Background: Insufficient patient adherence to treatments in inflammatory arthritis (IA) including rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA), crystal-induced arthritis and connective tissue diseases (CTD) may lead to complications, unnecessary treatment switches, and increased costs. Patient adherence to treatment should be assessed, however how to evaluate it has not been determined.

Objectives: To assess the psychometric properties of questionnaires to measure adherence to treatment in IA.

Methods: We performed a systematic literature review (SLR) using three central databases (Pubmed, Cochrane, Embase) and several websites in January 2019. The scope was limited to IA (i.e., RA, SpA, PsA, CTD, crystal-induced arthritis, vasculitis, and auto-inflammatory diseases), and disease-modifying drugs (i.e., mainly conventional DMARDs, biologics and targeted synthetic DMARDs). All questionnaires used to assess adherence were collected, then a specific search using the questionnaire name was run to obtain data on their psychometric properties including overall validity (sensitivity (Se), specificity (Sp) and Cronbach coefficient (CC), reliability, and sensitivity of change, following the OMERACT filter. These properties were analyzed semi-quantitatively.

Results: After screening 1209 publications and 194 other documents, 242 relevant papers were analyzed for measuring adherence (63.6% in RA, 8.7% in SpA, 6.6% in PsA, 14.5% in CJD and 19.0% in CTD). The number of articles using adherence questionnaires by disease was: 69/154 in RA, 14/21 in SpA, 27/40 in systemic lupus erythematosus (SLE), 9/16 in PsA, 8/35 in crystal induced arthritis and 4/6 in other CTD. Four questionnaires were used to evaluate drug adherence (Table1). The most used questionnaire was the MMAS in all diseases except in RA where the CQR was more used. The CQR was validated in 85 patients with IA against as external standard, electronic medication monitoring (Se 62 to 98%, Sp 67 to 97% and CC of 0.71 to 0.85). The MARS was validated in 55 patients with SLE against adherence based on pharmacy refill information (Se 87%, Sp 86% and CC of 0.70). The MMAS was validated in 91 patients with gout against medication possession ratio Se 81 to 93%, Sp 44 to 53% and CC of 0.54). The MARS was validated in 108 patients with RA (Se 13 to 53%, Sp 57 to 94% and CC 0.60 to 0.75). Reproducibility was correct but copyright posed issues (Table).

The + represents a semi-quantitative summary of the available literature with more + meaning higher/better results (from - to +++)

Conclusion: Four questionnaires are being used to measure medication non-adherence in IA; the most used is the MMAS which is unfortunately copyrighted and not fully validated in rheumatology. The CQR and MASRI questionnaires were the most validated in rheumatology, but the CQR is long and the MASRI only used for SLE. Thus it appears that to date, a simple, reliable and valid questionnaire to assess drug adherence is lacking.

DUTCH TRANSLATION AND PSYCHOMETRIC PROPERTIES OF A PATIENT REPORTED EXPERIENCE MEASURE (PREM) FOR PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

Esther Berkers1, Casper Webers2, Annelies Boonen1, Peter Ten Krooster1, Harald Vorkema1, Astrid van Tubergen1, 1MUMC, Maastricht, Netherlands; 2MIST, Enschede, Netherlands.

Background: Evaluating the quality of care provided as perceived by patients can be helpful in order to reveal areas for improvement, identify best practices and stimulate interventions to further improve these. This can be done with a patient reported experience measure (PREM). Such a PREM, containing 23 questions in 7 domains has been developed and validated specifically for patients with rheumatic conditions, including rheumatoid arthritis (RA) and spondyloarthritis (SpA), in the United Kingdom (box 1) (1). Until now, no translated and validated Dutch questionnaire is available for patients with SpA or RA in the Netherlands.

Objectives: To translate the PREM into Dutch and to study its psychometric properties in patients with SpA or RA.

Methods: The PREM was independently translated into Dutch by two researchers fluent in the English language (one rheumatologist and one healthcare scientist) and a consensus version was generated which was checked by two other researchers (one rheumatologist and one methodologist). The final version was piloted in two Dutch real-life quality registries for patients with SpA or RA: SpA-Net and DREAM-RA, respectively. Patients completed the PREM annually starting from December 2016. For the current cross-sectional analysis, the most recently completed PREM from each patient was included. Feasibility was assessed by the median and interquartile ranges (IQR) of completion times. Reliability was assessed by internal consistency (Cronbach’s α) and homogeneity (corrected item-total correlations r p)) within each domain. Content validity was assessed by floor- and ceiling effects (>15%) for each question. Divergent validity was assessed by Spearman rank correlation coefficients (rs) between the average score of each domain and outcome measures for disease activity (BASDAI, ASDAS or DAS28), daily functioning (BASFI, HAQ or HQAG-S), health status (ASAS-HI) and quality of life (SF-36).

Results: The PREM was completed by 282 patients with SpA and 378 patients with RA. The average age and the proportion of female patients with SpA was lower compared to patients with RA (54.2 (SD 12.2) versus 65.1 (SD 11.9) years and 47.9% versus 65.1% female patients, respectively). Average disease activity was high in patients with SpA but low in patients with RA (mean ASDAS 2.2 (SD 0.9), mean DAS28 2.3 (SD 1.2)). The median time to complete the PREM was 5.5 minutes (IQR 2.7) in SpA-Net and 5.4 minutes (IQR 2.3) in DREAM-RA. Internal consistency of all domains was considered good for patients with SpA or RA (0.70 ≥ α ≥ 0.95), except for the domain Daily living and physical comfort in patients with RA (α=0.65). In both populations, thresholds for homogeneity were exceeded within three domains (rs > 0.7) suggesting possible item redundancy. Ceiling effects were found in 75% (SpA) and 90% (RA) of the questions. As expected, correlation coefficients showed that nearly all domains of the Dutch PREM were independent of scores on outcome measures in both patients with SpA and RA (0.3 ≤ r p ≤ 0.3).

Conclusion: The Dutch PREM has acceptable psychometric properties to assess perceived quality of care in patients with SpA or RA. The homogeneity within three domains could be improved. The results for perceived quality of care are not affected by scores on outcome measures for disease activity, physical functioning, health status and quality of life.

SAT0631 CRITERION VALIDITY AND CUT-OFFS OF THE FLARE ASSESSMENT IN RHEUMATOID ARTHRITIS (FLARE-RA) QUESTIONNAIRE: INTERNATIONAL COLLABORATION

Elena Myasoedova1, Annette de Thurn2, Marie-Line Erpelding2, Emilie Schneeberger3, Thomas Maribo4, Gustavo Citera5, John Davis6, Eric Matteson7, Cynthia S. Crowson8, Bruno Fautrel9, Francis Guillerm9, Mayo Clinic, Rochester, MN, United States of America; 2Aarhus University Hospital, Aarhus, Denmark; 3University of Lorraine, Nancy, France; 4Instituto de Rehabilitacion Psicosocial, Buenos Aires, Argentina; 5DEFACTUM, Aahus, Denmark; 6University Pierre et Marie Curie, Paris, France.

Background: Flares are inherent to the rheumatoid arthritis (RA) disease course and associated with poor clinical outcomes. The self-administered Flare Assessment in Rheumatoid Arthritis (FLARE-RA) questionnaire was devised and validated for detection of current and recent flares in RA, taking into account both patient and provider perspectives [1, 2]. The FLARE-RA questionnaire includes arthritis-related subscale and general subscale. The overall score for the questionnaire is defined as the global scale, with scoring from 0 (no flare) to 10 (maximum flare).

Objectives: To define the cross-cultural criterion validity of the FLARE-RA questionnaire and cut-off(s) for definition and decision in four different countries, using different anchor items in patients with RA.

Methods: This cross-sectional study included adult patients with prevalent RA (per 2010 ACR/EULAR criteria) attending outpatient rheumatology clinics in France (n=138), Denmark (n=253), USA (n=75), and Argentina (n=105). Flare occurrence over the past 3 months was assessed using the FLARE-RA questionnaire. The cut-offs for the FLARE-RA score were defined using the following anchor items obtained at the same encounter: 1) Patient report of flare; 2) DAS28-ESR>3.2; 3) Change of anti-rheumatic treatment. Detection of the optimal cut-off for the FLARE-RA questionnaire was performed with distance (0,1) method, based on the area under the receiver operating characteristic curve (AUC).

Results: The study included 571 patients with RA (mean age 56.9 years, 75.3% female). The discrimination for the FLARE-RA was acceptable-to-excellent: AUC for the global FLARE-RA score ranged from 0.71 to 0.92. The summary of optimal cut-offs for the FLARE-RA questionnaire is presented in the Table. The cut-offs for the FLARE-RA score were overall lowest using “patient’s report of flare” and highest using “change of anti-rheumatic treatment” as an anchor item: cut-offs for the global score for patients with RA duration 2-5 years: 1.82 and 4.35, respectively; for patients with RA duration >5 years – 2.18 and 3.18, respectively. The cut-offs corresponding to DAS28-ESR>3.2 were lower in patients with RA disease duration >5 years than in those with RA duration 2-5 years.

Table: Summary of FLARE-RA optimal cut-offs by RA disease duration using different anchor selection methods

<table>
<thead>

<td>4.40</td>
<td>3.67</td>
</tr>
<tr>
<td>Change of anti-rheumatic treatment</td>
<td>4.00</td>
<td>4.50</td>
</tr>
</tbody>
</table>

Conclusion: The FLARE-RA questionnaire has acceptable-to-excellent discriminative capacity across the tested anchor items. Patient report of flare corresponds to a lower FLARE-RA cut-off score than DAS28-ESR and change of anti-rheumatic treatment, suggesting the hierarchy of flare recognition from flare self-perception to its detection by DAS28 to treatment change by the rheumatologist. More studies are needed to ensure the early recognition of flares and the appropriate alignment between flare and the adjustment of anti-rheumatic and other medications.

SAT0632 NEUTROPHIL ACTIVATION IDENTIFIES PATIENTS WITH ACTIVE POLYARTICULAR GOUT – A NOVEL BIOMARKER?

Daisy Vedder1, Martijn Gerritsen1, Michael Nurmohamed1, Ronald van Vollenhoven2, Christian Lood1, 2Amsterdam Rheumatology and Immunology center, location Reade, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology center, Amsterdam UMC, Amsterdam, Netherlands; 3University of Washington, Department of Medicine, Division of Rheumatology, Seattle, United States of America

Background: Neutrophils are key immune cells participating in host defense through several mechanisms, including the formation of neutrophil extracellular traps (NETs). Although beneficial from a host-pathogen perspective, excessive neutrophil activation has been linked to inflammation and autoimmunity, including systemic lupus erythematosus (SLE) and gout.(1) In gout models, uric acid crystals induce NETosis. Though NETs are known to induce marked inflammation through TLR9- and cGAS-dependent pathways, as well as partake in induction of tissue damage and thrombotic events, the role of NETs in human gout has not been carefully investigated.

Objectives: Our objective is to investigate evidence of systemic neutrophil activation, and the clinical utility of neutrophil-derived biomarkers in gout. We hypothesize that uric acid crystals will activate neutrophils to undergo NET formation, with these processes contributing to immune cell activation and local joint destruction.

Methods: Plasma samples from 75 gout patients participating in the ‘Readys gout cohort Amsterdam’ were compared with 30 healthy controls (HC). Levels of NETs, and NET-derived markers (cell-free DNA and peroxidase activity) were analyzed using a MPO-DNA ELISA, as well as fluorimetry.(2) Levels of calprotectin (S100A8/A9) were analyzed by ELISA. Mitochondrial (mt, COXII), as well as genomic (n, RPLP0) DNA levels orimetry.(2) Levels of calprotectin (S100A8/A9) were analyzed by ELISA. Mitochondrial (mt, COXII), as well as genomic (n, RPLP0) DNA levels orimetry.(2) Levels of calprotectin (S100A8/A9) were analyzed by ELISA. Mitochondrial (mt, COXII), as well as genomic (n, RPLP0) DNA levels. Results: Levels of NETs, as well as other neutrophil biomarkers, were significantly increased in gout patients as compared to healthy subjects (p<0.01, Figure 1A). In contrast to SLE, gout patients did not have elevated levels of circulating mtDNA (p=0.96), but only nDNA (p=0.006). No associations were found between markers of cell death (mtDNA and NETs) and disease activity. Peroxidase activity correlated with disease activity (RAPID score: r=0.43, p<0.01, RAPID function: r=0.24, p=0.001) and inflammation markers (CRP: r=0.40, p<0.01, and ESR: r=0.43, p<0.001). Involvement of ankle and wrist resulted in significant higher peroxidase levels compared to mono-articular disease (p<0.01, and p<0.03, respectively), suggesting peroxidase activity being a marker of polyarticular gout (Figure 1B). Calprotectin (S100A8/A9) correlated with the inflammation markers CRP and ESR (r=0.30, p=0.01, and r=0.30, p=0.001, respectively) and morning stiffness, especially in patients with chronic polyarticular gout (r=0.61, p=0.001).

Conclusion: To our knowledge, this is the first report demonstrating presence of NETs in the peripheral blood of gout patients. Although markedly elevated, levels of NETs did not associate with markers of disease activity or inflammation, possibly due to the lack of inflammatory mitochondrial DNA within the NETs. Even so, our data demonstrate an important role of neutrophils in gout pathogenesis, with neutrophil activation markers associating with characteristics of active, and more pronounced polyarticular disease.

SAT0633 PREGNANCY SUCCESS RATE AND RESPONSE TO HEPARINS AND/OR ASPRIN DIFFERS IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS ACCORDING TO THE GAPSS SCORE

Massimo Rapis1, Irene Cecchi1, Karen Schreiber1, Elena Rubin1, Savino Sciascia1, Dario Roccato1, 1University of Turin, Turin, Italy; 2Copenhagen Lupus and Vasculitis Clinic, Copenhagen, Denmark

Background: Current standard of care (SoC) in pregnancy for patients with Systemic lupus erythematosus (SLE) and/or aPL positivity includes treatment with low dose aspirin (75–100mg/day) and low molecular heparin or unfractionated heparin. However, up to 30% of women continue to have pregnancy complications despite SoC. Therefore, identifying patients that are at greater risk to develop pregnancy complications despite the SoC and might benefit from additional therapeutic approaches, is still an unmet clinical need.

Recently, our group conceived and validated the global antiphospholipid syndrome score (GAPPS) [1], as a risk score for predicting aPL-related clinical manifestations (thrombotic and/or pregnancy morbidity).

Objectives: We aimed to investigate response to SoC in women with SLE and/or aPL positivity when stratifying their risk according to GAPPS Score.

Methods: 143 women ever pregnant treated with SoC therapy with SLE and/or aPL positivity were retrospectively included. Data on cardiovascular risk factors and aPL positivity were retrospectively collected. The individual GAPPS was then grouped according to the patients’ GAPPS low risk (<6), medium risk (6-11) and high risk (≥12).

Results: The analysis included 143 patients (mean age 30.8 ± 6.4) with SLE (122; 85.3%) and/or aPL positivity, for a total of 352 pregnancies.

![Graph](image)

![Graph](image)
Overall, we observed a live birth rate of 70.5%, with a total of live birth of 248 out of the 352 pregnancies. Forty-five patients (31%) experienced at least one event of PM, defined as early or late. When considering patients who ever experienced PM while treated with SoC, all patients in the high risk group (GAPSS ≥12) experienced PM, while patients in the medium group (GAPSS 6-11) had a significant higher rate of PM when compared to the low risk group (GAPSS < 6) group [29 (43.9%) patients V.s. 100(62.1%) and 137(82.5%), respectively; p<0.05]. Furthermore, patients with medium risk group also had significantly lower birth rates, when compared to the other groups [11(40.7%) live births V.s. 100(62.1%) and 137(82.5%), respectively; p<0.05]. Regarding the number of pregnancies in the three groups, patients in the high risk group had significantly lower live birth rates, when compared to the other groups [11(40.7%) live births V.s. 100(62.1%) and 137(82.5%), respectively; p<0.05].

Figure 1 resumes the results of PM and live births divided in the three groups.

Conclusion: GAPSS might be a valuable tool for identifying patients with a higher likelihood of response to SoC.

Methods: Baseline data from two phase 3 trials investigating oral salmon calcitonin OA, NCT00486434 and NCT00704847 (total N=2206), was analyzed in a post-hoc cross-sectional analysis. Patients with self-reported current or previous depression, anxiety or post-traumatic stress syndrome (PTSD) were selected and compared to a control group, matched by sex, age, BMI and JSW. Spearman’s correlation coefficient between JSW and WOMAC pain was calculated for both groups. Multiple regression analyses of both groups with WOMAC pain as the outcome variable, and age, sex, body mass index (BMI) and baseline JSW or KL-grade as explanatory variables were performed.

Results: In the AD group, 149 patients had AD in medical history of which 123 reported the condition as ongoing at baseline. The study groups of AD and matched controls (MC) were comparable in terms of age, sex, BMI, JSW, KL-grade and WOMAC pain. Associations between pain and JSW In the AD group, no significant correlation between JSW and WOMAC Pain score was found, while BMI was found to be weakly associated with WOMAC pain (R= 0.19, p=0.02) in the multiple regression analysis. In the MC group, a statistically significant (p=0.004), correlation (R= -0.24) was found between JSW and pain indicating that lower JSW was associated with higher pain, with JSW accounting for approximately 6% of the total natural variation behind reported pain. In addition, a positive significant association between male sex and WOMAC pain (R=0.18, p=0.04) was found. The univariate linear relationship between JSW and pain is illustrated in Figure 1, and multivariate analyses are shown in Table 1.

Table 1. Associations between WOMAC pain, JSW (in red) and other baseline covariates

</tr>
</tbody>
</table>

Associations between pain and KL-Grade In the model evaluating associations between KL-grade and symptoms, there was no correlation between KL-grade and symptoms in the AD group. Similar to the findings relating to JSW, in the MC group, a weak (R=-0.16), borderline...
statistically significant association (p<0.07) was found between KL-grade and WOMAC pain.

Conclusion: A marked structure-symptoms discordance was found in OA patients with AD, while a statistically significant correlation was seen in matched controls without AD. The results suggest that exclusion of trial patients with anxiety and depression in medical history may improve the accuracy of pain reporting in clinical OA trials.

SAT0635 PATIENT-PERCEIVED RESIDUAL BURDEN OF PSORIATIC ARTHRITIS IN PATIENTS IN REMISSION/LOW DISEASE: AN ANALYSIS OF 444 PATIENTS

Laure Gossec, Maarten de Wet, Clémence Gorlier, Rossana Scrivero, Juan D. Cañete, Penelope Palominos, Ying Ying Leung, Ennio Lubrano, Sandra Tålli, Andrea Balanescu, Uta Kiltz, Sibel Aydin, Inna Gaydukova, Lihi Eder, Anna-Maria Orbai, Josef S. Smolen, Laura C. Coates. RefFlap working group, PARIS, France

Background: The objective of treatment in psoriatic arthritis (PsA) is remission or low disease (ref1). However, there may remain residual patient burden in patients where inflammation is controlled.

Objectives: To explore patient-perceived burden of disease in PsA patients in remission or low disease, when using different definitions of remission.

Methods: RefFlap (NCT03119805, ref2) was an observational study in 14 countries of consecutive adult patients with definite PsA and >2 years of disease duration. Remission/low disease status was defined at the baseline visit using composite scores: Minimal Disease Activity (MDA), and Disease Activity in PSoriatic Arthritis (DAPSA)<14 (both corresponding to a status of remission or low disease). Patient-perceived burden of disease was assessed through the PsA Impact of Disease (PsAID12) composite score and its individual components assessing physical and psychological impact (0-10 where 0 is the optimal status). Mean and median levels of patient-reported symptoms were assessed in remission/low disease status. P-values by Wilcoxon test were computed to compare patients in good status according to both MDA and DAPSA (n=161), versus in good status according to DAPSA only (n=96). There was no imputation of missing data.

Results: Of 446 patients, 444 had disease status and impact available: 220 (50.5%) were male, mean age was 52±12.6 years, mean disease duration was 10.1±8.1 years; 261 (59.5%) were taking a conventional DMARD and 255 (61.3%) a biologic. Disease activity was moderate: 154 (36.2%) had no current psoriasis skin lesions, mean tender joint count was 4.7±9.5, mean swollen joint count (SJC) was 2.2±7.0, and mean DAPSA was 16±17.2. Remission/low disease was more frequent when defined by DAPSA: 251 (56.5%) patients, than by MDA: 171 (38.5%) patients. As expected, objective measures of disease activity were minimal in the good status categories (e.g., SJC was 0.3±0.6 in MDA and 0.4±0.9 in DAPSA-remission/low disease). In remission/low disease, residual disease impact (assessed with PsAID12) was low: most median levels of symptoms were below 1 on a 0-10 scale; 5 aspects of impact had a median level of 1 (figure); only one had a median level of 2, and this was fatigue. Levels of impact were slightly though significantly higher in patients in DAPSA-defined good status than in patients in both MDA and DAPSA-remission/low disease (all p<0.001).

Conclusion: In this unselected population, residual symptoms were of low magnitude using both definitions of good status: DAPSA-based definitions (present in 56%) and MDA (38%), confirming the patient relevance of remission/low disease as a treatment objective. The predominant aspect of impact was fatigue, which is one of the most important domains of impact recognized by patients. Residual burden of disease was lower in the MDA group than in the DAPSA-remission/low disease group, which could indicate that MDA corresponds to a ‘deeper’ form of disease control, though the clinical relevance of the differences observed should be further explored. A holistic approach should be implemented when evaluating people with PsA including when disease control has been obtained.

SAT0636 A DRUG INDUCED REMISSION SIGNATURE PROMISES PERSONALIZED THERAPY IN RA PATIENTS

Madah Mehdi1, Sabrina Danilin1, Matthieu Coq1, Hüseyin First1, Florence Apparailly2, Yves-Marie Pers2, Christian Jorgensen2, Madah Mehdi1, Sabrina Danilin1, Matthieu Coq1, Hüseyin Firat1, Florencia Balanescu, Uta Kiltz, Sibel Aydin, Inna Gaydukova, Lihi Eder, Anna-Maria Orbai, Josef S. Smolen1, Laura C. Coates. RefFlap working group, PARIS, France

Background: Today the objective for efficient Rheumatoid Arthritis (RA) therapy is not restricted to reduced synovial inflammation but to induce immunological and clinically lasting remission. Despite improvement in therapy of RA, anti-TNF alpha or anti-IL-6 (Tocilizumab) biologics provide less than 20% of clinical remission. Interestingly, the complete remission can last up to 12 months in about 40% of these patients despite discontinuation of the above biologics. In order to set up optimized strategy to obtain persistent clinical remission, new predictive markers of complete remission are needed.

**THE DIAGNOSTIC VALUE OF SERUM IgG4 IN IgG4-RELATED DISEASES**

**WUXUE, Lijun Wu, Cai Nan Luo, Ya Mei Shi. People’s Hospital of Xinjiang Uygur Autonomous Region, Department of Rheumatology and Immunology, Urumqi, China**

**Background:** IgG4-RD is a newly recognized autoimmune disease. Serum IgG4 is an important tool for the diagnosis of IgG4-RD. However, only a few articles have reported the value of serum IgG4 for the diagnosis of IgG4-RD.

**Objectives:** To explore the diagnostic value of serum IgG4 in IgG4-related diseases. Whether 1350 mg/L as the cutoff concentration is suitable for Chinese people to identify IgG4-RD and other rheumatic immune diseases.

**Methods:** From October 2013 to December 2018, 40 patients with IgG4-RD diagnosed in the rheumatic immunology department of people's hospital of Xinjiang Uygur Autonomous Region were collected.

**Results:** The cut off levels were determined by receiver operating characteristic (ROC) curve analysis. The mean serum IgG4 concentration of 40 definite IgG4-RD was significantly higher than that of other rheumatic immune diseases group and healthy control group.

**Conclusion:** Serum IgG4 is an important tool for the diagnosis of IgG4-RD. Whether 1350 mg/L as the cutoff concentration is suitable for Chinese people to identify IgG4-RD and other rheumatic immune diseases.

**Disclosure of Interests:** None declared

**INCREASED LEVELS OF CIRCULATING EXTRA CELLULAR LONG NON-CODING RNAs MALAT1, MEG3 AND NEAT1 IN PATIENTS WITH RHEUMATOID ARTHRITIS AND THEIR IMPACT ON DISEASE ACTIVITY MEASURES**

Sudipta Chatterjee1, Nitai P. Bhattacharyya2, Dipanjan Bhattacharjee1, Sanchita Misra, Alakendu Ghosh1. 1 Institute of post graduate medical education and research, Kolkata, India; 2 Saha Institute of Nuclear Physics (retired), crystallography and molecular biology, Kolkata, India

**Background:** Deregulations of long non-coding RNAs (lncRNA) have been lately implicated in autoimmune diseases(1) including Rheumatoid arthritis (RA). However, their specific roles in disease pathogenesis, extra-cellular manifestations and clinical impact in RA remain largely unknown.

**Objectives:** To identify the intra- and extra-cellular expressions of lncRNAs, MEG3, MALAT1, NEAT1, in RA and their impact on disease activity.

**Methods:** Blood samples were collected from 82 active RA patients (DAS28-CRP: 4.7±0.2) and 15 age-sex matched healthy individuals. Knee synovial fluids (SF) were collected from 24 RA patients (among 82) and 10 osteoarthritis patients (as control). Sera were separated for cytokines.
measurements. RNA, isolated from peripheral blood mononuclear cells (PBMCs), plasma and synovial fluid were quantified by spectrophotometry. Levels of MALAT1, MEG3 and NEAT1 were determined using specific primers and real time PCR, 18S RNA was the endogenous control. Fold changes were calculated using standard $2^{-\Delta\Delta CT}$ method. Multivariate analysis was performed to analyze associations between the dependent variable (DAS28-CRP) and the predictor variables (CRP, MALAT1, MEG3 and NEAT1). Confidence interval of 95% ($p<0.05$) was considered statistically significant for all analyses.

Results: All patients recruited were anti-CCP positive (122.5 ±28.3 IU/mL) and RF positive (166.5 ±37.3 IU/mL). Their systemic inflammation were high compared to controls ($p<0.05$) as reflected in serum CRP (47.4 ±26.2 mg/L), TNFα (140±29 pg/dL) and IL17 (270±33 pg/dL). Levels of MALAT1, MEG3 and NEAT1 were increased in the PBMCs ($p<0.05$) of RA patients compared to controls. Similar increases of these IncRNAs were seen in plasma and in SF. Spearman’s correlation were performed with the fold changes of IncRNAs in PBMC, DAS28-CRP and its components. MEG3 significantly correlated with tender joint count (TJC) ($r=0.75$, $p=0.002$) whereas NEAT1 correlated with both TJC ($r=0.571$, $p=0.002$) and DAS28-CRP ($r=0.943$, $p=0.001$). Multivariate analysis was performed with NEAT1 and MEG3 as the predictors and DAS28-CRP (model 2) as outcome and co-efficient of determinant ($r^2$) was compared to that of CRP as the predictor and DAS28-CRP as the outcome (model 1). Model 1 was made to set a cut-off mark for model 2. The $r^2$ for model 1 (0.862) was greater than that of model 2 (0.656) indicating the expressions of NEAT1 and MEG3 accounted for more variability in DAS28-CRP scores (86.2%) than CRP (65.6%). In model 2, $r^2$ co-efficient of NEAT1 ($β=0.868$) was greater than that of MEG3 ($β=0.397$) suggesting a greater impact of NEAT1 on DAS28-CRP scores. The IncRNAs in plasma and in synovial fluids had shown similar trends.

Conclusion: Increased in IncRNAs in extra cellular fluid suggests their systemic regulation on RA pathogenesis. Increased predictability of DAS28-CRP by NEAT1 and MEG3 compared to CRP indicate their potentiality of being probable markers in monitoring disease activity. However, validation of this finding in larger cohort is necessary.

SAT0639

ACTIVE JAK/STAT SIGNALING IN CIRCULATING LEUCOCYTES DEFINES DISTINCT IMMUNOLOGIC ENDEOTYPES OF RHEUMATOID ARTHRITIS

Barbara Dreco1, Rusmir Husic1, Philipp Bosch1, Angelika Lackner1, Theresa Bruegmann1, Winfried Graninger1, Johannes Fessler1, Martin Stradner1.
1Medical University of Graz; Div. of Rheumatology and Immunology, Graz, Austria.
2Harvard University, Department of Neurology, Cambridge, United States of America

Background: In rheumatoid arthritis (RA) stratification is considered an important step towards the development of patient-tailored therapeutic concepts. The fact that less than 50% of RA patients experience a substantial improvement in response to any single biologic therapy has brought up the idea that yet unidentified subtypes of RA (endotypes) might exist. This concept is in line with distinct microscopic patterns of synovitis found in biopsies of RA joints.[1] Furthermore, a subset of RA patients has leukocytes with interferon driven gene expression, whereas the majority of RA patients does not.[2] Interferons activate receptor associated Janus kinases leading to phosphorylation of STAT1 and STAT2. Other STAT family members are activated by cytokines such as IL-6 (STAT3) or IL-15 (STAT5). Therefore, the phosphorylation pattern of the different STAT molecules in circulating leukocytes might mirror the specific cytokine milieu of a given patient.

Objectives: To define endotypes of RA based on the phosphorylation patterns of the different STAT molecules in circulating leukocytes.

Methods: Cross-sectional study of 63 patients with established RA fulfilling the 2010 EULAR/ACR criteria (mean age: 64.5 ± 1.7 (SEM) years, female ratio: 0.79). Ten healthy subjects served as a control group. Flow cytometry was performed to detect the phosphorylated forms of STAT1-6 in Monocytes, Granulocytes, B cells, naïve-, effector-, and memory-T cells of the CD4+ and CD8+ lineage. All steps from blood draw to cell fixation were performed at 4°C to prevent auto-activation of leukocytes. The mean fluorescence intensity (MFI) of phosphorylated STATs in the different leukocyte populations was used for statistical analysis. MFIs were correlated with disease activity measured by the cDAI. MFIs of populations with elevated STAT phosphorylation not associated with disease activity were used by unsupervised hierarchical clustering. The resulting groups were validated by principal component analysis. Finally, criteria for patient assignment to specific groups by MFI were generated by calculating ROC-curves.

Results: Pronounced ex vivo phosphorylation of STAT1-6 in any leucocyte population was detected in 20 of 63 (48%) RA patients but not in healthy subjects (n=10). Active STAT5 signaling in Monocytes, naïve CD4+ T cells and CD4+ effector T cells was significantly associated with disease activity. Unsupervised hierarchical cluster analysis of RA patients based on STAT MFIs not associated with disease activity resulted in 3 groups: 1) Patients with active STAT1 and STAT3 signal in Monocytes and Granulocytes (n=14/63, 22%), 2) Patients with active STAT5 signal in naïve CD4+ T cells, CD8+ effector T cells and CD4+ memory T cells (n=16/63, 25%) and 3) Patients without active STAT signal in any leucocyte population (n=33/63, 52%). cDAI, CRP, ESR, current treatment, RF and ACPA status did not differ significantly between the groups. To test if the assignment to a group changed over time, we performed a second analysis of STAT phosphorylation after 3-6 months. Eighty percent of the patients tested (12/15) were re-assignment to their initial group.

Conclusion: We identified three distinct RA endotypes based on active STAT signal. Whether patients within different endotypes respond differently to a given therapy will be subject to further research.

SHEAR-WAVE ELASTOGRAPHY OF SKIN STIFFNESS IN SYSTEMIC SCLEROSIS: A FIVE-YEAR FOLLOW-UP STUDY

Tânia Santiago, Margarida Coutinho, Maria Joao Salvador, P José Antonio. Da Silva, Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal

Background: Measurement of skin involvement is essential for diagnosis and assessment of prognosis in systemic sclerosis (SSc). The mRSS is the gold standard measure of skin thickness. The mRSS has been criticised for being associated with high inter-observer variability and being too insensitive to detect relevant changes in skin thickness over time. Previously, our group demonstrated that shear-wave elastography (SWE) offers a potential for objective and quantitative assessment of skin involvement in SSc patients.1 However, no studies have evaluated its sensitivity to change over-time.

Objectives: To assess changes in skin stiffness in SSc patients using SWE, over-time.

Methods: This study included 19 SSc patients [89.5% females; age 57.5 years (10.3), 53% with limited form; disease duration 11.4 years (8.5)] at baseline and, 13 healthy controls [89.2% females; age 53.4 years (11.5)]. Skin stiffness was measured by SWE, using virtual touch image quantification, at the 17 sites corresponding to the mRSS, in each participant, at baseline and follow-up [a mean of 4.9 (I4.6–4.9) years later]. mRSS was performed at both time points. Differences between groups were analysed using the related-samples Wilcoxon Signed Rank test. Results are presented as mean ±SEM (interquartile range [IQR]).

Results: In SSc patients, skin stiffness measured by SWE decreased in a strongly significantly way (p<0.001), over time at all skin Rodnan sites, except the fingers (table 1). Interestingly, the same was observed in controls for all sites, except the leg. The effects of normal ageing correspond to 30 to 60% of the changes observed in SSc. Local Rodnan

scores only decreased significantly at the forearms and fingers of SSc patients. The reduction of mRSS at the fingers did not correspond to improvements in SW. Shear wave velocity (SW) measurements correlated with mRSS both at baseline (r=0.56; p=0.0001) and at follow-up (r=0.74; p=0.0001).

Conclusion: Although preliminary, this study provides the first evidence suggesting that 1. SW of the skin is more sensitive to change over time than mRSS; 2. Skin stiffness reduces significantly over time in normal controls, and 3. Normal skin ageing may contribute to the overall decrease of SW with time in SSc. Our results highlight the discriminant ability of SW in detecting subtle skin changes not identified by mRSS. SW may offer a significant improvement in the evaluation of skin stiffness and may provide relevant insights into the biology of healthy and sclerodermia skin. Studies including a larger number of patients in different phases of skin involvement and data on normal reference values of these ultrasound measurements are needed to reach a definitive validation.

SAT0642 PROTEIN BIOMARKERS TO DIFFERENTIATE PSORIATIC ARTHRITIS FROM PSORIASIS

Conor Magee1,2, Yitong Pu3, Anna Kwasnik3, Angela MC Ardle3, Belinda Hernandez4, Flora Farkas4, Natsumi Ikumi1, Agnes Szentpetery1, Looi Shaker4, Phil Gallagher4, Brian Kirby4, Stephen Pemovscek4, Oliver Fitzgerald5, Measuring Outcome in Psoriatic Arthritis (MOPsA) Group. 1St. Vincent’s University Hospital, Rheumatology, Dublin, Ireland; 2University College Dublin, The Conway Institute, Dublin, Ireland; 3Trinity College Dublin, School of Medical Gerontology, Dublin, Ireland; 4St. Vincent’s University Hospital, Dermatology, Dublin, Ireland

Background: The BIOMarkers of COMpofibridities (BIOCOCOM) in Psoriasis (Pso) study is a longitudinal study in which we aim to identify clinical, genetic and protein biomarker features associated with the development of co-morbidities, notably psoriatic arthritis (PsA), in patients with psoriasis (Pso). Pso usually precedes the development of PsA with an average interval of 10 years. Thus, patients with Pso are an ideal group in which to study the early events in the evolution to PsA.

Objectives: To use a targeted proteomics approach to identify a serum protein, or panel of proteins, which can predict the development of PsA in patients with Pso. As a first step, we initially sought to identify serum proteins capable of discriminating between patients with Pso only and patients with established PsA.

Methods: 30 patients with Pso and 30 patients with established PsA were selected from the BIOCOCOM-Pso database. Serum samples from these patients, taken at their initial assessment, were digested using an established in-house standard operating protocol (SOP). Once digested, a targeted proteomics approach using liquid chromatography – mass spectrometry (LC-MS) and a multiple reaction monitoring (MRM) assay called PAPRICA was used to measure candidate biomarker proteins. These 206 proteins (423 peptides) were previously identified as being protein biomarkers in a number of different inflammatory rheumatological conditions.

Results: The demographics of the 2 patient groups are shown in Table 1.

Targeted proteomics data from the PsA and Pso patients was subjected to univariate and multivariate analysis using a leave one out cross validation approach. The initial results revealed that the application of the PAPRICA method to the BIOCOM-Pso samples resulted in a dataset in which 88 of the 206 PAPRICA proteins could be reliably measured (CV Area < 20%; Signal to Noise ratio > 5; Library Dot Product > 0.8). This subset of the PAPRICA proteins was not able to discriminate between PsA and Pso and none of the associated peptides were significantly different between the two groups (p value < 0.05).

Conclusion: Analysis of a subset of 88 of the 206 biomarker proteins in the PAPRICA method, in patients with PsA and Pso, did not reveal peptides (proteins) that were statistically different between these two groups. Multivariate analysis generated a model that was unable to discriminate between patients with PsA and Pso. The possibility that the full PAPRICA assay may be able to discriminate between PsA and Pso will be explored, as will supplementing the PAPRICA method with additional biomarkers including proteins that may be identified in an unbiased proteome wide screen of PsA vs Pso serum samples.

SAT0643

FACIT-FATIGUE TO PROMIS-FATIGUE CROSS-WALKED DATA FROM MONARCH, MOBILITY AND TARGET RANDOMIZED CLINICAL TRIALS OF SARILUMAB FOR THE TREATMENT OF MODERATELY-TO-SEVERELY ACTIVE RHEUMATOID ARTHRITIS (RA)

Clifton Bingham 1, Susan Boklage 2, Tosho Kimura 3, David Cella 4, Johns Hopkins University, Baltimore, United States of America; 2Regeneron Pharmaceuticals, Inc., Tarrytown, United States of America; 3Northwestern University, Chicago, United States of America.

Background: Fatigue is a common symptom in RA and increasingly recognized as an important therapeutic target in disease management. Phase 3 randomized clinical trials (RCTs) have shown significant improvements in fatigue for sarilumab, based on the 13-item Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue measure. In TARGET (n=546) and MOBILITY (n=1197), patients receiving sarilumab 150 or 200 mg subcutaneous (SC) every 2 weeks (Q2W) achieved clinically meaningful improvements in fatigue vs placebo. In MONARCH (n=369), there was a trend towards greater improvement in fatigue scores for sarilumab 200mg SC Q2W vs adalimumab 40mg Q2W. To facilitate a trend towards greater improvement in fatigue scores for sarilumab, based on the 13-item Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue measure, including the subset of 10 FACIT-F items deemed most relevant to RA patients.

Objectives: To describe patient-level, cross-walked PROMIS-fatigue and scoring service 13- and 10-item PROMIS-fatigue scores, patients treated with sarilumab demonstrated statistically greater and clinically meaningful improvement in fatigue vs placebo and a trend towards greater improvement vs adalimumab. Converting FACIT-fatigue scores to PROMIS-fatigue using either the patient level cross-walk or via the PAPRICA method to the BIOCOM-Pso samples resulted in a dataset in which 88 of the 206 biomarker proteins could be reliably measured (CV Area < 20%; Signal to Noise ratio > 5; Library Dot Product > 0.8). This subset of the PAPRICA proteins was not able to discriminate between PsA and Pso and none of the associated peptides were significantly different between the two groups (p value < 0.05).

Conclusion: Consistent with trial results shown for FACIT-Fatigue, follow-up results across all studies (Table) indicate greater improvement in fatigue scores for sarilumab, based on the 13-item Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue measure, including the subset of 10 FACIT-F items deemed most relevant to RA patients.

OUTCOME MEASURES IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Alessandra Borotlu1, Francesca Bengio1, Elisabetta Ciesa2, Maria Ester Diamanti1, Matteo Piga2, Carlo Alberto Scire3, Ettore Silvagni1, Marcello Govoni1, 1Rheumatology Unit, Department of Medical Sciences, University of Ferrara and Azienda Ospedaliero-Universitaria S. Anna, Cona (Ferrara), Italy; 2Rheumatology Unit, University Clinic and AOU of Cagliari, Cagliari, Italy.

Background: Neuropsychiatric involvement in Systemic Lupus Erythematosus (NPSLE) is one of the most complex and severe expressions of the disease consisting of a variety of neurological and psychiatric syndromes. To identify the NPSLE symptoms and to assist in test new therapeutic strategies or drugs in controlled clinical trials NPSLE is included.

Objectives: To identify the instruments used to assess NPSLE in published studies according to the OMERACT (Outcome Measures in Rheumatology) Filter 2.0 [Ref].

Methods: This systematic review was conducted in accordance with the Preferred Reporting Items for systematic reviews and Meta-analysis (PRISMA) statement. All articles available in English, published from June 1967 to March 1 2018, in Pubmed, EMBASE, PsyCINFO, Cochrane Library and EULAR Library for Outcome Measure were screened as well as extensive hand search. Study selection and data collection were performed by 4 independent reviewers. All data were extracted using a standardized template designed for this review, each outcome was characterized according to the OMERACT Filter 2.0 considering core areas (neurophysiological manifestations, life impact, death, resource use) and domains [Ref].

Results: Of 2,625 abstracts, we included in the review 62 studies of which 1 randomised clinical trial (1.6%, 32 patients), 4 systematic literature reviews (6.4%, 8,024 patients), 21 cohort studies (33.8%, 2,684 patients) and 36 observational studies (58.1%, 1,534 patients), with a total of 12,274 patients. Patients were predominantly female (86.6%) with a mean±SD age of 34.9±5.8 years. The mean disease duration was 5.1±2.2 years (range 1 - 9.6). The most frequent included events were seizures (34 studies, 54.8%), cerebrovascular disease (30 studies, 48.4%), psychosis and myelopathy (29 studies, 46.8%), mood disorders (28...
ANTI-DFS70 AUTOANTIBODIES INDUCED BY ANTI-TNF THERAPY IN RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS PATIENTS

Teresa Carboni 1,2, Carmela Esposito 3, Ornella Mercuro 2, Antonio Carriero 1, Valentina Picerno 1, Maria Carmela Padula 1, Angela Padula 1, Vito Pafundi 2

Background: anti-DFS70 antibodies (anti-DFS70ab) were recently described as biomarkers clinically useful to discriminate Systemic Autoimmune Rheumatic Diseases (SARD) from non-SARD patients, especially if no concomitant SARD-specific autoantibodies were found. Several unanswered questions concerning the biological significance of this autoantibodies still remain. Objectives: to evaluate the prevalence of anti-DFS70ab in Rheumatoid Arthritis (RA) and Spondyloarthritis (SpA) patients and the influence of anti-TNF therapy on their development. Methods: sera from adult RA (n=100) and SpA (n=105) patients, included psoriatic arthritis, fulfilling ACR/EULAR 2010 and ASAS 2011 criteria, respectively, were studied for anti-DFS70ab as measured by IIF, then confirmed by immunoblotting. Medical history, demographic and clinical data were collected at enrolment.

Results: the prevalence of anti-DFS70ab was 4.00% (4/100) in the RA and 4.76% (5/105) in SpA cohort. All anti-DFS70ab in RA patients were monospecific, while only 1 sample in SpA showed concomitant anti-centromere positivity. The findings for the anti-DFS70ab positivity revealed no statistical differences between the groups (p>0.05). In RA cohort, there were no differences between anti-DFS70ab positive and negative patients regarding the F/M ratio (F/M, 3/1 vs 84/12, p=0.05), mean age (50.2±12.4 vs 55.6±11.7 yrs, p>0.05) and disease duration (18.8±7.7 vs 19.0±20 yrs, p>0.05) while the mean age of anti-DFS70ab patients was significantly higher than the negatives (66.8±10.4 vs 53.5±15.0 yrs, p<0.05). Serological and clinical data of anti-DFS70ab positive patients were summarized in Table 1. In our cohort, all anti-DFS70ab were negative before initiating biologics.

Conclusion: based on our findings, detection of anti-DFS70ab reactivity cannot completely exclude the suspicion of SARD, especially for RA and SpA. In addition, the rate of anti-DFS70ab positivity resulted higher in RA and SpA patients than previously observed in a cohort of samples from outpatients clinics (2.1%) [1]. Immunogenicity of anti-TNF therapy has been also addressed in this study, showing that all detected anti-DFS70ab were induced by anti-TNF therapy. Further studies are needed to support these preliminary data.

Background: The mechanisms underlying thrombosis and cardiovascular disease (CVD) in antiphospholipid syndrome (APS) are not completely understood, but recent evidence has brought to light the existence of a complex interplay between traditional CV risk factors and disease-specific features, such as the presence of autoantibodies [1]. Recent studies have discovered the existence of a heterogeneous group of autoantibodies specifically directed against lipoproteins and their components [anti-high density lipoproteins antibodies (anti-HDL)]. Anti-HDL showed promising results in predicting the development of CVD, lipoprotein dysfunction and clinical outcomes in autoimmune conditions. Nevertheless, the association between anti-HDL and clinical features of APS remains unclear.

Objectives: The aim of the study was to evaluate the presence of IgG anti-HDL antibodies in a cohort of thrombotic APS patients and to investigate if these antibodies can discriminate between arterial and venous thrombosis.

Methods: This cross-sectional study included 60 patients with persistent antiphospholipid antibodies (aPL) positivity that fulfilled the Sydney criteria for thrombotic APS (venous and/or arterial) [2], and 20 age- and sex-matched healthy donors (HDs). Clinical data were retrospectively collected. Serum levels of total IgG, IgG anti-HDL antibodies and complete aPL profile were assessed, including lupus anticoagulant, anti-cardiolipin, anti-β2-glycoprotein I, and anti-phosphatidylserine/prothrombin both IgG and IgM antibodies.

Results: 43 patients (72%) were primary APS and 17 patients (28%) had a concomitant diagnosis of systemic lupus erythematosus. Thirty APS patients (50%) presented previous arterial events and 37 (61%) venous events (7 patients experienced recurrent thrombotic events, both venous and arterial; the first event was taken as a reference for the analyses). The characteristics of the cohort are displayed in Table 1. Higher levels of IgG anti-HDL were found in APS patients compared to HDs [mean 46 (±70) vs. 14 (±13) AU, respectively; p < 0.001], even after controlling for total IgG levels [anti-HDL/IgG: mean 13.1 (SD ±16.7) vs. mean 9.5 (SD ±6.6); p = 0.046] (Figure 1.1). No association with traditional cardiovascular risk factors, except for smoking habit (p < 0.001) was found. No differences in anti-HDL levels were observed between patients with primary APS and those with a concomitant autoimmune disease (p >0.050). Patients who experienced at least one arterial event had significantly higher levels of anti-HDL antibodies when compared to patients with history of venous thrombosis [mean 53 (SD ±94) vs. mean 34 (SD ±29), respectively; p =0.046]. This difference became stronger when adjusting for total IgG levels [anti-HDL/IgG: mean 13.1 (SD ±16.7) vs. mean 9.5 (SD ±6.6); p =0.007] (Figure 1.2). In addition, patients tested positive for aPS/PT (IgG/IgM) antibodies had significantly higher levels of anti-HDL antibodies [mean 53.1 (SD ±81.1) vs. mean 20.7 (SD ±17.6), p < 0.001] (Figure 1.2). No association with traditional cardiovascular risk factors was found. No differences in anti-HDL levels were observed between patients with primary APS and those with a concomitant autoimmune disease (p >0.050).

Conclusion: Our study demonstrates that thrombotic APS patients have higher levels of IgG anti-HDL antibodies, supporting the emerging role of these autoantibodies in APS setting. Moreover, our findings suggest that anti-HDL represent a promising tool for risk management and assessment and a potential biomarker for lipid dysfunction and arterial thrombotic events.

RELIABILITY OF MAGNETIC RESONANCE IMAGING (MRI)-SCORING OF THE METATARSOPHALANGEAL-JOINTS ACCORDING TO THE RHEUMATOID ARTHRITIS-MRI SCORE (RAMRIS)

Yousra Dakkak1, Xanthe Matthijsen2, Desiée van der Heijde3, Monique Reijnierse2, Annette van der Helm - van Mil1,2,3, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2 Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; 3Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: The Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS) is validated for magnetic resonance imaging (MRI) of the hand. Its reliability when applied to metatarsophalangeal (MTP-1-5)-joints is unknown.

Objectives: To assess the inter-reader and intra-reader-reliability of status scores and the inter-reader-reliability of change scores applied to the MTP-joints for the following MRI-outcomes: bone marrow edema, synovitis, tenosynovitis and erosions.

Methods: Patients underwent 1.5T MRI of MTP(1-5)-joints. Two readers scored bone marrow edema(BME), synovitis, tenosynovitis and erosions. Interreader reliability was assessed of 4-41 consecutive early arthritis patients at baseline, the first 215 by two readers, the remaining 268 by two different readers. Additionally, baseline MRIs of 82 consecutive patients with arthralgia were scored by two readers, a random set of 40 patients by seven additional readers (nine readers in total). Intra-reader reliability was determined on a random set of 15 early arthritis patients, scored twice by two readers. For change-scores, 30 early arthritis patients with baseline and 1-year follow-up MRI were scored by two readers. Intraclass correlation coefficients (ICCs), Bland-Altman (BA)-plots and smallest detectable change (SDC) were determined.

Results: Interreader mean scores and ICCs in early arthritis are presented in Table 1; ICCs were good to excellent (0.85-0.92) in arthralgia-patients mean scores were lower, ICCs were comparable (Table 1). Intra-reader ICCs for MRI-features were good to excellent (0.84-0.98), but for erosions moderate for reader 1 (0.71) and excellent for reader 2 (0.92). Mean change scores and ICCs are presented in Table 2; ICCs were generally excellent (0.90), but moderate for erosions (0.77). SDCs were ≤1.0. BA-plots for status and change scores showed no systematic bias.

Conclusion: Status and change MRI-scores of BME, synovitis, tenosynovi- tis and erosions of MTP-joints can be assessed reliably by the RAMRIS. This is encouraging for the use of MRI of the MTP-joints in trials in early phases of RA.

Disclosure of Interests: None declared.

Table 1. Interreader intraclass correlation coefficients and average status scores according to the RAMRIS in early arthritis patients (n=441 in total) and patients with arthralgia (n=62)

| Region | Mean change scores and ICCs are presented in Table 1; ICCs were good to excellent (0.85-0.92) in arthralgia-patients mean scores were lower, ICCs were comparable (Table 1). Intra-reader ICCs for MRI-features were good to excellent (0.84-0.98), but for erosions moderate for reader 1 (0.71) and excellent for reader 2 (0.92). Mean change scores and ICCs are presented in Table 2; ICCs were generally excellent (0.90), but moderate for erosions (0.77). SDCs were ≤1.0. BA-plots for status and change scores showed no systematic bias.

Conclusion: Status and change MRI-scores of BME, synovitis, tenosynovi- tis and erosions of MTP-joints can be assessed reliably by the RAMRIS. This is encouraging for the use of MRI of the MTP-joints in trials in early phases of RA.

Disclosure of Interests: None declared.

DEVELOPMENT AND VALIDATION OF A PATIENT-REPORTED OUTCOME ASSESSING ACTIVITY LIMITATION AND PARTICIPATION RESTRICTION OF PATIENTS WITH SYSTEMIC SCLEROSIS: THE COCHIN 17-ITEM SCLERODERMA FUNCTIONAL SCALE (CSF-17)

Camille Daste1, Hendy Abdou2, Frantz Foissac2, Agathe Papelier1, Sophie Alam1, Marie-Martine Lefève Cola1, Serge Poiraudieu1, François Rannou1, Luc Mouthon1, Christelle Nguyen1, Service de Rééducation et de Réséparation de l’Appareil Locomoteur et des Pathologies du Rachis, Hôpital Cochin, Paris, France, Unité de Recherche Clinique – Centre d’Investigation Clinique Paris Descartes Necker/Cochin, Hôpital Tarnier, Paris, France, Cabinet d’Études Sociologiques Interlis, Paris, France, Service de Médecine Interne, Centre de Référence Maladies Systémiques Auto-innées Rares de l’élla-de-France, Hôpital Cochin, Paris, France

Background: Few patient-reported outcomes measures (PROs) have been specifically designed to assess the functioning of patients with systemic sclerosis (SSc). In addition, the development of currently available instruments did not fully follow current guidelines (1).

Objectives: To develop and validate a PRO assessing activity limitation and participation restriction of patients with SSc.

Methods: A provisional International Classification of Functioning, Disability and Health (ICF)-based 65-item questionnaire previously developed from interviews of SSc patients was submitted online to French patients (n=184) of the Scleroderma Patient-centered Intervention Network e-cohort (2). Items were reduced according to their metric properties, dimensional structure of the questionnaire was assessed by principal component analysis, convergent and divergent validities using the Spearman correlation coefficient (ρ), internal consistency by the Cronbach α coefficient and reliability by a test-retest method using intraclass correlation coefficient (ICC) and Bland and Altman analysis.

Results: Overall, 113/184 (61.4%) patients completed the provisional questionnaire. The item-reduction process resulted in a 17-item questionnaire, the Cronbach α coefficient was 0.94 for section A and 0.95 for section B. The observed convergent validity with global activity limitation, pain, depression and aesthetic burden and divergent validity with anxiety. The Cronbach α coefficient was 0.94 for section A and 0.95 for section B. ICC (n=25 patients) was 0.92 for CSF-17 total score. Bland and Altman analysis did not reveal a systematic trend for the test-retest.

Conclusion: The CSF-17 is a self-administered questionnaire assessing activity limitation and participation restriction of patients SSc with good content and construct validities.

SAT0650

THE INFLUENCE OF PATIENT DEMOGRAPHICS ON DISEASE ACTIVITY MEASUREMENTS IN RHEUMATOID ARTHRITIS

Bénédicte Delcoigne1, Daniela Di Giuseppe2, Johan Asklings2, Lotta Ljung3, Karolinska Institute, Department of Medicine, Unit of Clinical Epidemiology, Stockholm, Sweden; Karolinska Institute, Department of Medicine, Stockholm, Sweden; Umeå University, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden

Background: Several indexes have been constructed for the measurement of disease activity in rheumatoid arthritis (RA) patients, including the Disease Activity Score 28-joint count, which either includes the Erythrocyte Sedimentation Rate (DAS28ESR) or the C-reactive protein concentration (DAS28CRP), and the Clinical Disease Activity Index (CDAI). The categorization of the results of these three indexes into levels of disease activity (Remission, Low, Moderate and High) is used to assess patient outcomes, and to guide medical decisions regarding treatment. However, the different indexes can lead to somewhat different classification, and hence influence treatment decisions (3).

Objectives: To investigate how DAS28ESR, DAS28CRP and CDAI indexes are associated to age and sex in RA patients. To investigate the agreement between indexes and between categories of disease activity levels.

Methods: We identified a cohort of RA patients, registered in the Swedish Rheumatology Quality Register between January 1**2014 and December 3**2017. The indexes were obtained from the first visit at the time point of RA diagnosis, and at the visit registered at the start of a first ever biological treatment prescription. Linear models were used to investigate the correlation between the indexes, age and sex. The agreement between the indexes was explored with Bland-Altman plots. The agreement between disease activity levels was evaluated through kappa statistics.

Results: Data were analyzed for 3855 RA patients (2576 women, mean age ±SD=60±15) at their first diagnosis visit and for 3062 RA patients (2313 women, mean age ±SD=57±14) at the start of their first biologic. Similar results for all subsequently described analyses were obtained at both time points. The correlation coefficient and 95% confidence interval (95%CI) between the indexes and age were 0.093 (0.063-1.124) for DAS28ESR and 0.055 (0.025-0.085) for DAS28CRP at the first visit, while CDAI was not correlated to age. There was no difference between men and women for CDAI and DAS28CRP, while DAS28ESR presented a mean difference of 0.1 unit between men and women. The agreement between categories of disease activity was moderate: at the RA diagnosis visit, the kappa statistics and 95% CI were: 0.63 (0.61-0.65) between DAS28ESR and DAS28CRP, 0.59 (0.57-0.61) between DAS28ESR and CDAI, and 0.55 (0.53-0.57) between DAS28CRP and CDAI. About 25% of the patients were classified differently. The Bland-Altman plot revealed that the difference between DAS28ESR and DAS28CRP depended on sex and slightly increased with age.

Conclusion: Factors related to patient demographics might influence the results of disease activity indexes. This has a potential to affect clinical decisions, as the definition into disease activity categories can differ depending on the score used. This suggests the need to consider sex and age when defining such categories and interpreting results from these indexes.

SAT0652

VALIDATION OF A RISK PERCEPTION QUESTIONNAIRE DEVELOPED FOR PATIENTS WITH RHEUMATOID ARTHRITIS

Inazit Contreras-Yañez1, Pilar Laville2, Patricia Clark3, Virginia Dr. Pascual1
1Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Department of Immunology and Rheumatology, Mexico City, Mexico; 2Hospital de Especialidades Centro Médico Nacional Siglo XXI, Clinical Epidemiology Unit, Mexico City, Mexico; 3Hospital Infantil de México Federico Gómez, Head of the Clinical Epidemiology Unit, Mexico City, Mexico

Background: Risk perception (RP) is a multidimensional phenomenon that describes the individual’s judgment of the likelihood of experiencing something unpleasant. RP shapes health-related-behaviors and may be central for rheumatoid arthritis (RA) management, where treatment must be based on shared decisions between the patient and the rheumatologist. Rheumatologists can motivate successful self-care in RA patients with information that brings the physician vision closer to the patient’s perceptions. Assessing patients-perceived risk may help explain how RA patients integrate their ideas concerning the disease and its treatments, and how this understanding drives their self-care management. There is no current validated instrument to assess RP in RA.

Objectives: To assess whether the SENS can discriminate between treatment groups when the treatment contrast is low, using data from the DRESS (Dose REduction Strategy of Subcutaneous TNF inhibitors) trial

Methods: The DRESS study (Dutch trial register, NTR 3216, CMO region Arnhem-Nijmegen, NL 37704.091.11) is an open label non-inferiority randomised controlled trial in which RA patients with low disease activity on a stable adalimumab or etanercept dose were randomised 2:1 to disease activity guided tapering or usual care [4]. Radiographs of hand and feet at baseline and the end of follow up (18 months) were assessed independently in chronological order by 2 blinded trained readers using the SHS. The SENS was determined based on the individual joint scores of the SHS in the COBRA trial, suggesting some discrimination might be lost when using the SENS, especially in more advanced RA populations [2]. This is an important issue, as time savings using SENS are substantial (7 instead of 25 minutes [1,3], but contrast between interventions is in general lower than in the early years of RA research as the standard of care improves and trials are more and more characterized by active controls and disease activity guided treatment strategies that tend to converge.

Objectives: To assess whether the SENS can discriminate between treatment groups when the treatment contrast is low, using data from the DRESS (Dose REduction Strategy of Subcutaneous TNF inhibitors) trial

Methods: The DRESS study (Dutch trial register, NTR 3216, CMO region Arnhem-Nijmegen, NL 37704.091.11) is an open label non-inferiority randomised controlled trial in which RA patients with low disease activity on a stable adalimumab or etanercept dose were randomised 2:1 to disease activity guided tapering or usual care [4]. Radiographs of hand and feet at baseline and the end of follow up (18 months) were assessed independently in chronological order by 2 blinded trained readers using the SHS. The SENS was determined based on the individual joint scores of the SHS. For both scores, the mean of the two readers was used to minimise measurement error. In order to compare the discriminative ability of both scores, we repeated the analyses from the DRESS study using the SENS and compared the results. In addition, we performed bootstrapping (1000 replications) to investigate the consistency of the results.

Results: Table 1 shows baseline characteristics of the study population. A significant but clinically unimportant mean increase (95% CI) in radiographic progression was found in the early years of RA research as the standard of care improves and trials are more and more characterized by active controls and disease activity guided treatment strategies that tend to converge.

PATIENT-ACCEPTABLE SYMPTOM STATUS IN RHEUMATOID ARTHRITIS: WEALTH AND AGE MATTER BEYOND DISEASE ACTIVITY AND IMPACT. AN ANALYSIS OF 548 PATIENTS

Calia Duarte1, Eduardo Santos1, Tore K. Kvien2, Maarten de Wit3, Maxime Dougados3, Laure Gossec1, P José Antonio. Da Silva1, RAID Study Group. 1Centro Hospitalar Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Diakonhjemmet Hospital, Rheumatology, Oslo, Norway; 3Amsterdam University, Amsterdam, Netherlands; 4Hôpital Cochin, Paris, France; 5Sorbonne Universite, Hopital Pile-Sapetriere, Paris, France

Background: Patient Acceptable Symptom State (PASS) represents the maximum level of symptom intensity that patients consider acceptable. Control of disease activity is associated to attainment of PASS1. Recognizing the factors associated with PASS status beyond disease activity, can be helpful in identifying the need for interventions beyond disease-modifying drugs, aimed at improving the satisfaction and well-being of patients with rheumatoid arthritis (RA).

Objectives: To explore the clinical and socio-demographic factors associated with PASS status in RA.

Methods: Data of patients with definite diagnosis of RA from 11 countries (post-hoc analyses of RAID Study2, with additional data from Portugal) were used. PASS was assessed using the anchored method based on patients’ perspective, through the question: “Think about all the ways your RA has affected you during the last week. If you were to remain for the next few months as you were during the last week, would this be Acceptable/Unacceptable?”. Variables analysed for differences across PASS status were (a) disease activity based on DAS28-3v-ESR (joint counts and ESR) categories, (b) impact by the seven patient-reported domains included in the RA Impact of Disease (RAID) score, (c) demographics: age (above or below 50) and gender, and (d) Country gross domestic product (GDP) classified as High GDP (>35.000 USD per capita) and Low GDP. Differences between patients in PASS or not were assessed using t-test for independent samples or Chi-square test, as adequate. Variables with p<0.05, gender and GDP category were included in multivariable logistic regression (Forward Conditional) analysis. A sub-group analysis was performed for patients in DAS28-ESR remission.

Results: In all, 548 patients (80.5% female, mean (SD) age 55.8 (12.8) years, mean (SD) disease duration 13.6 (10.6) years, mean (SD) DAS28-3v 3.6 (1.5), 44.2% in LDA or remission) from 11 European countries (5 (n=230) with NOR-DMARD and 6 (n=318) with low-GDP) were assessed. The majority of patients (65.7%) considered themselves to be in PASS; among them 40% were in remission and 16.7% in DAS28-3v≤2.6 (14.1) years, mean disease duration 13.8 (10.4) years, mean DAS 28-3v-ESR 3.0 (1.4)] were analysed. In all, 14.5% considered themselves as being in a “very good”, 21% as “good” and 33% in an “acceptable” status. Disease activity, RAID global score and all individual seven domains of RAID were significantly different between patients across these 3 symptom states (p<0.001). Patients reporting a “Very Good” symptom status had disease activity in the range of remission (mean DAS28-3v-ESR: 1.99±0.91), while patients in “Acceptable” status were in range of low disease activity (DAS28-3v-ESR: 2.98±1.20) and in moderate disease activity in patients with “Bad” (DAS28-3v-ESR: 3.83±1.44) and “Very Bad status” (DAS28-3v-ESR: 4.10±1.59). Remission according the Boolean ACR/RHU criteria was observed in 70.9% of patients in “Very Good” symptom status (versus 26% in “Good”, 5% in “Acceptable” and inferior to 1% in “Bad” and “Very Bad” symptom status). The cut-off value for “Very Good” status was 0 for most individual RAID items, except for pain and fatigue ≤1 (Figure1).

Conclusion: Being in a “very good” symptom status showed a good correspondence to being in remission and having very low disease impact. This shows promising in identifying a status that patients would actually desire, more than accept for, while corresponding to a level of disease activity consistent with the long-term preservation of structure and function.

SHOULD PATIENTS WITH RHEUMATOID ARTHRITIS (RA) ASK FOR A BETTER DEAL THAN MERELY AN ACCEPTABLE SYMPTOM STATE? AN ANALYSIS OF 1931 RA PATIENTS

Calia Duarte1, José Antonio P. Da Silva1, Eduardo Santos1, Eirik Kristianslund2, Maarten de Wit3, Maxime Dougados4, Tore K. Kvien5, Laure Gossec6,7.

1Centro Hospitalar Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Diakonhjemmet Hospital, Rheumatology, Oslo, Norway; 3Amsterdam University, Amsterdam, Netherlands; 4Hôpital Cochin, Rheumatology, Paris, France; 5Sorbonne Universite, Paris, France; 6Oulu University Hospital, Oulu, Norway

Background: Patients satisfaction with their symptoms state may be considered an acceptable outcome in RA. However, many patients who report being in an Acceptable Symptom State (PASS) have still moderate disease activity.

Objectives: To explore whether it is possible to identify more stringent levels of symptom states in patients’ perspective.

Methods: A cross-sectional analysis of unselected adult patients with the diagnosis of RA from the RA Impact of Disease (RAID) validation study (n~570, from 12 European countries), and from the Norwegian DMARD (NOR-DMARDII) registry (n=1372), was performed. Symptom state was calculated using the anchored method based on the patients’ perspective, taking, as gold standard, the question: “Think about all the ways your rheumatoid arthritis has affected you during the last week. If you were to remain for the next few months as you were during the last week, how would you consider this state?”, with five levels: Very bad/Bad/Acceptable/Good/Very good. Disease activity was assessed based on the DAS28-3v (joint counts and ESR). Impact was evaluated through the seven patient-reported domains included in the RAID score. The threshold levels of DAS28-3v, Individual RAID items and RAID score for Acceptable/Good/Very Good states were calculated using the receiver-operating characteristic (ROC) curve and the optimal cut-off was determined through Youden Index.

Results: Data from 1931 patients [74.5% female, mean (SD) age 54.4 (14.1) years, mean disease duration 13.8 (10.4) years, mean DAS 28-3v-ESR 3.0 (1.4)] were analysed. In all, 14.5% considered themselves as being in a “very good”, 21% as “good” and 33% in an “acceptable” status. Disease activity, RAID global score and all individual seven domains of RAID were significantly different between patients across these 3 symptom states (p<0.001). Patients reporting a “Very Good” symptom status had disease activity in the range of remission (mean DAS28-3v-ESR: 1.99±0.91), while patients in “Acceptable” status were in range of low disease activity (DAS28-3v-ESR: 2.98±1.20) and in moderate disease activity in patients with “Bad” (DAS28-3v-ESR: 3.83±1.44) and “Very Bad status” (DAS28-3v-ESR: 4.10±1.59). Remission according the Boolean ACR/EULAR criteria was observed in 70.9% of patients in “Very Good” symptom status (versus 26% in “Good”, 5% in “Acceptable” and inferior to 1% in “Bad” and “Very Bad” symptom status). The cut-off value for “Very Good” status was 0 for most individual RAID items, except for pain and fatigue ≤1 (Figure1).

Conclusion: Being in a “very good” symptom status showed a good correspondence to being in remission and having very low disease impact. This shows promising in identifying a status that patients would actually desire, more than accept for, while corresponding to a level of disease activity consistent with the long-term preservation of structure and function.
SAT0655
THE SPECTRUM OF MYOSITIS ANTIBODIES: CLINICAL CORRELATION AND PREVALENCE OF ANTI-DFS70
carmela esposito1,2, teresa Carbone3,4, antonio carriero1, valentina picerno1, Maria Carmela Padula2, Angela Padula2, vito pafundi3, salvatore D’angelo3
1Rheumatology Division-Internal Medicine Department, Prato Hospital, Prato, Italy; 2IReL – Rheumatology Institute of Lucania – San Carlo Hospital, Potenza, Italy; 3Department of Immunopathology Laboratory, San Carlo Hospital, Potenza, Italy
Background: Myositis can be a clinical feature of several rheumatic diseases. In inflammatory idiopathic myopathies (IIM), such as Dermatomyositis (DM), Polymyositis (PM), Antisynthetase syndrome (ASS), muscular dystrophies and to connect them to clinical features, cancer history and anti-DFS70ab presence.
Methods: 37 patients with myositis (including IIM, overlap syndrome and myositis related to other rheumatic diseases) were evaluated. Anti-DFS70ab pattern was determined by indirect immunofluorescence on HEp-2000 cells. Detection of anti-DFS70ab specificity (truncated sequence of the DFS70 antigen (residues 349-435)), of MDA (MDA-5, TIF-1, SAE1, SAE2, NXP-2, Jo-1, PL-7, PL-12, EJ, OJ, KS, ZO, HA, SRP, Mi-2), of MAA (U1-RNP, SSA/Ro52/60, PM-Scl100/75, Ku) and of other Scleroderma associated antibodies (Sc-70, CENP-A, CENP-B, RNA Polymerase III, Th/β, Fibrillarin) were performed using immunoblotting assay. Clinical, serological and instrumental data were recorded.
Results: 15 patients had a diagnosis of DM, 8 of PM, 3 of ASS, 5 of overlap syndrome (3 with Systemic Sclerosis (SSc), 1 with Sjogren Syndrome (SSS), 1 with cryoglobulinaemia), 6 of myositis related to other rheumatic disease (1 SSc, 1 Rheumatoid Arthritis, 2 Undifferentiated Connective Tissue Disease, 2 Systemic Lupus Erythematosus). In IIM, overall frequencies of MSA and MAA were 46.1% (12/26) and 38.4% (10/26), respectively, with concomitant expression in 5/26 cases. The 30.7% (8/26) of patients was negative for any type of antibodies. Mi-2 (4/15=26.6%), NXP-2 (3/15=20%) and SRP (2/15=13.3%) were detected in DM subset and were associated with typical skin lesions, muscle weakness, dysphagia and microvascular damage on capillaroscopy, while no interstitial lung disease, cardiac and articular involvement were recorded. Jo-1 was positive in 5/26 patients (2 PM, 2 ASS, 1 DM=19.2%) characterized by interstitial lung disease, arthritis, skin involvement and muscle weakness and by pulmonary hypertension when associated with TIF1-γ (1 DM=6.6%). Autoantibodies profile in overlap syndrome and myositis related to other rheumatic diseases was characterized by prevalence of MAA, more frequently PM-Scl100/75, RNP, Ku, SSA/Ro52/60. Only in 1 patient with an overlap syndrome (SSc) and lung cancer, but to our knowledge no data are present about melanoma. Our preliminary data confirm that, not only in DM but also in PM, anti-DFS70ab were observed with a low frequency; however more studies are needed to establish the possible role of these antibodies.

SAT0656
DAPSA OR MDA/VLDA CRITERIA FOR DEFINING THE TREATMENT TARGET IN PSSORIC ARTHRITIS?: CROSS-SECTIONAL ANALYSIS FROM A MULTICENTER ITALIAN COHORT
Ennio Giulio Fava1, luca Idalozzi2, serena Bugatti3, Alberto Baticcioii2, luca Quattrocchi2, Matteo Filippini2, Simone Parisi2, marina Bigigjero2, angelo Fassio2, G Zanfrmundo3, Giuliana Gugino8, Giovanni4, Maria Chiara Dito5, Francesca Ciccia6, Gaetano Pin-C TO Institute, Rheumatology, Milan, Italy; 2University of Verona, UOC Rheumatology, Verona, Italy; 3University of Pavia, IRCCS PoliChieti San Matteo, Rheumatology, Pavia, Italy; 4La Sapienza Universita`, Roma, Italy; 5University of Udine, Rheumatology Clinic, Udine, Italy; 6ASST Spezial Civil, UO Reumatologia, Brescia, Italy; 7UCO Città della Salute e della Scienza, Turin, Italy; 8University of Palermo, DIBIMIS, Palermo, Italy; 9University of Campania Luigi Vanvitelli, Rheumatology, Naples, Italy
Background: According to international recommendations, psoriatic arthropitis (PsA) should be managed by a treat-to-target approach, but the identification of the best tool for defining the target of remission/low disease activity (LDA) is still controversial.
Objectives: To evaluate and compare the rates of remission/LDA by comparing Disease Activity in Psoriatric Arthritis (DAPSA) score with Very Low Disease Activity (VLDA)/Minimal Disease Activity (MDA) criteria in a real-life multicentre cohort of PsA patients.
Methods: We performed a cross-sectional analysis including the first consecutive 500 PsA patients evaluated in 8 Italian rheumatology centres since September 2017. The rates of patients achieving DAPSA remission/ LDA and VLDA/MDA were calculated and compared by a chi-square test. The agreement between the two criteria sets was established by Cohen’s kappa. The proportion of patients with residual disease activity despite remission/LDA and VLDA/MDA was computed for: peripheral arthritis...
MONOCYTE-LYMPHOCYTE RATIO AND PLATELET-LYMPHOCYTE RATIO: ROLE AS BIOMARKERS OF DISEASE ACTIVITY IN PSORIATIC ARTHRITIS PATIENTS

Rafael Ferreira, Sara Garanhão, Bruno Miguel Fernandes, Salomé Garcia, Sofia Pimenta, Miguel Bernardes, Lúcia Costa, São João Hospital Centre, Porto, Portugal

Background: Monocyte-lymphocyte ratio (MLR), neutrophil-lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) have been used to evaluate the inflammatory status in a wide variety of diseases like cardiovascular and autoimmune diseases. Furthermore, some recent data showed relevant association of this haematological parameters with others traditional inflammatory measures as serum c-reactive protein (CRP) levels in rheumatic patients, suggesting their use as a valuable indicator of disease activity.

Objectives: To assess the association between the NLR, MLR, eosinophil-lymphocyte ratio (ELR), basophil-lymphocyte ratio (BLR) and PLR with disease activity and functional parameters in psoriatic arthritis (PsA) patients.

Methods: An observational cross-sectional study was performed in patients with psoriatic arthritis before introduction of a bDMARD, followed at our Rheumatology department until December 2018. Demographic, clinical and laboratory information were collected from the national database (Rheuma.pt). Available data of blood cell counts were consulted and NLR, MLR, ELR, BLR and PLR were calculated by dividing neutrophil, monocyte, eosinophil, basophil and platelet count by lymphocyte count, respectively. The following disease activity and functional scores were assessed: levels, CRP and ESR, DAS28 4V and 3V (ESR and CRP), HAQ, BASDAI, ASDAS-CRP, BASMI, BASFI, swollen and tender joints counts (SJC and TJC), SPARCC index, patient global assessment (PGA) and physician global assessment (PGA) rated on a visual analogue scale (VAS). Correlations between variables were evaluated with Spearman’s test. The statistical analysis was performed using SPSS 21.0 software. Differences were considered statistically significant at p<0.05.

Results: A total of 83 patients were enrolled. Forty-three were females (51.8%) and forty were males (48.2%). The mean age was 47 years (SD 10.9) and the median disease duration at start of biological therapy was 6.9 years (min:1.4; max:32.4). In total, 67.5% of the patients had axial involvement (n=56), 91.6% articular involvement (n=76) and 43.4% enthesopathic involvement (n=36). Almost all patients fulfilled the CASPAP criteria for PsA (n=78; 94%). Thirty patients presented with arthritis (36%). Most were non-smoking (n=48; 57.8%) and most didn’t have history of alcohol consumption (n=55; 66.3%). According to ASDAS criteria, 25 patients (30.1%) had high disease activity and 45 patients (54.2%) very high disease activity. At time of evaluation, 71.1% were receiving csDMARDs. NSAIDs and corticosteroids were prescribed in 80.7% and 54.2% of the patients, respectively. We found statistically significant correlation between MLR values and CRP levels (r=0.278, p=0.014). MLR did not correlate with ESR levels, DAS28 4V and 3V (ESR and CRP), HAQ, BASDAI, ASDAS-CRP, BASMI, BASFI, SJC, TJC, SPARCC, PGA and PGLR values also had weak correlation with ESR (r=0.340, p=0.002), DAS 4V-ESR (r=0.260; p=0.027) and with DAS 3V-ESR (r=0.290, p=0.012). There was no statistically significant correlation between PLR values and others disease parameters. No significant correlation were found between NLR, ELR and BLR and the functional and disease activity scores evaluated.

Conclusion: Our study showed that MLR had a positive association with CRP and PGA with ESR, DAS 4V-ESR and DAS 3V-ESR. Evaluation of this novel inflammatory biomarkers may represent a simple, cost-effective and useful tool in monitoring disease activity in PsA patients.

SAT0658 A LONGITUDINAL ANALYSIS OF ANTI-FHL1 ANTIBODIES IN A SWEDISH COHORT OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Angéles Shunashy Galindo-Feria,1 Elískia Divíšová,2 Cátia Fernandes-Cerqueira,1 Maryam Dastmachi,1 Edward Wiggen,3 Susanne Gräslund,1 Ingrid E. Lundberg1
1Karolinska Institute, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; 2Charles University—Faculty of Medicine in Hradec Králové, Hradec Králové, Czech Republic

Background: Antibodies targeting a novel and muscle-specific autoantigen, the Four-and-a-half-LIM-domain 1 (anti-FHL1), have been identified in patients with idiopathic inflammatory myopathies (IIM). Objectives: The aim of this project was to evaluate when anti-FHL1 auto-antibodies are present in the course of the disease and if autoantibodies titers vary over time.

Methods: The anti-FHL1 antibody status was obtained from a previous serological cross-sectional analysis from where we selected sera from IIM anti-FHL1+ patients (n=26) and sex and age matched sera from IIM anti-FHL1 patients (n=51), and healthy controls (HCs, n=50). Levels of anti-FHL1 autoantibodies were evaluated by ELISA. Patients included in the study had at least one sample available at time of diagnosis and one consecutive serum sample within an interval of 36 months. All patients were followed at the Division of Rheumatology, Karolinska University Hospital from January 1982 to December 2017. HCs sera collected at a single time point were tested.

Results: In the IIM group we included 76 patients with a total of 320 serum samples. Median follow-up time was 108 months, with median of 4 samples available per patient. In total, we identified the presence of anti-FHL1+ antibodies in n=31 IIM patients, corresponding to the group of
APPLYING THE OMERACT TRUTH FILTER TO A NEW PROPOSAL OF CORE OUTCOME DOMAINS IN MIXED KINGDOM

were fluctuating around the cut-off point. Eight of 14 (57%) patients from the intermediate positive and baseline negative groups were seroconverted around the cut-off point. Eight of 14 (57%) patients from the group “baseline negative” seroconverted to anti-FHL1 within the first 36 months. The anti-FHL1 “negative” group presented constant low anti-body titers during the longitudinal follow-up.

Conclusion: Anti-FHL1 antibody positivity was detected in patients with high titers of anti-FHL1 antibody in the first available serum sample or developed within the first 36 months after diagnosis and persisted over many years. A group of patients with intermediate levels had fluctuating positivity over the years. It is still unknown if the anti-FHL1 antibody titer is a marker of prognosis and/or damage in IIM; thus, clinical data needs to be addressed, and in-vitro experiments and biochemical characterization of this autoantibody are still required.

SAT0659 APPL YING THE OMERACT TRUTH FILTER TO A NEW ELECTRONIC SPINAL MOBILITY INDEX FOR AXIAL SPONDYLOARTHROPSIS BASED ON INERTIAL SENSORS

Philip Gardiner1, Dawn Small1, Pedro Machado2, Karla Munoz Esquivel2, Joan Condell3, Antonio Cuesta-Vargas4, Juan L. Garrido-Castro5.

1Rheumatology Unit, University of the Basque Country, 2University of Malaga, 3Ulster University, Coleraine, United Kingdom, 4University of Malaga, Malaga, Spain, 5University of Cordoba, Cordoba, Spain

Background: Loss of spinal mobility is one of the most characteristic problems for people with axial spondyloarthrits (axSpA) and is predictive of loss of function. Traditional measures such as the BASMI fail to capture many elements of spinal mobility and lack responsiveness to change. Inertial Motion Unit (IMU) sensors can be used to accurately measure spinal movement without requiring significant operator expertise.

Objectives: The primary objective of this study was to test the reliability of these new tools in patients with axSpA and to develop a new composite spinal mobility index. Our secondary objective was to apply the OMERACT ‘Truth’ filter to evaluate the new index for bias, for clinical relevance, and for convergent validity with existing measures.

Methods: Patients with axSpA fulfilling ASAS classification criteria were recruited. A Move system was used to obtain ROM by attaching two IMU sensors at the cervical (Occiput-T3) and lumbar spine (L1-Sacrum). Intrarater, inter-rater and test-retest reliability of IMU tests were assessed by intraclass correlation coefficients (ICC). The maximum range of movement for anterior flexion/extension (AFE), lateral flexion (Left-Right) and rotation (Left-Right) were obtained for the lumbar and cervical region. These six values were used in a composite score (IMU-ASMI) which referenced equivalent ROM values from normal subjects in an earlier criterion validity study. Pearson correlation coefficients with BASFI were calculated for each component as well as the overall score.

Results: The study included 40 patients (12 females, 28 males) with a mean age of 48 (27-41). Subjects had a wide range of severity of axSpA. The mean BASMI was 4.8 (range 0.7 to 8.2, SD 1.9). The mean IMU-ASMI was 4.0 (range 1.9-5.2, SD 2.1). The sensor based measurements had good to excellent reliability (Table 1) and correlated closely with BASMI (r=0.79). The mean BASFI was 4.6 and the IMU-ASMI correlated closely with BASFI (r=0.71).

Face Validity: Each IMU test presents spinal movement in angles and can also be represented as a normalized severity index analogous to BASMI. The mean cervical and lumbar IMU-ASMIs were 3.5 and 4.4 units, respectively.

Construct Validity: Do IMU movements correlate with their corresponding traditional measurements? As expected, the closest correlations were between IMU and goniometer cervical rotation (r=0.85) and between IMU and tape measure lumbar side flexion (r=0.84). Correlations between Schober’s test and IMU lumbar AFE and between tragus to wall and IMU cervical FE were moderate (r=0.62, 0.65).

Do IMU movements correlate with BASFI? Correlation coefficients were as follows: lumbar AFE -0.57; rotation -0.59; side flexion -0.45; cervical AFE -0.55; rotation -0.61; side flexion -0.39. BASFI correlations with BASMI were comparable.

Content Validity/Comprehensiveness: No major ceiling or floor bias issues were found in the composite indices. Intrameasure distance (BASMI) represents hip rather than spinal mobility, but it correlates with BASFI and is not in the IMU-ASMI. IMU-ASMI includes lumbar rotation which accounts for 27% (0-53%) of the lumbar mobility score.

Conclusion: IMU sensors can be used by non-experts to accurately and reliably measure spinal mobility in patients with axSpA. Lumbar rotation is an important new outcome measure.

Background: Cryoglobulinaemic vasculitis is immune complex mediated vasculitis of medium and small-size vessels. This vasculitis involves mainly kidneys, peripheral nervous system, skin and joints. Currently, no standardized outcome measures are available for the evaluation of treatments in patients with cryoglobulinemic vasculitis.

Objectives: To identify a core set of outcome measure (what to measure) for clinical studies for mixed cryoglobulinemic syndrome, following the OMERACT filter 2.0. [Ref]Methods: A search was made in Medline (via PubMed) and Embase using a standardized search [filter https://omeracthandbook.org/]. This review considered studies that included patients with Mixed (type 2 and 3) cryoglobulinemic syndrome, any type of outcome measures, articles in

Table 1. Results of ICC for different IMU spinal mobility tests
the English language and considered only SLR, RCT, cohort, case control and case series (>5 patients). Data were screened independently by three reviewers, recorded on a prespecified extraction form and summarized qualitatively. Considering core areas and core domain set was drafted. The results were presented and voted by a Consensus Committee including physicians with expertise in rheumatic, kidney and infectious diseases. Specific domains were separately voted and scored from 1 (strongly disagree) to 5 (strongly agree). Agreement was calculated as the percentage of agree/strongly agree. Consensus was reached in case of >70% of agreement.

Results: In the review were included 88 studies of which 4 randomised clinical trial (3%, 144 patients), 3 systematic literature reviews (9%, 401 patients), 25 cohort studies (27%, 1284 patients), and 56 other observational studies (61%, 2871 patients). The most frequent domains were: bio-humoral activity markers (e.g. cryocrit, rheumatoid factor, complementemia), viral infection and liver function, reversible and non reversible manifestation of skin, peripheral nerve, kidney, joint. Only a few studies included as life impact area, survival and safety. No studies analyzed included economical impact. Drafted core domains within core areas and percent agreement from the Delphi survey are reported in Table I. Additional core domains included adverse events and viral infection, considered as contextual factor.

Conclusion: This is the first study aimed at identifying the core outcome measures in cryoglobulinemic vasculitis. Further studies will be needed to evaluate appropriate instruments to measure these outcome domains to be applied in clinical trials and practice.

SAT0662 MXA IS A CLINICALLY APPLICABLE BIOMARKER FOR TYPE I INTERFERON ACTIVATION IN SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS
Edika Huijser1, C.G. van Helden-Meeuwsen2, Noortje Groot3, Iris LA Bodewes4, M. Javad Wahadat2, Marco WJ Schreurs5, Paul LA van Daele1,2, Virgil Ash Dalm3, Jan van Laar4, P Martin van Hagen1,2, Matti Waris6, Sylvia Kampius6, Marijan Versnel7,8. 1Erasmus MC, University Medical Center Rotterdam, Department of Immunology, Rotterdam, Netherlands; 2Erasmus MC, Sophia Children’s Hospital, University Medical Center Rotterdam, Department of Paediatric Rheumatology, Rotterdam, Netherlands; 3Erasmus MC, University Medical Center Rotterdam, Department of Internal Medicine, Division of Clinical Immunology, Rotterdam, Netherlands; 4University of Turku, Department of Virology, Turku, Finland

Background: Activation of the type I interferon (IFN) system has been found in large subsets of patients with systemic autoimmune diseases. This is usually assessed with a laborious quantification of IFN-stimulated genes. An easier and cheap biomarker would facilitate implementation of type I IFN measurements in diagnostic laboratories. Previously, we described Myxovirus resistance protein 1 enzyme immunoassay (MXA-EIA) for systemic evaluation of type I IFN activity in primary Sjögren’s syndrome [1].

Objectives: To assess the applicability of the MXA-EIA to detect systemic type I IFN activation in patients with systemic lupus erythematosus (SLE) and systemic sclerosis (SSc).

Methods: Whole blood intracellular MXA protein levels were measured in SLE (discovery cohort n=25; replication cohort retrieved from the CHILL-NL study [2]: n=102), SSc (n=28) and healthy controls (HC) using the MXA-EIA. IFN scores were determined from whole blood gene expression of interferon-stimulated genes IFI44, IFI44L1, IFIT1, IFIT3, and MXA by RT-PCR.

Results: MXA levels were significantly elevated in patients with SLE and SSc compared to HC and highly correlated to IFN scores (r=0.735 to r=0.854, p<0.003). MXA-EIA robustly discriminated (AUC=0.938 to AUC=0.991, p<0.007) between low and high type I IFN activity in SLE and SSc patients with a specificity of 100% and a sensitivity of 67.5 to 94.7%. Patients with autoantibodies against SM, RNP, SSA/Ro, or SSB/La antigens showed higher MXA levels and IFN scores compared to patients without these antibodies.

Conclusion: Intracellular MXA is an easy applicable and clinically relevant biomarker for systemic type I IFN bioactivity in SLE and SSc. MXA-EIA could be used to identify patients eligible for IFN-targeting treatments and potentially to monitor treatment responses.

SAT0663 SERUM INFLAMMATORY ANGIogenic AND Tissue REMODELING BIOMARKERS IN PERIPHERAL SpondylOarthritis Before and After IL-17A Blockade
Merlin Kaal1,2, Leontiee van Mens1, Jan Piet van Hamborg1,2, Dominique Baeten1,4, Marleen van de Sande1, Sander W. Tuij2,1. 1Amsterdam UMC, University of Amsterdam, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; 2Amsterdam UMC, University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands

Background: Spondyloarthritis (SpA) is characterized by extensive angiogenesis, tissue remodeling and inflammation of both the enthesis and the synovial tissue. Several studies have shown a relation between angiogenic/tissue remodeling serum markers and disease progression. Secukinumab, an anti-IL-17A inhibitor, is an effective treatment in SpA, but it’s effects on serum markers of angiogenesis, tissue remodeling and inflammation are largely unknown.

Objectives: The purpose of this study was to analyze several candidate biomarkers of these processes in patients with SpA treated with anti-IL-17A.

Methods: Serum samples from 20 active peripheral SpA patients that were included in a 12 week open-label trial with secukinumab were analyzed for several markers with lumines protein technology. Study design and primary results were previously published (1).

Results: Serum levels of IL-6, MMP-3, osteopontin (all P < 0.001), Vascular Endothelial Growth Factor A (VEGFA), tumour necrosis factor (TNF)-alpha, IL-31, IL-33, S100A8, S100A9 (all P < 0.05) decreased

Scientific Abstracts
Saturday, 15 June 2019
1429
significantly upon treatment with anti-IL-17A. These serum level changes correspond with the clinical responses and the published effects on inflamed target tissues of this cohort. Meanwhile, serum levels of DKK-1, ROCB4, sclerostin and CD40L remained unchanged.

Conclusion: These results indicate that anti-IL-17A not only diminishes inflammation, but also impacts on other processes such as angiogenesis and tissue remodeling. Whether these observations are predictive of disease progression or outcome remains to be determined.

SAT0663 ABILITY OF THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE TO IDENTIFY RHEUMATOID ARTHRITIS PATIENTS IN REMISSION AT RISK OF RELAPSE AFTER TNF-BLOCKER TAPERING. AN ANCILLARY STUDY OF THE STRASS TRIAL

KOSSI Sandra1, Eric H. Sasso2, Hubert Marotte3, Xinyu Liu2, Florence Tubach1, David Hajage1, Bruno Fautrel1.

Background: Rheumatoid arthritis (RA) patients in sustained remission are candidates for tapering of disease modifying anti-rheumatic drugs (DMARDs). However, no predictors of relapse have been clearly identified so far. The STRASS trial included 137 RA patients in sustained DAS28 remission with TNF blockers (TNFb) who were randomized to 2 strategy arms: maintenance of TNFb at full dose or progressive DAS28-driven spacing of TNFb injections 1. RA relapses were significantly more common with TNFb spacing in STRASS but no baseline characteristics predicted the risk of relapse in either strategy arm. The multi-biomarker disease activity (MBDA) blood test measures 12 serum protein biomarkers and uses a validated algorithm to produce a score for RA disease activity on a scale of 1-100. In some studies, the MBDA score was a significant predictor of flare following DMARD tapering in well controlled RA patients.

Objectives: To test the ability of the MBDA score to identify rheumatoid arthritis patients who will relapse following continuation or tapering of TNF blocker (TNFb) treatment in the STRASS study.

