensor, dorso-lateral and non-dominant lateral side muscle endurance (r=0.61, p=0.001; r=0.49, p=0.011; r=0.48, p=0.014; r=0.048, p=0.014, respectively) were measured. Spearman’s rank correlation test was used for analysis.

Results: There were significant negative correlations between trunk position sense and trunk flexor, extensor, dominant and non-dominant lateral side muscle endurance (r=0.61, p=0.001; r=0.49, p=0.011; r=0.48, p=0.014; r=0.048, p=0.014, respectively). There were also high significant negative correlations between trunk position sense and Mini BEStest score (r=0.73, p=0.001).

Disclosure of Interests: None declared

Conclusion: It was found that there were moderate to high correlations between trunk position sense, trunk muscle endurance and balance. Therefore, addition of trunk position sense training to the rehabilitation programs might be effective in improving trunk muscle endurance and balance in women with FMS.

THU0715-HPR ASSESSMENT OF SELF-CARE AGENCY AND ITS ASSOCIATION WITH SYMPTOMS AND QUALITY OF LIFE IN INDIVIDUALS WITH FIBROMYALGIA: A CROSS-SECTIONAL STUDY

Leticia Couto, Susan Yuan, Amelia Pasquale Marques. University of São Paulo, São Paulo, Brazil

Background: Fibromyalgia is a condition of high prevalence, which causes physical discomfort, mental distress and impairment of social relations. Self-care may be a relevant factor to improve the quality of life in individuals with fibromyalgia, since it is related to the act of empower- ment, leading individuals to have dominion over their own life.

Objectives: To assess self-care agency of individuals with fibromyalgia and verify its association with symptoms, quality of life and sociodemo- graphic variables.

Methods: The study included 40 women, aged between 19 and 59 years, with fibromyalgia according to the 2010 American College of Rheumatol- ogy diagnostic criteria, and elementary education. This study was approved by the Research Ethics Committee of the School of Medicine of the University of São Paulo. Informed consent was obtained from all study participants. Sociodemographic and clinical data (age, clinical status, educational level, social status and disease duration) were collected. Self- care was measured with the Appraisal Self-Care Agency Scale-Revised, pain with the Visual Analog Scale (VAS) and the Widespread Pain Index (WPI), severity of symptoms with the Symptom Severity (SS) Scale, and quality of life with the Revised Fibromyalgia Impact Questionnaire (FIQ). In data analysis, Pearson correlation coefficient was used for parametric data, and the Spearman correlation coefficient was used for non-paramet- ric data. The level of significance adopted was 5%.

Results: Moderate values were found for self-care agency (52.75 ± 10.25), VAS pain (5.84 ± 2.16), WPI (13.32 ± 3.78) and SS (9.30 ± 1.68). Severe impact on quality of life was found with the FIQ (63.98 ± 17.26). Additionally, significant correlations of self-care agency with the status of presence (r=0.391), function (r=0.338), overall impact (r=0.315), symptoms domains (r=-0.332) and total score (r=0.375) of the FIQ were observed.

Conclusion: The study suggests that individuals with fibromyalgia have a moderate level of self-care agency, and there is a weak association of self-care with quality of life and social status.

THU0717-HPR OVERVIEW OF THE MOST EFFECTIVE PHYSIOTHERAPY MANAGEMENT METHODS IN PEDIATRIC RHEUMATOLOGY

Emmanoula Ioannou, European University Cyprus, School of Sciences, Egkomi, Nicosia, Cyprus

Background: The majority of patients with pediatric rheumatologic conditions present with joint pain, morning stiffness and a high degree of fatigue which in turn affect their functional status, psychological wellbeing and activities of daily living (ADLs). Juvenile idiopathic arthritis - with a prevalence of 0.1-0.2/100 children - is the most common chronic pediatric rheumatic disease. When compared to healthy children, patients with juvenile idiopathic arthritis show decreased physical fitness, which necessitates systematic physiotherapy management.

Objectives: The current research was carried out to investigate the most reported physiotherapy methods for the management of common pediatric rheumatologic conditions.

Methods: PubMed and Google scholar databases were searched. Keywords were categorized into three groups. The first group included the most common pediatric rheumatologic conditions (juvenile chronic arthritis, juvenile spondyloarthropathy, juvenile psoriatic arthritis, dermatomyositis, systemic lupus erythematosus, vasculitis, scleroderma); the second group included physiotherapy management methods (physiotherapy, physical therapy, hydrotherapy, aquatic therapy); and the third group included outcomes (pain, pediatric pain, range of movement, quality of life, activities of daily living). Only primary research studies regarding patients with the aforementioned pediatric rheumatologic conditions were included.

Results: Notable variability was observed between studies as regards to applied methods and recorded outcomes. Additionally, results were not separately reported for the different diseases. Nevertheless, findings indicate that physiotherapy and hydrotherapy rehabilitation methods, focusing on reducing joint pain, joint protection, conservation of energy, and conservation of joint range of motion, achieved the treatment goals of representatives. The involvement of patients is structured thanks to the creation of the European Patient Advocacy Groups (ePAG). 3 ePAGs representing each disease pillar are members of the steering committee. The Ehlers-Danlos Syndromes (EDS) are represented in the ERN ReCoNNET with the exception of vascular EDS represented in the VASCERN.

Objectives: To raise awareness on the unmet needs related to EDS in the EU through attracting and engaging more experts, specialists and HCPs in order to address those needs.

Methods: At present, the EDS is represented by 2 HCPs and 2 official ePAGs, senior and junior disease coordinators have been identified both among HCPs and ePAGs, in particular the EDS ePAGs intensively sought for unmet needs of EDS into their wider European Community. All needs identified by ePAGs were discussed with the senior and junior coordinators and their contribution was added in a dedicated paragraph of the article, acknowledging them as co-authors. Among other activities, a state of the art on clinical practice guidelines (CPGs) has been performed also for EDS1, in which patients and clinicians highlighted the most important unmet needs.

Results: As the new 2017 International EDS nosology2 was only published in March 2017, EDS still lack Clinical Practice Guidelines and recommendations. The main EDS unmet needs identified concern the need to develop data on prevalence and clinical features, the identification of reliable biomarkers and the implementation of advanced instrumental imaging techniques. The management of pain, fatigue and psychological support have also been identified as a major topic to be addressed. More efforts should be put also on the education of healthcare professionals in order to provide faster diagnosis and better care to EDS patients. A stronger representation of EDS centres of expertise in the ERNs is needed, especially considering the crucial added value represented by the possibility of discussing clinical cases in the Clinical Patient Management System provided by the European Commission.

Conclusion: The ERN offers a real opportunity to develop better standards of care taking into account patients unmet needs. It is critical to increase EDS awareness and to attract HCPs for the follow-up and care of patients to be able to meet the unmet needs of the EDS patient population and healthcare professionals.

THU0717-HPR CLINICIANS’ AND PATIENTS’ UNMET NEEDS IN EHLERS DANLOS SYNDROMES, THE EXPERIENCE OF ERN RECONNECT

Charissa Hermine Frank1, Jürgen Grunert2, Birnweesel.be, Koersel, Belgium

1Deutsche Ehlers-Danlos Initiative e.V., Farth, Germany

Background: The European Reference Network for rare and complex connective tissue and musculoskeletal diseases (ERN ReCoNNET) is a European network of 26 healthcare providers (HCPs), that aims at developing a comprehensive and harmonized approach to 10 rare and complex connective and musculoskeletal diseases (rCTDs). The network gathers the community of health care professionals and patients...
The Patient Activation Measure (PAM): What Do Factors Associated with Pain Catastrophizing Mean to Patients with Rheumatic Conditions?

**Objectives:** To gather participants' perceptions of the suitability and acceptability of the Patient Activation Measure (PAM), particularly within a rheumatology context.

**Methods:** To identify factors associated with pain catastrophizing to detect possible susceptible targets in individuals with systemic lupus erythematosus.

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with a wide spectrum of clinical manifestations such as organ damage, pain, fatigue, sleep disorders, depression and cognitive deficits. It is known that pain catastrophising may have serious impact in individuals with SLE. Furthermore, catastrophising and maladaptive coping strategies are linked to higher levels of functional impairment and depression in SLE.

**Objectives:** The aim of this study was to identify factors associated with pain catastrophizing to detect possible susceptible targets in individuals with systemic lupus erythematosus.

**Methods:** A total of 104 individuals (mean age: 55.54±12.09 years; BMI: 27.17±4.01 kg/m²) with SLE participated to the study. The Pain Catastrophising Scale (PCS) was used to measure the extent to which people catastrophize in response to pain. The Tampa Scale for Kinesiophobia (TSK) was used to assess pain-related fear of movement. The Beck’s Depression Inventory (BDI) was used to measure characteristic attributes and symptoms of depression. The Body Awareness Rating Questionnaire (BARQ) was also used to rate their self-reported body awareness. The multiple stepwise linear regression models with R-square (R²) were used to compare across the models and explain the total variance.

**Results:** Mean PCS was 22.12±12.09; mean TSK was 49.94±7.76; mean BDI was 15.63±11.18 and mean BARS was 89.4±19.85. Linear regression analysis revealed that TSK, BDI, BARS and BMI were independently associated with PCS in predicting pain catastrophising in individuals with SLE (p<0.001; R²=0.52). There were no correlations between PCS and disease activity (mean SLAM-R: R=0.38; p<0.015) and organ damage (mean SLICC-DI: R=0.58; p<0.015) (p<0.05).

**Conclusion:** This study increases the understanding of the modifiable predictors to enhance pain coping behavior in accordance with the pharmacological treatment in SLE population. Results demonstrate major importance to explore the main stressors of pain catastrophising such as kinesiophobia, depression level, body awareness and BMI that affect coping behavior. Thus, pain catastrophising may limit the patients’ ability to perform from simple to complex activities. In addition, body image concerns SLE patients as they experience weight gain which negatively impact their self-esteem. The patient reported outcomes could guide health professionals to identify unmet needs of patients at risk to facilitate incorporation of the biopsychosocial model into SLE management.

**WOMEN’S EXPERIENCE OF THE JOURNEY TO CHRONIC WIDESPREAD PAIN – A QUALITATIVE STUDY**

Minam Svensson¹, Ingrid Larsson², Katarina Aili¹,²,²,

1Halmstad University, School of Health and Welfare, Halmstad, Sweden; ²RandD Spenshult, Halmstad, Sweden; ³Karolinska Institutet, Unit of occupational medicine, Institute of Environmental Medicine, Stockholm, Sweden

**Background:** Chronic widespread pain (CWP) is a major burden to both the person and the community. Non-tumor chronic pain is one of the most common causes for long-term sickness absence in Sweden. The prevalence of CWP in the general population is approximately 10%, and the condition is almost twice as prevalent in women, than in men. Increased understanding of how women with CWP describe triggering factors of pain and pain progress would be of importance when preventing poor pain prognosis, and when customizing the treatment strategy in a setting with person-centered care.

**Objectives:** To explore experiences of factors influencing the progress and severity of pain among women who have developed CWP within the last 21 years.

**Methods:** This is a descriptive study, using a qualitative content analysis with an abductive approach. Nineteen women reporting CWP in a survey 2016, between 45-67 (median 57) years of age, who had not reported CWP in a survey 1995, participated in the study. Data were collected through individual interviews with open-ended questions: “Can you describe how your CWP has developed the last 20 years?”, “How did your CWP change over time?” and “Have you experienced any important events that have influenced the development of your CWP?” Data were analyzed through a manifest qualitative content analysis and six categories emerged.

**Results:** The women described their journey to CWP in terms of triggering, aggravating and consolidating factors. Six different categories emerged; physical strain, emotional strain, social strain, work-related strain, biological strain and environmental strain. Physical strain included strenuous physical activities in leisure time, having muscle tension, inactivity or sleeping problems. Emotional strain included being depressed, worried and stressed, as well as neglecting the pain. Social strain included to prioritize other people before oneself and to meet distrust from the social surroundings. Work-related strain included heavy, monotonous and stressful work but also sedentary work. Biological strain referred to heredity, age and infections. Environmental strain meant that the climate or weather aggravated the pain.

**Conclusion:** The women in the study described how their journey to CWP was influenced by both external and internal strains. The six categories representing different types of strains were recurrent in a context describing triggering, aggravating and consolidating factors. This highlights the complexity of individual pain progress and argues for the importance of person-centred care approaches and rehabilitation programs. The fact that women with CWP feel mistrust from healthcare professionals indicates that the current care approach needs to be changed.

**DESIGNING A DIET INTERVENTIONAL STUDY FOR AUTOIMMUNE RHEUMATIC DISEASE: ASKING PATIENTS WHAT THEY THINK**

Lucia Martin-Gutierrez¹,², Coziana Curtin³, Elizabeth Jury³,¹, UNIVERSITY COLLEGE OF LONDON, Rheumatology, LONDON, United Kingdom; ²UNIVERSITY COLLEGE OF LONDON, Arthritis Research United Kingdom Centre for Adolescent Rheumatology at UCLH, UCL and Great Ormond Street Institute of Child Health, LONDON, United Kingdom; ³UNIVERSITY COLLEGE OF LONDON, Rheumatology at UCLH, UCL and Great Ormond Street Institute of Child Health, LONDON, United Kingdom.

**Background:** Despite recent progress investigating the pathogenesis of Sjögren’s syndrome (SS), there are currently no therapies able to influence disease progression. Patients with SS are usually treated symptomatically with variable success, therefore refining the research agenda according to patients’ priorities could provide a valuable insight into the most appropriate research questions.

**Objectives:** The aim of this study was to explore patients’ ideas and suggestions related to research in SS.

**Methods:** A questionnaire to investigate SS patient experience of diagnosis and ideas about research priorities in SS was designed. Over a 5 month period, patients attending outpatient clinics were invited to fill in the questionnaire. 27 patients completed our anonymous survey.

**Results:** The most important issue for patients with SS after they had been diagnosed was the lack of knowledge about this disease (25%), the diagnosis delay they had experienced (26%) and the persistence of symptoms of dryness (26%). Patients were interested in finding out what causes this disease (81%) and felt that our research should find a cure (92%) and better treatments (75%). The main two research priorities selected by patients were improved understanding of the disease (89%) and attracting funding for supporting research in to SS (89%). In addition, patients wanted to have a voice

**Disclosure of Interests:** None declared

and contribute to raising awareness of SS and to participate in patient and public involvement and engagement (PPIE) events. The majority of patients interviewed were willing to take part in research by donating blood samples and/or filling in questionnaires (96%). 58% of patients who completed the survey would either definitely or probably take part in discussion groups helping researchers to design future studies in SS.

Conclusion: This survey highlighted patients’ perception of the need for more meaningful research into the causes of SS, as their priorities were centred around finding a cure or better treatments for Sjögren’s Syndrome. The survey also identified patients’ lack of knowledge about their condition as well as their desire to help with shaping future research ideas and support funding for research. The results of this survey will be incorporated in our future PPIE events aiming at shaping our research strategy in SS.