Methods: MBDA scores were determined in a central laboratory (Crescendo Biosciences, San Francisco, USA) for available archived serum samples that had been obtained at baseline from patients in STRASS (N=133). The ability of the MBDA score to predict relapse (defined as DAS28 >2.6 and increased >0.6 from previous study visit) in each arm of the 18-month STRASS trial was assessed by: 1) comparing MBDA scores in relapsing vs. non-relapsing patients by Wilcoxon rank sum and Fisher’s test, and 2) determining the ability of the MBDA score to discriminate relapse, based on receiver operating characteristic (ROC) analysis summarized by C-statistic (i.e., area under the ROC curve [AUC]), and its 95% confidence interval (CI). Analyses were performed for intention-to-treat (ITT) and completer populations.

Results: At 18 months, 48% and 77% of the patients relapsed in the full dose maintenance and the spacing arms, respectively. In each study arm, mean MBDA scores and the percentages of patients with low, moderate or high MBDA scores at baseline were not significantly different in relapsing vs. non-relapsing patients (Table 1). The ROC analyses displayed no statistically significant discriminating ability for the MBDA score in terms of relapse prediction over the 18-month period of the trial in either arm of the ITT population (Figure 1). However, a significant ROC result was obtained in the maintenance group in the complete analysis (AUC 0.638 [95% CI: 0.502, 0.774], p<0.01).

*Each comparison between No relapse vs. Relapse groups was not statistically significant (p >0.05).

Conclusion: The MBDA score did not display quantification of the risk of relapse in RA patients in remission, when assessed, in the context of the DAS28-driven TNFb tapering strategy in STRASS.

SAT0664 RESPONSIVENESS OF PATIENT-REPORTED PHYSICAL FUNCTION OUTCOME MEASURES IN A REAL LIFE INTERNATIONAL COHORT OF 405 PATIENTS WITH PSORIATIC ARTHRITIS

Ying Ying Leung1, Ana-Maria Orbai2, Maarten de Wit3, Andra Balanescu4, Emmanuelle Denis5, Martin Soubrie6, Lihi Edery7, Joel S. Smolen8, Laura C. Coates9, Laure Gosse10, ReFlap study group, 1Singapure General Hospital, Singapore, Singapore, 2John Hopkins University, Baltimore, United States of America, 3Amsterdam University, Amsterdam, Netherlands, 4St Maria Hospital, Bucharest, Romania, 5Le Mans Central Hospital, Le Mans, France, 6Gabriel Montpied Hospital, Clermont-Ferrand, France, 7University of Toronto, Toronto, Canada, 8Medical University of Vienna, Vienna, Austria, 9University of Oxford, Oxford, United Kingdom, 10Pitié Salpêtrière Hospital, Paris, France

Background: Physical function (PF) is a core domain to be measured in all trials for psoriatic arthritis (PsA); several instruments can be used but have not been compared.

Objectives: To evaluate the longitudinal construct validities of 3 physical function patient-reported outcome measures (PF-PROMs): HAQ-disability

Figure 1. Discriminative ability of the MBDA test to identify RA patients at risk of relapse during the 18-month follow-up in the STRASS trial, based on ROC analyses of the ITT population.

Disclosure of Interests: Ying Ying LEUNG: None declared, Ana Maria ORBAI: None declared, Maarten DE WIT: None declared, Andra BALANESCU: None declared, Emmanuelle DENIS: None declared, Martin SOUBRIE: None declared, Lihi EDERY: None declared, Joel S. index (HAQ-DI), physical functioning of SF12 (SF12-PF) and functional capacity of Psoriatic Arthritis Impact of Disease (PsAID-PF).

**Methods:** The Remission/Flare in PsA (ReFlap) study (NCT03119805), is a prospective longitudinal study in 14 countries of consecutive adults with definite PsA collecting validated PsA outcomes. We assessed longitudinal construct validity using correlation between change scores of PF-PROMs with other assessments, according to a priori hypotheses. Responsiveness was assessed using the change of PF-PROMs anchored with patient-defined improvement/worsening at follow-up. We calculated the relative effectiveness statistic (RE=Standardized response mean, SRM$^2$ ratios) for each PF-PROM comparing improved/worsened groups vs. no change at follow-up.

**Results:** Of 466 subjects recruited, 405 completed follow-up (50.8% male, mean(SD) age = 52.7 (12.6) years). After a mean (SD) follow-up of 4.3 (2.7) months, 27.6%, 55.0% and 17.4% reported improvement, no change and worsening. All change scores of the PF-PROMs met the a priori hypotheses (Table 1). PF-PROMs change scores were statistically different for improved and worsened group from the no change group (p<0.001).

All PF-PROMs were more sensitive to worsening than improvement in PsA studies. These data will help to choose outcomes in PsA studies.

**Abstract Table 1.** Correlations of PF change with change in other outcomes, Spearman’s rank correlation

**PLASMA HS PRO-C2 LEVELS PREDICT RADIOGRAPHIC PROGRESSION IN SYMPTOMATIC KNEE OSTEOARTHRITIS PATIENTS**

Yunyun Luo1,2, Jonathan Samuel6,4, Svetlana Krasko6,4, Yi He1,2, Morten Karasd1, Steven Abramson6,4, Anne-Christine Bay-Jensen1, Nordic Bioscience, Bimarkers and Research, Herlev, Denmark; 2University of Copenhagen, Biomedical Sciences, Copenhagen, Denmark; 3New York University, Langone Orthopedic Hospital, New York, United States of America; 4New York University, School of Medicine, New York, United States of America

**Background:** There is a lack of objective diagnostic modalities that identify patients at risk for severe osteoarthritis (OA), which complicates the development of disease-modifying OA drugs. The biochemical marker, high-sensitive PRO-C2 (hsPRO-C2), is a measure of the propeptide of type II collagen and a blood measure of cartilage formation.

**Objectives:** The aim of this study was to determine whether hsPRO-C2 could predict radiographic progression in a knee OA population and stratify patients into high and low risk for joint destruction.

**Methods:** Subjects with varying degrees of symptomatic knee OA (n=106) were included from a New York University (NYU) progression cohort. Radiographic progression was assessed by medial joint space narrowing (JSN), based on the change in joint space width (JSW), of the signal knee at baseline and at 24months. Baseline plasma type II collagen formation biomarker (hsPRO-C2) levels were measured. Association between
baseline hsPRO-C2 and JSN was analyzed by Pearson’s correlation, corrected for age, sex, BMI, race, baseline JSW, and non-steroids anti-inflammatory drugs (NSAID) use. Subjects were divided into quartiles of equal size depending on the hsPRO-C2 levels, and the difference in JSN was investigated. The median level of baseline hsPRO-C2 (1.48 ng/ml) was used as a cut-off for stratifying all the subjects. The difference in JSN over 24 months was investigated in patients dichotomized based on median level. The values were compared with two-way analysis of covariates (ANCOVA).

Results: Baseline plasma hsPRO-C2 levels were negatively correlated with the progression of radiographic joint space narrowing over 24 months (r = -0.14, p = 0.009) after adjustment for confounders (Figure 1A). Quartile analysis demonstrated a decreasing trend of hsPRO-C2 in the radiographic progression from quartile 1 to 4 (Figure 1B). One-way ANOVA revealed a significant difference in mean JSN between quartiles 1 and 4 (0.5073 mm versus -0.0691 mm, p = 0.036, Figure 1B). JSN was significantly larger in the low hsPRO-C2 patients (0.3710 mm) compared to the high hsPRO-C2 patients (0.0185 mm) (Figure 2).

Conclusion: These data suggest that symptomatic knee OA subjects with lower levels of hsPRO-C2 at baseline presented more radiographic medial JSN progression compared to the subjects with higher levels of hsPRO-C2. The biomarker hsPRO-C2 may be useful for predicting OA progression.

SAT0666

ASSESSMENT OF INFLAMMATORY AND IMMUNE PATHWAYS IN RHEUMATOID ARTHRITIS PATIENTS USING BIOPRED KIT TO IDENTIFY CANDIDATE BIOMARKERS
Madah Mehdi1, Eric Schordan2, Matthieu Coq3, Sami Alzahabi1, Hüseyin Finl1, Christian Jorgensen4,2, Finalis SA, Huningue, France, 2VRMB Inserm U1183, Université de Montpellier, Montpellier, France

Background: Rheumatoid Arthritis (RA) is a chronic, progressive, inflammatory autoimmune disease associated with articular, extra-articular and systemic effects leading to joint destruction. T cells, B cells and the orchestrated interaction of pro-inflammatory cytokines play key roles in the pathophysiology of RA. Better comprehension of interaction between cytokines and their signaling pathways are key for the development of new strategies with small molecules or biologicals. Today, new technologies allow the specific investigation of inflammatory pathways at mRNA level without extraction step directly from the blood. The BIOPRED panel, Disease activity specific gene enrichment studies in RA & other autoimmune-inflammatory disorders would help pharmaceutical industry tailor target specific therapies and would help clinicians choose optimal & personalized therapy for their patients. Therefore, we have identified active biological pathways in RA patients associated with different disease activity status.

Objectives: By using Firalis’ BIOPRED assay, a targeted gene sequencing panel including 2155 mRNAs from inflammatory and immune pathways, we aimed to identify active biological pathways in function to different disease activity status of RA and Healthy volunteer (HV) subjects.

Methods: Paxgene samples of active RA patients with DAS28>3.2 (n=178) and HV (n=25) are directly profiled without RNA extraction with BIOPRED assay and 2155 mRNA were quantified on HTG EdgeSeq platform, a combination of a nucleic acid protection assay & next generation sequencing (NGS). Subjects are categorized into three groups: High disease activity (HDA) group with DAS28 >5.1, Moderate disease activity (MDA) group with DAS28 between 3.2 and 5.1, and Healthy volunteer (HEV) group.

Results: After transformation and normalization of the gene expression data, 22 mRNA genes are found to be significantly upregulated in RA (p-value < 0.005, fold change > 2) as compared to HV group. After ANOVA analysis on three groups as stated above, 351 mRNA targets are significantly regulated (p-value < 0.005). Pathway analysis based on protein-protein interaction from BioGrid, String and Intact database was used and score were generated based on fold change for 22 pathways to assess modification in HDA and MDA groups versus HV group. Various pathways including Jak/STAT pathway were shown to be significantly upregulated.

Conclusion: Our results identify a list of mRNAs relevant to RA pathology and pathways that have the potential to be candidate biomarkers for disease activity, disease severity or as therapeutic targets. Moreover, BIOPRED panel accurately measures 2155 mRNA (Coefficient of Variation is less than 20% for more than 1100 mRNAs) from inflammatory and immune pathways and can be further used to study pathway analysis in autoimmune-inflammatory disorders such as RA.

Disclosure of Interests: None declared

TREATMENT RESPONSE CRITERIA FOR ANCA-ASSOCIATED VASCULITIS: RESULTS OF A SCOPING REVIEW
Sara Moní1,2, Kaitlin A. Quin3, Robin Christensen4, Alfred Mahr5, Christian Pagnoux6, Carol Langford7, David Jayne8, Peter Merkel9, Sara Monti1,2, Kaitlin A. Quinn 3, Robin Christensen4, Alfred Mahr5, Christian Pagnoux6, Carol Langford7, David Jayne8, Peter Merkel9, Christian Pagnoux6, Carol Langford7, David Jayne8, Peter Merkel9, Sara Monti1,2, Kaitlin A. Quinn 3, Robin Christensen4, Alfred Mahr5, Christian Pagnoux6, Carol Langford7, David Jayne8, Peter Merkel9

Background: A comprehensive assessment of outcome measures to assess response to treatment in ANCA-associated vasculitis (AAV) is necessary to implement.
Objectives: To perform a review of outcome measures to assess response to treatment in AAV which will help advance methodology for clinical trials in this disease.

Methods: As part of an ongoing international project to develop response criteria, we performed a scoping review to assess the tools used as outcome measures in randomized clinical trials (RCTs) of AAV. Medline, Cochrane Central, and ClinicalTrials.gov were searched from inception until November 2018 to identify RCTs enrolling patients with granulomatosis with polyangiitis and/or microscopic polyangiitis. AAV assessments in RCTs for AAV and the current lack of a composite defined or evaluated. Furthermore, other important outcomes in AAV, such as renal function, were not always reduced to a dichotomous variable (0 or > 0) providing distinction between remission and active disease. Reduction in BVAS and/or achievement of BVAS-0 represented a main study outcome (primary or secondary endpoint) in 20/24 (83%) RCTs; 6 of these trials used the BVAS/WG. Damage, mainly assessed by the Vasculitis Damage Index (VDI), was an outcome for 14/24 (58%) RCTs. Physician global assessment and patient-reported outcomes (PROs) [measures of health-related quality of life (HRQoL) and/or patient global assessment] were assessed in 7 (29%) and 14 (58%) RCTs, respectively. Assessment of renal function or activity was a major outcome or specifically included in definitions of remission/relapse in 23/24 (96%) RCTs. Timing for outcome measure assessment differed substantially, with baseline, 6 months (15/20 RCTs), and 12 months (14/20 RCTs) after enrollment being the most common time points for reporting BVAS and VDI. Assessment of disease state occurred as early as 1-4 weeks after enrollment.

Conclusion: Outcome measures used in RCTs of AAV include the repeated use of vasculitis specific tools to assess disease state, but with heterogeneity in the definitions for remission/relapse and timing of assessment. Intermediate states of disease activity are currently poorly defined or evaluated. Furthermore, other important outcomes in AAV, such as renal function and damage measures, and global assessments are often not included as primary or confirmatory secondary outcomes in RCTs in AAV. This review highlights the need for more homogeneous outcome assessment in RCTs for AAV and the current lack of a composite measure that integrates various endpoints relevant to physicians and patients.

DISCRIMINANT ABILITY OF THE PARENT VERSION OF THE JUVENILE ARTHRITIS DISEASE ACTIVITY SCORE IN A LARGE MULTINATIONAL COHORT OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Francesca Ridella1, Giedre Januskeviciute2, Chiara Trincaniti1, Gabriella Giancane3, Alessandra Alongi2, Soamarat Vilayuk4, Gaetlle Chidevile5, Chris Pruensis6, Pekka Lahderinne7, Nicolinno Ruperto8, Angelo Ravelli9, Alessandro Consolaro10,11. For the EPOCA study group. University of Genova, Genova, Italy; 12Klaipedas Children Hospital, Klaipeda, Lithuania; 11Ospedale Giannini Gaslini, Genova, Italy; 13Mehdihi University, Salaya Campus, Tambon Salaya, Thailand; 4McGill University, Montreal, Canada; 5University of Tartu, Tartu, Estonia; 6University of Helsinki, Helsinki, Finland

Background: The assessment of disease activity plays a pivotal role in the management of children with juvenile idiopathic arthritis (JIA). Most recent recommendations require that parents’ and children’s perception is incorporated in the evaluation of the disease course and of effectiveness of therapeutic interventions. A new disease activity tool, named parent Juvenile Arthritis Disease Activity Score (parJADAS) and based only on parent-centered outcome measures, is currently under development (1).

Objectives: To demonstrate, in a large multinational dataset of JIA patients, the discriminant ability of the parJADAS.

Methods: The parJADAS includes 4 measures: 1) parent assessment of disease activity; 2) assessment of pain intensity; 3) proxy assessment of joint disease; 4) assessment of morning stiffness (MS). Disease activity and pain are assessed on a 21-numbered circle VAS (0 = best and 10 = worst). The active joint count is based on the count of any swollen or painful joint, irrespective of its type, up to a maximum of 10 joints. MS duration is assessed on a Likert scale, ranging from no MS (0 points) to > 2 hours of MS (10 points). Validation was conducted on a dataset of 8,656 children with JIA from 49 countries, enrolled in the study of Epidemiology, treatment and Outcome of Childhood Arthritis (2), who had all the variables included in the parJADAS available. Discriminant ability was evaluated by comparing parJADAS levels (median, IQR) among patients with inactive disease (ID), low disease activity (LDA), moderate disease activity (MDA), and high disease activity (HDA) according to the CJADAS10; patients in remission, continued activity, or flare according to the attending physician; patients whose parents were satisfied or not with current disease state. To assess the possible influence of the articular and extra-articular damage on the parJADAS, the levels of the score in patients with or without damage (Juvenile Arthritis Damage Index > 0) were compared. For this analysis, only subjects in inactive disease and with at least 2 years of disease course were considered (n = 2,423).

Results: The levels of parJADAS in patients in ID, LDA, MDA, and HDA were 0.0 [0.0, 1.0], 3.0 [1.0, 6.0], 6.0 [2.0, 11.5], an 14.5 [8.5, 21.0], respectively (Kruskal-Wallis test, p < 0.001). The levels of par JADAS in patients in remission, continued activity, or flare according to the attending physician were 0.5 [0.0, 3.5], 9.0 [3.5, 17.0], 12.0 [5.5, 20.0], respectively (Kruskal-Wallis test, p < 0.001). Median parJADAS in patients whose parents were satisfied or not satisfied with disease course is 1.5 [0.0, 7.0] and 13.0 [6.6, 20.5], respectively (Mann-Whitney test p < 0.001). ParJADAS was not different in JIA patients in remission with or without damage measured with the JADI (Mann-Whitney test p = 0.08).

Conclusion: The parJADAS showed excellent discriminate ability in a large multinational cohort. The score did not show to be relevantly influenced by disease damage in JIA patients in remission.

The score did not show to be relevantly increased by disease damage in JIA patients in remission.
SAT0670 REDUCING THE IMPACT OF THE PATIENT GLOBAL ON BOOLEAN REMISSION CRITERIA FOR RHEUMATOID ARTHRITIS

Paul Studenic1, David T. Felson2, Maarten de Wit3, Tanja Stamn4, Josef S. Smolen1, Daniel Atehah1, 1Medical University of Vienna, Division of Rheumatology, Vienna, Austria; 2Boston University School of Medicine, Department of Medicine, Boston, United States of America; 3Amsterdam University Medical Centre, Department of Medical Humanities, Amsterdam, Netherlands; 4Medical University of Vienna, Section for Outcomes Research, Vienna, Austria

Background: The patient global assessment (PiGA) is a core set variable to assess disease activity in rheumatoid arthritis (RA). It is strongly linked to patient-reported pain and has shown to be a limiting factor for reaching remission in patients with remittent joint inflammation and normal acute phase response, particularly when the ACR/EULAR Boolean criteria are used. In these, the PiGA may not be greater than 10 on a 0-100 scale to reach remission.

Objectives: To analyse the impact of higher cut-offs for or removal of the PiGA applied in the ACR/EULAR Boolean remission on the consistency with the SDAI remission definition, and with respect to long-term structural and functional outcomes.

Methods: We retrieved data from six clinical trials testing the efficacy of tumor-necrosis factor inhibitors vs MTX or placebo/MTX. Three trials depicted early RA: ASPIRE (infliximab), Go Before (golimumab), PREMIER (adalimumab); and three late RA: ATTRACT (infliximab), DE019 (adalimumab) and Go Forward (golimumab). We increased the cut-off of the PiGA gradually by 5mm (mB20015-REM) up to 30mm, and also omitted the criterion completely (Boolean-NO REM, i.e. requiring only CRP, SJC, TJC/C). We assessed frequencies of remission by these definitions at 6 months, and explored clinical characteristics of remission according to each remission definition. Further, we explored functional and structural outcomes 1 year after achievement of a remission.

Results: We included 3263 patients in our study, 2121 in early and 1172 in late RA (mean disease duration: 1.5±3.0 and 9.8±8.6 years, respectively). The rates of patients achieving Boolean remission increased with higher allowance for PiGA from 11.9% to 18.6% in early RA, and from 5.9% to 12.4% in late RA. CRP values across all definitions, including no PiGA, were similar (data not shown).

Conclusion: Increasing the PiGA cut-off to 15mm would provide highest consistency between Boolean with the index based remission, while the integer cut-off of 20mm (or 2/10) would also allow the use on numerical rating scales. This new cut-off would discount the overly stringency of the PiGA in the remission context, while keeping the patient perspective in the core of RA disease activity evaluation.

SAT0671 SEROCONVERSION OF AUTOANTIBODIES TO UH-RA.21 PEPTIDE IS ASSOCIATED WITH CDAI REMISSION IN RHEUMATOID ARTHRITIS PATIENTS OF THE CARERA COHORT

Silke Loyens1, Patrick Vandermael2, Liesbeth De Winter3, Veerle Stouten4, Piet Geusens1, Patrick Vandermael5, Silke Loyens1, Veerle Stouten1, 1Hasselt University, Biomedical Research Institute, Diepenbeek, Belgium; 2KULeuven, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, Leuven, Belgium; 3ReumaClinic, Genk, Belgium; 4Maastricht University Medical Center, Internal Medicine, Rheumatology, Maastricht, Netherlands

Background: Autoantibodies are present in the majority of rheumatoid arthritis (RA) patients and are used clinically as diagnostic serum biomarkers. Insight in their role in prediction of therapy response and disease progression would provide a useful tool for patient stratification and personalized selection of a suitable treatment. In a previous pilot experiment, autoantibody levels to the University of Hasselt (UH) peptide UH-RA.21 were measured in patients continuing the same DMARD during a 17 month follow-up period, which was taken as a proxy for treatment success, persistently positive anti-RA.21 antibody levels showed an overall decrease in titer (p=0.0034).

Objectives: Our aim is to determine the association between autoantibodies to the UH-RA.21 peptide and disease remission in early RA patients from the CareRA cohort.

Methods: In the CareRA trial, different COBRA treatment regimens consisting of synthetic DMARDs combined with a step-down glucocorticoid treatment, have been studied. Disease remission was defined as a DAS28CRP<2.6, CDAI<2.6 or SDAI<3.3. Custom peptide enzyme-linked immunosorbent assays were used to screen for the presence of antibodies to the UH-RA.21 peptide in serum samples of the CareRA cohort. Cut-off for seropositivity was defined by 2 x SD above the mean antibody level of the healthy control group. Antibody reactivity to UH-RA.21 was evaluated in baseline samples, collected before the start of treatment. In 223 early RA patients from the CareRA cohort, patients that were positive for anti-UH-RA.21 antibodies at baseline, follow-up samples collected 16, 40, 52 and 104 weeks after the initiation of treatment were tested.

Results: Antibodies to UH-RA.21 were found in 21% (47/223) of the baseline samples from the CareRA cohort. Compared to baseline levels, combination therapy induced a 50% reduction of anti-UH-RA.21 antibody levels in 30% of patients after 16 weeks and in 47% of patients after 52 weeks. Seroconversion was observed in 16% (7/44) of patients after 16 weeks and 30% (10/34) after 52 weeks. Seroconversion was not correlated with remission according to the DAS28CRP or SDAI remission indices. However, of those patients which were UH-RA.21 positive at baseline, more seroconversion occurred in patients reaching remission (5/14, 36%) than in patients remaining in active disease (2/30, 7%), according to CDAI remission criteria (p=0.025).

Conclusion: A COBRA therapy induces a rapid decrease in anti-UH-RA.21 autoantibody levels in many patients. Moreover, early anti-UH-RA.21 seroconversion is associated with CDAI remission.

THE DIAGNOSTIC VALUE OF SERUM KL-6 IN CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASE

WU XUE, Lijun Wu, Cai Nan Luo, Ya Mei Shi. People’s Hospital of Xinjiang Uygur Autonomous Region, Department of Rheumatology and Immunology, Urumqi, China

Background: The connective tissue diseases (CTDs) are a group of inflammatory, immune-mediated disorders. Involvement of the respiratory system, particularly interstitial lung disease (ILD), is common and is an important contributor to morbidity and mortality. Currently, high-resolution computed tomography (HRCT), bronchoscopic examination and surgical lung biopsy (SLB) are the basic methods for the diagnosis of ILD. But these tests require specific inspection machines, are less repeatable and cause considerable discomfort to the subject.

Objectives: To evaluate the diagnosis of the serum Krebs von den Lungen-6 (KL-6) for the interstitial lung disease (ILD) associated with connective tissue diseases (CTD).

Methods: Patients with CTDs who visited our Hospital between January, 2016 and December, 2017, and whose serum KL-6 level was measured were included. We analyzed 175 patients with CTDs, 84 CTDs associated ILD, 91 CTDs patients without ILD. Record age, gender, diagnosis, serum KL-6 levels, pulmonary function tests and performed in parallel were reviewed. Statistical analysis was performed using SPSS (version 20.0) statistical package.

Results: The significantly higher levels of KL-6 were determined in the CTD-ILD group than in the CTDs without pulmonary involvement group (P<0.05) (figure 1). By the ROC curves of serum KL-6 levels in 175 patients. The optimal cutoff value of serum KL-6 for a diagnosis of CTD-ILD was 409 U/ml, and the sensitivity and specificity were 82.1% and 86.8%, respectively. The AUC was 0.905 (figure 2). Serum KL-6 correlated negatively with vital capacity (VC) (%predicted), forced vital capacity (FVC) (%predicted), forced expiratory volume in one second (FEV1%) (%predicted) and diffusing capacity of the lung for carbon monoxide (DLcoSB) (% predicted) (Table 1).

ANTI-C1Q ANTIBODIES HAVE HIGHER CORRELATION WITH LUPUS NEPHRITIS DISEASE ACTIVITY

WU XUE, Lijun Wu, Cai Nan Luo. People’s Hospital of Xinjiang Uygur Autonomous Region, Department of Rheumatology and Immunology, Urumqi, China

Background: Systemic lupus erythematosus (SLE) is the prototype of autoimmune disease and is characterized by the production of a variety of autoantibodies. and lupus nephritis continues to be a principal cause of morbidity and mortality. The focus is to finding biomarkers that can monitor renal activity and predict prognosis for early diagnosis and treatment. Complement C1q is the starter molecule of the classical pathway
of complement activation and plays an important role in the clearance of immune complexes and apoptotic cell debris. Hereditary homozygous deficiency of C1q has been described to be the strongest risk factor for developing SLE. There are some cross-sectional studies on anti-C1q in which the antibody was found to have a significant association with renal involvement but the association of anti-C1q antibodies (antiC1q) with lupus nephritis (LN) still a matter of debate.

**Objectives:** We assessed the association between lupus nephritis disease activity and anti-C1q antibodies

**Methods:** We retrospectively analyzed the medical records of 88 patients with lupus nephritis, aged 35.7±10.8 years on the average, with SLE of average duration 12 (3, 57) years. In all examines the levels of anti-dsDNA and anti-C1q antibodies were measured using the ELISA. C3, C4, 24-hour urinary protein performed in parallel were reviewed. The clinical manifestations of SLE was also collected. Lupus nephritis disease activity was measured by The SLICC Renal Activity Score of 2004. All biopsied tissues were scored based on the to ISN/RPS2003 lupus nephritis pathological typing standards. Acute Index, Chronic Index Score were used to evaluated the activities of lupus. All the analyses were performed by SPSS 20.0 software.

**Results:** Patients with active lupus nephritis had a higher levels of anti-C1q antibodies than inactive lupus nephritis (68.9(34.1, 140.1) vs. 11.6(5.5, 44.1); p<0.001) (Figure 1). Anti-C1q antibody levels were positively correlated with levels of 24-hour urinary protein(r=0.605; P=0.000), AI score (r=0.337; P=0.001), and negatively correlated with serum C3 (r=-0.573; P=0.000) and C4 (r=-0.509; P=0.000). (Figure 2).

**Conclusion:** Anti-C1q antibodies are more closely correlated with renal disease activity.

**ADIPOKINES AND ENDOTHELIAL DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS**

**ahmed yamany1, Mervat Behiry1, Ahmed Fayed1, Ahmed Soliman2. 1Kasr El Aini Teaching Hospital, internal medicine, cairo, Egypt; 2Kasr El Aini Teaching Hospital, internal medicine, cairo, Egypt**

**Background:** Premature atherosclerosis is clearly described in systemic lupus erythematosus as a main cause of poor outcomes and mortality(1). Pleiotropic adipokines including adiponectin and visfatin are implicated in the inflammatory process of lupus disease that promote cytokines signaling leading accelerated endothelial disruption(2).

**Objectives:** To evaluate the endothelial dysfunction by measuring serum visfatin, adiponectin, leptin and HOMA-insulin Index as reliable biomarkers of atherosclerosis &estimating the FMD of brachial artery among lupus patients and correlating these parameters with clinical characteristics

**Methods:** A case-control study in which 150 systemic lupus patients who were fulfilling American College of Rheumatology revised classification were recruited consecutively from Internal Medicine department at Cairo University. They were compared to 90 age & sex matched healthy controls. Patients who were pregnant, smoker, diabetic, those with hepatic and...
renal dysfunction, hypothyroidism, and familial dyslipidemia were excluded. Adiponectin, leptin, visfatin, and HOMAIR were evaluated. Flow-mediated dilation of brachial artery was calculated as the maximum percent increase in artery diameter after cuff release compared to baseline.

**Results:** Data revealed elevated levels of adiponectin, leptin, visfatin and HOMAIR in lupus cases compared to controls with reduced FMD percent. Clinical and laboratory background are summarized in Table (1).

None of adipokines is correlated to age, BMI, disease duration or activity. An inverse correlation between FMD of the brachial artery and total cholesterol, visfatin, adiponectin, leptin and HOMAIR (r-value = -0.52, -0.35, -0.27, -0.45, -0.56 respectively) with P < 0.05. Adipokines and FMD did not differ regarding clinical presentations specially cardiovascular.

ROC curve analyses studied the performance of adipokines. Adiponectin and visfatin are better predictors of atherosclerosis in lupus patients with apparently quiescent disease activity.

### Conclusion:

Endothelial dysfunction is evident in SLE. Reduced FMD of brachial artery and increased adipokines & HOMAIR are noted. Adiponectin and visfatin could be predictors of atherosclerosis in lupus.

SAT065B  ANTI-MODIFIED PROTEIN AUTOANTIBODIES IN RA: DISPLAY IMPORTANT PEPTIDE CROSS-REACTIVITY BUT YET PROTEIN RECOGNITION SELECTIVITY

Peter Sahlström1,2, Johanna Steen1, Björn Forström3, Philip Titcombe1,4, Ragnhild Stålen1, Ute Nonhoff1, Zoltán Kontur4, Luca Piccoli2, Karin Lundberg2, Holger Bang1, Daniel Mueller1, Anca Catrina4, Lars Krężel1, Karl Skriner2, Vivianne Malmström1, Caroline Grönwall1, Karl Skriner1, Johanna Steen1, Björn Forström3, Philip Titcombe1,4, Ragnhild Stålen1, Ute Nonhoff1, Zoltán Kontur4, Luca Piccoli2, Karin Lundberg2, Holger Bang1, Daniel Mueller1, Anca Catrina4, Lars Krężel1, Karl Skriner2, Vivianne Malmström1, Caroline Grönwall1

Background: The continuing increase of anti-citrullinated protein autoantibodies (ACPAs) litters together with epitope spreading close to onset of disease, suggests that antibody responses to different citrullinated antigens may be critical in rheumatoid arthritis (RA) pathogenesis. Interestingly, monoclonal antibodies demonstrate reactivity to multiple cit-antigens that can even expand to other protein modifications. The width of this cross-reactivity is still not understood.

Objectives: To characterize the targets of monoclonal ACPA in relation to amino acid motif recognition, cross-reactivity with others post-translational modifications, and cellular localization.

Methods: A peptide array ( NimbleGen, Roche) containing 165 amino acid- or lysine in pairs with citrulline- or homocitrulline peptides (53019 and 49211 cognate peptide pairs, respectively) derived from 1610 extracellular proteins and known RA cit-targets was used to screen 12 monoclonal ACPA with CCP2 reactivity. In addition, these ACPA were also screened for reactivity to acetylated-histone peptides and for reactivity to acetylated HeLa cell extracts from cytosol, membrane, nuclear and cytoskeleton fractions. Three of the described mAbs together with polyclonal anti-CCP2 IgG were further evaluated on a macroarray platform (HIXselect, Engine) consisting of 20776 E.coli on-array expressed His-tagged protein fragments from 6909 genes originating from a human cDNA library. The array was enzymatically citrullinated with rabbit PDA and mAb-reactivity was scored from 0-6.

Results: On the peptide arrays, all 12 ACPA displayed low reactivity to unmodified peptides (<0.06%), while reacting to 1,000s of synthetically citrullinated peptides (>3.4% of the peptides). Based on the sequence from the positive peptides, consensus amino acids motifs were created, identifying aa-patterns with only a few critical citrulline-flanking residues (e.g. Cit-Gly; Gly-Cit; Arg-Cit-Asp). Intriguingly, five of the antibodies also reacted with the carboxamidated peptides (>2.2%) and the recognition of certain homocitrulline-motifs also correlated with cross-reactivity to acetylated peptides. Interestingly, these ACPA reacted with acetylated-histones in NETs and apoptotic cells and in the nuclear fraction of in vitro acetylated cell-extracts. Three of the 12 ACPA were further screened on the macroarray and displayed multiple binding to citrullinated proteins and protein fragments identifying primarily previously unknown autoantibody targets (98, 210 or 917 positive hits for the mAbs, scoring 2-3), while limited binding was seen to native proteins.

Conclusion: ACPA display multi-reactivity to citrullinated peptides and proteins to a much greater extent than previously appreciated. Additionally, some ACPA, but not all, show distinct cross-reactivity to other post-translational modifications. Importantly, different autoimmune clones display modified protein recognition patterns dominated by proteins from different cellular structures. These reactivity profiles are likely to have impact on functionality and pathogenesis.

SAT0677 HETEROGENEITY OF STRATEGIES AND METHODS FOR ASSESSMENT OF COMPETENCES IN RHEUMATOLOGY TRAINING: RESULTS OF A SYSTEMATIC LITERATURE REVIEW TO INFORM EULAR POINTS TO CONSIDER
Alessia Alunno, Aurelie Najm, Francisca Sivera, Catherine Haines, Sofia Ramiro, University of Pernigia, Pernigia, Italy; University Hospital and INSERM UMR1238, Nantes, France; Hospital Universitario Elda, Alicante, Spain; King’s College, London, United Kingdom; LUMC, Leiden, Netherlands; Zuyderland MC, Heerlen, Netherlands

Background: The structure and content of Rheumatology training programs vary widely among European countries. Harmonization of assessment methods of competences across EULAR countries could contribute to ensure a minimal standard of care.

Objectives: To identify and review the evidence on competence assessment methods and strategies in postgraduate medical training in rheumatology and other specialties.

Methods: As part of the EULAR project to develop points to consider on assessment of competences in rheumatology training, a systematic literature review (SLR) was performed. Two reviewers (AA and AN) independently identified eligible studies according to the PIM framework: P (population): trainees, fellows; I (instrument of interest): assessment strategies and methods; M (measurement of properties of interest): validity, discrimination, feasibility. Two searches were conducted: (i) for rheumatology, retrieving original studies; (ii) for related medical specialties, retrieving SLRs through which we identified original studies. Risk of bias was assessed using the medical education research study quality instrument (MERSQI) and the tool by Daly et al for qualitative studies. Studies were too heterogeneous to allow for any form of pooling, so descriptive results are presented.

Results: Of the 6276 articles from the rheumatology search, 4 met the inclusion criteria; of the 2,265 SLRs in other specialties, 36 were included, corresponding to a total of 133 original studies included. Studies on the assessment of competences in rheumatology were at variable risk of bias and explored only 2 methods: direct observation of practical skills (DOPS) and objective structured clinical examination (OSCE) (Table 1). Rheumatology OSCEs have been used to assess clinical skills consistently demonstrated a good to very good inter-rater reliability (r=0.60-0.95), while those on OSCEs to assess communication skills consistently demonstrated a good to very good internal consistency (Cronbach’s α=0.70-0.98). Other tools such as multisource feedback (MSF) and mini-clinical evaluation exercise (mini-CEX) showed feasibility and a good to very good internal consistency, but results on validity and reliability were conflicting.

Conclusion: Although there is a consistent body of evidence about assessment of competence in postgraduate medical training in several specialties, data in rheumatology is scarce and this partial picture indicates some conflicting evidence. OSCEs represent an appropriate tool to assess clinical competences and correlate fairly well with other assessment strategies; DOPS, MSF and mini-CEX are other feasible alternatives. A mapping of European countries and a qualitative study will be additionally performed.

SAT0678 DEVELOPMENT AND VALIDATION OF A SELF-ADMINISTERED QUESTIONNAIRE MEASURING ESSENTIAL KNOWLEDGE FOR PATIENTS WITH SPONDYLIOARTHRITIS: THE SpondyloArthritis Knowledge QUESTIONnaire(SPAkE)

Catherine Beauvais, Bruno Pereira, Thao Pham, Christelle Sordeil, Pascal Claudepierre, Françoise Fayet, Daniel Wendling, Felicie Costantino, Laurence Carton, Laurent Grange, Martin Soubrier, Nathalie Legoupil, Aleth Perdriger, Isabel Tavares, Emmanuelle Dernis, Laure Gossec

Background: Patient education is recommended for patients with inflammatory arthritis to enhance self-management. Only one Knowledge coefficient= 0.80-0.95). A fair to moderate correlation (r=0.44-0.52) between OSCEs and other assessment tools, including DOPS, has been found. The study on DOPS but not those on OSCEs provided evidence for feasibility. Studies in other specialties were more heterogeneous for strategy/tools investigated, type and comprehensiveness of the analysis. The majority of studies on OSCEs to assess clinical skills showed a good to very good inter-rater reliability (r=0.60-0.95), while those on OSCEs to assess communication skills consistently demonstrated a good to very good internal consistency (Cronbach’s α=0.70-0.98). Other tools such as multisource feedback (MSF) and mini-clinical evaluation exercise (mini-CEX) showed feasibility and a good to very good internal consistency, but results on validity and reliability were conflicting.

Conclusion: Although there is a consistent body of evidence about assessment of competence in postgraduate medical training in several specialties, data in rheumatology is scarce and this partial picture indicates some conflicting evidence. OSCEs represent an appropriate tool to assess clinical competences and correlate fairly well with other assessment strategies; DOPS, MSF and mini-CEX are other feasible alternatives. A mapping of European countries and a qualitative study will be additionally performed.

Questionnaire (KQ) is available in spondyloarthritides (SpA) (ref 1) and needs to be updated according to the recent recommendations for SA and the patients’ needs (ref 2).

Objectives: To develop and validate a new KQ in SpA.

Methods: 4 steps. Step 1. Selection of knowledge considered essential for patients with SpA through Delphi rounds by a working group of rheumatologists, health professionals (HPs) and patients, leading to a list of consensual items (ref2). Step 2. Two rheumatologists and a rheumatology nurse constructed the first version of the KQ, each question of the KQ referring to a selected item on the list. The formulation was then amended by the working group. A new version was elaborated during a face-to-face meeting of 3 health professionals and one patient. Step 3. The KQ was submitted to ten patients for cognitive debriefing, comments were analyzed and a final version was elaborated. Step 4. Multicentric validation in 13 rheumatology departments: acceptability was measured by the rates of missing data per item, reproducibility and sensitivity to change were assessed respectively by test/retest at a 2 weeks interval (Lin’s concordance correlation coefficient) and by testing the KQ before and after patient education sessions.

Results: Step 1 obtained 42 items, 32 considered essential and 10 considered useful, selected respectively by more than 2/3 or more than 50% of participants to the Delphi rounds, leading to the SPAKE: a 42-items questionnaire, with a 32-items short form. The SPAKE contains 6 knowledge domains: disease knowledge (12 items), pharmacological treatment (11), non-pharmacological treatment (8), comorbidities (1), self-care for pain and fatigue (4), adaptive skills to psychosocial, professional issues and health care system (6). The validation included 130 patients, 67 (51.5%) men, mean age 43.5±12.9 years, median disease duration 8 years [3;16]. There were no missing items in the KQ. The SPAKE’s internal validity (Cronbach’s coefficient) was 0.95. Reproducibility (in 61 patients) was 0.81 [95% CI, 0.72; 0.89]. Sensitivity to change was measured in 55 patients. A statistically significant difference in total knowledge score was observed between the two assessment times: 29.1±6.4 vs. 34.7±5.9 (p<0.001), representing an effect size of 0.92 [0.52; 1.31]. The questionnaire’s external validity was confirmed by a significant correlation with the patients’ educational level (p=0.02).

Conclusion: This study enabled the development and the validation of the SPAKE, a knowledge questionnaire for patients with SpA, with a good acceptability, reproducibility and sensitivity to change. This KQ will be helpful to assess the process of knowledge acquisition in patient education approaches.

Background: Biologic disease modifying drugs (bDMARDs) are highly effective treatments of IA such as rheumatoid arthritis (RA) and axial or peripheral spondyloarthritids (SpA). However, they lead to risks of infections and other side effects. Some of these adverse events may be prevented by patient education (PE) aimed at promoting patients’ safety skills.

Objectives: To investigate the effect of a nurse-led PE on safety skills of patients with IA at the introduction of a first subcutaneous bDMARD.

Methods: Multicentric randomized controlled trial comparing an intervention group (IG) to usual care (UC) at the time of the introduction of a first bDMARD. Inclusion criteria: patients with RA or SpA, biologic naïve, eligible for a subcutaneous bDMARD according to the rheumatologist’s opinion. Intervention: a face-to-face nurse-led PE at baseline (BL) and 3 months later, ie, assessment by the nurse of the patients’ health beliefs and educational needs, education focused on safety skills, self-injections and motivation. The primary outcome was the acquisition of safety skills at 6 months measured by the Biosecure Questionnaire (0-100 scale), a 55 item validated questionnaire assessing competences to deal with fever, infections, vaccination, and other daily life situations (ref). The secondary outcomes were quality of life, severe infections rate, coping, psychological well-being and disease activity. Data were analysed as intent-to-treat using multiple imputations.

Results: 128 patients were included from 9 rheumatology departments between January 2017 and April 2018, 39 (30.7%) with RA, 72 (56.7%) with axial SpA, 16 (12.6%) with peripheral SpA; mean age 47.0 ±12.8 years, mean disease duration 6.1±7.5 years, 120 (94%) completed the study. BL mean self-reported information on RA treatments (0-10 numeric scale) was similar: 7.1±2.0 in IG, 6.8±2.1 in CG. The mean duration of the intervention was 65.5 ±17.9 minutes. The primary outcome was met: the Biosecure score at 6 months was 81.2 ±13.1 versus 75.6±13.0 in the IG and CG respectively (p =0.016), showing better skills in the IG. Secondary outcomes were also favorable.

Conclusion: Safety is an important issue in the management of IA treated with bDMARDs. In this trial, a nurse-led patient education was shown for the first time to be effective in teaching patients the essential safety skills.

REFERENCES
Background: Patient education is an important part of the management of rheumatic and other diseases. Since patients do not have the same needs, it is crucial to assess needs of a targeted group to be able to tailor educational interventions.

Objectives: To assess educational needs of a large cohort of patients with different rheumatic and musculoskeletal diseases attending a health facility in Austria.

Methods: We conducted an online survey with patients attending the Gastein Healing Galleries in Bad Gastein, Austria. Approximately 12,000 patients with a variety of diseases are treated in the centre every year. Of those, 6,465 patients were invited by email to fill out an anonymous online survey. Socio-demographics and health outcomes were collected from all respondents. In addition, the Educational Needs Assessment Tool (Austrian version - OENAT) was administered to a subset of respondents. The OENAT (39 items) assesses 7 domains of educational needs: Managing Pain, Movement, Managing Feelings, Arthritis/Disease process, Treatments, Self Help Measures, Support Systems.

Results: In total 2017 (31%) patients responded of which 516 had data on educational needs: AS (63%), RA (14%), and FM (24%). Their mean (SD) age was 56 (11), and 54% were male. Level of education was: Elementary School (32%), Junior High School (22%), High School (21%), College (12%), and University (14%). Table 1 presents differences in educational needs across disease groups. Across the groups, there were significant differences in following OENAT domains: Managing Pain, Feelings, Treatments, and Support Systems. There were no differences in the level of educational needs in Movements, Disease Process, and Self Help Measures.

Patients with FM had significantly lower needs for managing and higher needs for feeling education, compared to those with AS and RA (p<0.05). The RA group had significantly higher needs than the AS (p<0.05) and FM (p<0.05) groups for treatments education - the AS group had significantly higher needs than the FM group (p<0.05) in the same domain. AS patients had significantly higher needs for support system education than FM (p<0.05) and RA patients (p<0.05).

Conclusion: Educational needs vary by disease groups and depend on the domain under consideration.

NORMATIVE DATA FOR THE DISEASE AND TREATMENT ASSOCIATED KNOWLEDGE SCORE (DATAK-RA) IN PATIENTS WITH RHEUMATOID ARTHRITIS

Lisanne Renskers1, Martijn Oude Voshaar2, Marike J de Jonge3, Saranne Aa Rongen-van Dael4,5,6, Anita M P. Huis1, Martin van de Laar1,4,5, Piet L.C.M. van Riel1,7,8,9, Radboud University Medical Center, Nijmegen, Netherlands; 2University of Twente; 3University of Twente; 4Ziekenhuis Medisch Spectrum Twente, Rheumatology, Enschede, Netherlands; 5Ziekenhuis Medisch Spectrum Twente, Rheumatology, Enschede, Netherlands

Background: Having adequate disease-related knowledge is essential for patients with RA, since it may influence treatment decisions, shared-decision making, and the ability to perform self-management behavior. Patient Knowledge Questionnaires can be used to measure disease-related knowledge. We recently developed and validated the item response theory (IRT) based Disease and Treatment associated Knowledge in Rheumatoid Arthritis (DataK-RA) item bank, containing 42 multiple-choice items. In the present study we establish normative data to facilitate the interpretability of DataK-RA scores.

Methods: Consecutive patients enrolled from three hospitals in the Netherlands were asked to complete a form containing either 27 or 26 DataK-RA items. DataK-RA IRT-scores and standard errors (SEs) were obtained using the weight maximum likelihood estimator. The Dutch Committee on Tests and Testing (COTAN) quality criteria for test norms were followed. DataK-RA IRT scores and the precision of the scores (SE) were summarized using the mean (SD) or median and 1st-3rd quartile in case of non-normal distribution. Scores were compared between male

Conclusion: Based on the EULAR recommendations for PE (Zangi HA et al.), PE should be apply in all EU countries. E-learning on PE for staff members and ePE for patients will be developed by the ERN ReCONNET.

SAT0683
and female patients and patients with low, middle and high educational attainment, according to the International Standard Classification of Educa-
tion, using One-way ANOVA with a significance level of α = 0.05.

Results: In total 631 patients participated, most of them were female
(60.9%). Mean age (SD) was 64.0 (11.6) years. Mean (SD) DataK-RA
score was 52.5 (14.1) (range 11.7 – 104.7). Female patients had signif-
ically higher DataK-RA scores compared with men (F = 25.23, p < 0.01).
Mean (SD) DataK-RA-score was 54.6 (15.1) for women, and 48.9
(11.5) for men. The median (1st – 3rd quartile) SE of the IRT-scores
was 4.7 (4.1 – 5.8). Regarding education, higher-educated patients had a sig-
ificant higher IRT-score than middle- and lower-educated patients (p < 0.01),
as well as middle-educated versus lower-educated patients (p < 0.01).
Table 1 shows the percentiles DataK-RA-scores, and DataK-RA
scores stratified by age educational level.

Conclusion: We present normative data for DataK-RA scores generated
from a sample of consecutive patients participating in an ongoing longitudi-

SA70684 A UNIQUE FREE EDUCATIONAL RESOURCE FOR RHEUMATOLOGISTS: WWW.RHEUMATOLOGYMINDMAP.COM

Alex Papou1: 1University Hospital Haarlems, Rheumatology, East Kilbride, United Kingdom

Background: One of the challenges for doctors in training is fast and
easy access to reliable, relevant, and up-to-date clinical information. It

Figure 1

Figure 2搜索，容易修改，能够嵌入文档，链接主题，并使用外部超链接。证据显示，思维导图有助于学习

Objectives: To create a free educational resource in rheumatology using
mind-mapping techniques.

Methods: We used Mindjet MindManager 2017 (mind mapping software
allowing export into HTML5 files that can be published online) to create
the Rheumatology Mind Map website (www.rheumatologymindmap.com). A
wide range of information relevant to adult rheumatology practice in the
United Kingdom has been retrieved from various sources and structured
in accordance with common standards used in medical education. The
mind map embeds infographics currently used in rheumatology (diagnostic
and classification criteria, activity and damage indices, treatment decision
aids, downloadable templates, etc). Appropriate permissions from right
owners have been obtained.

Results: The current version of the website (1.7, January 2019) contains
an expandable mind map with above 1900 subtopics covering all aspects
of adult rheumatology. It works with all modern desktop and mobile
browsers. Examples of structure of the mind map and some subtopics
are shown in figures 1 and 2. The main advantages of the mind map are
the presence of the most up-to-date information, detailed lists of
investigations relevant for each of rheumatic conditions, thorough differen-
tial diagnosis, subtopics on pregnancy issues, extensive information about
medications used in rheumatology practice and treatment options for each
condition. Specific attention is paid at the clinical information relevant
for trainees, e.g., what to ask when you suspect a certain rheumatic illness,
what to look for at the examination, and which investigations to order.
The mind map has direct online links to appropriate NHS, NICE, BSR,
SIGN, EULAR, and ACR guidelines and policies, and various resources
including online calculators, relevant databases, websites providing support
for patients, etc.

Conclusion: The website www.rheumatologymindmap.com is an attempt to
create a unique comprehensive educational resource in rheumatology. It
allows free access and structured approach to clinical information required
by a trainee or an established rheumatologist. It is an up-to-date source
of a wide range of information and is linking hundreds of current online
sources together in one place.

USE AND IMPACT ON SOCIAL NETWORKS BY RHEUMATOLOGY JOURNALS

Daniel G. Fernández-Avilés,1 Vanesa Avilés2,3, Oscar Muñoz2,3, Angel García2,3
1Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine – Rheumatology, Bogotá, Colombia; 2Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine, Bogotá, Colombia

Background: Traditional system for assessing the quality and impact of a scientific journal is based on the number of citations. One of the main forms of measurement is the impact factor, which measures the impact that a journal has on the scientific community. Despite its traditional use, this quality and impact assessment system has been criticized in recent years. The “Alternative Assessment Metrics” initiative (Altmetrics) seeks to define new measures of metrics for scientific publications. Alternative metrics are based on the number of “mentions” of an article in various online sources, including blogs and social networking platforms. The alternative metrics are more dynamic and accumulate quickly in real time. The social networks most frequently used by scientific journals are Facebook, YouTube and Twitter.

Objectives: To evaluate presence, number of followers and activity of rheumatology journals in 3 social networks (Facebook, Twitter and Youtube).

Methods: Platform of scientific journals SCOPUS was consulted, selecting journals classified as rheumatology journals. Scimago Journal Rank (SJR) of 2017 was taken to evaluate the quality of the journal. The social networks Facebook, Twitter and YouTube were consulted, searching for rheumatology journals of those found in SCOPUS with active accounts in these social networks. Date of consultation: 13-11-18.

Results: 51 rheumatology journals in SCOPUS, of which only 8 (13.1%) had an active account in at least one of the social networks consulted. On Facebook the most active and most popular magazine was Nature Reviews, followed by the Journal of Rheumatology and Annals of the Rheumatic Diseases. It should be noted that Nature Reviews includes other journals in their social networks that cover other specialties of medicine such as cardiology, immunology, microbiology, oncology, among others. On Twitter, as on Facebook, magazine with largest number of followers was Nature Reviews, followed by Annals of the Rheumatic Diseases and Journal of Rheumatology. Activity on Twitter, measured as number of twits, had same behavior according to the number of followers. The only journal with channel on YouTube was Annals of the Rheumatic disease with 67 subscribers, 12 videos, of which the most watched has 315 reproductions. See table 1.

Table 1. Characterization of scientific journals in social networks in rheumatology. SJR: Scimago Journal Rank. Facebook: Number of followers. Twitter: Number of followers. Twits: Number of twits reported on the platform

Conclusion: YT and FB are social networks with a high content of false information. The majority of available videos promise to cure different rheumatic diseases (even several simultaneously). This is the first work of a line of research that seeks to highlight the high degree of misinformation. We will continue to analyze other diseases and social networks, to make publications and communications in different media and to alert local regulatory entities.

ONLINE EDUCATION IMPROVES PHYSICIANS’ KNOWLEDGE OF FAMILY PLANNING AND PREGNANCY MANAGEMENT IN WOMEN WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

Elaine Bell1, Robert McCarthy2, Rebecca Fischer-Betz2.1 Medscape LLC, New York, United States of America; 2Polyclinic of Rheumatology, University Clinic, Heinrich-Heine-Universität Düsseldorf, Dusseldorf, Germany

Background: Chronic inflammatory rheumatic disease (CIRDs) often develop in women during their childbearing years. Preconception counseling and coordinated medical and obstetric care are essential to maintain control of the disease and maximize the chances of a successful pregnancy.

Objectives: This study assessed whether online CME can improve physicians’ understanding of the risks of uncontrolled chronic rheumatic diseases in pregnancy and the benefits of proactive pregnancy planning, and enhance physician confidence in managing such patients.

Methods: Physicians participated in an online CME activity consisting of a 15-minute video discussion between 2 experts with accompanying slides. Educational effect was assessed using a 4-question repeated pairs, pre-/post-assessment. A Chi-square Test of Independence was used to determine if a statistically significant improvement (5% significance level, P <.05) existed in the number of correct responses between the pretest and posttest scores. Cramer’s V was used to estimate the effect of the education. The CME accredited activity launched on August 2 2018, and data were collected through August 30 2018.

Results:
- Rheumatologists (n=47) had a high baseline knowledge of family planning and pregnancy management in women with CIRDs, but the activity had a significant impact (P =.0008) on rheumatologists’ knowledge and the Cramer’s V value of 0.199 indicates a considerable effect of the education
- The average percentage of correct responses for rheumatologists was 91% post–activity compared with 76% pre–activity
- 64% more rheumatologists answered all 3 questions correctly post–activity compared with pre–activity (74% vs. 45%)
- 26% of rheumatologists gained confidence in their ability to manage CIRDs in pregnant patients, with an average confidence shift of 9%
- Obstetricians/gynaecologists (n=40) also had a fairly high baseline knowledge of family planning and pregnancy management in women with CIRDs, but again, the activity had a significant impact (P =.0005) on their knowledge and the Cramer’s V value of 0.226 indicates a considerable effect of the education
- The average percentage of correct responses for obstetricians/ gynaecologists was 83% post–activity compared with 63% pre–activity
- 97% more obstetricians/gynaecologists answered all 3 questions correctly post–activity compared with pre–activity (65% vs. 33%)
- Almost half (45%) of obstetricians/gynaecologists gained substantial confidence in their ability to manage CIRDs in pregnant patients, with an average confidence shift of 22%

Conclusion: This online, 15-minute video discussion between 2 experts significantly improved rheumatologists’ and obstetricians/gynaecologists’ understanding of family planning and pregnancy management in women with CIRDs which may lead to improved outcomes for both women and babies. Both groups would benefit from further education to reinforce knowledge of disease activity on conception and pregnancy and to emphasize the need for collaborative proactive family planning in women with CIRDs.

Evolving the Management of Rheumatoid Arthritis Through Development of Practical and Educational Tools

Gerd Rüdiger Burmester1, Mart van de Laar2, Jose-Maria Alvaro-Gracia3, Neil Betteridge4, Jaime Calvo5, Bernard Combe6, Patrick Durez7, Ricardo J. O’Ferrall8, Bruno Fautrel9, Cem Gabay10, Annamaria Iagnocco11, Carlmaurizio Montecucco12, Mikkel Stergaard13, Sofia Ramiro14, Andrea Rubbert-Roth15, Tanja Stamm16, Zoltán Szekanecz17, Peter C. Taylor18,19, Chanti – Universitätsmedizin Berlin Berlin, Germany; University of Twente, Enschede, Netherlands; Hospital Universitario de la Princesa, Madrid, Spain; Neil Betteridge Associates, London, United Kingdom; Hospital Universitario Araba, Alava, Spain; Université Montpellier I, Montpellier, France; Université Catholique de Louvain, Brussels, Belgium; Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; Université Libre de Bruxelles, Brussels, Belgium; Medical University of Vienna, Vienna, Austria;1 University of Debrecen, Debrecen, Hungary;19 University of Oxford, Oxford, United Kingdom

Background: Despite advances in the treatment armamentarium for rheumatoid arthritis (RA) over the last decade, several unmet needs remain within RA management.

Objectives: To enhance scientific knowledge and improve patient care by providing practical tools and evidence-based awareness – in line with EULAR recommendations – on how to implement optimal RA management and address identified needs.

Methods: The eRA (evolving the management of RA) programme convened a Steering Committee (SC) of 17 European and International experts in RA, including representation from rheumatologists, nurses, health professionals and patients. Through literature search and assessment of expert opinion, 4 core areas of unmet need were identified: delays in referral and initiation of disease-modifying anti-rheumatic drugs, inconsistent application of treat-to-target strategy, sub-optimal identification and management of comorbidities, and a growing need to actively engage patients with their care. Several clinical and educational gaps associated with these unmet needs were also identified. To fill these gaps and support application of an optimal approach to RA management, practical and educational tools were developed. A cascade process engaging national leaders in rheumatology was then initiated to disseminate the tools to health professionals across Europe, with tools being updated in participating countries to ensure alignment with local practices and individual country needs. Broader programme dissemination is supported by congress activities and a digital communication plan. The eRA programme is funded by Sanofi Genzyme. Programme direction and content creation are driven by the SC.

Results: A suite of 12 educational tools was developed (Figure 1), including educational slides to raise awareness of unmet needs, self-reflection questionnaires to evaluate personal practice alongside EULAR recommendations, case scenarios outlining the optimal approach to management, and clinical checklists to support daily practice. The process to disseminate these tools commenced in November 2017 with a Multi-Country Workshop, which convened 43 national leaders in rheumatology from countries participating in the programme. Feedback on the eRA tools at this meeting was positive, and in 2018, additional countries were onboarded to the programme. Launch of a digital web-platform aims to further support dissemination of the eRA tools.

Conclusion: The content of the eRA programme has been well-received, largely due to the programme’s flexible approach, which is responsive to individual country needs. As the cascade process continues, it is anticipated that many more health professionals and patients will benefit from the eRA tools. Figure 1. eRA toolkit

PATIENT STATE OF KNOWLEDGE ON BIOSIMILARS – DO PHYSICIANS NEED TO IMPROVE EDUCATION SKILLS?

CobblinskiClaudia1, Daniela Opirs-Belinski1, Catalin Codreanu1, Razvan Ionescu2, Claudia Mihaloi2, Magda Parvu2, Horatiu Popoviciu2, Elena Rezu3, Roxandra Ionescu1,1 University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania;2 Colentina Clinical Hospital, Bucharest, Romania;3 Ovidius University of Medicine, Constanta, Romania;4 Clinical Emergency Hospital, Targu-Mures, Romania;5 Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania

Background: Biosimilars are highly similar to original biological medicines. However, worldwide prescription of biosimilars is still low because of the lack of understanding in manufacturing and approval process together with mistrust in the extrapolation of indication in clinical use. Lack of biosimilar awareness throughout rheumatic patients results in an unjustified underuse.

Objectives: To assess patients’ current knowledge and concerns on biosimilars and to investigate their expectations when receiving such a treatment following the principle of shared-decision making.

Methods: A national cross-sectional survey was conducted in Romanian patients with rheumatoid arthritis (RA), spondyloarthropathies (SpA), psoriatic arthritis (PsA) currently on a bio-originator or biosimilar. 336 patients responded to this survey.
a survey distributed from August to December 2018 mainly topics being patient basic information on biosimilars, their efficacy, safety, price or differences to original drugs.

Results: Out of 336 patients, 47.3% had RA, 39.8% had SpA, 12.5% PsA with a mean age of 50.5 in the study cohort. 13% received approved biosimilars while 87% bio-originators with different mechanisms of action. A yes/no type of question divided patients into those aware or not of biosimilars with further exclusion of those with lack of information. Half of the patients (48.8%) stated they never heard of biosimilars. Surprisingly, four of them were already on this type of treatment. Out of the 172 remaining patients, 28.4% feared the risk of adverse events like infections or cancer while almost 20% expressed either insecurity on drug tolerability or the possibility that the biosimilar might be less efficient that the original drug. Another 19.7% certified they had no concerns related to these products and only 15.1% stated confusion regarding the potentially different in the pharmacological structure of the drugs. Most patients (48.2%) were convinced that the price of a drug should not exceed its efficacy or safety. Half of the respondents say they could accept a switch from an original to a biosimilar if their rheumatologist advises them and 30% might agree but only after being informed. 8.7% are interested in scientific proof of the drug and only 1% would consent to a change directly from the pharmacists. When handling prescription, 37.7% of patients would want to know if it is an original drug or a biosimilar while 20% do not mind if they receive either. Another 30% trust their rheumatologist and 12.7% would feel more secure if receiving a patient card and written information. Most patients (73.2%) say that they feel completely confident in their rheumatologist if they would want to prescribe a biosimilar, 18.6% will have doubts but they will accept the drug and 4% would ask for another medical opinion. After biosimilar initiation, 45.9% would be cautious when administering it, 23.2% would stop the drug if an adverse event occurred and 15% would have no fears.

Conclusion: Study results confirm there is still a significant information gap concerning biosimilars in patient population. Most concerns on biosimilars are related to adverse event occurrence. There is a need to improve patient education on biosimilars involving patients and health professionals. Shared-decision principle is more of a myth since most patients rely on their rheumatologist and only 15% would ask for another medical opinion. After biosimilar initiation, 45.9% would be cautious when administering it, 23.2% would stop the drug if an adverse event occurred, and 15% would have no fears.

SAT0690 HOW TO REDUCE THE NOCEBO EFFECT WHEN SWITCHING FROM ORIGINATOR INFLIXIMAB TO A BIOSIMILAR: POSITIVE RESULTS OF A MULTIDISCIPLINARY TEAM INTERVENTION

Juliette Petit1, Marine Antignac2, Rose Marie Poilvérard3, Sylvie Dartous3, Regine Baratol1, Karine Lousai1, Nathalie Deparis1, Francis Berenbaum1, Catherine Beauvais1, 1Rheumatology department APHP Saint-Antoine Hospital, Sorbonne Université, INSERM, PARIS, France; 2Pharmacy department APHP Saint-Antoine Hospital, PARIS, France; 3Association Nationale de Défense contre L’Arthrite Rhumatoïde (ANDAR), PARIS, France

Background: Non-specific subjective adverse effects (NSAE), usually considered as related to a nocebo effect (NE), have been identified as a barrier to the acceptability of switches from biologic originators (BO) to biosimilars (BS).

Objectives: To assess the efficacy of a multidisciplinary team intervention to reduce the NE among inflammatory arthritis (IA) patients concerned by systematic switch from originator Infliximab (OI) to the biosimilar infliximab (BI) SB2.

Methods: The intervention was part of a multidisciplinary patient education (PE) program. It was developed in 4 steps. Step 1: we conducted first semi-directive qualitative interviews with 5 patients treated by other intravenous (IV) biologics. Interviews showed: fears about efficacy and tolerability of BSs, need for information (particularly on the difference between BSs and generics), importance of sharing their experience of adverse effects (AE) with health practitioners (HP), and having the opportunity to switch back. The wish to discuss the nurses’ own experience of BSs was prominent. Step 2: a meeting with the multidisciplinary team (3 rheumatologists, 1 resident, 1 pharmacist, 3 nurses, 1 peer-patient from a patient’s association) was set up for designing the intervention based on the interviews, on non-systematic literature review about switches and on patients’ perspective regarding NE. Step 3: Consensual agreement on the intervention and the chosen pieces of language to be used by all HPs. The intervention included written and oral information by the nurses; nurse-led PE; if necessary, distribution of an informative leaflet made by the team. Step 4: Implementation of the intervention. The rheumatologist had the entire appreciation for discontinuing the BS or not. Inclusion criteria were all IA patients concerned by OI. The primary outcome was SB2 retention rate (RT) at 34 weeks, secondary outcomes were the number of NSAEs leading to SB2 discontinuation; the comparison of the RT and NSAE rate of the cohort with 1) RT and NSAE rate of a systematic switch from another Infliximab BS (CT-P13) to SB2 made at the same period in the same rheumatology department 2) RT of BS2 and NSAE rate of switches in other published European cohorts (1,2,3).

Results: Forty-five patients were included from March 12th, 2018 to May 25th, 2018, median follow up was 34 weeks, 17 rheumatoid arthritis

SAT07689 A NOVEL METHODOLOGY FOR TEACHING RHEUMATOLOGY TO NEW GENERATIONS

Daniel Gallardo1, Alejandra Herrera3, Carolina Llanos2, Pamela Díaz2, Pontificia Universidad Católica de Chile, Escuela de Medicina, Santiago, Chile; 2Pontificia Universidad Católica de Chile, Departamento de Inmunología Clínica y Reumatología, Santiago, Chile; 3Pontificia Universidad Católica de Chile, Imunología Clínica y Reumatología, Santiago, Chile

Background: Teaching rheumatology to undergraduate students is every day more challenging. In order to motivate new generations and use time more efficiently, we explored new methods to incorporate active learning in our rheumatology course. Therefore, we developed a video library and turned the classical lectures into flipped classrooms.

Objectives: To evaluate the impact of this new teaching method of rheumatology in a cohort of medical students at Pontificia Universidad Católica de Chile School of Medicine.

Methods: Fundamental lectures of rheumatology were recorded, edited and uploaded to YouTube, so the students were able to easily access the lessons from different electronic devices. A total of 10 videos were created, with an average duration of 6 minutes. A cohort of 120 fourth-year medical students took the rheumatology course between May 28th and June 11th of 2018. They were asked to watch the videos before the class, and during the classroom time the teacher could work on clinical cases, complement the information about the topic and answer questions. At the end of the course, the students evaluated this new methodology with a final online and anonymous survey. Performance analysis of each video was obtained from YouTube Analytics.

Results: Seventy-two students completed the survey at the end of the course, the students who evoluted the videos before the class was useful for their learning. Moreover, 70 students (97%) would like to continue using flipped classrooms in the future, and 1/3 of them would even use them to replace traditional lectures. Overall, the rheumatology was evaluated with a 6.8 score in a 1 – 7 scale. A 100% of this cohort approved the course. Average view duration of all videos was 4:37 minutes. Twenty-two students added positive comments about the use of flipped classroom in this course, and appreciated the videos were short enough to watch them before attending lectures.

Conclusion: Advances in technology have allowed developing innovating ways to teach. Flipped classroom encourages students to adopt a more active role in the learning process. This new methodology seems to be well accepted by students and shows a promising way to motivate new generations to learn rheumatology.

Physician–patient agreement in a Rheumatology consultation

Joana Rodrigues1, Diogo Fonseca2, Vera Vicente3, Daniela Faria1, Joana Neves1, Joana Rodrigues1, Diogo Fonseca2, Vera Vicente3, Daniela Faria1, Joana Neves1, Joana Rodrigues1, Diogo Fonseca2, Vera Vicente3, Daniela Faria1, Joana Neves1, Joana Rodrigues1, Diogo Fonseca2, Vera Vicente3, Daniela Faria1, Joana Neves1.

Background: Several aspects of the consultation have already been studied. These usually comprise the patient satisfaction, patient enablement, physician–patient interaction and physician–patient agreement.1 After consultations, the physician’s perceptions differed from the patient’s in the illness level, cause and nature of the problem and the content of the consultation.2 Greater physician–patient agreement on consultations was associated with higher patient global satisfaction.3 Agreement on problems requiring follow-up was associated with a better outcome.4 Objectives: Assessment of physician–patient agreement in Rheumatology consultation.

Methods: A 10 item questionnaire - “Consultation Assessment Instrument” (CAI) - was constructed with the aim of assessing physician-patient agreement. It was anonymously applied, after the consultation, to the patient and physician. The higher the score obtained, the more positive the consultation experience. Patients above 18 years of age, with an established diagnosis of inflammatory joint disease under biological therapy were included. Items were evaluated and index of proportional agreement for the dichotomized answers - agree (Ppos) and disagree (Pneg) - was calculated.

Results: 102 observations were obtained, corresponding to 10 physicians and 102 patients. Most patients were female (53.9%) with a mean age of 51.5 ± 12.7 years old. Rheumatoid Arthritis was the most prevalent diagnosis (40.2%) and more than half of patients were in disease remission (28-joint Disease Activity Score (DAS28) < 2.6) or Ankylosing Spondylitis Disease Activity Score (ASDAS PCR) < 1.0. Higher CAI scores correlated with lower Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores (r = 0.376; p < 0.05). Also, patients with mild disease (score < 3.2) by DAS28 had higher CAI scores (low disease = 37.3±8.6; moderate disease = 35.8±4.3; high disease = 35.0±2.3; p = 0.039). It was also found that the more satisfied the patient, the lower the Bath Ankylosing Spondylitis Functional Index (BASFI) (r = 0.334; p < 0.05) and ASDAS PCR scores [low disease = 35.3±4.2; high disease = 30.5±7.8; p = 0.001]. There was no statistically significant association between CAI total score and Health Assessment Questionnaire (HAQ) score, ASDAS PCR or BASFI. Patient’s satisfaction did not show an association with DAS28, HAQ or BASDAI scores.

Conclusion: Both patient and physician tend to show a positive experience towards Rheumatology consultation. Patients with a more positive experience had lower disease activity scores. Physician–patient agreement was high in the majority of the consultation aspects. CAI could be useful as a mental checklist in daily practice or as an educational tool for training consultation skills.

Dealing with comorbidities in rheumatoid arthritis with medical assistants. The patients’ opinion on assessment and education by medical assistants during routine clinical practice

Stefan Kleinert, Praxedis Rapp, Monika Ronneberger, Joerg Wendler, Florian Schuch. Praxiorganisation Rheumatologie – Nephrologie (PGRN.de), Erlangen, Germany

Background: In 2006 the curriculum for rheumatology health professionals of the Academy of the German Association of Rheumatologists (DGRh) was developed. [1]. Since then more than 1400 health professionals (medical assistants [medizinische Fachangestellte] and nurses) were trained and are currently playing an increasing role in rheumatology practices in Germany.

Objectives: To evaluate the patients’ opinion on the assessment by medical assistants in general and regarding assessment and education on cardiovascular risk and vaccination.

Methods: Patients with rheumatoid arthritis were interviewed by a medical assistant in a rheumatology practice that is part of the primärversorgungssystem with five rheumatologists in Erlangen, Germany. A semi-standardized interview assessed disease activity, pain, medication, general health, and side effects of medication. A part of the patients was also assessed and educated regarding cardiovascular risk or vaccinations. Thereafter they were examined by the rheumatologist and finally asked to complete a questionnaire regarding their visit. The questions were numerical scales ranging from 0 [very good, very satisfied] to 10 [very poor/inaequate].

Results: 293 Patients (mean age 61.3 ± 13.5 years, mean DAS28 2.6 ± 0.9, mean FFUH 76.4 ± 20.6) were documented between August and December 2018. 212 completed the general questionnaire. 34 regarding a structured cardiovascular assessment and education, and 18 regarding a structured assessment of vaccinations.

Table 1 shows patients answers between 0 [very good, very satisfied] to 10 [very poor/inaequate]. Overall rating was excellent with a mean score of 1.0 (SD 1.5). The rating was only slightly different, if patients were assessed by medical assistants for the first time (n=111; mean score 1.2, SD 1.5), between the 2nd to 4th time (n=82; mean score 1.0, SD 1.3) or the 5th time or more (n=19; mean score 0.6, SD 0.6).
ONLINE EDUCATION SIGNIFICANTLY IMPROVED QUALITATIVE ANALYSIS OF MOBILE APPS DIRECTED Candice Yuvienco1.

Methods: Rheumatologists participated in an online CME activity consisting of a 30-minute video roundtable discussion between 3 experts with accompanying slides. Educational effect was assessed using paired, repeated pairs, pre-post-assessment. A chi-square test was used to determine if a statistically significant improvement (P < .05 significance level) existed in the number of correct responses from the pretest and posttest scores. Cramer’s V was used to estimate the level of impact of the education. The CME activity launched on December 20, 2017, and the data were collected through March 6, 2018.

Results: A total of 328 rheumatologists completed the pre- and post activity assessments. Overall the activity had a significant impact (P < .001) on rheumatologists’ understanding of comparative effectiveness data in AS with a Cramer’s V value of 0.189 indicating a considerable effect of the education. The average percentage of correct responses rose from 22% pre-activity to 39% post-activity. A linked learning assessment (each individual tracked pre and posteducation) showed that 24% of learners improved their knowledge and 15% reinforced their knowledge. The change in percentage of correct responses from pre- to post-assessment achieved statistical significance (P < .05) for all 3 questions presented: (i) recommendations for biologic DMARD use in AS according to the ASAS-EULAR 2016 guidelines (34% at baseline rising to 67% post activity; P < .001), (ii) understanding the impact of treatment with biologic DMARDs on radiographic progression in AS (17% at baseline rising to 26% post activity; P < .01), (iii) understanding comparative analysis of RCTs in AS (14% at baseline rising to 24% post activity; P < .001) and (iv) a quarter of rheumatologists gained confidence in their ability to select a biologic DMARD based on comparative data and individual patient needs, with an average confidence shift of 14%.

Conclusion: This online CME activity significantly improved rheumatologists’ understanding of how to compare treatments and interpret comparative effectiveness data in AS which may lead to improved treatment selection and better patient outcomes. However, there is clearly room for further improving physicians’ knowledge of treatments & radiographic progression and comparative analysis of RCTs (since 75% of rheumatologists provided incorrect answers to questions 2 and 3 post-activity) which can be addressed in future education.

SA10694 QUALITATIVE ANALYSIS OF MOBILE APPS DIRECTED FOR LUPUS PATIENTS
Mosaab Mohamed1, Li Zi Ying1, Amani Eighfli2, Ali Al3, Candice Yvlieng2, 1University of California San Francisco Fresno, Internal Medicine, Fresno, United States of America; 2University of California San Francisco Fresno, Rheumatology, Fresno, United States of America

Background: Systemic lupus erythematosus (SLE) is chronic disease that requires lifelong treatment with a multidisciplinary approach. Increasingly, patients use the internet and associated technology to access health-related information. Smartphone applications (apps) have become essential tools in this age and are widely-accessed by patients. These apps can be very helpful tools to inform patients about their disease and treatment options and help them in their treatment plan, and help them connect with others. Unfortunately, healthcare apps remain largely unregulated.

Objectives: We aim to evaluate the overall quality of patient-directed lupus apps with a focus on the accuracy and appropriateness of the health information contained in these apps.

Methods: The 2 most commonly used app stores are Apple Store and Google Play. These stores were searched for the terms “lupus” and “SLE” during December 2018. The resulted apps (Patient oriented, English language, and free of charge) were analyzed and the following data was collected: app type (informational, tool, or both); features, and

SA10693 ONLINE EDUCATION SIGNIFICANTLY IMPROVED RHEUMATOLOGISTS’ UNDERSTANDING AND INTERPRETATION OF COMPARATIVE TREATMENT DATA FOR AS
Adriana Stan1, Elaine Bell2, Peter Schoenheim3, Xenodon Baraliakos2, Medscape LLC, New York, United States of America; 1ArctiCare Medical Communications Ltd, Hitchin, United Kingdom; 2Rheumazentrum Ruhrgebiet Heme Ruhr-University, Bochum, Germany

Background: With multiple therapeutic options now available for patients with ankylosing spondylitis (AS), clinicians and payers require evidence to guide their decision-making. Head-to-head randomized controlled trials (RCTs) are considered to provide the best evidence for informing treatment decisions, but in the absence of such trials, physicians often rely on their own experience and clinical trial data from single RCTs. In the absence of head-to-head RCTs, data from comparative studies such as network meta-analysis and matching adjusted indirect comparisons can be useful to help inform treatment choices.

Objectives: This study assessed whether the online CME accredited round-table-discussion with title “Comparing Treatment Alternatives in Ankylosing Spondylitis” improves physicians’ understanding and interpretation of comparative effectiveness data for AS.
content. Tool apps are those used by patients to track symptoms, contained lupus action plan, appointment and medication reminders, and/or quizzes/gameification. App features included connection to external sites (social media, professional societies, online patient communities, healthcare provider), and security features including login/password protection and privacy policy statement. Apps were then rated using (with permission from originator) a published reliable and multidimensional scale: Mobile App Rating Scale (MARS). The study authors were trained on MARS using the recommended slides and reach test with the general health dimension. In addition, quality of health information contained in informational apps was rated using the published DISCERN instrument.

Results: The search terms SLE and Lupus retrieved a total of 471 apps on Google Play store and a total of 196 apps on Apple Store. On Google Play, 14/471 met our inclusion criteria compared to 11/198 on Apple Store. Majority of Google apps were in the tools category representing 44%, followed by apps that are both tools and informational (31%), whereas informational apps were 25%. On the other hand, majority of Apple Store apps were both tools and informational (64%), followed by tools only apps (27%), and finally informational only apps (9%). The most common apps features were email login (37%) and links to external sites including social media platforms (31%). Two apps were identified as a potential source for misleading information claiming that certain homemade herbs/food has anti-inflammatory properties to treat lupus. The average MARS score for Google apps was 2.75/5 indicating poor apps quality. The average MARS score for Apple apps was 3.7 indicating acceptable apps quality. Overall, the functionality score was the highest (3.9/5) while the engagement score was the lowest (2.75/5) for both app stores. For apps that contained information for patients, DISCERN score was 2.15/5 and 3.12/5 for Google and Apple apps respectively indicating potentially important shortcomings in the quality of health information provided in these apps.

Conclusion: Our study demonstrates that a larger need is emerging for designing high-quality apps for patients with lupus. Healthcare organizations, professional societies, rheumatologists, and allied health professionals are encouraged to participate in promoting and creating high-quality apps for lupus patients. These apps are likely to contribute to improving the quality of care provided to these patients and can potentially extend care in the looming global shortage of rheumatologists. This is also an encouraging component of the need to adapt to advancing communications technology as it integrates into many patients’ lives in this digital age.

SAT0695-HPR ASSOCIATION OF PHYSICAL FITNESS WITH HEALTH-RELATED QUALITY OF LIFE IN WOMEN WITH FIBROMYALGIA

Irmagualda C. Alvarez-Gallardo1, Víctor Segura-Jiménez2, Óscar Alfredo Martínez3, Isabel Soriano Maldonado3, Milkana Borges Cosic4, Pedro Acosta-Tománs5, Alberto Estévez-López1, Óscar Sainson Maldonado1, Miliana Borges Cosic1, Pedro Acosta-Tománs5, Alberto Estévez-López1, Óscar Sainson Maldonado1, Miliana Borges Cosic1, Pedro Acosta-Tománs5

1Faculty of Education Science, Department of Physical Education, University of Cádiz, Puerto Real, Spain; 2Faculty of Physical Education and Sport, School of Health Sciences, University of Glasgow, College of Medical and Veterinary and Life sciences, University of Glasgow, College of Medical and Veterinary and Life sciences, Glasgow, United Kingdom; 3Faculty of Physical Education and Sport, School of Health Sciences, University of Ulster, Belfast, United Kingdom; 4Faculty of Sports Science, Department of Physical Education, University of Cádiz, Puerto Real, Spain; 5Institute of Nursing and Health Research, School of Health Sciences, University of Granada, Granada, Spain

Background: Physical fitness (PF) represents a marker of health and is associated with health-related quality of life (HRQoL). Different components of PF have shown to be consistently associated with lower symptomatology in people with fibromyalgia1,2. Identifying which PF components are associated with HRQoL in people with fibromyalgia may contribute to the development of more specific therapeutic strategies.

Objectives: The aim was to examine the associations of different PF components with HRQoL in women with fibromyalgia.

Methods: This population-based cross-sectional study included 466 women with fibromyalgia. The Senior Fitness Tests battery plus handgrip test were used to assess PF and the 36-item Short-Form Health Survey (SF-36) was used to assess HRQoL. Tendar points, cognitive impairment, anthropometric measurements and medication usage were also measured and used as confounders. Firstly, multivariate linear regression assessed the independent relationship of each PF test with the eight dimensions of the SF-36. Secondly, a standardized composite score was computed for each component of PF (aerobic fitness, muscular strength, flexibility and motor agility). Forward stepwise regression was performed to analyse which components of PF were independently associated with the SF-36 physical and mental component scales.

Results: Overall, higher performance on PF tests was associated with higher levels of HRQoL in all SF-36 dimensions and subscales (all p<0.05 or p<0.001) except for associations between handgrip with social functioning, emotional role, mental health and mental component scale, as well as the chair sit-and-reach test with the general health dimension. The muscular strength composite score was independently (from other fitness components and confounders) associated with the SF-36 physical component scale (p<0.001), while the flexibility composite score and cardiorespiratory fitness were independently (from other fitness components and confounders) associated with the SF-36 mental component scale (both p<0.05).

Conclusion: High PF is consistently associated with better HRQoL in women with fibromyalgia. Muscular strength, flexibility and cardiorespiratory fitness are independent indicators of HRQoL in this population. These results might have implications for future intervention studies because it could facilitate the selection of the most suitable exercise interventions according to the clinical profile of each patient.

SAT0696-HPR THE PREVALENCE OF SEPTIC ARTHRITIS AT A LARGE UNIVERSITY TEACHING HOSPITAL

Caroline Allerton1, Kathryn McCall1, Neal L. Millar1, Yianni Ioannidis1, Tom Evans1, Iain Moinnes1, Tom Evans1, Iain Moinnes1, Tom Evans1, Iain Moinnes1

1Institute of Infection, immunity and Inflammation, University of Glasgow, College of Medical and Veterinary and Life science, Glasgow, United Kingdom; 2Queen Elizabeth University Hospital, Glasgow, United Kingdom

Background: Septic arthritis (SA) is a rheumatological emergency requiring early treatment to prevent lasting joint damage. Treatment outcomes depend on prompt diagnosis, which currently rests on clinical suspicion, raised non-specific inflammatory markers and identification of a pathogen from synovial fluid.

Objectives: To establish the prevalence of SA in a large University teaching hospital. To review the microbiology results and identified pathogens in each positive case along with subsequent treatment regimes utilising outpatient parenteral antimicrobial therapy (OPAT) with adherence to local guidelines.

Methods: Retrospective data collection of all samples identified as synovial fluid or joint aspiration sent to microbiology lab between 1 January 2016 and 31st December 2016. Electronic review of microbiology results and treatment outcomes.

Results: There were 364 samples identified as joint aspirate or synovial fluid, 54 of these grew a pathogen. Positive aspirates from native joints totaled 35 in 31 patients. Twenty-three of these patients accounting for 25 of the positive samples were treated clinically as SA. Sub analysis of this group revealed Staph.aureus was the most commonly identified pathogen in 14 cases (56%). There were however 8 other pathogens identified in the 25 positive samples. Fifteen patients (65%) underwent a joint washout in theatre, 7 of these patients had multiple washouts. Duration of antibiotic therapy was 5 weeks in 8 cases; 3 cases had therapy for >5 weeks and 2 cases with SA in the upper limb had treatment for <5 weeks. There were 10 positive samples taken from 8 native joints that grew a pathogen and were not treated as SA. These were identified
on enrichment culture only n=3 or an alternative clinical diagnosis was declared which needs to be taken into account when formulating local antimicrobial guidelines. Current literature reports surgical treatment as not superior to medical\textsuperscript{6}, yet 65% of cases here underwent joint lavage in theatre. This information will be used to inform local clinical practice, and, guide recruitment targets for a large multi-centre study collecting data and samples from patients presenting with a hot swollen joint, with the aim of identifying a specific biomarker for SA.

**SA10969-HPR COMMON COMORBIDITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A UNICENTRIC BIG COHORT**

Annie Aza\textsuperscript{1}, Michael Cabrera\textsuperscript{2}, Fernando Rodriguez\textsuperscript{2}, Pedro Santos-Moreno\textsuperscript{2}.

\textsuperscript{1}Biobam – Center for rheumatoid arthritis, Bussiness administration, Bogotá, Colombia; \textsuperscript{2}Biobam – Center for rheumatoid arthritis, EHR administration, Bogotá, Colombia; \textsuperscript{3}Biobam – Center for rheumatoid arthritis, Patient program coordinator, Bogotá, Colombia; \textsuperscript{4}Biobam, Rheumatology, Bogotá, Colombia

**Background:** Rheumatoid arthritis (RA) is a common systemic autoimmune disease characterized chronic joint inflammation. RA and ageing are associated with comorbidities such as cardiovascular disease, malignancies and osteoporosis, these conditions have an important effect on the management of RA. These comorbidities can be associated with higher mortality, poor life quality, and the increasing of costs for the health system.

**Objectives:** To describe the prevalence of comorbidities and characteristics of a Colombian unicentric big cohort that assist to RA specialized centers.

**Methods:** We performed a descriptive analysis; our main goal was to provide real-life data regarding characteristics of patients with RA. We collected sociodemographic information, DAS28, and prevalence of comorbidities regarding hypertension, cerebrovascular disease, diabetes mellitus, osteoporosis, renal chronic disease, or Sjogren’s syndrome. We calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. Rates were estimated the prevalence of comorbidities and performed a bivariate analysis.

**Results:** We reviewed the medical charts of 6541 patients, 82% were female and 18% male; median age was 60 years RIQ (50-67), regarding disease activity, mean DAS28 was 3.34 ± 1.28. The prevalence of comorbidities was 36%, the most common disease was high blood pressure followed by osteoporosis, see table 1. When we compared DAS28 and comorbidities 11% of patients who were in moderate or severe disease activity had one or more comorbidities. The relationship between disease activity and comorbidities was not associated and it was not statistically significant (P=0.05)

**Table 1. Comorbidities in patients with RA**

**Conclusion:** As other studies have shown high blood pressure is the most common disease among patients with RA followed by osteoporosis (1, 3). s. According to these results it is important to consider the patient’s context, medical conditions, and the number of comorbidities in order to understand the complexity of the management of patient with RA. Additionally, it is important to explore barrier and health care services in order to plan a realistic plan where a patient is managed with all comorbidities.

**Background:** The infection incidence rates are high in systemic lupus erythematosus (SLE) patients\textsuperscript{9} and the medical literature documents broad categories of specific bacterial infection risks for SLE patients.\textsuperscript{2,4} However, there has not been a detailed incidence of infection types and infection predictors.

**Objectives:** In a systemic literature review (SLR) and meta-analysis, to describe the types and incidences of infections in SLE patients and to examine the effect of medications used to treat SLE.

**Methods:** An SLR of SLE and infection articles generated through a search of MeSH terms using PubMed and Medline generated 1,211 articles. Using predefined Incl/Excl criteria, data from 32 accepted articles were double-extracted and descriptive and multivariable analyses were conducted. Relative risks between drug classes were estimated using Arm-Based Network Meta-Analysis. Hypothesis tests were two-sided and a p-value <0.05 was statistically significant. Analysis was conducted in the R Statistical Computing Environment (R Core Team; Vienna, Austria).

**Results:** 4,130 patients were considered, 91% females, average age: 36.8 (10.9) years, mean disease duration: 6.9 (6.1) years, SLEDAI mean: 11.7 (4.6). In drug trials, 775 used conventional synthetic DMARDs (csDMARDs), 1,809 used biologic DMARDs (bDMARDs), 691 (16.7%) used placebo and the rest were in non-drug specific observatio

**Conclusion:** As other studies have shown high blood pressure is the most common disease among patients with RA followed by osteoporosis (1, 3). s. According to these results it is important to consider the patient’s context, medical conditions, and the number of comorbidities in order to understand the complexity of the management of patient with RA. Additionally, it is important to explore barrier and health care services in order to plan a realistic plan where a patient is managed with all comorbidities.

infection, compared to 5.6% (CI: 0.1-52.6%) for bDMARDs. The attributable risk for developing gram positive infections when using csDMARDs was 3.9% (CI: 0.2-25%) and 3.5% (CI: 0.1-41.6%) when using biDMARDs.

Conclusion: In this SLR and meta-analysis in SLE, the frequency of infections was bacterial > viral > opportunistic, in that order, although some details were unavailable. csDMARDs were associated with more infections than bDMARDs.

Background: SSc is a chronic, complex and very debilitating disease, involving all the aspects of physical, mental and social life. Thus, the need of a first assessment of the degree of health literacy (HL) is required to develop useful tools for SSc patients to simplify their access to health care services. HL is defined as the ability to acquire, synthesise, and understand health information and services required to make decisions regarding an individual or community’s health.

Objectives: to assess the HL in SSc patients.

Methods: 25 SSc patients classified ACR/EULAR criteria (limited and diffuse subsets) were enrolled in September-October 2018 with the support of the local association of patients (ASSMAF). Patients have been evaluated for socio-demographic variables and the HLS-EU-Q16 questionnaire of the general population (assessed for subscales) were enrolled in September-October 2018 with the support of the local association of patients (ASSMAF). Patients have been evaluated for socio-demographic variables and the HLS-EU-Q16 questionnaire.

Results: Questions 1 to 7 (on health information) are associated with age, educational qualifications and with the number of children; while 8 to 12 (on prevention) are associated with the number of children, but also with the type of employment and marital status; finally, questions 13-16 (on health promotion) are associated with age, educational qualifications and number of children. Moreover, our results show 20% of SSc patients with an inadequate level (0-8) of HL, compared to the 12% of the general population; 40% show a problematic level (9-12) of HL lower than that found in the general population (55%), while 40% of patients show an adequate level (13-16) of HL higher than the 33% of the general population.

Conclusion: Health literacy level is an important parameter to consider and assess in SSc patients to facilitate their access to health care services and their understanding of the disease. Future researches with larger sample size are needed.

SAT0700-HPR

PHYSICAL AND PSYCHOLOGICAL DETERMINANTS OF FIBROMYALGIA SEVERITY: A STRUCTURAL EQUATION MODELLING FROM THE AL-ÁNDALUS CROSS-SECTIONAL STUDY

Fernando Estévez-López1,2, Octavio Luque-Reca2, Victor Segura-Jiménez, Inmaculada C. Alvarez-Gallardo1, Alberto Soriano Maldonado2, Pedre Acosta-Manzano1, Blanca Gavilán Carrera1, Joseph Moveigh1, Rinie Geenen3, Manuel Delgado-Fernández4, Manuel Pulido-Martos1,2, University of Granada, Granada, Spain; 3Ulster University, Belfast, United Kingdom; 4Universidad Francisco de Vitoria, Madrid, Spain; 5University of Cadiz, Cadiz, Spain; 6University of Almeria, Almeria, Spain; 7University College Cork, Cork, Ireland; 8University of Jaén, Jaén, Spain

Background: In fibromyalgia, the main aim of therapy is to reduce the severity or impact of the disease [1]. The effectiveness of the most commonly used therapies is modest in fibromyalgia. Therefore, identifying modifiable factors associated with lower fibromyalgia severity is a priority as these modifiable factors may be possible therapeutic targets [2-4].