THU0724-HPR RELIABILITY AND VALIDITY OF AN ACTIVITY LIMITATION MEASURE IN PERSONS WITH INCLUSION BODY MYOSITIS (IBM)

Malin Regardt1,2,1Karolinska Institutet, LIME, Stockholm, Sweden; 2Karolinska University Hospital, Function area Occupational Therapy and Physiotherapy, Stockholm, Sweden

Background: Persons with Inclusion Body Myositis (IBM) are affected in all areas of life.

Objectives: The aim of this study was to test validity and reliability of the questionnaire Disability in the Arm Shoulder and Hand (DASH) for patients with IBM. A second aim was to describe activity limitation measured by the Canadian occupational Performance measure (COPM).

Methods: Persons diagnosed with IBM were identified through the Swedish Myositis Network (SwedMyoNet) quality registry in Stockholm Sweden. A total of 36 persons with IBM were included in the registry and were invited to participate. A total of 17 men and 9 women agreed to participate. Median (Q1-Q3) age was 74 (70-79) years and the median (Q1-Q3) disease duration was 7 (3-8) years.

Activity limitation were assessed by the questionnaire Disability in the Arm Shoulder and Hand (DASH) and the The Canadian occupational performance measure (COPM) which investigate patient derived areas of daily activities.

The data collection was performed at the Karolinska university hospital in Stockholm Sweden. At baseline both DASH and COPM were performed. The participants received a second DASH questionnaire to be answered within two weeks (Follow-up) and send back to the researcher.

Results: There were good correlations between baseline measure and follow-up on DASH (rs 0.997; p<0.01) indicating that the DASH is consistent over a short period of time.

The results from COPM showed a variety of activities persons with IBM experienced problem with. Area with most activity limitations were basic self-care area such as dressing and grooming, fall, feeding, managing communication.

Instrumental activities such as managing instruments, shopping and meal preparation. Leisure activities such as playing an instrument, run, paint and social activities such as visit friends, social engagements. Some of these activities were found in the DASH but not all. E.g. missing socializing with friends and family, problems swallowing or were environment dependent.

Conclusion: The results indicate that DASH have a good test re-test reliability DASH includes some of the activities that persons with IBM experience difficulties with but not all. The participants experienced difficulties in all areas of life.

THU0725-HPR SCREENING OF SILENT MYOCARDIAL ISCHEMIA USING A STRESS TEST IN RHEUMATOID ARTHRITIS PATIENTS: ASSOCIATION WITH TRADITIONAL RISK FACTORS AND DISEASE ACTIVITY

Rawohta Tekaya1, Leila rouached2, Habib Ben Ahmed3, Aicha Ben Tekaya4, Otf Saidane1, Ines Mahmoud1, Leila Abdelmoula1,1 charlie nicole hospital, rheumatology, tunis, Tunisia; 2charlie nicole hospital, cardiology, tunis, Tunisia

Background: The rheumatoid arthritis is responsible of an increased risk of cardiovascular (CV) morbidity and mortality.

Objectives: The aim of the study is to determine, in established RA patients, the presence of silent myocardial ischemia using a stress test and its association with the disease activity and the CV risk factors and scores.

Methods: It is a transversal and prospective study in a rheumatologic center in Charles Nicolle hospital in Tunisia. 103 RA patients, asymptomatic for CV disease were submitted to a stress test. Demographic data, cardiovascular risk factors and the disease characteristics were assessed for all patients and risk factors of silent myocardial ischemia in RA patients were identified.

The comparison of qualitative variables was performed with the Chi square test and the comparison of qualitative variable and quantitative ones was performed with the Student’s test. The significance level was set at 0.05.

Results: There were 103 patients (sex-ratio=0.3) with a mean age of 53 ±10 years. The evaluation of the disease activity showed that the mean DAS28 CRP, CDAI and SDAI were 3.9±1.38; 17.1±7±11.4 and 33.9±26.5 respectively. A screening for CV risk factors revealed: 13% of patients had a cardiovascular inheritance, 25% of patients were either smokers or hypertensives, 18% had diabetes, 70% were obese or overweighted and 14 patients had dyslipidemia. The ischemic ratio (CT/HDL) revealed that 42% of patients had a moderate to high myocardial ischemic risk. Heart SCORE was high in 39% of cases. A silent myocardial ischemia in the stress test was found in 11 patients (10.6%) and was associated with male sex (p=0.03), advanced age (p=0.04), erosive character (p=0.05), the advanced age of the rheumatoid arthritis diagnosis (p=0.01) and the ischemic ratio (p=0.06). No relationship was found with the majority of traditional CV factors nor with disease activity variables.

Conclusion: Our results corroborated the hypothesis that the stress test could reveal subclinical CV dysfunction, supported the utility of the Heart score as a screening tool, and put in perspective the potential usefulness of complementary approaches in CV risk assessment in RA patients.

Disclosure of Interests: None declared

THU0726-HPR THE COMPARISON OF ARTERIAL STIFFNESS, FUNCTIONAL EXERCISE CAPACITY AND PHYSICAL ACTIVITY IN SYSTEMIC SCLEROSIS AND HEALTHY INDIVIDUALS

Aylin Tanriverdi1, Buse Ozcan Kahraman2, Serap Acar3, Nazenin Hande Sezgin1, Semra Savci4, Aydan Koken Avsar5, Ebru Ozpetek1, Ahmet Merih Birlik6, Dokuz Eylul University, Division of Rheumatology, Department of Internal Medicine, Izmir, Turkey; 1Dokuz Eylul University, Graduate School of Health Sciences, Izmir, Turkey; 2Dokuz Eylul University, School of Physical Therapy and Rehabilitation, Izmir, Turkey; 3Dokuz Eylul University, Division of Rheumatology, Department of Internal Medicine, Izmir, Turkey; 4Dokuz Eylul University, Department of Cardiology, Izmir, Turkey

Background: Systemic sclerosis (SSc) is characterized by abnormal production of fibrotic tissue in the skin and internal organs. SSc has a effect on large and conduit arteries damage as well as microvascular damage (1). It is known that sedentary lifestyle may contribute to vascular dysfunction (2). Therefore, it is important to evaluate arterial stiffness, exercise capacity and physical activity in people with SSc.

Objectives: The aim of this study is to compare arterial stiffness, functional exercise capacity and physical activity in SSc and healthy individuals.

Methods: Fifteen SSc (53 years) and 15 healthy (48 years) women were included in this study. Arterial stiffness was evaluated with pulse wave velocity that was obtained by measuring the carotid-to-radial pulse wave transit time. Functional exercise capacity was assessed by 6-minute walk test (6MWT). Physical activity was questioned International Physical Activity Questionnaire (IPAQ)-short form. The differences between the groups were analyzed with Mann-Whitney U test.

Results: Age, weight, height and body mass index were similar in the groups (p>0.05). There was significant difference in pulse wave velocity and pulse wave transit time between the two groups (p<0.05). The
The aim of this study was to investigate the factors affecting handwriting speed in patients with chronic disease (2).

42 patients (aged 6-18 years) who have an affected wrist joint with oligoarticular JIA were included in this study. Muscular strength was estimated at maximal isometric force for the muscles of the upper extremities by using a portable handheld dynamometer. Grip and pinch strengths were evaluated by a dynamometer. Handwriting speed was evaluated with a sentence writing duration of 24 letters. All tests were performed thrice and the mean values of all were recorded. The correlation between all parameters was analyzed by the Pearson Correlation Test. Also, relations between the factors affecting handwriting speed in JIA were assessed by multiple linear regression analysis.

Results: The mean age was 12.71±3.35 and the mean disease duration was 6.52±3.81 years. The mean of handwriting speed was 20.53±10.39 seconds. Significant relationships were found between handwriting speed and muscular strengths of shoulder and elbow (p<0.05). Also, significant relationships were found between handwriting speed and lateral (r=-0.352, p=0.022), tip (r=-0.309, p=0.047) and triple (r=-0.375, p=0.015) pinch strengths. According to linear regression analysis, handwriting speed was affected by only muscle strength of elbow pronation (r=0.515, p=0.037).

Conclusion: Handwriting is a complex functional activity simultaneously involving motor skills, cognitive and visual perceptual processing in all chronic disease. In the current study, it was found that handwriting speed was related with shoulder and elbow muscle strengths and pinch strengths in patients with JIA. Although patients with JIA had only affected wrist joint, only muscle strength of elbow pronation was the only primary predictor of handwriting speed. We suggested that handwriting speed should be considered in patients with juvenile idiopathic arthritis. So, accurate assessment of handwriting speed is essential for developing appropriate intervention programs and evaluating performance and outcomes in patients with JIA. Besides, not only affected joint, but also all upper extremity joints should be assessed multidimensionally.

THE FACTORS AFFECTING HANDWRITING SPEED IN PATIENTS WHO HAVE AN AFFECTED WRIST JOINT WITH OLIGOARTICULAR JUVENILE IDIOPATHIC ARTHRITIS
Nilay Arman1, Eia Tarakci2, Ozgur Kasapcopur3. 1Istanbul University-Cerrahpasa, Faculty of Health Science Division of Physiotherapy and Rehabilitation, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Faculty of Health Science Division of Physiotherapy and Rehabilitation, Department of Neurological Physiotherapy and Rehabilitation, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey

Background: Juvenile idiopathic arthritis (JIA) encompasses a complex group of disorders with arthritis. Patients with JIA may experience significantly decreased life skill owing to muscular weakness, joint pain, contracture, and reduced mobility (1). Poor handwriting speed is an example of an affected life skill that has been observed by educators and clinicians for patients with chronic disease (2).

Objectives: The aim of this study was to investigate the factors affecting handwriting speed in patients who have an affected wrist joint with oligoarticular JIA.

Methods: 42 patients (aged 6-18 years) who have an affected wrist joint with oligoarticular JIA were included in this study. Muscular strength was estimated at maximal isometric force for the muscles of the upper extremities by using a portable handheld dynamometer. Grip and pinch strengths were evaluated by a dynamometer. Handwriting speed was evaluated with a sentence writing duration of 24 letters. All tests were performed thrice and the mean values of all were recorded. The correlation between all parameters was analyzed by the Pearson Correlation Test. Also, relations between the factors affecting handwriting speed in JIA were assessed by multiple linear regression analysis.

Results: The mean age was 12.71±3.35 and the mean disease duration was 6.52±3.81 years. The mean of handwriting speed was 20.53±10.39 seconds. FOLLOW-UP CARE AND SELF-MANAGEMENT ACTIVITIES AFTER SPECIALIZED REHABILITATION FOR PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES
Helene Lindveld Valaas, Mari Klokkerud, Ingvild Kjeken. National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway

Background: Patients with rheumatic and musculoskeletal diseases (RMDs) benefit from rehabilitation in specialized care, but the effect seems to decline over time. Implementation of healthy self-management strategies and support over an extended period may prolong the effect. Rehabilitation trajectories with planned follow-up interventions and support in primary health care are therefore recommended. Still, evidence is not clear concerning what constitutes an optimal design of supportive follow-up interventions, and to which degree such follow-up care are planned and delivered.

Objectives: To describe current follow-up care practice and self-management after specialized rehabilitation for patients with RMDs.

Methods: This is a multicentre cohort study, including 523 participants with RMDs who received rehabilitation in specialized care in Norway. Participants completed a core set of outcome measures for rehabilitation in musculoskeletal diseases covering nine aspects of health and function in a web based data collection system [1]. At rehabilitation discharge, they additionally reported needed and planned follow-up care (FU-care) from listed professions and services in primary health care and plans for self-management activities (SMA). Received FU-care and adherence to SMA were reported at 4, 8 and 12 months follow-up. A multiple logistic regression analysis was performed to explore predictors for acceptable adherence to SMA.

Results: A total of 436 participants completed all assessments at discharge, of which 429 (98%) reported a need for FU-care. A need for FU-care by primary physician was most frequently registered, followed by physiotherapist and the Norwegian Labour and Welfare Service. However, only 239 (56%) reported that FU-care was planned at discharge. Of those reporting a need for FU-care, 201 (47%) participants reported receiving such care during the follow-up year, and these participants more often had a specific follow-up plan at discharge compared to those who did not receive the FU-care they reported needing (p=0.06).

Hundred and sixty-four (38%) participants were adhering to their SMA throughout the follow-up year. Higher age (OR=1.04, [CI 95% 1.02, 1.06], p=0.001), lower degree of depression and anxiety (OR=0.73, [CI 95% 0.58, 0.94], p=0.01), and performing physical activity on a regular basis (OR=3.35, [CI 95% 2.08, 5.39], p<0.001) at baseline were predictors for acceptable adherence. Participants with acceptable adherence reported more often a need for FU-care (p<0.001), and had more frequently received the FU-care they needed (p<0.001) than those without acceptable adherence.

Conclusion: Participants with plans were more likely to receive the FU-care they reported needing, indicating that discussing and planning follow-up should be an integral part of rehabilitation in specialized health care. The results further indicate that having structure and routines in one’s daily life enhance adherence to SMA, and that patients with anxiety and depression and a sedentary life style may need more support over a longer period to be able to implement behavioural changes for healthy self-management.

"I AM GOOD ENOUGH AS I AM EVEN IF I AM NOT PERFECT"– A QUALITATIVE STUDY OF FIBROMYALGIA PATIENTS’ EXPERIENCES FROM PARTICIPATION IN A MINDFULNESS-BASED GROUP-PROGRAMME

Heidi A. Zangi1, Gyda Singstad2, Ingrid Knutsen3. Improved management of patients with fibromyalgia: Evaluation of an integrated care model. 1 Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2 Oslo Metropolitan University, Oslo, Norway

Background: People with fibromyalgia (FM) suffer from widespread pain, non-refreshing sleep, fatigue and reduced mental wellbeing. No curative pharmacological treatment exists. Vitality Training (VTP) is a mindfulness- and acceptance-based group-programme that aims at enhancing participants’ health promoting resources, strengthening their inner authority and ability to act according to own values. It combines mindfulness with creative methods and group counselling. Two RCTs have shown significant improvements in mental wellbeing, pain coping and fatigue in patients with chronic musculoskeletal pain and inflammatory arthritis. The VTP is currently being evaluated in an ongoing study for patients with newly diagnosed FM[1].

Objectives: The aim of this qualitative study was to explore FM patients’ experiences from participating in the VTP, and if they perceived that it had any impact on their health and functioning.

Methods: Six qualitative in-depth interviews with participants from three VTP-courses were conducted following a semi-structured interview guide. Interviews were audio-recorded and transcribed. All three authors analysed the data by use of systematic text condensation.

Results: Three main themes were identified.

1. Understanding oneself in light of the group: Mutual understanding and acknowledgement had altered participants’ self-understanding – from a feeling that “something was wrong with me” towards perceiving themselves as “a normal person with similar challenges as others”.

2. Learning to accept oneself: Participants had obtained a greater understanding and acceptance for their emotions and reactions and had become kinder towards themselves. "I have realised how strict I have been towards myself... I am indeed good enough as I am even if I am not perfect”.

3. Coping with everyday challenges: Becoming aware of what had provoked stress and learn how to face it had helped participants take more control. "I can do small changes that really makes it better... the illness does not decide everything. Indeed I can decide something myself”.

Conclusion: Participation in the VTP had contributed to new ways of relating to oneself and the illness. The support and acknowledgement participants experienced from the group had helped them alter their self-understanding from only being ill towards also being healthy and normal. They had learnt ways to better cope with stress and everyday challenges. Although this was a small study, the findings correspond with findings in previous studies.

BENEFITS OF EMPOWERING THE PATIENTS TO SELF-ADMINISTER SUBCUTANEOUS LOW DOSE METHOTREXATE (LD-MTX) INJECTIONS IN PATIENTS WITH SYSTEMIC IMMUNO-INFLAMMATORY RHEUMATIC DISEASES (SIRDs): A STUDY BY RHEUMATOLOGY NURSES COUNSELLOR

Sadhana Baigel, Ravita Thakran, Christy Messi, Vlinay Yadav, Vivekanand Kashyap, Qamar Zaheer. Indian Spinal Injuries Centre, Rheumatology, New Delhi, India

Background: In recent years, early aggressive targeted treatment for SIRDs is recommended. LD-MTX is the “anchor drug” for these diseases. The administration of LD-MTX using subcutaneous route increases its therapeutic efficacy that ensures the maximum bioavailability and reduces gastrointestinal adverse effects. Therefore, it is preferred over the oral route. Increased use of subcutaneous self injection of medication has benefits for the patients and healthcare system (reduction in cost of hospitalisation, reducing dependency to the others, improving self-care and general health). drawbacks include getting trained to administer subcutaneous injection with a needle, cost of syringe and needle, and fear of needles. Empowering the patients to take self-injections could alleviate pressure on medical services by reducing hospital/clinic visits. Therefore, explaining the benefits of self administration of subcutaneous injection such as early disease control, increased drug adherence, positive attitudes towards life, decreased financial burden of administration cost, decreased dependency to the others, should be an imperative part of patient’s education.

Methods: This retrospective study included patients who were prescribed injectable LD-MTX for their treatment. Besides the demographic information (age, gender) and disease characteristics (diagnosis, duration, prior treatment), the patients were interviewed and counselled regarding the virtues to take subcutaneous LD-MTX self-injection. The technique for self-injection of LD-MTX subcutaneously was explained and demonstrated to the patients. All the information including the follow-up details, were recorded in a pre-designed form.

Results: Three hundred (n=300) consecutive patients who were advised weekly LD-MTX injections and taught the self-injection technique were enrolled in this study. On follow-up visit it was found that among them, 177 patients (59%) learned and started to administer their own subcutaneous injection of LD-MTX and they adhered to the injection schedule, in 50 (16.7%) patients the injections was being given by the attendant (who had learnt the injection technique because the patients had deformities), while the other 73 (24.3%) were not very compliant to injections due to psychological barriers towards self-injection, worried about pain and incorrect technique, adverse effects of the incorrect injections social stigma related to self-injections, and frustration or lack of acceptance of the illness.

Conclusion: By empowering the patients to self-administer LD-MTX injections subcutaneously, a majority (59%) of them successfully continued to take the medicine appropriately. This study shows the important role the nurses’ play in educating patients and helping them to overcome psychological barriers to self injection. Empowering the patients to self-administer injections would result in better long term treatment adherence, improving treatment flexibility and overall quality of life.

THE MAP OF THE RHEUMATOLOGY NURSE CLINICAL AND RESEARCH INTERVENTIONS IN THE VALENCIAN REGION (SPAIN)

Carmen Nájera Herranz1, Inés Cánovas Olmos1, Elena Grau García1, Amelia Carbonell Jordi1, Jenny de la Torre-Aboki1, Oscar Aranega Rodríguez2, Isabel Balaguer Trull1, Catalina Cano1, Carmen María Francés Amorós3, Lola Gil Gallego1, Alicia Gómez Clán1, Elizabeth Marín Martin1, V Núñez-Monje1, Nieves Martínez Alberola1,2, Nurses Working Group of the Valencian Society of Rheumatology (GE-SVR), 1Rheumatology Department, HUP La Fe, Valencia, Spain; 2Rheumatology Department, H. San Juan, Alicante, Spain; 3Rheumatology Department, HGU Alicante, Alicante, Spain; 4Rheumatology Department, H. Vilajoyosa, Alicante, Spain; 5Rheumatology Department, HGU Valencia, Valencia, Spain; 6Rheumatology Department, H Marina Baixa, Alicante, Spain; 7Pediatric Rheumatology Department, HUP La Fe, Valencia, Spain; 8Rheumatology Department, H Alocy, Alicante, Spain; 9Rheumatology Department, H Vinalopo, Alicante, Spain; 10Rheumatology Department, H Elda, Alicante, Spain; 11Rheumatology Department, HU Dr. Peset, Valencia, Spain.

Background: There is none defined competences framework for Rheumatology Nursing at the moment in Spain. This fact leads to an heterogeneous roles and interventions in each Rheumatology department which has not ever been described nor quantified.

Objectives: To describe and quantify the rheumatology Nursing interventions in the Valencian Region (Spain).

Methods: A descriptive study was performed by the completion of an online questionnaire with a list of clinical and research intervention. The questionnaire was sent to the Head of Rheumatology Department of 33 public hospitals from the Valencian Region.

Results: 32 hospitals of the Valencian Region fulfilled the questionnaire: 15 from Valencia, 13 from Alicante and 4 from Castellón. 50% of the hospitals had a Rheumatology nurse. In those hospitals, 50% had only 1 Rheumatology nurse working at the moment. The maximum Rheumatology nurses working in the same hospitals were 4; 2 hospitals used to have a Rheumatology nurse but do not have it anymore at this moment. 11 hospitals have an auxiliary nurse (3 of them without nurses and 8 with nurses). The year of incorporation of the Rheumatology nurse in the Department was quite heterogeneous, being the earlier in 1992 and the last incorporation in 2017.

The nurses worked mainly in a Rheumatology department full time (68.75%).

The 81% of the hospitals had a specific nursing agenda but only 7 hospitals had a monographic nurse-led clinic (osteoarthritis nurse-led clinic -25%, intravenous treatments nurse-led clinic -12.5% - or cardiovascular risk nurse-led clinic -6.25%)

Nurses clinical interventions are very heterogeneous covering the patient clinical management and practice nurses intervention activities. Nurses organized patient education workshops in 25% hospitals. In 11 hospitals, nurse undertook teaching activities. 56% participating in scientific workshops/congress, 44% teaching undergraduates nurses/registered nurses and 37.5% teaching other healthcare professionals.

In 11 hospitals, nurses undertook research activities. In 2 hospitals an specific research nurse was available. 56% of nurses participated in clinical trials, 50% participated in research projects and 50% participated in scientific congress. 25% of nurses lead research projects.

In 12 hospitals, nurses belong to a scientific society; in 11 hospitals, nurses participated in regional, national and/or international nurses working groups.

Conclusion: In at least 50% of the hospitals from the Valencian Region, nurse activity was registered. There are heterogeneous clinical activities performed by nurses. This fact raised the issue of the importance of having unified criteria for nurse’s intervention and competences framework comparable in each and every hospital. Teaching and research were also a common interventions mentioned. These activities are necessary for a constant recycling and updating of the nurses and will help to gain the necessary visibility for the rheumatology nurses.

“OSER ABOORDER” SURVEY ON THE CROSSOVER NEEDS OF A BETTER UNDERSTANDING OF SEXUAL HEALTH ISSUES BETWEEN PATIENTS SUFFERING FROM CHRONIC INFLAMMATORY RHEUMATISMS AND HEALTHCARE PROFESSIONALS INVOLVED IN PATIENT THERAPEUTIC EDUCATION

SAVEL Caroline1, Marie Sophie Cherillat2, Anne Marie Tronche3, Pauline Berland4, Candy Guiguet-Auclet5, Martin Soubrier6, Laurent Gerbaud7, Sandrine Malcholet8, 1Chu Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France; 2Chu Gabriel-Montpied, UTEP, Clermont-Ferrand, France; 3Chu Gabriel-Montpied, Psychiatry, Clermont-Ferrand, France; 4Chu Gabriel-Montpied, Public Health, Clermont- Ferrand, France; 5Chu Gabriel-Montpied, Clermont-Ferrand, France.

Background: Chronic inflammatory rheumatisms (RIC) may negatively impact patients’ sexual health and quality of life.

Overall, 31 to 76% patients suffering from rheumatoid arthritis (RA) report to suffer from sexual difficulties. Patients affected by spondyloarthritis (SA) report a negative disease impact on sexual activity in 38 to 50% of cases. On the other hand, while healthcare professionals (HP) are well aware of the utility to approach this issue, most do not carry on with it for they feel insufficiently trained in this domain.

According to the 2015 EULAR recommendations, therapeutic patient education (TPE) is an essential part of patient management in the RIC domain. TPE actually does take into account the overall patient experience including sexuality.

A survey primarily focused on needs and conducted among patients and healthcare experts involved in TPE was thus deemed necessary to better define both the content and format of TPE to be delivered to HP in order to help them dialogue with their patients, while overcoming certain obstacles on this path.

Objectives: To define the educational needs of HP involved in TPE of patients suffering from CIR, concerning sexual health issues.

Methods: Using an interdisciplinary team approach, we have elaborated two different questionnaires focused on assessing specific needs and designed for patients and healthcare professionals.

These questionnaires were filled in online from May 2017 to November 2017 via a secured server implemented in each of the 14 French rheumatology centers by CIR patients, TPE-involved HP, and members of three patient associations.

Results: 239 patients answered the questionnaire (60.7% suffering from SA, 6.7% from psoriasis rheumatism, and 32.6% from RA), as did 57 HP. Overall, 72% patients reported having suffered or being still suffering from sexual difficulties, whereas 80% of them had never approached the topic with their respective HP.

In 82% of cases, the patient claimed having addressed the issue, whereas 30% HPs reported having taken the initiative. Half of both the patients and HP reported they had not dared to approach the topic.

To ease communication, HP would appreciate to “have a team specifically dedicated to particular sexual healthcare issues”, “have specific tools available” and “undergo specific training sessions”.

In line with HP answers, patients’ primary expectations were to be heard and become well-informed. The people who were judged the most competent (63%) and with whom patients would feel the most secure (58%) were the psychologists. The topics thought to be the most useful by the patients were similar to those considered most useful for HP training, namely undesirable treatment effects on sexuality (95%), impact of rheumatism on sexual activity (92%), body image and chronic illness (81%), partner communication (77%), sexual dysfunctions (77%), as well as physiology of aging and sexual function (75%). About 70% HP expressed the need for complementary education, with 95% of them stressing the necessity to acquire further communications skills within this domain.

Of these, 88% preferred short training sessions, and 80% group training sessions.

Conclusion: This survey clearly demonstrates the usefulness of implementing educational training, along with its appropriate content, among HP, designed to enable them to approach sexual health issues and provide their patients with appropriate advices in this domain.

Genomics, genetic basis of disease and antigen presentation

Sonia Melo Gomes1, Ebun Omoiyinmi2, Juan Arostegui3, Ying Hong4, Nigel Klein5, Paul Brogan6, 1UCL Great Ormond Street Institute of Child Health, Rheumatology, London, United Kingdom; 2Hospital Clinic, Immunology CIBD, Barcelona, Spain

Background: Cryopyrin Associated Periodic Syndromes (CAPS) are caused by autosomal dominant gain of function mutations in the NLRP3 gene. However, a subset of these patients with typical clinical features and good response to anti-IL-1 treatment, have no mutation in NLRP3 detected by conventional Sanger DNA sequencing. Somatic mosaicism may account for between 19 to 69% of these, from previous reports. Genetic heterogeneity has also been implicated in patients with CAPS-like syndromes, reiterating the use of a wider NGS approach. At present it is unclear how the variants found in patients 6 and 7 could modulate the phenotype, therefore in patients a clear genetic cause is yet to be found. In conclusion, this study suggests that NGS approaches are superior to conventional sequencing for the molecular diagnosis of CAPS and NLRP3 like phenotypes since they can detect somatic mosaicism or alternative molecular diagnoses mimicking CAPS.

Disclosure of interests: Sonia Melo Gomes: None declared, Ebun Omoiyinmi: None declared, Juan Arostegui: None declared, Ying Hong: None declared, Nigel Klein: None declared, Paul Brogan: Grant/research support from: SOBI, Novartis, Roche, Novimmune, Chemocentryx, Consultant for: Roche, SOBI, Speakers bureau: SOBI, Roche, Novartis, UCB DOI: 10.1136/annrheumdis-2019-eular.7906
Objectives: To explore potential mechanisms for the SLE related IRF7 SNP on type I IFN production, which might indicate new theoretical basis for genetic therapeutic strategy.

Methods: We constructed different genotypes of SLE relevant SNP cell lines by Crispr/Cas9 technology, and confirmed them by sequencing. After TLR-ligand stimulation, the mRNA expression of IFNα was detected by real-time qPCR. The levels of IFNα, TNFα and IL-6 were detected by ELISA kit. The protein expression of IRF7/p-IRF7 was detected by western blot. The binding ability of endogenous IRF7 with typeIFN promoter was studied by chromatin immunoprecipitation.

Results: We got IRF7 SNP rs1131665 GG/AA cell lines by gene editing technique. After TLR-ligand stimulation, IRF7 SNP rs1131665 AA cell line showed higher IFNα expression than GG, which indicated statistical significance. IRF7 SNP rs1131665 AA cell line showed higher p-IRF7 expression than GG detected with western blot. Endogenous IRF7 in IRF7 SNP rs1131665 AA cell line showed stronger binding ability with IFNα promoter than GG, which indicated statistical significance.

Conclusion: The missense variant of G to A in IRF7 SNP rs1131665, increased the production of typeIFN, which indicated that IRF7 G to A missense variant increased the susceptibility of type I IFN associated diseases.

Disclosure of Interests: None declared
shown that the largest factor influencing disease susceptibility is genetics. Genome-wide association studies have successfully characterized genetic variants that are associated with RA, with the vast majority of them mapping to non-coding regulatory elements. Understanding the mechanisms by which this phenomenon leads to disease is essential to translate these results from genetic association studies to the clinic.

Objectives: There is evidence showing that autoimmune diseases are the consequence of erroneous wiring of the regulatory circuitry between enhancers and their target genes. The aim of this study is to characterize non-coding regions containing RA-associated variants, in order to determine the genes and pathways by which these regions act to increase the risk of disease.