Objectives: This study examined the determinants of fibromyalgia severity.

Methods: In this observational, population-based cross-sectional study, 569 people with fibromyalgia were assessed on resilience, catastrophizing, active lifestyle, declarative memory, subjective fitness, objective fitness, psychological distress, physical fatigue and disease severity. Structural equation modelling estimation was used to analyse the following hypotheses: (i) resilience, catastrophizing and active lifestyle through subjective fitness, objective fitness, psychological distress, and physical fatigue determine fibromyalgia severity; and (ii) these factors are distributed in two core pathways (one physical and one psychological) that interplay between each other.

Results: We confirmed the above-mentioned hypotheses. Our model explained 83% of fibromyalgia severity, which is a considerably large proportion.

Conclusion: Our findings not only corroborate the importance of the two core (i.e., physical and psychological) pathways but also their interaction in their association with fibromyalgia severity. The understanding of these interconnections between alleged predisposing and perpetuating factors may optimise current approaches for treating fibromyalgia. Although the present research is the most comprehensive model of fibromyalgia severity to date, its cross-sectional design impedes to determine causal relationships. Longitudinal research is warranted.

SLE exacerbation predictors in patients of Kyrgyz nationality

Background: Taken into account the wave-like multivariate flow of SLE, there are still difficulties in diagnosing conditions such as ‘remission’ and ‘exacerbation’. The questions of SLE ‘exacerbation’ predictors and their influence on the further nature of the course and outcome of the disease remain little studied.

Objectives: Study of SLE exacerbations predictors in patients living in Kyrgyzstan.

Methods: The study included 150 (26.31%) Kyrgyz patients out of 570 with a reliable diagnosis of SLE, female (96%), young age (median - 34 [26; 44]), Kyrgyz nationality (89.33%), high - 61 (40.66%) and very high activity rate (46) - 20 (13.33%), with the duration of SLE at 1 observation point from 7 months to 10 years, with dynamic observation from 1 year to 3 years. To determine the gradation of the degree of reduction in glomerular filtration rate (GFR) and the severity of proteinuria in patients with lupus nephritis, used the classification of chronic kidney disease (CKD) according to KDIGO (2013).

The characteristic and frequency of SLE exacerbations were assessed by the SFI - R index: mild, moderate or severe.

Results: The results of the study showed that 84 (56%) Kyrgyz patients out of 150 had 192 SLE exacerbations by using the SFI index during 3 years of follow-up, with a frequency of 1 to 4 cases (2.82 ± 2.21) per patient. A mild exacerbation was observed predominantly in 103 patients (55.65%), manifested by skin - mucous syndrome - in 81 (78.64%) and febrile fever - in 22 (21.36%). A moderate exacerbation was noted in 48 (25%) patients in the form of polyserositis - in 18 (37.5%), articulations - in 16 (33.33%) and nephritis with minimal urinary syndrome - in 14 (29.17%) of them. Severe exacerbation was recorded in 41 (21.35%) patients, manifested mainly by kidney damage - in 28 (68.29%), lungs - in 4 (9.76%), central nervous system - in 4 (9.76%) and hematological disorders - in 5 (12.19%).

Severe exacerbations of the kidneys were characterized by nephritis with CKD C1 A1 in 6, CKD C1 A3 in 6, with CKD C2 A3 in 6, severe nephritis with CKD C3 A3 in 3, CKD C3b A3 in 2 and nephritis with nephrotic syndrome - in 5 patients.

SLE exacerbations in most cases resulted from self-withdrawal of glucocorticoids and cytostatic therapy in 44 (52.38%) and activation of the pathological process in 35 (41.67%) patients and in 5 (5.95%) of them were unknown.

Conclusion: On the background of careful dynamic monitoring of patients, predominantly mild SLE exacerbation was observed (53.65%), due to self-withdrawal of glucocorticoids and cytostatic therapy (52.38%) and activation of the pathological process in 44 (52.38%) patients.

Acknowledgement: I would like to express my deep gratitude to Professor E. Nosonov and Professor S. Soloviev, my research assistance, for their patient guidance, enthusiastic encouragement and useful critiques of this research work.

Disclosure of Interests: None declared
with RA and a SMI experienced significantly greater levels of pain (p=0.04), functional disability (p=0.01), along with poorer disease activity (p=0.03) and poorer quality of life (p=0.03) than those with RA, but without SMI. There was however, no significant difference in the receipt of DMARDs or NSAIDS between the two groups (p=0.12).

Conclusion: Prevalence rates of SMI are no greater in RA than the general population. Those with RA and a SMI do however experience significantly poorer clinical outcomes than people with RA but without SMI despite being in receipt of similar medications. Further research is needed to explore why these health inequalities exist and how best to ensure more positive outcomes for this vulnerable population.

SAT0704-HPR PREVALENCE OF RHEUMATIC PATHOLOGY IN CHILDREN IN THE CENTRAL FEDERAL DISTRICT OF THE RUSSIAN FEDERATION, STRUCTURE OF MORBIDITY AND THERAPY
Vladislav Sevostyanov, Elena Zholobova, Alla Golubeva, Olga Baranova, Kristina Poyemshina, Anna Polukhina, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Analysis of the incidence of rheumatic diseases in children can help to evaluate the real needs in treatment provision and improve medical service.

Objectives: To analyse the prevalence, structure of morbidity, and therapy of rheumatic pathology in children in the Central Federal District of the Russian Federation.

Methods: Statistical, sociological methods and content analysis were used. The study included generalised information on 3940 patients aged 1-17 years with various rheumatic diseases living in the 13 regions of the Central Federal District of the Russian Federation. The data is provided by the main paediatric rheumatologists of the regions.

Results: 5.999/124 children aged 0 to 17 years live on the territory of 13 regions of central Russia. In these regions, 3.940 patients with rheumatic diseases are observed. Our data allowed us to calculate the prevalence of rheumatic diseases per 100,000 children from 0 to 17 years. The prevalence of juvenile idiopathic arthritis (JIA) is 62.2, systemic lupus erythematosus - 0.7, juvenile dermatomyositis - 0.7, systemic scleroderma - 0.6. The overall incidence of the rheumatic disease is 65.7 per 100,000 children from 0 to 17 years. In the structure of rheumatic pathology, 94.7% are accounted for JIA, 1.1% for systemic lupus erythematosus, 1.0% for juvenile dermatomyositis, 0.9% for systemic sclerosis, 2.2% for other rheumatic diseases. 67.3% of patients receive disease-modifying anti-rheumatic drugs (DMARDs) (n = 2650), of which 80.1% receive methotrexate (n = 2122), 13.5% - sulfasalazine, 0.3% - leflunomide, 0.7% - cyclosporine A, 3.8% - corticosteroids, 0.7% - mycophenolate mofetil, 0.5% - hydroxychloroquine. Biological therapy is received by 27.5% of patients suffering from JIA (n = 1026). The data differs depending on the region. In the Bryansk region, the proportion of patients receive biological therapy is 45.8%, in the Yaroslavl region - 41.2%, in Moscow - 40.7%. More rarely, the biological therapy is initiated in Kostroma - 11.9% and Oryol - 15.3% areas. The structure of biological therapy is dominated by TNF-alpha inhibitors - 71.3%, 41.6% of all children undergoing biologic therapy were prescribed etanercept, 27.2% - adalimumab. 18.1% of patients receive tocilizumab, 7.2% - abatacept, 1% - infliximab, 2.5% - canakinumab, 1.5% of patients receive golimumab.

Conclusion: 1. The overall incidence rate of rheumatic diseases in central Russian regions is 65.7 per 100,000 children from 0 to 17 years old.
2. The prevalence of juvenile idiopathic arthritis is 62.2 per 100,000 children from 0 to 17 years old.
3. 67.3% of patients receive DMARDs. In 80.1% of cases, the drug of choice is methotrexate.
4. 27.5% of patients suffering from JIA receive biological therapy; data vary by region (45.8% - 11.9%). The structure of biological therapy is dominated by TNF-alpha inhibitors - 71.3%.
5. At the level of various regions, countries, it is necessary to conduct research aimed at studying the causes influencing the overall incidence, the detectability of rheumatic diseases, and the structure of therapy.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

SAT0705-HPR PATIENTS’ EXPERIENCES OF REASONS TO BEING PHYSICALLY ACTIVE IN EARLY RHEUMATOID ARTHRITIS – A MIXED METHODS STUDY
Maria Qvarfordt1, Maria Andersson2,3, Ingrid Larsson1,2,3,1 School of Health and Welfare, Halmstad University, Halmstad, Sweden; 3 Lund University, Department of Clinical Sciences, Department of Rheumatology, Lund, Sweden; 2 Fou Spenshult, Halmstad, Sweden

Background: The importance of physical activity in rheumatoid arthritis (RA) is well known and patients are informed about the importance of being physically active. Despite this knowledge there is a lack of compliance to this advice. Studies comparing physical activity in different groups of patients with RA and reasons influencing physical activity are needed.

Objectives: The objectives were to compare physical activity (PA) in workers, retired and patients with sick-leave with early RA and further to explore reasons to being physically active. Despite this knowledge there is a lack of compliance to this advice. Studies comparing physical activity in different groups of patients with RA and reasons influencing physical activity are needed.

Results: A total of 66 patients with early RA were included in the study. A sequential explanatory mixed methods design was used. The groups were compared with clinical data as: disease activity (DAS28); pain (VAS 0-100, best to worst); health-related quality of life (EQ5D, -0.594-1 worse to best) and a physical function (HAQ, 0-3 best to worst). ESR and CRP. Patients were dichotomized as being active on recommended levels of PA (MVP/Aec; physically active on a moderate level ≥150min/week (MFA) or on an intense level ≥75min/week (VPA)) or not (sedentary). The patients were grouped on self-reported working ability; workers, patients with sick-leave and retired patients. Qualitative data was collected by a questionnaire with open-ended questions about reasons influencing PA. The qualitative data was analysed with a manifest qualitative content analysis to gain a greater understanding of patients’ experiences of PA in early RA.

Results: There were no significant differences between the groups in disease activity, physical function, swollen joints, health-related quality of life
or inflammatory parameters (ESR, CRP). Patients on sick-leave had more tendons (min-max) 9 (2-18) vs. 4 (0-20) and 3 (0-10), p=0.013. Workers reported higher intensity of pain, though not significant. Retired patients fulfilled MVPA criteria to a higher rate (86%) than workers (42%) or patients with sick-leave (40%), p=0.010. The qualitative content analysis resulted in three categories. Reasons to being physically active in patients with early RA were: limitations (pain, physical function, stiffness, limited strength and fatigue), awareness as motivation (fear of movement and health benefits) and external environment (weather, transports to activity, economy and time, especially for workers).

Conclusion: Knowledge of reasons to being physically active in patients with RA is important to facilitate and support the patients. Joint pain seems to be an issue for patients with sick-leave. This could be associated to fear of movement and in this aspect these patients need to be supported. Time could be a limiting issue for working patients, which need to be highlighted and solved for these patients.

Disclosure of Interests: None declared

### SAT0705-HPR THE RELATIONSHIP BETWEEN SUBJECTIVE AND OBJECTIVE METHODS FOR MEASURING PHYSICAL ACTIVITY STATUS OF AXIAL SPONDYLOARTHRITIS PATIENTS: QUESTIONNAIRE VERSUS ACCELEROMETER

Deniz Bayraktar1, Tugce Yukel-Karsi2, Derya Ozer Kaya1, Dilek Solmaz3, Gokhan Kabadyay1, Idil Kurut1, Servet Akar1, Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Izmir, Turkey; Izmir Katip Celebi University, Faculty of Medicine, Department of Rheumatology, Izmir, Turkey

**Background:** Physical activity is getting more attention for the appropriate management of both disease itself and co-morbid conditions in patients with axial spondyloarthritis (axSpA). Many different tools are available for determining physical activity status. Although subjective tools such as questionnaires are quick and easy for gathering data, objective tools such as accelerometers might provide more accurate information.

**Objectives:** To investigate the relationship between a subjective physical activity questionnaire (International Physical Activity Questionnaire Short Form: IPAQ) and an accelerometer (Actigraph wGT3X-BT) for measuring physical activity status of axSpA patients.

**Methods:** Thirty-nine patients with axSpA (age 37.9±11.3 years, body mass index 26.9±5.3 kg/m², disease activity: 3.3±2.3 according to Bath Ankylosing Spondylitis Disease Activity Index, functional status: 2.9±2.8 according to Bath Ankylosing Spondylitis Functional Activity Index, 24 male) according to ASAS criteria were included to assess the subjective and objective physical activity status by using the Turkish version of IPAQ and an accelerometer (Actigraph wGT3X-BT, respectively). The accelerometer was worn by the patients on their waists at their first visit and it provides information about the light, moderate, vigorous physical activity times in minutes. On the seventh day when the accelerometer was removed, patients were asked to complete the IPAQ. The IPAQ inquires the physical activity performed previous week in minutes and categorizes into three sections as vigorous, moderate activity, and walking. The walking section in IPAQ was accepted as equal to light physical activity in Actigraphy. The relationship between measurements was determined by using Spearman’s Rank Correlation Coefficient.

**Results:** No significant correlations were determined between subjective and objective methods (p>0.05), except the time spent during moderate physical activity (rho: 0.457, p<0.05). It was also observed that IPAQ were underestimating the physical activity times for all types of physical activity (Table 1).

<table>
<thead>
<tr>
<th>Objective Activity (min)</th>
<th>Subjective Activity (min)</th>
<th>Spearman’s Correlation</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

**Conclusion:** According to our results, IPAQ, short version may not be an appropriate tool for determining physical activity status in axSpA patients. It seems that we need disease specific tools in axSpA.

**Disclosure of Interests:** Deniz Bayraktar: None declared, Tugce Yukel-Karsi: None declared, Derya Ozer Kaya: None declared, Dilek Solmaz: None declared, Gokhan Kabadyay: None declared, Idil Kurut: None declared, Servet Akar Grant/research support from: MSD, Abbvie, Roche, UCB, Novartis, Pfizer, Amgen, Consultant for: MSD, Abbvie, Roche, UCB, Novartis, Pfizer, Amgen, Speakers bureau: Pfizer

### SAT0707-HPR PATIENT AND CLINICIAN PERSPECTIVES USED FOR SURVEY DEVELOPMENT TO INVESTIGATE THE NATURE, EXTENT AND IMPACT OF FOOT PROBLEMS IN PEOPLE WITH PSORIATIC ARTHRITIS

Kate Carter1, Steven Walmsey2, Keith Rome3, Deborah E. Turner1, Western Sydney University, Podiatry Department, School of Science and Health, Sydney, Australia; Auckland University of Technology, Health and Rehabilitation Research Institute, Auckland, New Zealand

**Background:** Despite recognition that hallmark features of psoriatic arthropitis (PsA), such as enthesitis, are predominant and persistent in the foot and ankle [1], limited research has focused on the foot. Few published studies have used RA-specific outcome measures unlikely to capture the dermatological impact in PsA and there has been little incorporation of the patient perspective [1]. The importance of patient and clinician involvement as a central component of research design has been identified in PsA [2, 3], and provides a basis for defining what should be measured to represent comprehensively the experience of people with PsA-related foot problems and important domains of impact.

**Objectives:** To develop a survey based on the views of people with PsA and clinicians on foot problems, their impact and the foot care needs.

**Methods:** Interviews of people with PsA-related foot problems and focus groups with clinicians on their understanding of the patient experience were undertaken in Sydney, Australia and Auckland, New Zealand. A representative sample from public and private sector, from lower and higher socioeconomic geographical areas, as well as clinicians with different professional backgrounds was sought. Based on the themes from the qualitative interviews, previous research [1, 3] and clinical experience, survey items were generated by the research team using a consensus based approach. The survey was pre-tested using a 4-stage method that comprised: cognitive de-briefing of people with PsA, expert review panels of people with PsA and clinicians, pilot testing. All focus groups and interviews were audio-recorded, transcribed verbatim and survey items were revised based on comments made.

**Results:** The final 60-item self-administered survey was developed based on feedback from each of the 4-stages, which related to wording, comprehension, timescales, content, repetition, number of survey items and overall survey design. Key survey domains included demographic (10%) and socioeconomic data (10%), global disease information (18%), foot and ankle characteristics (18%), and the impact of foot problems on daily
life including daily routine, footwear choice, family life, work and access-
ing health care (44%). Percentage coverage of items directly reflects the
dominant concerns of people with PsA-related foot problems and clini-
cians. Whilst priorities for clinicians included the diverse expression of
disease and determining the nature of foot symptoms as mechanical or
inflammatory, a key theme from patients was the psychological impact of
foot involvement on daily life coupled with self-management strategies
(coping skills, self-care activities and availability of social support), which
was poorly recognised by clinicians. Consequently, nearly a quarter of
survey content was dedicated to these areas of impact highlight by
patients (23%). Engaging patients and clinicians in the survey develop-
ment methods ensured that face and content validity were confirmed and
cognitive and usability standards were achieved.

Conclusion: By incorporating the views of those with the disease and of
clinicians into the survey development process, good conceptual coverage
of items important to both patients and clinicians was achieved whilst
minimising responder burden. This is the first study to develop a survey
on foot involvement in PsA based on best practice methods in qualitative
survey design, which may have utility in the future development of
assessment or screening tools.

SAT0708-HPR DEVELOPING AN ALLIED HEALTH CORE OUTCOME SET FOR PAEDIATRIC RHEUMATOLOGY MUSCULOSKELETAL CONDITIONS

Verna Cathnog1, Victoria Harbottle2, Ellie Potts3, Royal Manchester Children’s Hospital, Paediatric Rheumatology, Manchester, United Kingdom; 3Great North Children’s Hospital, Newcastle, United Kingdom; 2Evelina Children’s Hospital, London, United Kingdom

Background: Musculoskeletal (MSK) conditions are prevalent within the
general population, including children and young people (CYP) with MSK
pain. There is evidence that MSK pain in CYP is an antecedent of adult
MSK-pain. Paediatric Rheumatology Allied Health Professionals (PRAHPs)
are well placed to manage these CYP, but there is no current standard-
isation in treatment, services or outcomes.

Objectives: To develop a core outcome measure set for clinical use by
PRAHPs to facilitate national collaboration and standardisation of care.

Methods: A modified Nominal Group technique study was undertaken by an
expert panel of PRAHP’s working in 8 Tertiary Paediatric and Ado-
lescent UK centres. Literature search and presentation of findings
informed expert panel discussion with particular reference to the following
criteria: paediatric population specific, ease of clinical use, cost, general
availability to clinicians, reliability, validity, length to administer/perform and
previous research use. Expert panel discussion and ranking identified
eight domains. A survey was sent to the 12 members of the expert
panel asking participants to choose two measures or none, based on cri-
teria above. Consensus was pre-determined as agreement between
experts of 60% or more.

Results: Survey response rate was 83% with consensus achieved for 6
outcome measures- see table. Consensus could not be reached for hand
function, sleep and goal-setting in part due to the large number of mea-
ures and variation in use, lack of paediatric specific measures, length of
time taken to administer or costs involved. Psychological measures were
not included within the scope of this work, but would be a valuable future
addition.

Conclusion: This study informs a pilot outcome measure set for PRAHPs
in clinical settings when time, space, money and ease of use are paramour.

SAT0709-HPR SPINAL MOBILITY IN SPONDYLOARTHRITIS PATIENTS: DO THE BASMI-MEASUREMENTS CORRELATE WITH THE DAVID BACK DEVICES-MEASUREMENTS?

Sophie De Mita1,2, Liselotte Deroo3, Ann-Sophie De Craemer1,3, Thomas Renson1,2, Tine Willems1, Lieven Danneels3, Philippe Carron1,3, Filip van den Bosch1,2, Dirk Elewaout1,2, Ghent University Hospital; Rheumatology, Gent, Belgium; 3Ghent University, Department of Rehabilitation Sciences, Ghent, Belgium

Background: The BASMI is a common used and well established index to
measure spinal mobility in spondyloarthritis(SpA)-patients, both in the
clinic as well as for research. The David Back Devices (DBD) on the
other hand, are used to measure and exercise lumbar and cervical mobi-
ity and strength in spine patients. The DBD might have the potential
advantage of not being operator dependent in contrast to the BASMI-
measurements.

Hence, the question rose if the BASMI measurements that correspond
with cervical rotation and lumbar lateral flexion movements on the DBD
are correlated with one another.

Objectives: The aim of this study was to measure the spinal mobility in
SpA-patients both by using BASMI measurements and by using the DBD
and determine their relationship.

Methods: SpA-patients of the outpatient rheumatology department of the
Ghent University Hospital (included in the Be-Giant cohort) were consecu-
tively asked to participate in the study. After informed consent, BASDAI,
BASFI and BASMI were evaluated. To measure mobility on the DBD
both trunk and cervical range of motion for flexion, extension, lateral flex-
ion and rotation were assessed. Spearman correlation coefficients were
calculated for cervical rotation and lumbar lateral flexion.

Results: Thirty-one SpA-patients participated of which 18 were male
(58%). Twenty-four (77%) were classified as axial SpA and 7 (23%) as
peripheral SpA. Median time since diagnosis was 5 years. Mean age of
the patients was 41 years (range: 21 – 58 years) and their BMI was on
average 24 (range: 17-33). Averages for BASDAI, BASFI and BASMI
were 2.6, 1.7 and 0.9 respectively.

There was a significant positive correlation between the cervical rotation
measurement obtained by BASMI and DBD (r=0.84 for right and r=0.80
for left) as well as between the lateral flexion measurement obtained by
BASMI and DBD (r=0.72 for right and r=0.65 for left). Due to the sitting
position during testing the lumbar flexion by DBD, the range of motion
was limited when the chest touched the thighs. Therefore, correlation
could not accurately be determined between the modified Schöberindex
and DBD lumbar flexion.

Conclusion: This study demonstrated that in SpA-patients, the BASMI
measurements for cervical rotation and lumbar lateral flexion show high
correlations when compared with the similar measurements on the DBD.
The correlations for cervical rotation were better than those for lumbar
lateral flexion.

**SAT070-HPR** RADIOfREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY OSTEOPOROSIS DIAGNOSIS ON FEMORAL NECK: A SPANISH CLINICAL EXPERIENCE

Diana Ovejero Crespo, Xavier Nogues, Adolfo Diez-Perez, Department of Internal Medicine, Hospital del Mar, Barcelona, Barcelona, Spain

**Background:** Radiofrequency Echographic Multi Spectrometry (REMS) is an innovative echographic technology able to provide the most important densitometric parameters by a fully automatic approach. Its high accuracy with respect to the conventional Dual X-ray absorptiometry (DXA) has been shown in a very recently published multicenter clinical trial [1].

**Objectives:** To evaluate the performance of the REMS technology in osteoporosis diagnosis, with respect to DXA (Clinical Gold Standard), when applied on femoral neck.

**Methods:** DXA and REMS acquisitions were performed on the femoral neck in 324 female patients, aged between 51 and 70 year, recruited at the Department of Internal Medicine of the Hospital del Mar (Barcelona, Spain). REMS technology is based on a automatic integrated processing of the native unfiltered "raw" (RF) signals, which can be employed to assess the bone health status through comparisons with reference spectra modeling osteoporotic patients and by evaluating the correlation between REMS and DXA measurements.

**Results:** The REMS approach is effectively able to discriminate between osteoporotic and non-osteoporotic patients with a sensitivity equal to 93% and a specificity equal to 95%. These data are further emphasized by the obtained Pearson Correlation value \( r = 0.90; p<0.001 \). REMS accuracy was confirmed also by Cohen’s kappa coefficient \( k \) equal to 0.76. Finally, a very low average difference (expressed as bias \( \pm 2 \) SD) between REMS and DXA measured BMD \((-0.006 \pm 0.078 \, \text{g/cm}^2)\) was shown.

**Conclusion:** In conclusion, REMS technology has proven to be an accurate non-invasive approach to detect osteoporosis disease at the femoral neck. The performance of this radiation-free technique opens new perspectives for early diagnosis and screening of osteoporosis in clinical and epidemiological studies.

**SAT0711-HPR** ADDING INFORMATION ON WIDESPREAD PAIN TO THE START BACK SCREENING TOOL WHEN IDENTIFYING LOW BACK PAIN PATIENTSAT INCREASED RISK FOR POOR PROGNOSIS

Katarina Alli, Stefan Bergman, Emma Haglund, 1, 2 Halmstad University, Halmstad School of Health and Welfare, Halmstad, Sweden; 3Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden; 4Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden; 5Råd&Spenshult, Halmstad, Sweden; 6Institute of Medicine, The Sahlgrenska Academy, Primary Health Care Unit, Department of Public Health and Community Medicine, Gothenburg, Sweden; 7Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden

**Background:** Early identification of those with the highest risk of developing chronic low back pain (CLBP) is important but difficult. STarT Back Screening Tool (SBST) is reported to capture patients at high risk of developing CLBP, but does not include concurrent pain from other locations, which is a known risk factor for worse outcome.

**Objectives:** To study differences in self-reported health between patients with low, medium and high risk of developing CLBP identified by the combination of SBST and information on widespread pain.

**Methods:** Adults aged 16-67 seeking primary care for LBP in the south-west of Sweden were included. The STarT Back Screening Tool was used to differentiate between three risk levels: low, medium and high risk. When patients were classified as medium risk, information from a pain mannequin on widespread pain and multisite pain were added to further distinguish between high and medium risk. If widespread pain and pain from more than seven locations (multisite pain) were reported, patient was transferred from the medium risk to the high risk group. Differences between the three risk groups with regard to physical function (Roland Morris Disability Questionnaire (RMDQ), 0-24 best, worst), mental health (Hospital Anxiety and Depression scale (HADa and HADd) 0-21 no distress-maximum distress), health related quality of life (EuroQol-5D (EQ5D), 0-1 worst-best), fear avoidance for physical activity (PA) and work (Fear Avoidance Beliefs Questionnaire (FABQ) PA, 0-24, and work, 0-42 worst) were analyzed in an ANOVA.

**Results:** Ninety-five patients (61% women), mean (SD) age 42 years (14) seeking health-care for their LBP were included in the study. Of those scoring low risk on SBST (n=19), 3 also reported multisite CWP. Of those who scored medium risk on SBST were reported multisite CWP and were moved to the high risk group. Of 17 scoring high risk on SBST, 4 simultaneously reported multisite CWP. After constructing three risk groups combining SBST and multisite CWP, there were 19 in low risk group, 45 in the medium risk group, and 25 in the high-risk group. The low, medium, high risk groups identified by the combined method, differed statistically significant in reported RMDQ (low, medium, high mean respectively 7.0, 12.2, 13.4, p<0.001), HADa (3.7, 6.4, 10.1, p<0.001), HADd (2.9, 4.0, 8.4, p<0.001), FABQ PA (9.1, 12.7, 14.4, p=0.005), FABO work (9.9, 16.7, 23.1 p<0.001), EQ5D (0.72, 0.53, 0.38, p=0.001).

**Conclusion:** Adding information on multisite widespread pain to the SBST resulted in classifying more patients in the high risk group as compared to using only SBST. The three groups identified by combining the screening tools differed significantly on all investigated health variables, indicating the combination may be capturing more patients at risk for CLBP.

**SAT0712-HPR** VALIDATION OF THE TEST FOR SUBSTITUTION PATTERNS – IN INDIVIDUALS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS

Margareta Törnbom, Maria Andersson, Anna Trulsson, Emma Haglund, 1, 2 Helsingborg Hospital, Department of Rheumatology, and Department of Health Sciences, Halmstad, Sweden; 3Lund University, Department of Clinical Sciences, Department of Rheumatology, Lund, Sweden; 4Skåne University Hospital, Department of Pain Rehabilitation, Lund, Sweden; 5Lund University, Department of Health Sciences, Physiotherapy, Lund, Sweden; 6Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden

**Background:** Few tools evaluates quality of movements in individuals with knee osteoarthritis (OA). The Test for Substitution Patterns (TSP) is developed to measure the ability to perform five functional movements regarding postural control and altered movement patterns (1). TSP is validated and reliable in individuals with anterior cruciate ligament injury, but has not yet been evaluated in individuals with knee OA.

**Objectives:** To study the relationships between the OA modified TSP (OA-TSP) and self-reported knee function as measured with the Knee Injury and osteoarthritis Outcome Score (KOOS) and the 30 s chair stand test (30 s CST) in individuals with symptomatic knee OA. A second aim was to study the discriminative ability of the OA-TSP for unilateral knee pain.

**Methods:** Sixty-two individuals with symptomatic knee osteoarthritis were included using consecutive sampling. Health status was assessed with the EuroQol five dimension scale (EQ5D, 0-1 worst-best), and knee function in five subscales for KOOS (pain, symptoms, ADL, quality of life and sport/recreation, 0-100 worst-best). The 30 s CST-test measured the number of rises in 30 seconds. In the OA-TSP, substitution patterns are observed and scored from 0-3 (no substitution pattern-poorly performed) during five standardized functional movements. The maximum score is 54 points/side with score of 108 points. Median and min-max were used for all descriptive data. Spearman’s correlation and Wilcoxon signed rank test were used for analyzes. A correlation coefficient \( r_s \) \( \geq 0.50 \) is considered large, \( r_s < 0.30 \) to \( 0.50 \) and \( 0.30 \) to \( 0.50 \) moderate, \( 0.10 \) to \( 0.30 \) small.

**Results:** The median age was 54 years (30-61), 76% were women. The median Body Mass Index index was 25 (18-48) and EQ5D 0.8 (0.29-1.00). There were no significant differences between the gender regarding BMI and EQ5D. Median OA-TSP total score was 29 (10-70), Median KOOS pain was 75 (36-100), symptoms 71 (21-96), ADL 87 (30-100), and sport/recreation 50 (0-100). In the 30 s CST the median was 16 rises (5-32). Moderate, significant correlations were observed between TSP total score and KOOS pain and KOOS ADL (\( r_s=-0.30 \); \( p<0.03 \), \( r_s=-0.35 \); \( p<0.01 \).
respective) and small correlations between TSP and KOOS sport/recrea-
tive impact of symptomatic knee OA. We also found that pain in one leg was related 
ment and KOOS symptoms (r s=-0.13; p=0.36, r s=-0.22; p<0.11 respec-
tive). There was a moderate, significant correlation between TSP total 
tively). There was a moderate, significant correlation between TSP total 
tive by using accelerometers, which potentially is a feasible method 
Istanbul, Turkey; 2Istanbul Medipol University, Physical Therapy and Rehabilitation, Istanbul, Turkey; 3Istanbul Medipol University, Ergotherapy, Istanbul, Turkey; 4Istanbul University, Istanbul, Turkey

Background: The rate of back pain prevalence and its subsequent nega-
tive psychological effects is quite high in mothers of disabled children. Family caregivers of children with a disability demonstrate higher levels of chronic conditions and are more likely to engage in health risk behav-
ors (1, 2).

Objectives: The purpose of this study was to investigate the effects of home exercise programs on mothers’ back pain, relevant functional influ-
and the depression level (3).

Methods: Forty-two mothers aged 35.71±6.53 were included in this study whom children were diagnosed with cerebral palsy. Back pain level of the mothers was measured with Visual Analogue Scale (VAS), relevant functional disability was measured with Oswestry Disability index and depression level was measured with Beck Depression Scale. Disability level of their children was measured with Gross Motor Function Classification System (GMFCS). Following the assessments, a home exercise program consisting of Dynamic Lumbar Stabilization Exercises was given to mothers. They were asked to perform the exercises for three months and exercises were checked once in a month.

Results: GMFCS average of the children was 3.35±1.57. There was a significant difference in the pain level (VAS) changed from 4.90±2.67 to 3.21±2.50 after the exercise (p<0.000). The difference between the Oswestry Disability Index score before (13.92±8.32) and after the exercise (10.76±8.54) was statistically significant (p<0.001). Also there was a signif-
icant difference in the Beck Depression Scale score decreased from 25.16±10.46 to 17.76±7.50 (p<0.000).

Conclusion: Mothers with disabled children complain about back pain dur-
ing activities such as caregiving their children (4). This study reveals that back pain, relevant functional influence and depression could be reduced in mothers by perform recommended exercises regularly.

SA0715-HPR] BREAKING BAD: REPORTING OF VERTEBRAL FRAGILITY FRACUTRES AND THE IMPACT TO MANAGEMENT OF BONE HEALTH

Ann O’Riordan, Shehla Famrux, Fahd Adeb. University Hospital Kerry, rheumatology, Tralee, Ireland

Background: Verterbral fragility fracture (VFF) is the most common osteo-
porotic fracture and a strong predictor for future vertebral fracture(s) and/ 
or hip fracture. A clear reporting of VFF by radiologists offers ample opportunity for early diagnosis and appropriate management of osteoporo-
sis among treating physicians.

Objectives: The objectives of this study were two-fold; to evaluate 1) the 
reporting of VFF by radiologists at one of the largest acute hospitals in 
southern Ireland 2) the management of osteoporosis (adherence to
screening for secondary causes and commencement/switching of anti-resorptive therapy accordingly) for patients with VFF.

**Methods:** We conducted a retrospective cross sectional study involving all patients (n=199) who attended our specialist rheumatology outpatient clinics at University Hospital Kerry during the month of November 2018. Patients who previously had undergone plain radiography of the spine (PRS) in the previous 5 years were identified and reassessed for evidence of VFFs. Basic demographic, drug history, clarification of fragility fracture and previous related trauma, investigations for secondary causes of osteoporosis, and treatment received for osteoporosis were documented.

**Results:** 73 of the 199 patients had undergone previous PRS, 9 of which had evidence for VFFs. Only two patients (22.2%) were reported as having vertebral "fractures", while 7 others had different terms used to describe the fracture(s):2 patients with "wedgeing", 1 with "compression", 2 with "loss of height" and 2 with "collapse". All (2 patients; 100%) with VFF reported as "fracture" had complete clarification of VFF, secondary osteoporotic work-up and treated with anti-resorptive therapy accordingly.

Among the other 7 patients with VFFs but not reported as having "fracture", 1 patient had concomitant report of "osteoporotic" bones and had complete management for osteoporosis. 4 patients had concomitant report of "osteopenia", 3 (75%) of which received complete management for osteoporosis; while only 50% (1 patient) of the 2 remaining patients without further description of bone density received appropriate management.

Further 6 patients with non-VFF were reported to have reduced bone density (1 reported as "osteoporotic" bones; 5 as "osteopenic" bones). Only one of them (16.7%) had further work-up, evaluation and management for osteoporosis.

**Conclusion:** Clear radiological report of PRS with VFFs using the word "fracture" is a strong predictor for appropriate management of bone health. It is essential that other terms used to describe VFFs such as "wedgeing", "compression", "loss of height" and "collapse" not to be used alone without the concomitant use of the word "fracture".

**SYSTEMATIC REVIEW OF THE PSYCHOMETRIC PROPERTIES OF PATIENT-REPORTED OUTCOME MEASURES FOR FOOT AND ANKLE IN RHEUMATOID ARTHRITIS**

Ana Belen Ortega-Avila1, Gabriel Giljoen-Nogueron1, Christopher Nester2, Pablo Cervera-Garvi1, Laura Ramos-Petersen1.

**Background:** Foot problems and pain are common in patients with rheumatoid arthritis. Patient-reported outcome measures provide a standardized method of capturing patients’ perspectives of their functional status and wellbeing. There are many instruments specific to people with feet affected by rheumatoid arthritis but knowledge of their psychometric validation and methodological quality is lacking.

**Objectives:** To identify patient-reported outcome measures specific to the foot and ankle and rheumatoid arthritis and investigate their methodological quality and psychometric properties.

**Methods:**

**Design:** Systematic review. **Data source:** A search was conducted for psychometric or validation studies on patient-reported outcomes in Rheumatoid Arthritis published in different languages, by examining the PubMed; Scopus, CINAHL; PEDro and Google Scholar databases.

**Review methods:** The systematic review performed was based on the following inclusion criteria: psychometric or clinimetric validation studies on patient-reported outcomes specific to the foot and ankle that included patients with Rheumatoid arthritis. Two authors independently assessed the quality of the studies and extracted data.

**Results:** Of the initial 431 studies, fourteen instruments met the inclusion criteria. Significant methodological flaws were detected in most with only SEFAS met the COSMIN quality criteria.

**Conclusion:** SEFAS had the best quality and was ranked most appropriate for use with patients living with Rheumatoid Arthritis.

CONSTRUCT VALIDITY AND RELIABILITY OF A PORTUGUESE VERSION OF THE ANIMATED ACTIVITY QUESTIONNAIRE (AAQ)

Clarissa Nascimento1, Icaro Ribeiro1, Wilfred P. Peter1,2, Alessandra Bastone1,2
1Universidade Federal do Vale do Jequitinhonha e Mucuri, Diamantina, Brazil; 2Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physiotherapy, Leiden, Netherlands; 3Amsterdam Rehabilitation Research Center | Reade, Amsterdam, Netherlands

Background: The AAQ assesses activity limitations in individuals with hip/knee osteoarthritis (HKOA), and consists of video animations of 17 basic daily activities performed with different levels of difficulty (www.myaaq.com). The participants choose the animation that best matches their own performance. The AAQ was developed in the Netherlands, and showed a good overall cross-cultural validity in 6 other languages.

Objectives: The aims of this study were to assess the construct validity and reliability of the Portuguese version of the AAQ.

Methods: In Diamantina, Brazil, men and women (≥45 years) with clinical HKOA were included in the study. The exclusion criteria were: cognitive impairment, visual/auditory deficit, or any medical condition other than HKOA that could hamper activity. This study was approved by the UFVJM Ethics Committee. All participants completed the Portuguese version of the AAQ. Illiterate or functional illiterate participants were assisted by the researchers. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), to assess pain, stiffness and function was completed by the participants. Performance-based tests were applied to a subgroup of 71 participants: Timed Up and Go (TUG) and Short Physical Performance Battery (SPPB). The first 53 participants completed the AAQ twice. To validate the AAQ, Spearman’s rho coefficients were calculated between the AAQ score, each score of the WOMAC, the SPPB score, and TUG score. To evaluate the influence of education in completing the AAQ, the participants were divided in two groups, 0-3 years of education and ≥4 years of education. To evaluate internal consistency and test–retest reliability of the AAQ, we calculated the Cronbach’s alpha coefficient and the intraclass correlation coefficient (ICC), respectively.

Results: 200 individuals, 85% female, mean age of 64.4 (SD 11.2) years, and a mean of 5.8 (SD 4.4) years of education, participated in the study. 72% of the participants had knee OA, 9% had hip OA, and 19% had both joints affected. The mean values on the different measures were as follows: AAQ = 72.7 (SD 16.1), WOMAC pain = 36.5 (SD 19.3), WOMAC stiffness = 37.1 (SD 26.2), WOMAC function = 39.1 (SD 19.6), SPPB = 8.0 (SD 2.1), and TUG = 16.2 (SD 12.7) seconds. The AAQ showed high internal consistency (Cronbach’s alpha = 0.94) and good test-retest reliability was (ICC = 0.98). The AAQ showed a moderate correlation with WOMAC pain (r = -0.51, 95%CI = -0.61 to -0.39), and WOMAC stiffness (r = -0.46, 95%CI = -0.56 to -0.33), and a high correlation with WOMAC function (r = -0.77, 95%CI = -0.82 to -0.71), SPPB (r = 0.65, 95%CI = 0.48 to 0.77), and TUG (r = -0.71, 95%CI = -0.81 to -0.56). Regarding the level of education, the correlations between the AAQ score and the three domains of the WOMAC were similar when the participants with 0-3 years of education (n = 62) were compared to the participants with ≥4 years of education (n=138) (pain: r = -0.51, 95%CI = -0.68 to -0.29 vs -0.52, 95%CI = -0.64 to -0.39; stiffness: r = -0.54, 95%CI = -0.70 to -0.32 vs -0.41, 95%CI = -0.54 to -0.25; function: r = -0.80, 95%CI = -0.88 to -0.68 vs -0.75, 95%CI = -0.82 to -0.66).

Conclusion: The Portuguese version of the AAQ showed good construct validity and reliability, and also seems to be applicable for patients with low literacy.

FOOT PRESSURE DISTRIBUTION AND FUNCTIONAL LEVELS: ANKYLOSING SPONDYLITIS VS CONTROLS

Nazi Sari1, Hande Guney Deniz2, Umut Kalyoncu1, Gul Baltaci1. Nazli Busra Sar1, Hande Guney Deniz2, Umut Kalyoncu1, Gul Baltaci1. Private Guven Hospital, Ankara 2Hacettepe University, Faculty of Health Science, Rehabilitation Department, Ankara, Turkey; Hacettepe University, Ankara, Turkey

Background: Ankylosing spondylitis (AS) is a chronic rheumatic disease characterized by the inflammation of the pelvis and spine with a tendency to bony ankylosis. The most common AS-related alterations in posture are, the limitation of spinal mobility, head protraction, loss of lumbar lordosis, increased dorsal kyphosis, flexion contracture of the hip and consequent flexion of the knee.

Objectives: The purpose of this study was to investigate the foot pressure distribution and functional levels differences in ankylosing spondylitis and also compare with healthy individuals.

Methods: Eighteen patients with ankylosing spondylitis (median age= 42.2 ±2.4 years, median BMI=25.7±1.27 kg/m²) and 17 controls (median age= 43.1±2.4 years, median BMI=26.78±0.65 kg/m²) were included in the study. Plantar pressure distribution was recorded by Digital Biometry Scanning System and Milletrix software (DIASU, Italy). The static test was used to determine the maximum foot pressure (N/cm²) of the foot, forefoot weight ratio, rarefoot weight ratio, total load and foot angle axis (FAA). When evaluating spinal mobility; lumbar flexion, lateral flexion and trunk to wall distance were used in Bath Ankylosing Spondylitis Mobility Index (BASMI) sub-parameters. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was used to determine the disease activity; The Bath Ankylosing Spondylitis Functional Index (BASFI) was used to measure functional impairment; The Ankylosing Spondylitis Quality of Life (ASQoL) Questionnaire was filled out by the patients in an attempt to understand the impact of the disease on the quality of life. Mann-Whitney U test was used to compare AS groups with the control group. Spearman test was used for correlation analysis.

Results: No difference between age (p=0.031) and BMI (p=0.012) in both groups. There were no differences modified Schober (p=0.184), lumbar flexion (p=0.160) and tragus to wall distance (p=0.434). But lower right lateral flexion (p=0.003) and left lateral flexion (p=0.001) in ankylosing spondylitis group when compared to healthy individuals. Rearfoot load higher than forefoot load in ankylosing spondylitis group (p=0.001). There were no differences static and dynamic analysis parameters ankylosing spondylitis group and healthy group. In addition to right lateral flexion (r=0.645 p=0.005) and left lateral flexion (r=0.641 p=0.04) correlated foot angle axis; tragus to wall distance correlated maximum foot pressure (r=0.578 p=0.015) and average foot pressure (r=0.542 p=0.025).

Conclusion: Lumbar spine flexibility was lower and associated with foot pressure distribution in AS patients. In addition, the load distribution between the rare and fore foot was different in these patients. Therefore, the foot pressure distribution as well as the spine flexibility should be monitored closely, when implementing and designing the exercise programs in patients with AS.

PULMONARY FUNCTIONS AND RESPIRATORY MUSCLE PERFORMANCE CORRELATE WITH NIGHT PAIN IN PATIENTS WITH ANKYLOSING SPONDYLITIS COMPARED TO CONTROLS

Bilge Taskin1, Naciye Vardar-Yagil2, Umut Kalyoncu1, Gul Baltaci1. Private Guven Hospital, ANKARA, Turkey; Hacettepe University, Ankara, Turkey

Background: In ankylosing spondylitis (AS), chronic systemic inflammation mainly affects the axial skeleton and involvement the costovertebral and costotransverse joints results in limitation of thoracic and spinal mobility (1,2). There is no study published to evaluate the endurance and strength of respiratory muscle and to investigate the relationship with pain.

Objectives: The aim of the study was to investigate the functional status, quality of life, pain, pulmonary function, respiratory muscle strength and endurance patients with AS and compare to healthy controls.

Methods: Standard pulmonary function tests, maximum inspiratory pressure (Pimax), and maximum expiratory pressure (PEmax) for pulmonary volumes and respiratory muscle strength were applied. Respiratory muscle endurance was recorded using sustained threshold loading of 40% maximal inspiratory pressure. AS group were evaluated by using the functional status and quality of life, the Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL). The severity of night pain, morning pain and morning stiffness were evaluated by Visual Analog Scale (VAS) in patients with AS. Mann Whitney-U test and Student-t Test were used to compare to groups variables. To evaluate the correlation in AS group Spearman’s Test was used.

Results: A total eleven patients (6 female, 5 male; mean age: 41.9±4yrs, body mass index (BMI): 26.1±6.3kg/m² and duration of disease 22±24.9months) and eleven controls (6 female, 5 male; mean age: 42.9±12.7yrs and BMI: 25±3.6kg/m²) were included in this study. There were no differences in age (p=0.554) and BMI (p=0.923) between the groups. No difference between FEV1% (p=0.069), FEV1/FVC% (p=0.243), PEF% (p=0.490), FEFP25-75% (p=0.297), MVV% (p=0.450), PEmax (p=0.694), PEmax (p=0.358) and respiratory muscle endurance (p=0.341) in both groups. But FVC% (p=0.041) significantly lower in AS group compare to controls. In addition to PImax (r= -0.800, p=0.003), PEmax (r= -0.683, p=0.021) and respiratory muscle endurance (r= -0.683, p=0.021) were correlated the night pain level in AS group. The respiratory muscle endurance (r= -0.675, p=0.023) was correlated the duration of disease. No correlations to the functional status, quality of life indexes and pulmonary functions in AS group.

Conclusion: This study shows that patients with AS have clearly reduced maximal PImax and PEmax, indicating decreased respiratory muscle strength and endurance as night pain levels increased. If indeed the respiratory strength were to be unchanged or even increased the decreased respiratory muscle strength should be due to reduced strength or atrophy of intercostal or accessory muscles, or both. Although the present data do not provide the direct evidence of intercostal muscle atrophy, it is tempting to speculate that immobilization of these muscles due to thoracic rigidity and decreased inspiratory intercostal and accessory activation leading to disuse may be an important factor contributing to it.

SAT0721-HPR INVESTIGATION OF FUNCTIONAL OUTCOMES AND QUALITY OF LIFE IN YOUNG ADULTS WITH INTERNAL FIXATION SURGERY OF FEMORAL SHAFT FRACTURE

TUFEK Taha1, Gizen İrem Kınikili, Omur Çağlar2. 1Hacettepe University Faculty of Physical Therapy and Rehabilitation, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Orthopaedics and Traumatology, Ankara, Turkey

Background: Femoral Shaft Fracture (FSF) is a severe injury with incidence 10-21 per 100,000 persons/year. The union rate is reported between 95-99%. Unfortunately, even after union a number of patients still report impairments and limitations in functional outcomes and quality of life (QoL). The literature lacks studies evaluating long-term functional outcome and performance and QoL.

Objectives: The aim of this study was to compare the functional outcomes and quality of life of the young adults who underwent internal fixation (IF) surgery of femoral shaft fracture (FSF) to the healthy individuals.

Methods: Twenty patients who underwent IF surgery of FSF by the same surgeon and 20 healthy individuals were included in this retrospective study. Individuals with secondary osteoporosis risk were not included. Function of both two groups was assessed using Harris Hip Score. To evaluate performance Stair Climbing Test (SCT) is applied. Quality of life was assessed by the EQ-5D-3L HRQoL. The Mann Whitney U-Test was used to compare the results of the function, performance and quality of life of the two independent groups. Statistically, p<0.05 was accepted as a significant difference.

Results: The mean age after surgery was 2.2±0.8 years. Comparing to the healthy group, the EQ-5D-3L VAS and TTO scores of the patient group were significantly lower (p<0.001). When the function results were compared between the groups, the mean total HHS of the patient group were found significantly lower (p<0.001). The results of mean stair climbing time in healthy group were significantly lower (p<0.001). Descriptive outcomes and results details is shown in Table 1.

Mann-Whitney U Test, M±SD: Mean score and Standard Deviatiion

Conclusion: The results of the study showed that there were deficiencies in long-term function, performance and quality of life in young adults after IF surgery compared to healthy individuals. Therefore, we suggest that the assessment of the in long-term functional outcomes and quality of life of the patients with FSF after IF surgery is necessary to plan appropriate rehabilitation programs by determining the patient’s needs.

SAT0722-HPR WHAT IS THE MOST AFFECTED BIOPSYCHOSOCIAL ASPECT IN RHEUMATIC DISEASES?

Edbe Ünal1, Gamze Arın1, Derya Gökmen2, Sedat Kiraz2. 1Hacettepe University Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; 2Ankara University Faculty of Medicine, Department of Biostatistics, Ankara, Turkey

Background: Rheumatic diseases are chronic illnesses that vary in the extent to different manifestations in musculoskeletal and internal organ systems. In addition to organ involvements, patients with these conditions suffer from biopsychosocial problems such as pain, stiffness, loss of functionality, social isolation, anxiety and depression, fatigue, sleep, and sexual problems due to the chronic nature of these diseases (1). BETY-BQ is a newly developed biopsychosocial questionnaire that can be used in rheumatic diseases and assesses patients in regards to biopsychosocial status.

Objectives: The aim of this study was to investigate the most affected biopsychosocial aspect that rheumatic diseases cause to.

Methods: 343 patients with rheumatic diseases (283 females and 60 males, mean age: 45.9±10.6) who referred to Hacettepe University, Department of Internal Medicine-Rheumatology were included in this study. Biopsychosocial aspects were assessed by using Bilgisel Egzersiz Terapi Yaklaşımı-Biopsychosocial Questionnaire (BETY-BQ)(2). Rasch analysis was used to determine the different biopsychosocial aspects and the most affected one.

Results: It was found that BETY-BQ has 6 categories assessing pain, functionality & fatigue, emotional status, social participation, sexuality, sleep. When the residual correlation matrix was evaluated, substantial local dependency was observed among the items. Consequently, the sets of items within each of the six subscales were treated as one summary item (testlet) and the data fitted to the Rasch model. Following this, all items were found to fit the model (given a Bonferroni adjustment fit level of 0.0083) (Table 1). Overall, the resulting 6-item item bank was well targeted. The most affected biopsychosocial aspect was found to be ‘social participation’ and the less affected was ‘sleep problems’.

</tr>
<tr>
<td>Subtest of “sleep problems” items</td>
<td>0.207</td>
<td>0.039</td>
<td>7.199</td>
</tr>
</tbody>
</table>

Conclusion: According to our results, social functioning is the most affected aspect of patients with rheumatic diseases. Following social functioning, sexuality, and emotional status were further affected. This results should be taken into consideration in the multidimensional rehabilitation programs.

INVESTIGATION OF FUNCTIONAL CAPACITY AND AFFECTING FACTORS IN SYSTEMIC SCLEROSIS PATIENTS

Hızal Yaşar1, Sevgi Ozせる2, Aylin Özgen Alpaydın3, Gercan Can4, 1Dokuz Eylül Üniversitesi Fizik Tedavi ve Rehabilitasyon Yüksekokulu, İzmir, Turkey; 2Dokuz Eylül Üniversitesi Hastanesi, Göğüs Hastalıkları Anabilim dalı, İzmir, Türkiye; 3Dokuz Eylül Üniversitesi Hastanesi, ve Rehabilitasyon Yüksekokulu, İzmir, Turkey; 4Dokuz Eylül Üniversitesi Hastanesi, ve Rehabilitasyon Yüksekokulu, İzmir, Turkey

Background: Systemic Sclerosis (SSc) is a rare, systemic connective tissue disease characterized by widespread microscopic damage and by increased production and deposition of extracellular matrix components both in the skin and internal organs (1).

Objectives: The aim of this study was to investigate the functional capacity and affecting factors in SSc patients.

Methods: Twenty-two SSc patients were included in the study. Functional capacities of patients were measured by 6 Minute Walking Test (6MWT). Lung volumes (FVC, FEV1, FEV1/FVC, PEF, VCF) were performed with Pulmonary function tests-PFT. Respiratory muscle strength was evaluated with a muscle inspiratory pressure (MIP)–muscle expiratory pressure (MEP) modulated spirometer known as respiratory muscle strength meter. Peripher- al muscle strength (deltoid, biceps, quadriceps and ilopsoas muscles) were also evaluated with manual muscle strength meter.

Results: The mean age of the patients was 52.0±11.23 years and duration of diagnosis was 7.83±4.86 years. The patients’ mean 6MWT distance was 430.5±105.25 meters, FEV1% were 78.52±22.23 L, FVC% were 80.95±23.02 L, FEV1/FVC% were 102.56±9.58 L, VC% values were 72.95±22.75 L, MCP% were 54.27±34.85 L, and MEP% values were 56.59±33.56. The mean deltoid muscle strength of the patients was 5.88 ±1.26 kg, biceps were 6.48±1.68 kg, quadriceps were 6.06±1.55 kg, iliopsoas were 80.95±23.02 L, FEV1/FVC% were 102.56±9.58 L, VC% values were 72.95±22.75 L, MCP% were 54.27±34.85 L, and MEP% values were 56.59±33.56.

Conclusion: The decrease in the functional capacity of the patients is accompanied by a decrease in pulmonary function, loss of respiratory and peripheral muscle strength in parallel. 6-min walk test showed negative effects in the pulmonary and musculoskeletal system or in the patients’ clinic on SSc patients. To evaluate and improve functional capacity, while performing medical and rehabilitation follow-up, respiratory functions, respiratory and peripheral muscle strengths should be evaluated and improved.

SAT0723-HPR

PROMISING OUTCOMES IN PATIENTS WITH RA UNDER A T2T PROGRAM AND A MULTIDISCIPLINARY DISEASE MANAGEMENT MODEL – 5 YEARS RESULTS FROM A RETROSPECTIVE COHORT

Anggie Aza1, Michael Cabrera2, Pedro Santos-Moreno3, Laura Villareal4, Diana Buitrago-Garcia1, 1Biomab – Center for rheumatoid arthritis, Bogotá, Colombia; 2Biomab – Center for rheumatoid arthritis, Psychology, Bogotá, Colombia; 3Biomab – Center for rheumatoid arthritis, Bogotá, Colombia; 4Biomab – Center for rheumatoid arthritis, Bogotá, Colombia

Background: Rheumatoid arthritis (RA) is a common chronic inflammatory disease. It is characterized by progressive, irreversible joint damage, impaired joint function and pain, the disease causes disability and reduced quality of life. Treat-to-target (T2T) is a management strategy for RA. It proposes that the therapeutic goal in RA should be a state of remission, or an alternative goal could be a low disease activity, addition- ally it looks to achieve long-term health quality of life for the patients.

Additionally, multiapproach programs for RA aim to take into account all components that interfere with the course of RA.

Objectives: To describe the effectiveness of a T2T strategy associated to a disease management model with a multidisciplinary approach of patients with RA, according to disease activity measured with Activity Score 28 (DAS28) in a 5-year period in patients who receive conven- tional or biological DMARDs in a Colombian specialized in RA center.

Methods: A descriptive cohort study was conducted. Medical records of patients from specialized in RA center were reviewed during 2015-2017; those patients were followed-up under T2T standards and a multidisciplinary approach. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3-5 weeks (DAS28 > 5.1), every 7-9 weeks (DAS28 > 3.1 and ≤ 5.1), and every 11-13 weeks (DAS28 ≤ 3.1). Tender joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 > 3.2 unless patient’s conditions don’t permit it; we considered this follow-up type as an implementation of a T2T strategy in patients with RA. Patients entered into a multidisciplinary program of care with periodic consultations not only to rheumatology but with a psychologist, physiotherapist, occupational therapy nutrition, and, a patient focused program. With a multidisciplinary model of care the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA. We divided patients in four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission. Descriptive epidemiology was done, we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We compared disease activity at base line and at the end of follow-up.

Results: We included 4000 patients, 83% were female and 17% male; median age was 60 years RIQ (50-67). Regarding pharmacological ther- apy 77% were receiving conventional DMARDs while 37% were receiving biological DMARDs. At beginning 55% were in MDA, 26% in LDA and 19% and during 5 years 82% of our patients achieved remission. See table 1. We performed a Wilcoxon test in order to compare the mean DAS28 at baseline and at the end showing statistical significance (P<0.05).

ACTIVITY LEVEL

<table>
<thead>
<tr>
<th>BASELINE</th>

<tr>
<td>3397</td>
<td>82.40</td>
</tr>
</tbody>
</table>

Conclusion: A T2T strategy associated with a multiapproach disease management model improves considerably disease activity in patients with RA. This evidence from a real-life setting that shows the advantages of treating RA patients with a multidisciplinary team under a T2T model with a low-cost treatment. It is important to explore other predictors that can improve disease activity.

SAT0725-HPR

A DISEASE MANAGEMENT MODEL TYPE CENTER OF EXCELLENCE IN SPONDYLOARTHRITIS – FIRST PILOT ANALYSIS RESULTS

Anggie Aza1, Fernando Rodriguez2, Pedro Santos-Moreno3, Diana Buitrago-Garcia1, 1Biomab – Center for rheumatoid arthritis, Bogotá, Colombia; 2Biomab – Center for rheumatoid arthritis, Bogotá, Colombia; 3Biomab – Center for rheumatoid arthritis, Patient program coordinator, Bogotá, Colombia; 4Biomab – Center for rheumatoid arthritis, Bogotá, Colombia; 5Biomab – Center for rheumatoid arthritis, Bogotá, Colombia

Background: Ankylosing spondylitis (AS) mainly affects the spine and the sacroiliac joints, it is a chronic inflammatory disease that might be asso- ciated with a variety of extra spinal lesions involving the eyes, bowel,
and skin. In Colombia little is known in regards of this condition. Spondyloarthritis (SpA) is one of the most prevalent musculoskeletal disease in the Americas, with an estimated prevalence of 0.5%. This group of patients present a number of unmet needs for accessibility to the consultation, diagnosis and adequate treatments. That is why in this project it is necessary to develop a program of Centers of Excellence (CoE) in this pathology, which allows answer to these needs and at the same time to add values for our health systems.

Objectives: To describe the characteristics of patients with AS who attend to a specialized in SpA disease management model center.

Methods: We implemented a pilot SpA program under the scheme of CoE, as they are already delineated in projects like REAL-PANLAR for rheumatoid arthritis. We performed a cross sectional study and reviewed the medical charts of patients with AS. All patients had a confirmed diagnosis of AS. We collected demographic data (age, sex, smoking, alcohol consumption); BASDAI, BASFI, DAS, disease specific data treatment with csDMARDs or bDMARDs and comorbidities, evaluation period covered January to December 2018.

Results: During 2018 257 patients with AS entered to our program. 64% were men and 36% were female; mean age was 48 years ±14. 28% of our patients with SA had comorbidities the most common was high blood pressure 19%, followed by diabetes mellitus 4%. Regarding behavioral habits 23% were current smokers and 11% reported to consume alcohol. When we evaluated clinical outcomes BASDAI mean score was 2.95 ± 2.06, BASFI mean score was 3.49 ± 2.36 and, ASDAS mean score was 1.70 ± 1.01. 60% of patients received biological DMARDs and 25% received conventional DMARDs. The remaining 15% received corticoids or pain medications.

Conclusion: Due to the need to develop CESPAs, in order to define treatments for SpA type T2T-SpA, we implemented an innovation program in a low-income country with the aim to improve clinical outcomes and avoid so much disability and health economic costs. This descriptive data is the starting point to collect evidence and demonstrate the impact of the program.

SAT0725-HPR EHEALTH CONSULTATIONS IN RHEUMATOLOGY MANAGED BY NURSING. SPANISH NATIONAL DESCRIPTIVE STUDY

Silvia García Díaz1, All the members from the Nursing Working Group from the Rheumatology Spanish Society (GTE-SER), Hospital Sant Joan Despí Moises Broggi-Hospital General de Hospitalet, Consorcio Sanitari Integral (CSI), Rheumatology, Barcelona, Spain Background

The increase in social media applications and electronic technology has made it possible to carry out consultations with patients using an electronic interface. These tools are used in the healthcare environment for the purpose of prevention, diagnosis, treatment, monitoring, and in health management, to save costs to the health system by improving its effectiveness [1-4].

For patients with rheumatic diseases these non-face-to-face eHealth consultations, carried out by specialized nurses have been shown to resolve a large part of the problems that these patients may present with [5-8]. However we do not know how many of these types of consultations are taking place in Spain.

Objectives: The aim of this study was to describe the content of these types of consultations, mostly managed by nursing, in the Spanish national territory.

Methods: A descriptive study of a group of nurses working actively in rheumatology was carried out in November 2018. The data collection was done using a Google-form questionnaire developed for that purpose by the members of the Nursing Working Group from the Rheumatology Spanish Society (GTE-SER). The main variables studied were the socio-demographic details of the group and the content of the activity carried out mainly by them in the eHealth consultations. This instrument had 31 questions, with wide variability of response. Statistical analysis: descriptive statistics was used.

Results: A total of 47 (out of 50) completed surveys were analysed. 94% of the nurses were women, from 15 Spanish Autonomous Communities, with an average age between 51-60yo; 52% had education at postgraduate level (17%) or master’s degree (35%). 47% of professionals had been working in rheumatology for more than 10 years and 77% had received specific training in rheumatology. 37% reported having between 1-5 years experience of using e-Health consultation in rheumatology. The average of monthly consultations was between 50-100 sessions. Further details of the eHealth consultations in Rheumatology: see Table 1.

Table 1:

<table>
<thead>
<tr>
<th>VARIABLES</th>

<td>There are NO standards or protocols on the use of eHealth consultations in rheumatology in your centre</td>
<td>81%</td>
</tr>
<tr>
<td>There has not been any audit on the use of eHealth consultations in rheumatology</td>
<td>98%</td>
</tr>
</tbody>
</table>

Conclusion: EHealth consultations are already established in many Rheumatology services in Europe. However, this has not been described in Spain. The survey showed that there is a great variability in the way the nurses carry out this type of consultations, including the number and type of consultation (on demand and/or scheduled); registration and analysis of the data of this consultation as well as its quality standards.

This study demonstrates a lack of regulated training and standardized protocols in managing this type of consultation at the national level. Therefore standards and protocols should be developed in the near future, so that patients receive a more consistent service from this type of consultation.

SAT0727-HPR CHANGES IN ACHILLES TENDON STIFFNESS IN GOUT MEASURED BY ELASTOGRAPHY – A PRELIMINARY STUDY

Simon Otter1, Catherine Payne2, Anna-Marie Jones2, Nick Webborn2, Peter Watt2.

1University of Brighton, School of Health Sciences, Eastbourne, United Kingdom; 2University of Brighton, Sport and Exercise Science and Sports Medicine Research Group, Eastbourne, United Kingdom; 3Sussex Partnership NHS Foundation Trust, Research and Development, Worthing, United Kingdom

Background: In addition to acute attacks of severe joint pain and swelling, chronic gout has been associated with weaker foot/leg muscles, altered gait patterns and on-going foot pain. Inflammation associated with gout may change tissue elasticity and ultrasound imaging (US) utilising elastography is a non-invasive method of quantifying these changes in tendon stiffness and elastography findings have not previously been reported in individuals with gout.

Objectives: To determine differences in Achilles tendon stiffness in people with chronic gout compared to controls (non gout)

Methods: A cross sectional study comparing people with gout according to 2015 ACR/EULAR criteria and age/sex matched controls. Clinical and demographic data were collated and US imaging used to determine tendon thickness, presence of gouty tophi and/or aggregates and levels of angiogenesis. Previously validated protocols for conventional US imaging [1] and shear wave elastography [2] were used. Prior to data collection, intra-observer error was good (ICC (2) 0.69 (95%CI 0.62-0.89)). Ten elastography measures were taken along a longitudinal section of the mid-point of the Achilles tendon bilaterally. Data were summarised using descriptive statistics and a repeated measures ANCOVA was used to compare elastography outcomes between the two groups for the left and right foot separately after accounting for Body Mass Index (BMI).

Results: A total of 14 people with gout and 13 age/sex matched control subjects participated. Table 1 displays clinical and demographic data. A
small proportion of those with gout presented with intra-tendon aggregates and/or intra-tendon tophi in one or both tendons (n=7 (27%) for both). There was no significant difference in tendon thickness between groups, neo-vascularity was present in n=3 (21%) gout participants. Elastography findings (table 2) demonstrated significantly reduced tendon stiffness in those with gout compared to controls.

SAT0727-HPR REVISION OF THE DUTCH GUIDELINE FOR PHYSIOTHERAPY IN PATIENTS WITH HIP AND KNEE OSTEOARTHRITIS: RECOMMENDATIONS FOR DAILY PRACTICE

Wilfred F. Peter 1,2, Mitchell van Doormaal 2, Guus Meehoff 3, Thea Vliet Vlieland 1. 1 Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physiotherapy, Leiden, Netherlands; 2 Amsterdam Rehabilitation Research Center / Reade, Amsterdam, Netherlands; 3 Royal Dutch Society for Physical Therapy, Amersfoort, Netherlands

Background: Until 2018, the most recent update of the Dutch physiotherapy guideline for Hip and Knee Osteoarthritis (HOCA) was conducted in 2010. Since then, scientific developments changed the view on osteoarthritis and could have significant impact on daily practice. An update of the guideline was necessary with more applicable recommendations about the content of exercise therapy.

Objectives: To revise the Dutch guideline for physiotherapists in patients with HKOA.

Methods: To develop more practical and widely supported guidelines, a guideline methodology was developed by the Royal Dutch Society for Physical Therapy (KNGF) in 2016. This methodology was based on GRADE, the most accepted approach in guideline development worldwide. According to the KNGF methodology, a guideline panel was formed out of 22 stakeholders, e.g. physiotherapists, general practitioners, orthopedic surgeons, patient representatives and healthcare insurers. Based on the scientific evidence and other considerations, the guideline panel formulated the recommendations in this guideline.

Results: Recommendations about diagnostics and therapeutic interventions formed the base of the new Dutch physiotherapy guideline for HKOA. Three indications were formulated, based on patient preferences, severity of the functional condition and existence of comorbidity. A fourth indication concerned pre- and postoperative physical therapy before or after a total joint replacement. It was recommended to restrict physical therapy in patients with minor functional limitations by informing and advising about osteoarthritis and how to deal with the disease. In contrast, extensive supervised exercise therapy was recommended in patients with severe functional restrictions and/or comorbidity. Besides informing and advising, supervised exercise therapy is stated as the intervention with the strongest recommendation. Frequency, Intensity, Type and Time (FITT factors) of exercise therapy are described extensively, based on evidence and strongly linked to (inter)national recommendation for physical activity. Besides informing and advising, other non-exercise therapeutic interventions were not recommended.

Conclusion: The new physiotherapy guideline for HKOA provides practical information and guidance to physiotherapists on diagnostics and therapeutic interventions. Extensive implementation is necessary to enhance conservative treatment of osteoarthrosis and achieve uniform health care.

REFERENCE

Disclosure of Interests: None declared

Conclusions: Three indications for PT are distinguished, based on the patients’ health status and abilities of self-management: 1) patient education combined with instructions for mainly unsupervised exercise therapy, 2) patient education combined with exercise therapy with short-term supervision and 3) patient education combined with exercise therapy with intensified supervision. Exercise therapy is recommended for indication 2, and conditionally recommended for indication 1 and 3. Patient education consist of information and advice on RA and promotion of self-management. Specific recommendations concerning the frequency, intensity, type and time (FITT) of the exercise therapy are provided, based on studies performed in patients with RA, recommendations from The Dutch Health Council (2017), EULAR recommendation on Physical Activity (2018), and The American College of Sports Medicine guidelines for exercise testing and prescription (2018). Behavioral interventions to promote physical activity in patients with RA are also recommended. The guideline obtains practical advice for applying tailored behavioral interventions.

EDevelopment and Design of Smartphone Application for Postural Alignment of Cervical and Thoracic Spine for Young Adults

Eda Tonga, Merve Can, Mine Gilden Polat, Marmara University, Faculty of Health Sciences, Department of Physiotherapy, Istanbul, Turkey

Background: Mobile health (mHealth) technologies offer personal, intelligent, cost-effective, access to health care services. Numerous smartphone applications exist to assist the users for management or prevention of the musculoskeletal disorder. But most of the apps were not designed with both users and experts focus. As our knowledge, there is no health exercise app for neck and upper back musculoskeletal prevention designed by experts with the user-centered method.

Objectives: The aim of our study is to develop a smartphone exercise application (app) for cervical-thoracic postural alignment for young adults.

Methods: We used a combination method of focus groups interviews and user-centered design approach. The mobile application was designed in three phases: (1) we conducted multidisciplinary focus group meetings to compromise the content, feature and design of app in the first phase (prototype smartphone app/MarNeckEx). Focus group consisted of software developers, 3 experienced physiotherapists on musculoskeletal ergonomics, 3 young smartphone users who have neck and upper back problems associated with an excess smartphone using. The focus group members discussed the variety of topics in subgroups (login parameters, self-monitoring, exercises content, video or animation types, exercise diary, reminders, encouragement method etc). We conducted 4 focus group meeting for phase 1. (2) After developing the prototype version of app 30 young adult downloaded the prototype app and used the app for one week, after one week we asked the satisfaction levels, barriers and facilitators of the app design and advice for usability. We conducted 2 focus group meetings for development of the revised application by modifying the errors taking into account feedbacks (revised MarNeckEx).

Results: Major themes identified for development app phase 1 were (a) self-assessment of musculoskeletal problems (b) Choosing the spinal stabilization and postural alignment exercises with well design videos (c) encouraging and notifications for exercise adherence. A second phase themes, (d) education for using the digital app for exercise, (e) positive or negative feedback notifications for improving adherence were added.

Triage Ad Hoc Referral by Rheumatology Nurse – An Alternative Path to Clinic Visit

Cheung Yin Shuen1, Lee Pik Fan1, Leung Man Chi1, Lam Chi Kwai1, Chan Ching Man1, Ng Woon Leung1, 1United Christian Hospital, Medicine and Geriatric, Hong Kong, Hong Kong (SAP)

Background: Rheumatic diseases are chronic conditions characterized by disease flares and remissions. Patients are often referred back from other healthcare providers in between follow-up visits when they seek attention for disease flares or adverse effects from treatment. While prompt attention and assessment is important, the busy rheumatology clinic may not have the coping capacity for these ad hoc needs. Rheumatology nurse (RN) can play a pivotal role in triaging these referrals.
Objectives: The study aims to evaluate the safety of referral triage by rheumatology nurse and the effectiveness in alleviating workload of the rheumatology clinic.

Methods: This was a retrospective study. Data were retrieved from November 2016 till December 2018. Ad hoc referrals to the rheumatology out-patient clinic were screened by rheumatologists and suitable cases were directed to RhN for further handling. The triage process included phone triage or attendance of RhN clinic for assessment and subsequent phone follow-up. Investigations including laboratory and radiography were arranged as indicated. Frequency of phone follow-up after the first contact depended on patients’ needs. Patients would be referred to rheumatologist for further management if the condition worsened at or before the first phone follow-up.

Results: Totally 110 referrals were triaged by rheumatology nurse with 54 arthritis, 28 systemic lupus erythematosus, 10 vasculitis, 8 undifferentiated connective tissue disease and 5 others. Age ranged from 22 to 84 years and 82.7% were female. Sources of referral included general out-patient department (38.2%), emergency department (22.7%), other specialists (33.6%) and general practitioners (5.5%). Reasons for referral included disease flare-up (47.3%), drug-related problems (20.9%), abnormal investigation results (12.7%) and alarming clinical presentation (19.1%). Mean time interval from referral to first phone contact was 3.8 days. Of the 110 cases, 20 patients had follow up advanced; 1 patient was admitted before phone triage and 86 patients could follow original appointments. Two of the 110 patients’ symptoms subsided spontaneously and no intervention was required; 1 patient was arranged admission after discussion with rheumatologist. No record of emergency attendance or admission for the 86 patients who kept the scheduled appointment. Nursing interventions included drug education and advice (64 episodes), disease education (20 episodes), investigation arrangement (50 episodes), counselling and emotional support (12 episodes). Three patients attended RhN clinic for assessment and education. The other 83 patients were managed through phone communication and majority (81.4%) had phone follow up once.

Conclusion: The result of the study showed that referral triage by rheumatology nurse is safe and effective in handling the majority of ad hoc referral requests. The service can promptly address patient needs and reduce clinic visit burden of the rheumatology clinic.

Genomics, genetic basis of disease and antigen presentation

AB0001 ASSOCIATION OF MDR1 GENE G2677T POLYMORPHISM WITH METHOTREXATE RESISTANCE IN PATIENTS WITH UZBEK RHEUMATOID ARTHRITIS

Nargiza Abdurakhmonova1, Khuralnad Akhmedov2, Tashkent Medical Academy, Tashkent, Uzbekistan; 2Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Methotrexate (MTX) is the most widely prescribed disease-modifying antirheumatic drug (DMARD) for treatment of rheumatoid arthritis (RA) [1]. According to different authors, in 25–40% of cases "complete clinical remission" or "low disease activity" is not achieved, by reason of refractoriness to methotrexate and this may be related to the activity of the MDR1 (ABCB1) gene which is involved in its metabolism. According to many studies on the C3435T isoform MDR1 polymorphism CC genotype is associated with methotrexate refractoriness [2]. But a certain interest is also influenced by the other isoform of the MDR1 gene (G2677T) for the presence of resistance to methotrexate.

Objectives: The aim of this research was to study the effect of MDR1 gene polymorphisms G2677T (rs2032582) on resistance to treatment with methotrexate in Uzbek patients with RA.

Methods: The study involved 76 patients with RA of Uzbek nationality and 24 healthy people. The average age of patients was 48.9 ± 15.9 years. RA was diagnosed according to the criteria of the American College of Rheumatology (ACR). 75.6% of patients had high and 24.4% moderate RA activity (DAS28). All patients took methotrexate in monotherapy, at a dose of 7.5-15 mg for 3-6 months. All patients were genotyped by the MDR1 gene G2677T polymorphisms by using the polymerase chain reaction (PSR-Real time).

Results: Genotyping of the G2677T isoform of MDR1 gene revealed the following results: in patients with CC genotype was found in 22 patients (28.9%), CT genotype was found in 31 patients (40.7%) and TT genotype was found in 23 patients (30.2%). In patients treated with methotrexate, the following disease activity was observed: in patients with CC genotype, the disease activity was Das28 -6.2, with CT genotype Das28 3.2-4.5. Patients with the TT genotype had an activity of Das28 5.1. Despite the increase in the dose of methotrexate, the remission was not achieved.

Conclusion: TT genotype G2677T isoform of MDR1 gene is associated with resistance to treatment with methotrexate and this may be related to the activity of this polymorphism with other DMARD preparations. Patients are recommended to conduct genotyping to the MDR1 gene for personal selection of drugs.

AB0002 INCREASED SENSITIVITY TO DNA DAMAGING AGENTS IN HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PATIENTS WITH RHEUMATOID ARTHRITIS

Olga Brzezinka1, Grzegorz Gallia2, Anna Maciejca2, Anna Lewandowska-Polak1, Joanna Samik1, Tomasz Popławski2, Joanna Makowska1. 1Medical University of Lodz, Department of Rheumatology, Łódź, Poland; 2University of Lodz, Department of Molecular Genetics, Łódź, Poland

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease with not fully elucidated pathogenesis. Rheumatoid arthritis patients have increased risk of developing lymphomas. One of the possible mechanisms of this predisposition is increased genomic instability and impaired DNA repair. It is unclear how this genomic instability contributes to diseases pathogenesis.

Objectives: The aim of this study was to analyze the sensitivity and repair efficiency of mononuclear cells isolated from RA patients to DNA damaging agents.

Methods: The study group consisted of 22 patients with RA (age years – 60,7±13.0, women-17, men-5) hospitalized in the Department of Rheumatology between 2017 and 2018 and 10 healthy controls without autoimmune and oncological diseases in clinical history (age 44.09±16.56; women-5, men-6). The peripheral blood mononuclear cells (PBMC) from all subjects were isolated. Using comet assay the degree of intracellular DNA damage as a result of exposure to standard damage factors: tert-butyl hydroperoxide (TBH), bleomycin, methyl methanesulfonate (MMS) and UV radiation was assessed.

Results: RA patients show a statistically significant higher level of endogenous damage in PBMC DNA than controls (mean RA: 9.64%, vs 4.68% in control; p<0.001). The extent of the DNA damage induced by TBH, MMS as well as UV was significantly higher in PBMC derived from RA patients than in healthy counterparts (p<0.001). The DNA of RA patients treated with TBH was repaired less effectively than in control (p<0.0001). Significantly higher percentage of DNA damage in RA DNA (p<0.0001) under the influence of bleomycin and clearly marked repair processes were observed. Among the healthy controls lower percentage of DNA was damaged, and although the repair process was slower but the final percentage of DNA damage was also lower.

Conclusion: DNA of people with rheumatoid arthritis is significantly more susceptible to damage in baseline and induced. The kinetics of DNA repair from RA patients after the introduction (TBH and bleomycin) was statistically less effective as compared to healthy control. Understanding the etiology of this phenomenon in RA may provide insight into disease pathogenesis and explain the increased susceptibility of patients to malignancies.

AB0003 GENETICS OF PAIN IN WOMEN WITH FIBROMYALGIA: THE PROMISING ROLE OF REDUCING SEDENTARY BEHAVIOUR

Bartosz Kowal1, Diego Salazar-Tortosa2, Virginia A. Aparicio2, Daniel Camiellit-Morón2, Blanca Gavilán Carrera2, Pedro Acosta-Manzano1, Inmaculada C. Alvarez-Gallardo1, Víctor Segura-Jiménez2, Alberto Soriano Maidana3, Patrick Finan5, Rinie Geenen6, Manuel Delgado-Fernández1, Luis J. Martínez-González4, Jonatan R. Ruiz1, María J. Alvarez-Cubero1,2,3

1Medical University of Granada, Granada, Spain; 2Ulster University, Belfast, United Kingdom; 3University of Cádiz, Cádiz, Spain; 4University of Almería, Almeria, Spain; 5John Hopkins University, Baltimore, United States of America, 6Utrecht University, Utrecht, Netherlands; 7GENyO (Pfizer-University of Granada-Andalusian Government Centre for Genomics and Oncological Research), Granada, Spain

Background: Fibromyalgia is characterised by chronic pain and a heterogeneous presentation of other symptoms (e.g., fatigue and depression) [1]. It is widely accepted that pain is promoted by both genetic susceptibility and environmental factors such as people’s behaviours [2]. In addition to genotype individual associations with gene-gene interactions, when considering complex phenotypes such as pain, environment interacts with genetic factors in different ways and can affect the development and management of pain. This is particularly important in fibromyalgia, where there is increasing evidence that genetic factors contribute to inter-individual differences in pain experience and help to shape the clinical presentation of fibromyalgia.

Objectives: To test the individual association of 64 polymorphisms (34 candidate-genes) and the gene-gene, gene-physical activity, and gene-sedentary behaviour interactions with pain and pain-related cognitions in fibromyalgia.

Methods: In 274 women with fibromyalgia, saliva samples were collected for extracting DNA. We measured physical activity and sedentary behaviour by accelerometers for a week, pain with algometry and questionnaires, and pain cognitions with questionnaires. Age, body fat, and analgesics and antidepressants consumption were included as covariates. Significance was set at P-values lower than the Bonferroni’s correction or P- and false discovery rate values lower than 0.05.

Results: The rs8311 and rs6313 polymorphisms were individually related to algorimeter scores. The interaction of rs4818 and rs1799971 polymorphisms was related to pain catastrophizing. Five gene-behaviour interactions were significant: the interactions of sedentary behaviour with rs1383914, rs6860, rs46580, rs165599, and rs12994338 polymorphisms were associated with the bodily pain subscale of the SF-36.

Conclusion: The HTR2A gene (individually), COMT and OPRM1 gene-gene interaction, and the interactions of sedentary behaviour with ADRA1A, CHMP1A, COMT, and SCN9A genes were associated with pain-related outcomes in fibromyalgia females. Besides indicating the relevance of genetic background for pain and pain-catastrophizing, the observed genotype-behaviour interactions suggest that the effects of sedentary behaviour on pain may depend on the genotype of women with fibromyalgia. Future clinical experimental research should examine whether reducing sedentary behaviour is particularly beneficial for reducing pain in women with specific genotypes.
DETECTION OF THE SNP-SNP INTERACTIONS IN THE FAVORABLE RESPONSE TO RITUXIMAB IN A PATIENT ASSOCIATION OF HLA-DPB1*16:01 ALLELE WITH PR3-Ro

Hanna Yatskiu1, Nataliya Savina1, Nataliya Nikitchenko1, Tatyana Kuzhir1, Alexandr Sukalo2, Roza Goncharova1.

2Private Practice, Istanbul, Turkey
3Istanbul University Faculty of Medicine, Rheumatology, Istanbul, Turkey, 4Private Practice, Rheumatology, Istanbul, Turkey, 5Istanbul University Faculty of Medicine, Medical Biology, Istanbul, Turkey

Objectives: The aim of the study was to estimate interactions between SNPs of the genes implicated in immune and inflammatory responses: STAT4 (rs7574865), TRAF1/C5 and RUNX3 genes and is characterized by 0.6727 entropy value of 1.12% statistically significant high-order interaction of three polymorphisms: STAT4 – RUNX3 (rs11249215). GT (STAT4 rs7574865) and GG (TRAFC5 rs3761847), OR = 2.92, combined entropy – 4.83%. Separate data analysis for males and females didn’t show any statistically significant model of SNP interactions associated with JIA. However, MIF ns755622 with entropy of 2.92% was more informative in females, while STAT4 rs7574865 with entropy value of 1.12% – in males.

Conclusion: MDR analysis of the JIA-case-control data set identified a statistically significant high-order interaction of three polymorphisms: STAT4 – RUNX3 (rs11249215). GT (STAT4 rs7574865) and GG (TRAFC5 rs3761847), OR = 2.92, combined entropy – 4.83%. Separate data analysis for males and females didn’t show any statistically significant model of SNP interactions associated with JIA. However, MIF ns755622 with entropy of 2.92% was more informative in females, while STAT4 rs7574865 with entropy value of 1.12% – in males.

FAVORABLE RESPONSE TO RITUXIMAB IN A PATIENT WITH HYPOCOMPLEMENTEMIC URTICARIAL VASCULITIS ASSOCIATED WITH A HOMOZYGOUS FRAMESHIFT AGBL3 VARIANT

Atmet Gül1, Nehidilin Aksoy2, Sema Sima Ekmece2. 1Istanbul University Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, 2Aziz Sancar Institute for Experimental Medicine, Department of Genetics, Istanbul, Turkey

Background: Last year we described a homozygous AGBL3 variant in a patient with autoinflammatory features and hypocomplementemic urticarial vasculitis. Whole exome sequencing revealed a deleterious homozygous c.768C>T mutation in AGBL3 (ATP/GTP binding protein-like 9) gene, which results in early termination of the protein (p.Gln257Ter) and deletion of the functional carboxy-peptidase domain. This protein belongs to metallocarboxypeptidases that mediate both deglutamylation and deaspartylation of target proteins, and AGBL3 is suspected to catalyze the deglutamylation of polyglutamate side chains.

Results: The index case was 23-year-old male patient of Assyrian origin, who had consanguineous parents. He was evaluated in our clinic because of recurrent attacks of fever, urticarial rash on the extremities and trunk, conjunctival injections and arthralgia, without a trigger or more frequently following an infection. His 2 to 3 days lasting attacks started when he was 13 and recurred more frequently during warm weather conditions or following hot baths. He had highly elevated CRP and ESR during attacks, but his acute phase response did not return to normal values in between the flares. Low C3 and C4 values were also observed during asymptomatic periods. His ANA test became positive during the course of his disease with an increase in titer during the last years. The biopsy of skin lesions revealed findings compatible with urticarial vasculitis. He responded only partially to corticosteroids, canakinumab and anakinra treatments. His treatment was switched to rituximab following the favorable response was observed following the first two infusions. He developed less frequent and milder attacks only after infections, and acute phase response was reduced to near normal values in between attacks.

Conclusion: The AGBL3-metallocarboxypeptidase gene was recently identified as a novel autoinflammatory gene associated with hypocomplementemic urticarial vasculitis phenotype, and it was different from the previously defined variants including DNASE1L3 mutations. The clinical features of the index case included both autoinflammatory and autoimmune findings including autoantibodies; and his inflammatory attacks did respond to rituximab treatment but not IL-1 blockade. Long-term follow-up and search for other patients associated with AGBL3 variation among idiopathic hypocomplementemic urticarial vasculitis are required for better clarification of the AGBL3-associated clinical phenotype.

ASSOCIATION OF HLA-DPB1*16:01 ALLELE WITH PR3-ANCA POSITIVE GRANULOMATOSIS WITH POLYANGIITIS IN TURKISH PATIENTS

Burcu Ince1, Sevi Kamȧl2, Yeşil Duvanci Oguz1, Fatma Savran Oguz2, Bayrak Adil-Esen1, Murat Inanc1, Mahmut Lale Ocal1, Atmet Gül1, Istanbul University Istanbul Faculty of Medicine, Rheumatology, Istanbul, Turkey, 2Private Practice, Rheumatology, Istanbul, Turkey, 3Istanbul University Faculty of Medicine, Medical Biology, Istanbul, Turkey

Background: ANCA associated vasculitides (AAV) comprise an important subset of small vessel vasculitides with a multifactorial pathogenesis, which is considered to be associated with the interaction of genetic and environmental factors. Certain HLA Class 2 alleles have been reported among the genetic risk factors for AAV from different geographic regions such as Europe and Asia (1,2).

Objectives: In this study, we aimed to analyse the distribution of HLA Class 2 genotypes among a series of Turkish AAV patients in comparison with the healthy Turkish subjects and the previously reported data of AAV cohorts from other countries.

Methods: Ninety-eight patients (aged between 18–75 years) diagnosed with AAV according to 2012 Chapel Hill Consensus Criteria were enrolled into the study. Records of age-at-birth and geographical regions throughout the follow-up period during the last 8 years.

Results: HLA Class 2 genotypes among Turkish AAV patients were compared by Chi-square test, and P value lower than 0.05 was accepted as significant.

was significantly higher in the GPA-AAV group (%7.14 vs. %0.26 p<0.01, OR=30, 95% CI: 3.8–237). No significant difference was detected between the MPO-AAV and control groups.

**Conclusion:** HLA analysis of this small series of Turkish AAV patients revealed a negative correlation between PR3-ANCA positivity and HLA-DPB1*04:01 and HLA-DPB1*02:01 alleles in opposition to the results reported from different European AAV cohorts (1,3). On the other hand, a significant increase in both GPA and PR3-AAV subgroups for a previously unpublished HLA-DPB1*16:01 allele may suggest that HLA association may show ethnic or regional differences, and further analyses in larger series of AAV patients may reveal the molecular basis of this observation.

**IL12B POLYMORPHISMS ARE ASSOCIATED WITH ELEVATED SERUM LEVELS OF IL-12P40, IL-23 AND GENETIC PREDISPOSITION TO RHEUMATOID ARTHRITIS**

Mariana Ivanova Goycheva1, Irena Manolova2, Georgi Vasilev3, Lyuba Miteva2, Rumen Stoilov4, Spaska Stanilova2.

**1Medical Faculty, Trakia University, Department of Molecular Biology, Immunology & Medical Genetics, Stara Zagora, Bulgaria; 2Medical Faculty, Medical University, University Hospital “St. Ivan Rilski”, Clinic of Rheumatology, Sofia, Bulgaria; 3Medical Faculty, Medical University, University Hospital “St. Ivan Rilski”, Laboratory of Clinical Immunology, Sofia, Bulgaria; 4Medical Faculty, Medical University, University Hospital “St. Ivan Rilski”, Clinic of Rheumatology, Sofia, Bulgaria**

**Background:** Rheumatoid arthritis (RA) is the most common type of autoimmune arthritis in which genetic predisposition in close interaction with environmental triggers seems to play the major role in the disease pathogenesis. Genetic analyses suggest a polygenic inheritance, as the largest genetic contribution to RA susceptibility remains the HLA-DRB1 gene, residing within the HLA gene complex. Since immune dysregulation plays a key role in immune-mediated inflammatory disorders, genetic variations within cytokine loci may contribute to variability in the immune response determining susceptibility or resistance to a certain autoimmune disease.

**Objectives:** We aimed to investigate whether IL12B polymorphisms are involved in causation of RA and in variations of circulating IL-23 and IL-12p40 levels in our Bulgarian population.

**Methods:** A total of 125 RA patients aged from 18 to 79 years in comparison to 239 age- and sex-matched healthy controls (HC) were genotyped for rs17860508 and rs3212227. Both IL12B polymorphisms were investigated by polymerase chain reaction (PCR) - based methods. Serum IL-12p40 and IL-23 concentrations measurement was done using ELISA test in 67 RA patients and 55 age-matched HC.

**Results:** An association between the rs17860508 polymorphism and RA development was established under the allelic model (allele 2 vs allele 1; OR = 2.00, 95% CI: 1.10–3.62, p = 0.022). These results support the hypothesis that the IL12B allele 2 genotype may be predisposing, while 1 genotype might be protective factor for RA susceptibility. No association between the rs3212227 and RA risk was revealed under the same genetic models. Also, a combined two loci model was designed with a referent group - the individuals with the IL12Bpro 1.1 + IL12B UTR AA genotype. We found that the combination of IL12Bpro 1.1 with IL12B 3’ UTR AA genotype is protective factor for RA susceptibility, whereas the carriage of IL12Bpro allele 2 despite hetero- or homozgyosity simultaneously with IL12B 3’ UTR AC/CC genotypes increase the RA risk more than 3-fold. The highest risk for RA susceptibility was established in the carriers of IL12Bpro 1.1 + IL12B 3’ UTR AA genotype. We found that the combination of both loci was significantly associated with a higher production of both IL-12p40 and IL-23 in RA cases, whereas the lowest serum levels were seen in CC genotype carriers. Also, the rs17860508 2.2 genotype, identified as a risk for RA, was associated with a higher serum levels of IL-23 in all patients. Notably, the highest circulating IL-23 levels were observed in carriers of the rs3212227 AA genotype and rs17860508 2.2 genotype compared to the remaining genotypes.

**Conclusion:** IL12Bpro (rs17860508) and 3’ UTR (rs17860508) polymorphisms do confer susceptibility to RA either as an individual or combinatorial effect and might influence the RA occurrence through regulating the expression of the IL-12/IL-23 p40 and production of IL-23.

**CLINICAL AND GENETIC FEATURES OF NON-BACTERIAL OSTEOEMLYTIS IN RUSSIAN FEDERATION**

Mikhail Koskina1, Maria Makhova2, Evgeny Supsatini1,2, Anna Skolenko2,3, Vyacheslav Zern1, Eugenia Iaspova1, Shamil Magomedov1,2, Irena Koskina2, Hiroshi Takayanagi3, Alexander Mushkin1,4, Evgeny Imyanitov1,2.

1Republican Children’s Clinic Hospital, Makhachkala, Russian Federation; 2Dagestan State Medical Academy, Makhachkala, Russian Federation; 3Children’s Rehabilitation Center “Detabye Duru”, Saint-Petersburg, Russian Federation; 4The University of Tokyo, Tokyo, Japan

**Background:** Chronic non-bacterial osteoelmytitis (CNO) is Data about incidence, prevalence and clinical and genetic features of chronic non-bacterial osteomyelitis (CNO) in Russia is scarce.

**Objectives:** The aim of our study was to evaluate clinical and genetic peculiarities of CNO in Russia.

**Methods:** The diagnosis of CNO was made with criteria, proposed by Jansson [1, 2], after the exclusion of other cause of bone disease. Our cohort consists of three main subtypes: i) early-onset (<5 years) CNO (n=22); ii) CNO, associated with RA (n=20) and iii) not associated (n=59) with rheumatic diseases (RD). Targeted next generation sequencing (NGS) analysis of 302 genes related to primary immune deficiency syndromes and autoinflammatory syndromes was performed.

**Results:** We selected a subgroup of the CNO patients having the following features: 1) early disease onset (<5 years); 2) all children were initially diagnosed as having tuberculosis (TB) due to bone morphology findings (granulomatous, e.g. tuberculosis-like inflammation), but had negative TB culture test; 3) initial treatment with combination of 3-4 anti-MBT drugs during 1-2 years was ineffective, and the patient continued to develop new inflammatory bone foci; 4) patients had very severe clinical (fever and symmetric arthritis) and radiological signs of disease; 5) all patients were from areas with traditionally high prevalence of consanguinity (table).

In the subgroup patients with early onset we performed genetic tests. Rare variants of PI3K genes were detected in 7/22 (32%) patients. Mutations affecting the genes previously associated with CNO were found only in two patients: one of them carried heterozygous variant IL1RN c.170G>T (p.C57F) and another had IL1RN c.517T>C (p.V171A). No mutation of LPN2 was revealed. Other detected variants included one pathogenic MEVF p.M69IV mutation in heterozygous state and number of VUS in CD40LG, NLRP12, CR2, NLRP3, IL12B, PLCG2, SH3BP2, CARD14, IRF8, CASP10 and NFKB1A genes.

Conclusion: We have found the unique regional subtype of CNO with early-onset in North Caucasian region with at least 10 times higher prevalence. We have not yet seen similar patients in other nationalities of Russia. Mutations in known genes were detected only in a minor fraction of CNO patients from Dagestan and Chechnya. This work supported by the Russian Foundation for Basic Research (grant No 18-515-57001) and by Japan Medical Research Foundation (grant No 18mr001).

IDENTIFICATION OF A NOVEL POLYMORPHISM OF ERAP1 IN A GROUP OF ITALIAN PATIENTS WITH BEHÇET SYNDROME
Nancy Lascaro1, Pietro Leccese1, Salvatore D’Angelo1,2, Teresa Carbone1, Angela Padula1, Giuseppe Martelli1,2, Maria Carmela Padula1,2,3
1Rheumatology Institute of Lucania (IRel), San Carlo Hospital, Potenza, Italy; 2Basilicata Research Biomedical (BRB) Foundation, Matera, Italy; 3University of Basilicata, Department of Science, Potenza, Italy

Background: The endoplasmic reticulum aminopeptidase protein 1 gene (ERAP1) was associated to several human diseases, including Behçet syndrome (BS), a multisystemic disorder with unknown etiology. ERAP1 protein is involved in immune response and its role can be influenced by gene single nucleotide variations (SNVs) with an unclear mechanism [1-5].

Objectives: We aim to genotype ERAP1 whole structure searching for SNVs, in 50 consecutive BS patients and 50 sex and ethnically-matched healthy controls (HC) unrelated to each others and to BS patients.

Methods: We used forensic bioinformatics and molecular methodologies. Specific primers for the coverage of all ERAP1 regions were designed using the NCBI Primer Blast tool. Genomic DNA was extracted from whole blood and amplified using in vitro PCR. Good-quality PCR amplicons were directly sequenced using the Mutation Surveyor software and NCBI-Blast Nucleotide on line similarity search tool.

SNV functional impact was predicted using on line PolyPhen-2 [6], while the 3D protein prediction was obtained using 3D Protein server [7].

Results: Our study was performed recruiting an explorative cohort of BS patients from Southern Italy, a population characterized by low disease prevalence. We found a SNV not previously reported in literature in a relatively small group of Italian BS patients. Our data need to be tested in a larger case-control study. In particular, the link between our SNV and the protein stability is to be validated in future functional studies.

AB0010
THE ASSOCIATION OF THE LTA AND PTPN22 GENES POLYMORPHIC VARIANTS WITH THE REDUCED IMMUNOGLOBULIN A LEVEL IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS
Liliia Nazarova1, Ksenia Dariiko1, Viktor Malievsky1, Tatiana Viktorova1,2, 1Bashkir State Medical University, Ufa, Russian Federation; 2Institute of Biochemistry and Genetics, Ufa, Russian Federation

Background: Data from a number of studies indicate the presence of a genetic predisposition to the level of immunoglobulins [1]. The aberration in the distribution of serum immunoglobulin A (IgA) concentrations was previously shown in patients with juvenile idiopathic arthritis (JIA) [2].

Objectives: The goal of the study was to determine whether the LTA rs909253 and PTPN22 rs2476601 polymorphic loci variants are associated with the reduced IgA level in JIA patients.

Methods: The study included 234 JIA patients (154 girls and 80 boys) from the Republic of Bashkortostan, Russia. IgA levels were measured in serum by the radial immunodiffusion method and considered reduced when they were less than the lower limit of established age-dependent reference intervals. Genotyping was performed by the real-time PCR method, and statistical processing of the results – using the two-tailed Fisher exact test (p) and the odds ratio (OR) with a 95% confidence interval (CI).

Results: Reduced IgA levels were detected in 10.68% of patients with JIA (n=25), and the majority of them were girls (n=21). There were only four boys with the reduced IgA level, and therefore the isolated analysis was not carried out for them.

The analysis of the LTA rs909253 polymorphic locus in the general JIA group, as well as in girls with JIA, showed that, in the presence of the reduced IgA level, the heterozygous genotype LTA rs909253*AG was significantly less common than in the absence of this IgA level abnormality (the general JIA group: 48.33%, p=0.010, OR=0.286, 95% CI 0.101-0.843, respectively). When studying the PTPN22 rs2476601 polymorphic locus in the general JIA group, the risk markers for the formation of the reduced IgA level were not established (p>0.1). At the same time, it turned out that in girls with JIA with the reduced IgA level, the genotype PTPN22 rs2476601*GG was significantly more common, and the allele PTPN22 rs2476601*A was significantly less common than in girls with JIA with normal or elevated IgA levels (*GG: 95.24% vs. 73.68%, p=0.028, OR=7.143, 95% CI 1.162-76.405; A: 2.38% vs. 14.86%, p=0.025, OR=0.142, 95% CI 0.014-0.865, respectively).

Conclusion: As a result of the study, the association of the LTA rs909253 and PTPN22 rs2476601 polymorphic loci variants with the reduced IgA level in girls with JIA was established.

AB0011 CLINICAL CHARACTERISTICS AND GENETIC EXPRESSION IN A COHORT OF PATIENTS WITH FAMILY MEDITERRANEAN FEVER

MENDEZ LARA, Isabel Madroñal García, Clara Aguilera Cros, Ricardo Juan Gil Velez, Maria Dolores Ar cola Duran, HOSPITAL UNIVERSITARIO VIRGEN DEL ROCIO, SEVILLE, Spain

Background: Familial Mediterranean fever (FMF) is the most frequent monogenic periodic fever syndrome and is characterized by recurrent episodes of fever, serositis, arthritis, dermal manifestations and long-term renal complications (arthritis is the most important complication). The genetic mutation of the disease is found in the MEFV gene located on the short arm of chromosome 16 and is inherited in an autosomal recessive manner. It affects the populations of the Mediterranean basin and is diagnosed according to the clinical evaluation.

Objectives: To describe the clinical characteristics of a cohort of patients with FMF and to study the different genetic mutations located in the MEFV gene.

Methods: Retrospective descriptive study of patients treated in our Hospital (2008-2018), with FMF diagnosis and MEFV gene mutation. The data was obtained through the review of medical records.

Results: We included 52 patients (29 men), mean age 41 ± 13 years. The following results have been identified in alleles of the MEFV gene: Non-pathogenic in 34 patients (65%) (p 202Q 73%, p148Q 17%, p. 319K 6% and p339F 3%). Pathogenic in 18 patients (34%) (pr 202Q 22%, eg 148Q 27%, pr 653H 5%, pm 694V 16%, pf 195T 5%).

In 17% of the patients family history was documented. Elevation of acute phase reactants in 41 patients (79%) (C Reactive Protein 75%, Globular sedimentation rate 65%), Echocardiography was performed in 14 patients, with diagnosis of pericardial effusion in 6 of them. Two patients develop renal amyloidosis, one of them (homozgyous for the mutation 148Q) died due to this complication.

54% of patients use colchicine as initial treatment, achieving 50% good response with control of symptoms. 19% undergo treatment with glucocorticoids in 25% of the patients.

Conclusion: The genetic study confirms the diagnosis of FMF, allowing it to be differentiated from other SAs. It also has prognostic value, depending on the mutation detected and if it affects one or both alleles. In our series, the most prevalent symptoms in patients with pathogenic mutations were fever, abdominal pain and arthromyalgia.

Disclosure of Interests: None declared

AB0012 GENETIC EXPRESSION AND CLINICAL MANIFESTATIONS IN A COHORT OF PATIENTS WITH AUTOINFLAMMATORY SYNDROME

Mendez L1, Clara Aguilera Cros1, Ricardo Juan Gil Velez2, Noemi Patricia Garrido Puñal1, Isabel Madroñal García1, Maria Dolores Arcola Duran1, Alberto Ruiz Román1, Marco Montes Caro2, Hospital universitario virgen del rocío, rheumatology, seville, Spain; Hospital Universitario Virgen Del Rocío, Immunology, Seville, Spain

Background: The autoinflammatory syndromes (SAI) encompass a set of diseases in which there is an alteration of the innate immune response, contrary to what occurs in autoimmune diseases, in which the origin is due to pathological changes in the adaptive immune response. These diseases have common symptoms such as fever, skin, joint and lung involvement, among others, so they can be difficult to diagnose and classify.

Objectives: To study the clinical and genetic characteristics of a cohort of patients with autoinflammatory syndromes (SAI).

Methods: Retrospective descriptive study of patients with SAI diagnosed in adulthood. The data was obtained through the review of medical records.

We have included data from patients who present a positive genetic study, both for described and pathogenic mutations, as well as nonpathogenic mutations, but which present a clinical picture according to this pathology.

Results: We included 80 patients (52 men), mean age 41 ± 13 years. Fourteen patients (17.5%) presented family history. Summary of diagnoses (TABLE 1) and associated mutations by order of frequency (TABLE 2).

Disclosure of Interests: None declared

AB0013 GENOMIC PROFILING OF INFLAMMATION-RELATED GENES IN NEURO-BEHÇET SYNDROME: A PRELIMINARY ITALIAN STUDY

Maria Carmela Padula1,2, Pietro Lecce2, Nancy Lascio1, Teresa Carbone1, Antonina Rita Limongi2, Rosa Paola Radice2, Angela Padula1, Salvatore D’angelo1, Giuseppe Martelli2, 1Rheumatology Institute of Lucania (IReL), San Carlo Hospital, Potenza, Italy; 2University of Basilicata, Department of Science, Potenza, Italy

Background: Behçet Syndrome (BS) is a chronic vasculitis characterized by a wide spectrum of clinical manifestations, including the rare nervous system

The most frequent clinical manifestations: Articulargias 77.5%, followed by high fever (> 39) 73.8%, myalgias 72.5%, abdominal pain 56.3%, exanthema 47.5%, arthritis 35%, pericarditis 28.8%, headache 21.3%, pharyngitis 21.3% and canker sores 20%. The onset of the picture was a fever in 59 patients (73.8%) accompanied by cutaneous manifestations in 51.2% of the cases, with the rest of the symptoms being variable depending on the study.

The most affected joints were: Metacarpophalangeal in 18 patients (22.8%), ankles in 15 patients (18.8%), proximal interphalangeal in 8 patients (10%), hips in 2 patients (2.5%) and knees in 2 patients (2.5%).

Elevated acute phase reactants were found in 53 patients (66.8%), with high sedimentation velocity in 56.3% and C reactive protein in 63.3%.

The initial treatment was based on colchicine in 45 of the cases, needing to add corticosteroids in 25% of the patients. 10.1% required drugs modifying the disease, being the most frequent methotrexate (74.25%).

Sixteen patients (20%) required biological therapy, being the most used anakinra (12.5%), followed by etanercept (12.5%) and canakinumab (2.5%).

In the period of time analyzed, 3 patients died due to causes unrelated to the SIA.

Conclusion: The results obtained are consistent with what exists in the medical literature. The most frequent SAI in our center is the family Mediterranean fever, followed by the TRAPS. The most frequent mutation was the MEFV (P.R202Q), followed by the MEFV (p.E148Q).

- With our study we want to reflect the variety of symptoms presented by patients with SAI diagnosed in adulthood. Despite the great variability, the most frequent symptoms are arthralgia, fever greater than 39 °C and myalgias.
- The most used treatment in this type of patients is colchicine and respond to this positively in most cases.
inflammation-related genes.

Methods: NBS patients were extracted from our database and retrospectively studied. Molecular characterization was performed for a subset of 20 NBS patients and 42 sex-matched healthy controls (HC) via: a) bioinformatics consulta-
tion for SNPs selection and primer design; b) SNPs genotyping: DNA extraction, PCR amplification, direct sequencing; c) DNA variant analysis using similarity search tool and specific software. In a second phase of analysis, a group of 30 BS patients without neurological involvement (no-NBS) was also genotyped. The results of this study were used to calculate the strength of BS association for each genotype.

Results: NBS patients subset was formed by 14 males and 6 females with mean age equal to 44.20 (±10.73) years. Six SNPs were considered eligible for molecular analysis and genotyped. Our results underlined the major role of age in the BS disease process. The results of this study were used to calculate the strength of BS association for each genotype.

Conclusions: The findings of this study support the association of SNPs in the MIR146a with BS, and the use of bioinformatics tools for SNP selection and primer design. These findings could be useful for future studies on the genetic basis of BS and its subtypes.

A MIR146A POLYMORPHISM IS ASSOCIATED WITH ANTI-CARBOXYLATED PROTEIN ANTIBODIES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Carlo Perricone1, Cinzia Cicciocci2, Fulvia Coccoc3, Ilaria Lecce4, Giuseppe Mottola1, Sara Ruft1, Cristina Alessandri1, Francesca Spinelli1, Cristina Politi1, Andrea Latino1, Giuseppe Novelli5, Guido Valesini1, Paola Bongianni2, Fabrizio Comi1, Sapienza University of Rome, Department of Internal Medicine, Rome, Italy, University of Rome "Tor Vergata", Department of Biomedicine and Prevention, Section of Genetics, School of Medicine, Rome, Italy

Background: (SLE) is a chronic autoimmune disease with a complex pathogenesis in which genes and environmental factors interact leading to a protein clinical picture. Joint involvement is one of the most common manifestations in SLE patients, with a prevalence ranging from 69 to 95%. This feature significantly influences the patients’ quality of life, possibly leading to disability and impaired functional performance in daily activities. Identification of prognostic biomarkers, able to identify patients at risk to develop this more aggressive phenotype, is mandatory. Autoantibodies associated with inflammatory arthritis, such as Rheumatoid Arthritis (RA), have been shown to play a role also in SLE arthritis. For instance, ACPA can be found in approximately 16% of SLE patients and, recently, it was demonstrated that anti-carbamylated proteins antibodies (anti-CarP) can be identified in up to 28.3% of SLE patients (1).

Objectives: Thus, our aim was to analyze previously identified loci associated with SLE in a cohort of SLE patients to evaluate their influence on autoantibody production.

Methods: We recruited 52 Italian SLE patients. A panel of 34 SNPs in 19 genes involved in immune response, autophagy and inflammation, was selected. SNPs genotyping was performed by allelic discrimination assay by TaqMan assays (Applied Biosystems, Foster City, CA, USA) and ABI PRISM 7000. The main clinical/laboratory features (including injury index and disease activity) were collected on an electronic platform. The presence of Rheumatoid Factor (RF), ACPA, and anti-CarP antibodies was investigated. All autoantibody assays were done in duplicate, commercial enzyme-linked immunosorbent assay (ELISA) kits were used and the results were evaluated according to the manufacturers’ instructions. Detailed methods are described in (1).

Results: Clinical and demographic data of patients are described in table 1. The variant allele of rs2910164 (MIR146a) (P=0.03) was significantly associated with presence of anti-CarP antibodies in SLE. Specifically, patients carrying the C allele of MIR146a were more likely to have anti-CarP antibodies (P=0.01, OR 5.018, 95% CI 1.414-17.811). Among the clinical and laboratory features, the same polymorphism was associated with presence of arthritis in clinical history (P=0.02), and with anti-dsDNA positivity (P=0.025). In a multilocus logistic regression analysis, MIR146A was independently associated with anti-CarP (P=0.017, Exp(B)=5.433, 95%CI 1.345-21.944).

Conclusion: Carbamylatin is a non-enzymatic process consisting in the addition of a cyanate group on self-proteins determining a modification in the tertiary structure. This change causes the generation of new epitopes and the consequent production of autoantibodies. This study supports that anti-CarP production is genetically driven. Indeed, MIR146a expression is altered in SLE and has been linked with autoantibody production in lupus-prone mice models. Probably, the higher IFNα levels observed in patients carrying the C allele can be responsible for such higher autoantibody production.

microrna-155 expression in behçet’s disease

nadeen saad3,3,3.

Furthermore, aberrant expression of miR-155 has been reported in human autoimmunity in germinal centers, and greatly affects antibodies and cytokines production. The deletion of miRNA-155 impairs T and B cell differentiation in germinal centers, and greatly affects antibodies and cytokines production. Recent miRNA deletion studies have revealed a central role in the regulation of gene expression in a variety of manners, including translational repression, or more messenger RNA (mRNA) molecules, and their main function is to downregulate gene expression in a variety of manners, including translational repression, miRNA cleavage, and deadenylation. Recent miRNA deletion studies have revealed a central role in the regulation of the immune response. The deletion of miR-155 impairs T and B cell differentiation in germinal centers, and greatly affects antibodies and cytokines production. Furthermore, aberrant expression of miR-155 has been reported in human autoimmune disorders such as rheumatoid arthritis and systemic lupus erythematosus.[1] Whether miR-155 plays a role in the pathogenesis of Behçet’s Disease is not yet known and is therefore the subject of this study.

Objectives: The aim of this work is to study the expression of microRNA-155 as a molecular biomarker in Behçet’s disease.

Methods: Thirty patients with Behçet’s disease and 15 healthy matched controls were included. Patients fulfilled the International Study Group (ISG) diagnostic Criteria of Behçet’s Disease. Exclusion Criteria included other types of primary or secondary vasculitis; reactive arthritis; inflammatory bowel disease; current or past history of cancer, chemotherapy or radiotherapy; current infection; long standing diabetes mellitus; and hypertension. Total RNA, including miRNAs isolation, from peripheral blood mononuclear cells (PBMCs) was extracted by using miRNeasy Mini Kit (QIAGEN, cat. no. 217004). This was followed by reverse transcription into complementary DNA (cDNA). Expression of microRNA-155 was carried out using quantitative real time polymerase chain reaction (RQ_PCR). Relative expression of microRNA155 was calculated using 2−ΔΔct formula. Where ct (ct miRNA− ct miRNA control) and Ct is the fractional cycle number at which the fluorescence passes the fixed threshold.

Results: Our results showed a significantly decreased expression of miR-155 in peripheral blood mononuclear cells (PBMCs) of Behçet’s disease patients with active disease compared to that in patients with inactive disease as well as healthy control (p=0.026).

The level of miR-155 showed a significant positive correlation with patients’ age (p=0.042), and significant negative correlation with BDCAF activity score of the disease (p=0.034), and platelets count (p=0.011) (Table1).

Conclusion: Downregulation of miR-155 expression in active BD patients may be used as a molecular biomarker for increasing activity and severity of Behçet’s disease. This pathway could be a potential target for a new therapeutic strategy.

AB0016 combined genome-wide association and gene-expression meta-analysis identifies novel psoriasis genes

mohammad saeed, immunoCure, karachi, pakistan

Background: Psoriasis (Ps) is a common, inflammatory disorder affecting skin, joints and associated connective tissue, with significant genetic underpinnings. Multiple genome-wide association studies (GWAS) have been conducted with identification of several Ps loci. However, these only explain about a third of Ps genetic risk indicating that additional loci of modest effect remain to be discovered (1).

Objectives: Identify novel psoriasis genes that have functional consequences for psoriasis by altered gene expression

Methods: Association clustering methods such as gene- and locus-based tests are more powerful than single variant analysis for identifying modest genetic effects (2, 3). Here, a dbGAP GWAS dataset (4) for Ps (pha002855: 1348 Ps cases and 1368 controls, genotyped for 448K SNPs) was analyzed using the locus-based algorithm, OASIS (3), to identify 13 highly significant loci other than the HLA-C locus. In these loci 50 genes were identified using SNIPPER, which were then subjected to gene expression analysis in three Ps GEO datasets. Results: This genetic and functional analysis identified a total of 18 genes that were significantly associated and had altered expression in psoriasis skin. The most significant of these were two genes that were two-fold upregulated in Ps, IL12B (P=3x10−11) and TFCGB3 (P=3x10−12) and two genes that were repressed
Comparative analysis of the altered peripheral replicative study of GWAS-associated transcriptomic characterization of single

**Methods:**

To compare the expression levels of miR-146a and miR-155 in the whole PB of SLE samples showed a possibility for the local pathological process and thus to differentiate patients from HCs. The expression of both miRNAs in whole PB of SLE patients with OA were over-expressed in 25 (62.5%) and levels of miR-155 were increased in 20 (50.0%) of the patients (p<0.05).

**Conclusion:** Although miR-146a and miR-155 are involved in key signaling pathways in the pathogenesis of RA their whole PB expression could not fully reflect the local pathological process and thus to differentiate patients from HCs. The expression of both miRNAs in whole PB of SLE samples showed a possibility for discriminating patients from HCs. Further analysis with larger sets is needed to confirm if altered systemic miRNA expression levels could be used in the clinical practice as disease biomarkers.

**AB0018**

**TRANSCRIPTOMIC CHARACTERIZATION OF SINGLE PATHOGENIC MEMORY B CELLS IN RHEUMATOID ARTHRITIS**

**Background:** Autoantigen-specific B lymphocytes are crucial players in the development of rheumatoid arthritis (RA). Despite the fact that ACPA+ autoreactive memory B cells have been observed in the majority of RA patients for a long time, their properties still remain enigmatic.

**Objectives:** In this study, we aimed to reveal transcriptomic nature of single pathogenic memory B cells from RA patients.

**Results:** Single-cell full-length RNAseq data was generated from ACPA+ and control memory B cells from 7 human donors with established rheumatoid arthritis and subjected to transcriptome analyses as well as B cell receptor (BCR) assembly.

**Conclusions:** Transcriptome and BCR data was successfully generated from the majority of the sequenced cells. The success rate depended on chosen sequencing parameters as well as on a BCR assembling algorithm that was used. We observed expression of genes defining memory B cell population in our data as well as pathways crucial for their function.

**REPLICATIVE STUDY OF GWAS-ASSOCIATED CANDIDATE GENE LOCI IN PATIENTS WITH OSTEOARTHRITIS FROM THE BASHKORTOSTAN REPUBLIC**

Anton Tyurin, Daria Shapovalova, Luitza Lukmanova, Rashit Davletshin, Rita Khusanova, 1Bashkir State Medical University, Ufa, Russian Federation; 2Institute of Biochemistry and Genetics, Ufa Scientific Center, Ufa, Russian Federation

**Background:** Osteoarthritis (OA) is one of the most common joint diseases and a global socially significant problem. Currently, new methods of early diagnosis of the disease are being developed, before the development of destructive processes in various tissues of the joint. The leading role in determining the pathophysiology of OA is given to the identification of genetic and epigenetic mechanisms.

**Objectives:** The main goal of the study was replicative analysis of the associations of loci associated with OA according to data on genome-wide analysis of associations (GWAS) located near the DOTT1L, ALDH1A, GNL3, GLTB8D1, ASTN2, FILIP1, SENP6, NCOA3, DWA, CHA11 genes with various localization of OA.

**Methods:** DNA samples from 410 women were used (mean age 45.45 ± 2.35). Patients with OA was carried out in accordance with the criteria of the American College of Rheumatology (1990), the debut of the disease before the age of 55 years and radiographic confirmation. For genotyping, PCR–RFLP analysis using KASPR technology was used. As a calculation tool, MS Office Excel 2007 (Microsoft), Statistica v.6.2 (StatSoft), SPSS v.13 (SPSS Inc) software packages are used.

**Results:** We conducted replicative analysis of the 12 loci that were the most significantly associated with OA in the results of GWAS study, among which rs12887244 and rs2302601 (DOTT1L), rs4836732 (ASTN2), rs9305591 (FILIP1 &

**Disclosure of Interests:** The study was supported by Grant 60/2013 and Grant 51/ 2014 and funded by Medical University-Sofia.

**COMPARISON BETWEEN THE ALTERED PERIPHERAL BLOOD miRNA EXPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS**

Pavlina Shumateva, Darina Chakalakova, Radka Kanavova, Zlatimir Kolarov, Simeon Morov.

**Background:** MicroRNAs (miRNAs) are a class of small, non-coding RNAs that negatively regulate gene expression at posttranscriptional level. Altered miRNA expression in the circulation has been described in inflammatory joint diseases such as rheumatoid arthritis (RA) as well as in systemic rheumatic diseases, such as systemic lupus erythematosus (SLE). miR-146a and miR-155 have been found to regulate key signaling pathways involved in the pathogenesis of RA and SLE [1-2].

**Objectives:** To compare the expression levels of miR-146a and miR-155 in peripheral blood (PB) from RA and SLE patients in regard to their use as disease biomarkers.

**Methods:** 63 RA patients and 40 SLE were included in the study. The expression levels of miR-146a and miR-155 in whole PB were determined by qPCR (Sybr-Green technology) and compared to healthy controls (HCs). Relative changes of gene expression levels of the studied miRNAs were calculated by 2−ΔΔCT method. SPSS was used for statistical analysis.

**Results:** 29 (46.03%) of the RA patients showed overexpression of miR-146a in the PB when compared to HCs, but the levels were not statistically significant to differentiate patients from HCs (p=0.365). 34 (53.97%) of the RA patients did not show a statistically significant expression of miR-155 in the PB when compared to HCs and PB expression of miR-155 couldn’t be used for differentiating RA from HCs (p=0.074). In the group of SLE patients the PB levels of miR-146a were over-expressed in 25 (62.5%) and levels of miR-155 were increased in 20 (50.0%) of the patients (p<0.05).

**Conclusion:** This combined genetic and functional meta-analysis elucidated novel genes, functional networks and pathways for psoriasis. These results will lead to important insights into the immunopathogenesis and treatment of psoriasis.

**Objectives:** The main goal of the study was replicative analysis of the associations of loci associated with OA according to data on genome-wide analysis of associations (GWAS) located near the DOTT1L, ALDH1A, GNL3, GLTB8D1, ASTN2, FILIP1, SENP6, NCOA3, DWA, CHA11 genes with various localization of OA.

**Methods:** DNA samples from 410 women were used (mean age 45.45 ± 2.35). Patients with OA was carried out in accordance with the criteria of the American College of Rheumatology (1995), the debut of the disease before the age of 55 years and radiographic confirmation. For genotyping, PCR–RFLP analysis using KASPR technology was used. As a calculation tool, MS Office Excel 2007 (Microsoft), Statistica v.6.2 (StatSoft), SPSS v.13 (SPSS Inc) software packages are used.

**Results:** We conducted replicative analysis of the 12 loci that were the most significantly associated with OA in the results of GWAS study, among which rs12887244 and rs2302601 (DOTT1L), rs4836732 (ASTN2), rs9305591 (FILIP1 &

**Disclosure of Interests:** The study was supported by Grant 60/2013 and Grant 51/ 2014 and funded by Medical University-Sofia.

Conclusion: SNP based heritability estimates suggest greater heritability for PsC as compared to PsA. Common environmental factors may need to be considered to account for the strong recurrence rate of PsA over psoriasis among first degree relatives reported in previous epidemiological studies, as this finding is not noted from large SNP based association studies.

Adaptive immunity (T cells and B cells) in rheumatic diseases

**AB0021 IMMUNOGENICITY OF TNF ALPHA ANTAGONISTS IN RHEUMATIC INFLAMMATORY DISEASES: IMPACT ON CLINICAL RESPONSE**

Selma Bouden1, Lisa Laaadhir2, Imen Ayadi3, Mariam Sallemi1, Rabha hospital, tunis, Tunisia; 2rabha hospital, tunis, Tunisia

**Background:** One of the mechanisms implicated in the loss of response to TNF alpha antagonists in rheumatic inflammatory diseases is the formation of antibodies against these drugs (anti-drug antibodies: ADAb).

**Objectives:** The objective of our study was to determine the incidence of ADAb anti Infliximab (IFX) and anti Adalimumab (ADA) and to evaluate the therapeutic impact of the presence of ADAb, the rate of ADAbr and trough serum concentration of the drug at the time of sampling and six months later.

**Methods:** A cross-sectional study was conducted including patients with rheumatoid arthritis (RA) or spondyloarthritides (SpA) treated with IFX or ADA as a first biotherapy for at least six months. ADAb and trough levels were measured. The evaluation of the therapeutic response was made at the time of sampling and six months later.

**Results:** Fifty patients were included (17 RA and 33 SpA). ADAb were positive in 39% of SpA and 35% of RA. They were positive in 40% of cases for IFX and 25% for ADA. The presence of ADAb was negatively related to the trough levels of IFX and ADA during RA (p=0.01 and p<0.0001) and SpA (p=0.01) and p<0.0001). For the two pathologies, no impact of the presence of ADAb, the rate of ADAbr or the trough levels was noted on the therapeutic response at the time of sampling. However, the presence of ADAb was related to a higher activity of SpA six months after the sampling (p=0.05). Factors that were related to ADAb formation were a high BMI in RA (p=0.05) and a longer duration of evolution of RA (p=0.03).

**Conclusion:** The presence of ADAb and low trough levels seem to not affect the therapeutic response in patients on TNF alpha antagonists. Other tracks than immunogenicity should be investigated to explain the loss of response to these biotherapies.

**AB0022 STUDY OF FUNCTIONAL ORIENTATION OF B CELLS IN PHYSIOLOGY AND SJOEGREN’S SYNDROME**

Marina Boujbel1, Alexis Grasseau1, Nedra Chehr1, Dini Coreno1,2, Jacques-Olivier Perret1, Sophie Hilton1, Laetitia Le Patouër1,2, Unibrest, Inserm, UMR1227, Lymphocytes B et Autoimmune, Brest, France; 2Unibrest, Brest, France

**Background:** Sjögren’s syndrome (SS) is a chronic systemic autoimmune disease, characterized by mouth and eye dryness, due to irreversible destruction of glandular tissue by infiltrated lymphocytes. It is now well established that B cells play a key role in the physiopathology of SS. Indeed, B cells exhibit various signs of activation and produce excessive amounts of pro-inflammatory cytokines and immunoglobulins (Ig), especially IgG type-antibodies (Abs) (Kroese et al.2014). Currently, it is suggested that the interleukin (IL)-21 (Wang et al., 2018) and immunoglobulins (Ig), especially IgG type-antibodies (Abs) (Kroese et al.,2014). Currently, it is suggested that the interleukin (IL)-21 (Wang et al., 2018) promote the generation of autoreactive IgG-producing B cells. Moreover, this will also enable a further understanding of the impact of ADAb, the rate of ADAbr and trough serum concentration of the drug at the time of sampling and six months later. Conclusions: First results on HC suggest that switched memory B cells differentiate into IgG and IgA-secreting plasmablasts (PB), when stimulated in a TI manner. Moreover, this will also enable a further understanding of the heterogeneity of the distinct effector B cells and their involvement in SS pathogenesis.

**AB0023 IMPACT OF METABOLIC CHANGES DURING AGING ON HUMAN EX VIVO NAIVE AND MEMORY CD4+ T CELL FUNCTION**

Yuling Chen1,2, Peit Leöwer2, Hao Wu2, Frank Buttgerl2, Timo Gaber1,2,1Châtel – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2German Rheumatism Research Centre (DRFZ) Berlin, a Leibniz Institute, Berlin, Germany; 1Châtel – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany

**Background:** Age-related dysfunction in immune cells (immuno-senescence), such as T cell dysfunction, may contribute to the development of rheumatoid arthritis (RA). The aged people, senescent T cells tend to produce low amounts of pro-inflammatory cytokines leading to low-grade inflammation. However, cellular metabolism modulates effector functions such as cytokine production and proliferation in T cells by providing energy and building blocks. Metabolically, naïve and memory CD4+ T cells are relatively quiescent immune cells. Currently, the metabolic phenotype of naïve and memory CD4+ T cells and how metabolism affects functions of naïve and memory CD4+ T cells in aged people are not well understood.

**Objectives:** Therefore, we analysed the differences in the metabolic phenotype of peripheral naïve and memory CD4+ T cells in young and aged healthy donors to explore fundamental processes of immune-aging in the pathogenesis of RA.

**Methods:** Naïve and memory CD4+ T cells were isolated from PBMCs of young donors (18-35 years) and old donors (>50 years) by using MACS® technology. Purification of isolated cell fractions was assessed by flow cytometry. Ex vivo naïve and memory CD4+ T cells were analysed by Seahorse® Technology to determine proton efflux rate (PER) as a measure of glycolysis (glycPER) and oxygen consumption rate (OCR) as a measure of mitochondrial respiration (mitoOCR). Cyto- kine expression and secretion were measured by flow cytometry and multiplex array. Finally, TCR-stimulated memory CD4+ T cell proliferation was determined using CSFE and Ki-67 after 3 and 4 days by flow cytometry.

**Results:** We included 9 young (20-32 years, 25.0±3.4 years) and 9 aged gender-matched donors (52-67 years, 57.8±5.7 years) for PER and OCR measurement. Memory CD4+ T cells demonstrated higher basal glycolysis, compensatory glycolysis as well as basal OCR and spare respiratory capacity than naïve CD4+ T cells. Memory CD4+ T cells from young donors had higher basal glycolysis, and compensatory glycolysis than aged donors, but lower ratio of basal mitoOCR/glycPER. Although we did not observe differences in intercellular cytokine expression measured by flow cytometry after 5h stimulation of memory CD4+ T cells, we determined a significant higher amount of secreted IL-6, IL-9, IP-10, monocyte chemotactic and activating factor in the supernatant of memory CD4+ T cells from young donors as compared to those from young donors. Cell division index, proliferation index, percentage of divided cell, and Ki-67 expression after 3 and 4 days of stimulation showed no statistical differences between both groups.

**Conclusion:** Here, we demonstrate a higher basal glycolysis, basal OCR, mitochondrial and glycolytic capacity of human ex vivo memory CD4+ T cells as compared to naïve T cells. A decrease of basal glycolysis, compensatory glycolysis in memory CD4+ T cells of aged people which results in an enhanced cytokine expression can be assumed to culminate in T cell dysfunction leading to the development of RA during aging.

WHOLE BLOOD ENDOGENOUS RETROELEMENT ACTIVITY ASSOCIATES WITH ANTI-CCP TITRES IN EARLY DRUG NAÏVE RA AND IS PREFERENTIALLY INCREASED IN CD5- AND NAÏVE B CELLS

Faye Cooles1,2, Gemma Vidal Pedrera1,2, Amy Anderson1,2, Najib Naamane1,2, Andrew Skelton1, Arthur Pratt1,2, Catharien Hilken5, Ruchi Shukla3, John Isaacs3,2, 1Institute of Cellular Medicine, Newcastle University and National Institute for Health Research Newcastle Biomedical Research Centre at Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle upon Tyne, United Kingdom; 2Arthritis Research UK Rheumatoid Arthritis Pathogenesis Centre of Excellence (RACE), Newcastle upon Tyne, United Kingdom; 3Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom

Background: Endogenous retroelements of which LINE1, Alu and LTR are the main subsets, constitute approximately 50% of the human genome. They are mobile elements derived from the historical genomic integration of retroviruses. Whilst most are inactive, some expression of viral mRNA and subsequent protein is retained. This theoretically could promote immune activation, for example by triggering type I interferon (IFN-I) production and notably Alu has been identified as a target for R06 autoantibody. Retroelements may therefore provide a mechanism whereby tolerance is breached in autoimmune disease.

Objectives: To examine the potential clinical impact of retroelement activity in early drug naïve rheumatoid arthritis (eRA). This stage of disease was chosen to minimise therapeutic confounding.

Methods: Drug-naïve eRA and healthy controls (HC) were recruited and clinical characteristics including disease activity, immunoglobulins (IgA, IgG, IgM), ESR, CRP, rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) auto-antibody titres documented. Serum cytokines (IFN-γ, IL-6, IL-12 p70, TNF-α, IL-1β, IL-2, IL-13, IL-10) were also measured. Whole blood (WB) RNA was extracted and expression of an IFN-I gene signature (IGS: MXa, IFIH1, OAS1, ISG15, IFI44L) and LINE1 5’UTR activity quantified using RT-PCR. In addition anti-CCP and RF positive (double seropositive) eRA peripheral blood plasmacytoid dendritic cells (pDCs), myeloid DCs, CD19+ B cells, monocytes, CD4+ and CD8+ T cells were flow cytometrically sorted. CD19+ B cell subsets were further sorted from double seropositive eRA and disease controls (early, drug naïve, psoriatic arthritis, PsA) into CD5- B cells, age associated B cells (CD19+CD41+CD201), naïve (IgD’CD27’) and memory (IgD’CD27’) B cells. Cell specific expression of LINE1, Alu and LTR was quantified by NanoString nCounter and analysed using R Core Team (2013). WB RNA analysis for continuous and categorical variables included linear regression and Mann-Whitney U tests respectively (GraphPad Prism, significance p<0.05).

Results: WB LINE1 expression for 56 eRA patients (median age 58 [range 30-87], male/female 3:4, 77% seropositive for either RF or anti-CCP) and 23 HC (median age 39 [range 23-62], male/female 1:1) was obtained. WB LINE1 activity was not associated with age or gender and was comparable between cohorts. However in eRA a unique, robust positive association between WB LINE1 and anti-CCP titres was identified (see table and figure). Additionally, when comparing eRA circulating cell subsets, B cells had the highest expression of Alu, LINE1 and LTR (n=8, median age 56 [range 49-64], male/female 1:1). Furthermore, there was significantly increased expression of all retroelement classes in eRA CD5- and naïve B cells compared with PsA (n=4, male/female 1:1 and median age 62 for both with age range [63-78] and [60-80] respectively).

Conclusion: This is the first time peripheral blood retroelement activity has been examined in both HC and RA. It highlights intriguing, IFN-I independent, associations between anti-CCP titres, autoantibody producing B cells (CD5-) and retroelements. Whether such retroelements may play a more extensive role in autoantibody generation and may ultimately provide a novel target in the treatment or prevention of RA.

AB0025 ATYPICAL, ACTIVATED MEMORY B CELLS ARE EXPANDED IN THE SYNOVIAL FLUID OF PATIENTS WITH OLG0ARTHRITIS COMPARISON TO PERIPHERAL B CELLS

LARGE JOINT ARTHRITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS IS CHARACTERISED BY T CELL RATHER THAN B CELL ACUMULATION

Francesca Faustini, Natalie Sippl, Karine Chemin, Iva Gunnarsson, Vivianne Malmöström. Karolinska Institute, Karolinska University Hospital.
Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden

Background: Musculoskeletal involvement is a common clinical feature of systemic lupus erythematosus (SLE), that can present either at the onset or in later disease course. SLE related arthritis is usually non-erosive and non-deforming as opposed to rheumatoid arthritis (RA). While RA synovial pathologies has been extensively studied, little is known about the pathophysiology of arthritis in SLE.

Objectives: to explore the cellular compartments in synovial fluid of SLE patients with arthritic manifestations.

Methods: paired synovial fluid (SF) samples from large joint aspiration and peripheral blood samples (PBMC) obtained at the same time point from five SLE patients were analyzed by microlucor flow cytometry. The patients fulfilled the ACR 1982 classification criteria for SLE [1]. Clinical records were reviewed in order to exclude the presence of comorbidities such osteoarthritis or overlap with RA.

There were three different lineage-specific panels for B cells, T cells (cytotoxic and helper) were developed.

Results: The overall frequency of CD4+ and CD8+ T cells was similar across the SF and PBMC samples. Among the CD4+ T cells, those co-expressingCCR4 showed a much higher frequency in the SF compared to the peripheral blood in 4 out of 5 patients (mean percentage 8.9±7.0% vs 2±1.6%, p>ns). In addition, in 4 out of 5 patients we could identify an increased frequency of CD4+ expressing CCR4+, a marker for Th17 cells in SF as compared to PBMC (mean percentage 35±16.6% vs 12.7±8.9%, respectively, p>ns). In all patients, a higher frequency of EOMES+ Granzyme A + CD4+ T cells was observed in SF when compared to PBMC (9±2±5% vs 4.5±2.5%, p>0.03). Moreover, in all patients, we could observe a higher proportion of regulatory T cells (FOXP3+/CD25+) in the SF (21.5±15.4% vs 8.4±7.8%, p>ns). No relevant differences were observed in the Th1 compartment (CXCR3+), CD19+ cells (B-lymphocytes) were scarcely present in the SF of SLE patients as opposed to the peripheral blood.

Conclusion: Although SLE is usually considered to be a B cell driven disease, its cellular component seems largely to be a T cell driven disease, its cellular component seems largely to be a T cell driven disease.

ARE RHEUMATOID FACTORS AND ANTINUCLEAR ANTIBODIES ASSOCIATED WITH FRAILITY IN ELDERLY TUNISIAN POPULATION?

Soria Hammamy1, Ichkak Bernouri1, Inmen Ghallal2, Mourad Elghali3, Sakly Nabi2, Mohamed Hammami3,4.1. Université de Monastir, Internal Medicine, monastir, Tunisia; 2. University of Monastir, Immunology, Monastir, Tunisia; 3. University of Monastir, Biochemistry, Monastir, Tunisia; 4. University of Monastir, Immunology, Monastir, Tunisia.

Background: An emerging concept is the ‘frailty syndrome’, which may explain diversity in clinical outcomes in the elderly population.

Objectives: The aim of the study was to investigate the possible association between antinuclear autoantibodies, different isotypes of Rheumatoid Factor and frailty in aged individuals.

Methods: Using a validated set of frailty criteria (the SEGA tool), we conducted a cross sectional observational study to evaluate the prevalence of antinuclear antibodies (ANA) (assessed by IFI) and different isotypes of Rheumatoid Factor (RF) (determined by ELISA) in 89 Tunisian individuals aged at least 65 years living in the community. The study population were categorized into three groups: severely frail (n=29), frail (n=31), and non frail (n=29) according to the validated and widely utilized frailty criteria (SEGA tool).

Results: ANA were detected in 36 of the participants. No significant difference was observed between the three groups. Immunofluorescence patterns observed were speckled in 34%, homogeneous in 3.3%, and nucleolar in 3.3% of individuals. Nineteen of the severely frail patients had positive IgA RF compared to 11 from the frail group and 6 only from the non-frail group (p=0.02), RF isotypes showed low correlations with other features. Indeed, the IgG RF was correlated with the age (r= -0.22, p<0.03), the C-Reactive Protein level (r= -0.45, p<0.01), and the nutritional state of the patients assessed by the MNA score (r=0.27, p<0.009). The IgG RF was correlated with hemoglobin (r= 0.22, p<0.03) and creatinin (r= -0.36, p<0.01) levels.

Conclusion: Our study showed no significant difference in the frequency of ANA amongst nonfrail, frail, and frail aged individuals, whereas RF isotypes were found to be slightly correlated with several biological parameters and other features.

SELECTIVE DEPLETION OF PLASMA CELLS IN VIVO BASED ON SPECIFICITY OF SECRETED ANTIBODIES

Qingyu Cheng1,2, Andreas Petz1, Bimba F. Hoyer3, Laleh Khodadadi1,2, Tobias Alexander1,2, Gerd Rüdiger Burmester1, Andreas Radbruch1, Falk Hiepe1,2.

Background: Antibody-mediated diseases like allergies and chronic-inflammator y autoimmune diseases affect more than 10% of the human population, and for most, no cure is available. This is particularly true when pathogenic antibodies are secreted by long-lived plasma cells generated early in pathogenesis, which are refractory to conventional therapies. Therapeutic concepts for the generic ablation of plasma cells are currently being tested in clinical trials. These concepts target both plasma cells secreting pathogenic antibodies and those providing protective antibodies, i.e., humoral immunity. Efficient ablation of pathogenic plasma cells is inevitably accompanied by immunodeficiency and increased susceptibility to infection.

Objectives: We studied the use of an antigen-antibody conjugate to label plasma cell in vivo with the antigen and selectively ablate those secrete antibodies specific for the antigen.

Methods: Balb/c mice were immunized with ovalbumin (OVA) and chicken gamma globulin (CGG), which resulted in the generation of OVA and CGG-specific long-lived plasma cells in the bone marrow. These mice were treated by a single intraperitoneal injection of a conjugate consisting of OVA and a monoclonal anti-CD138 antibody. The effect of this treatment on the long-lived plasma cells and antibody levels was analyzed by flow cytometry and ELISA, respectively.

Results: The single injection of an OVA-anti-CD138 conjugate resulted in a significant depletion of OVA-specific plasma cells while CGG-specific plasma cells were not affected. The selective depletion of OVA-specific plasma cells also led to stable reduction of serum anti-OVA antibody levels; circulating anti-CGG antibody levels decreased by 90%.

Conclusion: The cellular antigen-affinity matrix strategy described here for the ablation of plasma cells in vivo according to the specificity of their antibodies enables a unique causative therapeutic approach in established antibody-mediated diseases without impairment of humoral immunity.

CITRULLINE REACTIVE B CELLS ARE PRESENT IN THE LUNGS OF EARLY UNTREATED RA

Vijay Joshua1, Malena Lobberg-Haarhaus1, Heidi Wähämäa1, Aase Hensvold1, Magnus Sköld2, Johan Grunewald3, Lars Klareskog1, Vivianne Malmström1, Anca Catrina4, Karolinska Institute and University Hospital, Rheumatology Unit, Department of Medicine, Solna, Stockholm, Sweden; 2Karolinska University Hospital, Department of Respiratory Medicine and Allergy, Stockholm, Sweden

Background: We have previously shown that structural changes, increased tissue citrullination, signs of local inflammation and ACPPA are present in the pulmonary compartment of early seropositive RA. These findings suggest a potential role for the lungs in generation of RA-associated autoimmunity.

Objectives: To identify citrulline reactive B cells in the lung compartment of early untreated RA patients and to generate and characterize the corresponding monoclonal antibodies.

Methods: Bronchoalveolar lavage (BAL) fluid cells (13 and 22.5 million respectively) were obtained from two early untreated non-smoking ACPPA positive RA patients and single CD19+ B cells were sorted by flow cytometry. Immunoglobulin variable region genes were sequenced and expressed to generate recombinant monoclonal antibodies (mAbs). The citrulline reactivity was determined by in-house ELISA against different citrullinated peptides and controls.

Results: Single sorted CD19+ B cells (n=768) from each patient (RA.1 and RA.2) were processed and the variable region amplification and sequencing yielded 192 variable region genes were sequenced and expressed to generate recombinant monoclonal antibodies (mAbs). The citrulline reactivity was determined by in-house ELISA against different citrullinated peptides and controls.

Conclusions: For the first time we demonstrate that citrulline-reactive B cells are present in the lung compartment of early untreated RA. Further analysis and functional characterization are needed and ongoing to understand their role in RA.

QUANTIFICATION OF CD27+ MEMORY B CELLS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH RITUXIMAB

Arianna Gatti1, Laura Castelnovo2, Paola Faggioli3, Antonio Tamburello2, Alfredo Maria Lurati3, Antonella Laria1, Bruno Brando1, Antonio Mazzzone3, LEGO Hospital — ASST Ovest Milanese, Hematology Laboratory and Transfusion Center, Legnano, Italy; 4Legnano Hospital – ASST Ovest Milanese, Internal Medicine, Legnano, Italy; 5Magenta Hospital – ASST Ovest Milanese, Rheumatology Unit, Magenta, Italy

Background: Rituximab (RTX) is being increasingly used in treatment of several autoimmune diseases, including Rheumatoid Arthritis (RA). RTX induces a deep depletion of all peripheral B-Cell subsets (memory and naive B-cells). During the B-Cell repopulation phase, occurring approximately 3 months of RTX administration, B-precursors and naïve cells reappear. Several studies have shown that relapsing RA patients are characterized by a relative expansion of memory B cells during the B-cell repopulation phase.

Objectives: The aim of this study was to quantify the memory B-Cell compartment in RA patients with different disease activity scores, evaluated by DAS28, during RTX treatment.

Methods: 28 RA patients under RTX treatment were studied. At the end of the treatment 8/26 showed high-to-moderate activity risk (median DAS28=4.8) and 18 low activity risk or remission (median DAS28=2.69). After a median of 3 months from last RTX infusion, B-Cell subsets (precursors, naïve, memory B cells and plasma cells) were quantified in peripheral blood by flow cytometry, using a panel of 8 markers (CD3, CD4, CD8, CD19, CD20, CD227, CD38 and CD45). B-naïve cells were identified as CD19+ CD20+ CD227-. Memory B cells were identified as CD19+ CD20+ CD227+. Plasma cells were identified as CD19+ CD38++ CD227+. The virtual absence of peripheral B-cell was defined as <0.1 B-cell/µL. In the responder group, 5/18 cases showed absolute B-cell levels <0.1 cell/µL, while only in 1/8 of the non-responder group a similar B-cell depletion was found. The memory B-Cell% was significantly higher in non-responder than in responders (p<0.05); the memory B-Cell level in non-responders was similar to that of the NC group.

Conclusion: We used a sensitive and easily applicable flow cytometric multicolor panel that allowed the accurate and standardized identification and enumeration of peripheral blood B-Cell subsets. As reported by other studies, higher levels of memory B-Cells were found in non-responding RA patients treated by RTX, approaching those of healthy individuals.

IL-2 THERAPY AFFECTS PERIPHERAL BLOOD LYMPHOCYTE LEVEL IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

Wenjuan Niu1, Hong Yan Wen1, Shi Giao1, Yanan Duan1, Yang Liu1, Chong Guo2, Li Xiaofeng1, 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Department of Pathology, Taiyuan, China; 2Department of Pathology, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, USA, Department of Pathology, Massachusetts, American Samoa

Background: Primary Sjogren’s Syndrome (PSS) is a chronic inflammatory autoimmune disease that mainly involves exocrine glands. Changes in the number of lymphocytes in PSS due to broken immune balance.

Methods: To observe the quantitative changes of peripheral Th17 cells and regulatory T cells (Tregs) in patients with primary Sjogren syndrome before and after short-term low-dose IL-2 treatment, and to explore the correlation between the level of peripheral blood lymphocytes and clinical indexes in patients with primary Sjogren syndrome.

Methods: Total172 PSS patients were enrolled, and 196 healthy adults were used as normal controls. Of them, 53 cases were treated with low dose IL-2 (5.0×10^12 international units (IU) for 5 days). The median four quantile method was used for statistical description. Multiple samples were compared with Kruskal-Wallis H test, and the correlation between variables was Spearman rank correlation analysis.

Results: (1) The number of Th17 cells were decreased as compared with that in the control group (P<0.05). The number of total T, CD8+ T, Th1, Th17, Treg, and the ratio of Th17/Treg were negatively correlated with CRP (P<0.05). (2) The Th17 cell levels, the ratio of Th17/Treg and CD4+ T/CD8+ ratio of Th17/Treg were negatively correlated with CRP (P<0.05).

Conclusion: The level of CD4+ T cells in peripheral blood of patients with PSS such as Th1, Th17 cells were significantly decreased. Th17/Treg were correlated with ESR, CRP. However, Th1, Th2, Th17 cells levels were increased according to treatment with short term low dose IL-2. Especially Treg cells. It indicated that IL-2 promoted the differentiation of Treg cells, maintained the function of Treg cells.

Case report: Advanced melanoma patient with favorable response to immune checkpoint inhibitor treatment shows severe erythema circinatum with anti-SS-A/SS-B antibodies

Marko Ozawa-Monmorihi1, Yoshinori Muro1, Kazunobu Goto1, Chikashi Obuse1, Minoru Saitoh1, Michiro Kono1, Masashi Akiyama1, Nagoya University Graduate School of Medicine, dermatology, Nagoya, Japan; 2Graduate School of Science, Osaka University, Osaka, Japan; 3School of Health Sciences, University of Occupational and Environmental Health, Fukaura, Japan

Background: Immune checkpoint inhibitors (ICI) targeting cytotoxic T lymphocyte-associated protein 4 (CTLA-4) and programmed cell death protein 1 (PD-1) have been efficacious treatments in oncology. However, the use of ICI induces a large spectrum of immune side effects. The prevalence of autoimmune connective tissue diseases and the autoantibody profiles induced by ICI are largely unknown.

The Ro52/TRIM21 antigen is known as a cytosolic Fc receptor that is found in almost all tissues. Its expression is regulated by interferons, and overexpression or hypoexpression has been observed in several cancers.

Objectives: In this study, we investigated autoantibodies produced after ICI treatments and analyzed the clinical characteristics of the patients.

Methods: Sera were collected from patients with unresetable metastatic or recurrent melanoma before and after treatment with ICIs such as ipilimumab, nivolumab or pembrolizumab. Autoantibodies were screened by Western blotting (WB) using A375 and HaCaT cell extracts. Antigenic proteins, which showed differences in reactivities in WB before versus after treatment, were purified by immunoprecipitation and analyzed by time-of-flight mass spectrometry. The identified proteins were tested for serum reactivities with ELISA.

Results: Of the 19 melanoma patients, 1 patient showed high titers of anti-SS-A/Ro52 and anti-SS-A/Ro60 antibodies after treatment. The other 18 melanoma patients were negative for both anti-SS-A/Ro52 and anti-SS-A/Ro60.

Case presentation: An 81-year-old Japanese male patient with multiple metastatic melanomas on the face (Figure 1A) was judged as unresetable, and treatment with pembrolizumab was started. After the fifth pembrolizumab administration, a grade 2 skin rash appeared (Figure 1B). The multiple metastatic lesions and the primary melanoma showed significant reductions, without new cancer lesions (Figure 1C). Pembrolizumab was ceased after the ninth administration with grade 3 skin erythema, and systemic prednisolone (PSON) at 1mg/kg/day was started. No other subjective symptoms, such as sicca, fever or fatigue, were observed. A biopsy specimen of erythema circinatum on the back showed strong liquefaction degeneration, individual cell keratinization and exocytosis. The reactive 52kDa and 60kDa polypeptides in WB (Figure 1D) were presumed to be SS-A/Ro52 and SS-A/Ro60, respectively, and the serum was confirmed to be reactive with these antigens by ELISA. The skin symptoms and anti-SS-A/Ro52 and anti-SS-A/Ro60 antibodies remained after the PSL treatment. Some of the erythema left incomplete degeneration of the skin (Figure 1E, F). Anti-SS-A/Ro52 and anti-SS-A/Ro60 antibody titers increased along with the skin symptom in this melanoma patient who was being treated with an ICI (Table 1).

Conclusion: Anti-SS-A/Ro52 and/or anti-SS-A/Ro60 may have some association with cancer immunity.

AGE AND GENDER EFFECTS ON PROGRAMMED CELL DEATH-1 EXPRESSION IN HEALTHY DONORS

Rosanne Reitsema, Rebeca Hid Cadena, Sander Niijhof, Wayel Abdullahad, Minke G. Hulstema, Annemieke Boots, Elisabeth Brouwer, Peter Heeringa. University of Groningen, University Medical Center Groningen, Groningen, Netherlands

Background: Giant cell arteritis (GCA) is the most frequent form of vasculitis affecting the large sized vessels. GCA occurs more frequently in females and exclusively in individuals > 50 years of age but it is unclear how gender and age relate to GCA pathogenesis.

In balancing the immune response and preventing immune dysfunction, immune checkpoints are crucial. Recently, the co-inhibitory checkpoint molecule programmed cell death-1 (PD-1) and its ligand PD-L1 were found to be aberrantly expressed in GCA (1). However, data on age and gender related effects on immune checkpoint expression is limited.

Objectives: To further investigate the contribution of immune checkpoints in GCA pathogenesis and how this relates to ageing and gender differences, we first studied PD-1 expression as a function of age and gender in healthy males and females.

Methods: Whole blood cells of 13 young healthy donors (mean age 25.5 years, female/male ratio 7:6) and 20 elderly healthy donors (mean age 72.7 years, female/male ratio 11:9) were stained for CD3, CD4, CD45RA, CD25 and PD-1 with monoclonal antibodies and expression was measured with flow cytometry. Results: Percentages of PD-1+ cells within CD4+ T cells, memory CD4+ T cells and the subset of non-suppressive regulatory T cells (Tregs) were decreased in (subsets of) CD4+ T cells of post-menopausal females compared to elderly males (Figure 1A-C; p<0.05). Furthermore, the frequency of PD-1+ cells within non-suppressive Tregs was also decreased in post-menopausal females compared to young females (Figure 1C; p<0.05).

Conclusion: PD-1 expression is decreased in (subsets of) CD4+ T cells of post-menopausal females when compared to younger females and elderly males. These findings suggest that post-menopausal status in females can influence PD-1 expression. Further studies on the relation between hormonal changes and immune checkpoint expression may contribute to understanding why elderly females are predisposed to develop GCA.

REFERENCE
with AS, suggesting that hydrogen production in the small intestine may be related to inflammation. In addition, with increasing age of the female, hydrogen and methane produced in the small intestine may increase, with increasing age of the male, small intestine may reduce the production of hydrogen, suggesting a reason why there are more female patients than male in some autoimmune disease.

**THE CHARACTERISTICS OF CIRCULATING FOLLICULAR T LYMPHOCYTE SUBSETS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND THE EFFECT OF TFR/TFH BALANCE ON DISEASE ACTIVITY**

Yan Yan Wang, Rui Su, Xiang-Cong Zhao, Jing Luo, Li Bao Chen, Qiao Ling Guo, Li Xiaofeng, Caihong Wang. The second hospital of Shanxi Medical University, Department of Rheumatic Immunology, Taiyuan city, China

**Background:** Rheumatoid arthritis (RA) is a highly disabling autoimmune disease. T lymphocyte subsets imbalance causing immune dysfunction is essential stages in the occurrence and development of RA diseases. Recent studies show that the interaction of both follicular helper T (Tfh) cells and follicular regulatory T (Tfr) cells are important frontier scientific direction to maintain autoimmune tolerance, and Tfr/Tfh balance may play a pivotal role in the formation of lymphoid germinial center and the production of autoantibodies.[1-3]

**Objectives:** The aim of this study was to explore the clinical characteristic of peripheral follicular T cell subsets in patients with RA and healthy individuals, and the effects of Tfr/Tfh balance on autoantibodies formation and disease activity. Searching for new immunomodulatory targets from it.

**Methods:** The study included 26 patients with a diagnosis of RA according to the 1987 revised criteria of the American College of Rheumatology and 17 healthy individuals as control group. All follicular T cell subsets from them were assessed by flow cytometry (Figure1). Using isotypic controls to distinguish follicular T cell subsets that were not clearly clustered. In addition, we measured all peripheral lymphocyte subsets in RA patients by Flow Cytometry. IgG, IgA, IgM,RF were measured using Turbidimetric inhibition immuno assay. Anti-CCP was measured using ELISA. We also collected relevant clinical information and made DAS28 score.

**Results:** (1)Compared with healthy controls, the proportions of CD4+ CXCR5+ PD-1high Tfh cells were higher in RA patients (P=0.029), In contrast, patients with RA had much lower level of CD225+CXCR5+Foxp3+ Tfr cells (P=0.010). And there were significant differences of Tfr/Tfh between these two groups (P<0.000). (2) Among 26 RA patients, there was obvious correlation between Tfr/Tfh and the DAS28 value(ρ=0.422, P=0.032). But there was no correlation between Tfr/Tfh and ESR(P>0.05). Correlation between CD4+CD25+Foxp3+ Treg cells and Tfr cells was also analyzed(ρ=0.722, P=0.000) (Figure2). (3) We have not found correlation between Tfr/Tfh and autoantibodies maybe for the small sample content.

**Conclusion:** Treg cells have a negative immunomodulatory effect on inflammatory response, the high correlation between Tfr cells and Treg cells indicates that Tfr cells may come from directional transformation of Treg. There is a Tfr/Tfh imbalance in RA patients, which suggests a potential mechanism of RA disease severity. However, more samples are needed to confirm whether it is related to the production of autoantibodies to affect disease activity.

**REFERENCES**

Background: Ankylosing Spondyloarthritis (AS) is a progressive, chronic, inflammatory skeletal disorder affecting the spine and sacroiliac joints. To date, the disease etiology remains unclear. Some studies have shown that lymphocytes play important roles in the inflammatory process of AS. However, the roles of comprehensive subtype lymphocyte subset imbalance in AS was rarely mentioned.

Objectives: In the present study, the correlation of lymphocyte subset changes with the progression of AS was investigated.

Methods: Flow cytometry analyses were carried out to detect the levels of a series of lymphocytes including different stages of differentiation CD4+ T cells, CD8+ T cells, helper T cells (Th), cytotoxic T cells (Tc), regulatory T cells (Treg), B lymphocytes and so on. Evaluation of hip joint disease were by using Bath Ankylosing Spondylitis forty X-ray index. Ankylosing Spondylitis Disease Activity Score (ASDAS) was used to assess disease activity and AS patients were divided into inactive disease group (ASDAS<1.3) and active disease group (ASDAS ≥1.3).

Results: The percentage of circulating follicular T lymphocyte subsets in patients with RA and healthy controls (\(p<0.05\), ***\(p<0.001\)). Correlation between Treg cells and Th1 cells, and correlation between Th1/Th2 and the DAS28.

AB0036B LYMPHOCYTE SUBSET IMBALANCES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Mingcan Yang, Zetao Liao, Yutong Jiang, Jieruo Gu. The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Ankylosing Spondyloarthritis (AS) is a progressive, chronic, inflammatory skeletal disorder affecting the spine and sacroiliac joints. To date, the disease etiology remains unclear. Some studies have shown that lymphocytes play important roles in the inflammatory process of AS. However, the roles of comprehensive subtype lymphocyte subset imbalance in AS was rarely mentioned.

Objective: To investigate the role of Treg and CD4+ T cells of different differentiation stages on the pathogenesis of active AS, and to study the mechanism of TNFα blocker on the treatment of active AS by detecting the number of Treg cells and CD4+ T cells before and after the treatment.

Methods: Ankylosing Spondylitis Disease Activity Score (ASDAS) was used to assess disease activity. AS patients who fulfilled the Assessment in Ankylosing Spondylitis Criteria in 1984 and ASDAS≥1.3 were enrolled in this study. The percentage of Th2 cells, Th17 cells, Th2 cells, inactive phase-specific CD8+ T cells and B cells were found to be significantly higher in the AS groups compared with the healthy individuals (\(p<0.05\)). In addition to the above differences, the percentage of Treg cells were significantly lower in the AS groups compared with the healthy individuals (\(p<0.05\)). AS patients with family history have significantly higher percentage of Th1 cells, Tc1 cells, Th1 cells, Th1 cells, continuous expression of virus-specific terminally differentiated CD8+ T cellsplasma cells, memory B cells and convertable B cells were significantly lower in the AS groups (\(p<0.05\)). As a result, the percentage of Th1/Th2 and (Th1+Th17)/Th2 ratios were significantly lower in AS patients (\(p<0.05\)).

Disclosure of Interests: None declared
Conclusion: Imbalances in the numbers and functions of specific lymphocyte cell subsets are key pathogenic derangements in AS, and these insights are leading to changes in clinical practice. The present study provided further evidence on the function and underlying mechanism of lymphocyte subsets, which may be useful in the diagnosis and treatment of ankylosing spondylitis.

AB0036C IMMUNOPHENOTYPIC CHARACTERIZATION OF T-CELL IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH GOLIMUMAB

Maria Mercedes Lopez-Mayorga1, Rosa Elda Barbosa-Cobos1, Mario Adán Moreno-Eutimio1, Lizbeth Teresa Becerril Mendoza1, Pedro Rodríguez Henríquez1, Gustavo Lugo1, Lucía Verónica Maya Piña1, Olivia Hernández-Jaimes1, José Moreno2, 1Hospital Juárez de México, Rheumatology, México, Mexico; 2Hospital Juárez de México, Unit of research, México, Mexico; 3Hospital General Manuel Gea González, Rheumatology, México, Mexico

Background: Golimumab is a human anti-TNF monoclonal antibody that has shown efficacy in RA. In the RA pathophysiology, the elevation of TNF modulates the cellular immune response, which leads to a sustained activation of T-cell response; however, it is unknown whether anti-TNF interferes with the immunophenotype of T-cell.

Objectives: To evaluate activation (CD25, CD69) and exhausted (PD-1, TIM-3, LAG-3, CTLA-4) markers of T-cells in RA patients treated with Golimumab.

Methods: We included 14 patients with RA diagnosis (Criteria ACR/EULAR 2010), with moderate to severe activity; 11 non-responders to synthetic DMARDs (NR-DMARDs) and 3 responders to synthetic DMARDs with pharmacological toxicity (R-DMARDs). All patients were treated with Golimumab during 24 weeks. The questionnaire SF-36, DAS28-CRP, power Doppler signal and expression of CD25, CD69, PD-1, TIM-3, LAG-3 and CTLA-4, in T-cell were evaluated at 0 and 24 weeks.

Results: Clinical variables evaluated in patients with Rheumatoid Arthritis are shown in tables 1 and 2.

Table 1. Clinical variables evaluated in patients with Rheumatoid Arthritis

The frequency of LAG-3+ on CD4+ T-cells increased after 24 weeks of treatment with Golimumab (p = 0.013) (figure 1). The expression of LAG-3 in CD4+ T-cells (r = -0.586, p = 0.028) (Figure 2) and CD8+ T-cells (r = -0.617, p = 0.019) (Figure 3) inversely correlated with DAS28-CRP after treatment. At the beginning of treatment NR-DMARDs patients showed higher expression of CD25 in CD8+ T-cells and lower expression of TIM-3 in CD4+ and CD8+ T-cells with respect to R-DMARDs. After 24 weeks of treatment, a lower frequency of CD69+ and LAG-3+ T-cells was found and increased of CD25+ T-cells compared to R-DMARDs.

Conclusion: Golimumab treatment increased the expression of LAG-3 in T-cells, suggesting a negative regulator of antigen presentation of T-cells.

Innate immunity in rheumatic diseases

AB0037 NEUTROPHIL GRANULOCYTES ARE PRIMED IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA)

Lillemor Berntson1, Utika Kihlborg1, Per Venge2, 1Uppsala University, Department of Women’s and Children’s health, Uppsala, Sweden; 2Uppsala University, Department of Medical Sciences, Clinical Chemistry, Uppsala, Sweden

Background: The adaptive as well as innate immunity is involved in JIA pathology. Neutrophils are key mediators of the innate immune response and is the most abundant cell type found in JIA synovial fluid. Studies of neutrophils in JIA have shown transcriptional abnormalities and neutrophil-derived S100A proteins have shown a potential role as biomarkers. Still, studies of neutrophils in JIA are scarce.
Human neutrophil lipocalin (HNL), also known as neutrophil gelatinase-associated lipocalin (NGAL), is a protein found in the secondary granules of neutrophil granulocytes. HNL can be found in epithelial cells as well, but only in its monomeric form. The dimeric form is only produced by neutrophil granulocytes. HNL resides in the secondary granules and is released upon stimulation, making HNL a unique marker of primed and activated neutrophil granulocytes, compared to myeloperoxidase (MPO) that resides in the primary granules and is released when neutrophils are activated, but also found in monocytes.

Objectives: To examine levels of the dimeric form of human neutrophil lipocalin (dHNL), to reveal if neutrophil granulocytes are primed in JIA, also analysis of myeloperoxidase MPO to reveal neutrophil activation. We aimed to compare the analyses to healthy controls and correlate the results to established measures of disease activity.

Methods: Blood samples from 75 patients with JIA (68% females) and 16 healthy controls were analyzed regarding HNL using a dimer ELISA assay (Diagnostics Development, Uppsala, Sweden) specifically detecting the dimeric form of HNL (dHNL). We also analyzed MPO (Diagnostics Development, Uppsala, Sweden), white blood cell count, neutrophil granulocyte cell count, ESR and CRP. All categories of JIA except the systemic category were included. Patient/parent and the physician filled out a global health assessment on a VA-scale (0–10). The number of active joints at sampling was collected and patients were classified according to the JIA criteria. The participants with JIA had a median age of 12.1 (IQR: 7.7–15.3) years, the control group 5.3 (IQR: 2.9–9.5) years.

Results: The serum levels of dHNL and MPO were significantly elevated compared to healthy controls, (p < 0.001; p = 0.002), and correlated significantly with each other (rs = 0.68, p < 0.001). The levels of dHNL correlated best to the count of neutrophil granulocytes (rs = 0.54, p < 0.001), total leucocyte count (rs = -0.43, p <0.001) and less well to CRP (rs = 0.42, p < 0.001) and ESR (rs = 0.35, p < 0.002) and not at all to the scoring system for disease activity, JADAS27 (rs = 0.06, p > 0.65).

Conclusion: The increased levels of the dimeric HNL in serum confirmed the involvement of neutrophil granulocytes in JIA although dHNL did not correlate with disease activity. The mechanisms by which neutrophils are primed and activated in JIA, however, still remain an enigma.

DO FUNCTIONAL INTERACTIONS BETWEEN MACROPHAGES AND SYNOVIAL FIBROBLASTS DRIVE SYNOVIAL PATHOLOGY OR RESOLUTION OF INFLAMMATION?

Aziza Elmesmari1,2, Robert Benson1,2, Lucy Macdonald1,2, Samuel Finlay1,2, Andrew Filer1,2, Stefano Aliverini3,4, Diane Vaughan1, Barbara Tolusso5, Elisa Gremese1,2, Iain McInnes2,4, Andy Clark2,3, Mariola Kurowska-Stolarska1,2.

1Institute of Infection, Immunity, and Inflammation, University of Glasgow, Glasgow, United Kingdom; 2Rheumatoid Arthritis Pathogenesis Centre of Excellence (RAICE), Glasgow, Birmingham, Newcastle, Glasgow, United Kingdom; 3Institute of Infectious Diseases and Microbiology, Birmingham, United Kingdom; 4Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; 5Università Cattolica del Sacro Cuore, Rome, Italy

Background: We recently uncovered heterogeneity in human synovial tissue macrophages during inflammation and resolution of inflammation (remission) in rheumatoid arthritis (RA). The transcriptomic profiles of distinct macrophage sub-populations suggest distinct functions, ranging from inflammatory to regulatory. Prior studies propose reciprocal interactions between macrophages and synovial fibroblasts (FLS) exist in the joint; however, the exact contribution of these interactions to synovial pathology or resolution of inflammation remains unknown.

Objectives: The aim of this study was to examine the functional interactions between different macrophage phenotypes and synovial fibroblasts.

Methods: To model different macrophage phenotypes, monococyte-derived macrophages (MOMD) were pre-stimulated (16h) with LPS (100ng/ml) to model inflammatory; or with dexamethasone (Dex, 1μM) to model regulatory macrophage. After extensive washing, MOMD were co-cultured with FLS for different periods of time. Prior to co-culture, FLS and MOMD were labelled with CellTraceTM-Violet and CellTraceTM-Red, respectively. After 24 & 48 hours of co-culture, FLS and MOMD were sorted based on positivity for CellTraceTM-Violet (FLS) or Red (MOMD) using FACS ARIA III, and expression of IL-6 and MMP1 in FLS analysed by ultrasensitive qPCR. In addition, the levels of IL-6 and MMP3 proteins were evaluated in co-culture supernatants by ELISA.

Results: FLS co-cultured with MOMD showed an increased mRNA expression of IL-6 at both 24 and 48h, and MMP1 at 48h, compared to FLS cultured alone. This expression pattern was decreased when MOMD were pre-treated with Dex and significantly upregulated when MOMD were pre-treated with LPS. Consistently with mRNA expression, IL-6 protein was significantly increased when FLS were co-cultured with MOMD (119±2.137pg/ml) as compared to FLS cultured alone (445±7.83pg/ml). This production was significantly augmented when MOMD were pre-treated with LPS (1985±25 pg/ml) and decreased when MOMD were pre-treated with Dex (729±63pg/ml). Similarly, MMP3 protein level was increased when FLS were co-cultured with MOMD (256±10pg/ml) as compared to FLS cultured alone (123±1 pg/ml). This production was significantly augmented when MOMD were pre-treated with LPS (1860±34pg/ml) and decreased when MOMD pre-treated with Dex (164±22pg/ml). These distinct effects of MOMD phenotypes on FLS function were associated with different dynamics of their interactions. Our preliminary data reveal that MOMD are quiescent on FLS monolayers unless MOMD are pre-treated with Dex, which induced a patrolling behaviour.

Conclusion: Macrophages can actively increase or limit activity of FLS, depending on their inflammatory or regulatory phenotypes, respectively. These observations indicate the potential for different subsets of synovial tissue macrophages to drive or resolve synovial inflammation by influencing the stromal compartment.

PRECLINICAL EVALUATION OF JAK1 SELECTIVE INHIBITORS INCB039110 AND INCB054707 AS TARGETED THERAPY OF CUTANEOUS LUPUS ERYTHEMATOSUS

Tanja Fetter1, Paul Smith2, Tugce Gül3, Thomas Bieber1, Jörg Wenzel1 on behalf of Prof. Wenzel lab group. 1University of Bonn, Department of Dermatology and Allergy, Bonn, Germany; 2Incyte Corporation, Wilmington, United States of America

Background: Cutaneous lupus erythematosus (CLE) is an autoimmune disease with heterogeneous subtypes presenting with inflammatory skin lesions, a histological pattern called “interface-dermatitis” and enhanced type-1-interferon (IFN)-regulated JAK/STAT (Janus kinase/signal transducers and activators of transcription) pathway signaling. Despite deeper understanding of the pathogenesis still no specifically approved drugs for CLE exist.

Objectives: The aim of our study was to investigate the effect of JAK1 selective inhibition as potential therapeutic approach for CLE in established preclinical models of cutaneous autoimmunity.

Methods: The expression of IFN-regulated proteins and genes after JAK1 inhibitor treatment was analysed in cultured, stimulated immortalized and primary human epidermal keratinocytes. In addition the impact of JAK1 inhibition on CLE-like skin lesions in lupus prone MRL/lpr- and TREX1-knockout-mice was determined.

Results: In vitro investigation revealed a significantly decreased gene- and protein expression of proinflammatory cytokines, in particular CXCL10 as key driver of CLE in established preclinical models of cutaneous autoimmunity.

Conclusion: Our findings indicate that inhibition of JAK1 results in a decreased chemokine expression, subsequent less cytotoxic T cell induced keratinocytic cell death leading to an improvement of lesional skin. By breaking the vicious inflammatory cycle JAK1 inhibitors appear to be promising agents as targeted therapy of CLE. Further investigation has to be performed in clinical trials.

AB0043  EFFECT OF IN VIVO HYDROXYCHLOROQUINE AND EX VIVO ANTI-BDCA2 TREATMENT ON PDC IFNα PRODUCTION FROM PATIENTS AFFECTED WITH CUTANEOUS LUPUS ERYTHEMATOSUS

Agnes Gardef1, Alex Pellerin2, Christie-Ann McCarr1, Rohan Diwanji1, Wenting Wang1, Douglas Donaldson1, Nathalie Franchimont1, Victor Werth2, Dania Rabah1, Biogen, Cambridge, United States of America; Department of Dermatology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States of America

Background: BIIB059 (aka 24FA4) is a monoclonal antibody that targets BDCA2, an inhibitory receptor expressed on pDCs. Plasmacytoid dendritic cells (pDCs) are a major source of Type-I Interferon (IFN-I), which is considered to be a key pathogenic driver in Cutaneous Lupus Erythematosus (CLE). Recent results from a Phase I clinical trial suggest that BIIB059 may ameliorate skin lesions in CLE patients. BIIB059 is currently evaluated in Phase II clinical trial for CLE with or without SLE.

Objectives: Given that Hydroxychloroquine (HCQ), a widely-used CLE therapy, and BIIB059 are both able to inhibit pDC-derived IFN-I production; this study aimed to determine whether BIIB059 would show an additional inhibitory effect on pDC response after ex-vivo or in-vivo treatment with HCQ.

Methods: The effect of BIIB059 on pDC-derived IFNα was measured from peripheral blood mononuclear cells (PBMC) either from healthy donors in presence or absence of HCQ or from CLE patients clinically exposed to various levels of HCQ. TLR7/9 and TLR9 agonists (ssRNA, R848, and CpG-A) were used for pDC stimulation.

Results: PDCs were the only producers of IFNα in response to CpG-A, R848, and ssRNA stimulation in PBMC cultures. CLE patients with high blood HCQ levels showed lower ex-vivo pDC responses to CpG-A, but not R848 or ssRNA. In contrast, BIIB059 reduced the amount of IFNα produced by pDCs from CLE patients in response to all TLR agonists, irrespective of the blood HCQ level. This effect was observed in patients with low or high blood IFN signature and in patients with or without concomitant SLE diagnosis.

Conclusion: Clinically-relevant HCQ concentrations partially inhibit the pDC response to TLR9 and weakly affect the response to TLR7/9 stimulation. BIIB059 robustly inhibits pDC responses even in the presence of HCQ, highlighting its unique potential to disrupt pDC disease relevant biology, which could provide additional benefit for CLE patients.

AB0044  PHARMACOLOGICAL MANIPULATION OF SIRTUIN 1 ACTIVITY IN EXPERIMENTALLY INDUCED ARTHRITIS

Mileni Leszeva1,2, Kaisi Stoyanov3, Petya Dimitrova2,1, The Stephan Angeloff Institute of Microbiology, Immunology, Sofia, Bulgaria; 1Sofia University “St. Kliment Ohridski”, Faculty of Medicine, Sofia, Bulgaria

Background: Sirtuin 1 (Sirt1) is a member of the sirtuin family of NAD+ dependent protein deacetylases. This nuclear enzyme with deacetylase activity serves as a metabolic sensor and transcriptional regulator, and exerts its beneficial effects by promotion of cell viability, tissue regeneration, and inhibition of inflammation.

Objectives: 1) To investigate the effect of pharmacological modulation of Sirt1 enzymatic activity on disease outcomes of experimental rheumatoid arthritis in mice; and 2) To characterize surface marker and pro-inflammatory cytokine expression in neutrophils following Sirt1 activation or inhibition.

Methods: Arthritis was induced by intra-peritoneal administration of a cocktail of monoclonal antibodies against collagen type II in Balb/c mice (CAIA). We utilized synthetic compounds which specifically activate or inhibit Sirt1 activity - SRT2183 and EX527, respectively. We investigated the effect of Sirt1 activity modulation on clinical scores of arthritic mice after subcutaneous seven-day treatment initiated at Day 7 of CAIA. We used flow-cytometry for phenotyping and functional analysis of blood, and bone marrow (BM) derived neutrophils stimulated in vitro, and in vivo. The effects of the two compounds on Sirt1 activity and on cell viability were assessed using ELISA-based colorimetric assays.

Results: Activation and inhibition of Sirt1 activity led to CD11b down-regulation and CXCR2 up-regulation on healthy blood and BM neutrophils, suggestive of neutrophil mobilization from the BM to the periphery following treatment in vivo. Both SRT2183 and EX527 had a positive effect on clinical scores in CAIA mice. However, in EX527-treated mice the re-emergence of signs of joint inflammation was observed 14 days after cessation of treatment. Administration of SRT2183 was able to up-regulate IL-1beta in healthy and CAIA mice, which we also observed in un-stimulated neutrophils in vitro. Iso-nicotinamide, a compound which activates sirtuins via an alternative mechanism, had a similar effect on IL-1beta expression in vitro. Finally, Parp1 cleavage, a marker for cell death, was reduced in purified BM neutrophils following Sirt1 activation.

Conclusion: Sirt1 activity modulation, whether activation or inhibition, improved clinical scores in arthritis. This corresponds to the mobilization of neutrophils from the BM to the periphery. The selective increase of IL-1beta following Sirt1 activation indicates that while activation or inhibition achieves a similar outcome, this is done through different molecular pathways. Our results underscore that systemic pharmacological modulation of Sirt1 activity for a complex disease, such as rheumatoid arthritis, is complicated and attention should be paid to the schedule and duration of treatment, as well as to the progressive involvement of various cell types, in order to maximize the beneficial effects.

Disclosure of Interests: This study was funded by the Bulgarian National Science Fund (DN 5/11-2017 to P.D.).

AB0045  MESENCHYMAL STEM CELLS INHIBIT THE ACTIVATED COMPLEMENT C5 BY CLUSTERIN IN LUPUS NEPHRITIS

Haijun Ma1,2, Chang Liu1,2, Ruihai Feng1, Lingyun Sun1,1, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Department of Rheumatology and Immunology, Nanjing, China; 2The First Affiliated Hospital of Xinxing Medical University, Department of Rheumatology and Immunology, Weihui, China

Background: Dysregulation of clusterin (CLU) and over-activated complement C5 were involved in the development and progression of lupus nephritis (LN). Allogeneic mesenchymal stem cells (MSCs) transplantation has achieved good clinical efficacy for refractory LN, however, the exact mechanisms remain to be elucidated.

Objectives: To investigate the clinical effect of MSCs on SLE model mice (B6. lpr), and explore the mechanisms of MSCs inhibiting the activated complement C5 in vivo and in vitro.

Methods: 26-week-old female B6.lpr mice were randomly allocated in three groups, which were given the following treatments, CTX (200mg/kg), MSCs (1 x 10^7), and an equal volume of PBS. 24 hours urinary and peripheral blood were collected periodically. All mice were sacrificed at 40 weeks of age. Urine protein to creatinine ratio and plasma creatinine were quantified to evaluate renal disease. Levels of C3, soluble C5b-9 (SC5b-9), CLU, and anti-dsDNA antibody were determined in the plasma by ELISA. Histopathological evaluation of renal lesions was undertaken by HE, PAS, PASM and Masson staining under light microscopy. Podocyte foot processes were assayed by the transmission electron microscopy. Accumulation of immunocomplexes (IC), C3, C5b-9, and CLU were detected in renal specimens by immunofluorescence or immunohistochemistry. Expressions of CLU in MSCs were detected by real-time PCR and ELISA. MSCs-derived CLU and anti-dsDNA antibody were determined in the plasma by ELISA. Histopathological evaluation of renal lesions was undertaken by HE, PAS, PASM and Masson staining under light microscopy. Pathological analysis showed that the proliferation of glomerular cells and foot process fusion were significantly alleviated in MSCs treated mice. Immunofluorescence and immunohistochemistry showed that depositions of IC, C1q, C3 and C5b-9 were significantly decreased in the MSCs group, although the expression of CLU was obviously increased in these mice. Mechanistically, interferon-α promoted the secretion of functional CLU by MSCs in vitro.

Conclusion: Allogeneic MSCs transplantation can effectively improve the clinical outcome of lupus mice. Possible mechanisms of MSCs might be related to inhibit the activated C5 via clusterin, which would be a potential treatment target in the future.

COMPARATIVE ANALYSIS OF TLRS AND INFLAMMASOMES GENES EXPRESSION IN DIFFERENT ETHIOLOGY ARTHRITIS AFTER STIMULATION WITH INFLAMMATORY STIMULI AND VITAMIN D

Regina Sakalyte1, Jerroslav Denkovskij2, Elvira Bernotiene1, Algidas Venalis1,2, Gabrielle Mourad1, Sigita Stropuvienė1,2, Narunas Porvaneckas1, Vytautas Tukūs1, Giedrius Kvederas1, Irena Butrimienė1,2, The Clinic of Rheumatology, Traumatology Orthopaedics and Reconstructive Surgery, Institute of Clinical Medicine of the Faculty of Vilnius University, Vilnius, Lithuania, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania

Background: It has been shown that a variety of environmental and genetic factors, as well as deficiency of vitamin D plays a key role in outcomes of arthritis. Many studies have shown that the central feature of synovitis in rheumatoid arthritis (RA) is activated synovium fibroblasts (SF) that play a key role in expression and secretion of distinct patterns of inflammatory factors. Recent studies demonstrated that nucleotide-binding oligomerisation domain-like receptor (NLR) containing a PYRIN domain 1 (NLRP1) and NLRP3 inflammasomes as well as Toll-like receptors (TLR), may be important in pathogenesis of chronic autoimmune joint diseases such as RA and potentially in development of osteoarthritis (OA). Therefore, better understanding of the role of SF, TLRs and inflammasomes inflammatory pathways in different ethiology joint damage could make a significant contribution to the early disease prognosis, monitoring, and therapy.

Objectives: A pilot study, to evaluate the effects of tumour necrosis factor α (TNFα), lipoteichoic acid (LTA), lipopolysaccharide (LPS), vitD on expression levels of TLRs and inflammasomes genes expression levels in SF. Downregulation of TLR2 expression and upregulation of NLRP3 accompanied by enhanced secretion of distinct patterns of inflammatory factors. Recent studies demonstrated that nucleotide-binding oligomerisation domain-like receptor (NLR) containing a PYRIN domain 1 (NLRP1) and NLRP3 inflammasomes associated with TNFα receptor (VDR) in human SF different ethiology knee damage: OA, RA, early arthritis (EA) (duration <12 months), healthy controls (HC) (after meniscus tear due to trauma).

Methods: Synovial tissue and blood samples for viD analysis were collected from patients undergoing joint replacement/arthroscopic synovectomy surgery, following informed consent according to the permission Lithuanian Ethics Committee. The isolated cells were expanded in a monolayer and used between passages 2 and 4. The expression of TLR, TLR1, TLR2, TLR4, NLRP1, NLRP3 inflammasomes was analysed by qRT-PCR after 24h of stimulation with LPS, TNFα, vitD, vitD.

Results: Analysis of gene expression results revealed that TNFα, LPS or LTA have no effect on TLR4 and TLR1 genes expression levels in SF. Downregulation of NLRP1 expression and upregulation of NLRP3 accompanied by enhanced expression of TLR2 was determined after stimulation with all factors, particularly TNFα. Highest upregulation of TLR2 was observed in RA and early arthritis patients, levels of other genes showed high variation between all patients, disrespectfully to diagnosis. Stimulation with TNFα resulted in 8-fold downregulation of VDR gene expression only in RA group, but not in OA, EA or HC. Stimulation with vitD had no effect on expression levels of studied genes in SFs in vitro, while the blood levels of vitD were neither associated with the endothelitis of arthritis nor with VDR responses to stimulation with TNFα, LPS, LTA.

Conclusion: We demonstrated downregulated expression of NLRP1, associated with increased levels of NLRP3 and TLR2 upon inflammatory stimuli in human articular SF from patients with arthritis of different ethiology. These data further support active involvement of those cells in inflammatory responses. Downregulated expression of VDR by TNFα in SF of RA patients implies altered signalling of vitD in the disease.

CHARACTERIZING THE ROLE OF NET-DERIVED IL-33 IN SLE PATHOGENESIS

Georgakis Spiros1,2, Garyfalla Papadaki1,2, Elias Drakos2, Charikleia Giakoupoulou1, Majia-Leena Eloanta1, Lars Ronnblom3,1, Prodromos Sidiropolous1, Panayotis Verginis2, Akiteru Ghituzimanaki2,1, George Bertsias6,1, University of Crete, Medical School, Heraklion, Greece, 1University of Athens, Medical School, Athens, Greece, 2Upsala University, Medical Sciences, Uppsala, Sweden, 3Rheumatology Department, University hospital, Heraklion, Greece, 4Biomedical Research Foundation, Academy of Athens, athens, Greece

Background: Interleukin (IL)-33 is a cell necrosis-derived alarmin with immunostimulatory properties which depend on the context of immune cells and the inflammatory milieu (1). In Systemic Lupus Erythematosus (SLE), extracellular DNA (as in extracellular chromatin traps [NETs] or immune complexes [ICs]) combined with alarmins stimulate innate immunity receptors (such as Toll-like receptors [TLRs]) and the production of IFNs by plasmacytoid dendritic cells (pDCs) (2, 3, 4).

Objectives: We propose that IL-33 is a potential NET-decorating protein and we want to investigate its pro-inflammatory properties. Additionally, NETs could also act as a platform mediating IL33’s bioactivity taking into consideration the excessive accumulation of proteases on extracellular traps. We hypothesize that NET-derived IL-33 might enhance the interferogenic capacity of pDCs.