Methods: We isolated CD4+ T-cells from blood obtained from RA patients. We studied patients in two subgroups, high disease activity (DAS28≥5.1, n=18) and low disease activity (DAS28<3.2, n=33). All samples were genotyped using Illumina Infinium Exome-24 v1.0 BeadChip arrays. RNA-Seq Libraries were generated for matching RNA samples using the Lexogen QuonSeq Library Prep kit and sequenced on an Illumina NextSeq500. For a subset of 6 samples (3 high disease activity and 3 low disease activity patients), capture Hi-C was performed to characterize chromatin interactions between all RA associated loci and their potential target genes.

Results: We observed numerous chromatin interactions between RA variants and potential causal genes. Preliminary results show that a number of disease-associated SNPs interact with compelling candidate genes situated several megabases away. Whilst some of these chromatin interactions are common to both patients groups, subsets of them are specific to each disease subgroup, which are correlated with differential gene expression.

Conclusion: These results suggest that there might be different biological pathways contributing to disease in RA patients with inactive disease compared to patients with high disease activity.

Disclosure of Interests: None declared

FRIO007

IDENTIFICATION AND VALIDATION OF PLASMA MICRO-RNA 425–5P AND –451A AS MICRO-RNAS ASSOCIATED WITH CARDIOVASCULAR DISEASE RISK OBSERVED IN RHEUMATOID ARTHRITIS PATIENTS

PAREDES SILVIA1, Delia Taverner2, Raimon Ferre2, Josep Maria Alegret3, Lluís Masana4, Joan Carles Valvé5, Hospital Universitari Sant Joan, Department of Rheumatology, Reus, Spain; 1Hospital Universitari Sant Joan, Department of Rheumatology, Reus, Spain; 3Hospital Universitari Sant Joan, Internal Medicine, Reus, Spain; 2Hospital Universitari Sant Joan, Department of Cardiology, Reus, Spain; 4Rovira i Virgili University, Lipid Research Unit, Reus, Spain

Background: Cardiovascular disease (CVD) risk is increased in Rheumatoid arthritis (RA) patients, and therefore, improved approaches for its early detection are needed. An accelerated atherosclerosis is considered the cause of the increase CVD risk. As microRNAs (miRNAs) are increasingly recognized as critical regulators in atherosclerosis and possess excellent stability in plasma, this study focused on using miRNAs as noninvasive CVD risk biomarkers in RA patients.

Objectives: To identify plasmatic miRNAs in RA patients that can facilitate earlier diagnosis of CVD and provide insight regarding the increase risk for CVD observed in these patients.

Methods: A discovery and validation studies were performed. To discover miRNAs candidates, we first compared plasmatic profiles of 754 miRNAs in 7 RA patients without CVD, in 7 patients with acute myocardial infarction (AMI) but without RA, and in 7 healthy controls matched for age and for classical CV risk factors. miRNAs commonly expressed in the two group of patients but differentially expressed from the controls were selected as miRNA candidates for validation. Selected miRNAs were validated in independent serum samples from 214 RA patients (validation cohort) by studying its association with subclinical atherosclerosis measured by carotid intima-media thickness (cIMT). Plasma profile of miRNAs in the discovery study was analyzed using validated TaqMan Open Array miRNA panels which enables the quantification of 754 human miRNAs.
Differential expression analysis was performed with Expression Suite software and selected miRNAs candidates were validated in the validation study by real-time PCR with LNA™ microRNA qPCR assays and analyzed with 2-ΔΔCT method. Kruskal-Wallis test, Dunns post-test and linear regression were used for statistical analyses.

Results: In the discovery study we were able to measure 379 (50%) of the miRNAs represented in the array. We observed 10 miRNAs (miRNA-let-7a, miRNA-96, miRNA-381, miRNA-451a, miRNA-518d, miRNA-425-5p, miRNA-572, miRNA-190b, miRNA-708, and miRNA-1180) were expressed at the same level in RA and AMI patients but were significantly downregulated compared with controls. These 10 miRNAs were selected as potentially miRNAs associated with the increase risk of CVD in RA patients. Four of those miRNAs were expressed at very low level and were discarded for the validation study. In the validation study with 214 plasma samples from RA patients, we observed that two of the six candidate miRNAs (miRNA-425-5p and miRNA-451a) were significantly associated with cIMT. Thus, adjusted multivariable linear regression analysis showed that miRNA-425-5p and miRNA-451a independently explained 1.4% of the cIMT variability. Furthermore, adjusted regression estimates of the effect of miRNA-425-5p and miRNA-451a on cIMT were β = 0.029mm; p = 0.037 and β = 0.035 mm; p = 0.039, respectively. No other miRNA candidate exhibited association with cIMT values. Furthermore, we observed that miRNA-451a was significantly correlated with ESR (r=0.136; p=0.024) and miRNA-451a with DAS28 (r=0.19; p=0.003), ESR (r=0.23; p=0.0001), CRP (r=0.15; p=0.016) and fibrinogen (r=0.28; p=0.0001). miRNAs concentrations were not affected by any of the AR treatments. No association was observed between the presence of cardiac plaque and the expression level of the microRNAs tested.

Conclusion: In the present study, we have identified miRNA-425-5p and miRNA-451 as potentially miRNAs involved in the CVD risk observed in RA patients.

FR0009 MOLECULAR PROFILING OF CIRCULATING B-LYMPHOCYTES REVEALS THE SUPERIOR PERFORMANCE OF METHYLMOLE 12 TRANSPICTOME DATA FOR DISCRIMINATING RHEUMATOID ARTHRITIS PATIENTS IN AN EARLY ARTHRITIS CLINIC: IMPLICATIONS FOR TRANSLATING “BIG DATA” INTO CLINICALLY USEFUL TOOLS

Nabir Naiman1, Nihantha Thayagasingam1, Nisha Naik1, Alexander Clar1, Amy Anderson1, Dennis Lendrem1, L. Louise Reynold2, Stephen Eyre2, Anne Barton1, John Isaacs1, Arthur Pratt1, 1Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; 2Manchester University, Arthritis Research United Kingdom Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, Manchester, United Kingdom; 3Newcastle University, Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom

Background: Defining optimal strategies for translating “big datasets” of transcriptome and methylene data into clinically valuable tools in RA will benefit from comparisons where potential confounders – including therapeutic background, disease phase and cell substrate heterogeneity – are controlled as far as possible.

Objectives: We have obtained paired B- and CD4+ T-lymphocyte whole genome expression and methylation data from drug-naïve early arthritis clinic patients at a single centre. Focussing on B-lymphocyte data we here ask which of these datasets has most value in discriminating early RA – and the additive value of combining them.

Methods: CD19+ B-lymphocytes were isolated by positive selection from fresh peripheral blood of 90 drug-naïve patients attending the Newcastle Early Arthritis Clinic (NEAC), comprising 36 RA patients and 54 disease controls matched, so far as possible, for age, sex and acute phase response. Paired RNA and DNA extracted. Gene expression was profiled using the Human HT12 v4 BeadChip, and DNA methylation at >850,000 CpG sites quantified with the MethylationEPIC array (both Illumina). Gene expression and/or DNA methylation classifiers for RA prediction were developed based on a combined approach of classification algorithm
Objectives: We aimed to evaluate the T-cell receptor-CD3 zeta chain (TCR-CD3ζ) gene expression profile in a cohort of patients with RA.

Methods: A case-control study on 150 consecutive RA patients diagnosed according to 2010 ACR/EULAR criteria and 150 matched healthy controls without familiar history of RA or other autoimmune diseases. RA patients with other autoimmune diseases, viral hepatitis B or C, malignancy or hematological disorders were excluded from the study.

All participants were subjected to history taking, clinical examination, assessment of disease activity (in RA patients) using DAS-28 and HAQ, routine laboratory investigations, inflammatory markers level, serological tests, as well as molecular analysis for TCR-CD3ζ mRNA expression by quantitative real-time polymerase chain reaction.

Results: TCR-CD3ζ gene expression was significantly lower in RA cases than in healthy controls (p<0.05) (Table 1). Expression of TCR-CD3ζ revealed a significant negative correlation with RA disease duration, RF, and ESR (p<0.05) in RA cases. The level of TCR-CD3ζ also showed a significant lower expression in +ve RF patients than in –ve RF patients (p<0.05). The AUC of TCR-CD3ζ level showed a moderate level of accuracy (AUC = 0.840, p=0.025) (Figure 1), and the calculated cutoff value (≥ 0.077) can precisely discriminate subjects with RA from those without RA with 93.5% sensitivity and 75% specificity (Table 2).

A TRANSCRIPTIONAL REGULATOR CONTROLLING SEVERITY OF EXPERIMENTAL ARTHRITIS

Åsa Andersson1,2, Samra Sardar2, Högskolan i Halmstad, Halmstad University, Halmstad, Sweden; 2Copenhagen, Copenhagen University, Dept of Drug Design and Pharmacology, Copenhagen, Denmark; 3Copenhagen, Nordic Bioscience, Copenhagen, Denmark

Background: Susceptibility to Rheumatoid Arthritis (RA) is dependent on complex interactions among genetic and environmental factors. Protein candidates and their role in pathways leading to chronic inflammation of the joints, in addition to their potential as drug targets, can be revealed with the help of experimental models for disease (1). From the results of functional genetic studies, we have recently shown that the T-box gene, TBX3, is a cancer gene in Collagen Induced Arthritis (CIA), an experimental model for RA (2). TBX3 encodes a transcriptional regulator involved in differentiation of several organs, including bone, during embryonic development. It has, in addition, been demonstrated important in oncogenesis (3). Our studies suggest that TBX3 has a role in B-cell activation and is important for the severity of disease in the CIA model (2).

Objectives: The objective of this project is to understand the role for the transcriptional regulator TBX3 in development of RA.

Results: Studies of CIA development in mice with single nucleotide polymorphisms (SNPs) in the regulatory region of TBX3. CRISPR/Cas9-introduced deletions and base modifications in human B-cell lines. Activation of genetically modified B-cells in vitro, followed by analyses of proliferative response and antibody production. No significant differences were seen in the proliferative response to Type II collagen upon re-challenge of lymph node cells in vitro higher in these mice, suggesting a more active response to the disease-inducing antigen. Because the TBX3 gene is conserved between mouse and human, we are investigating whether similar genetic variations are found in the regulatory region of the human TBX3 gene and whether the putative genetic variation would lead to a distinct B-cell phenotype upon activation in vitro.

Conclusions: Our data support the oncogene TBX3 is a novel candidate contributing to disease severity in experimental arthritis. Investigations of genetic variation in the TBX3 gene and its role in the activation of human B-cells will reveal whether this protein is a candidate for influencing also development of RA.

FR0014 GENETIC VARIABILITY IN MOLECULES REGULATING BONE REMODELING. DO THEY INFLUENCE SEVERITY OF DISEASE AND BONE MASS IN PATIENTS WITH EARLY-ONSET ARTHRITIS?

Noelia García Castañeda1, Amalia Lamana1, Nuria Montes1, Ana Ortí2, Dolores Martínez-Quintanilla Jiménez2, Cristina Valero1, Pablo Moreno Fresneda1, Irene Llorente1, Javier Martín Ibáñez2, Carmen Martínez2, Rosa P. Gomariz4, Ana Triguero-Martínez1, Santos Castañeda1, Isidoro González-Álvaro1. 1H.U. La Princesa, IIS-IP, Madrid, Spain; 2Instituto de Parasitología y Biomedicina López-Neyra, CSIC, Granada, Spain; 3Facultad Medicina, Universidad Complutense de Madrid, Madrid, Spain; 4Facultad de Ciencias Biológicas, Universidad Complutense de Madrid, Madrid, Spain

Background: In the last few years, an association has been described between lower bone mass at the onset of disease and higher severity of nontraumatic arthritis (RA).

Objectives: To identify single nucleotide polymorphisms (SNPs) in genes related to bone remodeling associated with severity of disease and bone mineral density (BMD) in patients with early-onset arthritis.

Methods: We included 268 PEARL (Princess Early Arthritis Register Longitudinal) patients genotyped with Illumina Inc. Immunochip. This array includes 556 SNPs with different density levels in semaphorins 4b, 4d and 4f, DKK1, 2 and 3, sclerostin, osteoprotegerin (OPG), RANK and...
RANKL. All SNPs with genotyping rate <98%, with frequency of the minor allele <1% and those that were not in Hardy-Weinberg equilibrium, were excluded. In addition, among the SNPs in linkage disequilibrium, a representative one was chosen, so that only 159 were finally studied. The intensity of treatment, the activity of the disease measured by the DAS28 and HUPI indices, as well as having achieved at least low activity after 2 years of follow-up were chosen as surrogate severity variables. The association of each of the SNPs with these variables was analyzed by linear regression, and ordered logistic regression according to the variable, and adjusted for potentially confusing variables, such as age, sex and presence of anti-cyclic citrullinated peptide antibodies. We selected those SNPs that were consistently associated with ≥3 surrogate severity variables, and then, the relationship of the selected SNPs with BMD of the forearm, lumbar spine and hip (Hologic-4500 QDR) was analyzed by means of linear regression adjusted for age and sex.

Results: As shown in the attached table, 11 SNPs were associated with the severity of the disease, 7 of them were also associated with BMD, although only 3 confirmed the previously described relationship between severity of disease and BMD.

**Conclusion:** This preliminary study highlights the relationship between gene variants of molecules involved in bone remodeling and the severity of early-onset arthritis. However, more studies are needed to confirm this relationship and validate it in other populations. This would confirm the relationship between severity of disease and BMD.

Background: Autoimmune rheumatological disorders (AIRD) have been described in myelodysplastic syndrome (MDS) and related-myeloid disorders but its association remains unclear. Immunosuppressive treatment of AIRD could cause therapy-related myeloid neoplasm (t-MN) or confound the secondary diagnosis of MDS. The prevalence of cytopenia in patients with AIRD is unknown and the mutation profile of patients with AIRD and concomitant MDS have not been well characterised.

Objectives: This study aims to evaluate the prevalence of cytopenia in AIRD and analyse the mutation profile of patients with concomitant diagnosis of AIRD and MDS by interrogating the databases of 2 large institutions - Royal Adelaide Hospital Rheumatology Department (RAH-RD) and South Australia-Myelodysplastic Syndrome (SA-MDS).

Methods: Demographic, clinical, laboratory and treatment data of 2663 patients from RAH-RD and 1157 patients from SA-MDS were analysed according to the idiopathic cytopenia of undetermined significance (ICUS) criteria. Patients with persistent cytopenia (>6 months) were defined as follows: haemoglobin <100g/L, absolute neutrophil count <1.5x10^9/L, and platelet <100x10^9/L. Within the SA-MDS registry, 237 bone marrow samples were analysed for 43 myeloid neoplasms associated genes and 20 Fanconi (FA) DNA repair pathway genes with targeted massively parallel sequencing. An in-house filtering pipeline was used to identify somatic mutations.

Results: Within RAH-RD database, 79 patients (3%) fulfilled the criteria for at least 1 cytopenia. 21 patients underwent bone marrow biopsy, with 9 bone marrow samples being diagnostic of MDS. Neutropenia was most common (27/79 patients, 34%), followed by anaemia (20/79 patients, 25%) and thrombocytopenia (6/79 patients, 8%). Within SA-MDS database, 62 patients (5%) had concomitant AIRD. Rheumatoid arthritis is the most common AIRD diagnosis (21/62 patients, 34%) in the SA-MDS database. Combined analysis of both databases revealed that 71/3820 patients (1.9%) had a concomitant diagnosis of both AIRD and MDS.

The cytogenetic and mutational profile of patients with concomitant diagnosis of AIRD and MDS within the SA-MDS database were analysed and 56 mutations were discovered in this group. Mutation in ASXL1 was the most common (6/20 patients, 30%), followed by TET2 (5/20 patients, 25%) andLastly TP53 (4/20 patients, 20%). There is significantly higher frequency of IDH1 mutation in the AIRD-MDS cohort compared to patients with MDS only. Three patients with TP53 mutation developed MDS following treatment for AIRD (therapy-related MDS).

Conclusion: In a large cohort of patients with AIRD, 3% of patients developed ongoing cytopenia and 0.3% were diagnosed with MDS. This finding is higher than the incidence of MDS in the general population (0.03-0.05%). Within the SA-MDS registry, 5% of patients had concomitant diagnosis of AIRD. Our findings warrant further study and have potential implications for selection of disease-modifying drugs for patients with AIRD.

FRID0016 MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME IN PATIENTS WITH AUTOIMMUNE RHEUMATOLOGICAL DISORDERS

FRID0017 DIFFERENTIAL METHYLATION AS A PREDICTOR OF TOCILIZUMAB RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS
MicroRNA-146a plays an important role in regulation of autoinflammatory diseases including gout[1]. Growing evidences have demonstrated that association of miR-146a gene single nucleotide polymorphisms (SNPs) with risk of several diseases[2], but no genetic relevance studies of miR-146a gene polymorphisms to gout have been reported by now.

**Objectives:** To investigate the potential association of gout and the functional rs57095329 SNP of miR-146a in the Chinese Han population.

**Methods:** The rs57095329 SNP was detected in 448 primary gout patients (containing 76 tophi patients) and 418 healthy control subjects. Peripheral blood mononuclear cells (PBMCs) miR-146a expression was measured in 81 gout patients (including 32 tophi patients and 49 non-tophi patients) and 47 healthy subjects.

**Results:** No significant difference was detected in the distribution of miR-146a rs57095329 between 448 gout patients and 418 healthy subjects (P>0.05). However, significant differences were observed between 76 gout with tophi patients and 418 healthy subjects, between gout with tophi (76) and with no tophi patients (372) both in genotypes and allele distributions (P<0.01, respectively). Gout patients carrying AG/GG genotypes with tophi patients and 418 healthy subjects, between gout with tophi patients and 418 healthy subjects, between gout with tophi patients and 418 healthy subjects.

**Conclusion:** Our study shows a novel, significant association between the miR-146a rs57095329 polymorphism and a lower risk of tophi in gout patients. Furthermore, our findings suggest that this gene polymorphism might affect the genetic predisposition to tophi development and modulate the expression of miR-146a level in tophi patients. This new knowledge about miR-146a may be clinically important and confirms a role for miR-146a in the pathophysiology of tophi, with potentially important therapeutic implications.

CORRELATION BETWEEN EXPRESSION LEVELS OF miR-146A AND miR-223 IN SYNOVIAL FLUID AND ULTRASOUND SCORES FOR ACTIVE SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS

Russka Shumnaljeva,1,2 Darina Kachakova, Radka Kanava, Zlatimir Kolarov, Simeon Monov

Clinic of Rheumatology, Department of Internal Medicine, Medical University-Sofia, Sofia, Bulgaria; Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical University-Sofia, Sofia, Bulgaria

Background: MicroRNAs (miRNAs) are a class of small, non-coding RNAs that negatively regulate gene expression at posttranscriptional level. In recent years studies have shown that in rheumatoid arthritis (RA) the systemic and local expression of certain miRNAs is altered [1-2]. The correlation between their expression levels and scores for disease activity and progression in RA make them possible candidate for biomarkers in the clinical practice.

Objectives: To analyze the expression levels of miR-146a and miR-223 in synovial fluid (SF) from RA patients in regard to the ultrasound scores for disease activity.

Methods: A total number of 48 RA patients according to the 1987 ACR criteria were included in the study. Expression levels of miR-146a and miR-223 SF were determined by qPCR (SybrGreen technology) and compared to healthy controls (HCs). Relative changes of gene expression were calculated by 2^-ΔΔCt method. Musculoskeletal ultrasound (MSUS) examination was performed by two independent examiners on ESAOTE, MyLab60 using both grey scale and power Doppler technic. A semi quantitative assessment of the peripheral joints was performed for detecting joint inflammation and determining the grade of synovial thickening and the degree of vascularization. Ultrasound features for active disease were correlated to the local expression of the studies miRNAs. SPSS was used for statistical analysis.

Results: RA SF showed overexpression of miR-146a (in 70.83%, p=0.007) and of miR-223 (in 79.17%, p=1.64x10-3) when compared to HCs. There was a statistically significant correlation between the presence of synovitis and the degree of the power Doppler signal on MSUS and the local expression of miR-146a (p=0.030 and p=0.049, respectively) and miR-223 (p=6.19 x 10^-4 and p=0.003, respectively). SF levels of miR-223 correlated also with the degree of synovial hypertrophy on MSUS (p = 0.013).

Conclusion: We found correlation between the SF expression of miR-146a and miR-223 and the ultrasound features of active joint inflammation. Further analysis with larger sets is needed to confirm if altered local miRNA expression could be used in the clinical practice as biomarker for disease activity especially in cases with subclinical synovitis.

ORAL HYGIENE STATUS IN RA PATIENTS AND PLACE OF RHEUMATOLOGIST IN THERAPEUTIC EDUCATION ON ORAL DENTAL HEALTH

saloua allal1, Hanan Rkain1,2, Aatif Allalou2, Oum Keltoum Ennibi2, Tahiri Latifa1, Nadia Alami1, Fadoua Allal1,1, El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rheumatology B, rabat, Morocco; 2Laboratory of Physiology, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, rabat, Morocco; 2Periodontology department, Faculty of Dentistry, Mohammed V University, Rabat, Morocco, rabat, Morocco

Background: The relationship between oral hygiene and rheumatoid arthritis has been demonstrated by several studies.

Objectives: To evaluate oral hygiene status in rheumatoid arthritis (RA) patients.

To inform about the therapeutic education given by the rheumatologist on the importance of adequate oral hygiene in the management of RA.

Methods: This is a cross-sectional study that included 100 consecutive RA patients (89% female, mean age 46.7 years, median disease duration of 8 years, mean specialized care duration of 3 years). A questionnaire evaluating oral hygiene status was administered. It focused on following items: the daily frequency of brushing, the modalities of brushing, the use of other means of oral hygiene, the regular follow-up at a dentist’s doctor and the place of the rheumatologist in therapeutic education on the oral dental hygiene status.

Results: Table I illustrates the results of oral hygiene evaluation in RA patients.

Rheumatoid arthritis - comorbidity and clinical aspects.

EVALUATION OF DYSFUNCTIONAL HIGH-DENSITY LIPOPROTEIN LEVELS WITH MYELOPEROXIDASE/PARAOXONASE 1 RATIO IN RHEUMATOID ARTHRITIS

Background: Rheumatoid arthritis (RA) is a chronic, systemic and autoimmune disease with inflammatory arthritis. Atherosclerosis and cardiovascular diseases are common in RA patients. Although chronic systemic inflammation in RA patients is considered to be the main cause of this condition, the relationship between systemic inflammation and vascular pathophysiology is not clear [1]. While high density lipoprotein (HDL) is known to be a negative risk factor for atherosclerosis by reverse cholesterol transport, recent studies show that HDL can be pro-atherogenic (dysfunctional, inflammatory) by losing this characteristic in cases of inflammation and oxidative stress. Myeloperoxidase (MPO)/paraoxonase 1 (PON1) ratio is a valuable marker that can be routinely used as an indicator of dysfunctional HDL. PON1 is a lipoprotein-derived enzyme which provides antioxidant properties of HDL. Although MPO is a bactericidal enzyme derived from granulocytes, it causes oxidative modification of circulating lipoproteins [2].

Objectives: The aim of this study is to evaluate the levels of dysfunctional HDL in RA patients and to explore the relationship between dysfunctional HDL and coronary artery disease (CAD) in RA patients.

Methods: Sixty-seven healthy individuals and 130 RA patients without diabetes mellitus, hypertension and hyperlipidemia were included to study. Blood samples taken from patients and healthy volunteers were centrifuged to separate serum and these serum samples were stored at -80 °C until the study day. Total cholesterol (TC), triglyceride (TG), HDL, Low-density lipoprotein cholesterol (LDL), MPO and PON1 levels were measured. The MPO/PON1 ratio was calculated as a dysfunctional HDL marker. Cardiology notes of the patients were examined to detect patients who also have CAD.

Results: The mean age of the patient and control groups were 54.6 ± 11.3 and 52.0 ± 10.0, respectively (p=0.107). The mean DAS28 score of the patients was 2.77 ± 0.96. There were no significant differences between two groups in TC, TG, HDL and LDL (p > 0.05). Moreover, PON1 and dysfunctional HDL levels were significantly higher in the RA group compared to control group (p < 0.001, p < 0.023; p < 0.001; respectively).

Dysfunctional HDL levels were higher in 44 RA patients with CAD compared to 86 RA patients without CAD (p = 0.002). 58 patients with active RA had higher dysfunctional HDL levels compared to 72 patients with remission (p = 0.002). There was a positive correlation between DAS28 scores and dysfunctional HDL levels (r= 0.357, p < 0.001).

Conclusion: Our study shows that, although there is no abnormality in lipid profile parameters, dysfunctional HDL levels were higher in patients with active disease than patients with RA in remission and RA patient with CAD than without CADs. This condition could be associated with CAD in RA patients. Disturbance as a result of inflammation on HDL functions such as inhibition of LDL oxidation and reverse cholesterol transport, could be the cause of CAD in RA patients. As a result screening of conventional cardiovascular risk factors in RA patients with normal lipid panel might be inadequate. Therefore as an additional parameter, dysfunctional HDL are promising to evaluate cardiovascular risk of RA patients.

CARdiovascular risk and vitamin D deficiency in patients with rheumatoid arthritis in therapy with TNF-alpha inhibitors

Dania Anghel1, Liviu Oltcan2, Maria Magdalena Negrui3, Radu Bursuc1, Anca Mandache1, Elena Busuio1, Valeriu Smedescu1, Adrian Anghel1, Florentina Cristina Plecas1, Ciprian Jurcu1, Dr. Carol Davila Central Military Emergency University Hospital, Internal Medicine, Bucharest, Romania; “St. Stanislaus’ Complex Clinic, Internal Medicine and Rheumatology, Bucharest, Romania

Background: Cardiovascular disease is the main cause of mortality and morbidity in patients with rheumatoid arthritis (RA). Correlation between vitamin D deficiency and atherosclerosis in patients with rheumatoid arthritis is a subject of medical interest.

Objectives: We studied the correlation between vitamin D deficiency, body mass index (BMI) and carotid intima-media thickness (CIMT) in patients with rheumatoid arthritis with anti tumor necrosis factor-alpha (TNF-α) therapy.

Methods: Our study included 75 RA patients with anti-TNF-α therapy (Adalimumab, Infliximab, Etanercept) and 30 RA patients with DMARDs (Methotrexate/Leflunomide). The patients were diagnosed with RA according to ACR/EULAR (2010) classification criteria. CIMT was measured using high-resolution Doppler ultrasonography. CIMT ≥ 0.9 mm is considered as a marker of atherosclerosis. Vitamin D deficiency was defined as serum 25-OH-vitamin D level <20 ng/mL. Other parameters included are age, body mass index (BMI=18.5-24.9 kg/m² - normal weight; BMI>25kg/m² - overweight) and disease activity (DAS28<2.6: remission; DAS28=2.6-3.2: low disease activity, DAS28>3.2-5.1: moderate disease activity; DAS28>5.1: high disease activity).

Results: Patients with current use of vitamin D supplements were excluded. The anti-TNF group included 29 patients with Adalimumab (38.7%), 25 with Etanercept (33.3%) and 21 patients in treatment with Infliximab (28%). Their mean age was 52.0 years. We evaluated patients at baseline and after 12 months with treatment. In anti-TNF group we found 9 patients (12%) with normal BMI and normal vitamin D level correlated with high CIMT (p=0.001), 21 patients (28%) with overweight and normal vitamin D level correlated with high CIMT (p=0.003), and 31 patients (41.3%) with overweight and low vitamin D level correlated with high CIMT (p=0.001). 14 patients (18.7%) with normal vitamin D level and normal overweight (9) or overweight (5) were correlated with normal CIMT (p=0.001). In DMARDs group we followed the same correlation. Patients with normal BMI and normal vitamin D level had a low correlation with CIMT increase (p=0.01). Patients with overweight and low vitamin D level had a significant correlation with CIMT increase (p=0.003) than group with anti-TNF-alpha therapy.

After 12 months of therapy, patients treated with Adalimumab had lower CIMT levels than patients treated with Etanercept. Conclusion: Rheumatoid arthritis patients treated with TNF inhibitors and with vitamin D deficiency but with normal BMI have been correlated with lower increase of CIMT than patients with DMARDs therapy. Normal vitamin D level was associated with low increase of CIMT in these patients.

Disclosure of Interests: None declared

AA AMYLOIDOSIS AND LUNG DISEASES IN RHEUMATOID ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 147 PATIENTS

Ágnes Ápaló1,2, Miklós Bély1,3,1St. Margaret Clinic Budapest, Department of Rheumatology, Budapest, Hungary; 2St. Margaret Clinic, Budapest, Department of Rheumatology, Budapest, Hungary; 3Hospital of the Order of the Brothers Saint John of God in Budapest, Department of Pathology, Budapest, Hungary

Background: Systemic AA amyloidosis (AAa) is one of the most important complications of rheumatoid arthritis (RA) [1]. A wide spectrum of lung diseases may complicate RA or associate with RA [2-4].

Objectives: The aim of this study was to determine the influence of AAa on lung diseases related or not related to RA.

Methods: We studied 161 random autopsy patients with RA [1]. RA was confirmed clinically according to the criteria of the ARA [5]. Tissue samples of the lungs were available for histological evaluation of 147 patients.

Disclosure of Interests: None declared
The prevalence of AAa and of distinctly different forms of multilocal inflammation, such as purulent bronchitis and bronchiolitis (purBr) or bronchopneumonia (BrPn), infect with pneumonia (InfPn), occlusive pneumonia (OcclPn) – local pneumonia caused by compressive peribronchial nodules, lymphoid hyperplasia or bronchial blockage by a necrotic nodule – were examined. In addition, rheumatoid pneumonia (RhPn), furthermore interstitial pneumonia (IPn) [1-4] were determined at autopsy and confirmed in a detailed review of extensive histological material. The possible role of AAs on the prevalence of purBr or BrPn, InfPn, OcclPn, RhPn and IPn was analyzed with Pearson’s chi-squared ($\chi^2$) test.