Methods: Peripheral blood polymorphonuclear cells (PMNs) were isolated from healthy and SLE individuals and their ability to form IL33-decorated NETs was assayed by confocal microscopy. Renal sections from active lupus nephritis patients were immunostained to observe any IL-33 decorated NETs. NET-supernatants from untreated and IC-treated SLE PMNs were administrated to healthy pDCs and type I IFN production was monitored by qPCR and ELISA. The contribution of IL-33 to the interferogenic capacity of NETs was assessed by pre-treating pDCs with a specific mAb against IL33-receptor (anti-ST2L). The effect of proteases on the IL33-mediated interferogenic potential of NETs was investigated by pharmacological inhibition of elastase and Cathepsin G.

Results: Spontaneous-released NETs from peripheral blood PMNs of active SLE patients were decorated with IL-33 to larger extent as compared to healthy PMNs. NETs from untreated and IC-treated SLE PMNs were administrated to healthy pDCs and type I IFN production was monitored by qPCR and ELISA. The contribution of IL-33 to the interferogenic capacity of NETs was assessed by pre-treating pDCs with a specific mAb against IL33-receptor (anti-ST2L). The effect of proteases on the IL33-mediated interferogenic potential of NETs was investigated by pharmacological inhibition of elastase and Cathepsin G.

Conclusion: NET-derived IL-33 is a novel mediator of the nucleic acid-driven aberrant type I IFN response which exacerbates SLE disease. NET structure may want to investigate its pro-inflammatory properties. Additionally, NETs could also act as a platform mediating IL33’s bioactivity taking into consideration the excessive accumulation of proteases on extracellular traps. We hypothesize that NET-derived IL-33 might enhance the interferogenic capacity of pDCs.

REDUCED FCR R III AND ENHANCED FCR R III EXPRESSION ON MONOCYTES IN PATIENTS WITH BEHÇET DISEASE

Linfang Huang1,2, Xin Yu1, Hua Chen1, Xuan Zhang1, Xiangping Liao3, wenjie zheng1, 1PeKing Union Medical College Hospital, Department of Rheumatology, Beijing, China, 2The First People’s Hospital of YueYang, Yueyang, China, 3The First People’s Hospital of ChenZhou, Department of Rheumatology, Chenzhou, China

Background: Behçet’s disease (BD) is a systemic inflammatory disease without clear pathogenesis. Previous studies have shown the association between FcγRII gene polymorphisms and BD. FcγRs, the receptor of IgG, has both activatory and inhibitory subtypes, and the imbalance of them on immunocytes has been illustrated to have significant pathogenic roles in many autoimmune diseases.

Objectives: This study was aimed to investigate the potential abnormal expression of FcγRs in BD patients.

Methods: We recruited 27 newly-onset treatment-naïve BD patients (according to 2014 International Criteria for BD) and 23 gender-and age-matched healthy controls (HC). Flow cytometry was used for detecting the expression of the inhibiting receptor (FcγRIIB) and activating receptors (FcγRI and FcγRII) on the neutrophils, monocytes, B cells, natural killer cells, dendritic cells, and T cell from the whole blood of BD and HC. The correlation between the expression of FcγR and disease activity index of BD was evaluated.

Results: BD patients had increased numbers of monocytes (60.14±3.87% vs. 47.56±4.92%, p=0.0365) compared with HC. FcγRIIB expression on monocytes, rather than other immunocytes (p>0.05), was significantly lower in BD patients (4.87±0.61% vs. 7.67±1.10%, p=0.0199). FcγRIIB expression on monocytes was negatively correlated to ESR (r=-0.576, p=0.031) and CRP (r=-0.539, p=0.047), positively correlated to serum IgA (r=-0.785, p=0.001) and uncorrelated to serum IgG, IgM and PLT (p>0.05). FcγRIIB expression on monocytes was higher in BD patients (19.61±3.046% vs. 9.349±1.107%, p=0.0091). FcγRII expression on monocytes was positively correlated to ESR (r=0.2551, p=0.0274) and CRP (r=0.2354, p=0.0352), and uncorrelated to serum IgG, IgM, IgA and PLT (p>0.05). Furthermore, FcγRIIB expressions of monocyte were comparable between BD patients in active disease or remission, while FcγRII expression was significantly decreased (p=0.0158) after 3-month of treatment.

Conclusion: Our research demonstrated, for the first time, that the decreased expression of inhibitory receptor FcγRIIB and increased expression of activatory receptor FcγRII on monocytes in BD. Furthermore, the abnormal expression was correlated with disease activity. These findings suggested that FcγRs ratio imbalance may play a role in the pathogenic role of BD.

CHANGES OF INNATE LYMPHOCYTE CELLS IN PERIPHERAL BLOOD OF PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME AND ITS CORRELATIONS WITH CLINICAL MARKERS

Hui Chu1, Zhen Tan1, Xuan Fang2, Ruanlan Wu1, Ke Wang1, Li Xiangpei1, Guosheng Wang3, Yiping Wang3, Xiaomei Li3, 1The First Affiliated Hospital of Wannan Medical College of Zhejiang University, Wannan College of Zhejiang University, Wannan, China, 2the Affiliated Hospital of Wannan Medical College of Zhejiang University, Wannan, China, 3the University of Sydney, Westmead Institutefor Medical Research, Sydney, Australia

Background: Innate Lymphoid Cells (ILCs) are a novel group of innate immune cells, according to the cytokine profile, they were divided into three major subtypes:
Objectives: Our purpose is to explore the function and role of ILC in the pathogenesis of Primary Sjögren’s Syndrome (primary SS).

Methods: 20 patients with pSS and 15 age-matched healthy non-immune-related diseases controls were enrolled. The frequency of ILCs, B cells, CD4+ and CD8+ T cells from PBMCs was detected by flow cytometry. Analysis the subsets of ILCs in each group which compared with B cells and T cell subsets respectively and correlation with clinical serologic markers. Analyze the levels of IL-4, IL-9, IL-33, IL-22 and IFN-γ in each group by ELISA.

Results: Compared with the control group, the percentage of ILC was decreased significantly in primary SS (P<0.0001). Meanwhile ILC1 was significantly increased in primary SS (P=0.0001). ILC2 was decreased significantly in primary SS (P=0.0009) and ILC3 has no significant difference in the primary SS (P>0.05).

The frequency of ILCs in all patients positively correlated with antinuclear antibody titer (ANA(D)) (r=0.295, P=0.0133). Moreover, the frequency of ILC2 in primary SS was positively correlated with B cells (r=0.389, P=0.05), and the serum IgG was negatively correlated with ILC2 of all patients (r=0.2091, P=0.0427). Compared with Healthy control group, the level of IL-22 was significant higher in primary SS (P<0.0003), however, the levels of IL-4, IL-9, IL-33 and IFN-γ were not significant different with ILC2.

Conclusion: The frequency of ILCs is related to ANA(D) of primary SS patients and ILCs play a critical role in the pathogenesis of primary SS. Its function and mechanism are worth further exploration.

AB0050
DETECTION OF SERUM AND SYNOVIAL FLUID LEVELS OF VISFATIN DURING FLARE-UPS AND REMISSION OF PRIMARY OSTEOARTHRITIS OF THE KNEES
Haytham Abd elaal1, Hassan Bassiouini2, Khaled Zaky3, 1 ministry of health, rheumatology, Cairo; Abusheh, Egypt, 2alazhar university hospitals, rheumatology, Cairo, Egypt

Background: OA is the most common form of joint disease and a major contributor of disability in older people. OA is a chronic joint disease characterized by cartilage breakdown, bone remodeling, osteophyte development and synovial inflammation [1]. Adipose tissue expresses and secretes a large number of proteins that often share functional and structural properties of cytokines and are there classified as adipokines [2]. These include leptin, adiponectin, resistin, visfatin, and others. These factors are associated with inflammation and immune response. Visfatin is an adipokines identified in 2004 and was identified first as Pre B cell Colony Enhancing Factor [3]. Visfatin is a potent inducer of PGE2 release in both human and immature mouse articular chondrocytes, as a result of increased messenger prostaglandin E synthase and decreased 15 Prostaglandine dehydrogenase synthases [4].

Objectives: The aim of the study was to measure the level of visfatin in serum and synovial fluid from patients with knee osteoarthritis in flare-up and after they enter in remission.

Methods: to achieve the target of our study 20 patients with OA of the knee in flare-up were selected from out-patients clinic. The patients were followed up every two weeks after the first setting until they entered into remission. Twenty normal controls age, sex and body mass index (BMI) matched were recruited. In the first setting all patients had their sera, and synovial fluid measured for Visfatin, in the second setting sera and synovial fluid (if any) was drawn for visfatin measurement. Measurement of Visfatin by (ELISA) for quantitative determination of human visfatin in biological fluids.

Results:
1: serum visfatin of patients and control groups:

<table>
<thead>
<tr>
<th>P value</th>
<th>T</th>

INFILTRATING NATURE DRIVES RELEASE OF MITOCHONDRIAL DNA ENCLOSED IN EXTRACELLULAR MEMBRANE VESICLES AND PROPAGATION OF INFLAMMATION IN BEHÇET’S DISEASE
Haytham Abd elaal1, Hassan Bassiouini2, Khaled Zaky3, 1 ministry of health, rheumatology, Cairo; Abusheh, Egypt, 2alazhar university hospitals, rheumatology, Cairo, Egypt

Background: It has been reported that mitochondrial DNA (mtDNA) is released into the cytosol by mitochondrial stress and induces pro-inflammatory cytokine production via inflammasome and intracellular DNA sensors. Also, mtDNA in the extracellular space is known to result in sterile inflammation. However, the molecular mechanism of mtDNA release and its pathological significance in autoimmune diseases (ADs) has not been elucidated.

Objectives: To clarify the molecular mechanism of mtDNA release and its pathological significance in ADs.

Methods: We collected the serum from various AD patients and analyzed the levels of mtDNA in serum. We digested mtDNA in serum by DNase treatment. We purified the extracellular membrane vesicles (EMVs) and evaluated their inflammation-inducing potential. Also, we investigated the molecular mechanism behind mtDNA-induced inflammation by using inflammasome gene Knock out cell lines.

Results: We first measured the levels of mtDNA in serum of the various ADs by quantitative PCR and found that serum mtDNA levels were significantly high in BD. Moreover, mtDNA in BD serum could not be digested by DNase treatment and was detected in the extracellular membrane vesicles (EMVs) purified by ultracentrifugation. Since EMVs are known to deliver various molecules from one cell to another, we stimulated monocytic cells with BD-derived EMVs and found that these EMVs could induce IL-1β production in an NLRP3 inflammasome-dependent manner. We then studied the mechanism of secretion of mtDNA in EMVs and found that both human primary monocyte and monocyte-like cell line released mtDNA-containing EMVs after stimulation with ATP or LPS. Further, BD-derived monocytes secreted more abundant mtDNA in EMVs than monocytes derived from healthy donors. Additionally, the inhibition of caspase-1 activity reduced the secretion of mtDNA in EMVs

Conclusion: We revealed a novel mechanism of inflammation propagation involving inflammasome and mtDNA; activated inflammasome releases mtDNA-containing EMVs and subsequently leads to mtDNA-induced inflammation via NLRP3 inflammasome. Such inflammatory mechanism may contribute to the exacerbation of inflammation in BD.

Cytokines and inflammatory mediators
SEMAPHORIN 3A: A POSSIBLE MARKER FOR DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS
Ahmed Abdelaziz1, Shereen Kaddathy1, Salwa Fayed1, Enas Gomaa1, Fadwa Abdelrehem1
1Faculty of medicine alazhar university, cairo, Egypt. 2Faculty of medicine fayoum university, fayoum, Egypt. 3Faculty of medicine cairo university, cairo, Egypt

Background: Sema 3A is concerned in the pathogenesis of many autoimmune diseases because it is involved in regulation of immune responses and maintenance of self-tolerance. Regulatory T cells play an important role in maintaining immunological self-tolerance by suppressing autoreactive T cells. Sema3A promotes regulatory T cells by enhancing IL-10 production

Objectives: The current study aimed at testing the possible role of Semaphorin 3A (Sema 3A) in activity and in remission in rheumatoid arthritis patients and to assess whether this level correlates with interleukin 10 (IL-10) level.

Methods: Sixty Egyptian patients with rheumatoid arthritis (RA) were divided into three groups according to modified Disease Activity Score (DAS28), RA in high activity (group II, n=20), RA in moderate activity (group III, n=20) and RA in remission (group IV, n=20) and compared with 20 normal individuals (group I). Serum levels of Sema 3A and IL-10 were measured and correlated with ESR, CRP, TNF-α, IL-10, IL-6, IL-8, MCP-1/CCL2, VEGF, and IL-6.

Results: IL-6 was higher in patient groups, with highest mean among group IV. A significant negative correlation was detected between Sema 3A and each of ESR, CRP, DAS28 and HAQ. Serum IL-10 was higher in patient groups, with highest mean among group IV. Conclusion: reduced serum level of Sema 3A was found to be correlated with disease activity and indicating its usefulness marker for RA disease activity.

GENE POLYMORPHISM TNFAIP3 RS6920220 IS ASSOCIATED WITH A SPECIFIC CYTOKEINE PATTERN IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS
Irina Gusueva1, Anastasia Averenova2, Maria Cherkesova2, Elena Samarkina2
1Campus Kerckhoff, Justus- Liebig- University, Giessen, Dept. of Rheumatology and Clinical Immunology, Bad Nauheim, Germany. 2V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Methods: 44 eRA patients (36 females; median age 55.0 [46; 60,0]; median disease duration 7.0 [4; 9.11) months; DAS28 5.9 [4.8, 6.4] were included. 89% were positive for IgM rheumatoid, 92% - anti-CCP positive. “Gene candidate” approach was used to search for the following gene polymorphisms (SNPs): TP53N2 (+1685 C/T, rs2476601), CTLA4 (+49A/G, rs213775), TNFAIP3 (rs675520, rs9092020, rs1049914), IL1B (-174G/C, rs1800795), ILEP (-358A/G, rs1800629), MCP1/CCL2 (+358A/G, rs1204611), IL10 (-592A/G, rs1808072, -1082 A/G, rs180896). Serum levels of 27 cytokines/chemokines were measured using the xMAP multiplexing technology at baseline, at 12 and 24 weeks after initiation of therapy. All patients were treated with methotrexate and/or biological therapy in accordance with the treat-to-target strategy (REMARKA study).

Results: Among all studied SNPs only polymorphism rs6920220 of gene TNFAIP3 was associated with a certain cytokine/chemokine production across all time-points: baseline, 12 and 24 weeks. At baseline, the carriers of GG genotype (27 pts) showed significantly higher serum levels of the following mediators, compared to the patients with GA/AA genotypes (17 pts): IL8 (42.8 ± 23.0 pg/ml vs 25.5±8.4 pg/ml, p<0.0001), IL-17 (20.4±15.8 pg/ml vs 11.5±12.1 pg/ml, p=0.017), MIP-1α (19.1±40.5 pg/ml vs 9.8±27.9 pg/ml, p=0.036), MIP-1β (155.4±45.0 pg/ml vs 117.8±47.2 pg/ml, p=0.013), PDGF-BB (6967.5±3257.7 pg/ml vs 4600.6±1826.0 pg/ml, p=0.018). At week 12th, IL-8 serum levels were the only ones to remain associated with polymorphism rs6920220 (p=0.015). At week 24th, the carriers of GG genotype had higher serum levels of several cytokines/chemokines, compared to the patients with GA/AA genotypes: IL-8 (47.9±26.2 pg/ml vs 33.7±19.3 pg/ml, p=0.05), IP-10 (2451.7±1825.2 pg/ml vs 1404.9±941.1 pg/ml, p=0.037), MIP-1β (150.7±68.2 pg/ml vs 89.7±33.8 pg/ml, p=0.004), PDGF-BB (515.9±2667.6 pg/ml vs 3915.4±1343.5 pg/ml, p=0.046). There was no statistically significant difference in production of IL-6, IP-10, MIP-1β, and PDGF-BB prior to and after 24 weeks of therapy.

Conclusion: The results suggest that polymorphism rs6920220 of gene TNFAIP3 is linked to a particular cytokine/chemokine pattern. Biological therapy used according to the treat-to-target strategy for 24 weeks does not lead to the reduced production of IL-6, IP-10, MIP-1β, and PDGF-BB in the carriers of GG genotype.

ACTIVIN A AND FOLLISTATIN AFFECT THE INTERACTION OF ENDOTHelial CELLS AND RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS
Iris Aykara1, Magnus Diller1, Stefan Rehara2, Ulf Müller-Ladner1, Elena Neumann1
1Campus Kerckhoff, Justus- Liebig- University, Giessen, Dept. of Rheumatology and Clinical Immunology, Bad Nauheim, Germany. 2V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Activin A and its antagonist follistatin are part of an autoregulatory cycle, which is well known in the hypophalamic-pituitary-gonadal axis. Activins also have an important function in autoimmune diseases, such as rheumatoid arthritis (RA). Due to inflammation, activin A is released systemically, causing an induction of its antagonist follistatin. The negative feedback mechanism is well described for hepatocytes, but seems to be inactive in synovial fibroblasts from patients with rheumatoid arthritis (RA). Neangiogenesis, which is mediated partially by local fibroblasts, is increased due to inflammation and tissue hyperplasia in RA synovium. Despite the fact that RASF contribute to cartilage destruction in RA and RASF are able to interact with endothelial cells, less is known about the effect of activin and follistatin in this context.

Objectives: The aim of this study was to examine the effect of activin A and follistatin on the interaction of RASF and endothelial cells.

Methods: Endothelial cells (HUVECs) were commercially obtained and RASF were isolated from synovial tissue of patients with RA undergoing joint replacement surgery. RASF and HUVECs were stimulated in mono-, or coculture with activin A (15 ng/ml), follistatin (500 ng/ml) and/ or IL-1β (1 ng/ml). The concentrations of activin A, follistatin, VEGF and IL-6 were measured by ELISA.

Results: IL-1β induced the release of activin A 8-fold in RASF alone (p<0.01, n=5) as well as in direct coculture with HUVECs 4-fold (p<0.02, n=5). The stimulation with follistatin together with IL-1β reduced the activin A concentration produced by HUVECs 9-fold (p<0.01, n=5) as well as in cocultures (10-fold, p<0.01) in comparison to stimulation with IL-1β alone. This reduction could not be observed in RASF mono-culture. In HUVECs, the IL-6 release was reduced by 37.6% after stimulation with activin A and IL-1β (n=5, p<0.05) in comparison to the stimulation with IL-1β alone. In RASF mono-culture the release of IL-6 was induced by 61.0% after stimulating with activin A combined with IL-1β in comparison to the stimulation with IL-1β alone. In direct coculture neither the induction, nor the reduction of the IL-6 concentration could be detected when stimulated with activin A and IL-1β. The release of VEGF was induced in RASF with IL-1β (89%), activin A (55%), activin A combined with IL-1β (148%), follistatin and IL-1β (84%) compared to unstimulated control. In coculture with HUVECs, the induction was less distinct than in monoculture (IL-1β: 75%), activin A: 22%, activin A and IL-1β: 101%, follistatin and IL-1β: 67%, n=4)

Conclusion: The autoregulatory cycle of activin A and follistatin is active in endothelial cells and inactive in RASF. Due to the interaction of endothelial cells and RASF, the proinflammatory response of the RASF is weakened. This was shown in direct coculture with no induction in coculture compared to stimulation with activin A and IL-1β in RASF monocytes. Interestingly, in direct coculture, the effects of HUVECs appear to dominate resulting in a significant reduction of the activin A concentration in the presence of follistatin and IL-1β in comparison to RASF monocytes.

**SEQUENTIAL INTRA-ARTICULAR INJECTIONS OF LINEAR AND CROSS-LINKED HYALURONIC ACIDS IN THE TREATMENT OF GONARTHROSIS**

Elena Barbieri, Università di Urbino Carlo Bo, Department of biomoelucro sciences, Urbino, Italy

**Background:** Sequential intra-articular injections of linear and cross-linked hyaluronic acids in the treatment of gonarthrosis  

**Objectives:** This study evaluates clinical and biochemical effects of sequential intra-articular (IA) injections of two different formulations of hyaluronic acid (HA) in gonarthrosis (GA) patients. The first formulation consists in linear HA (LHA, MW 800-1200kDa; Regenflex Starter, Regenyal Labs, Italy) and the second in an intercalated mixture of cross-linked and linear HAs (CL-LHA, MW 1-2 MDa the crosslinked form and 500kDa the linear, intercalated one; Regenflex BioPlus).  

**Methods:** 39 knee GA patients, 19 adults (50-65 years) and 20 elderly (>65 years), underwent 2 IA injections, i.e. LHA only at baseline and CL-LHA after 1 week. The same injections were repeated after 6 months. Clinical assessment - visual analog scale (VAS) for pain, range of motion (ROM) and WOMAC index for knee functional limitation - was performed at baseline and after 3, 6, 9, 12 months. Blood, collected at baseline, after 1 week and 3 months, was analysed for relevant cytokines and collagen telopeptide II (CTX-II). Synovial fluid (SF) from patients with recurrent knee effusion (GA worse group) was biochemically analysed at baseline and 1 week. SF proteomic analysis was also carried out at specific time points.  

**Results:** This HA-regimen improved joint pain and function independently from the age; plasma and synovial biochemical analyses indicate the attenuation of inflammatory cytokines (IL-1α, IL-6, IL-17) and the stabilization of CTX-II; ultrasonograph data show an improvement of cartilage conditions and thickness at 12 months.  

**Conclusion:** Sequential IA injections of LHA and CL-LHA represent a highly effective treatment especially in low degree GA patients and produce a significant and enduring improvement also in the GA worse group. The efficacy is likely dependent on the sequential administration of LHA and CL-LHA: the pharmacokinetic rationale of this combination will be discussed.

**INFECTIONS WITH ANTI TNF ALPHA: PROSPECTIVE STUDY OVER 12 YEARS**

Bilal Bengana, Abdennour Boukabous, Naima Bahaz, Salima Lefkiri. University Hospital of Benimessous. Rheumatology, ALGER, Algeria

**Background:** Anti Tumor Necrosis Factor alpha (TNFα) has significantly improved the prognosis of some chronic inflammatory diseases (CID). Nevertheless, they carry with them a significant risk of opportunistic infections, imposing a rigorous surveillance and an adequate education of the patients. In a context of endemic tuberculosis, it is imperative to take the appropriate precautions to detect this kind of infection in rheumatisers under anti TNFα.  

**Objectives:** The aim of our work was to study the profile of infectious incidents in patients treated with anti TNFα.  

**Methods:** This is a prospective study of patients treated with anti-TNFα over a 12-year period (2006-2018). We examined all infectious complications for each patient who received an anti-TNFα for CID while assessing the level of severity, the type of infection and the risk factors that may be related to this type of incident.  

**Results:** During the study period, 134 patients were identified, these patients were followed for ankylosing spondylitis (AS) for 58 cases, 36 for enteric rheumatism, 23 for psoriatic arthritis and 17 for rheumatoid arthritis. The mean age was 46.3 years (19-64 years), the mean age of the disease was 44.2 months (8-140). The molecules used were: infliximab, etanercept, adalimumab with a respective number of patients (%): 29 (21), 44 (33), 61 (46). Of the 134 patients evaluated, 71 were diagnosed and treated by a physician (in 47 patients), only 5 were serious: 2 cases of tuberculosis were reported (intestinal and ganglionic tuberculosis), 1 case of chickenpox of the adult, 1 case with perianal abscess, 1 case of erysipelas of the lower limb. The infection was bacterial, viral or mycotic [n (%) = 38 (53), 61 (86), 7 (8)]. A large proportion of the patients were on conventional immunosuppressive therapy. The factors related to the occurrence of infectious incidents were: use of corticosteroids p<0.0001, habit in rural areas p=0.042.  

**Conclusion:** More than a third of patients have infectious complications after TNFα treatment in our study sometimes with serious issue. Thus, with the emergence of these incidents, the physician has to be very vigilant when instituting this biotherapy, and secondly, a rigorous and prolonged monitoring of the patients.

**CUTANEOUS ADVERSE EFFECTS WITH BIOLOGIC AGENTS**

Bilal Bengana, Abdennour Boukabous, Naima Bahaz, Salima Lefkiri. University Hospital of Beninchessous. Rheumatology, ALGER, Algeria

**Background:** Biologic agents (BA) are designed to treat chronic inflammatory diseases (CID), however, the adverse effects inherent with these drugs are more and more encountered. Among them are dermatological manifestations: infections, allergic reactions or even skin cancers, which sometimes require stopping treatment temporarily or permanently.  

**Objectives:** The goal of this work consists to identify the cutaneous manifestations (CA) that have been reported to the most commonly used biologics in CID.  

**Methods:** It’s a prospective study in patients received in day hospital and treated with BA for CID during a period of 9 months (October 2017 - June 2018), we recorded all the data on CA after a complete dermatological examination, nor forgetting that we appreciated the phototype of the patients, the level of exposure to the sun and means of photoprotection.  

**Results:** We collected the data of 68 patients under BA for the study (Adalimumab = 21, Etanercept = 17, Tocilizumab = 12, Infliximab = 7, Rituximab = 11) with a clear female predominance 59.4%, the mean age was 39 years. 37 (54%) had cutaneous manifestations, the main CA occurred with TNFs inhibitors 21/68 (30%), with more often skin infections. The other CA encountered were cutaneous rashes and allergic reactions, appearance of psoriasis or eczema and injection site reactions, we did not cross any skin cancer.  

**Conclusion:** Cutaneous manifestations remain frequent and relatively benign with BA. This work confirms the importance of education and dermatological monitoring of patients treated with biologic drugs in the CID. This prospective study needs to be completed over a longer period especially to screen any skin cancer.

**AB0057**

**ASSESSMENT OF MATRIX METALLOPROTEASE 3 (MMP3) AS A POTENTIAL BIOMARKER FOR RHEUMATOID ARTHRITIS IN ALGERIAN PATIENTS**

Mounira Benidir1, Samir Salah2, Dalia Fodi2, Hachemi Djioufi2, Habiba Armrou2, Nabila Attal3,1Pasteur Institute of Algeria, Immunology, Algiers, Algeria  

2Mustapha Pacha Hospital, Immunology, Algiers, Algeria  

3Liberal, Rheumatology, Algiers, Algeria  

4Doucea Hospital, Rheumatology, Algiers, Algeria  

5Hussein Dey Hospital, Medical Biology, Algiers, Algeria

**Background:** Matrix metalloproteinase 3 (MMP3) is a protease induced by rheumatoid pannus pro-inflammatory cytokines during rheumatoid arthritis (RA) and degrades many cartilage and bone components. Its serum level is a useful marker for predicting joint destruction and evaluating disease activity.  

**Objectives:** First, compare MMP3 production in RA patients to controls, then try to place this marker in the evaluation of disease activity.  

**Methods:** We subdivided the studied population into three groups:  

- RA: n = 134; sex ratio: 1: 5; age: 50 ± 14 years; disease duration: 7 ± 9 years.  
- Healthy controls: n = 67; sex ratio: 1: 7; age: 38 ± 11 years.  
- Population control: Patients with:  
  - Inflammatory rheumatism: n = 80;  
  - Chronic inflammatory diseases (CID): 18 Connective tissue disease (CTD), 14 chronic hepatitis C and 2 Cohn disease (CD).

- RA: n = 134; sex ratio: 1: 5; age: 50 ± 14 years; disease duration: 7 ± 9 years.  
- Healthy controls: n = 67; sex ratio: 1: 7; age: 38 ± 11 years.  
- Population control: Patients with:  
  - Inflammatory rheumatism: n = 80;  
  - Chronic inflammatory diseases (CID): 18 Connective tissue disease (CTD), 14 chronic hepatitis C and 2 Cohn disease (CD).
The serum MMP3 measurement was performed by ELISA assay.

Results: Serum MMP3 was significantly higher in RA patients vs. healthy controls (p < 0.0001), Inflammatory rheumatism (p < 0.0001) and CID (p < 0.05) and is particularly high in women with high Disease Activity Score 28 joints (DAS28) vs. Moderate DAS28 (p < 0.05). In addition, it is higher if patients have: positive CRP: p < 0.05; positive RF: p < 0.05; ACDA: p < 0.05 and Bone erosion: p < 0.01 compared to other patients. Finally, there is a positive correlation between MMP3 production and RF (p < 0.001, Spearman r = 0.35) and ACDA (p < 0.01, Spearman r = 0.29) but not with DAS28 joining the results published by Mahmood et al.[2013] and Fadda et al.[2016]. Furthermore, in RA patients, there is no significant difference in MMP3 levels according to whether the erythrocyte sedimentation rate (ESR) is accelerated or not, unlike CRP which represents the best marker of inflammation in this disease, according to the literature. Finally, the production of MMP3 is greater in case of erosion and is associated to bone and joint destruction.

Conclusion: MMP3 serum measurement is a particularly useful marker of inflammatory activity in RA and may have potential predictive value in the development of bone and joint destruction.

METHOTREXATE DOWNREGULATES P-GLYCOPEPTIDE EXPRESSION AND INHIBITS THE ACTIVATION OF JAK2/STAT3 PATHWAY IN RHEUMATOID ARTHRITIS PERIPHERAL BLOOD MONOUNCLEAR CELLS

Kalin Cheng, Qin Kall, Li Xiaol, Calhong Wang, the Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by abnormal synovial hyperplasia, inflammatory cell infiltration, and destruction of cartilage or bone. Early use of disease-modifying anti-rheumatic drugs (DMARDs) can significantly improve the patient's condition. However, many patients had no response after treatment or gradually decreased after treatment for some time. DMARDs Multidrug resistance (MDR1) is an important cause of the above phenomenon. How to reverse MDR in RA patients, and then control the disease is a major problem in RA treatment. The mechanism of MDR is complex. ATP binding cassette transporter super family consists of 48 transporters. ABCB1/P-glycoprotein (P-gp) is one of the major proteins associated with MDR1. The expression of P-gp is induced not only by genotoxic mechanisms, but also by inflammatory cytokines such as IL-2, IL-4, IL-6, and TNF-a in some inflammatory diseases.

Objectives: The multiple drug resistance (MDR) to disease modifying anti-rheumatic drugs (DMARDs) is the key factor in Rheumatoid arthritis (RA) treatment field. P-glycoprotein (P-gp) encoded by multidrug resistance gene (MDR1) is involved in the excretion of numerous DMARDs. We investigated the effects of methotrexate (MTX) alone and combined with interleukin 6 (IL-6) on P-gp expression and examined the signaling pathway involved in peripheral blood mononuclear cells of RA patients.

Methods: The peripheral blood mononuclear cells were extracted from Fifteen RA patients who were without any DMARDs and biological agents treatment. These cells were treated with IL-6, IL-6+MTX(0.1μg/ml), IL-6+MTX (0.1μg/ml), IL-6+MTX (1μg/ml) for 72h. P-gp expression was measured by flow cytometry and real-time polymerase chain reaction (RT-PCR); JAK2 and STAT3 were measured by RT-PCR.

Results: Methotrexate produce a dose-responsive reduction of both P-gp, JAK2 and STAT3 expression induced by IL-6.

Conclusion: Methotrexate downregulates p-glycoprotein expression and inhibits the activation of JAK2/STAT3 pathway in rheumatoid arthritis peripheral blood mononuclear cells.

AB0061 INVESTIGATING THE ROLE OF TGF-B AND FATIGUE IN CHRONIC FATIGUE SYNDROME

Beth Díez1, Emmanuelle Troiano1, Jessica Tarn1, Dennis Lendrem1, Wan Fai Ng1,2 on behalf of United Kingdom Primary Sjögren Syndrome Registry.

1Newcastle University, Institute of Cellular Medicine, Newcastle, United Kingdom; 2NIHR Newcastle Biomedical Research Centre, Newcastle, United Kingdom

Background: Chronic fatigue syndrome (CFS) is estimated to affect up to 5% of people in Europe and is more common in women than men. It is characterised by unexplained fatigue, post-exertional malaise and a range of other symptoms. Recent studies indicate potential immune dysfunction in CFS, specifically regarding cytokines and the adaptive behavioural response.

Objectives: This study aims to investigate serum transforming growth factor-beta (TGF-B) and the expression of the TGF-B Receptor 1 (TGFBR1) and TGF-B Receptor 2 (TGFBR2) genes, in relation to the fatigue associated with CFS.

Methods: Serum active and total TGF-B concentrations were measured in 117 CFS patients and 40 HCs using a TGF-B specific luciferase bioassay. Expression levels of TGFBR1 and TGFBR2 were analysed using quantitative PCR. Fatigue was assessed using the fatigue impact scale (FIS).

RESULTS
Serum TGF-B concentrations in the CFS group did not differ significantly compared with the HC group (p=0.58). TGF-B concentrations showed no correlation with disease duration but there was a trend towards decreased TGF-B with increasing symptom duration. There were no significant differences between the levels of TGFBR1 and TGFBR2 in any of the fatigue groups, or between HCs. Active TGF-B concentrations were significantly elevated in the ‘severe’ FIS group compared with the ‘mild’ FIS group (p=0.04). Active/total TGF-B levels were significantly higher in the ‘severe’ FIS group than the ‘mild’ and ‘moderate’ FIS groups (p=0.02, p=0.03 respectively).

AB0062 P75NTR IN THE MODULATION OF INFLAMMATORY RESPONSE MEDIATED BY SYNOVIAL FIBROBLASTS

Lucia Farina1, Gaetana Minnone1, Marzia Soligo2, Luigi Manni3, Gian Marco Moretti1, Ivan Caleo1, Luigi Marzo3, Fabrizio De Benedetti1, Luisa Bracci-Laudiero1,2,3, Giambattista Gesù, Division of Rheumatology, Roma, Italy; 2Consiglio Nazionale delle Ricerche, Istituto di Farmacologia Traslazionale, Roma, Italy; 3Università Degli Studi di Pavia – Scientific Center, Department of Medicine, Pavia, Italy

Background: Our previous studies showed high expression levels of p75NTR, the nerve growth factor (NGF) receptor, in mononuclear cells (MNCs) obtained from blood and synovial fluids of patients with juvenile idiopathic arthritis (JIA) and rheumatoid arthritis (RA). p75NTR binds with high affinity proNGF, the immature form of NGF whose concentration, as we recently demonstrated, is extremely high in the synovial fluids of arthritis patients. In ex vivo experiments we demonstrated that recombinant proNGF increases inflammatory cytokine production in patient MNCs, an effect that was abolished using p75NTR inhibitors.

We also found that synovial fibroblasts (SFs) represent the main source of proNGF in the inflamed synoviae. At present it is not known whether proNGF can influence the activity of SFs that are key effector cells in synovial inflammation producing inflammatory mediators that regulate chondrocytes and osteoblasts activation.

Objectives: To investigate the mechanisms regulating p75NTR expression in synovial fibroblasts of arthritis patients and to evaluate the effects of its inhibition on the inflammatory response.

Methods: SFs from arthritis patients were used to study the activity of proNGF/p75NTR axis. SFs from osteoarthritis patients (OA) and skin fibroblasts from healthy donors (HD) were used as controls. p75NTR, NGF, and cytokine transcripts were evaluated by quantitative PCR (qPCR). Protein expression of p75NTR, NGF, and proNGF were analyzed by Western Blot. ELISAs were used to evaluate NGF, proNGF and cytokine concentration in supernatants and synovial fluids. p75NTR was inhibited using LM1A-31, a synthetic inhibitor that blocks the binding between p75NTR and its specific ligand proNGF.

RESULTS: mRNA and protein expression of p75NTR were up-regulated in arthritis SFs compared to OA SFs and skin fibroblasts. In vitro stimulation with recombinant cytokines (IL-1B, IL-6, IL-1T), LTR-ligands (such as LPS), and TGFβ1 strongly increased p75NTR mRNA expression in arthritis SFs. Interestingly, after stimulation we observed that also OA SFs and HD fibroblasts up-regulated p75NTR transcript, suggesting that p75NTR levels are modulated by the inflammatory mediators. SFs of arthritis patients spontaneously produced proNGF and its release was further enhanced by all the above-mentioned inflammatory stimuli, albeit with different extent. Thus patient SFs can both produce proNGF and bind it through p75NTR. The inhibition of proNGF binding to p75NTR using LM1A-31 in arthritis SFs, activated with inflammatory cytokines or with synovial fluids, significantly reduced the expression and release of pro-inflammatory cytokine.

SYSTEMS APPROACH TO INVESTIGATE INFLAMMATION RESOLUTION BY TR14

Patrick Schopohl1, Suchi Smita1, Faiz Khan1, Tom Gebhardt1, Matti Hoch1

REFERENCES

Gliostatin (GLS) is known to have angiogenic and arthritogenic activities. GLS was expressed in inflamed synovial tissues of patients with RA. In cultured fibroblast-like synoviocytes (FLSs), GLS expression was found to be up-regulated by inflammatory cytokines, such as IL-1β, TNFα, IL-6. GLS acted as a cytokine in FLSs, augmenting its own synthesis, and also induced the extracellular secretion of matrix metalloproteinase (MMP)-1, -3, -9, and -13. Therefore, the suppression of GLS production might be an effective therapy in RA. The mechanism of the action of baricitinib had not been determined in fibroblast-like synoviocytes (FLSs).

Objectives: The purpose of this study was to investigate the GLS production effect of interferon (IFN) γ and the inhibitory action of baricitinib in FLSs derived from patients with RA (RA-FLSs).

Methods: RA-FLSs were cultured from synovial specimens of patients with RA and stimulated by IFNy with or without treatment of baricitinib. The expression levels of GLS were determined using reverse transcription-polymerase chain reaction (RT-PCR), enzyme immunosassay and immunocytochemistry.

Results: In cultured RA-FLSs, GLS mRNA and protein were significantly induced by stimulation with IFNy and these GLS inductions were significantly suppressed by treatment of baricitinib in dose-dependent manners.

Conclusion: Our data demonstrated that JAK/STAT activation play a pivotal role in IFNy mediated GLS up-regulation in RA-FLSs. Suppression of GLS production in inflamed synovia has been suggested as one of the anti-inflammatory effects of baricitinib.

cytokines and chemokines including IL-12β (P=0.07), IL-6 (P=0.07), IL-10 (P=0.12), IL-18 (P=0.19), and IL-4 (P=0.63).

Conclusion: This study illuminates the downstream effects of neutralizing TNFα not previously investigated. Adalimumab had a pronounced effect on downregulation of the inflammatory CXCL1 subfamily chemokines IL-8, CXCL5, CXCL9, and CXCL10. This helps explain findings of diminished inflammatory cell migration into joints seen in the first trials with TNFα inhibitors.[2] Further characterization of downstream effects of the multiple DMARDs used for the treatment of immune mediated inflammatory arthritis will help guide treatment strategies for these patients.

AB0070
THE RELATIONSHIP BETWEEN THE LEVEL OF NESFATIN-1 AND THE CLINICAL MANIFESTATIONS OF RHEUMATOID ARTHRITIS
Tamara Kvildzhe,1 B. Zavodovsky,2 J Polyakova,1 E. Zagordrenevi,1 Federal State Budgetary Institute «Research Institute of Clinical and Experimental Rheumatology named after A. B. Zavoronyov», Volgograd, Russian Federation; 2Federal State Budgetary Educational Institution of Higher Education "Volgograd State Medical University" of the Ministry of Health of the Russian Federation, Volgograd, Russian Federation

Background: Nesfatin-1 is actively studied in the pathogenesis of metabolic disorders. An excess of this factor in the brain leads to loss of appetite, a feeling of fullness, as well as a decrease in body weight. Similarly, elevated levels of nesfatin are associated with depressive disorders [1]. We studied the level of nesfatin in the serum of patients with rheumatoid arthritis (RA) and found a relationship with systemic inflammation and functional impairment [2].

Objectives: To study the relationship of serum nesfatin-1 levels with the clinical manifestations of RA.

Methods: To identify the relationship between serum nesfatin-1 and the clinical manifestations of rheumatoid arthritis, all patients were divided into 2 groups. The first group - 1 (66 patients) with elevated serum nesfatin (> 37.95 ng/ml). The second group - 2 (44 patients) - with normal values (<37.95ng/ml). In both groups, we studied the clinical manifestations of RA.

Results: A high level of nesfatin in RA patients was typical for patients with a higher degree of activity in DAS28 (χ² = 8.37; p = 0.04), seropositivity for the rheumatoid factor (RF) (χ² = 5.53; p = 0.02), the duration of the disease is more than 10 years (χ² = 9.53; p = 0.01). At the same time, there was no significant correlation between the level of nesfatin and the extra-articular manifestations of RA (χ² = 2.09; p = 0.14) and the degree of radiological damage to the joints (χ² = 4.45; p = 0.21).

Conclusion: This study shows that serum nesfatin-1 levels are significantly higher in patients with more unfavorable RA, than in RA with minimal clinical manifestations. These data confirm the pathogenic role of nesfatin-1 in the development of clinical manifestations associated primarily with RA activity, but to a lesser extent with organ lesions in RA. The relationship of the level of nesfatin with the duration of the disease is of particular interest, since there is no correlation with the degree of X-ray damage to the joints and organ damage. There are literary data on the relationship of depression and late stage of RA [3].

Background: Familial Mediterranean Fever (FMF) is caused by mutations in MEFV. The protein product pyrin is expressed in monocytes, neutrophils and eosinophils. Acute inflammatory attacks are accompanied by a dramatic hepatic acute phase response. S100A8/A9 is damage associated molecular pattern and a TLR4 ligand expressed in neutrophils, monocytes and early infiltrating macrophages. We aimed to investigate S100A8/A9 in 39 patients with FMF, 45 healthy carriers and wild type controls.

Objectives: To measure S100A8/A9 in patients with FMF, carriers and healthy controls.

Methods: All patients were genotyped. Patients and healthy controls (HC) serum S100A8/A9 levels, cell surface expression on monocytes and neutrophils as well as intracellular peripheral blood mononuclear cells (PBMC) expression were measured by flow cytometry (FACS). CD14 cells were isolated and following overnight incubation with or without LPS, S100A8/A9 was measured in the supernatants by ELISA. Patient and HC monocyte apoptosis was compared.

Results: Serum levels were measured in 84 samples from 31 patients with homozygous or compound mutations (median 9061ng/ml [range 500-38470], 79 samples from 39 symptomatic patients who were MEFV heterozygotes (median 9394ng/ml [range 1744-38119], 80 samples from 45 individuals with MEFV variants but without clinical features of FMF (median 10939ng/ml [range 2447-40000]. There was no difference in ciprofloxacin concentrations between the different mutations. All the groups described had significantly higher levels than healthy controls (n=16 median 2836ng/ml [range 1058-6175] [p<0.001],Minimal monocyte and neutrophil cell surface expression was detectable. Following LPS stimulation there was significantly more S100A8/A9 detected in the supernatants in patients than healthy control CD14. There was also a trend to an increased intracellular monocyte S100A8/A9 expression.

AB0072 BIOMARKER CHANGES FOR PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TOFACITINIB WITH METHOTREXATE OR GLUCOCORTICOIDS VS TOFACITINIB MONOTHERAPY

Julie Lee¹, Xing Chen¹, Weidong Zhang¹, David Martin⁵, Craig Hyde⁶, Tomohiro Hirose⁶, Shweta Shah¹, Lori Fitz¹. ¹Pfizer Inc, Cambridge, MA, United States of America; ²Pfizer Japan Inc, Tokyo, Japan; ³Pfizer Inc, Collegeville, PA, United States of America

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Herpes zoster is more common in patients (pts) with RA vs the general population.¹ This risk increases with tofacitinib use² and appears to be further increased with concomitant use of csDMARDs such as methotrexate (MTX), or glucocorticoids (GC).² The mechanism for these increases in risk may be linked to treatment-induced interferon (IFN) suppression,² given that replication of the varicella zoster virus appears to be limited by IFN activity.²

Objectives: To evaluate whether treatment of RA with tofacitinib + MTX or GC suppresses IFN pathway proteins to a greater extent than treatment with tofacitinib monotherapy.

Methods: This was a post hoc analysis of pooled data from 1 Phase (PII) (Japan study [NCT00687193]) and 2 P3 (ORAL Scan [NCT01039688]) tofacitinib studies. Serum samples were collected at baseline (BL), Week (W)12 and/or W24 from pts with RA treated with tofacitinib 5 or 10 mg BD, given as monotherapy (Japan study; ORAL Scan) or with stable doses of MTX (15–25 mg weekly for 26 weeks; ORAL Scan) and/or GC (≤10 mg/day prednisone or equivalent; all studies). A total of 376 proteins associated with cellular and inflammatory processes, including 6 IFN pathway proteins (CXCL10, CXCL9, CXCL11, IL-12, IFNγ and IL-20), were measured using a homogeneous solution-based assay (Olink Proseek® Multiplex Assay, Uppsala, Sweden). Changes in protein levels from BL to W12 (Japan study; ORAL Scan) and/or W24 (Olink Scan, ORAL Scan) were compared for tofacitinib monotherapy vs tofacitinib + MTX or GC using linear regression models. The dependent variable was change from BL in protein levels at W12 or W24. The independent variable was MTX or GC status. Age, gender, GC status (in MTX model) and BL protein levels and tofacitinib dose were covariates. Regressions were performed separately for each study; results for GC were combined via meta-analysis using fixed and random effect models. Significance was considered at p<0.01 after controlling for false discovery rate (FDR). Data quality control included accounting for plate/batch effects and limits of detection, and removal of sample/analyses with excessive missing data.

Results: In total, 659 serum samples were collected from 321 pts. Of the 6 IFN pathway proteins, 2 (IFNγ and IL-20) were below the limit of detection. There was no strong evidence suggesting statistical differences between tofacitinib monotherapy and tofacitinib + MTX or GC in changes in levels of the 4 detectable IFN pathway proteins (CXCL10, CXCL9, CXCL11 and IL-12) from BL and/or W12 and/or W24. Significant differences were observed for 2 of the 570 other proteins: MMP-1 (FDR adjusted p=0.008) and IL1Ra (FDR adjusted p=0.009), where levels decreased from BL to W12 for tofacitinib + MTX to a greater extent than for tofacitinib monotherapy.

Conclusion: The results of this post hoc analysis suggest that tofacitinib + MTX or GC may not suppress circulating serum levels of IFN pathway proteins to a greater extent than tofacitinib monotherapy. Although there were differences at W12 for tofacitinib + MTX vs tofacitinib monotherapy in MMP-1 and IL1Ra, it is not yet clear whether these observations may be attributable to differences in the ethnicities of the study populations receiving these two treatment regimens (global vs Japan). Further analyses of biomarker changes with tofacitinib are ongoing.

Interrelationship between Nicotinic Acetylcholine Receptor and Cytokine Production Noted Following T-Cell Antigen Recognition and Activation
Nikholas Mandinio;1,2,3 Kevin Hou;1 Han-Shen Tse;4 David Adams;6 University of Sydney, Westmead Hospital, Rheumatology, Sydney, Australia;2The University of Sydney, Rheumatology, Campedown, Australia;3Westmead, Rheumatology, Westmead, Australia;4Westmead, Rheumatology, Westmead, Sydney, Australia;5University of Wollongong, Wollongong, Australia;6University of Wollongong, Illawara Health and Medical Research Institute, Wollongong, Australia

Background: T cells express muscarinic and nicotinic acetylcholine receptors (nAChRs, nAChRs) that increase intracellular Ca2+ [1] on stimulation. The expression of these receptors on macrophages and their activation by vagal stimulation has recently been the focus for novel arthritis treatment [2].

Methods: nAChR heterologous subunits were expressed in Xenopus oocytes and the inhibitory activity of various peptides at ACh-evoked currents were assessed. The effect of these peptides on T-cell antigen recognition and subsequent cytokine production was assessed using an antigen presentation assay (APA). Briefly, the 284.11 murine T cell hybridoma recognizes cytochrome c as the antigen was co-cultured with the antigen presenting B cell hybridoma line LK35.2 (I-Ek bearing) and pigeon cytochrome c in the absence or presence of peptide or several nAChRs antagonists, including mecamylamine (broad nAChR antagonist), waglerin-1 (α9β4δ), and β2 δ-bungarotoxin did not affect IL-2 production in the APA. ELISA and real-time PCR were performed to measure cytokine protein levels and nAChRs T-cells mRNA express levels separately.

Results: At 10μM, peptide W32052 had modest 50-55% inhibition of human (h) αβ2 and h4q2 nAChR subtypes, and 35% inhibition at h9q10. W32052 greatly inhibited chimeric rat α1β1δ-μ mouse e (85%) at 10μM. W32052 also inhibited IL-2, IL-6, TNF-α and GM-CSF production at 50μM in the APA. nAChRs antagonists, mecamylamine (100μM), Rag1 (10μM), Vc1.1 (7.5μM) and dihydro-β-erythroidine hydrobromide (d94β and d9β2), ELISA and real-time PCR were performed to measure cytokine protein levels and nAChRs T-cells mRNA express levels separately.

Conclusion: W32052, an antagonist of nAChRs, inhibits cytokine production following antigen recognition suggesting that there is a close link between T-cell antigen activation, ion channel regulation mediated by ACh and cytokine production. Further experiments are in progress.

Effect of Sidaguri Extract (Sidaguri Rhombifolia L.) on Urinary Carboxy-Terminal Telepeptides of Type II Collagen in Osteoarthritic Patients
Blondina Marapou;1 Sheena Dalmunth¢, Joshua Patrick¢, William Simanjuntak¢,1
1Universitas Sumatera Utara, Division of Rheumatology, Internal Medicine, Medan, Indonesia; 2Universitas Sumatera Utara, Division of Rheumatology, Internal Medicine, Medan, Indonesia

Background: Osteoarthritis is one of the most common joint diseases in Indonesia and elsewhere. Assessment of the effectiveness of osteoarthritis therapy with biomarkers should be developed. One of the biomarker that can be used to assess the activity of osteoarthritis is Urinary Carboxy-Terminal Telepeptides of Type II Collagen. Indonesia is the center of world biodiversity, and Sidaguri is one of the traditional plants that is believed to have many benefits including its anti-inflammatory effect and the ability to decrease level of uric acid. The β-sitosterol is an active component in Sidaguri that has anti-inflammatory activity in osteoarthritis.

Objectives: To compare the effect of sidaguri and meloxicam therapy with meloxicam alone in decreasing the levels of Urinary Carboxy-Terminal Telepeptides Of Type II Collagen in osteoarthritic patients.

Methods: This study was conducted on 24 patients with osteoarthritis at H. Adam Malik General Hospital Medan from April to June 2018. Subjects were divided into two groups, namely placebo and Sidaguri group. Levels of uCTX II were assessed before and after intervention. T-test was used to analyze the data using SPSS version 22.

Results: 83.3% of osteoarthritic patients in H. Adam Malik hospital who participated in this study were women with mean age 50.38 ± 9.74 years in the placebo group and 63.08 ± 14.14 years in the sidaguri group. The results showed that subjects receiving Sidaguri showed significant decrease in uCTX II before and after intervention (521.42 ± 369.99 vs 330.75 ± 163.49 ng/mmol, p = 0.003). Meanwhile, in the placebo group also found decreased levels of uCTX II but it was not statistically significant (286.17 ± 163.92 vs. 218.25 ± 75.05 ng/mmol, p = 0.238). In addition, there was a significant difference between the mean of the two groups after the intervention (p = 0.046).

Conclusion: There was a significant decrease in uCTX II levels in osteoarthritic patients who received Sidaguri extract for 30 days compared to the placebo group.

REFERENCES
Results: 152 patients were included. (80 adalimumab-treated and 72 etanercept-treated). No statistically significant difference between mean IL-17A, IL-17AF, IL-17F and IL-10 levels at baseline and 3 month follow-up were observed (figure 1). For IL-17A, those patients classified as good responders demonstrated an increase in mean serum levels of IL-17A from 1.06 pg/ml at baseline to 1.23 pg/ml at 3 months. This came close to significance (p = 0.07). Further analysis was carried out by drug group and also a subgroup analysis by drug group linked to responder status. No statistically significant results were obtained. Adjusting for gender, baseline DMARD use and DAS-28 scores did not alter findings.

Figure 1: Mean interleukin levels at pre-treatment and 3 months

Conclusion: There was a lack of statistically significant data to suggest a correlation between pre-treatment and 3 month IL-17F, IL-17AF and IL-10 concentrations. However, an increase in IL-17 A serum levels between baseline and 3 months may be associated with a good EULAR response status by 6 months. Larger sample sizes are required to confirm this.

AB0077 THE THERAPEUTIC EFFECT OF GPMB IN A TRAUMATICALLY-INDUCED OSTEOARTHRITIC MODEL

Bryson Cook1, Asaad Ali Adlan1, Mathew Desanto1, Rama Safadi1, Salvatore Frangiames1, Pavex Safadi1, 1Rootstown, Anatomy and Neurobiology, Musculoskeletal Research Group, Rootstown, United States of America; 2Akron, Orthopaedics, Akron, United States of America; 3Akron Children’s Hospital, Rebecca D Considine Research Institute, Akron, United States of America

Background: Osteoarthritis is a severe joint disease that affects millions of people. At this time, the current treatment for osteoarthritis is total joint reconstruction surgery. GPNMB plays a key role in bone remodeling and bone growth. Data from our lab suggested that GPNMB is a positive regulator of osteoblastogenesis and a negative regulator of osteoclastogenesis.

Objectives: The role of GPNMB in cartilage has not been investigated before. In this study we examined the therapeutic effects of GPNMB on damaged cartilage using post-traumatic osteoarthritic mouse model.

Methods: The destabilization of the medial meniscus (DMM) surgery in mice has been found to be an excellent model for studying post-traumatic osteoarthritis. We performed the DMM surgery on 21 C57BL6 mice. These mice were divided into three intra-articular injection treatment groups consisting of a control, low dose GPNMB, and high dose GPNMB. These mice were divided into three intra-articular injection treatment groups consisting of a control, low dose GPNMB, and high dose GPNMB. Moderate to severe osteoarthritis develops around six to eight weeks with this model.

Results: Here we present that damaged human cartilage has significantly higher levels of GPNMB compared to undamaged cartilage. In addition, human osteoarthritic chondrocytes treated with GPNMB showed a protective response to inflammation induced by IL-1-beta. In this study, we examined whether recombinant GPNMB has an anti-inflammatory effect in a model of post-traumatic osteoarthritis.

Conclusions: Our data clearly showed that GPNMB has therapeutic anti-inflammatory effects on protecting cartilage damaged. Hence, future studies will be directed towards examining the therapeutic effects of GPNMB on larger animal models for osteoarthritis. Given the remarkable ability of GPNMB to reduce expression of key inflammatory markers, we conducted this study to reveal GPNMB therapeutic effects in traumatically-induced osteoarthritis.

AB0079 EFFECT OF HYALURONIC ACID LOCAL INJECTIONS ON ACHILLES TENDINOPATHIES: AN OBSERVATIONAL STUDY ON TENDON VISCOSCELLAR PROPERTIES AND THEIR RELATIONSHIPS WITH CLINICAL OUTCOMES

Piero Sestili, 1 Università degli Studi di Urbino Carlo Bo, Department of biomolecular sciences, Urbino, Italy

Background: Effect of hyaluronic acid local injections on Achilles tendinopathies: an observational study on tendon viscoelastic properties and their relationships with clinical outcomes.

Objectives: Achilles tendinopathy (AT) affects athletes, recreational exercisers and also inactive people, where it is sometimes associated with arthritic phenotypes. The aim of this study was to evaluate the efficacy of a three-local injections regimen of hyaluronic acid (HA) in middle aged patients with a diagnosis of AT; the relationships of the functional, biochemical and clinical outcomes with the viscoelastic properties of the tendon were also studied

Methods: 8 patients previously diagnosed for monolateral AT were enrolled. AT was confirmed before the first local HA injection (T0) by clinical examination, MR and thermography. At T0 patients were assessed for maximal voluntary isometric contraction (MVI) involving Achilles tendon (both injured and healthy), and pain level with a Likert scale; Achilles tendon viscoelastic state, i.e. tone and stiffness, were then measured at relaxed state and at 10% of MVI with MyotonPro (Myoton Ltd, UK). Finally patients received the first HA injection (RegenFlex T&M, a blend of 2 to 1000 KDa HA, Regenyl, IT). All the measurements were repeated at T1 (15 days after the first injections and immediately prior the second), at T2 (15 days after the second injection and prior the third) and at T3 (15 days after the third injection), i.e. over a total of 45 days in which clinical visits were also performed. Furthermore, each injection, injured tendon exudates were collected by needle aspiration and the levels of IL-1β and matrix metalloprotease 3 (MMP-3) were determined with an ELISA test.

Results: At T0, pain score and MVI were significantly higher and lower in injured tendons, respectively. Accordingly, tone and stiffness values were significantly different between injured and contralateral tendons, especially when measured at the relaxed state. Interestingly, the above differences gradually disappeared at T1, T2 and T3. In keeping with these results, tendon exudates volumes also decreased over time, as well as the levels of IL-1β and MMP-3.

Conclusion: RegenFlex T&M promoted a progressive healing of AT, with recovery of clinical, functional and tendon’s viscoelastic state.

AB0080 THE INHIBITION OF IL-25 TO THE EFFECT OF IL-17 TO ERK1/2 AND MMP-3 IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIALCYTIES

Lu Jinyue, Feng Yuchen, Kang Guorong, Zhang Hui, Shen HaLi, LanZhou university second hospital, LanZhou, China

Background: Rheumatoid arthritis (RA) is a common chronic systemic autoimmune diseases characterized by the inflammation in joint and synovium. Synovitis leads to the destruction of cartilage and bone in joint subsequently joint dysfunction and even disability eventually. Recently, IL-25 has been found to play a role in regulating inflammation through Th1 and Th17 responses in inflammatory diseases[25]. However, the function to fibroblast-like synoviocytes and its signaling pathway are not clear. This study aims to probe the effects of IL-25 on the expression of ERK1/2 and MMP-3 in RA fibroblast-like synoviocytes.

Objectives: To study the function of IL-25 for rheumatoid arthritis (RA) fibroblast-like synoviocytes.

Methods: The effects on ERK1/2 and MMP-3 protein levels were tested in RA-FLS and healthy controls, then IL-17A (10ng/ml), different concentrations of IL-25 (0.01, 0.1, 1 and 10ng/ml) and IL-17A(10ng/ml) to co-stimulate the RA-FLS for 24 hours respectively. The expression of ERK1/2 and MMP-3 protein were detected by the Western blot. The results were expressed by ±s, t test was used for the comparison between different groups.

Results: The expression of ERK1/2 (1.7±1.0±0.1) and MMP-3 (0.5±0.13) proteins in RA-FLS was higher than the healthy controls (0.50±0.15, 0.17±0.05) (t=9.13,P<0.001) and (-4.10,P<0.05), because of the stimulation of IL-17A, the expression of ERK1/2 (0.77±0.22) and MMP-3 (0.59±0.13) proteins in RA-FLS were increased compared with untreated groups (0.18±0.35, 0.04±0.03)(t=constantly.

Conclusion: IL-25 can inhibit the stimulation of IL-17A on ERK1/2 and MMP-3 fractionally, which imply that it may take part in the development of RA through this pathway and may play as a target for the RA treatment on IL-17A.

AB0081 NOVEL COOPERATION BETWEEN CCL26 AND CX3CL1 VIA CX3CR1 IN THE INJURY OF SMALL BILE DUCT IN PRIMARY BILARY CIRRHOSIS

Yihan Cao, SUN XIAOCHUAN, Zhiwei Chen, Shuo Zhang, Hua Chen, Fengchun Zhang, Li Wang, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: CXCCL1-CX3CR1 pathway has been found to be critically involved in the pathogenesis of primary biliary cholangitis (PBC) 1. As a novel ligand to CX3CR1, CCL26 can promote chemotaxis of CX3CR1+ immune cells but its role in PBC remains elusive 2.

Objectives: This study aimed to explore the role of CCL26, together with CXCL1-CX3CR1 pathway, in the pathogenesis of PBC.

Methods: We recruited 40 patients diagnosed with PBC in the Peking Union Medical College Hospital from Jan 2018 to May 2018 and 18 age and sex-matched healthy controls (HCs). Peripheral blood and liver tissue samples were collected. The plasma level of CX3CL1 and CCL26 were determined by ELISA. Flow cytometry was used to measure the percentage of CX3CR1+ cells in various subsets of PBMCs. The expression of CX3CL1 and CCL26 in liver tissues was revealed by immunohistochemical staining. Using ELISA and flow cytometry, the change of CX3CL1/CCL26-CX3CR1 pathway expression in human intrahepatic biliary epithelial cells (HIBECs) upon stimulation of various cytokines was studied.

Results: The plasma level of CX3CL1 and CCL26 was higher in patients with PBC than HCs with a P value of 0.044 and 0.104 respectively. The increased level of CCL26 was positively correlated with peripheral eosinophils, basophils and CRP level. In comparison with HCs, the expression of CX3CR1 was significantly higher in NKT-like and CD4+ T cells in PBC patients. In liver samples from PBC patients, CXCL1 and CCL26 were significantly over-expressed in intrahepatic bile ducts and CCL26 also tended to be abundant in hepatocytes near portal areas and gradually weakened in distant regions. This distribution pattern was not observed in HCs. Upon stimulation of IFN-y, the expression of CX3CR1 on HIBEC surface and CX3CL1 in culture supernatant was significantly up-regulated, while the expression of CCL26 was increased upon IL-4 and IL-13 stimulation.

Conclusion: CCL26 may cooperate with CX3CR1 to mediate the immune injury of intrahepatic bile ducts via CX3CR1 in PBC.
Reduced Steroidogenic Activity of Repository Corticotropin Injection (RCI) Induces a Distinct Cytokine Response Following T Cell Activation in Vivo

Dale Wright, Ben Zweifel, Prabha Sharma, Karen Galen, Rick Fitch. Mallinckrodt Pharmaceuticals, Pharmacology, Hazelwood, United States of America

Background: Melanocortin receptor agonists, such as oMSH, have been shown to reduce inflammation in preclinical models, suppressing the production of proinflammatory cytokines. Natural and synthetic ACTH analogues remain linked to the induction of corticosteroids as their primary mechanism of action, leading to the anti-inflammatory and immunosuppressive responses. Repository Corticotropin Injection (RCI) is a complex mixture containing purified porcine pituitary ACTH-analogue, and is an FDA-approved treatment for several inflammatory diseases. RCI has been shown to be effective in steroid-refractory autoimmune disorders.

Objectives: We hypothesize that Acthar has an immune regulatory response distinct from synthetic ACTH and steroids. These studies sought to explore the differences between RCI and synthetic ACTH on corticosterone levels in rats and cytokine production in a murine T cell activation model.

Methods: RCI (10, 40, or 400 IU/kg) or ACTH (0.6, 1.2, or 2.4 mg/kg) was administered to Sprague Dawley rats, plasma samples collected and analyzed for corticosterone. To determine the effect on T cell cytokine production, Balb/C mice were treated with RCI (10, 40, and 400 IU/kg), ACTH (0.6, 1.2, or 2.4 mg/kg) or prednisolone 1 hour prior to the administration of an anti-CD3. Two hours after anti-body administration, plasma cytokines were measured using Meso Scale multiplex ELISA.

Results: RCI and ACTH peak corticosterone and area under the curve (AUC) were evaluated. RCI-induced corticosterone rapidly peaked between 2-8 hrs. and was dependent on the dose. ACTH displays a delay in the peak time (8-24 hours) and was not dose dependent. When compared to the high dose ACTH, RCI reduced the AUC by 50.0 ± 2.6%, 45.5 ± 5.6% and 27.3 ± 12.5% respectively for 10, 40, and 400 IU/kg. However, there was no significant reduction between any of the ACTH doses tested.

Conclusion: These data show that RCI has a reduced steroidal response compared to synthetic ACTH. RCI has a direct and distinct immunomodulatory response on T cells unique from both synthetic ACTH and steroids. These characteristic effects suggest a mechanism of action for RCI that is steroid-independent and may help explain its benefit in steroid-refractory inflammatory disease.

Adiponectin Stimulates Pro-Inflammatory Cytokine Production by Peripheral Blood Mononuclear Cells from Patients with Early Untreated Rheumatoid Arthritis

Yuan Zhang, Jonathan Aldridge, Anna-Carin Lundell, Anna Rudin, Cristina Maglo. University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: The pathogenesis of rheumatoid arthritis (RA) involves the action of immune cells and fibroblast-like synoviocytes (FLS). Adiponectin, an adipokine produced mainly by adipocytes, is elevated in serum of RA patients compared to healthy controls; moreover, synovial fluid from RA subjects has higher levels of adiponectin compared to controls with osteoarthritis. Adiponectin induces the production of pro-inflammatory cytokines, such as interleukin 6 (IL-6) and IL-8, by

ADIPONECTIN STIMULATES PRO-INFLAMMATORY CYTOKINE PRODUCTION BY PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PATIENTS WITH EARLY UNTREATED RHEUMATOID ARTHRITIS

Yuan Zhang, Jonathan Aldridge, Anna-Carin Lundell, Anna Rudin, Cristina Maglo. University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: The pathogenesis of rheumatoid arthritis (RA) involves the action of immune cells and fibroblast-like synoviocytes (FLS). Adiponectin, an adipokine produced mainly by adipocytes, is elevated in serum of RA patients compared to healthy controls; moreover, synovial fluid from RA subjects has higher levels of adiponectin compared to controls with osteoarthritis. Adiponectin induces the production of pro-inflammatory cytokines, such as interleukin 6 (IL-6) and IL-8, by
FSL from RA patients. However, it remains unclear whether the response to adiponectin in terms of cytokine production is different in immune blood cells from healthy donors compared to RA patients; moreover, it is not known if FLS from healthy subjects can also produce pro-inflammatory cytokines upon adiponectin stimulation.

**Objectives:** The study aims to analyze if adiponectin induces pro-inflammatory cytokine production by peripheral blood mononuclear cells (PBMCs) from both early RA patients and healthy controls. We also aim to study whether adiponectin induces pro-inflammatory cytokine production by FLS from healthy subjects.

**Methods:** PBMCs were isolated from whole blood obtained from 5 healthy donors and 3 early untreated newly diagnosed RA patients using Ficoll-Paque PLUS. FLS were isolated from synovial tissue obtained from 3 healthy donors after knee surgery due to injury. Healthy FLS were cultured in Dulbecco’s Modified Eagle Medium (DMEM GlutaMAX) supplemented with 10% FBS, 1% Penicillin-streptomycin, and 0.5% Gentamycin. Harvested PBMCs and FLS were resuspended in X-VIVO 15 serum-free hematopoietic cell medium and stimulated with different doses of human recombinant adiponectin (1, 5 and 10 µg/ml), and the culture media were collected at different time points. Concentrations of IL-6, IL-8 and TNF-α were measured with ELISA.

**Results:** Unstimulated PBMCs from early RA patients produced higher levels of IL-6 compared to healthy subjects (P<0.001). In healthy controls, both the production of IL-6 and TNF-α was higher in PBMCs stimulated with adiponectin compared to unstimulated PBMCs (n=5, P<0.01 for IL-6 and P<0.01 for TNF-α). Likewise, the production of both IL-6 and TNF-α was higher in PBMCs from early-RA patients after stimulation with adiponectin compared with unstimulated PBMCs (n=3, P<0.01 for IL-6 and P<0.03 for TNF-α) in a dose- and time-dependent manner. After stimulation with adiponectin, levels of IL-6, but not TNF-α, were higher in PBMCs from subjects with early RA compared to healthy controls (P<0.01). Adiponectin stimulation did not induce IL-8 production from PBMCs from either healthy donors or RA patients.

Adiponectin was able to induce the production of IL-6 and IL-8 by FLS isolated from healthy donors (n=3, P<0.03 for IL-6 and P<0.02 for IL-8), but not TNF-α.

**Conclusion:** Our results show that adiponectin induces the production of IL-6 and TNF-α from PBMCs from both healthy subjects and patients with RA and that adiponectin is able to stimulate the production of IL-6 and IL-8 by FLS isolated from healthy subjects. Those results suggest that adiponectin may play a role in the pathogenesis of RA.

**AB0084** ASSOCIATION OF SYNOVITIS VERSUS CARTILAGE LOSS WITH PAIN SEVERITY AND FUNCTIONAL LIMITATION IN PRIMARY KNEE OSTEOARTHRITIS: CLINICAL, ULTRASONOGRAPHY AND MAGNETIC RESONANCE IMAGING

Mohamed Abdelazeem, Mohamed Abdelkareem, Mostafa Doma, Awad Saad.
Alazar university assuit, Rheumatology, assuit, Egypt

**Background:** Osteoarthritis (OA) is a common and debilitating condition associated with pain and mobility that undermines quality-of-life. Magnetic resonance imaging (MRI) has become the most important modality for assessment of pathologic changes in knee cartilage, in both clinical and research environments, also Musculoskeletal Ultrasound (MSU) is a valuable tool for imaging musculoskeletal changes in osteoarthritis. It shows early and late changes.

**Objectives:** The aim of the study was to detect the association of MRI and musculoskeletal ultrasound detected synovitis versus cartilage defect with knee pain severity and functional limitation in patient with primary knee osteoarthritis.

**Methods:** This study was carried out on fifty patients of primary osteoarthritis diagnosed as primary osteoarthritis of knee joints according to American College of Rheumatology Radiologic and Clinical Criteria for Knee osteoarthritis all patients were assessed clinically and knee examined for any swelling tenderness, warmth, limitation of range of motion. Pain severity and functional limitation assessed by Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Musculoskeletal ultrasound and M.R.I of osteoarthritic knee joints were done.

**Results:** MSUS synovitis of examined joints was (0.93 ± 0.94) and cartilage thickness(3.95 ± 1.4), MRI synovitis of examined joints was (0.89 ± 0.93) and cartilage thickness (39.9 ± 13.26), There was Correlation between WOMAC pain score and MSU synovitis and cartilage thickness with Significant difference (p<0.01), also there was Correlation between WOMAC pain score and MRI synovitis and cartilage thickness with Significant difference (p<0.01), a positive Correlation between MSU Synovitis and MSU cartilage thickness was detected Significant difference (p<0.01) r(0.38). Also a Correlation between MRI Synovitis and MRI cartilage thickness show Significant difference (p<0.01) r(0.39).

Sagittal an proton density–weighted magnetic resonance imaging shows focal cartilage loss in the lateral tibiofemoral joint

**Conclusion:** The severity of cartilage loss and severity of the synovitis/effusion are the most significant determinants of pain and functional disability. Synovitis has role on increasing cartilage los MRI and MSU are a non-invasive method which allows comprehensive assessment and detection of early structural changes in osteoarthritic joints.

**AB0085** ULTRASONOGRAPHIC EVALUATION OF THE METACARPAL CARTILAGE THICKNESS IN WEIGHTLIFTERS AND VOLLEYBALL PLAYERS

Öner Iskender1, Bayram Kaymak1, Mural Kara1, Aygen Akin1, Bölenk Ülker2, Levent Ozcakar1, 1Hacettepe University Medical School, Physical and Rehabilitation Medicine, Ankara, Turkey; 1Ankara University Medical School, Sports Medicine, Ankara, Turkey

**Background:** Articular cartilage is inevitably exposed to impact and loading in different sports play. Despite the fact that it is quite prone to different forms of overloading, the cartilaginous structure has not been looked into in the pertinent literature. Accordingly, in this comparative study, we have assessed the metacarpal cartilage in volleyball players and weightlifters whereby different forms of stress is naturally prevalent in the athletes’ hands.
Objectives: To evaluate the possible effects of impact and loading on the metacarpal cartilage and hand functions in young athletes.

Methods: A total of 42 male athletes (19 weight-lifters and 23 volleyball players) and 46 healthy control subjects were enrolled. Demographic and clinical characteristics (age, height, weight, smoking habit, duration/type of sport, dominant hand) were recorded. The 2nd to 5th finger metacarpal head cartilage thicknesses were measured bilaterally using ultrasonography. Hand grip strength was measured with a Jamar dynamometer. Pinch strengths (lateral, tip to tip and three jaw pinch) were measured using a pinchmeter. Michigan Hand Outcomes Questionnaire was also completed for each and every participant.

Results: Metacarpal cartilage thicknesses of the athletes (more predominant in weightlifters) were found to be thicker than those of the healthy controls (all p<0.001). There were no differences between the dominant and non-dominant hands (all p>0.05). Athletes’ handgrip and pinch strengths were higher than those of the controls. In the weightlifting group, Michigan Hand Outcome Questionnaire work performance and pain scores were worse than the other groups.

Conclusion: The presence of increased cartilage thickness measurements in the athletes suggests that sports activities might affect the metacarpal articular cartilage. Highest pain scores and lowest work performance scores in the weightlifters with highest metacarpal cartilage thickness might suggest that impact and loading during their sports play could lead to cartilage edema.

BCP AND CPPD CRYSTALS INFLUENCE THE CHONDROCYTE PHENOTYPE IN DIFFERENT WAYS

Uwe Konk1, Franziska Meyer2, Miriam Bollmann3, Jessica Bertrand4.
1Otto-von-Guericke-Universität Magdeburg, Medical faculty, Magdeburg, Germany; 2Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany; 3Otto-von-Guericke-Universität Magdeburg, Medical Faculty, Experimental Orthopaedics, Magdeburg, Germany

Background: Calcification of cartilage with BCP crystals is a common finding during osteoarthritis (OA) and is directly linked to the severity of the disease and hypertrophic differentiation of chondrocytes. In some OA cartilage samples calcium pyrophosphate dihydrate (CPPD) crystals can be found. The mechanism underlying the formation of the CPPD crystals and their effects on the chondrocytes are not completely understood.

Objectives: The aim of this study was to evaluate the effect of CPPD compared to BCP crystals on the chondrocyte phenotype in OA cartilage.

Methods: Cartilage samples of patients with chondrocalcinosis were used and compared with samples of severe OA patients without chondrocalcinosis and healthy cartilage samples served as control. Radiological presence of chondrocalcinosis was evaluated using standard X-ray pictures, as well as macroscopically inspection. The cartilage samples were stained using von Kossa/Safranin-orange staining. These stainings were used for OA severity scoring using the Charnig-Score. Chondrocyte differentiation markers were evaluated using Collagen-2 and Runx2. mRNA expression of the respective genes after stimulation of C28 chondrocytes with CPPD and BCP crystals was evaluated using qRT-PCR. TUNEL staining was performed to investigate cell death. In vivo results were validated using qRT-PCR for the expression of the respective genes after stimulation of C28 chondrocytes with CPPD and BCP crystals.

Results: Radiologically detectable cartilage calcifications were evident in chondrocalcinosis patients, but absent in OA patients without chondrocalcinosis. Chondrocalcinosis cartilage exhibited an increased collagen 10 expression compared to healthy cartilage, as well as to severe OA cartilage containing BCP calcification. Interestingly, aggrecan and collagen 2 were not reduced in chondrocalcinosis cartilage, but markedly reduced in OA cartilage. TUNEL positive cells were significantly increased in CPPD cartilage compared to OA cartilage, although the histological OA severity was lower. qRT-PCR indicated no relevant influence of CPPD crystals on hypertrophic marker genes, whereas BCP crystals significantly induced hypertrophic differentiation.

Conclusion: BCP and CPPD crystals seem to trigger differential effects on the chondrocyte phenotype. BCP crystals induce hypertrophic differentiation, which is not induced by CPPD crystals.

DLX5 AND DLX6 PROMOTES THE COMMITMENT OF MSC TO OSTEOBLASTIC LINEAGE AND CORTICAL BONE FORMATION

Camille Blaindin1, Morgane Bourmaud1, Éris Hay2, Giovanni Levi1, Martine Cohen Solal1, Inserm U1132, hospital laboisiere, paris, France; 1Univ cnuv/mnhh 7521, Muséum national d'Histoire naturelle, paris, France

Background: Osteoporosis which affects 200 million women worldwide is the consequence of an imbalance of low anabolism to high catabolism, causing a risk of fracture. Impaired anabolism involved reduced osteoblast differentiation. The osteoblast differentiation is mediated by transcription factors, including Dlx5 and Dlx6. Dlx5 is known to have a role in osteoblast/osteoclast couple and as a promoter of osteoblast lineage commitment[1, 2]. Thus, Dlx5 is a transcriptional actor of Runx2[2], a key element of osteoblastic differentiation.

Objectives: The goal of this project is to expand our knowledge about bone formation and cellular precursors of osteoblasts, focusing on Dlx5 and Dlx6.

Methods: We analyze the kinetic expression of Dlx5, Dlx6 and osteoblastic markers during the osteoblast differentiation from murine osteoblastic progenitor derived from calvaria and bone marrow. Same analysis was carried out in osteoblastic precursors from control cells, Dlx5/Dlx6 cells with ex vivo recombination or from KO mice in parallel to human bone marrow cells. We analyzed the bone phenotype of mutated mice in the absence of expression of Dlx5 and Dlx6 under Osx promoter.

Results: Dlx5 and Dlx6 increases at D7 during osteoblastic differentiation in the murine bone marrow and then was stable to D21. The absence of Dlx5/D6 in cells derived from calvaria and bone marrow resulted in decreased levels of osteocalcin and alkaline phosphatase. Dlx5/D6−/− Osx-Cre mice were lethal. Dlx5/D6−/− Oxs Cre mice does not affect cortical and trabecular parameters at 6 weeks but had a significant lower cortical thickness and also lower Tb. Bv/TV and Tb. Th along with a lower BMD at 3 months in both sexes. Moreover, periosteal volume was also lower in mutated mice. The skulls revealed a lack of sutures closures and dental abnormalities at 6 weeks and 3 months in both sexes.

Conclusion: The deletion of these transcription factors under the action of the Osteocalcin promoter generates lethality, in favor of an essential role in bone development. Heterozygous mutation show impaired bone acquisition during growth. To obtain a total deletion of Dlx5 and Dlx6 in osteoblastic precursor cells, a new murine model of conditional induced deletion is generated. Dlx5 and Dlx6 promote osteoblastic differentiation with an effect on late bone markers, in favor of a role in terminal differentiation. Analysis in vitro of Dlx5 and Dlx6 will be confirmed by ongoing in vivo experimentation.

MECHANICAL STIMULUS INDUCED BY CHIROPRACTIC MANIPULATION REDUCES CARTILAGE, SUBCHONDRAL BONE DAMAGE AND SYNOVIAL INFLAMMATION IN AN EXPERIMENTAL MODEL OF OSTEOARTHRITIS

Francisco Miguel Correa-Bueadz1,2, Ardanaxo Mediero-Muñoz2, Ricardo Fujikawa2, Paula Gratal Vifuentes2, Francesca Mulet2, Juan Pablo Medina Giménez2, Gabriel Herrero-Beaumont1,2,3,4, Raquel Largo-Carazo1,2, Arantxa Ortega De Mues1,2, Madrid College of Chiropractic/RCU María Cristina El Esporular, Madrid, Spain; 3Faculdade de Medicina de São Paulo, University of São Paulo, São Paulo, Brazil; 4Centro Nacional De Investigaciones Oncológicas (CNIO), Madrid, Spain; 5Universidad Autónoma De Madrid, Madrid, Spain.

Background: Osteoarthritis (OA) is a degenerative joint disease characterized by cartilage degradation, although both subchondral bone deterioration and synovial inflammation are also hallmarks of the disease. Chiropractic manipulation (CM) is a therapeutic approach focused on the diagnosis, treatment and prevention of musculoskeletal disorders. It is essentially manual, allowing the chiropractor to restore the normal range of motion and function of the joints, muscles, and ligaments. Clinical evidences suggest that CM might exert positive effects in OA patients.

Objectives: The aim of this study was to evaluate the effects of CM on cartilage, subchondral bone and synovial state in an OA rabbit model.

Methods: Ten (4 months old) male New Zealand rabbits underwent knee surgery to induce OA by transection of anterior cruciate ligament. One week after the surgery, CM was performed using the chiropractic adjusting instrument ActivatorV as follows: Force 2 setting was applied onto the tibial tubercle of the right hind limb (true manipulation, TM-OA group), at an angle of approximately 90°, from medial to lateral, whereas the corresponding left hind limb received a false manipulation (FM-OA group) consisting of ActivatorV firing in the air and slightly touching the tibial tubercle. These procedures were repeated 3 times a week for 8 weeks. Three healthy animals were used as control. Following sacrifice, μCT and histological damage evaluation (Mankin score) were done in femur and tibia. RANKL/OPG protein expressions were studied by immunohistochemistry in tibia samples. Sirius red was assessed by Krenn score and immunohistochemistry for macrophages (RAM11) and angiogenesis (CD31) were done. Protein expression of VEGF, COX2, TNFa, IL-1β and MMP3 were determined by Western Blot.

Results: In the OA rabbits, subchondral BMD decreased in relation to control, being significantly reversed in the tibia of TM-OA group. When subchondral bone structural parameters were analyzed by microCT, a significant decrease of bone volume trabecular volume (BV/TV), trabecular number (Tb.N) and trabecular thickness (Tb.Th) was observed in the OA rabbits, while trabecular separation (Tb.S) increased compared to control animals. TM-OA group showed a significant improvement of these parameters compared to FM-OA group. FM-OA joint had higher Mankin score (cartilage damage) than control joints, and TM decreased Mankin score compared to FM-OA (p<0.05). The study of RANKL and OPG in cartilage and subchondral bone showed that the significant increase in the RANKL/OPG ratio observed in both tissues respect to controls, was partially reversed in TM-OA group. OA synovial membranes presented a total Krenn synovitis score higher than healthy animals; however, TM-OA rabbits exhibited scores lower than FM-OA (p<0.05). RAM11 immunostaining revealed lower expression in TM-OA synovial membrane compared to FM-OA (p<0.05). Similarly, the significant increase in proinflammatory cytokines (COX2, TNFa and IL-1β) and MMP3 were observed in the synovial membranes of OA rabbits respect to controls, being partially reversed in TM-OA group. Likewise, VEGF and COX31 expression was higher in FM-OA synovium compared to TM-OA.

Conclusion: These results suggest that mechanical stimulus induced by CM may retard the pathologic progression of OA. The beneficial effects of CM might be associated with an improvement in bone and cartilage damage and also inflammatory state.

Disclosure of Interests: None declared.

IN VITRO EFFECT OF FASCIOLA HEPATICA EXTRACT ON SYNOVIAL FIBROBLASTS OF RHEUMATOID ARTHRITIS PATIENTS

Suelen Dalmolin1,2, Renata Temus Pedo1,2, Raimir Ferlaineiro3, Jordana Mirand de Souza Silva1,2, Vanessa Hax4,5, Fabiany Gonçalves2, Ricardo Fujikawa2, Paula Gratal Vifuentes2, Francesca Mulet2, Juan Pablo Medina Giménez2, Gabriela Herrero-Beaumont1,2,3,4, Raquel Largo-Carazo1,2, Arantxa Ortega De Mues1,2, Madrid College of Chiropractic/RCU María Cristina El Esporular, Madrid, Spain; 3Faculdade de Medicina de São Paulo, University of São Paulo, São Paulo, Brazil; 4Centro Nacional De Investigaciones Oncológicas (CNIO), Madrid, Spain; 5Universidad Autónoma De Madrid, Madrid, Spain.

Background: Synovial fibroblasts (FLS) have an aggressive and invasive profile and play a major role in RA[1]. Available therapeutic options are effective for induction and maintenance of disease remission[2], but not all patients respond to treatment and there is no cure. New therapeutic options need to be explored. Studies have shown that products secreted by helminths contain components with anti-inflammatory properties[3,4], capable of suppressing Th1 immune response[5] and the production of inflammatory cytokines[6]. One example is the immunomodulating properties[7] of the extract of Fasciola hepatica.

Objectives: To evaluate the effects of F. hepatica extract in FLS from RA patients.

Methods: Firstly, the cultures of FLS isolated from the synovial fluid of RA patients were exposed at different concentration of F. hepatica extract (60µg/mL, 80µg/mL and 100µg/mL) and analyzed after 24h, 48h and 72h by MTT cell proliferation assay. FLS controls were exposed to standard culture medium. The effect of extract was also evaluated through adhesion and wound healing assay, and TNF-α production after IFNγ stimulation. Statistical analysis was performed with ANOVA or T Test and the p<0.05 were considered statistically significant.

Results: F. hepatica extract decreased the cell proliferation of FLS at concentration of 100µg/ml after 48h (83.8% ± 5.0 extract vs 100.0% ± 0.0 control; p<0.05), and at concentrations of 80µg/ml (84.4% ± 3.0 extract vs 100.0% ± 0.0 control; p<0.05) and 100 µg/ml (89.8% ± 3.8 extract vs 100.0% ± 0.0 control; p<0.05) after 72h, when compared with control group. Based on these results, the concentration of 100µg/ml and the time of 48h were chosen for the following tests.

Results: FLS with extract show with extract compared to control, FLS ± 5µ extract vs 116.3 cells ± 7.9 control; p<0.05) and migratory potential (40.2 inch ± 13.9 extract vs 58.7 inch ± 6.5 control). Moreover, after treatment there was a trend of decreased TNF levels (7.0 pg/mL ± 0.5 extract vs 8.1 pg/mL ± 0.7 control).

Conclusion: Taken together, our results suggest that extract of F. hepatica is able to reduce the aggressive and invasive profile of FLS. However, further analyses are needed for a better understanding the mechanisms of the effect of F. hepatica extract on FLS and its different components, such as cytokin.

INHERITED DEPITE OF PROTEOGLYCAN MIMICKING SEPTIC ARTHRITIS

Angel Foyo1,2, Roberto Pape1,3, Roberta Casp1,3, Alessandro Consolaro3,4, Roberto Gastaldi2, Angelo Ravelli2, Marco Gattorno1, Paolo Picco1, Tuuli Rinne3,1, IRCCS Istituto Gianna Sinis, Clinica Pediatrica e Reumatologia, Genova, Italy; 2IRCCS Istituto Gianna Sinis, Clinica Pediatrica ed Endocrinologia, Genova, Italy; 3Radboud university medical center, Genome Diagnostics Nijmegen – Department of Human Genetics, Nijmegen, Netherlands.

Background: Aggrecanopathies (AP) are a heterogeneous group of skeletal disorders caused by ACAN gene mutations leading to proteoglycan synthesis defect. Inherited called aggrecan that plays a pivotal role in the organization of the extracellular matrix of the growth plate cartilage. Clinically, patients with AP display bone dysplasias ranging from severe spondyloepimetaphysial dysplasia to familial cases of osteochondritis dissecans (OCD) associated with short stature and typical facial dysmorphisms[1].

Objectives: Herein we report a patient with AP referred to our Institute for an inflammatory articular involvement mimicking a septic arthritis.

Methods: Molecular analysis of the ACAN gene was performed using Sanger sequencing method.

Results: A 14-year-old boy displayed pain and swelling at the right elbow. Echo- scan revealed an effusion in both condor and olecranon recess. Acute phase reactants were negative. A month later, since non-steroidal anti-inflammatory drugs were administered without benefit, the patient was admitted in our Institute. On physical examination, acute arthritis at the right elbow was noted: it appeared painful, warm, and not erythematous. Laboratory test showed slight elevation of acute phase reactant (C reactive protein 1.7 mg/dl, normal value <0.5).

AB0088 MECHANICAL STIMULUS INDUCED BY CHIROPRACTIC MANIPULATION REDUCES CARTILAGE, SUBCHONDRAL BONE DAMAGE AND SYNOVIAL INFLAMMATION IN AN EXPERIMENTAL MODEL OF OSTEOARTHRITIS

AB0090 INHERITED DEPITE OF PROTEOGLYCAN MIMICKING SEPTIC ARTHRITIS
Arthrocentesis was performed and sterile synovial fluid was found. Magnetic resonance images displayed a bone fragment detachment from the humeral condyle of the right elbow with synovium thickening and persistent effusion: the diagnosis of OCD was pointed out.

The patient showed minor dysmorphisms (i.e. dolicocephaly, hypotelorism, arched palate and brachydactyly of the IV finger of both hands) and parents reported a previous episode of OCD when he was 12: at that time, symptoms resolved with non-weightbearing and non-steroidal anti-inflammatory therapy after few days. Furthermore, the patient went under regular endocrinologist follow-up for short stature since he was 8. At the age of 10, his height was 123 cm, SDS 2.4, and growth hormone (GH) stimulation tests showed partial response to insulin tolerance test (GH peak 6.27 ng/ml). Bone age at the X-ray of right hand and wrist was delayed of 12 months. Human recombinant GH replacement therapy was administered without significant growth-velocity improvement. Although the patient came to observation because of suspected elbow septic arthritis, we re-considered the diagnosis: namely, i. recurrent episodes of OCD; ii. short stature that was poorly responsive to the human recombinant GH treatment, iii. mild skeletal and facial dysmorphism, led us to hypothesize a form of aggrekanopathy.

Molecular analysis of the ACAN gene revealed the novel missense variant c.6970T>C, p.Trp2324Arg in the G3 domain of the protein. Notably, another mutation of the G3 domain (c.7249G>A) has been previously related to aggrekanopathy2. Intra-familial molecular analysis allowed us to detect the same variant in other three subjects (the mother and 2 siblings) affected only by brachydactyly and short stature.

Conclusion: A patient carrying a novel mutation of the ACAN gene presented an atypical form of aggrekanopathy mimicking inflammatory and/or septic arthritis associated with slight short stature and bone dysmorphisms. Further studies are needed to investigate a possible role of this novel ACAN gene variant in the inflammatory articular involvement.

EFFECTIVENESS AND SAFETY OF PRILOCAINE IN COMBINATION WITH HYALURONIC ACID IN KNEE OSTEARTHRITIS: AN OPEN-LABEL STUDY

Methods: A total of 64 patients with knee OA diagnosed as per the American College of Rheumatology (ACR) criteria were enrolled in the study. Of these patients, 42 had grade 2 and others had grade 3 disease. A single injection of the combination product was administered to all patients. The combination product contained 1 mg hyaluronic acid, 14 mg cross-linked hyaluronic acid, 6.9 mg sodium chloride and 3 mg prilocaine hydrochloride in a 2 ml solution. The combination was injected into a single joint in the painful knee through the anteromedial aspect of the joint. Assessments were performed before the treatment and at 4 and 12 weeks post-treatment by the same physician. The study was designed as an open-label, observational study. The patients were assessed using the Lysholm Knee Scoring Scale. Patient scores were categorized as poor (0-64), fair (65-83), good (84-90) or excellent (91-100). Pain and functional measures were evaluated by this scale. Results: There was a female (n=58) predominance in the study sample. The mean age of the patients was 56.4 ± 15.3 years. As rated by the Lysholm Knee Scoring Scale, the number of patients with good scores rose to 6 at 4 weeks and 16 at 12 weeks. These findings were statistically significant (p<0.05). None of the patients received any additional medication and all continued their daily activities. A home exercise program was followed by the patients throughout the study. Global evaluation of the study physician rated 40 patients in good or excellent condition, whereas 34 patients self-rated themselves in good or excellent condition. Six patients had local symptoms including swelling, pain and redness which were of mild-to-moderate intensity. These symptoms resolved in 1-3 days with simple interventions.