**Results:** AAa complicated RA in 34 (23.13%) of 147 patients. Pulmonary blood vessels of different caliber and various tissue structures of the lungs were involved in 25 (73.53%) of 34 cases; the lungs were not involved by AAa in 9 (26.47%) of 34 cases. purBr or BrPn were associated with RA in 19 (21.1%), InfPn in 5 (3.4%), OcclPn in 2 (1.4%), RhPn in 3 (2.1%) of 147 patients (only the fatal cases were considered). IPn – characterized by interstitial cellular infiltration with or without edema, fibrinoid deposition, with or without fibrosis, and with or without corresponding pleuritis was present in 35 (23.8%) of 147 patients; IPn alone was not fatal in our cohort and contributed to the death only in association with cardiac, circulatory or cardio-respiratory insufficiency.

Pulmonary amyloid A deposition (m=25) was associated with purBr or BrPn in 1 (5.26%) of 19, InfPn in 1 (20.0%) of 5, OcclPn in 2 (100.0%) of 2, RhPn in none (0.0%) of 3, IPn in 12 (34.29%) of 35 patients. The relationship between pulmonary AAa and purBr or BrPn ($\chi^2=1.2836$, p=0.25), InfPn ($\chi^2=0.1800$, p=0.67) or RhPn ($\chi^2=0.00205$, p=0.98) was not significant. There was a significant and positive correlation between pulmonary AAa and OcclPn ($\chi^2=4.8313$, p=0.032) or between AAa and IPn ($\chi^2=9.7106$, p<0.0018).

**Conclusion:** The main complications of RA, such as AAs, may influence the prevalence, clinical course and symptoms of associated diseases and vice versa. Knowledge of these relationships is important to estimate the relative danger they potentially represent. The significant correlation between AAa and OcclPn or IPn suggests a positive influence of pulmonary amyloid A deposition on OcclPn or IPn. The statistically not significant correlations suggest that purBr or BrPn, InfPn and RhPn are independent entities which are not influenced by AAa.

**DOES COMORBIDITY IMPACT ON THE ACTIVITY AND MANAGEMENT OF RHEUMATOID ARTHRITIS?**

**Aida Babayeva**1, Elena Kahlina1, Maxim Zvonorenko2, Karina Solodenkova2.

1Volgograd State Medical University, Volgograd, Russian Federation; 2I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

**Background:** Patients with rheumatoid arthritis (RA) are in increased risk of developing comorbid conditions. Recent data suggest the relationship between severity of RA and concomitant diseases [1, 2]. Drug therapy is considered as important risk factor for numerous comorbidities. On the other hand, comorbidity can impact negatively on the RA course and on the pts management [3].

**Objectives:** The aim of our study was to evaluate the prevalence of concomitant conditions in RA pts, to compare the RA activity and management in relation with comorbidities.

**Methods:** 168 pts with established and longstanding RA were observed at-in-patient clinic for RA clinical assessment and revealing concomitant diseases (cardiovascular, gastrointestinal, liver, pulmonary, endocrine, blood). The activity of disease according to DAS28-ESR index in RA subgroups with and without comorbidities was compared. The spectrum and used doses of anti-rheumatic medications (DMARD, biologics, GC) in these subgroups was analyzed in term to assess the RA rational treatment. The majority (88.1%) of observed RA pts had concomitant condition. The most frequent associated diseases were: cardiovascular (AH, IHD, HF, AF) in 86.9% and gastrointestinal (gastritis, duodenitis, gastro-duodenal ulcer, colitis) in 64.3% less common comorbidities were anemia (30.9%), liver and kidney abnormalities (hepatomegaly, steatohepatitis, CKD, pyelonephritis) in 25% and 12.5% respectively, endocrine (type 2 diabetes mellitus, thyroid disorders) in 16.7%. Multimorbidity determined as combination of different system disorders in the setting of RA was detected in 54.6% of RA pts. We found out significant difference in RA activity on the basis of DAS28 between RA subgroup without concomitant conditions (the 1st) on the one hand and RA subgroups with comorbidities (the 2nd) (11=2.76, p<0.01) or multimorbidities (l2=2.73, p<0.01) on the other hand (tab.1).

In RA with comorbidities/multimorbidities the mean doses of MTX and SSZ were lower than in RA without comorbidities, while the dose of GC and frequency of GC use was significantly higher in the 2nd and 3rd groups (2=4.25, 4.41 respectively). 55% of pts from the 1st group and only 19.6% of total amount of pts from the 2nd and 3rd groups were treated with biologics (2=4.67).

**Conclusion:** Obtained data suggest that comorbidities have a negative impact on the severity of RA and can interfere in the implementation of T2T strategy in daily clinical practice.

**SYSTEMIC, RENAL AND CARDIAC AA AMYLOIDOISIS IN RHEUMATOID ARTHRITIS – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 PATIENTS**

**Miklos Bély1, Ágnes Apáthy2. 1Hospital of the Order of the Brothers Saint John of God in Budapest, Department of Pathology, Budapest, Hungary; 2St. Margaret Clinic, Budapest, Department of Rheumatology, Budapest, Hungary**

**Objectives:** The aim of our study was to determine the incidence of systemic AA amyloidosis (sAAa) in RA, to appraise the prevalence and severity of amyloid A deposition in different tissue structures of the kidneys and heart, to outline the development of renal and cardiac AA amyloidosis (rAAa and cAAa), and to estimate the role of rAAa and cAAa in mortality.

**Methods:** One hundred sixty one (161) non-selected autopsy patients with rheumatoid arthritis (RA) were studied. RA was confirmed clinically according to the criteria of the ACR [1]. sAAa was specified histologically, based on evaluation of $5$ organs (heart, lung, liver, kidney and pancreas). Amyloid A deposition was diagnosed histologically according to Romhányi by a modified (more sensitive) Congo red staining [2]. Amyloid...
A deposits were confirmed in serial sections by immunohistochemical and histochemical methods.

Results: sAAa complicated RA in 34 (21.12%) of 161 patients; in 127 (78.88%) of 161 patients amyloid A deposits were not found. Amyloid A deposits were found in 29 (87.88%) kidneys of 33 patients with sAAa; kidneys were negative for amyloid in 4 (12.12%) of 33 cases (in 1 of 34 patients with sAAa tissue blocks of kidneys were not available).

Amyloid A deposits were found in 29 (87.88%) hearts of 33 with sAAa; the heart was negative for amyloid in 4 (12.12%) of 33 cases (the heart of one patient with sAAa was not available). Renal amyloid A deposition led to death in 17 (50.06% of 34) patients with sAAa due to massive amyloid A deposition in the kidneys, leading to renal insufficiency and uremia. Cardiac amyloid A deposition led to death in 3 (8.82%) of 34 patients with sAAa (and contributed to the lethal outcome in further 5). Forteen (41.18%) of 34 patients with sAAa died of other causes such as peritonitis, lethal septic infection, etc.

sAAa was clinically diagnosed in 9 (26.47%) and missed in 25 (73.52%) of 34 patients, and only cases with massive renal amyloid A deposits were recognized. Cardiac AAa or its pathogenic role in mortality was not diagnosed.

Conclusion: sAAa is one of the main and the most insidious complications of RA affecting the kidneys and heart with high prevalence and severity. sAAa is related to the cardiovascular system, and rAAa or cAAa are associated with it. sAAa, rAAa and cAAa may develop in both sexes, and at any time in the course of the disease.

Systemic, renal and cardiac amyloid A deposition is a progressive and cumulative process, involving in its early stage only a few structures in some organs, and increasingly more in the later stages of the disease. In sAAa the renal and cardiac amyloid A deposition starts after a latent stage. This latency may be caused by a not specified local protective mechanism, e.g. great excretion capacity of the kidneys, due to motility of the heart or oxygenisation etc. Amyloid A deposition starts in the most frequently involved structures of the kidneys or heart with more massive deposits. The chronology of amyloid A deposition allows an indirect assessment of the stage of renal or cardiac amyloidosis, which may have a prognostic value in everyday surgical pathology.

Half of the patients with sAAa died of uremia caused by massive rAAa and only 9 of these were clinically recognized. Renal and cardiac amyloid A deposition should be considered a very serious, life-threatening complication of RA.

FR10027   PROGNOSTIC MARKERS FOR PRECLINICAL CARDIOVASCULAR DISEASE IN RHEUMATOID ARTHRITIS AND CORRELATION WITH DISEASE ACTIVITY

Annetes Blanken1, Rabia Agca1, C.J. van der Laken2, Michael Nurmohamed1,2, 1Amsterdam Rheumatology and immunology Center location Reade, Amsterdam, Netherlands; 2Amsterdam Rheumatology and immunology Center location VUmc, Amsterdam, Netherlands

Background: Patients with rheumatoid arthritis (RA) have an elevated cardiovascular (CV) disease risk, explained both by an increased prevalence of traditional CV risk factors and the presence of chronic systemic inflammation that impairs vascular function, leads to thickening of the arterial wall and increased arterial stiffness.

Objectives: In this study we investigated the effect of anti-inflammatory treatment on prognostic markers for preclinical cardiovascular disease (arterial wall thickening and arterial stiffness) and the correlation of these markers with RA disease parameters.

Methods: Carotid ultrasound (using Artlab echotacking system) was used to determine carotid intima media thickness (IMT) and pulse wave analysis was done with SphygmoCor tonometry to calculate pulse wave velocity (PWV) and augmentation index (AIx). Paired t-test was used to compare PWV, AIx and IMT prior and after 6 months of therapy. Pearson correlation was calculated to investigated the correlation of PWV, AIx and IMT with (natural logarithm of) C-reactive protein (CRP), (natural logarithm of) erythrocyte sedimentation rate (ESR) and disease activity score 28 (DAS28). For correlations, data from both time points were pooled.

Results: In total 61 consecutive RA patients (50% early arthritis starting with csDMARD and 50% established RA starting with adalimumab) were asked to undergo arterial analysis just prior to start of therapy and after 6 months. PWV was performed in 45 patients at baseline and 39 at follow-up, IMT in 56 and 45 patients respectively and AIx in 51 and 44 patients respectively. Both signs of arterial stiffness (PWV and AIx) decreased after 6 months of therapy (mean difference 0.7 and 0.8 respectively; table 1), although this did not reach statistical significance. IMT remained stable during 6 months of therapy.

Table 1. Prognostic markers of atherosclerosis prior and after 6 months of anti-inflammatory therapy

<td>43</td>
<td>0.68</td>
</tr>
</tbody>
</table>

Conclusion: Arterial stiffness as measured with PWV tended to decrease after 6 months of anti-inflammatory treatment. Arterial stiffness and arterial intima media thickness correlated with clinical disease parameters. Altogether, these changes might suggest that effective anti-anerithmatic therapy has favorable cardiovascular effects. Whether or not this ultimately leads to a significant reduction of "hard" cardiovascular endpoints remains to be established in prospective studies.

FR10028   LOW SERUM IGF1 IS ASSOCIATED WITH AN INCREASED RISK AND HIGH PREVALENCE OF CARDIOVASCULAR EVENTS IN MIDDLE-AGED FEMALE PATIENTS WITH RA – A 5-YEAR FOLLOW-UP

Malin Erlandsson1,2, Rachelle Espino1, Lovisa Lyngfelt1, Sofia Töyrä Silfverswärd1, Mira Nadali1,2, Karin Me Andersson1, Rille Pullerits1,2,3, Mari I Bokarewa1,2, 1University of Gothenburg, Dept of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2 Sahlgrenska University Hospital, Rheumatology Unit, Gothenburg, Sweden; 3University of Gothenburg, Dept of Clinical Immunology and Transfusion Medicine, Gothenburg, Sweden

Background: Recent meta-analysis reported that rheumatoid arthritis (RA) is associated with high frequency of hypertension and stroke (1). IGF1 is an important angioprotector and its deficiency predisposes to development of ischemic stroke (2). Objectives: Since levels of active IGF1 are affected by systemic inflammation, we analyze if low IGF1 is associated with increased cardiovascular disease (CVD) in women with RA.

Methods: The CVD risk was estimated (eCVR) in 184 female RA patients (median age 53 years, range 21-71) using the Framingham
algorithm. A 5-year prospective follow-up for new CVD events, type II diabetes and medication for hypertension and hyperlipidemia was completed in all the patients. The event-free survival curves were built and the Mantel-Cox analysis was performed with respect to serum IGF1, where IGF1 levels below or equal to the median 139 ng/ml were considered low.

**Results:** Low IGF1 was clinically significant. These patients were recognized by high prevalence of hypertension (26% vs. 7.9%, p=0.001), overweight (19% vs. 6.8%, p=0.016) and hypercholesterolemia (71% vs 48%, p=0.0025), which resulted in a higher eCVR in these RA patients (72% vs. 3.3%, p<0.001). When adjusted by age, low IGF1 group had higher serum IL6 (pg/ml: 2.1[0.2-3.0] vs 0.7[0.1-4.2], p=0.038) and ESR (mm/h: 12.7[15.5]) vs 5.9[8], p=0.02), and higher prevalence of MTX monotherapy (59% vs. 39%, p=0.024). At prospective follow-up, 12 CVD events were registered. The median age at CVD event was 67 years and disease duration 14 years. Among the new CVD events were 4 ischemic strokes, 3 chronic atrial fibrillations and 2 incidentally aorta aneurysms, which all could be viewed as directly related to hypertension. Low IGF1 showed high probability for new CVD events (OR 4.96, [95%CI:1.17-34.2], p=0.029). Additionally, low IGF1 group had a significant increase in medication for hypertension (+19.5% vs +4.8%, p=0.0001), but not type II diabetes or statins. In a prediction model, a combination of low IGF1 and RA duration>10 years indicated 80.5% specificity for development of new CV events.

**Conclusion:** We identified low normal levels of IGF1 to be associated with higher prevalence of CVD events in RA patients. Importantly, low IGF1 appeared to be an independent predictor of hypertension in middle-aged female patients.

**DEVELOPMENT OF AN ALGORITHM FOR THE CLASSIFICATION OF CARDIOVASCULAR COMORBIDITY IN RHEUMATOID ARTHRITIS: DATA FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE**

Kangping Cui1,2, Mohammad Movahedi3, Claire Bombardier3,4,5, Bindee Kurija4,6,1

1Western University, London, Canada; 2University Health Network, Toronto, Canada; 3University Health Network, Toronto General Hospital Research Institute, Toronto, Canada; 4Institute for Health Policy, Management and Evaluation, Toronto, Canada; 5University of Toronto, Medicine, Toronto, Canada; 6Mount Sinai Hospital, Rheumatology, Toronto, Canada

**Background:** Cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA). The ability to accurately identify CVD and its risk factors is important for primary and secondary prevention strategies. RA registries collect comorbidity data, but discordance between physician-reported and patient-reported comorbidities often exists.

**Objectives:** We aimed to develop an algorithm for the classification of CVD and CVD RF in a representative RA registry.

**Methods:** Data were collected from the Ontario Best-practices Research Initiative (OBRI), a clinical registry of RA patients followed in routine care in Ontario, Canada. Clinical information, including patient medication profile, was obtained at registry entry, through physician visits and patient telephone interviews. Cardiovascular disease (CVD) was defined as having ≥ 1 of myocardial infarction (MI), coronary artery disease (CAD), cerebrovascular accident (CVA, including transient ischemic attack and stroke), or peripheral arterial disease (PAD). CVD risk factors included hypertension (HTN), dyslipidemia (DLD), diabetes mellitus (DM), and current smoking.

**Results:** An algorithm for classifying CVD and CVD risk factors was developed including the 2033 subjects with baseline data. At cohort entry, the prevalence of CVD was 5.4% (n=110), HTN 670 (32.9%), DLD 401 (19.7%), DM 165 (8.1%), and current smoking 346 (17%). Seventeen (15.7%) subjects were not identified as having CVD by physician-report, but were classified as having CVD upon medication review. Discrepancy between physician and patient-reported CVD RF were: 207 for HTN (31%), 291 for DLD (73%), and 22 for DM (13%). Chart review of 55 patients showed sensitivity of 100% for CVD, 78% for HTN, and 42% for DLD classification.

**Conclusion:** An algorithm for classification of CVD has been successfully developed in a representative RA registry. The discrepancy between physician and patient-reported CVD highlights the importance of utilizing information from multiple sources when classifying comorbidities.

**FEELINGS OF GUILT AND SHAME IN PATIENTS WITH RHEUMATOID ARTHRITIS**

BOUSSAA HIRA, Alia Fazaa, Saoussen Miladi, Moura Owensch, Leila Souabni, Ahmed Laatar.

1Institute for Health Policy, Management and Evaluation, Toronto, Canada; 2University of Quebec, Montreal, Canada; 3Institute for Health Policy, Management and Evaluation, Toronto, Canada; 4Institute for Health Policy, Management and Evaluation, Toronto, Canada; 5University of Toronto, Medicine, Toronto, Canada; 6Mount Sinai Hospital, Rheumatology, Toronto, Canada

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease which causes functional disability, pain, and joint destruction. The disease has a major impact on patient’s independence, social activities and self-image.

**Objectives:** The aims of this study were to assess whether RA is associated with increased feelings of shame and guilt, and to examine possible correlates with socio demographic characteristics and disease activity.

**Methods:** To measure feelings of shame and guilt, in patients with RA (ACR/EULAR 2010), we used the Experience of Shame Scale (ESS) [1] and the Test of Self Conscious Affect- Version 3 (TOSCA-3S) [2]. The ESS is a 25-item questionnaire that assesses the frequency of characteristic, behavioral and bodily shame experiences over the past year. Respondents rate each item on a scale ranging from 1 (not at all) to 4 (very much), with higher scores indicating greater shame. The TOSCA-3S is presented with 11 brief hypothetical scenarios followed by 3 common reactions, which reflect shame, guilt and externalization of blame. Each possible response is rated on a five-point scale from 1 (not likely) to 5 (very likely). For the purpose of this study, only the shame and guilt response items were analyzed. Total scores for Shame Self-Talk and Guilt Self-Talk were calculated and compared to the scoring interpretation. A p<0.05 was considered significant.

**Results:** A total of 40 patients with RA were included, 36 women and 4 men, with a mean age of 54.2 years old [25-75]. Nine patients (22%) were illiterate, 42.5% were professionally active and 82.5% were married. The mean disease duration was 12.8 years [3-33], 80% of patients were on prednisone at a daily posolog of 7 mg [2.5-12.5], 62.5% were on csDMARDs and 27.5% on bDMARDs. The mean DAS 28 ESR and CRP were respectively 4.3 [1.6-6.9] and 3.6 [1-6.2]. The mean total score of the ESS was 45.3 [27-81] with subscale means of: 19 [12-37] for characteristic shame, 19 [10-30] for behavioral shame and 7.4 [4-16] for bodily shame. For the TOSCA-3S, the mean “shame self-talk Total” score was 33.8 [17-44], and the mean “guilt self-talk Total” score was 48 [37-55], which corresponds to ‘you often use’ for men and ‘you use an average amount’ for women, a shame and guilt self-talk.

**Conclusion:** Our RA patients experienced general feelings of shame and guilt, which correlate with demographic items and disease activity.
However, a case-control study with a larger population is necessary to determine whether patients with RA express more shame and guilt than their peers without RA.

ASSESSMENT OF EFFICACY, SAFETY AND IMMUNOGENICITY OF A TRIVALENT SPLT-VIRUS INFLUENZA VACCINE IN PATIENTS WITH RHEUMATIC DISEASES

Daria Bukhanova, Boris Belov, Galina Tarasova, Andrey Gordeev, Natalia Demidova, Shandor Erdes, Tatiana Dubinina, Maria Cherkasova, Mikhail Dzitilov, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: In current rheumatology practice concurrent infections produce significant negative impact on patients’ morbidity, mortality and quality of life. Based on WHO estimations the annual incidence of influenza in adult population amounts to 5-10% worldwide. Influenza can lead to hospitalization (3 to 5 million cases per year) and even death (250-500 thousand cases per year). Flu and its complications rates are higher in patients with rheumatic diseases (RD) as compared to general population. Therefore, prevention of influenza should be viewed as integral part of RD population management.

Objectives: To study the safety, efficacy and immunogenicity of inactivated split-virus influenza vaccine in patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS).

Methods: 126 subjects (90 females and 36 males, aged 22 - 82 y) with recent acute respiratory viral infections (ARVI) and flu episodes in medical records were enrolled, including 52 RA patients, 34 AS patients and 40 healthy volunteers as the control group. 39 RA pts received methotrexate (MTX), 12 - TNF inhibitors +MTX, 8 - Lefunomide, 2 – abatacept, 2 – sulfasalazine, 1 – tocilizumab + MTX. 19 AS patients were treated with nonsteroidal anti-inflammatory drugs (NSAIDs), 15 – with TNF inhibitors. The RD duration ranged from 2 months to 46 years. All participants were injected subcutaneously with one dose (0.5 ml) of the trivalent inactivated influenza vaccine containing the actual influenza virus strains, with ongoing therapy. The control visits were scheduled at baseline, and in 1, 3 and 6 months after vaccination (Visits 0, 1, 2 and 3, respectively). Standard clinical and laboratory tests were performed during each visit. Immunogenicity of vaccine was measured with ELISA test kits.

Results: Vaccine tolerability was good in 103 participants (77.4%). Post-vaccination pain, swelling and redness of the skin up to 2 cm in diameter were registered in 20 cases (15%), low-grade fever, myalgia and malaise were presented in 10 cases (7.5%). There was no casual relationship between these reactions and principal therapy, therefore, no modifications of therapeutic regimens were required, and complete resolution occurred within 24 hours without additional interventions. No RD exacerbations or new autoimmune disorders were observed during the FUP. At baseline mean pts’ DAS28 and BASDAI scores were 3.56 and 3.85, improving up to 1.99 and 3.09, respectively, 6mo post-vaccination. For the entire FUP there were no cases of influenza or influenza-like illness registered.

The portion of respondents to the vaccine is 70% in the group of patients with RD and 75% in the main group. The level of humoral immune response was not significantly different in the group of patients with RD and in the control. It is noteworthy that there were no significant differences in the level of post-vaccination response after a month (p = 0.6) or after 3 or 6 months of observation. In patients with AS, there were significantly more responses to vaccines in patients with a long duration of the disease and low activity according to the BASDAI index (p <0.05). There was no significant effect of the treatment of RH on the level of post-vaccination response; there were also no differences in the level of post-vaccination response between patients with different RD.

Conclusion: Therefore, our results show good tolerability, efficacy and immunogenicity of inactivated split-virus influenza vaccine in RA and AS patients. Future studies on larger patients’ populations are warranted for more complete evaluation of vaccine safety and efficacy.

Disclosure of Interests: None declared

FRI0032

HIGH INDEX OF SEDENTARY BEHAVIOR IN PATIENTS WITH INITIAL RHEUMATOID ARTHRITIS: DATA FROM A LONG COHORT OF INITIAL RA

Camilla Cadenas1,2, Ana Paula Gomides2, Talita Souza2, Luciana Muniz3, Pedro Henrique Almeida4, Sandor Balasamo5, Lia Mota2, Universidade de Brasília, Faculdade de Educação Física, Brasília, Brazil; 2Tribunal Superior Eleitoral, Fisioterapia, Brasilia, Brazil; 3Hospital Universitário de Brasilia, Brasilia, Brazil; 4Universidade de Brasília, Faculdade de Ceilândia, Brasilia, Brazil; 5UNEURO/GEPEFS, Brasilia, Brazil

Background: The abandonment of a healthy lifestyle can have great impact on the quality of life, the response to the treatment and the control of the symptoms, like pain and fatigue on RA patients. Smoking is a proven trigger in the pathophysiology of RA, but studies show that it also participates in inflammatory activity throughout the course of the disease. RA patients are more likely to develop various comorbidities and increased cardiovascular risk when compared to the general population.

Objectives: To access physical activity engagement along with alcohol and cigarette consumption.

Methods: A cross-sectional study was carried out with patients with rheumatoid arthritis who received treatment on the initial stage of RA and followed up during 15 years in an initial RA cohort of a University Hospital. Participants underwent standardized clinical evaluation and analysis of complementary exams. The study was approved by the Ethics Committee.

Results: A total of 107 RA patients were evaluated. In the sample, 98% of the women were found, with a median age of 52 years. The mean duration of illness was 12.8 years and 11.3% had erosive disease. In relation to the habits of life, the physical activity level, prevalence of alcoholism and smoking were investigated. In general, our population was characterized by non-alcohol users (93.5%), non-smokers (75.7%) and not engaged into regular physical activities (56.1%). In relation to frequency, 21.5% of the patients exercised a minimum of three times a week, 16.8% once or twice a week and 5.6% once or twice a month. The practice of physical activity may be difficult for the patient with RA, who often has functional limitations, but is still of great importance, since it improves the response to treatment, prevents the onset of other comorbidities, or worsening of previous diseases, complications and promotes the improvement of the quality of life.

Conclusion: Even with a multidisciplinary approach and health care professionals qualified to instruct and emphasize the importance of engaging in an active lifestyle, RA patients remain mostly sedentary after 15 years of follow up. Perhaps other strategies of intervention should be investigated to improve such habits.

FRIO033 QUANTIFERON GOLD-PLUS AND TUBERCULIN SKIN TEST REACTIVITY PREDICTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Juan Pablo Cárdenas-Luna1, Dioniñol Gómez-Pulido2, Graciela Serna-Peña1, Gisela García Aréellano1, Mayra Antonio-Castillo-Nava1, Juan Manuel Muñoz-Ayala1, 1Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico; 2Hospital Universitario Dr. José Eleuterio González, CIPTIR, Monterrey, Mexico

Background: RA patients have high latent tuberculosis (LTBI) prevalence (20-37%). In Mexico, ranges from 21.7% to 31.3% using tuberculin skin test (TST). The methods to detect LTBI are TST and IGRA. Quantiferon (QFT-Plus) uses an antigen tube (TB1) that stimulates CD4+T cells and an additional tube (TB2) that also stimulates CD6+T cells.

Objectives: Determine the LTBI prevalence, variables that predict QFT-Plus and TST results and the concordance between TST and QFT-Plus in RA patients.

Methods: A cross-sectional study in RA patients from the rheumatology department of the University Hospital "José E. González" in Mexico between October 2017 and June 2018. RA patients with EULAR 2010 classification criteria without a history of tuberculosis (TB) were included. QFT-Plus was performed according to manufacturer instructions. TST was applied with the Mantoux technique; a 5mm cutoff was used. The square chi and Fisher test were used for proportions, Mann-Whitney to compare means, trend analysis using linear trend test and a binary logistic regression model for variables related to positivity to both tests.

Results: We included 111 patients (table 1), the mean age was 51.9 years, 92.3% were women, disease duration 8.7±8.8 years. QFT-Plus was positive in 46 (41.6%) patients. TST was positive in 31 (27.9%) patients. Agreement between tests was 73.7% (kappa=0.45, p<0.001). The majority of patients were using conventional DMARDs (86.7%), none of the patients were using biologic DMARDs. In the linear-to-linear association analysis there was a trend towards TST negative result with the use of ≥2DMARDs (p=0.049 for trend) (figure 1). In the logistic regression model we found a significant relationship between a positive TST active TB exposure (OR 8.5, CI 95% 1.4-51.7; p=0.01) and an inverse relationship between the positive TST and antimalarials (OR 0.11, CI 95% 0.001-0.8), none of the variables interfered with QFT-Plus results.

Conclusion: The LTBI prevalence in RA patients in our study is similar to countries with a high TB burden. We recommend considering RA patients as a high-risk population for LTBI. An intermediate agreement between TST and QFT-Plus was found. The use of antimalarials and ≥2DMARDs influence the TST reactivity, none of the variables altered the QFT-Plus results. Based on the results, we recommend the Quantiferon Gold Plus over TST for the LTBI screening in RA patients.

FRIO034 A LATIN-AMERICAN PREVENTIVE CARDIO-RHEUMA CLINIC: A CASE-CONTROL STUDY

Dionicio Ángel Galaz-Delgado1, José Ramón Azpíri-López2, Irís Izamín Colunga-Pedraza1, Marilyn Casco-González1, Karla Paola Cuéllar-Calderón1, Íñigo Cecilia Reynosa-Silva1, Carolina Marlene Martínez-Flores2, Guillermo Contreras1, Cinthia Yaneth Guillet-Gutiérrez1, Guillermo Elizondo1, 1Hospital Universitario “Dr. José Eleuterio González”, UANL, Rheumatology, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González”, UANL, Cardiology, Monterrey, Mexico; 3Hospital Universitario “Dr. José Eleuterio González”, UANL, Radiology, Monterrey, Mexico

Background: It has been described an increased prevalence of cardiovascular diseases (CVD) in rheumatoid arthritis (RA) patients. When compared with the general population, CVD mortality is 50% higher in RA (1). It is reported a 35.3% prevalence of CVD in Latin-American population with RA (2). Cardio-rheuma (CR) clinics were designed to enhance detection, prevention and treatment of CVD in patients with rheumatic conditions. Our clinic located in the University Hospital in Monterrey Mexico, is the first and only established in Latin-America since 2014.

Objectives: To describe the characteristics of patients with RA attending to a Latin-American CR clinic and compare the findings by carotid ultrasound (US) and echocardiography to controls.