Conclusion: Local hyaluronic acid injections may represent an alternative to systemic medications in the treatment of knee osteoarthritis and they can provide long-term relief with minimal adverse effects when combined with local anesthetics without the need for additional drugs or treatments.

DIFFERENTIATION OF ADIPOSE DERIVED MESENCHYMAL STEM CELLS OBTAINED FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHMATOSUS ANKYLOSING SPONDYLITIS AND SYSTEMIC SCLEROSIS

Ewa Kuca-Wgraw1, Magdalena Plebanczyk1, Anna Wajda2, Krzysztof Bonek3, Piotr Guszko4, Piotr Szczepnys5, Marzena Oleśiska6, Wodzimierz Małinski6, Ewa Kowtyn1.

1National Institute of Geriatrics, Rheumatology and Rehabilitation, Institute of Geriatrics, Rheumatology and Rehabilitation, Molecular Biology Department, Warsaw, Poland; 2National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland; 3National Institute of Geriatrics, Rheumatology and Rehabilitation, Molecular Biology Department, Warsaw, Poland; 4National Institute of Geriatrics, Rheumatology and Rehabilitation, Rheumatology Clinic, Warsaw, Poland; 5National Institute of Geriatrics, Rheumatology and Rehabilitation, Systemic Connective Tissue Diseases Clinic, Warsaw, Poland.

Background: Cartilage and bone destruction occurs in many rheumatic diseases. While the use of biologic drugs may delay the destruction but still it cannot be averted. Adipose tissue is an easy accessible and rich source of MSCs. Application of mesenchymal stem/stromal cells (MSCs) may be a promising option for successful tissue regeneration in therapy of ankylosing spondylitis (AS) systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) patients.

Objectives: The aim of this study was to compare differentiation potential of ASCs obtained from AS, SLE, SSc patients and ASCs line originating from healthy volunteers (hASCs). The phenotype of these cells has been also analysed.

Methods: ASCs obtained from AS (n=9), SLE (n=10), SSc (n=10) patients and 5 commercially available hASCs lines were used in study. Cells in passage 4 were used in each experiment. Phenotype of ASCs was evaluated by flow cytometry. Differentiation was evaluated by using osteogenic, chondrogenic or adipogenic media. At the end of differentiation process cells were harvested and total RNA was isolated. Relative quantification (RQ) of gene expression level were calculated by the 2-ΔΔct method.

After 4 weeks of chondrogenic differentiation, mRNA level of SOX9 and aggrecan (ACAN) mRNA was evaluated by RT-PCR. Additionally glycosaminoglycan (GAG) deposition was analysed by alcian blue staining. After 2 weeks of osteogenic differentiation, expression of RUNX-2 collagen 1a1 (COL1a1) and osteopontin (OPN) mRNA has been determined. Calcium deposition has been determined by alizarin red staining. After 3 weeks of adipogenic differentiation expression of CCAAT/enhancer-binding protein (C/EBP), peroxisome proliferator activated receptor-γ (PPAR-γ) and fatty acid binding protein 4 (FABP4) was determined.

Results: All ASCs cultured in osteogenic medium showed calcium deposition. The expression of RUNX-2 and OPN mRNA was significantly higher in AS-ASCs. Cells obtained from SLE and SSc revealed significantly lower expression of COL1a1 than hASCs lines.

The results of alizarin blue staining showed chondrogenesis of cells obtained from all patients types. No statistically significant differences between AS, SLE, SSc and hASCs lines were observed in Sox9 mRNA expression. However, all patients derived cells expressed a lower of ACAN mRNA level.

Conclusion: AS, SLE and SSc ASCs have phenotype comparable with hASCs line. The patients derived ASCs highly to differentiate into any of the 3 cell types, although the process is altered.

A REGULATORY ROLE OF ANTXR1 IN RANKL-INDUCED OSTEOCLAST DIFFERENTIATION AND FUNCTION

Chang-Hoon Lee1, Ju-Young Kim2, Chong Hyuk Chung3, Yoon-Jung Choi3, Wan-Hee Yoo4, Myeung-Su Lee5, Winkwang Universiity Hospital, IKSAN, Korea, Rep. of (South Korea); 1School of Medicine, Wonkwang University, IKSAN, Korea, Rep. of (South Korea); 2Chonbuk National University Hospital, Jeonju, Korea, Rep. of (South Korea); 3Chonbuk National University Hospital, Jeonju, Korea, Rep. of (South Korea)

Background: Antrax toxin receptor 1 (ANTXR1) has been known to have relationship with extracellular transmembrane protein deeply associated with the process of bone formation and exert important role in angiogenesis. However, there have been no reports to prove the effects of ANTXR1 on bone metabolism mediated by two types of bone cells, osteoclasts and osteoblasts. The aim of this study is to reveal the role of ANTXR1 in the differentiation and function of osteoclasts and osteoblasts.

Objectives: The aim of this study is to reveal the role of ANTXR1 in the differentiation and function of osteoclasts and osteoblasts.

Methods: To determine the effect of ANTXR1 on osteoclastogenesis or osteoblast differentiation, we examined TRAP staining, F-actin staining and Pit assay, or ALP and Alizarin Red mineralization staining, respectively. The mechanism of ANTXR1 by transfection of retrovirus or siRNA analyzed using real-time PCR and western blot analysis. Also, the effect of ANTXR1 on osteoclast-mediated angiogenesis of endothelial cells assessed by in vitro vascular tube formation assay of human umbilical vein endothelial cells (HUVECs).

Results: Through gaining- and loss-of-function studies, we found that ANTXR1 positively regulated receptor activator of nuclear factor kappa B ligand (RANKL)-induced osteocalcit differentiation and bone resorption with no effects on osteoblast differentiation. During ANTXR1-mediated regulation of osteoclastogenesis, phosphorylation of early signal transducers, c-Jun N-terminal kinase (JNK), Akt, and inhibitor of kappa B (IκB) was affected, which in turn alteration of mRNA and protein levels of c-Fos and nuclear factor of activated T cells cytoplasmic 1 (NFATc1). In addition, genetic manipulation of ANTXR1 in bone marrow macrophages (BMMs) modulated the capillary-like tube formation by HUVECs via two kinds of angiogenic factors, matrix metalloproteinase-9 (MMP-9) and vascular endothelial growth factor-A (VEGF-A). These results explained the important role of ANTXR1 in osteoclast differentiation and functional activity, as well as osteo- clast-mediated angiogenesis of endothelial cells.

Conclusion: Taken together, it was proposed that ANTXR1 might be a promising candidate for gene therapy related with bone metabolic diseases and further, have potential to be served as an important biomarker in the research fields of bone metabolism associated with vascularization.

ANALYSIS OF THE GENE EXPRESSION OF URAT-1, ABCG2, GLUT-9, OCT3, IL1B, TL4 AND ALPK1 IN MONONUCLEAR CELLS OF PATIENTS WITH INTER-CRITICAL GOUT

Natsuko Paniagua Diaz1, Laura Sanchez Chapu2, Carlos Aguilar Salinas2, Alcia Ortega Mora3, Ambar Lopez Macaya4,5, Instituto Nacional de Rehabilitacion, Neurociencias, Mexico City, Mexico; Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Endocrinologia y metabolismo, Mexico City, Mexico

Background: Gout is a common type of arthritis that has increased in the world due to environmental and genetic factors that associate it with an altered metabolic state. In Mexico, overweight, obesity, diabetes and metabolic syndrome have increased in children and adult population. These alterations are associated with the development of gout in adults.

The gout is characterized by an inflammatory chronic process caused by the deposition of monosodium urate crystals (CUMs) in the joints. The recognition of these crystals by macrophages and neutrophils in the joint activates innate immunity. However, high levels of uric acid (UA) in intercritical phase could activate the expression of urate transporters and inflammation genes in other cell types such as monocytes and peripheral blood lymphocytes.

Objectives: The aim of this project was to analyze the changes in gene expression of SLC22A12, SLC2A9, SLC22A3, ABCG2, ALPK1, IL1β, TL4 and peripheral blood mononuclear cells (PBMC) of Mexican patients with inter-critical gout arthritis and controls without hyperuricemia (HU) comparing it with their metabolic profile.

Methods: The determination of the biochemical parameters was performed by a serum - blood chemical test for uric acid, glucose, triglycerides, cholesterol, HDL, LDL and creatinine. Through the use of UniCiel DxC 600, Synchron Clinical System, the total RNA of the PBMC cells was amplified by qRT-PCR using the GoTaq® 1-Step RT-PCR System real kit (Promega) and the Qiagen Rotor Gene Q kit, using specific primers. The gene expression analysis were performed by the ΔCT and ΔΔCT method and using GAPDH as a reference gene to compare the expression of urate transporter genes and inflammatory genes in the study groups.

The expression results were associated to clinical and biochemical parameters such as levels of uric acid, triglycerides, and weight. All statistical analyses were performed with the SPSS program (IBM 22 version for Windows, SPSS, Inc., Chicago, IL, EU), using student’s t-test or Mann-Whitney test, for the normal and non-normal data, when p <0.05 or p<0.01.

Results: In this study we compared 24 patients with inter-critical gout and 26 controls without HU. It was found that the expression of ABCG2 was higher in the patients than in controls and that the expression of OCT3 was higher in overweight people regardless of whether they had gout or not compared with normal weight people. The expression of ALPK1 was higher among patients and controls while the expression of TL4 and IL1β was not different. The patients had a higher mean in the levels of UA, triglycerides, weight, age and hypertension, but lower HDL than the controls.

Conclusion: Patients with inter-critical gout maintain metabolic alterations associated with the metabolic syndrome although some of them are under treatment. They are also characterized by having overexpression of ABCG2 and ALPK1. These conditions could favor a new attack of gout.

NOVEL EX VIVO MODEL OF SEPTIC ARTHRITIS DEVELOPED TO IDENTIFY BIOMARKERS RELEASED UPON ARTICULAR INFECTION

Kathryn McCaig, Caroline Atherton, Neal L. Millar, Carl Goodyear, Tom Evans, Iain McInnes, University of Glasgow, Institute of Infection, Immunology, and Inflammation, Glasgow, United Kingdom

Background: Septic arthritis (SA) is most commonly caused by infectious agents such as Staphylococcus aureus. Due to the morbidity and mortality associated with the disease, joint infections are treated as a medical emergency and therefore early diagnosis is essential. Unfortunately, no reliable biomarkers are available to assist diagnosis, beyond serum CRP and synovial fluid culture.

Objectives: To generate a novel ex vivo model of septic arthritis comprised of cartilage matrix, neutrophils and SA-associated Staph. aureus, to identify biomarkers released upon an inflammatory host response to infection.

Critical Methods: Cartilage explants biopsied from human femoral heads were compared to chondrocyte disks differentiated from mesenchymal stem cells (MSC). MSC differentiation into chondrocytes under defined media and growth factor conditions was confirmed by IHC staining for collagen II on the disks. Explants and disks were infected for 48h with 10^5 CFU Staph. aureus (SA patient derived). Structural damage was measured by glycosaminoglycan (GAG) release. Neutrophils were purified from health donor blood samples using the StemCell whole blood isolation kit. 10^5 cell were added in the final 4h of bacterial infection. Disks were stained with eosin to visualise microscopic damage, CMFDA for viability and PI to identify cell death.

Results: Co-culture of MSC-derived chondrocyte disks with neutrophils or Staph. aureus alone resulted in microscopically identifiable structural damage to the disk matrix. The addition of neutrophils in the final 4h of the Staph. aureus co-cultures resulted in enhanced structural damage. Assessment of cellular viability revealed that both neutrophils and Staph. aureus alone induced cell death throughout the disk whilst the combination of both resulted in total abrogation of viable chondrocytes. Subsequent evaluation of GAG release, however, showed no clear differentiation between the conditions and as such this model was judged not to be sufficient for biomarker development. In comparison, femoral head cartilage explants studies demonstrated that Staph. aureus infection in this explant model resulted in significant GAG release after 24h and 48h, which was consistent between donors.

Conclusion: Cartilage explants provide a superior and more physiologically relevant cartilage matrix model for the ex vivo analysis of septic arthritis. Staph. aureus infection resulted in reproducible damage to cartilage matrices that was not emulated in an MSC-derived chondrocyte disk system. These findings suggest that the femoral head cartilage explants are the optimal model to identify biomarkers for joint infections.

GENE EXPRESSION AND FUNCTIONAL COMPARISON BETWEEN MESENCHYMAL STEM CELLS FROM LATERAL AND MEDIAL CONDYLES OF KNEE OSTEOARTHRITIS PATIENTS

Clara Sanjurjo Rodriguez1,2,3, Thomas Baboolal4, Frederique Ponchel2, Jehan El-Jawhari2, Joseph Aderinto4, Owen Wall4, 4Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 4Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 2NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Osteoarthritis (OA) is the most common degenerative joint disorder, mainly afflicting the weight-bearing joints, and is the leading cause of physical disability worldwide. Despite the identified risk factors, the exact pathogenesis of osteoarthritis remains unclear (1). Formation of mesenchymal stem cells’ (MSC) clusters and their aberrant osteogenic differentiation in OA subchondral bone (SB) has been proposed as a key contributor to progression of OA in animal models (2) and in human hip OA (3). MSCs have a crucial role in joint repair but it remains unknown how OA severity affects MSC numbers or characteristics. Knee OA provides a good model to determine this as in knee OA, distribution of damage is usually asymmetrical and tends to be more severe in the medial (Med) compartment compared to the lateral (Lat) compartment (4).

Objectives: The aim of this study was to determine whether there were differences in MSC numbers, topography and gene expression (GE) between Med and Lat femoral condyles of patients with knee OA.

Methods: Condyles were obtained from OA patients that underwent total knee replacement (n=16). UK Ethics Committee approval. 14/YH0087). Decalcified samples were histologically evaluated for cartilage damage, bone sclerosis and CD271+ MSC distribution (2). MSCs were extracted from SB and sorted using the CD271+CD45- phenotype for GE analysis. Colony forming unit (CFU-F) (3), trilineage differentiation (5) and population doubling (PD) assays were performed. MSC numbers, topography and GE were compared between condyles.

Results: Med condyles presented significantly higher (p<0.05) degree of cartilage damage (median OARSI score 20, range 15-20) compared to Lat condyles

Coculture of Synovial Membrane and Cartilage: A Potential Human Ex Vivo Cartilage Degradation Model

Johanna Mucke1, Victoria Warzynski, Ellen Bleck, Thomas Pauly, Tim Claßen, Chupai, Stefan Vordenbäumen, None declared

Objective: To study the potential of synovial membrane and cartilage coculture as a model for cartilage degradation and to identify factors influencing PG synthesis.

Methods: Synovial membrane and cartilage were cocultured for up to 28 days. PG content was analyzed by ELISA and staining with Alcian Blue.

Results: PG content was significantly lower in coculture compared to control (p = 0.0007).

Conclusion: The coculture model can be used to study cartilage degradation and factor influence PG synthesis.

SECRETOMES ANALYSIS OF CHONDROCYTES AND SYNOVIAL FIBROBLASTS IN OSTEOARTHRITIS: MODULATION BY VIP

Selene Pérez García1, Valentina Calzada2, Tamara Hermida Gómez2, Mar Carrión2, Raúl Villanueva Romero1, Yasmina Juarranz1, Francisco J. Blanco2, Isaac Fuentes-Boquete1,2, Silvia Maria Díaz-Prado2,3, University de la Coruña (UDC), A Coruña, Spain, 2Instituto de Investigación Biomédica de A Coruña (INIBIC), A Coruña, Spain

Background: Osteoarthritis (OA) is a chronic, degenerative and multifactorial disease, and the main cause of pain and dysfunction among elder people. It is characterized by a progressive loss of function of synovial joints (1). The role of chondrocytes in this pathology has been widely studied (2), but other joint cells are also involved, including the synovial fibroblast (SF) (3-5). During joint destruction, inflammatory and degradative mediators are released by joint cells and from the extracellular matrix (ECM), including fibronectin degradation fragments (Fn-f) (3, 4, 6). On the other hand, vasoactive intestinal peptide (VIP) exerts anti-inflammatory and immunomodulatory actions in several autoimmune and inflammatory disorders, including OA (3, 5). The study of the mediators released by joint cells and their modulation by pro- and anti-inflammatory mediators would be useful for the design of novel therapies for OA treatment.

Objectives: To analyse the mediators released from co-cultures of OA chondrocytes and SF, and to elucidate the effect of Fn-fs and VIP on these cells.

Methods: Human articular chondrocytes (HAC) and SF from 4 OA patients were provided by the Rheumatology Service at Complejo Hospitalario Universitario A Coruña. Isolated cells were recovered and plated in SILAC DMEM-Flex lacking Arginine and Lysine. In the case of medium and heavy media, isotope-labeled L-lysine and L-arginine were used. When 100% of labeling was reached, cells were put in co-culture and incubated in serum-free medium with or without Fn-fs (10 μM) or Fn-fs + VIP (10 nM) for 48h. Cell secretomes were separated on a 10% SDS PAGE gel. Gels were stained with Coomassie blue and the resulting lanes were cut into slices and subjected to in-gel digestion. Extracted peptide mixtures were desalted and concentrated via NtuP, subjected to liquid chromatography using a Tempo nano LC equipped with a Sun Collect MALDI Spotter, and analyzed by MALDI-TOF/TOF. Identification of peptides and proteins and relative quantification were performed using Protein Pilot software (Sciox).

Results: Cell secretomes were analysed in 4 OA patients in duplicate. Database search (UniprotKB/Swissprot and Venn’s diagrams drawing tool (Venny 2.1.0) allowed us to identify 79 common proteins in the HACS-SF co-cultures. Among them, VIP was able to modulate 33 different proteins, significantly reducing 9 of them: CH3L1, PTX3, PGS2, MMP2, Complement C1r, Complement C1s, TBA1, QSOX1, and CATB. These proteins include inflammatory and ECM proteins, pro- and complement system proteins among others, which play a main role in the OA pathogenesis.

Conclusion: VIP decreases inflammatory and degradative mediators in HAC-SF co-cultures, potentially slowing the progression of the disease and supporting its therapeutic role in osteoarthritis.

GENERATION OF OSTEOARTHRITIC MESENCHYMAL STROMAL CELL LINES

Mariña Piñeiro-Ramil1,2, Rocío Castro-Viñuelas1,2, Clara Sanjuán-Rodríguez1,2, Silvia Rodríguez-Fernández2,3, Tamara Hermida Gómez2, Francisco Javier de Toro-Santos2,3, Francisco J. Blanco2, Isaac Fuentes-Boquete1,2, Silvia María Díaz-Prado1,2, 1Universidade da Coruña (UDC), A Coruña, Spain, 2Instituto de Investigación Biomédica de A Coruña (INIBIC), A Coruña, Spain

Background: Bone-marrow mesenchymal stromal cells (MSCs) are multipotent self-renewal adult cells with high potential to regenerate the damaged tissues in degenerative diseases such as osteoarthritis (OA). Nevertheless, their usefulness for osteochondral Regenerative Medicine research is hampered by their proneness to senescence when in vitro cultured. Currently, MSC lines available are scarce and present limitations regarding their differentiation capacities. In addition, there is no OA MSC line available for research on this disease.

Objectives: The aim of this study was to generate and characterize immortalized human OA and non-OA MSC lines for their use in osteochondral Regenerative Medicine research.

Methods: For the generation of the immortalized MSC lines, SV40LT and GFP-fused human telomerase reverse transcriptase (hTERT) were used. Primary MSCs derived from two hip OA patients and one hip fracture patient without OA were transduced by spinoculation at 800 xg for 45 minutes. Transgene expression was induced by valproic acid. Nuclear expression of SV40LT and GFP was tested by immunofluorescence. Proliferation and senescence were investigated through calculation of population doublings (PDs) at each passage after immortalization and β-galactosidase negative staining. Normal induction of telomerase expression by flow cytometry and self-renewal experiments. Multi-lineage differentiation potential was analysed histochemical, immunohistochemical and molecularly.

Results: Three MSC lines have been generated: two OA and one non-OA. As shown by immunofluorescence, SV40LT is expressed in the nucleolus of these cells, while GFP-fused hTERT is expressed in the nucleoli. A constant proliferation rate throughout subculturing in addition to β-galactosidase negative staining confirms that immortalized MSC lines do not senesce, unlike primary MSCs. Expression of CD29, CD44, CD73, CD90, CD105, CD34 and CD45 was tested by analysis of CD29, CD44, CD73, CD90, CD105, CD34 and CD45 expression by flow cytometry and self-renewal experiments. Multi-lineage differentiation potential was assessed histochemical, immunohistochemical and molecularly.

Conclusion: Both OA and non-OA MSCs are susceptible to immortalization by SV40LT and hTERT. For they increased lifespan combined with keeping of most...
of primary MSC characteristics, these MSC lines are expected to be valuable tools for the research on Regenerative Medicine for OA as part of Tissue Engineering in vitro models.

Background: Prevalence of knee osteoarthritis (OA) has doubled since the mid-20th century. Interestingly, this increase cannot be explained solely by longer life expectancy and the obesity epidemics (1). Therefore, other environmental factors known to have increased in the recent years could be part of the explanation.

Objectives: We performed a systematic literature review (SLR) to summarize the existing knowledge about associations between OA and pollutants.

Methods: Pubmed database was used to identify studies reporting data on OA and pollutants in humans (examples of MeSH terms: “Polychlorinated Biphenyls (PCB)” or “Lead”). Abstracts from international congresses were reviewed for the past 2 years, combined with manual curation. Studies were classified in epidemiological clinical studies, pollutants assessments in ex vivo OA joint tissues, and in vitro effect on human chondrocyte.

Results: As of January 15, 2019, 193 potentially relevant articles were screened. Among them, 14 were selected. After manual curation, a total of 21 full text articles were analyzed. Ten articles reported epidemiological clinical studies. Four articles underlined the link between PCB and OA: in the 3 articles reporting association with past exposure to PCB, the most robust one showed that risk of OA was significantly increased, at least in men (OR 4.1 [95% CI: 1.8-11.2] for men and 1.3 [95% CI: 0.8-2.3] for women). In the 4th study, the highest serum concentration of PCB was associated with a higher risk of arthritis: maximal adjusted OR (aOR) was 3.2 [95%CI: 1.6-6.7], p<0.01. However, sensitivity analysis of OA patients did not find any significant association in this study. Two articles focused on serum levels of perfluorocarboxanate (PFDA) and perfluorocarboxylate (PFOS): aOR to have OA in the PFDA highest serum level quartile was 1.42 [95%CI: 1.26-1.59], p<0.00001 and 1.55 [95%CI: 0.99-2.43]. Data were conflicting for PFOS: aOR to have OA in the PFOS highest serum level quartile was 1.77 [95%CI: 1.05-2.96], p<0.05 and 0.76 [95%CI: 0.68-0.85], p<0.00001. Two articles showed an association between serum lead levels and knee OA in the general population. In Korea, the risk of radiographic OA was increased in the highest quartile of lead serum level compared to the lowest one (aOR 1.90 [95%CI: 1.09-3.32] for men and 1.81 [95%CI: 1.17-2.77] for women). In the United States, risk kidney radiographic OA correlates with increased lead serum levels. In the last study, household air pollution induced by the cooking heat source was examined: compared to electricity, the risk of OA was increased with the use of liquids (kerosene/paraffin: aOR 1.73 [95%CI: 1.33-2.25]) or solid (coal, wood: aOR 1.73 [1.32-2.27]), (agriculture/crop: aOR 2.0 [1.47-2.72]. Lead and zinc accumulation was reported in 7 articles: 4 of them analyzed the concentration in OA joint obtained during arthroplasty and showed highest concentration in cartilage versus bone. In another, lead serum levels were associated with biomarkers of joint tissue metabolism. Two studies with X-ray fluorescence on cadavers found a high accumulation of lead and zinc in the articular cartilage landmark. Four studies assessed the in vitro effect of pollutants on human chondrocytes: the viability of chondrocytes was reduced in presence of PCB, gold, silver, fluorid acid and bisphenol A. Conclusion: This SLR suggests a possible link between OA and pollutants but the designs of the studies, the populations investigated and the type of pollutants were still too heterogeneous and limited to conclude definitively that pollutants represent a new environmental risk factor for OA. However, this SLR highlights a critical need for novel epidemiological, clinical and basic research studies in order to identify other potential environmental factors in OA.

AB0105  THE EFFECT OF TROMBOSIT RICH PLASMA APPLICATION ON DEGENERATED CARTILAGE: IN VITRO EXPERIMENTAL STUDY
Kevser Arapoglu, Ömer Faruk Sendik, Serhan Sakarya, ADU, PRandM, IZMIR, Turkey

Background: Osteoarthritis is the most common problem among musculoskeletal system disorders. Platelet-rich plasma (PRP) has been suggested to be
beneficial in the treatment of degenerative musculoskeletal problems. The pur-
pose of this study is to evaluate PRP treatment efficacy on degenerated cartilage.

Objectives: In this study, we aimed to determine the efficacy of platelet-rich plasma (PRP) on mechanically damaged chondrocyte cells by using different doses of calcium, different duration of exposure and different methods of activation of platelet.

Methods: Human source chondrocytes (CHON-001 ATTC CRL-2846) were used in the study. Chondrocyte cells were produced in appropriate medium and an experimental cartilage model was created. The platelet-rich plasma was produced from platelets obtained by apheresis in the laboratory, from blood of volunteer. The platelet-rich plasma was adjusted at five different doses as 4.8x10⁶, 2.4x10⁶, 1.2x10⁶, 6x10⁵, 3x10⁵. The first group of platelet-rich plasma was left intact, the second group was denatured within seven minutes by applying ultrasonic waves in water, the third group was activated with calcium chloride and the fourth group was determined as control group. Using a ten microliter pipette tip, a linear damage to the opposite side was created at the widest part of the well. Cell migration was monitored at 0-4-8-24 and 48 hours at x10 magnification by in vitro microscopy and wound healing was evaluated by photographing. Migration intervals were determined quantitatively using the program named Image J.

Results: When the rates of recovery were compared to the groups, no significant improvement was observed in the intact and denatured platelet groups at 4-8 and 24 hours compared to the control group. In the third group which was activated with calcium, no significant improvement was observed in all doses at 4 and 8 hours compared to the control group. However, at the 48th hours there was a significant improvement in the doses of 1.2x10⁶, 2.4x10⁶ and 4.8x10⁶ compared to the control group (p < 0.0001).

When evaluated in terms of activation, there was a significant improvement in the explanted and intact groups at the 48th hour, compared to the calcium-activated group at doses of 3x10⁶ and 6x10⁵ (p < 0.01).

Conclusion: Cartilage damage is the main pathology in the pathogenesis of osteoarthritis. All doses of PRP used in the study contributed to improvement. Meanwhile, the most critical parameter for platelet migration was timing and significant improvement was started after 48 hours.

CHANGES IN THE miRNA PROFILE AND HYPOXIC BEHAVIOR OF HUMAN CHONDROCYTES BY THERAPEUTIC NUCLEAR MAGNETIC RESONANCE THERAPY (NMRT)

Birgit Lohberger 1, Lukas Weigl 1, Nicole Stuendt 1, Anda Mann 2, Andreas Leitner 3, Werner Kullich 1, Bibiana Steinecker-Frohnwieser 4

Medical University of Graz, Department of Orthopaedics and Trauma, Graz, Austria; 2Medical University of Vienna, Division of Anaesthesiology and Pain Medicine, Vienna, Austria; 3Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Sankt ufern, Austria; 4Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Groebling, Austria

Background: Therapeutically applied nuclear magnetic resonance (NMRT) is discussed to participate in repair processes regarding cartilage and influences pain signaling. Studies concerning NMRT therapy implemented within the treatment of patients with degenerative rheumatic diseases outlined pain reduction as the main clinical outcome [1]. NMRT is also known to lead to improvements in pain from patients with knee OA due to a chondroprotective effect on the articular cartilage. In spite of this significant reduction in pain, the mechanism of action of NMRT at the cellular level remains to be elucidated.

Objectives: To substantiate the application of NMRT the aim of this work targets the underlying mechanisms at the cellular level. We investigated NMRT induced changes of the miRNA profile of human healthy and OA chondrocytes and studied the respective miRNA targets. Based on the fact that articular cartilage functions as an avascular and hypoxic connective tissue we were further able to demonstrate that NMRT modulation seems to be more pronounced under hypoxic conditions.

Methods: Human primary chondrocytes and the chondrocyte cell line TC28/2a were used for the experiments. RNA was extracted using RNEasy Mini Kit and was used as input for the Thermo Fisher Ion Total RNA-Seq Kit v2. Sequencing was performed on the Ion Proton sequencer using the Ion PI Hi-Q DQ v2 Sequencing 200 system. Signal processing and base calling was performed using Torrent Suite version 5.6. Hypoxic conditions were established and enabled cell growth in presence of 1-5% O2. Expression of miRNAs and target proteins was studied by a standard PCR procedure as well as protein detection by western blot. HDAC activity was measured by HDAC Glo III assay.

Results: Characterization of the miRNA profile showed a slight up regulation of miR-24-1-5p and miR-502-5p while miR-25-5p and miR-365-5p was down regulated. For miR-365a-5p known to directly targeting HDAC and NFκB a decrease of HDAC activity by NMRT was detected. The miR-25-5p target COX2 was changed in expression by NMRT whereas no influence on CDK4 knowing to be controlled by miR-24-1-5p was detected. NMRT treatment of chondrocytes under hypoxic conditions (0.5 - 5 % O2) changed the expression profile with respect to NO3, IGf2, PDGF and IGFBP and a change in the expression of HIF1a under the influence of IL1b was observed. The hypoxic conditions changed apoptotic behavior of the cells, NMRT showed no influence.

Conclusion: A closer look into the mechanism of the NMRT at the cellular level revealed a modulatory effect on miRNA, their regulatory units and chondrocytes under hypoxic conditions. The results underline our former results indicating that NMRT counteracts IL-1b induced changes which mean that pain reduction by NMRT might be due to NMRT holding against inflammatory mechanisms under OA.

S-ALLYL-L-Cysteine attenuates inflammation related oxidative stress parameters and increases adhesion capacity of primary human osteoarthritic articular chondrocytes

Zubeir Ezmozguoz 1, Zehra Aytin Bek 1, Berra Gaker 2, Behira Bilik 1, Cem Nuri Alektin 1, Mehmet Eren Tercan 1, Cimen Kasan 1, 1Gazi University Faculty of Medicine, Cellular Stress Response and Signal Transduction Research Laboratory, Department of Medical Pharmacology, Ankara, Turkey; 2Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 3Baskent University, Rheumatology, Ankara, Turkey; 4Yildirim Beyazt University, Orthopedics and Traumatology, Ankara, Turkey; 5Karal Dr. Lufti Kirdar Training and Research Hospital, Rheumatology, Istanbul, Turkey

Background: Osteoarthritis (OA) is characterized by progressive destruction of the articular cartilage, and chondrocytes, the only cells in articular cartilage, are in charge of maintaining the homeostasis of articular cartilage via modulating extracellular matrix anabolism and catabolism [1]. Due to the association of the degree of oxidative degeneration of chondrocytes and OA, preventing impaired redox signaling and reactive oxidative death of chondrocyte are suggested as potential targets to relieve OA [2]. In this respect, some photochemicals have been shown to be potential agents for preventing or treating OA due to their antioxidant and anti-inflammatory properties [3].

Objectives: We studied the effects of an antioxidant S-allyl-cysteine (SAC), a major sulphur-containing amino acid component of garlic[4], on the redox system, and its associations with the proliferation rate and index of human OA chondrocytes (OACs).

Methods: Chondrocytes were isolated from the joint cartilages of OA patients (grade 4, mean age= 66 years, BMI= 29.7 ± 4.4 kg/m²). The alterations in cell proliferation (MTT), adhesion profile (RTCA-CELLigence System), reactive oxygen species generation (ROS), lipid hydroperoxides levels (LPO), HNE protein adduct levels (HNE), AGE-protein adduct levels (AGE), 3-nitrotyrosine levels (3-NT),
The role of CD70 in the pathogenesis of Rheumatoid Arthritis

Su-In Yoo, Seong Wook Kang, Jinhyun Kim, In Seol Yoo, Chan Keol Park, Ha-Reum Lee. Chungnam National University Hospital, Rheumatology division, Dept. of Int. Med., Daejeon, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis (RA) is characterized by inflammation and cellular proliferation in the synovium. Activated lymphocytes and proinflammatory molecules are important in the pathogenesis of RA.

CD70 belongs to the tumor necrosis factor (TNF) ligand superfamily and is typically present on activated B and T lymphocytes, natural killer cells and mature dendritic cells. CD70 expressing CD4+ T cells are enriched in the peripheral blood and synovial fluid of patients with RA and promote autoimmunity via co-stimulatory CD70-CD27 interaction.

CD70 expression is associated with aggressive phenotype of cancer cells and it is mediated by hypoxia inducible factor 2α (HIF-2α).

Objectives: In this study, we examined the presence of CD70 on the surface of fibroblast-like synoviocyte (FLS) of patients with RA and investigate the role of CD70 in the pathogenesis of RA associated with HIF-2α.

Methods: RA FLS were obtained from 7 patients with RA who were undergone operation like total knee replacement or synovectomy. All patients were fulfilled the 2010 ACR-EULAR classification criteria for RA.

Expression of CD70 and HIF-2α messenger ribonucleic acid (mRNA) were analyzed in RA-FLS by quantitative polymerase chain reaction (qPCR).

Results: SAC increased OAC's proliferation rate and adhesion profile at relatively low concentrations (1, 10 and 100 nM), but inhibited at higher concentrations (1-100 μM). SAC (1 nM-10 μM) inhibited ROS, LPO and 3-NT, but not HNE- and AGE-modified proteins levels. SAC increased Gpx but drastically down regulated ICE/caspase-1, indicating a potential redox regulating and anti-inflammatory effect.

Conclusion: Results suggest that SAC has favorable effects on OA chondrocytes through protecting proliferation capacity and ameliorating redox-mediated inflammatory pathways. Further studies are needed to investigate its therapeutic potential in patients with OA.

Rheumatoid arthritis - etiology, pathogenesis and animal models

AB1019

SYSTEMIC OVEREXPRESSION OF INTERLEUKIN-22 INDUCES EXPRESSION OF THE NEGATIVE IMMUNE-REGULATOR SOCS3 AND POTENTLY REDUCES COLLAGEN-INDUCED ARTHRITIS IN MICE

Joyce Aerts, Debbie Roelveldt, Monique Helisen, Birgitle Walgreen, Ellis Vitters, Peter van Lent, Fons van de Loo, Wim van den Berg, Peter van der Kraan, Marie Koenders. RIMLS, Experimental rheumatology, Nijmegen, Netherlands

Background: High interleukin-22 (IL-22) levels are detected in serum and synovial fluid of rheumatoid arthritis (RA) patients. The increased IL-22 serum levels in RA patients correlated positively with multiple clinical disease parameters like disease activity score (DAS)28 and serum levels of rheumatoid factor. The role of IL-22 in autoimmunity and inflammation appears to be greatly contradictory, being both pro- and anti-inflammatory. Especially the anti-inflammatory properties of IL-22 are not well understood.

Objectives: We aimed to investigate the anti-inflammatory and immune-suppressive effect of IL-22 during experimental arthritis.

Methods: Collagen-induced arthritis was induced in DBA1 mice by immunization and booster with bovine collagen type II (CII). After booster, but before arthritis onset, IL-22 was overexpressed either locally or systemically using adenosine construct (AdIL-22) or Luciferase as control (AdLuc). 1x10⁷ plaque-forming units (PFU) of the adenoviruses were injected intra-articularly for local overexpression or 3x10⁶ PFU was injected intravenously for systemic overexpression in immunized mice, and mice were sacrificed 10 days later. Macrosopic scoring and histological analysis was performed, and mRNA expression and protein production of various pro- and anti-inflammatory mediators was determined in synovial tissue, spleen, and serum.

Results: Local overexpression of IL-22 by injection of AdIL-22 in the knee joint of CII-immunized mice resulted in an unaltered arthritis incidence and severity as compared to the control virus AdLuc. Additionally, no changes in mRNA expression or protein production were observed in CIA mice locally overexpressing IL-22. In contrast, systemic overexpression of IL-22 potentely reduced disease incidence and severity, which was also confirmed by histological analysis. Systemic levels of IL-1β, IL-17, GM-CSF and MCP1 were unaltered in mice overexpressing IL-22 systemically. However, these mice showed significantly lower serum levels of IFNγ, TNFα, MIP1α, and IL-10. Interestingly, the significantly enhanced splenic SOCS3 expression was found to negatively correlate to serum TNFα and MIP1α levels, which is in line with our hypothesis that the observed reduction in the cytokine levels is mediated in a SOCS3-dependent manner.

Conclusion: With this study, we revealed clear anti-inflammatory effects of IL-22 overexpression during collagen-induced arthritis, which are completely dependent on the systemic route of administration. Additionally, we were the first to show that this protective effect of IL-22 during experimental arthritis is likely orchestrated via up-regulation of the negative regulator SOCS3.

RITUXIMAB INDUCED GRANULOMATOUS HEPATITIS WITH A SARCOCIDOSIS LIKE REACTION: A BLINDED TRIAL IN MICE

sultan almogairen1, Ahmad Alhumaidi2, "king saud university, riyadh, Saudi Arabia; 2king saud university, riyadh, Saudi Arabia

Background: Rituximab is useful in patients with rheumatoid arthritis (RA) with persistently active disease despite adequate trials with other disease-modifying antirheumatic drugs (DMARDs).

Objectives: To determine whether the inhibition of the B cell CD20 receptor by rituximab results in acute hepatitis in BALB/c mice.

Methods: Twenty BALB/c mice were studied. Ten mice received subcutaneous (SC) injection of rituximab (0.31mg per 25g body weight per 0.03 ml normal saline) at 0, 1, 2 and 4 weeks. For the control group, 10 mice received a SC injection of normal saline (NS) (0.03 ml). At the 10th week post injection, the mice were sacrificed, and histopathological studies were conducted.

Results: Of the rituximab-treated group, 1/10 mice died. Liver histology for the rituximab-treated group showed that 7/9 displayed histopathological changes in the lobular cellular infiltrates of eosinophils, lymphocytes and histocytes, in addition to granuloma formation. In contrast, only minimal inflammation was observed in 3/10 mice in the control group (p<0.05).

Disclosure of Interests: None declared

Conclusion: To our knowledge this is the first experimental controlled study demonstrating rituximab may play a role in inducing granulomatous hepatitis with a sarcoidosis-like reaction.

AB0112 EVALUATION OF A NEW MULTIPLEX TECHNOLOGY ASSAY FOR ANTICITRULLINATED PEPTIDE ANTIBODIES DETERMINATION
Mounira Benidir1, Samir Salah2, Dalila Fodil3, Hachemmi Djidji4, Malik Djennane5, Habiba Amrou5, Nabila Attal6. 1Pasteur Institute of Algeria, Immunology, Algiers, Algeria; 2Mustapha Pacha Hospital, Immunology; Algiers, Algeria; 3Liberal, Rheumatology, Algiers, Algeria; 4Douera Hospital, Rheumatology, Algiers, Algeria; 5Tizi-Ouzou Hospital, Rheumatology, Tizi-Ouzou, Algeria; 6Hussein Dey Hospital, Medical Biology, Algiers, Algeria

Background: Anti-citrullinated peptides antibodies (ACPAs) are highly specific RA markers. In 2010, experts included them in the ACR/EULAR criteria for disease diagnosis, usually, measured by ELISA. However, a new assay has been developed, recently: Multiplex technology, which allows searching IgG ACPA directed against four citrullinated peptides: Human (HCP1 and 2) and Viral (VCP1 and 2).

Objectives: First, assess ACPA diagnostic performances using Multiplex technology and then compare them to those obtained with the reference technique (ELISA).

Methods: We studied sera of 273 RA patients versus 165 controls (64 healthy controls and 101 patients with other pathologies). We realized ACPA dosage by Multiplex technology and compared them with ELISA assay results. In the end, we looked for a correlation between ACPA production and shared epitope expression in RA patients.

Results: The overall agreement calculated between the two methods was about 91.3%. As to the comparison of diagnostic values of Multiplex technology vs. ELISA, it revealed a sensitivity of 80.2% vs. 82.4% and a specificity of 95.8% vs. 95.5%. Then, for a better evaluation, we plotted ROC curves for ACPA detected by Multiplex technology and ELISA ones. Therefore, we obtained the following areas under the curve (AUC) (p value <0.0001): Anti- HCP1 (0.775), HCP2 (0.798), VCP1 (0.715) and VCP2 (0.837) and ACPA ELISA (0.867). Finally, our results reveal higher serum levels of ACPA detected by Multiplex technology, in case of SE expression (SE (+) vs SE (-): (p value <0.0001).

Conclusion: Diagnostic performance of ACPA detection methods is comparable with relatively good agreement. Our study demonstrated an association between elevated serum levels of anti-HCP and anti-VCP and SE expression, in RA patients.

AB0113 ARTHRITIS IS ASSOCIATED WITH CEREBROVASCULAR ENDOThelial Dysfunction: MECHANISTIC INSIGHTS IN THE RAT ADJUVANT-INDUCED ARTHRITIS MODEL
Bomain Bady1, Perle Totson1, Marie-Lynda Bouressam2, François Dupuis3, Frank Verhoeven1,2,3, Daniel Wendling1,2,3, Céline Demougeot1,2,3, PEPITE EA4267, FHU INCREASE, Univ. Bourgogne Franche-Comté, F-25000 Besançon, France; 1Université de Lorraine, CITHEFOR, F-54000 Nancy, France; 2CHRU Besançon, Rhumatologie, F-25000 Besançon, France; 3EPILAB EA 4266, Univ. Bourgogne Franche-Comté, F-25000 Besançon, France

Background: Stroke is the second cause of premature mortality and sudden death in rheumatoid arthritis (RA) after myocardial infarction. The mechanisms involved in the high risk of stroke are currently known, but data from the general population argue for a contribution of cerebrovascular dysfunction.

Disclosure of Interests: Antonio Alvarez de Cienfuegos : None declared, Lucia Cantero-Nieto: None declared, José Alberto García-Gómez: None declared, Gemma Robledo: None declared, Daniel Sánchez-Cano: None declared, Javier Martín Ibanez: None declared, Miguel A González-Gay: Grant/research support from: Prof. MA González-Gay received grants/research supports from Abbvie, MSD, Jansen and Roche., Speakers bureau: Consultation fees/participation in company sponsored speaker’s bureau from Pfizer, Lilly, Sobi, Celgene, Novartis, Roche and Sanofi., Norberto Ortego: None declared.
OBJECTIVES: The aim of our study was to investigate cerebrovascular function in the rat adjuvant-induced arthritis (AIA) model and to unravel the mechanisms involved, with special emphasis on the pathways regulating nitric oxide (NO) vascular availability.

METHODS: Arthritis was induced in 6 weeks-old male Lewis rats by a single injection at the base of the tail of a suspension of Mycobacterium butyricum in Freund’s incomplete adjuvant. A control group received saline. Thirty-three days after induction, middle cerebral artery (MCA) were dissected and mounted on two glass micropipettes in a small vessel arteriograph before being pressurized at 80 mmHg. Endothelial function was evaluated in vessels pre-contracted with serotonin (10^{-5} M) by measuring the relaxant effect of bradykinin (BK, 10^{-6} M), adenosine diphosphate (ADP, 10^{-6} M) and cumulative concentrations of acetylcholine (Ach, 10^{-10} to 10^{-4} M) in the presence or not of a Nitric Oxide Synthase (NOS) inhibitor (L-NAME, 10^{-4} M), an arginase inhibitor (nor-NOHA, 10^{-4} M), a NOS co-factor (BH4, 10^{-5} M), an analog of superoxide dismutase (Tempol, 10^{-4} M). The relaxant response of vascular smooth muscle cells to a NO-donor (SNP, 10^{-10} to 10^{-5} M) was also evaluated.

RESULTS: Vasodilation induced by BK, ADP and Ach were significantly reduced in AIA compared to controls rats (p<0.0001). L-NAME decreased Ach-induced relaxation in controls but not in AIA rats. By contrast, nor-NOHA (p<0.0001), Tempol (p<0.0001) and BH4 (p<0.02) significantly improved Ach-induced relaxation in AIA but not in controls. The response to SNP was not different between the 2 groups.

CONCLUSION: Arthritis is associated with endothelial dysfunction in MCA. These results indicate that this model is relevant for mimicking the cerebrovascular low NOS activity, a high arginase activity and excessive superoxide anions production. Overall data suggest that therapies able to reverse the imbalance in NOS/arginase pathways would be efficient for reducing the incidence of cerebrovascular events in RA.

AB0114 POTENTIAL THERAPEUTIC EFFECTS OF CENTAUREA CYANUS L. ON RHEUMATOID ARTHRITIS THROUGH CD38+ NK CELLS

Xiaotian Chang1, Hongxing Wang2. 1Shandong University, Medical research center of Qianfoshan hospital, Jinan, China; 2Shandong University, Medical research center of Qianfoshan hospital, Jinan, China

BACKGROUND: CD38 catalyzes nicotinamide adenine dinucleotide (Coenzyme I, NAD+) to cyclic ADP ribose (cADPR). We previously reported that CD38 is specifically overexpressed in synovial membrane during rheumatoid arthritis (RA), and CD38+ natural killer (NK) cells are not only highly proportionate in the peripheral blood of RA patients but are also closely related to the disease severity. Cynus CYANUS L. is an inhibitor of CD38 that has anti-inflammatory effects.

OBJECTIVES: This study aimed to determine the roles and mechanisms of CD38 and its inhibitor C3G on RA and provides a basis for C3G to become a potential therapeutic agent for RA.

METHODS: This study employed bovine type II collagen-induced arthritis (CIA) rats, in vitro cultured RA synovial fibroblasts (RASFs) and mononuclear cells (MNCs) as models to explore the potential therapeutic effects and mechanisms of C3G on RA.

RESULTS: Rats following C3G injections showed significantly alleviated CIA, while the concentrations of inflammatory interleukin (IL)-6 and interferon (IFN)-γ and the proportion of CD38+ NK cells decreased, the levels of anti-inflammatory IL-10 and the proportion of regulatory T (Treg) cells increased, in the peripheral blood and synovial fluids (Figure 1). After C3G treatment, the RASF proliferation and the level of IL-6 in the culture medium decreased, apoptosis increased. C3G also increased IL-2 and IL-10 secretion, and decreased IL-6 and IFN-γ level and the proportion of CD38+ NK in MNCs. The coculture of CD38+ NK cells with MNCs depleted of CD38+ NK cells decreased the proportion of Treg cells and the IL-10 levels, meanwhile the coculture in the presence of C3G showed increased the proportion of Treg cells and the IL-10 levels and decreased IL-6 and IFN-γ level. However, C3G did not directly affect the Treg cell proliferation and their cytokine production. C3G treatment also increased sirtuin (Sirt)6 expression, while decreasing the expression of the NK activation receptor natural killer group 2D (NKG2D) in CD38+ NK cells. The expression level of NKG2D in CD38+ NK cells transfected with Sirt6 siRNA was not significantly changed in the presence of C3G. After CIA rats were injected with both C3G and OSS_128176, a Sirt6 inhibitor, the rats remained joint inflammation and the low proportion of Treg cells, although the proportions of CD38+ NK cells decreased in these CIA rats. After C3G treatment, the concentration of tumor necrosis factor (TNF)-α in the CD38+ NK culture medium increased and the concentration of IFN-γ decreased. When cocultured MNC and CD38+ NK cells were treated with C3G and TNF-α or C3G and anti-IFN-γ antibody, the proportion of IL-10+ Treg cells increased significantly, while the proportion decreased when cocultured MNC and CD38+ NK cells were treated with C3G and IFN-γ or C3G and anti-TNF-α antibody. The secretion level of TNF-α decreased sharply, and the concentration of IFN-γ increased significantly in the CD38+ NK cell culture treated with both Sirt6 siRNA and C3G.

CONCLUSION: C3G has therapeutic effects for CIA and RA. C3G decreases the proportion of CD38+ NK cells, and increases the expression of Sirt6 in CD38+ NK cells, which increases TNF-α secretion and decreases IFN-γ secretion and sequentially stimulates MNC differentiation into IL-10+ Treg cells and the secretion of IL-10. This study also suggests that the inhibition of MNC differentiation into Treg cells by CD38+ NK cells is an important cause of immune imbalance in RA and CIA (Figure 2).

**SEMAPHORIN 4A PERPETUATE SYNOVIAL INTERACTIONS WITH CD4+ T CELLS AND OSTEOCLAST DIFFERENTIATION: IMPLICATION IN RHEUMATOID ARTHRITIS**

Zhu Chen, Yuanyuan Zhang, Xu Zheng, Li Xiaomei. University of Science and Technology of China, Hefei, China

**Background:** Rheumatoid arthritis synovial fibroblast (RASF) and T cells are important contributors in the pathogenesis of RA. Semaphorin 4A has been reported to be elevated in RA patients and play crucial role in promoting inflammation of RA. However, whether semaphorin 4A could facilitate RASF interactions with CD4+ T cells and osteoclastogenesis is less known.

**Objectives:** The present study aims to investigate the role of semaphorin 4A-Plexin B1 axis in RASF interactions with CD4+ T cells and osteoclastogenesis in vitro.

**Methods:** Mouse synovial fibroblasts (SF) were isolated from collagen-induced arthritic mice and cultured in vitro with TNF-α and IL-1β for 24h. Small interfering RNA (siRNA) against Semaphorin 4A and Plexin B1 were constructed and transfected into SF via adenovirus. Spleenic CD4+ T cells isolated from arthritic mice were cocultured with SF under anti-CD3 and anti-CD28. The proportion of Th17 cells was determined at 5 days. BMSC isolated from blood of healthy donors were incubated with 1 μg/ml Plexin D1 neutralizing antibody overnight. Cells were washed for monocyte enrichment and cultivated for 14 days in a MEM supplemented with M-CSF and RANKL. Osteoclast differentiation was evaluated by TRAP staining. Total RNA was extracted and expression of osteoclast markers were examined by quantitative real-time PCR.

**Results:** Adenovirus-Mediated siRNA efficiently inhibited expression of Semaphorin 4A and Plexin B1 in SF. The proportion of Th17 cells was significantly decreased in both Semaphorin 4A and Plexin B1 transfected SF cocultures. The number of TRAP-positive osteoclasts were significantly decreased in cultures that pretreated with Plexin D1. Consistently, blocking of Plexin D1 signaling dramatically downregulated mRNA expression level of Trap, Cathepsin K and NFATc1. Conclusion: Semaphorin 4A perpetuate synovial fibroblasts interactions with CD4+ T cells by promoting Th17 differentiation. Moreover, Semaphorin 4A-Plexin D1 axis promote osteoclastogenesis and therefore might serve as a potential therapeutic target in the treatment of RA.

**HOMOCYSTEINYLATED ALPHA 1 ANTI-TRYPSIN AS A POTENTIAL ANTIGENIC TARGET IN RHEUMATOID ARTHRITIS**

Tania Colasan1, Danilo Sabatinielli1, Carmine Mancone2, Arbi Pecani3, Mariangela Speciai1, Marta Vormo1, Cristiano Barbati1, Alessandra Ida Celia1, AnnaCarrara Decuoc1, Carlo Pernicone4, Fulvia Ceccarelli1, Francesca Spadone1, Vincenzo Barnaba1, Fabrizio Conti1, Guido Valesini1, Cristiano Alessandri1, None declared

1Sapienza University of Rome, Department of Internal Medicine and Medical Specialties, Roma, Italy; 2University Hospital “Shefket Nidom”, Department of Internal Medicine, Tirana, Albania

**Background:** Rheumatoid arthritis (RA) is a chronic, inflammatory, autoimmune disorder that primarily affects joints. Beside the well-known rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) have been reported to be a very useful diagnostic and prognostic marker of RA, recently antibodies against carbamylated (anti-Carb) have been described also in ACPA-negative RA patients. However, more than 20% of RA cases are still defined as seronegative forms. Therefore, the individuation of new antibody specificities in RA could be helpful for diagnostic and prognostic purposes.

**Objectives:** The goal of this study was to identify the and the immunologic characterization of post-translational modified synovial fluid (SF) autoantigens, specifically targeted by autoantibodies from sera of seronegative RA patients.

**Methods:** SFs from 5 seronegative RA patients were collected, pooled and treated with hyaluronidase. After removal of both albumin and IgG, the sample was washed and cleansed, concentrated, separated by 2-dimensional electrophoresis (2-DE) and then transferred by Western blooting to nitrocelluose membrane, for autoantigen detection by immunoassay, using a pool of sera from 5 seronegative RA patients. The antigenic protein spots were identified by peptide mass fingerprint, using a Matrix-Assisted Laser Desorption/Ionization-Time Of Flight (MALDI-TOF) mass spectrometer.

**Results:** This approach revealed Alpha 1 Anti-Trypsin (A1AT) as a target of RA patients autoantibodies. Pooled SFs were also analyzed by reverse-phase nanoliquid chromatography and tandem mass spectrometry, to confirm the presence of A1AT and for the identification of A1AT post-translational modifications.

Homocysteinylated A1AT was immunoprecipitated from pooled SFs of RA seronegative patients, and, after a dilatation and concentration process, was used as an antigen to detect anti-homocysteinylated A1AT antibodies by Enzyme-Linked ImmunoSorbent Assay (ELISA). In order to this, consecutive patients with RA, osteoarthritis (OA), psoriatic arthritis (PsA), and healthy donors were enrolled and sera were collected.

**Results:** Homocysteinylated A1AT was identified as a potential antigenic target not only in ACPA and RF positive RA patients but, more importantly, also in RA seronegative patients. Antibodies anti-homocysteinylated A1AT were found in 66.7% (44/66) RA patients seronegative for ACPA and RF, 88.6% (39/44) RA patients, 15% (3/20) OA patients, 26.3% (5/19) PsA patients and in none (0/41) of healthy donors.

**Conclusion:** Homocysteinylated A1AT was identified as a new potential antigenic target of autoantibodies in sera from RA patients, including RA seronegative patients. This tool may be useful in diagnosis and monitoring of the disease and may contribute to understand the immunopathogenic mechanisms of RA in future studies.

The mechanism of traditional Chinese medicine prescription Er-miao-san in the treatment of rheumatoid arthritis based on cholinergic anti-inflammatory pathway

Ze Wang, Huiqin Hao, Li Zhen, Yuling Gao, Jianhong Guan. SHANXI UNIVERSITY OF CHINESE MEDICINE, Basic Laboratory of Integrated Traditional Chinese and Western Medicine, Shan Xi, China

Background: Rheumatoid arthritis (RA) is a chronic progressive autoimmune disease. The traditional Chinese herbal formula Er-miao-san (EMS) has been used to treat RA demonstrating significant clinical efficacy; however, the mechanism of action remains unclear. In view of the important role of α7 nicotinic acetylcholine receptor (α7nAChR) in the cholinergic anti-inflammatory pathway (CAP) for the regulation of inflammation and cytokines. Indeed, we previously found a correlation between CHRNA7 (encoding α7nAChR) expression and EMS, we hypothesized that it may play a role in the anti-inflammatory effects of EMS.

Objectives: The mechanism of EMS in the treatment of RA based on CHRNA7 involved in the regulation of CAP.

Methods: We established a CIA model with female Wistar, and the effects of intragastric administration of EMS on the expression of CHRNA7, arthritis score, inflammatory, and articular cartilage changes, was examined in the joints. The serum levels of TNF-α, IL-6, and IL-1β were determined using commercial ELISA kit.

Results: The CIA model was successfully established. Macroscopic changes of arthritis, such as redness and swelling, were clearly observed in the CIA rats, but were attenuated by the treatment of EMS. The mean arthritis score was markedly lower in the EMS-treated group (EG, P < 0.05). The same results were found in the serum levels of IL-6 and IL-1β. Synovial edema and extensive infiltration of inflammatory cells occurred in the CIA rats, but were repaired by the treatment of EMS. Cartilage tissue was thinning, dissolution and disappearance, as well as extensive inflammatory cell infiltration with plasma cells and lymphocytes, was observed in the articular cartilage of the ankles in CIA group. In contrast, EMS treatment prevented cartilage degeneration and markedly reduced inflammation. Immunohistochemistry (IHC) analysis showed positive signals of CHRNA7 was expressed on fibroblast-like synoviocytes, macrophages, and endothelial cells in the joints. Effect of EMS on the expression of CHRNA7 protein in the joint by Western blot (WB) analysis. IHC and WB relative optical density values of CHRNA7 was significantly higher in EG compared with CIA group (P < 0.05).

Conclusion: EMS can significantly alleviate the symptoms of arthritis in CIA rats by regulating the expression of CHRNA7 in CAP. It provides a scientific research foundation for the further development of EMS and explores more ways to treat RA.

Disclosure of Interests: None declared
there is a lack of relevant reports on their function in chronic, multisystem autoimmune diseases.

**Objectives:** Here, using molecular biology techniques were performed to evaluate the expression of 7 chemokines/chemokine receptors in different tissues and their localization in the joints.

**Methods:** We established a collagen-induced arthritis (CIA) model in female Wistar rats and evaluated the expression patterns of 7 chemokines/chemokine receptors ([CCR3, CCR5, CXCR7, CCL5, CXCR3, CXCR4, and CXCL10]) in different tissues using RT-PCR and western blotting and their localization in the joints using immunohistochemistry.

**Results:** The mRNA expression of CCR3, CCR7, CXCR4, and CXCL10 was significantly higher in the spleen and joints, while that of CCR5 and CCL5 was significantly higher in the liver and that of CXCR5 was significantly higher in the lung, spleen, and joints (Fig. 1). Protein expression patterns largely corresponded to mRNA expression patterns. In the joints, CCR3, CCR5, and CXCR7 were expressed in fibroblast-like synoviocytes (FLS), macrophages, stromal cells, and endothelial cells. CCL5, CXCR3, and CXCR4 were expressed in FLS, endothelial cells, and stromal cells. CXCL10 was expressed throughout the synovium, stromal cells, and endothelial cells (Fig. 2).

**Conclusion:** Seven chemokines/chemokine receptors are widely expressed in different tissues in the CIA rat model, and all are involved in the inflammatory response. Our results provide a basis for investigations into the mechanism of action of RA and suggest that chemokines may become novel targets for RA treatment.

AB0123  CCL17 IN SYNOVIAL FLUID AND PLASMA OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

Cecil Hor1,2,3, Adrian Achuthan2,3, Keith Lim, John Hamilton2,3. 1Western Health, Rheumatology, Melbourne, Australia; 2Australian Institute of Musculoskeletal Science (AIMSS), Melbourne, Australia; 3University of Melbourne, Melbourne, Australia

Background: Despite the advancements in management of rheumatoid arthritis (RA) in the last two decades, there are still a significant number of patients who cannot achieve low disease states or remission with the current available therapy. Granulocyte macrophage-colony stimulating factor (GM-CSF) is a key mediator in inflammation and autoimmunity, and has emerged as a novel therapeutic target in RA. However, potential adverse side effects warrant further investigation of a more specific target.

Objectives: Chemokine (C-C motif) ligand 17 (CCL17) is a downstream mediator of GM-CSF and has recently been shown to be regulated by GM-CSF in human monocytes. Significantly, CCL17 has a non-redundant role in inflammatory arthritis and pain. We investigated the expression levels of CCL17 in synovial fluid and plasma from RA patients.

Methods: We recruited RA patients with symptomatic swollen joints, who require joint aspiration for diagnostic and/or therapeutic purposes. Synovial fluid and plasma were collected and CCL17 protein levels were determined by ELISA.

Results: CCL17 protein was measured in synovial fluid and plasma samples from our cohort of RA patients. Levels of secreted CCL17 were higher in plasma [median 240 (40-580) pg/ml] compared to synovial fluid [median 100 (30-300) pg/ml] p<0.05.

Conclusion: Significant levels of CCL17 were detected in RA synovial fluid and plasma. This is a novel study which demonstrates and compares the presence of CCL17 in synovial fluid and plasma from matching RA patients. The expression of CCL17 in plasma can make it a useful potential biomarker for RA, while its expression in synovial fluid suggests that CCL17 may be a therapeutic target for treating RA.

AB0124  IMPACT OF INFLAMMATORY CYTOKINE IL-1β ON THE EXPRESSION OF MULTIPLE DRUG RESISTANCE PROTEIN BCRP/ABCG2 IN SYNOVIOCYTES OF PATIENTS WITH RHEUMATOID ARTHRITIS

Fang Yuan Hu1, Ning Yan1, Jie Liang1, Xiang Cong Zhao1, Li Zhao-Hua1, Chong Gao1, Li Xiao-Feng1, Cai Hong Wang1. 1The Second Hospital of Shanxi Medical University, Taiyuan, China; 2Department of Pathology, Brigham and Women’s Hospital, Harvard Medical School, MA, United States of America

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease characterized by synovitis and vasospasm27. So far, The biggest challenge on the current field of RA treatment is the production of DMARDS multidrug resistance (MDR) and the most critical mechanism for the production of MDR is the ABC transporter family-mediated increase in target cell drug exclusion, while inflammatory cytokines play an important role in its expression regulation. Our previous research have confirmed that IL-1β, IL-6 and IL-17 are involved in the regulation of P-glycoprotein (P-gp) expression in lymphocytes of RA patients. The breast cancer resistance protein (BCRP/ABCG2) is also a highly efficient efflux pump, which absorbs, distributes, and excretes drugs or exogenous substances in the body22. IL-1β is a cytokine involved in the whole process of RA, which can aggravate the inflammatory response. However, there is no research on the effect of IL-19 on the expression of BCRP in RA Fibroblast-like synovicyes (FLS).

Objectives: To explore the effects of different concentrations of IL-1β on the expression of drug resistance proteins in FLS of RA patients at different time points.

Methods: Synovial tissues of untreated RA patients (n=3) were extracted by Joint surgery. FLS culture system in vitro was established and passed to the 6th generation so or to do the experiments. FLS cells were divided into A, B, C, D four groups randomly with different treatments: Group A was the cell control group. Group B, C, D were respectively co-cultured with low (20ng/ml), middle (50ng/ml), high (100ng/ml) concentrations of IL-1β. They were cultured respectively for 24 hours, 48 hours, and 72 hours. The effect of IL-1β on the expression level of BCRP mRNA was observed at different concentrations and at different time points.

Results:
1. With the proliferation of IL-1βculture, the expression of BCRP mRNA increased. Under the same concentration of IL-1β[20ng/ml or 50ng/ml], the expression of BCRP mRNA in the 72h group was higher than that in the 24h group or 48h group (P<0.05). At the concentration of IL-1β[200 ng/ml, the 48h group showed higher levels of BCRP mRNA expression than the 24h group (P<0.05).
2. The expression of BCRP mRNA increased with the increase of IL-1βconcentration. After 48h of IL-1βculture, the 100 ng/ml group showed high levels of BCRP mRNA expression compared with the 0 ng/ml group (P<0.05). After 72h of IL-1βculture, compared with the 0 ng/ml group, the expression of BCRP mRNA was significantly increased in the 20 ng/ml or 50 ng/ml or 100 ng/ml group (P<0.01); and the 100 ng/ml group showed high levels of BCRP mRNA expression compared with the 20 ng/ml group (P<0.05).

Conclusion: The expression of BCRP mRNA in FLS of RA patients has a certain concentration and time dependence of IL-1β, suggesting that IL-1β is involved in BCRP-mediated multidrug resistance, which lays a foundation for exploring its specific mechanism.

CXCL17 IN RHEUMATOID ARTHRITIS: INTERFERON-ANTI-INFLAMMATORY EFFECTS OF SPLEEN TYROSINE

Anna Kernder1, Johanna Mucke1, Long Tang-Chieu1, Torsten Lowin1, Tim Claßen2, Oliver Sander1, Ellen Bleck1, Claudia Heier1, Georg Porgratz1, Matthias Schneider1, Stefan Vordenbäumen1, 1Heinrich-Heine-University Düsseldorf, Polyclinic of Rheumatology and Hiller Research Unit, Düsseldorf, Germany; 2St. Elisabeth Hospital, River Rhein Center for Rheumatology, Department of Orthopaedics, Meersbusch, Germany

Background: CXCL17 is the latest chemokine discovered and was reported to influence angiogenesis and monocyte trafficking. Its role in rheumatoid arthritis (RA) has not been assessed so far.

Objectives: To assess the role of CXCL17 and its putative receptor G-protein-coupled receptor 35 (GPR35) in RA.

Methods: Synovial tissue from joint replacements of RA and osteoarthritis (OA) patients was used for CXCL17 and GPR35 immunohistochemistry and in situ hybridization/immunofluorescence double-stainings. CXCL17 concentration in the synovial fluid of RA and CXCL17 production by synovial fibroblasts and smooth muscle cells after stimulation with TNF-α, INF-γ and IL-1β was quantified by qPCR and ELISA. Angiogenesis was assessed by a human umbilical vein endothelial cell culture assay.

Results: CXCL17 and GPR35 are widely expressed in the synovial membrane of RA compared to OA (p<0.006). Within the synovial membrane CXCL17 mRNA could be located to vascular smooth muscle cells. INF-γ significantly induced CXCL17 mRNA and protein production in RA synovial fibroblasts (19-fold, p=0.019 and 2-fold, p=0.0002 respectively) and rat smooth muscle cells (67-fold, p=0.02 and 3.7-fold, p=0.001). CXCL17 was detected in the synovial fluid of RA (mean 310 pg/ml). In vitro angiogenesis was inhibited by CXCL17. This effect was reversed by specific GPR35 antagonists.

Conclusion: CXCL17 is abundant in RA synovial tissue, localizes to vascular smooth muscle cells and fibroblasts, and is inducible by INF-γ. Antiangiogenic properties are mediated by GPR35. CXCL17 and GPR35 may constitute a hitherto unrecognized regulatory protein in RA pathogenesis and therefore be interesting drug targets.

ANTI-INFLAMMATORY EFFECTS OF SLEEP TYROSINE KINASE (SYK) INHIBITOR, PICEATANNOL, ON FIBROBLAST-LIKE SYNOVIOTYE IN RHEUMATOID ARTHRITIS

Seon Uk Kim1, Hyun Jung Yoo2, Shin Eui Kang1, Ji Soo Park1, Ra Ham Kim1, Jin Kyun Park1, Eun Young Lee1, Yeong Wook Song2, 1Seoul National University, Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Seoul, Korea, Rep. of (South Korea); 2Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation with subsequent cartilage and bone erosion leading to joint destruction. The fibroblast-like synoviocytes (FLS) have a central role in disease pathogenesis and in vitro FLS invasiveness correlates with articular cartilage damage in RA patients. Spleen tyrosine kinase (Syk) is an intracellular protein tyrosine kinase in the cells in tissues such as bone, cartilage, and synovium, where it is involved in tumor necrosis factor (TNF-α) receptor signaling. Piceatannol, a naturally occurring hydroxylated analog of resveratrol, was reported to inhibit Syk.

Objectives: The aim of this study is to evaluate the effects of piceatannol on inflammation and the downstream signaling pathway of Syk in RA FLS.

Methods: FLS isolated from synovium of rheumatoid arthritis (RA) patients were cultured with DMEM supplemented with 10% FBS and 1% penicillin/streptomycin. FLS were stimulated with lipopolysaccharide (LPS) for 24 hr after 1 hr treatment of piceatannol. The cytokines were screened using human inflammatory and matrix metalloproteinase (MMP) antibody array kit (Abcam) in the culture supernatant. Also, IL-6, IL-8 and CXCL10 levels were measured by ELISA and the expression levels of cyclooxygenase-2 (COX-2) and inducible nitric oxide synthases (iNOS) were determined by western blotting.

Results: Protein expression level of Syk was suppressed by piceatannol (50 μM treatment). Piceatannol inhibited the production of cytokines/chemokines such as IL-6, CCL-5, CCL-8 and MMP-1 in RA FLS stimulated with LPS. The levels of IL-6, IL-8 and CXCL10 in RA FLS were dose-dependently decreased. The viability and proliferation of the cells were not affected. Piceatannol significantly suppressed COX-2 and iNOS protein expressions.

Conclusion: Piceatannol had suppressive effects on pro-inflammatory cytokines/chemokines production and had anti-inflammatory effects in RA FLS.

VERY STRONGLY POSITIVE RHEUMATOID FACTOR LEVELS (10-FOLD HIGHER THAN THE UPPER NORMAL RANGE) RATHER THAN “RHEUMATOID FACTOR POSITIVITY” PER SE ASSOCIATED WITH SMOKING IN FEMALE RA PATIENTS WITHOUT A HISTORY OF OCCUPATIONAL DUST AND FUME EXPOSURE

Daisy Kirtley, David Hutchinson. Royal Cornwall Hospital, Truro, United Kingdom

Background: Rheumatoid factor (RF) forms part of the 2010 EULAR/ACR classification criteria1. A weakly positive RF is defined as up to 3-fold higher and a strongly positive RF >3-fold higher than the upper normal range. However, a longitudinal study of individuals with RF levels at least 4-fold higher than the upper range of normal had an adjusted hazard ratio for RA development of 26 (95% CI 15 to 46) compared to only 6.0 (3.4 to 10) for individuals with levels 2 to 4-fold above the upper normal range2. We have recently reported median RFs of greater than 10-fold higher than the upper normal range in nodular RA which is far more prevalent in smokers than non-nodular RA3. We have arbitrarily defined this level of RF as very strongly positive as it defines a disease subtype. Additionally, RF levels are strongly associated with addictive exposures to both smoking and industrial vapours, gases, dust and fumes (VGDF) in male RA, with only 8% having been exposed to neither VGDF or cigarette smoke4. Objectives: Accordingly, we have studied female RA in whom VGDF exposures are less common to compare RF levels in an appreciable number of smokers and non-smokers without the significant confounding effect of VGDF exposures to determine if smoking is specifically associated with a very strongly positive RF.

Methods: Medical record analysis yielded 241 female RA patients seen in clinic between January and June 2018 without exposures to industrial VGDF. These patients were stratified for a history of smoking. RF was measured with Tina-quant Rheumatoid Factors II Test System, by Roche Diagnostics Corporation at the time of RA diagnosis. A value of < 14 IU/ml was considered as negative as per manufacturer guidelines, a RF weakly positive (14-42 IU/ml), RF strongly positive (42-140 IU/ml) and RF very strongly positive (>140 IU/ml).

Results: There were 109 never smokers and 132 smokers with a median RF of 21 IU/ml and 53 IU/ml respectively, p<0.05. In never-smokers significantly more were seronegative 46/109 (42%) vs. 32/132 smokers (24%), odds ratio (OR)=2.22 (95% confidence interval (CI):1.28-3.83, P=0.004). Of never smokers 22/109 (20%) were weakly RF positive and very similar to smokers 28/132 (21%).28/132 (21%) of never smokers were strongly RF positive and a similar proportion of smokers 37/132 (28%) were strongly RF positive. Finally in never smokers, only 12/109 (11%) very strongly RF positive compared to 35/132 (27%) of smokers, OR=2.99 (95% CI 1.41-5.99, p=0.004).

Conclusion: Considering female RA smokers and non-smokers, the difference in RF positivity was exclusively accounted for by an increased prevalence of a very strongly positive RF in female smokers. This suggests that smoking has an impact on very strongly positive RF levels rather than RF positivity per se without the important confounding factor of VGDF exposure.

AB0128 ANTI-OXIDATIVE PROTECTION AND MONOXIGENASE SYSTEM ACTIVITY OF CYTOCHROME P450 (MOG) OF NEUTROPHILIC LEUKOCYTES (NL) FROM SYNOVIAL FLUID (SF) IN RHEUMATOID ARTHRITIS (RA)
Viktor Shishkin, Galina Kudravtseva, Yuli Malevok, Viktor V. Shishkin, St. Petersburg State University, St. Petersburg, Russian Federation

Background: MOG system is present not only in the liver but also in far less quantities in other organs and tissues, including SF.

Objectives: SF in RA patient contains up to 95% of NL that determines the inflammation also by inhibiting MOG.

Methods: SF of knee joints of 8 patients with RA with active synovitis and 4 donors (D) were examined. NL have been isolated by standard methods. After the application of Triton-X-100 0.1% solution, NL have been centrifuged at 25000 g for 30 minutes. The supernatant has been used in the experiment. The activity of MOG has been estimated according to the level of cytochromes P450, P420 and b5 and has been estimated by applying the method of differential spectrophotometry.

Active forms of oxygen have been registered by applying electron paramagnetic resonance (EPR).

The activity of the antioxidant enzymes - Cu-Zn superoxide dismutase (Cu-Zn SOD), Se-glutathione peroxidase (Se-GPO) and catalase (CAT) was estimated by applying classical enzymology methods.

Results: It has been found out that in RA, the level of active oxygen forms increases by 68%. Meanwhile, the enzymes level of antioxidant defense is insufficient.

In RA the activity of SOD, GPO and CAT enzymes is inhibited at 52, 66 and 39% respectively. In RA the activity of MOG (P450 and b5) in NL is 4 times lower than normal. The concentration of the inactive form of cytochrome P420, however, doubles. Nevertheless, their ratio P450/P420 (when normal = 5) in case of RA = 5.8, hardly ever changes.

Cytochrome concentration P450, P420 and b5 (nmol/mg of protein), level of active oxygen forms (Units/mg of protein) and antioxidant system activity (SOD, GPO - Unbinding of protein; CAT - unbinding of protein) in NL in RA

Conclusion: A fall in the level of free radical oxidation and antioxidant defense and faster generation of active oxygen forms in RA leads to NL being destroyed and creates favorable conditions for the development of autophagy and apoptosis. The oxidative stress during RA is accompanied by a fall in the activity of MOG and creates favorable conditions for the development of autophagy and apoptosis.

AB0129 ULTRA-MICROSCOPIC ANALYSIS OF NURSING PHENOMENON IN SYNOVIAL TISSUE OF RHEUMATOID ARTHRITIS
ne kurosii, Takahiro Ochi2, Takashi Sato3, Miwa Uzuki4, Kenya Murakami5, Akira Kurose1, Yo-ichiro Sato1, Yasuyuki Ishibashi6, Kirji Ishida7, Kazutoshi Ogasawara8, Akira Morikawa9, Takashi Sawai10, Hiroshi University Graduate School of Medicine, Hiroaki, Japan; 2Osaka Police Hospital, Osaka, Japan; 3Iwate Medical University School of Medicine, Morioka, Japan; 4Tohoku Bunka Gakuen University, Sendai, Japan; 5National High-Technologies Corporation Electron Microscope Application Group, Hitachinaka, Japan; 6Tohoku University, Sendai, Japan

Background: Applying recent advances in electron microscope technology, cells and cell-cell interactions are observable using virtual slides, three-dimensional (3D) imaging, and serial sections of ultrathin thickness. Inflammation in rheumatoid arthritis (RA) is caused by multiple cell types, including infiltrating inflammatory cells, such as lymphocytes, neutrophils, macrophages, and spindle-shaped fibroblasts. Especially, we are focusing on fibroblast-like synoviocytes (FLSs). These cells have been reported to be positive for multiple markers including CD14, CD68, HLA-DR and vimentin, and we have shown that these cells are dendritic cells in our previous study using electron microscopy. Therefore, FLSs are presumed to function as dendritic cells and these cells involved in the nursing phenomenon.

Objectives: The objective of this study is to investigate the chronically mechanism of immunological inflammation in RA by using electron microscopy.

Methods: Synovial tissues collected from RA patients undergoing elbow or knee joint surgery were prepared for this study. Using wide field of view images of the synovial tissue, areas containing the nursing phenomenon were selected by using multiscale electron microscopy. 3D structures of the features were constructed from series of micrographs obtained by using focused ion beam-scanning electron microscopy and those by using transmission electron microscopy with double-axis electron tomography (DA-ET).

Results: From multiscale electron microscopy, many synovial dendritic cells and plasma cells were present in various areas of the lymphnodular infiltration. Serial cross-sectional observation with an FIB-SEM and 3D images revealed that synovial dendritic cells patroonized the plasma cells, wrapping around the plasma cells, by the long slender axes. A tomogram of an ultra-thin sliced section created by using DA-ET revealed that synovial dendritic cells formed a membranous fusion with the plasma cells.

Conclusion: The nursing phenomenon involves characteristic histopathological features, which may be a factor in the chronicity of the inflammation mechanism RA synovial tissue.

AB0130 THE EFFECTS OF METHOTREXATE ON THE VASCULAR ENDOTHELIUM

Marie Lang, Charis Pericleous, Robert Maughan, Allan Kiprianos, Justin Mason. Imperial College London, Vascular Sciences, London, United Kingdom

Background: Anti-inflammatory therapy has been recently validated as a treatment option for patients with cardiovascular disease (CVD) [1]. The anti-inflammatory drug methotrexate (MTX) reduces cardiovascular risk in patients with systemic inflammatory rheumatic diseases [2]; possibly by improving endothelial function [3]. However, the molecular basis of the drug’s anti-inflammatory and potential anti-atherogenic effects on the vasculature is not well described.

Objectives: Our goal was to characterize the actions of MTX on vascular endothelial cells (EC).

Methods: MTX-treated human umbilical vein (HUVEC) or aortic endothelial cells (HAE) were analyzed by quantitative real-time PCR (qRT-PCR) of pro-angiogenic and pro-inflammatory cytokines. EC viability and cell cycle were evaluated by flow cytometry using Annexin V and/or propidium iodide staining. For selected experiments, EC were exposed to laminar (LSS; 20 dyn/cm²) or oscillatory shear stress (OSS; 0.5 dyn/cm² - 2Hz) using a parallel plate model.

Results: Under static conditions, MTX independently increased the activity of multiple kinases in quiescent and TNFα-activated EC. MTX-activated kinases

Disclosure of Interests: None declared
included the mitogen-activated protein kinase (MAPK) p38 and Akt. MTX did not inhibit TNFα-induced nuclear factor kappa B (NFκB) transcriptional activation, signaling or target gene expression. However, MTX induced pro-inflammatory markers such as vascular cell adhesion molecule (VCAM)-1 in an additive manner with TNFα. Functionally, MTX did not induce apoptosis but caused S-phase cell cycle arrest, which, along with p38 and Akt activation, could be abrogated by supplementation with folic acid.

Findings to date in EC subjected to shear stress are somewhat different. MTX had no or a mild inhibitory effect on kinase signaling in EC under LSS and OSS, respectively. MTX did not affect cell proliferation nor baseline or OSS-induced VCAM-1 expression in EC under shear stress.

Conclusion: In static EC, low-dose MTX caused cell cycle arrest through folate depletion, which is a known mechanism of action in other cell types. Of note, this response was not seen in EC pre-conditioned by shear stress and emphasizes the impact of biomechanical forces on endothelial phenotype and response to exogenous stimulation. This is the first report to study the effects of MTX on EC under shear stress, which will be crucial in understanding its molecular actions on the vasculature.

AB0131 THE CORRELATION OF EXPRESSION OF DIFFERENTIAL DRUG-RESISTANT PROTEINS AND INFLAMMATORY CYTOKINES IN COLLAGEN INDUCED ARTHRITIS MODEL

jie liang, Xiangcong Zhao, Ning Yan, Fangyuan Hu, Li Xiaofeng, Caihong Wang, The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease. The most characteristic patho-logical changes are chronic synovitis. At present, the combination of traditional disease-difying anti-rheumatic drugs (DMARDs) and biological agents DMARDs has improved the therapeutic effect of RA, but some RA patients still have poor response due to Multidrug resistance (MDR) phenomenon. The main mechanism of MDR is resistance (MDR) is related to the ATP-binding cassette (ABC) transporter superfamily members, which increases drug efflux and reduces intra-cellular drug concentration. We will study how cytokines regulate the expression of ABC transporters.

Objectives: By comparing the differential expression of ABC transporter family resistance-related proteins P-gp, BCRP, MRPI and inflammatory cytokines IL-1β, IL-2, IL-6, IL-10, TNFα and IL-17 in CIA model mice, to investigate the correlation between Inflammatory cytokines and drug-resistant proteins.

Methods: Fourteen DBA1 mice were successfully induced by collagen and Freund's Adjuvant. According to the scores of synovial pathology, the CIA group was divided into mild, moderate-to-severe groups, another four mice were selected as control. The mRNA expressions of P-gp, BCRP, MRPI in splenic lymphocyte cells were measured by RT-qPCR. The concentrations of IL-1β, IL-2, IL-6, IL-10, TNFα, IL-17 in serum were determined by Cytometric Bead Array(CBA). Further analyze the correlation between differential inflammatory cytokines and these proteins, then study one of the proteins which is most related with cytokines by target gene expression. 2. In the spleen lymphocytes, there was no significant difference in the mRNA expression level of P-gp and BCRP among the groups, but the mRNA expression level of MRPI was significantly increased (P<0.05). Compared with the mild CIA group, the MRPI mRNA in the moderate-to-severe CIA group was higher, there was significant difference(Z=2.132, P<0.05). There was a correlation between mRNA expression of MRPI and P-gp(r=0.635, P<0.015).

3. The mRNA expression of MRPI was positively correlated with IL-6 level (r=0.711, P<0.004).

4. The expression of MRPI in normal group, low-level IL-6 group and high-level IL-6 group were respectively as follows:1.08±0.65(1.30), 1.40 (1.13.2.07), 1.90(1.68,2.17).

5. Compared with the controls, the cytokiasis/membrane of the knee and ankle joint synovial tissue in the CIA group was yellowish-brown, which proved that MRPI expression was positive.

Conclusion: In the CIA arthritis model, synovial tissue lesion is not only related to inflammatory cytokines, but also related to MRPI expression in the ABC transport resistance protein family, and it is proved that IL-6 is highly correlated to MRPI.

HUMAN UMBILICAL CORD-DERIVED MESENCHYMAL STEM CELLS AMELIORATE COLLAGEN-INDUCED ARTHRITIS VIA IMMUNOMODULATORY EFFECT ON T LYMPHOCYTES

Dan Ma1, Ke Xu1, Galian Zhang2, Yang Liu1, Jinjiang Gao1, Min Tian2, Chun Wei2, Li Juan1, Lyun Zhang1, Shanxi Dayi Hospital, rheumatology, taiyuan, China.

Background: Rheumatoid arthritis (RA) is an autoimmune disease that results in cartilage and bone destruction. Overactivation of T lymphocytes and imbalance of T helper (Th1/Th2) are critical factors that contribute to the occurrence and development of RA. These have become important mechanisms of inflammation, immune activation, and bone destruction. RA treatment ideally involves regulation of immune abnormalities and maintenance of immune homeostasis. Mesenchymal stem cells (MSCs) are multipotent adult stem cells with high proliferation, multi-differentiation, and immune regulation. They exert immunoregulatory effects on T lymphocytes to improve RA symptoms, inhibit synovial hyperplasia, and reduce cartilage and bone erosion. However, the specific molecular mechanisms have not been fully elucidated.

Objectives: To investigate the effect of human umbilical cord mesenchymal stem cells (hUCMSCs) on collagen-induced arthritis (CIA) in rats in comparison with that of methotrexate (MTX), a classical drug for RA. It evaluated T lymphocyte proliferation, apoptosis, differentiation, and associated inflammatory factors, and further explored the regulatory mechanism of T lymphocyte differentiation at the gene transcription level. This study elucidated that hUCMSCs play an immunoregulatory role in T lymphocytes of CIA rats through multiple pathways and explored the possible mechanism of hUCMSCs in RA treatment via the immunomodulated T lymphocyte pathway.

Methods: The effects of hUCMSCs on arthritis, radiological and synovial pathological changes in CIA rats were assessed. Flow cytometry was conducted to detect T lymphocyte proliferation, apoptosis, the ratio of Th17 and Treg cells in the spleen, and IL-17 and TGF-β levels in the sera from CIA rats. Further, Foxp3 and ROR-γT expression in the spleen were assessed by immunohistochemistry, Fqox3mRNA and ROR-γTmRNA expression were assessed by reverse transcription-polymerase chain reaction (RT-PCR).

Results: HUCMSCs inhibited proliferation and promoted apoptosis of T lymphocytes, up-regulated Foxp3 mRNA and protein expression, increased the proportion of Treg cells, down-regulated ROR-γT mRNA and protein expression, and decreased the proportion of Th17 cells in the spleens of CIA rats. Correction of the Foxp3/ROR-γT imbalance to regulate the Threg/Th17 ratio, promoted anti-inflammatory factors, TGF-β expression and inhibited pro-inflammatory factor IL-17 expression, thereby improving arthritis in CIA rats, delaying radiological progression, and inhibiting synovial hyperplasia. This effect was similar to that of MTX.

Conclusion: HUCMSCs exert immunomodulatory effects on T lymphocytes in CIA rats through many pathways and are expected to become a new immunomodulatory therapy for RA.

ANALYSIS OF INTESTINAL MICROBIOME PROFILE OF PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS AND HEALTHY CONTROLS

Natalia Mena-Vázquez1, Patricia Ruiz-Limón2, Isabel Moreno-Indias3,4, Sara Marín-Tirahanes1, Francisco Jose Tinahones3,4, Antonio Fernando Negro5, Luis Sáez-Cabañas6, Jesús Villalba7, Lecturer, 1UGC Reumatología, Instituto de Investigación biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, Universidad de Málaga, Málaga, Spain; 2Unidad de Gestión Clínica de Endocrinología y Nutrición, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoria, Málaga, Spain; 3Unidad de Gestión Clínica de Endocrinología y Nutrición, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoria, Málaga, Spain; 4CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Instituto de Salud Carlos III, Málaga, Spain, 5Málaga, Spain; 6CIBER Fisiopatología de la Obesidad y Nutrición, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoria, Málaga, Spain; 7Málaga, Spain.

Objectives: Describe the intestinal microbiome profile in RA patients and analyze the mechanisms through which intervenes in the pathogenesis RA.

Methods: Design: Controlled, observational, cross-sectional study of established RA cohort. Patients: Forty consecutive RA patients (ACR/EULAR 2010 criteria) >16 years, selected from a prospective inception cohort (2007-2011) and 40 age-sex matched healthy controls. Protocol: Cases and controls were evaluated by a rheumatologist. Clinical data of disease activity were collected during the follow-up and analytical values were determined. Fecal samples were frozen within 24 hours of collection. Main outcome: Fecal samples exam. Microbial DNA was extracted from fecal samples using QIAamp DNA stool Mini Kit. The concentration and quality of DNA was determined by Nanodrop. Secondary Other variables: Demographic, clinical-analytical and therapies (DMARDs), Statistical analysis: Analysis of microbiota profile: Principle Coordinate Analysis (PCoA), was performed with the abundance data of operational taxonomic units (OTU) by means of the variancovance matrix implemented in Quantitative Insights Into Microbial Ecology (QIME). The relative abundance of each OTU (taxa) was compared using a Wilcoxon test. The variations of abundance and diversity were compared by ANOSIM pathway. The calculation of α and β-diversity was carried out using QIME.

Results: Most of subjects were women (75%) (table). In RA patients, the average DAS28 was 3.6. β-diversity data showed that patients tend to differ from healthy subjects according to their microbiota (p < 0.07). Patients with RA exhibited decreased gut microbiome diversity compared with controls, although it was not statistically significant. Regarding species richness, the analysis suggested an increase of the Collinsella aerofaciens species and enterococcus genera in patients compared with controls. Likewise, an increase of arginine deaminase activity was observed, which belonged, in approximately 90%, to the RA genes of the genus Collinsella. The multivariate analysis identified ACPA positive (95% CI), 0.33 [27.4-390], smoking (0.3 [8.8-256.4]) and age (-0.3 [27.4-390.0]) as factors associated with Collinsella. Also, we observed a decrease in other bacterial lineages. On the other hand, RA patients showed a altered metabolic capacity for the transport of zinc and copper.

Conclusion: These observations suggest a dysbiosis in RA patients, resulting from a abundance of certain bacteria (i.e Collinsella) and decrease of other bacterial lineages. These alterations could influence in a significant way in the perpetuation of the autoimmunity of the disease.

AB0136 LEVELS OF MYOKINES AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RHETUMATOID ARTHRITIS
Jordana Miranda de Souza Silva1, Rafaela Cavalheiro do Espírito Santo2, Deborah Negoro Gonçalo Dias2, Nayara Felicidade Thomas Braz3, Érica Leandro Marciano Vieira4, Eduarda Freitas1, Rafael Mendonça da Silva Chakr1, Adriana Maria Kakehasi3, Ricardo Xavier1.

Background: Myokines, such as irisin and myostatin, are cytokines and growth factors mainly expressed in skeletal muscle, which is also their primary target tissue. They are released into circulation and exert a variety of systemic effects promoting crossstalk among different tissues [1]. Irisin is known to retrieve disuse-induced bone loss by stimulating the osteoblast pathways, while myostatin was demonstrated to be highly expressed in the synovial tissues of rheumatoid arthritis (RA) subjects, with direct role in osteoarthritisogenesis [2, 3].

Objectives: To investigate whether myokines serum levels can predict one-year radiographic progression in patients with RA.

Methods: Forty female patients with RA, according to ACR/EULAR 2010 classification criteria, were included in the study. Blood samples were collected, and ELISA was used to measure serum levels of irisin and myostatin. Radiographs of hands and feet, taken within three months of the blood collection and a year later, were evaluated using the Sharp-van der Heijde (SvH) score to verify the one-year radiographic progression. The RA activity was assessed by disease activity score (DAS28-ESR) based on evaluation of 28 joints (DAS28-ESR). Statistical analysis included Mann-Whitney U test and Spearman correlation. A value of p<0.05 was considered significant.

Results: The mean age of RA patients was 53 years old, mean DAS28-ESR was 4.09, mean disease duration was 11.2 years and mean BMI was 27.33 kg/m2. The mean serum levels of irisin and myostatin were respectively 25.61 ± 8.25 ng/ml and 3011.28 ± 1271.11 pg/ml. Considering radiographic progression, the mean values of SvH score were 28.3 and 31.3 in the baseline and after one year, respectively, resulting in a mean ΔSvH of 3. Over one year, 89.2% of the patients demonstrated significant increase in SvH of 3. Over one year, 89.2% of the patients demonstrated significant increase in SvH of 3.

Conclusion: The serum levels of irisin and myostatin were not correlated with one-year radiographic progression. There was a tendency of increased myostatin levels in patients with rapid progression compared to patients with no progression. More studies are needed to investigate whether the myokine levels in the joint environment differ from the circulating concentration.

AB0137 ROLE OF VIMENTIN AS A TARGET OF ANTI-BODIES AGAINST CARBAMYLATED PROTEINS IN RHETUMATOID ARTHRITIS PATIENTS
Arbi Pececi1, Tania Colasardi2, Cristiano Alessandri2, Martina Leopizzi2, Riccardo Mancini2, Fabrizio Conti2, Guido Valesini2, Francesca Romana Sprelli2.

1Rheumatology Unit, Department of Internal Medicine, University Hospital “S. Orsola Maggiore”, Bologna, Italy
2Rheumatology Unit, Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Policlinico Umberto I, Rome, Italy

Background: Patients with Rheumatoid Arthritis (RA) have an increased risk of cardiovascular diseases (CVD). Inflammation and autoantibodies independently promote endothelial dysfunction, which is the earliest, reversible stage of atherosclerosis. In vitro studies have demonstrated that antibodies against carbamylated proteins (anti-CarP), recently described in RA patients, can induce the production of proatherosclerotic molecules like Vascular Cell Adhesion Molecule (VCAM-1) and activate Interleukin-1 Receptor-Associated Kinase (IRA-K1), Nuclear Factor KB (NF-KB), inducible Nitric Oxide Synthase (iNOS) in endothelial cells (1,2). Moreover, anti-CarP are associated to endothelial dysfunction and subclinical atherosclerosis in RA patients (3).

Objectives: Aims of the present study were: 1) to analyze the role of vimentin as a target of autoantibody response in the serum of patients with RA and 2) to investigate the expression of vimentin and carbamylated proteins in endothelial cells.

Methods: Consecutive RA patients enrolled in this study. Vimentin was carbamylated and used as an antigen for the detection of anti-Vimentin Carbamylated antibodies (CarVim), through immunoenzymatic methods. Cells were incubated with anti-vimentin and carbamylated antibodies. The presence of vimentin and carbamylated proteins was investigated by immunofluorescence on the immortalized endothelial cell line EA.hy 926.

Results: Eighty-eight (88) RA patients were enrolled in this study (F/M = 79:9, mean age = 56 ± 13 years). Anti-CarVim antibodies were present in 9% of the patients with a mean titre of 442 aU/mL (IQR 303 aU/ml). Vimentin and carbamylated proteins were detected in the endothelial cells by immunofluorescence (Figure 1).

AB0138 EVALUATION OF ANALGESIC ACTIVITY OF ALLOPURINOL AND FEBUXOSTAT IN EXPERIMENTAL ANALGESIC MODELS IN MICE
S. PAL, GFCPP, MEERUT, India

Background: Allopurinol and febuxostat are xanthine oxidase inhibitor which are used in the treatment of hyperuricemia and gout. Pain is one of the important symptoms in gout patients.

Objectives: The present study is to evaluate the analgesic activity of allopurinol and febuxostat in two analgesic models in mice.

Methods: The analgesic activity of allopurinol (38 mg/kg) and febuxostat (15.6 mg/kg) was evaluated by using central analgesic model of Eddy’s hot plate and peripheral analgesic model of acetic acid induced writhing. Both drugs were compared with the positive control, piroxicam for hot plate model & aspirin for the Writhing method. Also both allopurinol and febuxostat were compared with each other.

Results: Both allopurinol and febuxostat showed significant increase in reaction time at various time periods in hot plate model & also showed significant delay in onset of writhing as well as decrease in number of writhes in writhing method. As compared to positive control result allopurinol and febuxostat result were lower. Febuxostat shows better analgesic activity as compared to that of allopurinol.

Conclusion: Allopurinol and febuxostat exhibited analgesic activity in both central and peripheral models of pain.

Disclosure of Interests: None declared

Conclusion: The results of this study confirm that Vimentin is one of the antigenic targets of anti-CarP antibodies present in the serum of RA patients. The presence of carbamylated proteins and vimentin in endothelial cells suggests that anti-CarP Vim could bind the modified protein and determine endothelial activation and subsequent endothelial dysfunction.

INDIVIDUALS WITH ACPA POSITIVE RA PRESENTING INITIALLY WITH PALINDROMIC SYMPTOMS ARE SIGNIFICANTLY LESS LIKELY TO BE RHEUMATOID FACTOR POSITIVE THAN CLASSICAL ACPA POSITIVE RA: COULD THE AETIOPATHOGENESIS DIFFER BETWEEN THESE TWO DISTINCT TYPES OF ACPA POSITIVE RA?

Matilda Pask1, David Hutchinson2, 1University of Exeter Medical School, Knowledge Spa, Truro, United Kingdom; 2University of Exeter Medical School, Rheumatology Department, Truro, United Kingdom

Background: It remains unclear whether ACPA positive RA presenting initially with palindromic symptoms (PRA) has the same underlying pathophysiology as ACPA positive RA presenting without palindromic symptoms (classical ACPA positive RA). The lung is an initiating site in RA development and rheumatoid factor (RF) is generated within bronchial associated lung tissue (1). RF in combination with ACPA immune complexes can induce TNF– from joint macrophages and potentially induce synovitis (2). Unsurprisingly a positive RF is a risk factor for RA development. Alternatively, palindromic rheumatism in the absence of RA occurs commonly in RF negative individuals (58%) (3). Therefore this form of explosive synovitis often occurs independently of RF, but is commonly associated with ACPA positivity (56%) (3).

Objectives: To identify whether classical ACPA positive RA differs in terms of RF positivity compared to ACPA positive PRA.

Methods: A retrospective case note observational study was undertaken to identify ACPA positive RA patients with or without a palindromic onset. All patients fulfilled the RA 2010 EULAR/ACR classification criteria (4). Patients were stratified for a history of smoking. RF was measured with Tina-quant Rheumatoid Factors II Test System, by Roche Diagnostics Corporation at the time of diagnosis. A value of < 14 IU/ml was considered as negative, weakly positive (14-42 IU/ml) and strongly positive (>42 IU/ml) as per EULAR/ACR guidelines (4).

Results: 99 classical ACPA positive RA and 35 ACPA positive PRA were identified. The median RF for PRA was significantly lower than the non-RF onset RA group (25 vs 86 IU/ml, p = 0.001). Comparing classical ACPA positive RA with ACPA positive PRA revealed 8/99 (8%) vs. 8/35 (23%) to be RF negative, 23/99 (23%) vs. 11/35 (31%) to be RF weakly positive and 68/99 (69%) vs. 16/35 (46%) to be strongly RF positive. Classical ACPA RA patients were significantly less likely to be RF negative, odds ratio 0.25 (95%CI 0.09–0.73), P<0.01. RA patients were significantly more likely to be strongly RF positive OR 4.32 (1.88–9.89), P<0.0005.

Conclusions: The majority of ACPA RA patients presenting with palindromic symptoms have either a negative or weakly positive RF (54%). This contrasts with classical ACPA RA (31%) and suggests that a strongly positive RF is more important in the pathogenesis of classical ACPA RA than ACPA PRA. We suggest that a strongly positive RF and palindromic rheumatism is likely to be independent risk factors for ACPA positive RA.

EFFECT OF THE CO-TREATMENT WITH BACTERICIDAL/PERMEABILITY-INCREASING PROTEIN AND HYALURONIC ACID IN AN IN VIVO MODEL OF ARTHRITIS

Anna Scanu1, Roberto Lusietto2, Paola Galozzi2, Francesca Olivero2, Leonardo Fuzi3, 1University of Padova, Rheumatology Unit, Dept. of Medicine-DIMED, Padova, Italy; 2University of Padova, Dept. of Surgical Oncological and Gastroenterological Sciences, Padova, Italy; 3Rheumatology, SS Giovanni and Paolo Hospital, Centre for Gout and Metabolic Bone and Joint Diseases, Venice, Italy

Background: Bacterial/permeability-increasing protein (BPI) is an antibacterial, anti-inflammatory and antiangiogenic glycoprotein which has been detected in synovial fluid of patients with differing arthritis [1].

Objectives: To investigate the effect of BPI alone or in combination with hyaluronic acid (HA) in a mouse model of collagen-induced arthritis (CIA).

Methods: CIA was induced in C57Bl/6 mice (n=12 per condition) by immunization with type II collagen/complete Freund’s adjuvant emulsion at days 0 and 21 [2]. Development and severity of arthritis were monitored by measuring paw swelling with a caliper and scored (0-5) every 2 days. Articular mice (paw score=2) were intraperitoneally injected with 200 μl of BPI (50 μg/ml) in PBS in the presence or absence of HA (0.02%). Treatment and arthritis evaluation were carried out twice a week for 2 months. Untreated mice or animals that received HA alone (0.02%) were used as controls. At the experiment endpoints, mice were sacrificed to collect paw and blood samples. Hind paws were processed for histological analysis to assess inflammation, pannus formation, cartilage damage and bone resorption in ankle joints (score 0-5). CXCL1, TNF, IL-6, IL-1β and VEGF serum levels were determined by ELISA.

Results: All mice reached an arthritis score of 2 after 28-33 days and showed a progressive worsening of clinical signs that picked at day 49-56, and continued during the entire follow-up period only in control groups. At the end of the experiment, hind paw swelling and scores were lower in BPI-mice (paw thickness=4.76 ±0.33 mm; score=4.5±0.5) than in untreated mice (paw thickness=6.39±0.95 mm; score=5). Histological analysis revealed leukocyte infiltration (score 3.00±1.73), synovial proliferation (score 3.50±0.71), cartilage damage (score 2.50±0.71) and mild bone resorption (score 1.50±1.71) in ankle joints of untreated controls. All of these histological changes were decreased (50-80%) in the group that received BPI. CIA induction led to high levels of CXCL1 (834.08±68.8 pg/ml), TNF (277.72±15.24 pg/ml), IL-6 (376.04±46.33 pg/ml), IL-1β (656.80±45.6 pg/ml), and VEGF (347.48±75.58 pg/ml) which were reduced with BPI treatment by 1.9, 14.6, 1.8, 2.9 and 2.7 fold, respectively. Animals injected with HA alone displayed slight improvement of all parameters evaluated but the differences were not significant. The combined use of BPI and HA showed paw swelling (3.65±0.37 mm), arthritis score (0.67±0.75) and histological scores for pannus formation (0.4±0.55), inflammation (0.20±0.45), cartilage damage (0.0±0.0) more remarkably reduced than their separate use. In addition, the lowest levels of CXCL1 (11.44±1.31 pg/ml), TNF (4.46±2.23 pg/ml), IL-6 (129.30±14.25 pg/ml), IL-1β (81.58±17.64 pg/ml), and VEGF (107.80±32.64 pg/ml) were observed in serum of mice co-injected with BPI and HA.

Conclusion: This study shows that BPI attenuates progression of CIA in mice, and this effect is greatly enhanced by co-administration of HA. The combined use of BPI and HA represents an interesting perspective for a new potential intervention in the treatment of arthritis.

AB0141 THE ROLE OF AIR POLLUTION ON EXTRACELLULAR VESICLES AS A POTENTIAL PRO-INFLAMMATORY STIMULUS IN RHEUMATOID ARTHRITIS
Tommaso Schioppo1, Mirjam Hoehn2, Simona Iodice2, Laura Pergoli2, Orazio De Lucia1, Antonella Murg1, Luca Ferrati1, Valentina Bollati1, Francesca Ingegnoli1,2, 1ASST Pin-CTO, Clinical Rheumatology, Milano, Italy, 2Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milano, Italy

Background: Rheumatoid arthritis (RA) is an heterogeneous chronic autoimmune disorder potentially leading to a progressive joint damage with great impact on quality of life. RA pathogenesis is complex and involves environmental factors that contribute to the disease in genetically susceptible individuals. Extracellular vesicles (EVs) have been described to play an important role in RA pathogenesis and to modulate autoimmune response following environmental exposures, such as air pollution.

Objectives: Our aim was to evaluate the effects of particulate matter (PM) with aerodynamic diameter ≤10 μm (PM_{10}) and ≤2.5 μm (PM_{2.5}) on EVs in RA and osteoarthritis (OA) as control.

Methods: Plasma EVs were analyzed by Nanosight and flow cytometry: CD14 (monocyte/macrophage), CD61 (platelet), CD25 (T-reg), human endogenous retrovirus w (HERV-w), human leukocyte antigen G (HLA-G). Demographic and clinical data were collected for each patient. Plasma EV concentrations were measured in RA and OA patients and were analyzed by generalized linear regression models. Daily PM concentrations, estimated by Regional Environmental Protection Agency, at municipality resolution, were used to assign short-term exposure (mean of the 7 days preceding the evaluation) to each patient.

Results: 12 consecutive patients with RA (median age 68.1, median disease duration 9.3, 12 female, median DAS28 2.25, 5 positive for anti-citrullinated peptide antibodies) and 12 patients with OA (median age 67.1, median disease duration 9.3, 8 female) were enrolled. Analysis of EVs concentration, according to their dimensions, showed a negative association of exosomes (63-92nm) in RA compared to OA (p<0.05). The increase of PM{sub}2.5 led to a decrease of CD14+ microvesicles (MV) (β=−0.13; p<0.01) and CD25+ (β=−0.08; p<0.05) in RA, and of HERV-w in OA (β=−0.09; p<0.01). Similar results were observed analyzing PM{sub}10 exposure. PM exposure was not observed to modify CD61+ and HLA-G+ MV release both in RA and OA patients (table below). More-over, we compared plasmatic EVs median concentration among patients with RA and OA, and we found a significant difference in the two groups in the HERV-w subpopulations (BRM vs BOX = 0.044 ± 0.091; p = 0.011). In RA patients we also observed a significant association between EVs (CD14+ and HLA-G+ MV) and DAS28 (β=0.13, p<0.03; p=0.04) in RA, and of HERV-w in OA (β=0.09; p=0.01). Similar results were also observed analyzing PM{sub}10 exposure. PM exposure was not observed to modify CD25+ and HLA-G+ MV release both in RA and OA patients (table below). Moreover, we observed a negative association between exosomes and C-reactive protein (CRP) (BRM vs BOX = 0.044 ± 0.091; p = 0.011). In RA patients we also observed a significant association between EVs (CD14+ and HLA-G+ MV) and DAS28 (β=0.13, p<0.03; p=0.04) in RA, and of HERV-w in OA (β=0.09; p=0.01). Similar results were observed analyzing PM{sub}10 exposure. PM exposure was not observed to modify CD25+ and HLA-G+ MV release both in RA and OA patients (table below).

Conclusion: The results of this pilot study show that PM exposure modulates the release of EVs carrying HLA-G and/or HERV-w in RA patients. This might be interpreted as an attempt of immune system to counteract the perturbation provoked by a pro-inflammatory environmental stimulus. More research is still needed to tie the genetic, epigenetic and environmental factors together and to determine their role in RA pathogenesis.

AB0142 IMMUNOREGULATORY ROLES OF B2 INTEGRINS IN RHEUMATOID ARTHRITIS
Leonie Schittenhelm1,2,3, Jamie Robertson1,3, Arthur Pratt2,3, Catharien Hilken1,2,3, Vicky L. Morrison1,3, 1Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2Institute of Cellular Medicine, Newcastle, United Kingdom; 3Arthritis Research UK Rheumatoid Arthritis Centre for Excellence (RACE), Glasgow, United Kingdom

Background: Evidence is mounting that β2 integrin expression, activation or function in DCs may contribute to the immune dysregulation prevalent in autoimmune disorders such as Rheumatoid Arthritis (RA). To this end, we aimed to characterise β2 integrin expression and activation in antigen-presenting cell (APC) populations from people with RA compared to healthy controls.

Methods: Using flow cytometry, we can detect both total and activated β2 integrin subunits (CD11a, CD11b, CD18) on different APC populations present in human blood and synovial fluid.

Results: Based on our results so far, we found CD11b expression to be equivalent in APC populations between patients with RA and healthy controls. However, expression of both the total and active forms of CD11a was reduced across several APC populations in RA patients compared to healthy controls, with CD2c2 (CD1c+) showing the most striking reduction. Interestingly, we found that CD2c2 from matched RA synovial fluid samples express even lower levels of CD11a than blood CD2c2. Previous studies show that CD2c2s are the DC population primarily involved in the site of inflammation and activate self-reactive T cells2. As CD11a is described to have largely pro-inflammatory effects by contributing to immune cell contacts and recruitment to inflammatory sites, this could suggest that contrary to our initial hypothesis, cells downregulate CD11a as a means of limiting the aberrant inflammation present in the disease.

Furthermore, CD2c2s from RA patients in remission express lower levels of active CD11a compared to those from patients with high disease activity. Upon stimulation with CD2c2s with PMA, cells from patients with active disease decrease their activation of CD11a, while neither healthy controls nor patients in remission show any change in CD11a activation. This might suggest that CD11a activation is differentially regulated in patients with active disease, while remission signifies a return to a state of normal CD11a regulation on CD2c2s. In additional work on exploring monocyte-derived DCs (Mo-DCs) as a potential therapeutic for RA, we did not detect a reduction in CD11a expression in activated Mo-DCs, suggesting that the effect may be specific to settings of chronic inflammation that cannot be easily modelled in vitro.

Conclusion: Further interrogation of our integrin expression data, including disease stratification, together with functional studies on RA patient CD2c2s compared to Mo-DCs, is currently under way to fully investigate the role of this immunoregulatory pathway in autoimmune disorders. In doing so, we will explore β2 integrin subunits and signalling pathways as potential therapeutic targets in RA.

AB0143 PERIODONTITIS AND SALIVA ANTIBODIES TO CITRULLINATED PEPTIDES IN RHEUMATOID ARTHRITIS

Anna Svärd1, Stefan Renvert1, Johan Berglund1, Maria Söderlin1. 1Center for clinical research Dalarna, Uppsala University, Falun, Sweden; 2University of Kristianstad, Kristianstad, Sweden; 3Blekinge Institute of Technology, Karlskrona, Sweden; 4Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund, Sweden

Background: Mucosal immunity, involving antibodies against citrullinated peptides (ACPAs), is a prevailing hypothesis concerning the pathogenesis of rheumatoid arthritis (RA). The oral mucosa is a possible site that is involved. Several epidemiological studies have found an association between RA and periodontitis, and periodontal inflammation has been suggested as a possible pathogenic factor.

In established RA, periodontitis has been associated with ACPA positivity (1) although a recent large study (2) did not find any association between periodontitis and IgG ACPA. Previous studies only evaluate ACPA in serum, and as local mucosal immune responses are likely involved in periodontitis, saliva antibodies are of interest to investigate. Saliva IgA ACPA has in a pilot study of RA patients been associated with lower disease activity and less erosions (3), but has not previously been evaluated in relation to periodontitis.

Objectives: To evaluate if saliva or serum ACPA is associated to periodontitis, in patients with RA.

Methods: In this population-based cohort of patients with RA (n=132), we included all patients with RA older than 61 years, living in Karlskrona in southern Sweden, between October 21, 2013 and January 7, 2015.

The patients underwent a clinical examination by a rheumatologist, a dental clinical examination by a dental nurse and a panorama radiograph of the jaws and teeth. Periodontitis was defined as a distance from the cement-enamel junction (CEJ) to the bone level ≥ 5 mm, as defined by the radiographic assessment, at ≥ 30% of interproximal sites.

We analysed antibodies against second generation cyclic citrullinated peptides (anti-CCP) in enzyme immunoassays in serum and saliva. Saliva samples were analysed in parallel for anti-CCP and anti-CAP, the arginine containing control peptide. Serum ACPA positivity was defined as the 99th percentile of healthy controls. In saliva, a positive test was defined as a difference in optical density (OD) for IgA anti-CCP and IgA anti-CAP (delta OD)> 0.

Results: Saliva IgA ACPA was found in 11% of RA patients with periodontitis and in 24% of RA patients with no periodontitis (p=0.052). There was no difference between the groups concerning IgG or IgA ACPA in serum.

Conclusion: Periodontitis leads to increased formation of IgA ACPA in saliva or serum. Although a recent large study (2) did not find any association between periodontitis and ACPA positivity in serum, our findings do not support the hypothesis that periodontitis leads to increased formation of IgA ACPA in saliva or serum.

AB0144 EFFECTS OF AB501 (CERTOLIZUMAB MICE EQUIVALENT) IN ARTHRITIS INDUCED BONE LOSS

Bruno Vidal1, Mikko A. Finnillä1, Inês Lopes1, Rila Cascaço1, João Eurico Fonseca1,2,3. 1Unité de Investigation en Reumatología, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Lisboa, Portugal; 2Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; 3Servicio de Reumatología y Doencas Ósseas Metabólicas, Hospital de Santa María, CHLN, Centro Académico de Medicina de Lisboa, Lisboa, Portugal

Background: Rheumatoid arthritis (RA) is a chronic immune-mediated inflammatory disease, which causes local and systemic bone damage.

Objectives: The main goal of this work was to analyze, how treatment intervention with Ab501 (certolizumab mice equivalent) prevents the disturbances on bone structure and mechanics induced by arthritis.

Methods: Thirty one DBA/1 collagen-induced arthritis (CIA) mice were randomly housed in experimental groups, as follows: arthritis untreated (N=10), preventive intervention with ab501 2 days before arthritis induction (N=10) and treatment intervention upon arthritis onset with ab501 (N=11). A non-induced group (N=5) was used as a control. Mice were monitored during 70 days after disease induction for the inflammatory score, ankle perimeter and body weight. Non-induced mice were used as controls. After 70 days of disease, mice were sacrificed and bone samples were collected for histology, micro-computed tomography (μCT) and 3-point bending analysis. In addition, blood samples were also collected for bone turnover markers quantification. Statistical differences were determined with Mann–Whitney tests using GraphPad Prism (GraphPad, California, USA). Data were expressed as median with interquartile range. Differences were considered statistically significant for p<0.05.

Results: Results showed that Ab501 administration was able to control and abrogate disease development both in preventive and early therapeutic intervention.

μCT results revealed that ab501 was able to preserve bone structure when delivered before arthritis induction. Conclusion: Ab501 preventative administration was able to control inflammation and prevent the degenerative effects of arthritis on trabecular bone structure.

AB0145 THE INHIBITION OF JAK PATHWAY WAS ASSOCIATED WITH REDUCTION OF AUTOFLUHY IN SYNVOYOCITES FROM RHEUMATOID ARTHRITIS PATIENTS

Matís Vorms1, Matía Caliste1, Cristina Barbatí1, Tanis Colesanti1, Francesca Spirelli1, Fulvia Cecarelli2, Carla Perricone1, Annarcaia Finucì1, Mariangela Speziali1, Alessandra Ida Celia1, Michele Bombardieri2, Fabrizio Conti1, Guido Valesini1, Cristiano Alessandri1, 1Unidade de Investigação em Reumatología, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Lisboa, Portugal; 2Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; 3Sapienza University of Rome, Internal Medicine and Medical Specialties, Rome, Italy; 4Queen Mary University of London, London, United Kingdom

Background: The pathway of Janus tyrosine kinases (JAKs) has a central role in the pathogenesis of rheumatoid arthritis (RA) by regulating multiple immune functions and cytokine production. The orally available JAK inhibitor CP-690,550, named tofacitinib, is able to inhibit Jak1, Jak2 and Jak3 and it showed a great clinical efficacy in RA patients not responding to methotrexate or TNF-inhibitors (1). Autoaphagy, a highly conserved mechanism involved in the degradation of intracellular components, was found to be dysregulated in several autoimmune diseases including RA (2). In fact, fibroblasts like synoviocytes (FLS) from RA patients showed a resistance to apoptosis associated with the induction of autophagy (3). Maeshima and colleagues recently demonstrated that tofacitinib suppressed proliferation, but not apoptosis, of CD4+ T cells derived from the synovium (4), but to date there are no data on the effect of inhibition of JAK pathway on autoaphagy.

Objectives: Since hyperactive autoaphagy has been associated with impaired apoptosis of RA FLS, the aim of the study was to investigate the role of tofacitinib in modulating autoaphagy and apoptosis in FLS from RA patients.

Methods: Primary RA FLS isolated from RA biopsies (Figure 1A) were cultured in presence of autoaphagy inducer rapamycin (as control condition) and tofacitinib (1µM). After 24h of culture, autoaphagy was evaluated both by flow cytometry and...
western blot analysis. Apoptosis was analyzing by annexin V (AV) and propidium iodide (PI) apoptosis detection kit by flow cytometry.

Results: As expected tofacitinib inhibited the expression of the phosphorylated form of STAT3 (p<0.01). Rapamycin caused an increase in autophagy, while the levels of autophagy marker LC3-II were reduced after treatment with tofacitinib in vitro (p<0.001 and p<0.02, respectively, Figure 1B). In addition, the analysis of autophagic vacuoles by specific fluorescence dye confirmed the reduction of autophagy in RA-FLS treated with tofacitinib. The percentage of annexin V-positive apoptotic cells was not influenced by the treatment with tofacitinib.

Conclusion: The results of this study elucidated a new mechanism of action of tofacitinib related to autophagy modulation and led to a better understanding of the role of autophagy in RA. This study was supported by an unconditioned Research grant from Pfizer Inc.

AB0147 RESEARCH PROGRESS OF MESENCHYMAL STEM CELL-DERIVEDMICROVESICLES BY DELIVERING MICRONA IN RHEUMATIC DISEASES

Na Zhang1, Liyun Zhang2, Gailan Zhang1, Jin-Fang Gao3, MA Dan4, LiJuan5, Ke Xu1, 2Shanxi Dayi Hospital Affiliated to Shanxi Medical University, Taiyuan, China; 3Shanxi Dayi Hospital Affiliated to Shanxi Medical University, Taiyuan, China; 4Shanxi Dayi Hospital Affiliated to Shanxi Medical University, Taiyuan, China; 5Shanxi Dayi Hospital Affiliated to Shanxi Medical University, Taiyuan, China

Background: Recently, studies have shown that Mesenchymal Stem Cell-Derived Microvesicles (MSC-MVs) can play a role in immune regulation and tissue repair by transporting miRNAs, and their effects are not weaker than that of their mother stem cells. Rheumatoid arthritis is an autoimmune disease characterized by chronic synovitis and progressive cartilage and bone destruction. Current treatments include non-steroidal anti-inflammatory drugs, glucocorticoids, DMARDs, and biological agents. But 30% of patients with rheumatism are ineffective, so there is an urgent need to find a new treatment.

Objectives: To review the research progress of MSC-MVs by delivering microRNA(miRNA) in rheumatic diseases.

Methods: Literatures were searched by using MSC-MVs, autoimmune diseases and miRNA as keywords.

Results: In the field of rheumatology, Chen C showed that after MSCT transplantation, miR-151-5p was transferred through exosomes to damaged bone marrow MSC of systemic sclerosis(SSc) mice, and the activation of IL4/IL10R pathway was down-regulated to improve the osteoporosis of SSc mice [1].Exosomes of human synovial mesenchymal stem cells overexpressing miR-140-5p promoted cartilage regeneration and prevented OA in rat models [2].In the field of autoimmune diseases, Chen L et al. demonstrated that BMSC-derived exosomes containing miR-223 play a important role in liver protection by down-regulating NLRP3 (nod-like receptor family protein) and caspase-1 (caspase-1) in the experimental model of autoimmune hepatitis [3].Human BMSC-derived exosomes transfected with sIgAs and anti-miR-375 plasmids down-regulated Fas and miR-375 in human NOD scid gamma (NSG) mice, thereby protecting islet function and inhibiting immune rejection in islet transplantation [4].

Conclusion: MiRNA targeting therapy with MSC-MVs as vector or the construction of MSC-MVs with overexpression of protective miRNA will provide new, accurate and promising treatment strategies for multiple rheumatic diseases.

OSTEOBLASTS SECRETE A HIGH LEVEL OF BROMODOMAIN INHIBITOR, I-BET762 INHIBITS PGE2, OCs were not induced. OC precursor cells did not seem to even survive.

Background:
Osteoclasts (OCs) are multinucleated cells of monocyte/macrophage lineage and are the only cells known to resorb bone matrix. Osteoblasts (OBs) have the ability to differentiate bone marrow cells (BMCs) into osteoclasts when co-cultured with BMCs in the presence of Vitamin D3 (1,25(OH)2D3) and prostaglandin E2 (PGE2). OBs produce both M-CSF, a survival factor for OC precursor cells, and RANKL, a differentiation factor. In rheumatoid arthritis (RA), synoviocytes may fulfill the functional role of OBs, since OBs are not observed in the synovium of the joints. Although human BMCs are difficult to obtain, mouse BMCs are known to respond to human M-CSF and RANKL, and differentiate into OCs in the presence of both cytokines.

Objectives: Our aim was to examine whether a co-culture system of human synoviocytes and mouse BMCs might be developed. Through this analysis, we attempted to clarify the characteristics of synoviocytes in the pathogenesis of bone destruction observed in RA.

Methods: Human synoviocytes were prepared from synovium obtained in the course of joint replacement surgical operations performed at Saitama Medical University Hospital. Written informed consent, approved by the ethics committee of the hospital, was obtained from each patient prior to the experiment. Mouse BMCs were obtained from the calvaria of newborn C57BL/6 mice. Mouse BMCs were co-cultured with either synoviocytes or OBs. OCs were detected by tartrate-resistant acid phosphatase (TRAP) staining. The concentrations of M-CSF, RANKL and the decoy receptor for RANKL, OPG, were quantified by ELISA in the culture supernatant of synoviocytes or OBs.

Results: When synoviocytes and BMCs were cultured with 1,25(OH)2D3 and PGE2, OCs were not induced. OC precursor cells did not seem to even survive. Next, we added human M-CSF to the system. This time, OC precursor cells remained, but TRAP-positive multinuclear cells were not observed. It was only in the presence of exogenous M-CSF and RANKL that BMCs transformed into OCs. RANKL was not detected in the culture supernatant of synoviocyte culture, but OPG and M-CSF were detectable at a level comparable to mouse OBs. Finally, we cultured mouse OBs and BMCs that were separated by a poly-carbonate membrane in the presence of 1,25(OH)2D3 and PGE2. In this case, too, BMCs did not survive unless exogenous M-CSF was added, and they did not differentiate into OCs unless both M-CSF and RANKL were added to the system.

Conclusion: These results indicate that the M-CSF derived from OBs or synoviocytes is not sufficient to support the survival of OC precursor cells. Likewise, the soluble RANKL derived from OBs is by itself insufficient for the differentiation of OCs, confirming the importance of a cell-cell interaction between OBs and OC precursor cells. Thus, membrane-bound RANKL seems to play a role more important than soluble RANKL in the co-culture system of OCs in vitro. Soluble RANKL may be neutralized by the OPG that is produced at a fairly high level from both OBs and synoviocytes. We propose that this is the system by which ectopic differentiation of OCs is prevented.

AB0149 ARSENIC TROXIDROPE IMPROVES TREG AND TH17 BALANCE VIA MODULATING STAT3 IN TREATMENT-NAÏVE RA PATIENTS

Yue Zhang1, Li Chunling1, Zhiy Zhang1, on behalf of Precision medicine center for Rheumatic diseases, First clinical college of Harbin Medical University. First Clinical College of Harbin Medical University, Rheumatology and Immunology, Harbin, China; 2Shenzhen Futian Hospital for Rheumatic Diseases, Shenzhen, China

Background: We have a long-term interest in novel arsenic trioxide As2O3 (ATO) medical application since some acute promyelocytic leukemia (APL) patients have been cured by first using ATO and survived for more than 45 years successfully treated by Prof. Zhang Tinglong in our institute. Moreover, our previous studies have shown that ATO significantly suppress angiogenesis and induced fibroblast like synoviocytes (FLS) apoptosis in collagen induced arthritis (CIA) model[1, 2]. However, the extract mechanism by which ATO anti-rheumatic and whether this occurs via modulation of immune system are still unclear.

Objectives: To investigated the immunologic mechanism by which ATO may inhibit T helper 17 cells (Th17) differentiation while promote regulatory T cells (Treg) generation via modulating signal transducer and activator transcription 3 (STAT3) in treatment-naive RA patients.

Methods: Naïve CD4+ T cells sorted by fluorescence-activated cell sorting (FACS) from treatment-naive RA patients and healthy controls were used to investigated the effect of ATO on its polarization process and related cytokines. Knockdown or enforced expression of STAT3 transfection experiments were conducted by small interfering RNA (siRNA) and lentivirus STAT3 to verify the mechanism of ATO on Th17/Treg balance in vitro. Collagen-induced arthritis (CIA) model was constructed to detect the clinical score, histopathological change, bone destruction, Th17/Treg proportion and joint tissues immunohistochemistry. Single cell sequencing and other methods have been applied too.

Results: We found that ATO prevented activated naïve CD4+ T-cell differentiates into Th17 cell and reduced cytokine production by activated Th17 cells by downregulating their signature transcription factors, STAT3 and orphan nuclear receptor (RORγt). Notably, ATO reduced Th17 cells frequency while increased Treg cells frequency under specific polarizing conditions from treatment-naïve RA patients by transfecting siRNA STAT3 and lentivirus STAT3. Furthermore, we have noticed that intervention of ATO in CIA model attenuated joint inflammatory infiltration and bone destruction, significantly improved the imbalanced Th17/Treg ratio. In-detail single cell sequencing analysis is ongoing.

Conclusion: ATO may be an immune modulator candidate for treatment-naive RA patients via balancing well Treg/Th17 cell ratio through STAT3 regulation.

AB0116 BROMODOMAIN INHIBITOR, I-BET762 INHIBITS PRODUCTION OF PRO-INFLAMMATORY MEDIATORS BY DOWN-REGULATING BROMODOMAIN AS AN EPGENETIC READER IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

Ra Ham Kim1, Hyun Jung Yoo1,2, Shin Eul Kang1, Ji Soo Park1, Seon Uk Kim1, Eun Young Lee1, Jin Kyun Park1, Yeong Wook Song1,2, Seoul National University, Department of Moleculer Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Seoul, Korea, Rep. of (South Korea), 2Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea).

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disorder, characterized by joint inflammation and bone destruction. The fibroblast-like synoviocyte contributes to the pathogenesis of RA through proliferation and production of cytokines. Recently, blockade of the bromodomain and extra-terminal domain
AB0139 ASSOCIATION OF RS17004921 ADORA2A GENE POLYMORPHISM WITH EFFICACY OF MTX TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Vera Milic, Milka Grg, Nemanja Djamjan, Biljana Jelic. Institute of Rheumatology, Faculty of Medicine, Belgrade, Belgrade, Serbia; Institute of Human Genetics, Faculty of Medicine, Belgrade, Belgrade, Serbia; Institute of Rheumatology, Faculty of Medicine, Belgrade, Belgrade, Serbia

Background: Adenosine A2A receptors (ADORA2A) are part of the adenosine-mediated antiinflammatory pathway. These receptors are over-expressed in the peripheral blood leukocytes of patients with rheumatoid arthritis (RA). Methotrexate (MTX), the gold standard for therapy, exerts its antiinflammatory effects via increased release of adenosine into the extracellular space. Adenosine binds to ADOR A2 and A3 and initiates an antiinflammatory response. Therefore, ADOR gene polymorphisms could have an impact on MTX therapy outcome.

Objectives: To examine the role of adenosine receptor 2A gene (ADORA2A, rs17004921) polymorphism on outcome of MTX treatment in RA.

Methods: A total of 123 patients with RA (mean age 56.5±10.7; 91 (74%) females), treated with MTX for 6 months (mean dose 12.2±3.20 mg/week) were enrolled in a prospective study. Genotypeisation within ADORA2A gene was performed using the KASP genotyping assays. MTX efficacy assessment was based on the changes in the Disease activity score (DAS28) after 6 months of treatment according to the EULAR response criteria. Patients with good and moderate response were classified as ‘responders’, whereas patients with poor response were considered ‘nonresponders’. Data of adverse effects were collected during this period. MTX efficacy and toxicity were compared among patients with different genotypes. All statistical analyses were performed by SPSS version 16.0.

Results: Median DAS 28 at the beginning of MTX treatment was 7.43±0.89. According to EULAR response criteria, 111 (90.2%) patients with RA were classified as responders. Among all RA patients, 97 (78.9%) had CC, 20 (16.3%) CT and 6 (4.9%) TT genotype. The distribution of ADORA2A genotypes in responders (CC 77.5%, CT 17% and TT 5.4%) was not significantly different from nonresponders (CC 91.7%, CT 8.3%), p>0.05. After 6 months, 26 carriers of T allele (CT +TT) had higher reduction DAS 28 (7.16 vs. 3.88) in comparison to other 97 patients (7.50±4.84, p<0.013). Adverse effects were reported in 24 (19.5%) patients. Most of patients had hepatotoxicity and nausea, 14 (56%) and 9 (37%) respectively. No statistically significant association between ADORA2A genotype and side events has been observed (p>0.05).

Conclusion: According to our results, T allele of ADORA2A rs17004921 polymorphism may have favourable influence on efficacy in RA patients treated with methotrexate.

AB0150 IMMATURE GRANULOCYTES LEVEL IS A POTENTIAL BIOMARKER IN PERIPHERAL ENTEHISIS

Ahweer Al-Ansari1, Iman Hussien2, 3. Mediclinic Airport Road Hospital, Rheumatology, Abu Dhabi, United Arab Emirates; 4. Lileline Hospital, Rheumatology, Abu Dhabi, United Arab Emirates

Background: Immature granulocytes (IG) level in peripheral blood is used as early sign of infection. On the other hand, IG could be elevated in other conditions like inflammatory or cancerous diseases and in pregnancy. Similar to CRP, we have observed a series of cases of peripheral enthesitis associated increased level of IG and correlated with CRP elevation and clinical activity.

Objectives: To test the concept of IG as a biomarker in peripheral enthesitis, this observation might be a reflection to the innate immunity role in pathogenesis of enthesitis.

Methods: We have identified 13 cases over the last 12 months at the Rheumatology clinic in our centre who have shared two features (clinical enthesitis and elevated IG) those 13 cases are mainly presented with recurrent foot and ankle pain and swelling of entheses nature.

Results: The cohort is of equal gender distribution 46/54% respectively and age range 31-53 years (mean age 38.5), only 3 patients are known to have Psoriatic arthritis whilst the rest either undiagnosed or diagnosed Rheumatoid arthritis or gout prior to clinic visit. The rheumatologist clinical diagnoses are of enthesitis of foot, ankle, knee and hip area as shown on the table [1] apart from one patient who has spinal symptoms mainly. 4/13 patients have the history of psoriasis and after their visits we find them fit in the CASPAR criteria for psoriatic arthritis. All these cases are associated with increased absolute number of IG as well as differential (IG) number compare to 10/13 of these cases are having high CRP. The 3 cases with normal CRP do have relatively slight increase in (IG) number. The main correlation is of response to therapy and was seen in 7 cases who have followed up at the time of submission and it shows a 100% correlation between CRP, absolute (IG) and differential (IG) values. There are 3 patients who have elevated (IG) but normal CRP and it would possible indicate (IG) test has a better yield than CRP in peripheral enthesitis.

Conclusion: Immature granulocytes can be elevated in inflammatory disease and more notably in peripheral enthesitis of the lower limbs of inflammatory rather than mechanical nature and do correlate with CRP elevation as well as response to therapy. Larger studies are needed to assess the usefulness and validity of (IG) level in clinical practice.

AB0151 EXPRESSION OF ANXIETY AND DEPRESSION IN PATIENTS WITH ANKYLOSING Spondylitis DEPENDING ON THE STATE OF THE AUTONOMIC NERVOUS SYSTEM AND INTENSITY OF THE PAIN SYNDROME

Irina Blaginina, Olga Rebrova, Anna Blagodarenko, Pavel Bakhtyarov, Olga Yavorskaya, Lugansk State Medical University, Lugansk, Ukraine; Lugansck republican clinical hospital, rheumatology, Lugansk, Ukraine

Background: Chronic pain syndrome, immanent in the majority of immune-inflammatory processes, is one of the pathophysiological mechanisms of the development of emotional and affective disorders. It has been proven that high levels of “pro-inflammatory” mediators are predictors of depression, and increased anxiety leads to an imbalance in the autonomic nervous system (ANS). It is also known that the pain syndrome worsens the autonomic supply of the organism. However, this problem remains insufficiently studied today.

Objectives: To assess the severity of anxiety and depression in patients with ankylosing spondilitis, depending on the state of the ANS and pain syndrome.

Methods: The study included 75 patients with ankylosing spondylitis (AS), who studied the frequency of anxiety-depressive disorders and their severity on the Spielberger anxiety and Hamilton depression scales. The autonomic state was investigated according to the methods “Wayne-patient” - WP, filled by the patient (more than 15 points - possible autonomic dysfunction (AD)) and “Wayne-doctor” - WD, filled by a doctor (more than 25 points - confirms the presence of signs of AD); we evaluated the indicators of heart rate variability (HRV) - mode (Mo), mode amplitude (Amo), autonomic equilibrium index (AEI), regulatory systems tension index (TI), the standard deviation of the normal RR intervals (SDNN), the square root of the mean squares of the difference between successive RR intervals (RMSSD) and the balance ratio of the activity of the sympathetic and parasympathetic divisions of the ANS (LF/HF). Pain syndrome and the patient's own health index (POH) were assessed by a visual analogue scale (VAS) by patients, and by a physician - by counting the number of painful joints (NPJ), index BASDAI and ASDAS indices.

Results: In 25.3% of patients with AS, a high situational anxiety was observed and in 36% of patients high personal anxiety (PA) was observed. Depressive disorders were found in 57 patients with AS (76%). The severity of pain in the joints and the spine influenced the increase in PA (F = 2.75, p = 0.047; F = 3.54, p = 0.037, respectively) and the level of depressive disorders (F = 3.28, p = 0.03; F = 3.44, p = 0.047, respectively), and the level of depression is also POH (F = 3.49, p = 0.048), 68% patients had an AD (according to WP and WD methods). They constituted the 1st group of observation, and the remaining 24 patients were included in the 2nd group. In group 1, signs of anxiety disorders were identified in 64.3% of cases, and in patients without AD - 45.8% of cases. Depressive disorders were observed in 94% of patients with autonomic disorders (11 cases of psychotic, 37 - non-psychotic depression) and in 37.5% in patients without signs of AD - signs of non-psychotic depression.

In both groups, there was a decrease in SDNN and RMSSD in comparison with normative ones, which indicates an increase in sympathetic regulation. In the 1st group, there was a more significant increase in LF/HF (4.15 ± 0.64) and a decrease in SDNN (22.4 ± 5.6 ms) than in the 2nd (3.0 ± 0.86; 29.1 ± 8.4 ms), which indicates the connection between the strengthening of the sympathetic regulation link and the presence of signs of psycho-emotional disorders. The growth of Amo in the 1st group (47.9 ± 8.4%) reflects the degree of mobilizing influence of the sympathetic division and indicates an increase in the activation of the central contour and the growth of sympathetic regulation in patients with AS and AD.

Conclusion: Patients with AS have a high incidence of clinically significant anxiety and depression, which were affected by the intensity of the pain syndrome. The presence of autonomic imbalance and dysregulation of the sympathetic link of the ANS also contribute to the strengthening of psycho-emotional disorders in this category of patients.

AB0153 CLINICAL SIGNIFICANCE OF MONOCYTE TO HEMOGLOBIN RATIO AND PLATELET TO ALBUMIN RATIO IN PATIENTS WITH AXIAL SPONDYLOARTHROPSIS

Yukai Huang, Qidang Huang, Meng Liu, Zheng Zhong, Fan Feng, Jiawei Jiang, Yuqi Liu, Li Tianwang. Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China

Background: Axial spondyloarthropathy (axSpA) is a progressive, chronic, inflammatory skeletal disorder. Platelet to hemoglobin ratio (PHR) and platelet to albumin ratio (PAR) have been recommended as prognostic factor of cancer. However, none of study has focused on the clinical significance of PHR, PAR, neutrophil to hemoglobin ratio (NHR), neutrophil to albumin ratio (NAR), monocyte to hemoglobin ratio(MHR) to albumin ratio(MAR) for axSpA.

Objectives: To study the reason of clinical significance of NHR, NAR, MHR, MAR, PHR, PAR for axSpA.

Methods: A total of 198 axSpA patients and 48 healthy subjects were enrolled in the study retrospectively. Neutrophil, monocyte, platelet, hemoglobin, albumin, CRP, ESR, MHR, NAR, MHR, PAR, NAR, MAR were included. AxSpA patients were divided into remission group (BASDAI<4) and active group (BASDAI≥4). Relationships between the parameters and BASDAI were assessed by the Spearman’s correlations analysis.

Results: Neutrophil, monocyte, platelet, NAR, MHR, MAR, PHR, PAR were higher in active group than those of control group, while albumin and hemoglobin were lower (P<0.05). ROC curve results showed that the AUC value of PHR for axSpA was 0.808 (CI95%: 0.738-0.878), yielding a highest AUC value than other parameters. The optimal cutoff value of MHR for axSpA was 0.002447, with the Youden index of 0.498, sensitivity of 87.4% and specificity of 62.5%. The closely positive correlations were found between MHR, and BASDAI were collected. AxSpA patients were divided into remission group (BASDAI<4) and active group (BASDAI≥4). Relationships between the parameters and BASDAI were assessed by the Spearman’s correlations analysis.

Receiver operation characteristic (ROC) curves were used to discriminate axSpA patients from healthy subjects and active group from remission group.

Results: Neutrophil, monocyte, platelet, NAR, MHR, MAR, PHR, PAR, CRP, ESR in axSpA group were higher than those of control group, while albumin and hemoglobin were lower (P<0.05). ROC curve results showed that the AUC value of PAR for active group was 0.693 (CI95%: 0.610-0.775), yielding a highest AUC value than other parameters. The optimal cutoff value of PAR for active group was 5.967, with the Youden index of 0.354, sensitivity of 83.3% and specificity of 52.1%.
Conclusion: MHR was elevated in axSpA patients with a highest diagnostic value. PAR was elevated in active axSpA patients, showing a significant correlation to the disease activity.

AB0154 WNT-BETA CATENIN PATHWAY MAY BE UPRERGULATED IN ANKYLOSING SPONDYLITIS
Marina Magrey1, Tarig Haqqi2, Nora Singer1, Maya Breitman3, Maricela Haghiac4.
1Case Western Reserve University School of Medicine at MetroHealth, Cleveland, United States of America; 2North Ohio Medical University, Rootstown, United States of America; 3MetroHealth Medical Center, Cleveland, United States of America; 4MetroHealth Medical Center, Cleveland, United States of America

Background: The Wnt–β-catenin pathway may play a critical role in new bone formation in ankylosing spondylitis. Wnt–β-catenin signaling depends primarily on the activity of glycogen synthase kinase-3β (GSK3β) that plays a key role in controlling β-catenin stability/degradation. It has been clearly established that phosphorylation of serine 9 in GSK3β correlates with the inhibition of its kinase activity and stabilization of β-catenin. Dickkopf-1 (DKK1) and sclerostin (SOST) are both upstream inhibitors of the Wnt/β-catenin pathway. Given that AS is associated with new bone formation we are interested in the molecular pathways that lead to this clinical phenotype.

Objectives: The objective of our studies was to test the hypothesis that “alterations in the Wnt–β-catenin activity may be a contributing factor in the pathogene- sis of AS”.

Methods: 5 healthy donors and 12 patients (mean age 48 y.o., HLA-B27+ 70%) with AS based on New York classification criteria were enrolled. RNA was extracted from whole blood collected in PAX tubes following PreAnalytix method were used to quantify the data (normalized to RPLP0(60S acidic ribo- somal protein P0)). Protein lysates were prepared using NucleoSpin RNA/Pro-tein kit (Takara) from PBMCs isolated from blood collected from the same 12 patients. Equal amounts of protein were loaded on 4–12% SDS gels and trans- ferred to PVDF membranes. Membranes were blocked with 5% milk in TBST and probed at 4°C overnight with primary antibodies [rabbit anti-phos- phoGSK3β (Ser9) (1:500; Cell Signaling, #9336), rabbit anti-GSK3β (1:500; Santa Cruz Biotech- nology, #2859), and ΔΔCt- method were used to quantify the data (normalized to RPLP0(60S acidic ribosomal protein P0)]. Protein lysates were prepared using NucleoSpin RNA/Protein kit (Takara) from PBMCs isolated from blood collected from the same 12 patients. Equal amounts of protein were loaded on 4–12% SDS gels and trans- ferred to PVDF membranes. Membranes were blocked with 5% milk in TBST and probed at 4°C overnight with primary antibodies [rabbit anti-phos- phoGSK3β (Ser9) (1:500; Cell Signaling, #9336), rabbit anti-GSK3β (1:500; Santa Cruz Biotech- nology, #2859), and mouse anti-β-actin (1:1000; Santa Cruz Biotech- nology, sc-7778)}. Appropriate HRP-conjugated secondary antibody was applied at room temperature for 1 hour. Immunoreactive protein bands were visualized using ECL (Pierce) and imaged with VisionWorks Image Acquisition and Analysis Software (Analytik Jena US, Upland, CA). β-actin was used as a loading control.

Results: Compared to healthy controls the mRNA levels of DKK1 and SOST were significantly lower in AS patients (p < 0.01), while the mRNA level of β-catenin was significantly higher in AS patients than in healthy controls (p < 0.05) (Fig 1).

Conclusion: These data indicate that altered Wnt–β-catenin activity may be contributing to the new bone formation in AS patients and thereby contributing to the disease pathogenesis and can be targeted for therapeutic development.

Disclosure of Interests: Marina Magrey Grant/research support from: M. Magrey received research funding from AbbVie and UCB for clinical trials, served as a consultant for Novartis, and was a member of advisory boards for Eli Lilly, Novartis, and UCB, Tarig Haqqi: None declared, Nora Singer: None declared, Maya Breitman: None declared, Maricela Haghiac: None declared

AB0155 INTESTINAL MICROBIAL SIGNATURE IN ANKYLOSING SPONDYLITIS
Anca Cordoneanu1, Alexandra Buriu1, Catalin Codreanu1, Elena Rezus1, 1University of Medicine and Pharmacy “Georgiu T Popa”, IASI, Romania; 2Clinical Center of Rheumatic Diseases “Dr Ion Stoia”, Rheumatology, Bucharest, Romania

Background: Intestinal microbiota analysis is a current subject because of its important role in the pathogenesis of various autoimmune diseases such as intestinal inflammatory diseases or spondylarthropathies.

Objectives: The objective of this paper was to perform a quantitative determination of the intestinal microbiota in patients with ankylosing spondylitis (AS) and to highlight the main characteristics of intestinal dysbiosis in these cases.

Methods: We conducted a case-control prospective study that included 28 patients with AS and 32 control cases (healthy individuals). Intestinal microbiota analysis was performed by real-time PCR (polymerase chain reaction) in faeces. Intestinal microbiota analysis focused on the following bacterial species: Bacteroides, Bifidobacterium, Clostridium cocoides (XIVa) (C. Cocoides), Clostridium leptum (IV) (C. Leptum), Faecalibacterium prausnitzii (F. Prausnitzii), Lactobaci- lus, Escherichia coli (E. coli).

Results: Intestinal dysbiosis in AS patients was characterized by a significant bacterial decrease compared to the control arm. Some bacterial species showed a numerical growth: Bacteroides, C. cocoides and C. leptum, F. praussnitzii. In other bacterial groups there was a significant decrease: Bifidobacterium, Lactobacillus and E. coli. Statistically significant correlations were observed only for Bifidobacte- rium, significantly increased in the axial form of AS compared to the peripheral form (p = 0.035). Other bacterial groups were numerically elevated in the axial form of AS (except Bacteroides), without statistically significant differences. In all AS cases, a moderate disease activity was evidenced (mean BASDAI = 4.83, mean BASFI = 9.11). BASDAI score inversely correlated with the total bacteria group (p = 0.010, r = -0.606) - intestinal dysbiosis worsens as disease activity increases. Also, direct proportional correlations were highlighted between BAS- DAI and F. prausnitzii (p = 0.000, r = 0.764), respectively Lactobacillus (p = 0.047, r = 0.488). An increase in AS activity is associated with an increase in proinflam- matory bacteria. BASFI score statistically correlated with the total bacterial count (p = 0.000, r = -0.764), F. prausnitzii (p = 0.010, r = 0.606), Bifidobacterium (p = 0.016, r = 0.843) and E. coli (p = 0.016, r = 0.575). An important decrease in the functionality of these patients correlates with a decrease in total bacterial diversity. Improvement of intestinal dysbiosis has been observed in patients on synthetic and biological immunosuppressive therapy compared to the control arm.

Conclusion: The study highlights the characteristics of intestinal dysbiosis in AS patients. There is a direct relationship between the composition of intestinal microbiota and the AS activity scores. Specific treatment for AS leads to a decrease in proinflammatory bacteria, improving gut dysbiosis.

A NOVEL ASSOCIATION OF TLR-2 (23 BPINS/DEL: RS111200466) POLYMORPHISM WITH ANKYLOSING SPONDYLITIS – A POSSIBLE ROLE IN DISEASE SUSCEPTIBILITY: A HOSPITAL BASED CASE-CONTROL STUDY

Abhishek Sabu1, Rina Tripathy1, Aditya Kumar Panda2, Manoj Kumar Panda2, Saumya Ranjan Tripathy3, Biduyat Kumar Das1, S.C.B Medical College, Medicine, Cuttack, India; 4S.C.B Medical College, Biochemistry, Cuttack, India; 5Khulnato University, Life Science, Brahmapur, India; 6S.C.B Medical College, Rheumatology, Cuttack, India

Background: Role of innate immunity in pathogenesis of ankylosing spondylitis (AS) has been well documented. Higher expression of TLR2 has been reported in AS patients and associated with clinical severity. Recently, a functional 23bp ins/del polymorphism of 5’UTR of TLR2 gene has been reported and association of variant with elevated TLR2 surface expression and proinflammatory molecules has been elegantly demonstrated. This is associated with high TNF-alpha levels, one of the key molecules in the pathogenesis of AS. In this preliminary study, we investigated the possible role of TLR2 (23bp ins/del) polymorphism with AS in a cohort from Odisha, India.

Objectives: To investigate the role of TLR-2 (23 bp ins/del: rs111200466) Polymorphism in Ankylosing Spondylitis

Methods: AS patients (n = 101), who fulfilled the ASAS classification criteria for peripheral spondyloarthritis or ASAS classification criteria for peripheral spondyloarthritides were enrolled along with 100 healthy age matched controls from similar geographical areas. Patients were examined in detail and BADA/BASFI recorded. TLR2 (23 bp ins/del) polymorphism was genotyped by polymerase chain reaction. Genotype and allele distribution among patients and controls were compared by Fisher’s exact test.

Results: All patients enrolled in the present study were males. The mean age of AS patients and healthy controls was 31.21±11.43 and 28.28±9.62 years, respectively. At the time of enrolment, mean disease duration of patients was 2.07±1.13 years. BASDAI and BASFI scores were above 5. Distribution of TLR2 (23 bp ins/del) polymorphism was in accordance with Hardy-Weinberg Equilibrium. No significant association of TLR-2 polymorphism was observed with disease severity.

Conclusion: TLR2 5’UTR homozgyous mutants (23 bp deletion) were significantly associated with patients of AS in but not with disease severity. Larger sample size and levels of TNF alpha and IL17 in the mutants will further improve the understanding of its role in AS.

SYNOVIAL FLUID PROTEOMICS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Channa Nam Son1, Jihyun Lee1, Byeong-Wook Song1, Hye-Jin Jeong1, Jin Nyeong Chae1, Ji-Min Kim1, Sang-Hyun Kim1, Jinsae Rhee2, Jong-Seo Kim3.

1Keimyung University, Daegu, Korea, Rep. of (South Korea); 2Keimyung University Dongsan Medical Center, Daegu, Korea, Rep. of (South Korea); 3Center for RNA Research, Institute of Basic Science, Daegu, Korea, Rep. of (South Korea)

Background: Ankylosing Spondylitis (AS), affecting 0.5% of the population, is a chronic inflammatory rheumatic disease affecting the axial skeleton and peripheral joints. When peripheral arthritis in ankylosing spondylitis (AS) develops early in the disease course it is a predictor of more aggressive disease. SF is in contact with the primary tissues affected by arthritic diseases and has been implicated in disease pathophysiology. Therefore it is an excellent source for discovery of biomarkers.

Objectives: We used proteomic analysis using SFs from AS patients and other arthritic patients in order to discover novel diagnostic markers for AS. Our aim was to identify differentially expressed protein mediators in synovial fluid of ankylosing spondylitis.

Methods: A Total of 40 SF samples from 10 AS and each 10 controls [Osteoarthritis (OA), Rheumatoid Arthritis (RA), gouty arthritis (Gout)] were collected. Liquid chromatography and tandem mass spectrometry (LC-MS/MS), to identify differentially expressed proteins based on the ratios of the extracted ion current of each protein between the four groups. Among the 9 proteins showing 1.5 fold change, 8 were verified with the exception of the abundant protein Haptoglobin (HP), Matrix metalloproteinase-1(1MMP1) and Matrix metalloproteinase-3(3MMP3) were used as a positive control, and the remaining 6 proteins were subjected to western blot analysis.

Results: We identified 9 proteins that were found to be more than 1.5-fold differentially expressed in SF of AS patients compared to control groups. Proteins such as HP, MMP1, MMP3, Serum amyloid P-component (APCS), Complement factor H-related protein 5(CFHR5), Fumarylacetacetase(FAH), Mannose-binding lectin2(MBL2), Complement component C9(C9) and Complement C4-A(C4A) were found to be upregulated in the SF of AS patients. CFHR5 and C9 were reported in previous studies with AS serum. APCS was reported in SF as well as serum. However, FAH, C4A and MBL2 were newly discovered through this analysis. We were able to verify the unique expression level of C9 and CFHR5 in AS sample using western blot analysis compared to other three diseases.

Conclusion: We performed quantitatively proteomic profiling of the respective SF sample from 4 diseases, i.e., AS, OA, RA, and GOUT, by LC-MS/MS. The systematic comparative proteomic analysis of the four groups together was carried out for the first time, leading to several differentially expressed proteins in AS. Among them, we expect C9 and CFHR5, which expression levels were confirmed by western blot analysis, can be a potential biomarker for AS.

FREQUENCY AND SPECTRUM OF ANEMIC SYNDROME IN PATIENTS WITH ANKYLOSING SPONDYLITIS: PECULIARITIES OF CYTOMETRIC CHARACTERISTICS AND HEMOPOIESIS

Sensi Shevchuk, Oxana Zviahina, National Progov Memorial Medical University, Vinnytsya, internal medicine, Vinnytsya, Ukraine

Background: Anemia is one of the most common extraarticular manifestations in patients with ankylosing spondylitis (AS). According to various sources, from 18.5 to 45.8% of patients with AS have anemia. In the pathogenesis of anemic syndrome in the AS, a leading role is given to proinflammatory cytokines (IL-1, IL-6, and TNF-alpha), which is associated with the development of anemia of chronic disease (ACD) in this category of patients. Another type of anemia in patients with AS is iron deficiency anemia (IDA), and the relationship between the latter and the ACD varies significantly according to various literature data. As for other types of anemia in the AS, they are represented by anemia caused by drugs. ACD varies significantly according to various literature data. As for other types of anemia in the AS, they are represented by anemia caused by drugs.

Objectives: The purpose of the work was to investigate the prevalence of anemia in the Ukrainian population of patients with AS and evaluate the hematopoiesis in patients with the main types of it.

Methods: The group with anemia included patients whose haemoglobin levels were below 120 g/l. The diagnosis of AS was determined according to the modified New York criteria (1984). Laboratory methods of research (general analysis of blood, erythrocytes, haemoglobin, color index, serum iron, total iron binding capacity (TIBC) included in the list of standard examinations of patients were performed according to standard methods. To verify the diagnosis of ACD, ferritin (FN) and levels of soluble transferrin receptor (sTfR) were determined.

Results: 118 patients with AS were included into the study, 11 (32.3%) females and 23 (67.7%) males. It was found that 34 patients (28.8%) had anemia. Anemia of mild degree was manifested in 27 (79.4%) patients and with moderate severity - 7 (20.6%) patients. Among 34 patients with anemia, patients with ACD - 15 (44.1%) predominated. In the second place, 10 (29.4%) showed a combination of ACD and iron deficiency anemia, and 2 (5.9%) patients had signs of IDA. Only one of the subjects had signs of scarce anemia. Consequently, anemic

OCULAR CAUSES OF THE INITIATION OF SYSTEMIC THERAPY PATIENTS WITH SPONDYLOARTHROPATHY (SPA) AND UVEITIS
Marta Garío Bufón1, Carlota Vigués2, Ana Garrote2, Carolina Álvarez Castro3, Miguel Cordero-Coma1.
1Teaching Hospital of Valladolid, Rheumatology, Valladolid, Spain; 2University Health Care Complex of Leon, Rheumatology, Leon, Spain; 3University Health Care Complex of Leon, Ophthalmology, Leon, Spain.

Background: Uveitis is the most frequent extra-axial manifestation in Spondyloarthritis (SPA). It is a complication that affects patients with SPA and requires treatment with Steroid Therapy (ST). The causes of uveitis in patients with SPA are well defined, they are not when dealing with eye involvement.

Objectives: To evaluate the ocular causes of the initiation of systemic therapy in patients with SPA.

Methods: Retrospectively, we analyzed the ocular causes of the initiation of systemic therapy in patients with SPA. The follow-up of these patients was between 2015 and 2019. The causes of uveitis were divided into: viral, autoimmune, neoplastic, biochemical, infectious and idiopathic.

Results: A total of 32 patients were analyzed. The causes of uveitis were as follows: viral (12%), autoimmune (31%), neoplastic (12%), biochemical (25%), infectious (6%) and idiopathic (4%).

Conclusion: Uveitis is a frequent complication in patients with SPA. The causes of uveitis in patients with SPA are well defined, but they are not when dealing with ocular involvement.

DECREASING AUTOPHAGY IN SALIVARY GLANDS OF PRIMARY SJÖGREN’S SYNDROME PATIENTS COULD BE ASSOCIATED WITH AN INCREASED EXPRESSION OF INFLAMMATORY MARKERS
Maria-José Barrera1, Sergio Aguilar2, Patricia Carvajal2, Isabel Castro1, Daniela Jara3, Sergio González4; Claudio Molina5, Soledad Matus6, María-Julieta González1, 2, 3, 4., Facultad de Odontología, Universidad San Sebastián, Santiago, Chile; 2Clinica INDISA, Santiago, Chile; 3ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile; 4Departamento Tecnología Médica, Universidad de Chile, Santiago, Chile; 5Educaela Odontología, Universidad Mayor, Santiago, Chile; 6Fundación Ciencia y Vida, Santiago, Chile

Background: Salivary glands (SG) of primary Sjögren’s syndrome (pSS) patients show high levels of IL-6 and endoplasmic reticulum (ER) stress1. In response to ER stress salivary epithelial cells trigger the unfolded protein response, seeking to alleviate ER stress through several mechanisms, such as autophagy. The autophagy does not only eliminate misfolded protein aggregates, but also decreases the inflammation selectively removing proteins related to TLRs and inflammasomes. Interestingly, the activation of IL-6/STAT3 signaling pathway inhibits the autophagy through an increase in MCL-1 expression2. Given the role of the autophagy as anti-inflammatory mechanism, it is interesting to evaluate if SG from pSS patients show a decrease in autophagy and if this correlates with the increased expression of inflammatory markers.

Objectives: To evaluate the expression of autophagy markers in labial SG (LSG) from pSS patients and 3D-acini deficient in autophagy. In addition, the expression of inflammatory marker IL-6, as well as, autophagy inhibitor MCL-1 was determined in 3D-acini control or deficient in autophagy, evaluating the possible participation of IL-6/STAT3 signaling pathway.

Methods: In LSG of 11 anti-Ro/La seropositive pSS patients and 10 control subjects, mRNA levels of ATG5, mTOR and Beclin-1 were measured by qPCR. ATG5, p62 and LC3B protein levels were measured by Western blot in LSG or 3D-acini deficient in autophagy by knocking down ATG5. HSG cells were transduced with lentiviral vectors expressing shRNAs against ATG5 mRNA or a control vector. Later, 3D-acini were generated from shATG5 and control cells. Acini were incubated with 10 ng/mL recombinant IL-6 in the presence or absence of 1.5 μM of JAK inhibitor tofacitinib for 24 h. The mRNA levels of IL-6 and MCL-1 were measured by qPCR.

Results: A significant decrease in mRNA levels of ATG5, mTOR and Beclin-1 was observed in LSG of SS-patients. In addition, a significant decrease of ATG5 protein levels was observed similar to SS-patients. Although, an increase in mRNA levels of MCL-1 was determined in 3D-acini stimulated with IL-6 and reverted with tofacitinib. Moreover, an increase in mRNA levels of IL-6 was measured in shATG5 3D-acini compared to 3D-acini control.

Conclusion: Our results suggest an attenuation of autophagy in salivary epithelial cells from anti-Ro/La seropositive pSS patients, which could be associated with an increased expression of inflammatory markers. We postulate that a plausible via involved in the autophagy attenuation in LSG from pSS patients could be the IL-6/JAK/STAT3 pathway, which induces MCL-1 expression. Further experiments are needed to elucidate this proposal.

Silent Cerebral MRI Findings in Lupus Nephritis and Non Nephritis Patients

Yumn Ahmed. Cairo University, Giza, Egypt

Background: Lupus nephritis carries high morbidity and mortality and whenever added to neuropsychiatric manifestations lead to more unfavorable prognosis. The current work focused on LN patients comparing them to those without kidney affection, studying their cerebral MRI and its correlation with the histopathological classes of LN and disease activity.

Objectives: To study the effect of renal affection on the brain in SLE and their clinical significance with early detection and management of such lethal comorbidity

Methods: Cerebral MRI and MRA were studied in 40 SLE patients without neuropsychiatric manifestation: 20 LN patients with different histopathological classes and 20 patients without kidney affection. Disease activity was assessed for all patients using SLE disease activity index

Results: Abnormal MRI brain findings were more common in LN patients “though non significant” (P=0.9). The most common lesions were white matter hypointense lesions. Number and size of such lesions were significantly higher in LN patients (1.8 fold that of non nephritis, P=0.003 and 0.03, respectively) and positively correlated with urea, creatinine, urinary albumin/creatinine ratio, SLEDAI, ESF, CRP, and grades of renal biopsy and negatively correlated with c3 and c4, cortical atrophy and preponite space dilatation were also significantly higher in LN patients (P<0.01).

Conclusion: Asymptomatic MRI brain lesions in LN patients, they are usually clinically significant and correlate to laboratory parameters of LN, grades of renal biopsy, and disease activity independent to age, sex and hypertension.

Lupus Podocytopathy–Case Report

Hana alahmar. King khaled university, abha, Saudi Arabia

Background: Lupus podocytopathy is a recently recognized new entity of lupus nephritis characterized by diffuse foot process effacement with or without mesangial expansion. Capillary wall immune deposits and glomerular proliferation are lacking in the histopathological analysis. (1) Clinically, it is manifesting as nephrotic proteinuria in the majority of reported cases.(1) Nevertheless, there is insufficient knowledge about the epidemiology, precipitant etiology and choices of management. Here, we describe a case presented with significant proteinuria secondary to podocyte effacement which is unusual underlying pathology.

Methods: 45 years old female diagnosed to have SLE 14 years back in the setting of malar rash, alopecia, arthritis and positive serology (ANA, Ds DNA). She was doing fine on HCQ till a years ago when she presented to the clinic with gradual onset lower limbs swelling.

Laboratory results showed a significant proteinuria 2781 mg/dl/day, urine analysis showed RBC 1-2 cells/microlitter, WBC 2-3 cells/microlitter, normal renal profile and normal C3-C4 counts. Kidney biopsy taken and described a picture of minimal change glomerulonephritis with mild mesangial expansion. In addition, the study was negative for the presence of immunocomplementation deposition with the absence of capillary basement membrane and tubulointerstitial inflammation. Patient was treated with Mycophenolate Mofetil 2 grams twice per day and 1 mg/kg/day oral steroids. 3 months later, protein was noticeably reduced in urine to 731 mg/dl/day but the patients had a side effect of MMF inform of significant weight loss, gastritis, and diarrhea. Azathioprine had been instituted alternatively with low dose prednisolone 10 mg. Proteinuria level had peaked again after 4 months of starting azathioprine to reach 5660 mg/dl. Kidney biopsy performed again which showed minimal light microscopic changes, the ultrastructural study showed extensive podocyte injury and foot process effacement up to 70% by the electron microscope.

Conclusion: Lupus podocytopathy is a recently recognized new entity of lupus nephritis characterized by diffuse foot process effacement without capillary wall immune deposits and glomerular proliferation. This case presentation illustrates an attention toward this new lupus entity. However, the lack of efficient knowledge about the frequency, clinical features and treatment necessitate further investigation.

Clinical Associations and Diagnostic Potential of Regulatory-Like B-Cells in Sjögren’s Syndrome

Filipe Barbosa1,2,3, Catarina Martínez2, Carlos Geraldes4, Ana Luísa Papoila4, Joana Cardigos3, Glória Nunes3, Teresa Lopes5, Nuno Alves6,7, José Vaz-Pato5, Jaime Branco2, Luis Miguel Borrego2,3. 1Instituto Português de Reumatología, Lisboa, Portugal; 2Hospital Cuf Descobertas, Lisboa, Portugal; 3Nova Medical School, Chronic Diseases Research Center, Lisboa, Portugal; 4Nova Medical School, Lisboa, Portugal; 5Centro Hospitalar de Lisboa Central, Ophthalmology, Lisboa, Portugal; 6Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

Background: Some B-cell subsets contribute to the regulation of immune responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses, mainly through the secretion of interleukin-10, which suppresses T-cell responses.

Objectives: To evaluate the distribution of regulatory and effector T and B-lymphocytes, in patients with pSS and healthy controls (HC), and the relation between regulatory-like B-cell subsets and the pSS phenotype.

Methods: Fifty-seven pSS patients (2002 AECG criteria) and 24 HC were included. Circulating T and B-lymphocytes were characterized by flow cytometry and groups were compared. Significance was considered for p<0.05.

Results: Compared to HC, pSS patients had lower percentages (19.9 vs 32.0%, p=0.001) and absolute numbers (28 vs 81 cells/µL, p=0.001) of Breg-enriched CD24+CD27- B-cells, and a decrease in CD24−CD38+ B-cells percentages (6.2 vs 7.7%, p=0.09).

Lower frequencies of CD24−CD27− B-cells were found in anti-SSA-positive patients, compared to anti-SSA-negative patients (15.0 vs 19.6%, p=0.170), as well as lower absolute counts (26 vs 31 cells/µL, p=0.173). Anti-SSA-positive patients presented higher CD24−CD38− B-cells percentages (6.2 vs 4.2%.

Disclosure of Interests: None declared

p=0.260) and absolute counts (10 vs 5 cells/µL; p=0.343) compared to anti-SSA-negative patients. Although CD24hiCD27+ B-cells frequencies and absolute counts did not differ between patients with active (n=27) or inactive disease (n=30), (16.9% vs 17.0%, p=0.946; 25 vs 31 cells/µL, p=0.166; 19 vs 24 cells/µL, p=0.179), patient activity (ESSDAI≥5) (n=9) presented lower absolute counts of CD24hiCD27+ B-cells (18 vs 31 cells/µL, p=0.096) and lower CD24hiCD27+ B-cells (4 vs 10 cells/µL, p=0.075), and higher Th1/Breg CD24hiCD27+ ratios (16.2 vs 9.2, p=0.064).

Considering all patients, a negative correlation was found between the ESSDAI score and the absolute numbers of either CD24hiCD27+ B-cells (r=−0.277, p=0.037) and Tregs (r=−0.311; p=0.019).

Correlations with ESSDAI was stronger when looking at patients with ESSDAI≥5: for the percentages of CD24hiCD27+ B-cells, r=−0.705, p=0.023; for CD24hiCD27+ B-cells absolute counts, r=−0.644; p=0.045; and for the absolute counts of Tregs, r=−0.862; p=0.001.

To study the effect of hydroxychloroquine on the level of anti-cardiolipin antibodies, IgM/IgG at 3 and 6 months from the start of therapy. Statistical data processing was performed using non-parametric methods (Wilcoxon Signed Ranks Test). Comparison of dependent samples confirmed APS. All patients were characterized by a history of three or more reproducible positive ANA, and 14% of them were confirmed APS. In patients treated with HC, levels of antibodies to cardiolipin (IgM/IgG) were 30.4% lower (p=0.001) after 6 months of therapy compared to the initial one [Me 21.43 (95% CI 20.2-24.2), p = 0.001]. By the sixth month of therapy, a reduced level of antibodies to cardiolipin remained unchanged; there was no statistically significant difference between the rates after 3 and 6 months of therapy. The level of antibodies to β2GPI (IgM/IgG) after three months from the start of therapy remained at the level of the indicator before inclusion in the study. A statistically significant decrease in the level of antibodies to β2GPI by 28.5% compared to the initial one was determined 6 months after the start of HC administration [Me 19.17 (95% CI 10.8-27.4), p = 0.003].

Conclusion: The study showed that, against the background of additional administration of hydroxychloroquine in patients with APS with low-level SLE, a decrease in the level of antibodies to cardiolipin (IgM/IgG) by 30.4% (p = 0.001) was observed after 3 months of therapy, to β2-glycoprotein I (IgM/IgG) - by 28.5% (p=0.003) after 6 months of therapy.

AB0163 THE ROLE OF IMMUNOREGULATORY MOLECULES ON FATIGUE IN PRIMARY SJÖGREN’S SYNDROME

Kalipana Dhai, Emmanuella Traiano, Jessica Tam, Wan Fai Ng. 1School of Clinical Education, Newcastle University, Newcastle upon Tyne, United Kingdom
2Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

Background: Primary Sjögren’s syndrome (pSS) is a chronic autoimmune rheumatic disease characterized by exocrine gland dysfunction. The clinical presentation of pSS can vary considerably from predominantly sicca symptoms such as dry eyes and dry mouth to systemic manifestations such as arthralgia, vasculitis and fatigue. Previous work from our laboratory has suggested that immunoregulatory pathways might play a role in fatigue development in patients with pSS. The first aim was to measure the serum levels of three candidate immunoregulatory molecules (melatonin, TGF-β and IL-10) and determine any relationship with fatigue severity. The second aim was to compare molecular profiles of the immunoregulatory mediators between pSS patients and healthy controls. The third aim was to identify key predictors of fatigue in pSS.

Methods: Serum levels of the three molecules were measured in 124 patients with pSS and 28 healthy non-fatigued controls selected from the United Kingdom Primary Sjögren’s Syndrome Registry using various assays. IL-10 concentrations were measured using a cytometric bead array-based immunoassay, melatonin levels were determined using ELISA and TGF-β concentrations were quantified using a bioassay in which HKC-8 cells were stably transfected with a TGF-β inducible CAGA-luciferase reporter construct. Patient fatigue levels were evaluated with a validated self-complete questionnaire and the scores were compared with the immunoregulatory molecular levels using analysis of variance. Significance in immunoregulatory mediators between the patients and controls was determined using the Wilcoxon test. Ordinal logistic regression analysis was performed in a smaller subset of patients (N = 75) to identify the key predictors of fatigue in pSS.

Results: IL-10 was significantly higher in the sera of patients with pSS compared to the healthy controls (p<0.0001). Melatonin showed a positive correlation with fatigue levels within the patient cohort (p=0.0164) whereas IL-10 and TGF-β were inversely related to fatigue severity (p=0.1265 and p=0.0643 respectively). The regression model used the three investigated immunoregulatory molecules, disease specific, haematological and clinical parameters as well as patient reported depression, anxiety and pain as predictors. The model was able to predict fatigue levels to a 7% accuracy.

Conclusion: The study suggests that melatonin may play a role in regulating the immune response in pSS and may affect fatigue levels in patients. Dryness, anxiety, pain and melatonin appear to be the most powerful predictors of fatigue in pSS. Further research into the effects of these immunoregulatory molecules is necessary to gain a better understanding of the pathophysiology of fatigue in pSS.

AB0162 IMPLEMENTATION OF HYDROXYCHLOROQUINE AT THE PRE-CONCEPTIONAL STAGE IN THE TREATMENT OF ANTIPHOSPHOLIPID SYNDROME ASSOCIATED WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Dmitrii Bublikov, Marina Nikolaeva, Altay State Medical University, Barnaul, Russian Federation

Background: The problem of correcting the antiphospholipid syndrome (APS) at the planning stage of pregnancy of patients with systemic lupus erythematosus (SLE) is an important task of rheumatology.

Objectives: To study the effect of hydroxychloroquine (HC) on the level of antiphospholipid antibodies titer in women with SLE of low degree of activity at the planning stage of pregnancy.

Methods: The study included 7 women aged from 18 to 44 years with a definite diagnosis of low-level SLE (1–5 points according to the SLEDAI2K scale) and confirmed APS. All patients were characterized by a history of three or more reproductive losses in the gestational age of 10 weeks or more. According to standard laboratory tests, the level of antibodies to cardiolipin (IgM/IgG) and/or to β2-glycoprotein I (IgM/IgG) in a titre above 99 percentile was determined twice in a 12-week interval. Before inclusion in the study, patients received methylprednisolone and acetazolamide in the recommended dosages. Other drugs potentially affecting the activity of SLE or hemostasis indicators of the patient during the observation period were not administered. At the time of inclusion, patients were prescribed with hydroxychloroquine (HC) in a dose of 400 mg per day orally, in addition to the therapy received earlier. The level of antibodies to cardiolipin (IgM/IgG) and antibodies to β2GPI (IgM/IgG) was determined at three times: initially, after 3 and 6 months from the start of therapy. Statistical data processing was performed using the MS Excel 2010 statistical software package and MedCalc Version 17.9.7. Data of laboratory parameters are presented in the form of median (Me) and 95% confidence interval (95% CI). Comparison of dependent samples was performed using non-parametric methods (Wilcoxon Signed Ranks Test).

The statistical significance of the hypotheses was accepted at a level of p<0.05.

Results: The initial SLEDAI2K index constituted 4.0±1.0 points. The median of the level of antibodies to cardiolipin is defined as 69.2% [95% CI 57.4 - 80.0] U/ml.

antibodies to β2GPI - 69.24 [95% CI 49.7 - 87.5] U/ml. After 3 and 6 months from the start of HC administration, the SLEDAI2K index did not statistically significantly change (p=0.09). 3 months later, a statistically significant decrease in the level of antibodies to cardiolipin (IgM/IgG) by 30.4% was determined relative to the initial one [Me 21.43 (95% CI 20.2-24.2), p = 0.001]. By the sixth month of therapy, a reduced level of antibodies to cardiolipin remained unchanged; there was no statistically significant difference between the rates after 3 and 6 months of HC therapy. The level of antibodies to β2GPI (IgM/IgG) after three months from the start of therapy remained at the level of the indicator before inclusion in the study. A statistically significant decrease in the level of antibodies to β2GPI by 28.5% compared to the initial one was determined 6 months after the start of HC administration [Me 19.17 (95% CI 10.8-27.4), p = 0.003].

Conclusion: The study showed that, against the background of additional administration of hydroxychloroquine in patients with APS with low-level SLE, a decrease in the level of antibodies to cardiolipin (IgM/IgG) by 30.4% (p = 0.001) was observed after 3 months of therapy, to β2-glycoprotein I (IgM/IgG) - by 28.5% (p = 0.003) after 6 months of therapy.

AB0164  THE EXPRESSION AND CLINICAL SIGNIFICANCE OF DIFFERENT FORMS OF LILRA3 IN SYSTEMIC LUPUS ERYTHEMATOSUS

Yan Du, Meiju Zhou, XinYu Wu, Jing Xue, Huaxiang Wu, Yujie Jiang. Zhejiang university school of medicine second affiliated hospital, Hangzhou, China

Background: LILRA3 is a member of the LILR family produced as a soluble molecule by monocytes and macrophages. A 6.7-kb deletion in the gene of LILRA3 results in a null allele and an absence of function. The frequencies of the 6.7-kb deletion vary greatly in different populations, considerably higher in Northeastern Asians (0.56–0.84) compared with Africans (0.10) or Europeans (0.17). The homozygous LILRA3 deletion (nonfunctional LILRA3) has been demonstrated to be associated with Sjogren’s syndrome (SS) and multiple sclerosis (MS) in Caucasians. However, in our previous studies, we found that in Chinese Han population, the LILRA3 non-deletion (namely functional LILRA3) contributes to susceptibility and subphenotypes of SLE and SS. With respect to the significant role of LILRA3 in immune-modulatory functions, we studied the role of LILRA3 in SLE.

Objectives: Our previous study has shown that functional LILRA3 contributes to susceptibility and subphenotypes of systemic lupus erythematosus (SLE). However, the mechanism remains unclear. We aimed to evaluate the role of LILRA3 in SLE.

Methods: 126 SLE patients and 48 healthy controls were recruited in this study. Functional studies were performed using intracellular flow cytometry and ELISA.

Results: Both LILRA3 levels in serum and CD14+ monocytes were significantly elevated in SLE patients compared with healthy controls. Elevated LILRA3 level was found positively correlated with SLEDAI. Furthermore, more elevated LILRA3 levels were found in patients with higher SLEDAI, presence of lupus nephritis and thrombocytopenia.

Conclusion: Both LILRA3 levels in serum and CD14+ monocytes significantly increased in SLE and positively correlated with disease activity and severity. The up-regulation of LILRA3 expression may serve as a biomarker of disease activity and severity of SLE.

Background: The obstetric antiphospholipid syndrome (OAPS) is an autoimmune disease defined by the presence of obstetric complications related to antiphospholipid antibodies. EUROAPS project is the biggest published European registry on obstetric antiphospholipid syndrome and it is ongoing.

Objectives: To analyse the clinical features, laboratory data and foetal-maternal outcomes, and follow them up on a cohort of 1100 women with obstetric antiphospholipid syndrome (OAPS).

Methods: Thirty hospitals throughout Europe have collaborated to carry out this registry. Cases with obstetric complaints related to antiphospholipid antibodies (aPL) who tested positive for aPL at least twice were included prospectively and retrospectively. The eight-year survey results are reported.

Results: 1100 women with 3653 episodes were included of which 2553 were retrospectively. The eight-year survey results are reported.

Background: Primary Sjögren’s Syndrome (pSS) is a chronic systemic autoimmune disease that is affecting primarily women near the menopausal age, causing exocrine gland dysfunction, with clinical manifestations varying from dry eye and mouth to multi-systemic disorders [1]. The lack of automated means for data quality improvement in pSS cohorts and the huge time effort needed for manual curation, yield data that are irrelevant and incomplete, introducing undesirable implications in their analysis.

Objectives: To enhance the quality of the clinical data in pSS using automated data curation.

Methods: Anonymized clinical data were recruited from 380 patients with pSS from the University of Athens (UoA) cohort (300 patients, mean age 68.79±14.84) and the Harokopio University of Athens (HUA) cohort (80 patients, mean age 59.2±13.92). The features consist of SS-related measures (see [2] for details). The curation tool produces 3 files: (i) a quality report, including the metadata, the presence of outliers (using the z-score [3]), unknown data types, and missing values, on a feature-basis (data imputation [4] is used to fix features with ≤ 50% missing values), (ii) the curated dataset, where the inconsistencies are marked using color notations, and (iii) a standardization report, where the features that share common terminology with those from a reference model [5] (i.e., a set of parameters that describe the pSS minimal requirements) are identified using lexical matching [6].

Results: For the UoA cohort, out of 167 features, 80 were classified as “bad”, 30 with unknown data type, and 12 were marked for outliers (Fig. 1). An example of an outlier was found for the IgM (1370 mg/dL). For the HUA cohort, out of 204 features, 69 were classified as “bad”, 5 with unknown data type, and 13 were marked for outliers. The standardization process successfully matched 82 out of 88 (93.18%) pSS-related terms for the UoA cohort and 61 out of 69 (88.4%) terms for the HUA cohort.

Conclusion: Our strategy enhances the quality of the pSS clinical data through data curation and reduces the time effort needed for manual curation, yield data that are relevant and complete, introducing undesirable implications in their analysis.

SNP (1513A>C AND 489C>T) OF P2X7 RECEPTOR IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH SEROSITIS

Federica Furini1, Anna Lisa Giuliani2, Mattia Erminio Parlati2, Marcello Govoni1, Francesco Di Virgilio2, Alessandra Bortoluzzi1. 1Section of Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant’Anna di Ferrara, Department of Medical Sciences, Cona (FE), Italy; 2University of Ferrara, Department of Morphology, Surgery and Experimental Medicine, Ferrara, Italy

Background: our preliminary data demonstrated that expression and activity of P2X7R was impaired in Systemic Lupus Erythematosus (SLE) and associated with a reduced production of IL-1β. Serositis is a typical manifestation of SLE characterized by a marked inflammation, which has been suggested to be an “inflammase driven” manifestation.

Objectives: to investigate the role of 1513A>C (rs3751143) and 489C>T (rs208294) Single Nucleotide Polymorphisms (SNPs) which are differently associated with loss or gain of function, respectively, of P2X7R, a potent activator of the NLRP3 inflammasome and IL-1β release in patients with SLE and in a history of serositis (SLE-S).

Methods: DNA was extracted from whole blood and used for evaluation of 2 P2X7R SNPs (1513A>C and 489C>T). Considering the combined action of these two SNPs, the overall activity of P2X7R was divided, into three groups: GOF (gain of function), normal function (NF), and LOF (loss of function). In addition, peripheral mononuclear cells (PBMCs) were isolated from venous blood and employed to evaluate P2X7R and NLRP3 expression by RT-PCR, assess P2X7R activity as Benzoyl ATP (BzATP)-induced intracellular Calcium ([Ca2+]i) increase and evaluate in vitro IL-1β following stimulation with lipopolysaccharide (LPS) and BzATP, either separately or in combination.

Results: 33 SLE patients (pts), 11 with (SLE-S) and 22 without serositis (SLE-NS) were enrolled. Mean age was 49.0±10.9 years and disease duration was 135.3±108.6 months. No significant difference in disease activity and clinical characteristic was found between the two groups (table 1). Evaluating 1513A>C SNP, 20 pts were positive for A/A and 13 for A/C phenotype respectively, while in case of 489C>T SNP, 7 pts presented C/C, 12 C/T and 14 T/T phenotype with a comparable distribution between SLE-NS and SLE-S (table 1). After combination of different phenotypes, 9 pts presented normal function (NF), 22 gain of function (GOF) and 2 loss of function (LOF) with no significant difference between SLE-S and SLE-NS (table 1). P2X7R activity, (evaluated as IL-1β production and [Ca2+]i increments) and expression (evaluated with RT-PCR) were comparable between SLE-S and SLE-NS. No significant difference was found between expression and activity of P2X7R and the two SNPs evaluated (table 2).

| DISEASE IN AB0169 AND 489C>T OF P2X7 RECEPTOR IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH SEROSITIS

Conclusion: our data indicate that the 1513A>C and 489C>T SNPs do not seem linked with reduced activity and expression of P2X7R that we previously observed in our cohort of lupus patients. Furthermore, no significant association was found between expression of these SNPs and development of serositis.

TUBERCULOSIS IN PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES: THE TUNISIAN EXPERIENCE

Sonia Harrampni1, Hela Sakly1, Melek Kechida1, Syrine Daada1, Rim Kili2, Hager Ben Brahmi2, Mohamed Chaikourt1. 1University of Monastir, Internal Medicine, Monastir, Tunisia; 2University of Monastir, Infection diseases, Monastir, Tunisia

Background: The incidence of tuberculosis among patients with systemic rheumatic diseases is much higher than in the general population. The clinical manifestations of both systemic rheumatic disease activity and tuberculosis, (i.e. fever, weight loss, asthma) may overlap or lead to confusion. The immunosuppression of systemic diseases makes the management of patients with tuberculous more complicated.

Objectives: The purpose of our study was to describe the clinical characteristics of patients with systemic rheumatic diseases and tuberculosis.

Methods: A retrospective study, from 1998 to 2018, in the internal medicine service in Fattouma Bourgiba hospital, Tunisia, of 59 patients suffering from connective tissues disease, treated by corticosteroids linked in one or several treatments to immunosuppressors, who subsequently developed tuberculosis.

Results: Fifty nine patients were included (46 women and 13 man) with a mean age of 47 years (range from 18-83 years). Systemic illnesses were: systemic lupus erythematosus (13.6%, n = 8), Gougerot-Sjögren syndrome (secondary or primary) (16.2%, n = 11), systemic scleroderma (5.1%, n = 3), rheumatoid arthritis (n = 1), Takayasu arteritis (n= 2), Behcet’s disease (n = 1), osteoarticular (n = 2) and more than one location in 23.7% of the cases. The localization of the tuberculosis was pulmonary (32.3%, n = 19), ganglionic (33.9%, n = 16), urogenital (20.3%, n = 12), lymphatic (n = 5), abdominal (n=4), cerebral (n=2), ocular (n=2), osteoarticular (n=2) and more than one location in 23.7% of the cases. The diagnosis of tuberculosis was confirmed by bacteriology in 13.6% (n = 8) and in thirteen cases, histologically (22.0%). The systemic rheumatic disease was clinically active at the time of the diagnosis of tuberculosis in 8 patients. The diagnosis of systemic rheumatic diseases was made before that of tuberculosis in 13 patients and concomitantly in 5. Under tuberculosis treatment by four drugs then by two drugs, the evolution of tuberculosis was favourable in most of our patients. Three of the patients developed an allergy in isoniazid. Nine patients have developped hepatotoxicity with pyrazinamide. Retrobulbar neuritis was observed in 3 cases treated with ethambutol.

Conclusion: This study confirms the often extra-pulmonary character of tuberculosis in patients with systemic disease as well as the difficulty of diagnosis and problems multiplied by this association. The screening strategies for tuberculosis should probably be extended in all patients with systemic rheumatic diseases receiving glucocorticoids and/or immunosuppressive therapy.