Methods: Cross-sectional, observational, comparative study. RA patients aged 40 to 75 years that fulfilled the 2010 EULAR criteria and matched controls were included. Patients with prior atherosclerotic CVD and other lap syndromes were excluded. Clinical history, blood samples, physical exam, carotid US and echocardiography were performed. Carotid plaque (CP) was defined as a focal narrowing ≥0.5 mm of the surrounding lumen or a carotid intima media thickness (cIMT) ≥1.2 mm, and increased cIMT was defined as ≥0.9 mm. Transthoracic echocardiogram was performed and reviewed by 2 board-certified cardiologists. Differences were solved by consensus. Categorical variables are expressed as total number (%), and numerical variables as median (q25-q75). Chi square and Mann-Whitney U-test were used to compare groups and considered significant if p<0.05.

Results: A total of 336 RA patients and 144 controls were included (Table 1). Table 2 summarizes echocardiographic and carotid US findings; ejection fraction was higher in controls than RA patients, prevalence of bilateral CP and increased cIMT was significantly higher in RA patients.
Inflammatory Arthritis Induced by Immune-Checkpoint Inhibitors: Results from a Combined Rheumatology/Oncology Outpatient Clinic

Disclosure of Interests: None declared

References:

Conclusion: RA patients from this clinic had lower ejection fraction, more prevalence of cIMT and bilateral CP when compared to controls. It is important that rheumatologists perform a complete evaluation of their patients, in which cardiovascular assessment should be included.

EFFECTS OF DISEASE ACTIVITY, ILLNESS PERCEPTION, SOCIAL SUPPORT AND COPING METHODS ON QUALITY OF LIFE IN THE PATIENTS WITH RHEUMATOID ARTHRITIS AND FIBROMYALGIA SYNDROME

Hakan Kesmen, Ahmet Ilyas Ergenci, Ayhan Bilgic, Samsun Education and Research Hospital, Physical Medicine and Rehabilitation, Samsun, Turkey; 19 Mayis University Faculty of Medicine, Medical Medicine and Rehabilitation, Samsun, Turkey

Background: In chronic diseases, social support, illness perception and coping methods have important effect on quality of life.

Objectives: In the present study, we aimed to compare the quality of life (QOL) of the patients with rheumatoid arthritis (RA) with fibromyalgia (FMS) patients and healthy controls and to assess the relationship between QOL and illness perception, social support, disease coping methods in the patients with RA and FMS.

Methods: Fifty-eight patients with RA, 50 patients with FMS and 50 healthy controls were enrolled in the study. Visual Analogue Scale (VAS), QOL (Short Form SF-36), illness perception (Revised Illness Perception Scale, IPQ-R), social support (Multidimensional Perceived Social Support Scale, MSPSS) were assessed in the patients. In RA patients, disease activity was evaluated with DAS 28 and Clinical Disease Activity Index (CDAI), and functional status was evaluated with Health Assessment Questionnaire (HAQ). Fibromyalgia Impact Questionnaire (FIQ) scale was used in the clinical assessment of FMS patients.

Results: While RA and FMS patients had higher COPE-emotional and COPE–problem scores than the healthy controls (p<0.05), there was no significant difference between the patients with RA and FMS (p>0.05).

Regarding the all MSPSS scores, there was no significant difference between the three groups (p>0.05). FMS patients had lower scores than the RA patients and healthy controls regarding the physical function, pain, social functioning and mental health subscales of SF-36 (p<0.05).

In RA patients, MSPSS-friend and MSPSS-special one scores were positively correlated with all subscales of SF-36. IPQ-R consequences scores were positive correlations between IPQ-R treatment control and SF-36 mental and high risk subscales (p<0.05).

Conclusion: In RA and FMS patients, QOL and physical functions were found to be related with illness perception, social support and coping methods as much as disease activity.

DIAGNOSTIC PERFORMANCE OF CURRENT CVR SCORES FOR THE DIAGNOSIS OF CAROTID PLAQUE IN MEXICAN-MESTIZO RA SUBJECTS

Dionicio Angel Galarza-Gallego1, Iris Jazmin Colunga-Pedraza1, Jose Ramon Azpin-Lopez2, Karla Paola Cuellar-Cadera1, Jelena Cecilia Reynoso-Silva3, Marlida Castro-Gonzalez4, Carolina Marlene Martinez-Flores2, Jose Dioniso Castillo-Ortiz5, Alberto Cardenas1, 1Hospital Universitario ‘Dr. Jose Eleuterio Gonzalez’; UANL, Rheumatology, Monterrey, Mexico; 2Hospital Universitario ‘Dr. Jose Eleuterio Gonzalez’; UANL, Cardiology, Monterrey, Mexico; 3Unidad de Artritis y Reumatismo, Guadalajara, Mexico

Background: Rheumatoid arthritis (RA) is an inflammatory disease with an increased mortality compared to the general population. The measurement of carotid intima media thickness (CIMT) is used as an independent marker of subclinical atherosclerosis.

Objectives: To determine the prevalence of carotid plaque (CP) in a cohort of Mexican RA subjects and diagnostic performance of cardiovascular risk (CVR) calculators for the prediction of augmented CIMT and CP.

Methods: A cross-sectional study of subjects aged from 40-75 years that fulfilled the 2010 ACR/EULAR RA criteria. Exclusion criteria: previous CV disease and overlap syndromes. CVR was calculated by 6 scales: ACC/AHA 2013, Framingham-lipids (FRS-lipids), Framingham-Body Mass Index (FRS-BMI), Reynolds Risk Score (RRS), QRISK2 and SCORE. Carotid ultrasound (US) was performed by a board-certified radiologist and reviewed by other two. We defined an augmented CIMT as ≥0.9 mm and CP as CIMT ≥1.2 mm. We categorized subjects in 3 groups: 1) normal carotid US, 2) augmented CIMT, and 3) CP. We used Kruskal-Wallis test to compare the groups.

Results: 130 patients were included, 124 (95.4%) were females with median age of 57 years old and disease duration of 9.7 years. Almost 50% of the subjects with CP were in the low-risk strata of every CVR calculator. The presence of CP was higher in subjects categorized as moderate/high risk using ACC/AHA 2013 CVR score (p=0.013), moderate/ high risk strata of QRISK2 (p=0.004), and high-risk strata of ACC/AHA 2013 CVR score (p=0.02). Of these 3, the highest sensitivity was obtained by the moderate risk stratum of QRISK2 with 51%; the highest specificity was obtained by the high-risk stratum of the ACC/AHA 2013 CVR score with 84%.

</tbody>
</table>

Conclusion: Increased CIMT or CP might be unidentified if the risk is exclusively determined by CVR calculators. Patients with a CIMT ≥0.9 mm had an average score that placed them in the low-risk strata, leading to an underestimation of their real CVR. Calculators can be helpful to estimate the CVR, however, they don’t seem to be an adequate screening tool for an increased CIMT or CP. Meanwhile, to assess CVR precisely, a carotid US should be performed in all RA patients.

HERPES ZOSTER IN RHEUMATOID ARTHRITIS: PROSPECTIVE SINGLE CENTER STUDY OF 390 RA PATIENTS FOR 5YEARS

Lucia Dominguez1, Vanessa Calvo-Rizo1, Paz Rodriguez-Cundin2, Virginia Portilla2, Nuria Vegas-Renega1, Francisco Manuel Antollín-Juan2, Maria Henar Rebollo Rodriguez1, Alfonso Corrales2, D. Prieto-Peria, Monica Calderon-Goecke1, Miguel A. Gonzalez-Gay1, Ricardo Blanco1, 1Hospital Universitario Marques de Valdecilla, Rheumatology, Santander, Spain; 2Hospital Universitario Marques de Valdecilla, Preventive Medicine, Santander, Spain

Background: Immunosuppressed patients such as Rheumatoid Arthritis (RA) patients have a greater risk (1.5-2 times) of presenting herpes zoster (HZ). Both, the disease itself and the use of immunosuppressive...
THE LUNG IN AN ENGLISH COHORT OF RHEUMATOID ARTHRITIS PATIENTS – AN OVERVIEW OF DIFFERENT TYPES OF INVOLVEMENT AND TREATMENT

Anna Catarina Duarte1, Joanna Porter2, Maria José Leandro3, 1Hospital García de Orta, Rheumatology Department, Almada, Portugal, 2University College London, Respiratory Medicine, London, United Kingdom, 3University College London, Rheumatology Department, London, United Kingdom

Background: Lung disease is described in 5-20% of patients (pts) with Rheumatoid arthritis (RA) and affects parenchyma, pleura, airways and vasculature; drug-induced pulmonary disease also occurs. It is associated with a higher mortality and identification of safe and effective drugs is essential.

Objectives: Characterize lung involvement in a RA cohort; evaluate rituximab (RTX) effectiveness and safety in RA associated interstitial lung disease (ILD).

Methods: Retrospective analysis of the electronic records from RA cohort followed at University College Hospital. Lung involvement was based on high resolution computed tomography. Demographic data, smoking status, complementary exams at baseline/follow-up and therapies used were analysed. A sub-analysis of pts treated with rituximab (RTX) evaluated response at 12, 24 and 36 months. Declines of 15% in gas transfer from baseline and/or 10% in forced vital capacity were recognized.

Results: From 1129 RA pts, 87 (7.7%) had documented lung involvement. Mean age at last follow-up was 68.3±12.2 years, 74.7% were female and 85.1% Caucasian. Median disease duration was 14 (IQR 8-29) years. 54% of pts had erosive disease. Rheumatoid factor was positive in 88.1% and anti-citrullinated protein antibodies in 87.8%. 23 pts had positive antinuclear antibodies (25 missing data) and 4 anti-Ro, 2 anti-Scl-70 and 2 anti-PL12. Secondary Sjögren’s syndrome occurred in 6.9%, cutaneous rheumatoid nodules in 5.7% and cutaneous vasculitis in 1.1%. 11.5% and 43.7% were current and previous smokers, respectively. Mean interval between onset of articular and pulmonary symptoms was 12.3 years; 2 pts had lung disease as a prior manifestation. Types of lung involvement are shown in table 1.

At last follow-up appointment 22 pts were still on methotrexate (MTX) and 27 had previously received it. MTX-acute pneumonitis occurred in 2 pts, both in the 1st year of treatment. RTX was used in 26 pts (57.8%) with IILD (14 nonspecific interstitial pneumonia-NISP, 8 usual interstitial pneumonia-UIP, 2 organising pneumonia-OP). The mean number of cycles was 4 (range 1-12). Two pts were concomitantly receiving mycophenolate mofetil and 1 azathioprine. RTX treatment outcomes are shown in table 2.

FR10039
There were 18 (20.7%) deaths, 7 of them related to ILD (4 UIP, 3 NSIP) and occurred 8.8 years after ILD diagnosis. Two were due to infection, but none was felt to be directly related to immunosuppressive therapy.

Conclusion: Lung disease occurred in 7.7% of our cohort, with ILD being the commonest presentation (51.7%). MTX was widely used in pts with lung disease with only 2 cases of acute pneumonitis. Although the number of ILD pts treated with RTX was small, the drug improved/stabilized the disease in most NSIP and OP pts. UIP is usually progressive, but our data suggest that disease progression might be put on hold with RTX, at least in a subset of pts.

PR0040 GENDER DISCREPANCY IN RHEUMATOID ARTHRITIS: PATIENTS’ AND PHYSICIANS’ PERSPECTIVE
Ilaria Ducci, Francesca Spinelli, Alessio Altobelli, Bruno Lucchino, Chiara Gioia, Carmelo Pirone, Guido Valesini, Fabrizio Conti, Manuela Di Franco, Policlinico Umberto 1, Rheumatology, Department of Internal Medicine and Medical Specialities, Roma, Italy

Background: Rheumatoid Arthritis (RA) is more prevalent among female individuals. Sex and gender differences may influence disease’s progression and prognosis. To date, the influence of physicians’ gender in the evaluation of RA activity is still largely unknown.

Objectives: aim of the study was to investigate a possible discrepancy in the assessment of disease activity in RA patients evaluated by male and female physicians. Further aim was to compare patient and evaluator perceptions about disease activity and global health status.

Methods: we enrolled consecutive RA patients. Each patient was separately visited by a female and a male rheumatologist of the same age and training level. Tender (TJ) and swollen joints (SJ) count was performed. Global Health (GH), physician’s (E-VAS) and patient’s (P-VAS) disease activity were reported using a visual analogue scale (VAS 0-100). Both examiners were blinded on ESR and CRP. A third rheumatologist assessed disease activity by DAS28-ESR, CDAI and SDAI.

Results: we enrolled 154 patients (122 F, 32 M). GH and P-VAS were significantly higher when collected by the female examiner compared to the male one (respectively, 41.1 ± 24.4 vs 36.1 ± 24.3, p<0.0001 and 41.7 ± 26.2 vs 35.3 ± 25.4, p<0.0001; figure 1), as well as DAS28-ESR values (3.19 ± 1.5 vs 2.97 ± 1.5, p=0.0001; figure 2) but not CDAI and SDAI. On the contrary, male E-VAS was significantly higher compared to female one (26.8 ± 27 vs 20.5 ± 20.8; p<0.0001; figure 1). GH, P-VAS and DAS28 significantly differ when the analysis was restricted to female patients (p=0.0001); among male patients, only P-VAS was significantly higher when collected by the female examiner (36.5 ± 24.7 vs 30.4 ± 25.4; p<0.0001). According to the DAS28-ESR cut off, 39.6% of patients were in remission when evaluated by the female examiner compared to 42.9% when examined by the male physician; the probability of being judged as having an active disease was not different between the female and the male examiner (p=ns). Overall, the agreement between the female and male evaluation of disease activity was high [Intraclass correlation coefficient (ICC-K) 0.92 for GH; 0.81 for E-VAS; 0.89 for P-VAS; 0.95 for DAS28-ESR; p<0.0001]. When comparing patient and examiner perception of the disease activity, P-VAS values were significantly higher than E-VAS in both female and male examiners (41.7 ± 26.2 vs 20.5 ± 20.8; 35.3 ± 25.4 vs 26.8 ± 27.1; p<0.0001; figure 3).The general agreement between male and female examiner and the whole patient population was moderate (K 0.65 and 0.62, respectively; p<0.0001), with the lowest agreement between female patients and male examiner (K 0.58; p<0.0001). Female physician had an higher agreement with both male and female patients (K 0.78, K 0.62 respectively; p<0.0001).

Conclusion: subjective measure of global health status and disease activity (GH, P-VAS) are generally higher when collected by a female examiner compared to a male one, especially among female patients. This gender discrepancy in subjective measures could influence the evaluation of disease activity indices; however, this does not affect the probability of being defined in remission. Overall, patients have a higher perception of disease activity compared to the health care providers, and the agreement between physician and patients is only moderate, with female patients having the worst perception. Female physician tend to be more in agreement with the patients’ judgement of disease activity maybe because of a more emphatic setting established by the female health care provider.