AB0172 EXPRESSION OF SLAMF6 AND ITS FUNCTIONAL SIGNIFICANCE IN PODOCYTES OF LUPUS NEPHRITIS
Takashi Iwaga, Kunihiro Ichinose, Mizuna Eguchi, Monoko Okamoto, Yushiro Endo, Sousuke Tsuji, Ayako Takatani, Toshimasa Shimmizu, Remi Sumiyoshi, Tomohiro Koga, Shir-ya Kawashiri, Naoki Iwamoto, Mami Tamai, Hideki Nakamura, Tomoki Origuchi, Atsushi Kawakami, Nagasaki University, Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Division of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: Systemic lupus erythematosus (SLE) is a multisystem disorder whose expression of nephritis (LN) is frequent complication and one of the most serious manifestations of SLE. The expression of nephritis, as podocyte marker, is reduced in various renal diseases that develop into nephrotic syndrome. The alteration of the structural protein in podocytes is known as a mechanism of proteinuria in LN.

Objectives: The signaling lymphocyte activation molecule family (the SLAM family) of type I transmembrane receptors consists of nine related members of the immunoglobulin superfamily and has been reported to mediate important regulatory signals between immune cells through their homophilic and heterophilic interactions. The 1q23 region (Step17 region in mouse) on human chromosome 1 including the SLAMF cluster of genes, containing SLAMF6 has been identified as a lupus susceptibility locus. It has been shown that the expression of signaling lymphocyte activation molecule family 6 (SLAMF6) is enhanced in CD4+ T cells of SLE patients and is involved in IL-17 production. We sought to examine the functional role of SLAMF6 in lupus podocytes.

Methods: We evaluated the co-expression of nephritis in nephritis (LN) and podocytes of normal controls and LN patients, also in B6 and MRL/lpr mice at the age of 6 wk and 10 wk by immunofluorescence analysis. We also examined nephrin positive SLAMF6 expression in isolated podocytes from B6 and MRL/lpr kidneys. Then, we analyzed the expression of SLAMF6 in CD4+ T cells of isolated kidney and spleen in B6 and MRL/lpr mice. We treated human podocytes with IgG from healthy individuals and LN patients for 24 h and 48 h and analyzed the expression of SLAMF6 by real-time PCR.

Results: In the histopathology, the expression of SLAMF6 was increased in nephritis in LN patients and MRL/lpr mice compared to control groups. Among the expression of nephritis in MRL/lpr mice kidney at 16 wk old decreased compared to B6 mice at same age, the expression of SLAMF6 in podocytes increased in diseased MRL/lpr mice compared to B6 mice. Similarly, the expression of SLAMF6 in CD4+ T cells increased in diseased MRL/lpr mice kidney and spleen compared to B6 mice. The level of SLAMF6 mRNA elevated in human podocytes exposed to LN-derived IgG compared to healthy individuals-derived IgG.

Conclusion: The expression of SLAMF6 is enhanced in LN podocytes, suggesting that the possibility of Cooperating with CD4+ T cells contributing to its dysfunction. Further examination is needed to investigate in detail how SLAMF6 is involved in the development of LN in the future.

AB0171 THE REGULATION AND PHARMACOLOGICAL MODULATION OF IMMUNE COMPLEX INDUCED PRODUCTION OF TYPE III IFN BY PLASMACYTOID DENDRITIC CELLS
Karin Hirtt1, Niklas Hagberg2, Olof Benggren2, Maj-Lena Elenora2, Lars Ronnblom1, Uppsala University, Dept of Medical Sciences, Rheumatology, Uppsala, Sweden; 1Uppsala University, Dept of Medical Sciences, Rheumatology, Uppsala, Sweden

Background: The type I Interferons (IFN-α) are the most important drivers of the IFN gene signature in Systemic Lupus Erythematosus (SLE). However, both type II and type III IFNs (IFN-λ) can be measured in a proportion of patients with SLE and contribute to the IFN signature. The exact role of type III IFNs in SLE is not completely clear, but serum levels of type III IFN correlate with disease activity and specific organ manifestations, such as arthritis, nephritis and anti-dsDNA antibodies. Type III IFN can be induced in DCs by nucleic acid containing immune complexes (IC), has, to our knowledge, not been investigated before.

Objectives: We asked if RNA containing immune complexes (RNA-IC), which trigger the synthesis of large amounts of IFN-α by plasmacytoid dendritic cells (pDCs), can act as stimuli for type III IFN production, and how this production is regulated by Natural Killer (NK) cells and different cytokines. We also investigated if the type III IFN production could be blocked by hydroxychloroquine (HCQ) and an interleukin receptor 1 associated kinase 4 inhibitor (IRAK4i).

Methods: Peripheral blood mononuclear cells (PBMCs) from SLE patients or healthy individuals were used to isolate PDCs and natural killer (NK) cells, or were depleted of monocytes. Cells were stimulated with RNA-IC, and cytokines were measured by immunoassays. mRNA expression in RNA-IC stimulated pDCs and NK cells was analyzed with a microarray. The effect of HCQ and IRAK4i on IFN-λ1 production was investigated in pDCs and NK cells from healthy individuals.

Results: Type III IFN mRNA expression was strongly upregulated in co-cultures of pDC-NK cells stimulated with RNA-IC. High levels of IFN-λ1 and IFN-λ2 (medians 2000 pg/ml and 100 pg/ml) were detected in supernatants from RNA-IC stimulated pDC-NK cell co-cultures. IFN-κ2 enhanced IFN-λ1 and IFN-α production by purified pDCs. Interleukin (IL) -3, -6, and -10, and GM-CSF significantly enhanced IFN-λ1 production (4-5 fold) by RNA-IC stimulated pDCs. Monocyte depleted PBMCs and pDC-NK cell co-cultures from 15% and 9% of SLE patients produced IFN-λ1 in response to RNA-IC stimulation. Exogenous IFN-α and GM-CSF in pDC-NK cell co-cultures increased the proportion of patients responding to RNA-IC stimulation from 9 to 36%. IFN-λ1 production by RNA-IC stimulated pDCs and pDC-NK cells was significantly inhibited by HCQ (by 99% and 93% respectively) and an IRAK4i (by 98% and 96% respectively).

Conclusion: pDCs produce both type I and type III IFN in response to RNA containing immune complexes. This is promoted by activated NK cells as well as a number of pro-inflammatory cytokines, including IFN type I and type III, considered important in SLE. Consequently, in order to achieve a proper control the IFN driven autoimmune process in SLE, both type I and type III IFN need to be targeted. In this system of stimulated, co-cultivated pDCs and NK cells, HCQ and an IRAK4 inhibitor blocked the type III IFN production.

Disclosure of Interests: None declared
LONG NON-CODING RNA, LINC00487 EXPRESSION IS UPREGULATED IN B CELLS AND CORRELATES TO DISEASE ACTIVITY IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

Jun Inamori1, Katsuya Suzuki1, Masaru Takeshita1, Yoshiaki Kase2, Rina Kurisu2, Makio Takiguchi2, Yuumi Okuzono2, Shinya Tasaki1, Tsutomu Takeuchi1, Keio University School of Medicine, Tokyo, Japan; Takeda Pharmaceutical Company Limited, Tokyo, Japan

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease characterized by interferon signature [1] and exocrine gland dysfunction which leads to dryness of the eyes and mouth [2]. B cells are considered to play an important role in the pathogenesis of pSS. Dysregulation of B cells can lead to production of anti-Sjögren’s syndrome-related antigen A (anti-SSA) autoantibodies.

Objectives: We investigated the differential gene expression of peripheral B cell subsets to reveal the precise role of B cells in the pathogenesis of pSS.

Methods: We enrolled pSS patients (n=6) and healthy controls (HC) (n=6), with matching for age and sex. Peripheral B cells acquired from the participants were separated by cell sorting into 4 subsets: CD38-IgD+, CD38+IgD+, CD38highIgD+ and CD38±IgD-. Total RNA was extracted and gene expression was measured using the Human Genome U133 Plus 2.0 Array (Affymetrix). The data were bioinformatically analyzed with reference to the corresponding clinical information.

Results: Using principal component and clustering analyses, we found that transcript expression patterns depended on cell type rather than clinical condition (pSS or HC). Interferon signaling was the most upregulated pathway in many of B cell subsets of pSS patients. As well as HLA and interferon signature genes, LINC00487 was upregulated significantly in all B cell subsets. Its fold changes in CD38-IgD+, CD38+IgD+, CD38highIgD+ and CD38±IgD- were 8.4 (p=0.038), 11.3 (p=0.014), 8.5 (p=0.089) and 6.37 (p=0.078), respectively. In addition, the normalized intensity value of LINC00487 was significantly correlated with disease activity score in all pSS B cell subsets, namely CD38-IgD+ (Figure A, r=0.96, p=0.002), CD38+IgD+ (Figure B, r=0.90, p=0.015), CD38highIgD+ (Figure C, r=0.81, p=0.049) and CD38±IgD- (Figure D, r=0.96, p=0.003). The expression of LINC00487 in B cell lines was regulated by IFNβ.

Conclusion: Compared to HC, patients with pSS showed upregulation of the interferon signaling pathway and LINC00487 gene in all B cell subsets. This upregulation correlated with disease activity and regulated by IFNαs in B cell lines. These results may suggest that long non-coding RNA contributes to B cell dysregulation in patients with pSS and the precise role of LINC00487 in B cell and pathogenesis of pSS requires further study.

ESSDAI; EULAR Sjögren’s Syndrome Disease Activity Index

production of pro-inflammatory cytokines were analyzed in urinary myeloid cells of patients with LN.

Results: Myeloid cells were identified by the expression of CD45+ and CD11c+ in the urine of patients with LN. The frequency and absolute numbers of myeloid cells were markedly increased in patients with proliferative LN than non-proliferative LN. In addition, titers of anti-dsDNA antibodies were correlated with the frequency or numbers of urinary CD11c+ myeloid cells. These urinary CD11c+ myeloid cells showed the phenotypes of infiltrated monocyte-derived cells rather than tissue-resident macrophage. In addition, CD11c+ myeloid cells were localized in tubulointerstitial and had capacity to produce pro-inflammatory cytokines including IL-6. Further, we found that there was a significant population of tubule cells in the urine, which is correlated with the frequency of CD11c+ myeloid cells.

Conclusion: Our results indicate that CD11c+ myeloid cells are present in the urine and contribute to tubulointerstitial inflammation in proliferative LN.

ABSOLUTE REDUCTION OF PERIPHERAL CD4+CD25+FOXP3+ T REGULATORY CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Xiaqing Liu, Yanan Duan, Nalin Lai, Gaiqin Chai. The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: T lymphocytes are important contributors to systemic lupus erythematosus (SLE). Regulatory T (Treg) cells, with the capacity to suppress immune responses, effector T cells (Teff), which promote inflammation, have been intensively studied in recent years. However, previous reports describing the respective changes of Treg and Teff, especially T helper cells (Th17) in SLE patients were controversial. Here, we investigated both absolute number and percentage of CD4+CD25+Foxp3+Treg (CD4Treg) cells and effector cells on a large scale and the role of low-dose interleukin-2 (IL-2) in SLE.

Objectives: To investigate both absolute number and percentage of CD4+CD25+Foxp3+Treg (CD4Treg) cells and effector cells on a large scale and the role of low-dose interleukin-2 (IL-2) in SLE.

Methods: Two hundred and thirty-five SLE patients (219 women and 16 men), with mean age of 37.80±14.00 years, were enrolled. The absolute count and percentage of subpopulation of peripheral blood (PB) lymphocyte in these patients were measured by flow cytometry combined with internal microscope standard. And low-dose IL-2 was used among 127 patients at a dosage of fifty IU every day for five days. Immunological and clinical assessments were performed again at the end of IL-2 treatment. Ninety healthy volunteers, matched for patients’ age and gender, were also included for the estimation of lymphocyte subsets.

Results: As compared to healthy controls (median of Treg cells: 33.09 cells/μl), the absolute number of circulating CD4Treg cells were significantly decreased in SLE patients (median: 15.49 cells/μl, P<0.001). The median ratios of Th17/Treg cells in patients were greatly higher than that of healthy volunteers [0.42 (0.19, 0.88) vs. 0.21 (0.15, 0.34), P<0.001], while there was not a significantly different in peripheral Th17 cell between two groups. Besides, Th1, Th2, CD8+T, B cells and their respective ratios to Treg cells were like that of Th17 cells as well. Moreover, CD4Treg cells were negatively correlated with ESR and SLEDAI score (r=-0.198, P=0.01; r=-0.25, P=0.002). While no obvious correlation was seen between Th17 cells and SLEDAI score. After IL-2 therapy in SLE, there was a four-fold increase in circulating CD4Treg cells [43.73 (24.08, 74.22) vs. 11.95 (7.51, 20.34), P<0.001], whereas Th17 cells were increased slightly. The ratio of Th17/Treg was decreased significantly in patients with IL-2 treatment [0.19 (0.09, 0.41) vs. 0.52 (0.23, 0.95), P<0.001], tended to balance and had no difference with healthy individual (P=0.275). Similarly, there were same trends in Th1, Th2, CD8+T, B and NK cells.

Conclusion: The reduction of CD4Tregs but not the elevation of effector cells may be the major reason for imbalance of Teff:Treg, indicating that SLE is an autoimmune disease triggered by the defect of immunotolerance. More importantly, low-dose IL-2 might promote the proliferation of various lymphocyte subpopulation, and mainly modulated the abundance and immunosuppression activity of Tregs, which effectively induced autoimmune tolerance and further improved clinical symptoms.

MITOGEN- AND STRESS-ACTIVATED PROTEIN KINASE-1 (MSK1) AS THE LINK BETWEEN MIR-130A-DYSREGULATION AND CDC2-ACTIVATION IN SJÖGREN’S SYNDROME

Ana P. Lopes1, Joel van Rooij1, Sofie Blokland1, Maoje Wang2, Eleni Chourli3, Aike-A. Kruijs2, Boudewijn Burgering3, Martin Rossato1, Timmy R. Radstake1, Marten Hiilten1.

1University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Laboratory of Translational Immunology, Utrecht, Netherlands; 2University Medical Center Utrecht, Department of Molecular Cancer Research, Center Molecular Medicine, Oncode Institute, Utrecht, Netherlands; 3University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands and dryness of mouth and eyes. T and B lymphocytes that infiltrate the salivary glands play a central role in local production of autoantibodies and cytokines, associated with dryness and tissue-damage. Type 2 conventional dendritic cells (cDC2) are very potent antigen-presenting cells and have the ability to produce a variety of cytokines involved in T and B cell activation, germinal centres formation and autoantibody production.

Objectives: Considering the critical role of microRNAs (miRNAs) in regulation of cell activation, we investigated their potential dysregulation in circulating cDC2s of patients with pSS compared to healthy controls (HC).

Methods: CD1c-expressing cDC2s were isolated from peripheral blood of pSS patients and controls from two independent cohorts. In the donors from the discovery cohort (15 pSS, 6 HC) the expression of 758 miRNAs was screened; the replication cohort (14 pSS, 11 HC) was used to confirm consistent differential expression of 18 identified miRNAs. A quantitative mass spectrometry-based technique (qPSILAC) in HEK-293T cells was used to identify novel targets of the replicated miRNAs. Target-miRNA interaction was replicated in primary cDC2s. Differences in cytokine production between pSS and HC cDC2s were evaluated by FACS. cDC2s were cultured in the presence of different MSK1-inhibitors to examine their effect on cytokine production.

Results: The expression of miR-130a and miR-708 was consistently decreased in cDC2s from pSS patients compared to HC in both cohorts, and both miRNAs were downregulated upon stimulation via TLR3 and TLR7/8. MSK1 was identified as a novel target of miR-130a and overexpression of miR-130a reduced MSK1 protein expression in both HEK-293T cells and primary cDC2s. In-line with the regulation of MSK1 by miR-130a, MSK1 expression was higher in cDC2s of pSS patients as compared to controls. An increased frequency of cDC2s producing-IL-12 and TNF-α was observed in pSS patients compared to HC, consistent with the central role of MSK1 in regulation of cytokine production. Exposure to either of two different MSK1 inhibitors in vitro reduced cDC2 cytokine production and the production of IL-12, TNF-α and IL-6.

Conclusion: We here provide the first evidence of molecular dysregulation of cDC2s in pSS, including increased expression of miR-708 and miR-130a, which can result from TLR activation, and enhanced production of pro-inflammatory cytokines. In view of its central role in NF-κB signalling, inhibition of MSK1 to decrease cell activation and inhibit pro-inflammatory cytokine production represents a novel therapeutic avenue for treatment of Sjögren’s Syndrome.

Disclosure of Interests: None declared

DOI: 10.1136/annrhumdis-2019-eular.6806
Methods: The study involved 80 (59-f and 21-m) APS patients (pts) 24 pts had PAPS and 56 pts had APS following SLE. In the whole study group the mean age was: 39.3± 12.7 years (range 18-71), the duration of the disease was 8.8 ± 8.3 years (range 0-37).

The presence of aPL was detected in patients’ serum using the commercially available tests: aPL-immunodot assay Anti-Phospholipid 10 Dot, for the qualitative detection of IgG or IgM antibodies. The statistical data analysis was performed using Statistics v13.0

Results: In the study group of 80 patients we have detected the presence of the following aPLs: a-cardiolipin IgM -37%, IgG -50.6%; a-phosphatidic acid IgM -19.7%, IgG -13.3%; a-phosphatidylycholine IgM and IgG -1.2; a-phosphatidy- lethanolamine IgM -1.2% and IgG -5.0%, IgG -12.5%; a-phosphatidylinositol IgM-10.0%, IgG -12.5%; a-phosphatidylserine IgM -31.0%, IgG -50.6%; a-annexin V IgM -20%, IgG -10%; a-β2-GP I IgM 44.5%, IgG -35.0%; a-prothrombin IgM -44.5%, IgG -30%.

The following clinical symptoms of APS were also present: stroke -10%, arterial/venous thrombosis -34%, pulmonary embolism-16.3%, obstetric complications-25.4%, nephropathy – 30.0%, hypertension-43.8%, valve defects 15.0%, livedo reticulars 11.2%, convulsions/chorea-6.2%, thrombocytopenia- 23.7% of the study group.

During the study we detected statistically significant differences in the frequency of occurrence of aPLs between groups with PAPS and SAPS: a-phosphatidylglycerol p=0.0045; a-β2-GP I IgM p=0.0045; a-prothrombin IgM p=0.0108 a-phosphatidylcholine acid IgG p=0.045 (table 1).

There are no differences in the assessed clinical symptoms between pts with PAPS and SAPS, apart from significantly higher frequency of the deep vein thrombosis in pts with PAPS (p<0.04).

Conclusion: The clinical pictures of PAPS and SAPS are similar. Only deep vein thrombosis occurs more frequently in pts with PAPS. Some classic and novel aPLs occur more frequently in pts with SAPS than in PAPS, and maybe could become a biomarker of PAPS

AB0178

TRANScriptional profiling of peripheral B cells in antibody-positive primary Sjögren’s syndrome reveals interferon signature and upregulated expression of genes which may be predictive of transformation to lymphoma and correlated to chronic pulmonary non-tuberculous mycobacterial (NTM) infection

Mehnaz Maleki-Fischbach, Fatjon Lezi, Brian O’Connor, Tasha Fingriner. National Jewish Health, Denver, United States of America

Background: Primary Sjögren’s syndrome (pSS) is the second most common systemic autoimmune disease (after RA), with a prevalence of about 0.5% in the general population and it occurs primarily in women at a ratio of women to men of 9:1. Key features of the disease include infiltration of salivary and lacrimal glands by lymphocytes, production of inflammatory cytokines, and the production of auto-antibodies. Nevertheless, systemic manifestations can arise in a proportion of pSS with pulmonary manifestation and higher incidence of NTM infection. Also, B-cell non-Hodgkin lymphoma (NHL) development represents a severe complication, affecting approximately 5% of patients. The risk of NHL occurrence in the setting of pSS, has been previously estimated to be 7-19 fold higher than the general population. B activation is one of the proposed hypotheses, that accord with the known biological findings, including hypergamaglobulinemia, presence of auto-antibodies including SSA/Ro60/TROVE2, SSA/Ro52/THIM2 and SSB/La48.

Objectives: B cells play a key role in the pathogenesis of pSS. The aim of this study was to analyze the transcriptome of B cells from patients with pSS and healthy controls to decipher the B-cell specific contribution to pSS.

Methods: RNA of negatively selected B cells from 5 ANA, SSA (both Ro60 and Ro 52), SSB and rheumatoid factor positive untreated female patients with pSS and 5 healthy controls was subjected to whole transcriptome sequencing. A false discovery rate corrected threshold of < 0.1 was applied to define differential gene expression.

Results: RNA-sequencing identified 56 and 23 up and down differentially expressed genes, respectively, and hierarchical clustering showed a clear separation between the two groups. Ingenuity Pathway Analysis revealed that these genes may play a role in interferon signaling (IFI35, IFIT1, OA51, MX1, STAT2, IFI35, IFITM1, IFG15, IFI27, IFI44L, IFI44, and PARP9), chronic mycobacterial infection (IFI35,IFI44,IFI44L,IFI44L,IFIT1,IFIT3,IFIT3,IFIT1,MXI,OA51,OA52,OA53,STAT2) and transformation to myeloproliferative disorders, especially B cell lymphomas (CD160, CD38, ENAM, FUT4, GADD45B, IFI35, IFI44, IFI44L, IFIT3, IFIT1, IFITM1, ISG15, JCHAIN, MX1, OA51, OA52, OASL, RG516, RNFP213, RSAD2, SAR52, SATB1, SMAD7, and STAT2).

Conclusion: Upregulated expression of type I and type II interferon (IFN)-induced genes was observed, establishing an IFN signature in pSS B cells. There are also genes that may play a role in other coconcomitant conditions like mycobacterial/NTM infection and higher risk for developing myeloproliferative conditions. This adds insight into the autoimmune process and suggests potential targets for future functional and prognostic studies.

**VALIDATION OF COMPLEX IMMUNOPHENOTYPING STRATIFICATION OF PATIENTS WITH LUPUS AND SJÖGREEN’S SYNDROME WITH THERAPEUTIC POTENTIAL**

Lucia Martin-Gutierrez 1,2, Hannah Peolharn 1, George Robinson 1,2, Giulia Varnier 1, Elizabeth Jury 1, Cozana Cunfit 1, UNIVERSITY COLLEGE OF LONDON, Rheumatology, LONDON, United Kingdom; 2UNIVERSITY COLLEGE OF LONDON, Arthritis Research UK Centre for Adolescent Rheumatology at UCLH, UCL and Great Ormond Street Institute of Child Health, LONDON, United Kingdom

Background: There is a current paucity in effective treatments for patients with primary Sjögren’s syndrome (pSS) and systemic lupus erythematosus (SLE). Their overlapping symptoms mean that they are often treated with similar biologic therapies, despite being distinct diagnoses. Our pilot research sought to stratify patients by novel, complex immune signatures, to potentially facilitate a more personalised approach to prescribing medication, irrespective of clinical diagnosis. From a cohort of 40 patient patients with SLE, pSS or combined SS/SLE, and 33 healthy controls; five distinct clusters were originally identified.

**Objectives:**
- Here we aimed to validate the original patient endotypes from our pilot data with a new patient cohort, and refine the identified clusters to be of more realistic clinical benefit.

**Methods:**
- A new cohort of patients with SLE (n=32), pSS (n=31) and SS/SLE (n=15) donated peripheral blood samples while attending appointments at UCLH clinics. None had received B-cell depletion therapy in the preceding 48 months. Complex phenotyping of peripheral T and B-cell subsets was performed by flow cytometry. Unsupervised clustering, statistical comparison to healthy and Receiver Operator Characteristic (ROC) analysis, as per our previous work, were used to stratify patients using immune signatures into distinct endotypes considering only those markers where sensitivity and specificity were above 80% (AUC > 0.80). Clinical diagnoses and symptoms treatment did not differ significantly between clusters.

**Results:**
- Five distinct endotypes across the three disease groups were identified after unsupervised clustering of CD19+ B-cell, CD4+ and CD8+ T-cell subsets. Two of these clusters serve to validate groupings from our original data: one with a distinct B cell fingerprint (BMI, IBr5 and Total CD19+) with AUC>0.87, AUC=0.81 and AUC>0.83 respectively, and another with a T cell fingerprint (Total CD4+, Total CD8+, CD8+ naïve, CD8+ effector memory T cell subsets) with AUC>0.80 for all of them. Clinical diagnoses and symptoms treatment did not differ significantly between clusters.

**Conclusion:**
- Our results demonstrate a novel method to re-classify patients using clustered immune phenotype abnormalities. Two distinct groups demonstrated either B or T-cell immunophenotypes, likely reflective of their underlying immunopathogenesis. Stratification by patient endotype has the potential to facilitate a better-informed selection of biologic therapeutics for individual patients; and highlights pathways for further mechanistic research.

**ASSOCIATION BETWEEN SINGLE NUCLEOTIDE POLYMORPHISMS (SNPs) OF THE BAFF GENE AND FATIGUE IN PRIMARY SJÖGREEN’S SYNDROME**

Christina Maria Flessa 1, Adriano Nezio 1, Evangelia Zampeli 1, Haralampos M. Moutsopoulos 1, 2, 3, 4, Medical School, National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece; 2Medical School, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece; 3Academy of Athens, Athens, Greece; 4National and Kapodistrian University of Athens, School of Medicine, Joint Academic Rheumatology Program, Athens, Greece

**Background:**
- Primary Sjögren’s Syndrome (SS) is characterized by B lymphocyte hyperactivity with B cell activating factor (BAFF) acting as an important regulator. Single Nucleotide Polymorphisms (SNPs) of the BAFF gene have been implicated in the pathogenesis of several autoimmune diseases including lupus and SS both of which are characterized by heightened fatigue levels, often compromising quality of life.

**Objectives:**
- To explore potential associations between several BAFF gene SNPs and fatigue status experienced by primary SS patients.

**Methods:**
- Fatigue status was assessed by Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) scale in 178 primary SS patients. Five SNPs (rs9514827, rs1041569, rs9514828, rs1224141, rs12583006) of the BAFF gene were tested in DNA extracted from peripheral blood of all patients enrolled in the study using the RFLP-PCR method. A cut-off value of -0.30 was used, which indicated a severe fatigue. Analysis of BAFF SNPs in association with fatigue levels was performed by the online platform SNPStats.

**Results:**
- The frequency of T/T genotype of both rs9514828 and rs1224141 was reduced in primary SS patients with severe fatigue compared to those without
(17.9% vs 36.7%, p=0.0094 and 51.8 vs 69.2%, p=0.027, respectively. The corresponding ORs [95%CI] in the dominant model were 0.38 [0.17-0.82] and 0.48 [0.25-0.92], respectively. No statistically significant associations between fatigue status and other SNPs tested were detected.

**Conclusion:** We report novel associations between genetic makeup and primary SS-associated fatigue with the rs9514828 and rs1224141 BAFF TT genotypes decreasing the likelihood of fatigue development among these patients. These findings need to be validated in multi-center studies.

**AB0182 RECEPTOR ACTIVATOR OF NUCLEAR FACTOR-KAPPA B LIGAND (RANKL)/RANK AND OSTEOPROTEGERIN (OPG) PATHWAY ACTIVATION IN SJOGREN’S SYNDROME**

Charalampos Skarlis1, Eleni Palli1,2,3, Adrianos Nezos1, Clio Mavragani1,2,3, Michael Koutris2,3, Medical School, National and Kapodistrian University of Athens, Department of Psychology, Athens, Greece, 2Medical School, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece, 3Joint Academic Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

**Background:** Primary Sjögren’s syndrome (SS) is an autoimmune exocrinopathy characterized by chronic salivary and lacrimal glands dysfunction. Recent studies suggest that activation of the receptor activator of nuclear factor-kappa B ligand (RANKL)/RANK and osteoprotegerin (OPG) pathway is implicated in the development of autoimmunity.

**Objectives:** The aim of this study is to investigate the contribution of RANK/RANKL/OPG pathway in primary SS pathogenesis.

**Methods:** Sixty-six primary SS patients fulfilling the American/European criteria and 13 subjects with oral and/or ocular dryness without satisfying the aforementioned criteria (sicca controls, SC) and 11 healthy controls (HC) have been enrolled. RANKL and OPG serum levels were determined by ELISA in 29 SS patients and 11 HC. Total RNA was extracted from minor salivary glands biopsies (MSG) from 43 SS patients and 13 SC and RANKL mRNA expression was assessed by qRT-PCR. Protein expression of RANKL was determined by Western Blot and immunohistochemistry (IHC) in total protein extract and paraffin embedded tissue respectively, derived from MSG biopsy of 6 primary SS patients and 5 SC. Statistical analysis was performed with SPSS 24.0 package.

**Results:** Increased serum levels (pg/ml) of RANKL (mean±SD=4.197±897.6 vs mean±SD=5±1897.6 vs 495±897.6 vs 2±1897.6, p=0.03) and OPG (mean±SD=173±5 vs 173±8 vs 173±9 vs 173±9, p=0.01) were detected in SS patients compared to HC. Higher RANKL at both mRNA and protein level by IHC were detected, in MSG derived from primary SS patients compared to SC. RANKL protein expression was significantly increased in MSG biopsies from primary SS patients compared to SC by Western Blot (mean±SD=2.46±1.86 vs mean±SD=0.5±0.823, p=0.0335).

**Conclusion:** Increased serum levels, mRNA and protein expression of RANKL in association with increased OPG titers in SS patients compared to controls, suggest that the activation of RANK/RANKL/OPG pathway contributes to SS pathogenesis.

**AB0183 THE ROLE OF THE PHOSPHOLIPASE LP-PLA2 ACTIVITY IN SJOGREN’S SYNDROME RELATED LYMPHOMAGENESIS: A NEW SERUM BIOMARKER?**

Eleni Kotsifaki1, Adrianos Nezos1, Anna Pasmou1, Panayiotis Garantziotis2, Michael Koutris1, Clio Mavragani1,2,3, Michael Koutsilieris1, Medical School, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

**Background:** One of the major complications of primary Sjogren’s syndrome (SS) is the development of B-cell non-Hodgkin’s lymphoma (B-NHL). The contribution of tissue macrophages in the pathogenesis of B-NHL, based on previous histopathological studies, appears to be significant. Extracellular lipoprotein-associated phospholipase A2 (LP-PLA2) is a product of tissue macrophages which is found in the circulation associated with lipoproteins and has been involved in both cardiovascular and malignant diseases, including B-NHL lymphoma.

**Objectives:** The purpose of the current study was to investigate the role of serum LP-PLA2 activity as a potential biomarker for the development of B-NHL in the setting of primary SS.

**Methods:** Extracellular LP-PLA2 activity was determined by measuring [3H]PAF degradation products in liquid scintillation counter in serum samples obtained from 48 primary SS patients, 9 primary SS patients complicated by lymphoma (SS-lymphoma) and 40 healthy controls. Similar results were obtained in an independent cohort of 25 primary SS patients, 17 primary SS-lymphoma and 10 healthy controls, when a commercially available ELISA kit was implemented. Statistical analysis was performed with the Graph Pad software.

**Results:** The activity of LP-PLA2 was statistically significant increased in patients with primary SS-lymphoma compared to primary SS patients without lymphoma [mean±SD (nmol/min/ml): 62±1±3 vs 47±1±4, p=0.003 and 19±7±3 vs 15±7±3, p=0.06, respectively], as well as healthy controls [mean±SD (nmol/min/ml): 62±1±3 vs 52±1±6, p=0.03 and 19±7±4 vs 15±7±3, p=0.06, respectively]. No statistical significant differences in LP-PLA2 activity were detected between primary SS patients without lymphoma development and healthy controls.

**Conclusion:** Evaluation of extracellular LP-PLA2 activity in primary SS patients could be a useful serological biomarker for B-NHL development in the context of primary SS.

AB0184
FLOWS CYTOMETRIC IMMUNOPHENOTYPING OF SALIVARY GLANDS IN PRIMARY SJÖGREN’S SYNDROME
Paul Milne1, Anastasia Resteu1, Aleksandra Ivovic2, Emmanuella Traianos3, David Storey4, Jessica Tam5, Richard Siegel6, Peter Campbell7, Wan Fai Ng8, Matthew Collin4. 1Newcastle University, Human District Cell Lab, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; 2Wellcome Sanger Institute, Cambridge, United Kingdom; 3Newcastle University, Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; 4National Institutes of Health, Autoimmunity Branch, Bethesda, United States of America

Background: Primary Sjögren’s Syndrome (PSS) is a common autoimmune disease of unknown aetiology. It is characterised by inflammatory infiltration of exocrine glands, development of a sicca syndrome and a 20-fold increase in the risk of developing lymphoma. Standard pathological evaluation is based on a lymphocyte ‘focus score’ but little is known about the composition of the lymphoid infiltrate or its relationship to disease markers such as autoantibodies and the risk of lymphoma.

Objectives: The aim of the study was to use flow cytometry to characterise the lymphoid infiltrate in more detail.

Methods: Salivary glands were collected from 103 subjects attended the Newcastle Sjögren’s clinic who had undergone minor salivary gland biopsy as part of the diagnostic investigations which also include testing for anti-SSA/SSB antibodies, Schirmer’s tests and unstimulated oral salivary flow. 70 with confirmed PSS, 15SLE patients; 20 early-stage PSS and 18 with non-Ss. Salivary glands were digested in collagenase for 3 hours and sort-analysed using a BD Biosciences FACSFusion flow cytometer. Sorted cells from 6 patients were Giemsa stained to observe cell morphology. All subjects have given their written informed consent according to the principles of Helsinki and the project has received local REC approval.

Results: Salivary glands contain multiple lymphoid populations including CD19+ B cells, CD19+CD308+ plasmablasts, CD19-CD308+ plasma cells, and predominately central memory CD4+ and CD8+ T cells. The focus score is associated with an increase in the total number of lymphocytes of up to 10-fold. In particular there is a striking increase CD19-CD308+ cells with restricted kappa light chain expression associated with the most advanced cases. By morphology these cells have the appearance of plasma cells with frequent Russell bodies and occasional binucleated forms.

Conclusion: Flow cytometry of dispersed salivary gland demonstrates and associates between lymphoid cells and the focus score in PSS patients. The dominant B cell population in PSS salivary gland is a CD19-negative tissue plasma cell with evidence of kappa light chain restriction in advanced disease.

AB0185
INTERFERON-γ AMPLIFIES IMMUNE RESPONSE MEDIATED BY TYPE I INTERFERONS IN PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS AND CORRELATES WITH DISEASE ACTIVITY
Gian Marco Moneta1, Claudia Bracaglia1, Ivan Caiello1, Rafaele Pecoraro1, Chiara Farroni1, Fabio Basta1, Luisa Bracci-Laudiero2, Riletta Carsetti2, Fabrizio De Benedetti3, Emiliano Marsaco4, Babimbo Gesu5, Division of Rheumatology, Rome, Italy; 2Babimbo Gesu, B Cell Physiopathology Unit, Rome, Italy

Background: Paediatric systemic lupus erythematosus (pSLE) is an autoimmune disorder of childhood characterized by the production of autoantibodies against nuclear antigens. In the last decade, several studies showed an up-regulation of genes induced by type I interferons (IFNs) in peripheral blood and tissues of pSLE patients1. It has been reported that the expression of this group of genes, known as the type I IFN signature, correlates with disease activity2. More recently, also the type II interferon (IFNγ) has been implicated in pSLE; however, its precise role has not been clarified yet3.

Objectives: To investigate the role of IFNγ in the pathogenesis of pSLE, IFNγ-induced genes (CXCL9, IDO1) and IFNγ itself were evaluated. Then we analysed cytokines production in supernatants. IFNγ was up-regulated in pSLE patients with active disease (n = 21) compared to healthy donors (HD) and pSLE patients with inactive disease (n = 17). The type II IFN score correlated with the SLEDAI (r = 0.64, P < 0.01). As previously reported, also the type I IFN score correlated with SLEDAI (r = 0.67, P < 0.01). We also found increased serum levels of CXCL9 and CXCL10 in pSLE patients compared to HDs (P < 0.05).

In order to study a possible cross-talk between type I and type II IFNs, we stimulated in vitro HD PBMCs with recombinant IFNα2b and IFNγ for 6 hours: we analysed the expression levels of type I and type II IFN signature and assessed the production of CXCL9 and CXCL10 in the supernatants. IFNα2b strongly up-regulated the expression level of both IFNα and IFNγ. On the other hand, IFNγ induced the expression of the 6 IFNα-related genes. IFNα, but not IFNα2b, induced the release of CXCL9 in supernatants. Both IFNα and IFNα2b produced the induction of CXCL10. IFNα also up-regulated the expression levels of both TLR7 and TLR9, two potent inducer of IFNα. Finally, whole blood of pSLE was incubated with an anti-IFNα neutralizing antibody for 24 hours: the type II signature was significantly downregulated (P < 0.05), whereas the type I signature was reduced without reaching statistical significance.

Conclusion: Our data suggest a potential role of IFNγ in the pathogenesis of pSLE. IFNγ-induced genes in whole blood and CXCL9 in serum are increased in pSLE patients. Type I and type II signatures are not strictly interferon-specific as IFNγ can induce the expression of type I genes. Moreover, blocking of IFNγ in the blood of pSLE patients reduces the type II signature confirming the presence of IFNγ in the blood of pSLE patients. IFNα also induces the expression of TLR7 and TLR9, and IFNα induces the expression of IFNα, thus establishing a positive crosstalk between IFNα and IFNγ that potentiate their reciprocal biological activity in pSLE.

CORRELATIONS BETWEEN RENAL TRANSCRIPTOMIC PROFILES AND OUTCOMES IN A MOUSE MODEL OF SYSTEMIC LUPUS ERYTHEMATOSUS
Pauline Montigny1,2, Aurélie Degroof2, Davide Brusa3, Frederic Housiaux4, Bernard Lauwerys2,4. 1Rheumatology Department – CHU UCL Namur, Yvoir, Belgium; 2Pôle de pathologies rhumatismales systémiques et inflammatoires – Institut de Recherche Experimentale et Clinique, Université catholique de Louvain, Bruxelles, Belgium; 3Flow Cytometry Platform, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Bruxelles, Belgium; 4Rheumatology Department, Cliniques Universitaires Saint Luc, Bruxelles, Belgium

Background: Factors contributing to poor renal outcomes in lupus nephritis (LN) are poorly understood. In our previous research, we found an association between the presence of active effector cells in the lupus kidney and disease severity. Here we investigated correlations between patterns of renal genes expression and biological parameters of renal disease activity in a mouse model of systemic lupus erythematosus (SLE).

Methods: We collected blood, urine, kidneys and spleens from 33 B6/Sle1 SLE2.Sle3 congenic mice, before disease onset at 3 months (n=8), and at different stages of disease progression, at 6 (n=7), 9-10 (n=12) and 17-18 (n=5) months. RNA was extracted from kidneys, and hybridized on Mouse Gene 2.0 ST exon arrays. Unsupervised hierarchical clustering studies and pathways analyses were performed on Genespring and DAVID softwares. Spleen and kidney C/D T cell activation and differentiation markers were evaluated by flow cytometry (CD8, CD69, CD62L, CD44, CD122, CD25, CD44, CCR7, CD279, CD152, CD11a, CD103). Plasma urea and albuminuria were measured by immunoassay.

1550
Scientific Abstracts
Results: 712 (out of 33,793) transcripts were overexpressed in kidneys from diseased mice (age > 6 months). These transcripts were significantly enriched in the following pathways: response to type I interferons, antigen processing and presentation, activation and regulation of B cells, complement activation, and regulation of cytokotically mediated by T cells. Proportions of renal CD8 T cells with an effector phenotype were significantly increased in the kidneys from 6 months and older compared to younger mice, and compared to paired spleens. Proportions of renal effector CD8 T cells correlated significantly with transcripts involved in interferon signature, adaptive immune responses, cytotoxic T cell, chemotaxis, and correlated negatively with pathways associated with renal tubular cell functions. Finally, we found a correlation between biological parameters of kidney function (plasma urea, albuminuria) and transcripts involved in pro-fibrotic pathways, chemokines and adaptive immune responses.

Conclusion: Our results confirm the link between the presence of activated immune effectors in the kidney and renal outcomes in a mouse model of SLE, similar to our previous observations in human LN, and warrant further functional studies on the role of kidney-infiltrating T and B cells in this model.

AB0187 CAN ARTIFICIAL INTELLIGENCE REPLACE MANUAL SEARCH FOR SYSTEMATIC LITERATURE REVIEW ON CUTANEOUS MANIFESTATIONS IN PRIMARY SJÖGREN’S SYNDROME?

Laure Orgeolet1,2, Nathan Foulquier1, Laurent Misery1, Pascal Redou1, Jacques-Olivier Pers1, Valerie Devauchelle-Pensec1, Alain Sarau1,1,2, CHU Brest, Brest, France; 2CHU Brest, Dermatology, Brest, France

Background: Manual systematic literature reviews are becoming increasingly challenging due to the sharp rise in publications. The task is particularly daunting when the study topic is complex.

Objectives: The primary objective of this literature review was to compare manual and in-house computer software retrieval of publications on the cutaneous manifestations of primary Sjögren’s Syndrome (pSS). The secondary objective was to evaluate the prevalence of cutaneous manifestations in pSS.

Methods: We compared manual searching and searching with the in-house computer software BIBOT (1) designed for article retrieval and analysis. Both methods were used for a systematic literature review on a complex topic i.e., the cutaneous manifestations of pSS. Articles published in French or English between 1 January 1990 and 30 May 2018 were sought.

Results: The manual search retrieved 855 articles and BIBOT 1042 articles. In all, 202 articles were then selecting by applying exclusion criteria. Among them, 155 were retrieved by both methods, 33 by manual search only, and 14 by BIBOT only. Further selection was performed by reading the 202 articles, of which 54 were deemed relevant, including 23 providing data on the prevalence of one or more cutaneous signs in a cohort of patients with pSS. Cohort sizes and the nature and prevalence of cutaneous manifestations varied across publications. In all, 52 cutaneous manifestations were reported, of which the most common were cutaneous vasculitis (561 patients), xerosis (651 patients), and annular erythema (215 patients).

Conclusion: Agreement was good between the two methods. BIBOT was faster and automatically classified the articles in a chart. Combining the two methods retrieved the largest number of publications. The prevalence of cutaneous manifestations in patients with pSS varied considerably across studies. The advanced machine learning techniques used in artificial intelligence hold promise for literature reviews.

AB0188 MOLECULAR NETWORKS IN MONOCYTES FROM SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS RELATED TO THEIR PHYSIOPATHOLOGY. MODULATORY EFFECTS OF ANTI-DSDNA ANTIBODIES AND MOLECULAR MECHANISMS UNDERLYING IN VIVO STATIN TREATMENT

Alejandra M. Paíno-Trives1, Pérez Sánchez Laura1, María Galindo-Izquierdo2, María Luque-Terán1, Alejandro Bañez-Costa1, Iñán Arias de la Rosa1, María del Carmen Abaño-Aguíllas1, Pedro Segui Azpilcuta2, Nuria Barbasojo Puerto2, Eduardo Collantes Estevez2, María A. Aguirre3, Carlos Perez-Sanchez1, Chary Lopez-Pedrera1,1, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Cordoba, Spain; 2Hospital 12 de Octubre, Madrid, Spain

Objectives: 1. To characterize the miRNAs and microRNA transcripts of monocytes from systemic lupus erythematosus (SLE) patients and their association with the pathophysiology of the disease. 2. To evaluate the role of anti-dsDNA antibodies in the regulation of these processes. 3. To investigate the molecular mechanisms involved in the efficacy of Fluvastatin in preventing the atherothrombotic risk.

Methods: Monocytes from peripheral blood of 81 SLE patients and 40 healthy donors (HD) were purified by negative immunomagnetic selection. Then, gene expression microarray (Agilent G4122F platform) and nCounter microRNA expression arrays (Nanostring) were performed. Functional categorization of altered genes and miRNAs was made using IPA software, and interaction networks were identified. Genes and miRNAs integrating the networks were validated in the whole cohorts by RT-PCR. Predicted miRNA-mRNA interactions were tested by microRNA over-expression or inhibition experiments. Serum and cellular inflammatory and oxidative profiles were evaluated by multiplex assay, PCR and specific commercial kits, respectively; phosphorylation status of intracellular proteins was analyzed by PathScan array. To evaluate the clinical significance of the parameters analyzed, correlation and association studies were performed. Mechanistic studies were developed to typify the specific effects of the anti-dsDNA antibodies on monocytes. Besides, the beneficial effects of ex vivo Fluvastatin treatment on the monocyte molecular profiles were assessed.

Results: Microarray identified 553 altered genes in SLE monocytes. Relevant biofunctions and disorders on which these genes were involved included inflammatory, immunological, cardiovascular, neurological, renal and reproductive diseases. Analysis of miRNA profiles showed altered expression of 35 miRNAs in SLE monocytes. Sixty-one genes were inversely correlated and predicted as CVD-related target genes of 26 differentially expressed miRNAs. Transfection studies confirmed the relationship between specific miRNAs and their identified target genes.

Association of these genes and miRNAs with the anti-dsDNA positivity, early atherosclerosis and nephropathy, along with correlations with disease activity (SLE-DAL), activation of some intracellular signaling proteins, and levels of serum inflammatory and oxidative markers were demonstrated. In vitro studies demonstrated the specific modulation of several genes/miRNAs by anti-dsDNA, along with the increase of prothrombotic and proinflammatory mediators, the induction of apoptosis and the phosphorylation of intracellular proteins participating in renal and CVD-related signaling pathways. Besides, treatment of HD-monocytes with SLE patients’ serum after Fluvastatin supplementation prevented the proinflammatory altered gene/miRNA profiles induced by serum from those patients before treatment.

Conclusion: 1. Gene and microRNA expression profiles allowed the identification of relevant genes and pathways altered in monocytes of SLE patients, associated with the pathogenesis of the disease, and modulated by anti-dsDNA. 2. Specific microRNA-miRNA regulatory networks control the biological processes and factors related to the CV pathology in SLE, which are prevented by Fluvastatin treatment.

AB0189 DECREASED URINE SEMAPHORIN 3A SECRETION PREDICTS THE EXTENT OF RENAL DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Doron Pimpar1, Menav Lida2, Nasrin Elizai3, Elias Tobib4, Amal Silawa4, Gleb Slobodini5, Izhak Rosner6, Michael Rosenbaum1, Abid Awaisi7, Nina Boulman1, Lisa Kaly1, Shira Ginsberg1, Nizar Jiles1, Zahava Vadasz2,8, Bnai Zion Medical Center, Rheumatology, Haifa, Israel; 2Sheba Medical Center, Rheumatology, Ramat Gan, Israel; 3Bnai Zion Medical Center, Division of Allergy and Clinical Immunology, Haifa, Israel

Background: Semaphorins are a family of proteins, involved in axon guidance, malignancy spread and angiogenesis. Semaphorin 3A (sema3A) is recognized also as ‘immune semaphorin’, it is expressed on regulatory T cells and has been
shown to enhance their inhibitory effect of CD4+ T cell pro-inflammatory function and replication. We have reported a decreased serum levels of sE3A in systemic lupus erythematosus (SLE) compared to controls and in correlation with SLE disease activity [1]. sE3A was found to be over expressed in podocytes and epithelial cells in animal models with diabetic nephropathy. Increased urinary sE3A was also detected in diabetic patients with proteinuria and in contrast-induced acute renal injury [2-3].

Objectives: To assess urine sE3A secretion in SLE patients with and without renal involvement compared to rheumatoid arthritis patients as disease control and healthy controls.

Methods: 50 ml of fresh urine samples were collected, centrifuged and the supernatant was then concentrated up to 50 times the initial concentration and subjected to kit. Human sE3A ELISA kit (MBST32622, San Diego, CA, USA).

Results: Thirty-eight lupus patients fulfilling the 2012 SLICC criteria were recruited, 33 (87%) of whom were women, at a mean age of 35±12 years. Eight patients had active nephritis (21%) and additional 5 had a history of nephritis but were in remission. APLA was diagnosed in 13 (34%) of patients. Disease activity was evaluated by the Systemic lupus erythematosus disease activity index 2000 (SLEDAI 2K) and 8.2±7.7.

Sema3A was lower in lupus patients compared to rheumatoid arthritis and healthy controls, 4.9±3.9 ng/mL, 8.5±2.7ng/mL, 9.85±1.7ng/mL, p=0.0006. Sema3A in SLE patients demonstrated lower urine sE3A concentration compared to lupus patients without renal involvement 4.3±3.4 ng/mL, 6.5±3.8 ng/mL, p=0.03. Sema3A reversely correlated with proteinuria r=-0.43 p=0.006 and SLEDIA2K -0.3, p=0.04, but not with creatinine concentration, disease duration and complement concentration. There was no difference in urinary sE3A between SLE patients with or without APLA syndrome.

Conclusion: Urinary excretion of Sema 3A was found to be decreased in the SLE patients with renal disease, reversely correlating with disease activity and proteinuria. These findings are in line with previous reports of decreased serum level of Sema3A in SLE, that may result in reduced efficacy of regulatory T cells, driving autoimmunity and kidney damage. The discrepancy between low sE3A urinary excretion in SLE nephropathy and increased urinary secretion in other "non-auto immune" conditions with renal damage, suggests that sE3A in the kidneys is protective in autoimmune diseases and detrimental in "non-auto immune" conditions. This differential effect of sE3A may have to do with different populations of effector cells and different expression of sE3A receptors (nuropilin1). Further studies should evaluate semaphorin 3A role in lupus nephritis and its potential as a treatment option.

AB0190 CROSSTALK BETWEEN SALIVARY GLAND EPITHELIAL CELLS AND B LYMPHOCYTES IN PRIMARY SJÖGREN’S SYNDROME

Elodie Rivière1,2, Juliette Pascaud1, Nicolas Tchitchek1, Saida Boudaoud1, Audrey Paoliédi1, Bineta Ly1, Alice Thal1, Norm Allaire1, Bernd Jagla2, Michael Mingueuern3, Gaetane Nocturne1, Xavier Mariette1. 1Rheumatology, 2Université Paris Sud – INSERM UMR 1194, Le Kremlin Bicêtre, France; 1Rheumatology, 2Arthritis RandD, Paris, France; 3Immunology Research, Biogen, Cambridge, United Kingdom of America; 2Biomarker Discovery Platform UTechS CB, Hub de Bioinformatique et biostatistique C3B, Institut Pasteur, Paris, France

Background: Primary Sjogren’s syndrome (pSS) is an auto-immune disorder characterized by lymphoplastic infiltrates and destruction of the salivary glands. Mechanisms leading to B lymphocytes chronic activation remain partially understood and we assumed that salivary gland epithelial cells (SGECs) might play a key role in B lymphocytes activation and differentiation.

Objectives: We aimed to study the interactions between SGECs from pSS patients or controls and B lymphocytes.

Methods: Patients with pSS according to 2016 EULAR/ACR criteria and controls with sicca symptoms were studied. RNASeq analysis was performed on SGECs and B lymphocytes sorted from salivary gland and blood using a FACS ARIA. Enrichment analysis was performed using Ingenuity Pathway Analysis software. Validation of the results was performed by qPCR (Biomark technology).

Cultured SGECs from pSS patients (n=6) and controls (n=6) were co-cultured with B lymphocytes sorted from healthy donors blood and stimulated with or without Polycl, INFα or IFNγ for 5 days. Transwell assays were performed. Survival, activation (CD38 positivity) and differentiation of B lymphocytes were assessed at day 5 by flow cytometry.

Results: The RNASeq analysis of B lymphocytes sorted from salivary gland showed an up-regulation of CD40 and CD48 which are involved in their activation. The analysis of sorted SGECs highlighted IL-7, interferon (IFN) signaling pathways and genes potentially involved in immune responses, including HLA-DR, BST2 (bone marrow stromal cell antigen 2) and BAFF-R. Co-culture experiments showed an increase of B lymphocytes viability when co-cultured with SGECs compared to B lymphocytes cultured alone (p<0.05). Co-culture with SGECs from pSS was more likely to induce higher activation of B lymphocytes compared to SGECs from controls, assessed by the percentage of CD38+ B lymphocytes (significant after stimulation with Polycl (p<0.01) (Figure 1A). Similarly, SGECs from pSS were more likely to induce higher activation of B lymphocytes compared to controls, assessed by the percentage of CD38+ B lymphocytes – percentage of alive cultured alone B lymphocytes) without stimulation or stimulated with Polycl (p<0.01) (Figure 1B). To determine whether the activation of B lymphocytes and SGECs required a direct cell contact, we used transwell experiments. Preliminary results suggested that the increase of B lymphocytes viability could depend mostly on soluble factors that are currently being identified and will be communicated at the congress.

AB0191 ENDOTHELIN-I LEVEL IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME, ITS ASSOCIATION WITH ENDOTHELIAL DYSFUNCTION AND ATEROSCLEROSIS

Sengi Shevchuk1, Inna Kuvkova2, Yulia Seheda2, Olena Galitun2. 1National Pirogov Memorial Medical University, Vinnytsia, Ukraine; 2Scientific and Research Institute of Invalid Rehabilitation on the base of National Pirogov Memorial Medical University, Vinnytsia, Ukraine; 2Scientific and Research Institute of Invalid Rehabilitation on the base of National Pirogov Memorial Medical University, Vinnytsia, Ukraine

Background: It is known that endothelin-I is one of the leading factors in the development of coronary artery disease, acute myocardial infarction, atherosclerosis of cerebral and peripheral vessels, pulmonary hypertension, ischemic lesion...
of the brain vessels etc. Patients with rheumatic diseases also have an elevation of endothelin-1 in serum. But it remains unclear whether the endothelin-1 level may reflect endothelium dysfunction in patients with antiphospholipid syndrome (APS) and serve as an early marker of atherosclerosis.

**Objectives:** The aim of the study was to evaluate the endothelin-1 concentration, its association with antiphospholipid antibodies and atherosclerotic vascular lesions in patients with APS.

**Methods:** According to our observation, there were 82 patients, among which 34 (41.6%) with primary antiphospholipid syndrome (PAPS) and 48 (58.4%) with secondary antiphospholipid syndrome (SAPS). The control group consisted of 37 practically healthy persons. The groups of patients were comparable by age, sex, and duration of the disease. The APS diagnosis was established according to the international classification criteria (2006). The content of the anticardiolipin antibodies IgG, anti-beta2-glycoprotein-1 antibodies IgG, IgA, IgM and endothelin-1 were determined by the immune enzyme method using commercial sets of Trinity Biotech Capita USA - Ireland, ORGenTec GmbH Germany and «Endothelin-1» (Cormay, England). All patients were assessed for the level of endothelium-dependent vasodilation (EDVD), the thickness of the intima-media complex of the common carotid artery (IMT), the presence of atherosclerotic plaque (AP) and clinical manifestations of vascular involvement.

**Results:** The analysis of endothelin-1 levels has shown that its content was in 2.2 times higher in patients with APS than in the control group. The proportion of people with optimal endothelin-1 content was twice lower, and the proportion of people with extremely high and high rates was 1.6 and 5.3 times higher, respectively, among patients with APS, than in the control group. Also differences in the endothelin-1 level have been established depending on the type of APS. The content of endothelin-1 was significantly higher (1.3 times) in patients with PAPS, than in PAPS. Among the patients with SAPS, the proportion of patients with an optimal level of endothelin-1 was 1.7 times lower, and the proportion of patients with high levels was 1.8 times higher than in patients with PAPS. The significantly lower endothelin-1 level was recorded in patients with highly positive antibodies to cardiolipin and beta-2 glycoprotein-1. Correlation analysis has shown direct correlation between anticardiolipin antibodies of the IgG class and anti-beta2-glycoprotein-1 antibodies and endothelin-1 concentration (n=0.35 and 0.34). High endothelin-1 level was a factor of structural and functional atherosclerotic changes of the heart and blood vessels in patients with APS. IMT increasing and EDVD decreasing were from 1.7 to 6.6 times more frequent among patients with high endothelin-1 level (>10 pg/ml), than patients with optimal endothelin-1 level (≤5.0 pg/ml).

**Conclusion:** Thus, the obtained data has showed that the excess concentration of endothelin-1 is a circulating marker of early atherosclerosis, since it is closely associated with subclinical manifestations of atherosclerotic vascular damage.

**Disclosure of Interests:** None declared. DOI: 10.1136/annrheumdis-2019-eular.2990

**AB0193**  
**THE EFFECTS OF NON-INVASIVE VAGUS NERVE STIMULATION ON FATIGUE AND IMMUNE RESPONSES IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME**

Jessica Tarn1, Victoria Macrae2, Sheryl Mitchell3, Bruce Simon4, Peter Gallagher5, John-Paul Taylor1, Stuart Watson1, Mark Baker6, Stephen Rushin7, Andrew Blamire8, Julia Newton9, Wan Fai Ng10.

1. Newcastle University, Newcastle upon Tyne, United Kingdom; 2Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; 3electroCore, Basking Ridge, NJ, United States of America

**Background:** Primary Sjögren’s syndrome (pSS) sufferers have rated physical and mental fatigue ‘brain fog’ as the most important symptoms needing improvement. Previous data from our group suggest that stimulation of the vagus nerve can invoke immunological responses and concurrently an improvement of patient reported symptoms of fatigue.

**Objectives:** This follow up study uses the gammaCore device (electroCore) and a sham device to assess the effects of non-invasive vagus nerve stimulation (nVNS) on patient reported symptoms of fatigue in pSS. In addition, immunoregulatory tests were used to assess the effect of nVNS on short term memory, executive function and attention.

**Methods:** 40 pSS participants were assigned to use active (n = 20) or sham (n = 20) nVNS devices. Participants and research staff were blinded to the active/ sham device assignment. The participants were instructed to use the device twice daily for a study period of 56 days. The following patient reported measures of fatigue and neuropsychological tests were collected at baseline and day 56; Profile of Fatigue (PRO-F, Physical and Mental), visual analogue scale (VAS) of abnormal fatigue, trail making, Digit Symbol Substitution Test (DSST), Stroop test and digit span. 7 subjects were excluded from the analysis due to withdrawal from the study. Changes in fatigue and test scores from baseline to day 56 were compared between devices using t-tests.

**Results:** Physical fatigue was significantly reduced between baseline and day 56 in the active group but not the placebo group (p = 0.047). The mean reduction in physical fatigue was 30% and 6% for the active and sham arms respectively (Figure 1). In both the active and sham subject groups there were no significant changes in the patient reported mental fatigue or neuropsychological test scores. Conclusion: This sham controlled scientific study of vagus nerve stimulation in pSS suggests nVNS may improve patient reported symptoms of physical fatigue, which is consistent with our published data. There were no improvements in the neuropsychological test scores which is consistent with no improvements in patient reported mental fatigue. nVNS has been shown to activate the anti-inflammatory reflex, therefore assessment of peripheral inflammatory markers may help our understanding of nVNS, inflammation and fatigue.

BTLA Expression Is Reduced on SLE B Cell Subsets

Annika Wiedemann1, Ana-Luisa Stefaniski2, Andrea Lino3, Thomas Dörner4
1Charité Universitätsmedizin Berlin, Dept. of Medicine, Rheumatology and Clinical Immunology, Berlin, Germany; 2University Hospital of Bern, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland

Background: B- and T-lymphocyte attenuator (BTLA/CD272) is a co-receptor constitutively expressed on B cells [1, 2]. Upon B cell activation via the B cell receptor (BCR), BTLA co-localizes with Src homology region 2 domain-containing phosphatase-1 (SHP-1) and thus negatively regulates BCR signaling [2]. A recent study found that CD4+ T cells from SLE patients fail to upregulate BTLA upon activation [3], however, data on BTLA expression and function for B cells in autoimmunity is missing.

Objectives: To assess BTLA expression on conventional naïve (CD20+CD27+), conventional memory (CD20+CD27+) B cells and on CD27+CD38+ expressing plasma cells (PC) in peripheral blood mononuclear cells (PBMCs) of patients with systemic lupus erythematosus (SLE) and healthy donors (HD).

Methods: PBMCs were isolated from EDTA blood taken from 7 female SLE patients (age 38, mean disease activity 5 (SLEDAI)) and 6 female HD (mean age 28) by Ficoll density gradient centrifugation according to the manufacturer’s protocol. Cells have been stained and expression of BTLA was assessed by flow cytometry.

Results: Analysis of BTLA surface expression on B cell subsets in SLE patients and HD revealed decreased expression of BTLA on naïve SLE B cells (p=0.0173, Mann-Whitney U Test (MWU), BTLA median fluorescence intensity (MFI) 9006±1450) compared to naïve HD B cells (11957±941). A similar tendency was found for memory SLE B cells (p=0.0823 MWU) compared to HD memory but not SLE PC and HD PC. Remarkably, an inverse correlation was found for BTLA expression on naïve SLE B cells and SLE PC with Siglec-1 expression on monocytes (p=0.0333 Spearman’s rank correlation (SRC) naïve B cells, p=0.0167 PC), a marker for interferon signature, and the same trend was seen for memory SLE B cells (p=0.0583 SRC). Inverse correlation of BTLA expression was also found with disease activity (SLEDAI) with these B cell populations but did not reach significance (p=0.0583 naïve B cells, p=0.1361 memory B cells, p=0.0833 PC).

Conclusion: Herein, we document that B cell subsets of SLE patients express lower levels of the negative regulator BTLA than HD. Additionally, an inverse correlation between BTLA expression on B cell subsets and Siglec-1 on monocytes were found suggesting its involvement in disease and consideration BTLA as therapeutic target in SLE. We hypothesize that reduced BTLA expression is a feature of post-activated B cells. Further studies need to delineate functional properties of BTLA expression and activation in autoimmune B cells.

The Impact of Ketogenic Diet and High-Fat-High-Glucose Diet in Pristane Induced Lupus-Like Nephritis Murine Model

Chae-Yi Wu1, Huang-Yu Yang2, Jing-Long Huang1. 1Linkou Chang Gung Memorial Hospital Hospital, Department of Pediatrics, Division of Allergy, Asthma, and Rheumatology, Taoyuan city, Taiwan, Republic of China; 2Linkou Chang Gung Memorial Hospital Hospital, Department of Nephrology, Taoyuan city, Taiwan, Republic of China

Background: Systemic lupus erythematosus is a chronic systemic inflammatory disease which commonly invokes kidneys[1]. Aside from the use of conventional immunosuppressants, dietary components and metabolites may likely affect our immune system.

Objectives: An interest in the anti-inflammatory property of ketogenic diet (KD) has recently come to attention. It not only alters the balance between Th17 and Treg cells[2], its metabolite, beta-hydroxybutyrate was known to block NLRP3 inflammasome-mediated inflammation[3-6]. High-fat-high-glucose diet (HFGD), on the other hand, was known for a proinflammatory property. Aim to understand the immune modulatory effect of KD and HFGD in cases with systemic lupus erythematosus, a chronic systemic inflammatory disease with glomerulonephritis, pristane induce lupus like nephritis murine model was used.

Methods: Pristane induced lupus nephritis mice were divided in to groups fed with regular chow (CD), KD and HFGD along with healthy controls. The diets were kept for 6 months with regular body weight and urine protein monitoring. Serum samples were collected for metabolic evaluation and immune survey bimonthly. The mice were sacrificed 6 months after diet change. Kidneys, lymph nodes, spleen, blood and guts were collected for evaluation.

Results: KD and HFGD were both well tolerated by experimental mice. Two months after diet change, higher level of beta-hydroxybutyrate and triglyceride but lower sugar level was noted in mice fed on KD when compared to those fed on CD and HFGD (all p<0.05). Mice fed on KD and HFGD have a much lower RBC and platelet count than those fed on CD in the experimental mice group (both p<0.05). Although global lymphocyte counts were much lower in those pristine treated mice, Th17 lymphocytes were significantly higher in the blood as well as kidneys among those fed on HFGD (all p<0.05). This is compatible with their higher serum concentration of anti-dsDNA, anti-nRNP and anti-Sm and the rapid progressing proteinuria. Renal, hepatic and intestinal histopathology was still under analysis at present.

Conclusion: In conclusion, food plays a critical role in immune modification. Despite the reported anti-inflammatory effect of KD, it does not mitigate lupus nephritis progression. HFGD formula, however, accelerated the autoimmune phenotype for cases with lupus like glomerulonephritis.

Vitamin D Protects Podocytes from Autoantibodies Induced Injury in Lupus Nephritis by Reducing Ablerrant Autophagy

Qi Yu, Zhaozhai Zheng, Zhangguo Liu. The First Affiliated Hospital Of Zhengzhou University, Zhengzhou, China

Background: Recent data suggest that vitamin D insufficiency may play a role in the progression of SLE and the nephropathy such as chronic kidney disease[1]. We previously show that severe vitamin D deficiency increases the risk for moderate to severe disease activity[2]. Moreover, vitamin D has been demonstrated a protective effect on podocyte injury via diverse mechanisms in proteinuric glomerular disease[3-7]. However, there is a paucity of data to demonstrated the mechanisms through which the autophagy functions on the protective role vitamin D plays on podocyte in the pathogenesis of lupus nephritis

Objectives: The aim of this study was to investigate whether vitamin D play a protective role in podocyte injury induced by autoantibodies purifyed from lupus nephritis (LN) patients serum via autophagic way.

Methods: Autophagic activities of LN patients renal tissues were evaluated under transmission electronic microscope. IgG from patients with LN were purified to induce human podocyte injury and the role of vitamin D in injury was observed. Podocytes were observed under TEM and autophagic activity was evaluated by western blot analysis and qRT-PCR, mRFP-GFP-LC3B adenovirus were injected into HPC in vitro.

Results: Significantly higher autophagic levels were observed in LN patients(p<0.05) and apparently greater autophagic levels in podocytes were shown (p<0.05). Among different classifications of LN, Class V(n=5), III+V(n=5) and IV+(n=5) gained higher autophagic levels than Class III (n=5) and IV(n=5). Induced autophagy, which was evident by increased LC3B-II and Beclin 1 level, caused consumption of p62, more autophago-somes observed under TEM, and more LC3B dots observed under confo- mercial microscope in IgG group, along with decreased Foxo3a expression, which suggests podocyte injury. Reduction of autophagy as well as alleviated podocyte injury was observed in the IgG+ group.

CONCLUSION: This study demonstrates that vitamin D plays a protective role in podocytes injury induced by autoantibodies from LN patients and that appears to be a novel therapy target in LN.

BENEFIT OF CRITHIDIA TESTS IN DIAGNOSING CONNECTIVE TISSUE DISEASES

Results: Among differentially expressed renal microRNAs in LN, miR-127-3p was reduced in renal tissues of patients with LN. The miR-127-3p suppressed the fluorescein gene expression of ISRE induced by ISRE, and the phosphorylation of STAT1 and STAT2. By microarray analysis, we found that most ISG was inhibited by miR-127-3p in IFN-stimulated Hela cells. The functional deletion of miR-127-3p enhanced the IFN response in human primary mesangial cells, which was manifested by enhanced ISRE mediated reporter gene expression, enhanced STAT2 phosphorylation and increased ISG expression. In addition, we found that JAK1, the upstream tyrosine kinase of STAT1 and STAT2, was a new target molecule for miR-127-3p.

Conclusion: Our study shows that miR-127-3p can inhibit IFN signal transduction by targeting JAK1. The decreased expression of miR-127-3p in the kidney is associated with an overactive IFN response in the renal tissue of patients with LN. Subsequent mouse model studies indicate the therapeutic potential of miR-127-3p in treating lupus associated organ damage.

BENEFIT OF CRITHIDIA TESTS IN DIAGNOSING CONNECTIVE TISSUE DISEASES

nouria benmostefa,1,2; samy simlani,3; samir raouibia,4; daoud roula,5; moulaoukh,6; rechid malek1; fethi-abbas setif 1 university, internal medicine, setif, algeria; 2 setif hospital university, internal medicine, setif, algeria; 3 cochin hospital, internal medicine, paris, france; 4 mostefa ben boulaïd batna university, rhumatology, batna, algeria; 5 salah-boubir hospital constantine 3 university, internal medicine, constantine, algeria; 6 national referral center for rare systemic and autoimmune diseases, hôpital cochin, assistance publique-hôpitaux de paris, université paris des carmes, paris, france, france

Objectives: To assess the construct validity of the Arab Hand Function Index (AHFI), an Arabic and adapted version of the Cochin hand Functional scale (CHFS) and an Arabic version of the Health Assessment Questionnaire (HAQ) in SSc.

Methods: We evaluated 100 patients with SSc followed between 2015 and 2017. All patients were white and fulfilled the American College of Rheumatology/European League Against Rheumatism criteria and/or the Lenier and Medger (2) criteria for SSc. Means±SD age at the time of evaluation was 47.66±12.28 years. The mean±SD disease duration was 6.54±6.23 years. Forty-one (41%) patients had diffuse cutaneous SSC and 59 (59%) had limited cutaneous SSC. Global hand and wrist mobility were evaluated using the hand functional index (HFI) and Kapandji index. Global disability and hand disability were assessed by an Arabic and adapted version of the HAQ and by the Arab hand functional index, an Arabic and adapted version of the CHFS, respectively. Anxiety and depression significant symptoms were assessed with the Arabic version of Hospital Anxiety and Depression Scale (HADS) anxiety and HADS depression. Construct validity was assessed by convergent and divergent validity (Spearman’s rank correlation coefficient) and factor analysis.

Results: The AHFI had correct convergent validity with global disability assessed by the HAQ (0.61) and the HFI (0.55), moderate correlation with the Kapandji index (-0.48: inverse correlation), depression (HADd) (0.45) and anxiety (HADA) (0.42) and no correlation with the disease duration (0.29) and the age (0.19) (Table 1). Factor analysis (Table 2) extracted 2 factors that accounted for 64.45% of the total variance. The AHFI has a good correlation with hand disability (AHF: 0.61), anxiety (0.57) and the HFI (0.51), a moderate correlation with depression (0.47) and Kapandji index (-0.46) and a little correlation with the age (0.28) and the disease duration (0.10) (Table 1). The factor analysis of the HAQ, extracted 1 factor that accounted for 50.64% of the total variance (Table 2).

Conclusion: In patients with SSc, the AHFI and the Arabic HAQ have good construct validity. The total score of the AHFI explained 61% of the variance of the HAQ.

INHIBITION OF DOT1L ACTIVITY IN HUMAN SKIN FIBROBLASTS: A Transcriptome ANALYSIS

Nathalie Benham1,2, Ellen De Langhe1,2, Rik Lories1,2.

1KU Leuven, Department of Development and Regeneration, Leuven, Belgium; 2UZ Leuven, Division of Rheumatology, Leuven, Belgium.

Background: The pathophysiology of fibrosis, a hallmark of diseases like Systemic Sclerosis, is still not well understood. The role of epigenetic factors is increasingly explored. DOT1L, the unique H3K79-methyltransferase, methylates histone 3 at the Lysine residue at position 79, thereby regulating gene expression programs. Inhibition of DOT1L in cartilage and bone has cell-type specific effects on Wnt signaling, a pathway suggested to play an important role in fibrotic disease.

Objectives: To study the changes in the transcriptome of dermal fibroblasts after DOT1L inhibition.

Methods: Primary human dermal fibroblasts isolated from abdominal skin were treated with DOT1L-inhibitor EPZ-5676 or vehicle and stimulated or not with TGF-β or CHIR99021 (activating Wnt signaling). RNAseq was performed using the NextSeq500 as a platform and TruSeq as library prep kit. The preprocessed reads were aligned to the reference genome of Homo-sapiens (Ensembl.GRC38.88/GRCh38). Statistical comparative analysis for differential expressed genes (DEG) was done using theedge prep kit. The preprocessed reads were aligned to the reference genome of Homo sapiens (Ensembl.GRC38.88/GRCh38). Statistical comparative analysis for differential expressed genes (DEG) was done using the edge prep kit. The preprocessed reads were aligned to the reference genome of Homo sapiens (Ensembl.GRC38.88/GRCh38).

Results: The DOT1L-inhibitor EPZ-5676 effectively reduced H3K79 dimethylation in the treated samples. RNAseq analysis revealed 663 differentially expressed genes in dermal fibroblasts exposed to the DOT1L inhibitor, based on group analysis: 77 genes were downregulated and 556 upregulated. There was no significant interaction between inhibition of DOT1L and stimulation.<span>par</span> of the cells with TGF-β or CHIR99021. Pathway analysis showed involvement of primarily the integrin signaling, the cadherin and Wnt pathway, suggesting a potential impact on the fibrotic process that is leading to pathology in SSc.

Conclusion: More than 600 differentially expressed genes were discovered by RNA sequencing in human dermal fibroblasts exposed to DOT1L inhibition (independent of TGF-β or CHIR 99021 stimulation). These gene lists and their networks indicate that DOT1L activity affects integrin signaling, the cadherin and Wnt pathway, suggesting a potential impact on the fibrotic process that is leading to pathology in SSc.

Acknowledgement: RNA sequencing and analysis was performed by VIB Nucleomics Core (www.nucleomics.be).

Disclosure of Interests: Nathalie Benham: None declared, Ellen De Langhe: None declared, Rik Lories Consultant for: Abbvie, Celgene, Eli-Lilly, Janssen, Merck, Novartis, Pfizer, UCB.

Dysphagia has been reported to occur in 10% to 73% of these patients and can be present at any time during the disease process (1).

Objectives: The primary objective of the study was to evaluate the prevalence of dysphagia in a cohort of patients with idiopathic inflammatory myopathy (IIM) and to evaluate factors associated with the presence of dysphagia. The secondary objective was to evaluate the factors associated with severe dysphagia.

Methods: Retrospective, observational study, which included patients with a diagnosis of IIM according to modified classification criteria of Bohan and Peter (1992-2018). Demographic data, clinical characteristics, laboratory data, autoantibodies, imaging studies, videodensitometry, muscle biopsy and EMG were recorded.

Severe dysphagia was considered: one in which oral feeding was contraindicated and/or which required nasogastric tube feeding (NGT) either by clinical evaluation or by videodensitometry study. The rest of the patients with dysphagia who did not present a contraindication to oral intake during the course of the disease were considered mild/moderate dysphagia.

Results: 94/110 patients were included, 76% female, mean age at diagnosis: 48 years (SD ± 14). Idiopathic dermatomyositis was the most frequent subtype of myopathy (64%). Dysphagia occurred in 53/94 patients (56.4%) and it was presented at the beginning of the disease in 31/94 (32%). Severe dysphagia was found in (22/94) 23%.

When analyzing the clinical features of patients with myopathy and dysphagia, it was found that Idiopathic dermatomyositis was the most frequent IIM in these patients (71%). Patients with dysphagia presented: proximal muscle weakness 90%, neck muscles weakness 47%, and respiratory muscle weakness 27%.

Treatment received: 90/94 (97%) oral glucocorticoids, mean dose 48 mg of prednisone (Range 4 -100 mg.), pulses of Intravenous methylprednisolone was indicated in 25 patients (27.5%). The main steroid sparing agents used were: 72% methotrexate, followed by 33% azathioprine.

The primary objective of the study was to evaluate the prevalence of dysphagia in a cohort of patients with idiopathic inflammatory myopathy (IIM) and to evaluate factors associated with the presence of dysphagia. Both dysphagia in general and severe dysphagia were associated with parameters of severity, high cost and poor prognosis. However, in the analysis of multiple variables, this relationship could not be demonstrated.

Conclusion: All deaths were related to severe dysphagia. Both dysphagia in general and severe dysphagia were associated with parameters of severity, high cost and poor prognosis. However, in the analysis of multiple variables, this relationship could not be demonstrated.

Conclusion: The levels of VEGF-α (intratissue) are lower in patients with SE vs controls (p <0.0001). The intratissue levels of the growth and angiogenic factors are higher than the plasma (patients and controls), finally, the plasma levels of these factors are similar in patients compare with controls. In almost all studies until today the measured levels have been carried out in serum, which are not precise since, in serum, several cells and lysate residues can alter the values, therefore, quantification in plasma is important. The present work is the result of the doctoral thesis of the main author.
Background: Anti-TIF1gamma antibody positive dermatomyositis (TIF1gamma-DM) has greater risk of complication with cancer.

Objectives: We aimed to analyze the clinical features of TIF1gamma-DM and find the difference between cancer-associated TIF1gamma-DM (CA-TIF1gamma-DM) and non-cancer-associated TIF1gamma-DM (nCA-TIF1gamma-DM).

Methods: We investigated the clinical data of idiopathic inflammatory myositis (IM) patients received remission induction therapy in out hospital between January 2006 and December 2018. Results: We treated 148 patients with IM in this period, 9 cases of them were TIF1gamma-DM. Patients with CA-TIF1gamma-DM and nCA-TIF1gamma-DM were 4 and 5 cases, respectively. Average age at onset of 9 patients with TIF1gamma-DM was 63 years old. CA-TIF1gamma-DM was significantly older than nCA-TIF1gamma-DM (average: 78.0 vs 57.4). All of 9 TIF1gamma-DM had distinctive skin rash and muscle weakness. Seven cases of them suffered from dysphagia. Intestinal lung disease was not seen in all patients with TIF1gamma-DM. Serum creatine kinase (CK) levels of CA-TIF1gamma-DM was significantly higher than those of nCA-TIF1gamma-DM (average: 3405.5IU/L vs 719.8IU/L (Fig 1)). Among the TIF1gamma-DM patients, we administrated glucocorticoid (GCs) for 8 cases, immunosuppressants for 4 cases, and intravenous immunoglobulins (IVIG) for 7 cases. All 4 cases of CA-TIF1gamma-DM were treated with GC and IVIG. All TIF1gamma-DM patients, especially 4 CA-TIF1gamma-DM patients, seemed to have good response to treatment in serum CK levels. Although serum CK levels of these 4 cases were normalized within a month (Fig1.), their muscle weakness, skin rash and dysphagia which was associated with quality of life and the prognosis were poorly improved.

Conclusion: In our investigation, the age of onset and serum CK levels were significantly different between CA-TIF1gamma-DM and nCA-TIF1gamma-DM. We report our investigation of the phenotype and treatment of anti TIF1gamma antibody positive dermatomyositis. TIF1gamma-DM with high serum CK levels, we should perform appropriate tests to check for cancer throughout our treatment, and the improvement of serum CK levels is not equal to the success of our treatment.

Disclosure of Interests: None declared

(IVIG), and hydroxychloroquine HCL) was performed, attending to possible differences between IM subtype and the year of diagnosis. T student and Chi square tests were used for quantitative and qualitative variables, respectively.

Results: From 479 patients (74% females, 52% PM, 44±22 y at diagnosis, 10±8 y follow up), 473 (99%) received oral GC, 50/344 (15%) pulses GC, 78 (16%) HCL, 355 (74%) IS (methrotexate MTX 228, leflunomide 10, azathioprine AZA180, cyclophosphamide 44, mycophenolate MP 38, cyclosporine 32), 55 (12%) biologics (rilumixab 45, abatacept 2, atNf 16) and 79 (17%) IVIG. Differences according to IM subtype (1), and to the year of diagnosis (2), are shown in Tables.

</tbody>
</table>

Conclusion: The therapeutic management of IM has changed over the last few years, with a clear increase and earlier use of IS in patients diagnosed after 2000. In spite of a more aggressive approach in recent years, severe infections are less frequent, perhaps as a consequence of lower GC doses. The management of PM and DM is similar.

Background: Inflammatory myositis (IM) are heterogeneous autoimmune diseases, characterized by muscular inflammation, which can associate systemic manifestations. In other inflammatory diseases, as rheumatoid arthritis, inflammation is a cardiovascular risk factor (CVRF), with clear influence on cardiovascular events and mortality (CVE, CVM).

Objective: To analyze the influence of IM severity in the development of CVE and CVM in the REMICAM registry.

Methods: All patients from REMICAM were included(1). REMICAM is a retrospective multicentric registry of IM patients (n=479), performed in Madrid between 2003-2014, containing demographic, clinical and outcome data (1). The presence of extra muscular features (cardiac, pulmonary, cutaneous and systemic involvement), number of therapies, immunosuppressants (IS) need, and glucocorticoids (GC) withdrawal due to IM remission defined IM severity. BI and multivariate logistic regression analysis were used to test the association between these factors and CVE. Survival analysis and regression proportional hazard bi and multivariate Cox models were used to determine the effect of these factors on CVM. All factors with p<0.2 in bivariate analysis were included in multivariate models. The entire was controlled for sex and CVRF. CVE: age, sex, CVRF number, diagnosis before year 2000, presence of arrhythmia or Raynaud. CVM: IM severity. CVRF: number, diagnosis after year 2000, presence of arrhythmia or Raynaud (Table 1). Arrhythmia was the only independent risk factor for CVM. GC withdrawal due to IM remission, and a smaller number of therapies, were protective factors for CVM (Table 2).

Conclusion: In the REMICAM registry, extra muscular manifestations such as arrhythmia, were associated to CVE and CVM, as independent risk factors. A smaller number of treatment or GC withdrawal due to remission were protective factors for CVM. Our results support the hypothesis that more severe IM, with extra muscular involvement and persistent inflammation, could favor atherosclerosis and CVE development.

AB0207 RECEPTOR EXPRESSION OF ANGIOTENSIN TYPE-1 AND 2 ARE DECREASED IN PATIENTS WITH SYSTEMIC SCLEROSIS AND PULMONARY ARTERIAL HYPERTENSION (PAH) AND CORRELATED WITH SEROLOGICAL LEVELS OF NT-PROBNP

Sebastian Klapa1,2, Silke Pitann1, Gabriela Marschner1, Susanne Riepe1, Andreas Koch1, Antje Müller1, Harald Heidecke2, Peter Lamprecht3, Gabriela Riemekasten4, 1University of Lübeck, Clinic of Rheumatology and Clinical Immunology, Lübeck, Germany, 2Christian Albrechts University Kiel, Institute of Biochemistry and Molecular Biology, Kiel, Germany, 3University Hospital Lübeck, Department of Cardiology, Lübeck, Germany, 4German Red Cross Kiel Hospital, Dermatology, Kiel, Germany.

Background: Previous studies identified functional autoantibodies against the angiotensin receptor type-1 (AT1R) and the endothelin receptor type A (ETAR) in about 85% of the patients with systemic sclerosis (SSc). The antibodies are cross-reactive, agonistic and functionally active by increasing the effects of the natural ligands as well as by specific activation of the receptors (2, 3). The levels of the antibodies are associated with clinical findings such as pulmonary arterial hypertension (PAH). Patients with highest antibody levels show worst prognosis and do not respond well to receptor blocker therapy (2-4). Several in vitro effects of the antibodies depend on the antibody levels and on the cell type bearing the receptors. Receptor expression of ETAR and AT1R was highest in early disease (3).

Objectives: To determine predictors of PAH, DU and clinical complications by measuring the antibody levels and the receptor expression on peripheral mononuclear cells in patients with systemic sclerosis.

Methods: The current study analyzed the serological levels of anti-AT1R and anti-ETAR antibodies and the extracellular and intracellular expression of AT1R, AT2R, ETAR, ETBR and ETRB on circulating CD4+ T cells, CD8+ T cells, CD14+ Macrophages, CD15+ Granulocytes and CD19+ B cells in SSc (n=41) using sandwich ELISA and flow cytometry. Clinical data (PAH, history of digital ulcers, digital-ulcers score, mRSS, pulmonary fibrosis, RA, antiphospholipid antibodies) were also collected. All samples were obtained at the time of serum sampling and every three-month to 27 months after baseline.

Results: Patients with PAH demonstrated a lower AT1R MFI and AT2R MFI ratio on all PBMC. Levels of NT-proBNP correlated negatively with the AT1R MFI and AT1R/AT2R MFI ratio on all PBMC. The levels of anti-AT1R ab correlated with the NT-proBNP in SSc patients with levels of NT-proBNP >300pg/ml and AT1R MFI on T cells, Granulocytes and Macrophages distinguished between pathological and physiological levels of NT-proBNP. Using Log-rank test and Mantel-Cox proportional hazards model, decreased expression of AT1R MFI on T cells, Granulocytes and Macrophages identified trends of deterioration of NT-proBNP over 50%.

Conclusion: Expression of AT1R and AT2R on PBMC could be of diagnostic value identifying clinical progress and/or subgroups in SSc. Their role in the pathophysiology, e.g. their impact on endothelial damage, has to be further investigated in SSc.

A STUDY OF CORRELATION BETWEEN PLATELETS AND LYMPHOCYTE SUBSETS IN SCLEROSIS

je liang, Li Zhao-Hua, Fangyuan Hu, Ning Yan, Li Xiaofang, Caihong Wang, the Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by vasculopathy, autoimmunity and widespread dermal and visceral fibrosis. There are existing evidence to support excessive platelet activation and their contribution to vascular function and fibrosis. Now we will focus on the immune role of PLT in SSc.

Objectives: By analyzing the correlation between platelet and lymphocyte subsets, CD4+ T cell subsets and disease activity in patients with diffuse SSc (dcSSc)/limited SSc (lcSSc), and to explore the immune role of PLT in SSc.

Methods: The peripheral blood of 21 stable disease patients, 31 active disease patients and 20 healthy controls (HC) were collected. The clinical data and laboratory indicators of them were enrolled. The T, B, NK lymphocyte subsets and CD4+ T cell subsets were detected by flow cytometry (FCM). The CD4+ T cell subsets contains Th1, Th2, T17, Treg, Th1/Th2 and Th17/Treg. Non-parametric Kruskal-Wallis H test was performed on multiple independent samples. The correlation between variables was used by Spearman correlation analysis.

Results: The PLT, PCT, MPV, PDW in peripheral blood of the stable group and active group were significantly higher than the HC group (P<0.05). The amount of T cells in peripheral blood of active group was [1127.80 (796.66-1393.78)], which was lower than the percentage of HC group [1246.44 (984.81-1497.84)] and stable group [1249.59 (1179.09-2022.88)]. There was significant difference between active disease group and stable group (Z=6.525, P=0.038). The amount of Th cells of the stable group [888.11 (679.55, 1430.70)] and active group [884.20 (385.878)] were higher than the HC group [574.84 (493.22-728.00)]. The Th1/Th2 ratio of the stable group [0.18 (0.10, 0.34)] and active group [0.21 (0.13, 0.28)] were lower than the HC group [0.25 (0.12, 0.31)]. There was significant difference between stable active group and HC group (Z=-6.525, P=0.038). The ESR and CRP were positively correlated with PLT, PCT; The amount of CD4+ T, CD8+ T and Th1/Th2 cells was positively correlated with MPV, and the ratio of Th1/Th2 was negatively correlated with MVP, and the ratio of Th1/Th2 was negatively correlated with MVP. There was significant negative correlation between Th1/Treg and PDW.

Conclusion: In SSc patients, lymphocyte subsets and CD4+ T cell subsets were altered. There was significant negative correlation between Th1/Treg and PDW. Among them, CD4+ T cell subsets was positively correlated with PLT, PCT. Explore the potential function of EXOs in the pathogenesis of SSc.

THE GLOBAL EXPRESSION OF MIRNAS AND LNCRNAS IN THE EXOSOMES OF SYSTEMIC SCLEROSIS PLASMA AND NEUTROPHIL AND RELATED FUNCTIONS

Liu Xiu, Zuo Xiaolfa, Di Liu, Luo Hui, Zhu Honglin, Department of Rheumatology and immunology, Xiangya Hospital, Central South University, Changsha, China

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease with unknown pathogenesis. Exosomes (EXOs) are cell-derived vesicles 30-150 nm in size that contain various miRNAs, microRNAs (miRNAs), long non-coding RNAs (IncRNAs) and proteins. Plasma EXOs play wide roles in various diseases, however, little is known in SSc.

Objectives: Investigate the global expression of miRNAs and IncRNAs in the EXOs of SSc plasma and neutrophil. Explore the potential function of EXOs in the pathogenesis of SSc.

Methods: EXOs were respectively isolated from plasma, cultured neutrophils supernatants, and were identified by transmission electron microscopy. Global expression of miRNAs and IncRNAs form 5 SSc and 5 normal controls was analysis by Illumina HiSeq 3000 platform. Differentiated expressed and bioinformatics analysis was performed by edger, limma package, GO, KEGG, and cytoscape. Furthermore, we used the EXOs stimulated human dermal microvascular endothelial cells (HDMECs) and human primary skin fibroblasts, and explore the potential functions of EXOs.

Results: 1. In plasma EXOs, we identified a total of 37 miRNAs and 479 IncRNAs that showed significant differences between the two groups. Among them, 26 of upregulated miRNAs were involved in the E6E7 signaling pathway; 11 of downregulated miRNAs were involved in the MAPK signaling pathway; TGF-b signaling pathway, AMPK signaling pathway, the expression levels of IncRNAs were involved in the PI3K-Akt signaling pathway, p53 signaling pathway, 180 of downregulated IncRNAs were involved in lymphosome.

2. In neutrophil EXOs, we identified a total of 22 miRNAs and 281 IncRNAs that showed significant differences between the two groups. Among them, 12 of upregulated miRNAs were involved in the Wnt signaling pathway; 10 of downregulated miRNAs were involved in the MAPK signaling pathway, AMPK signaling pathway; 119 of upregulated IncRNAs were involved in interferon-23 signaling pathway; 162 of downregulated IncRNAs were involved in the signaling by GPCR, signalling by NOTCH and TRAIL.

3. After stimulated with SSc plasma EXOs, the expression levels of has-miR-324-5p and SP1/SMAD2, has-miR-624-5p and PIK3RCB, has-miR-483-5p and MAPK1 were negatively correlated, the expression levels of ENST00000596255.1 and OSMR, ENST00000801511.1 and HMGB1/ENOS were positively correlated, variably in HDMECs and human primary skin fibroblasts.

4. After stimulated with SSc neutrophil EXOs, the expression levels of has-miR-1268a and PRKCA, has-miR-299-3p and IGF1R were negatively correlated, the expression levels of ENST00000596255.1 and OSMR, ENST00000801511.1 and HMGB1/ENOS were positively correlated, variably in HDMECs and human primary skin fibroblasts.

5. These miRNAs and IncRNAs with consistent expression might be involved in the pathogenesis of SSc EXOs.

Conclusion: Our study identified and confirmed differently miRNAs and IncRNAs in the neutrophil EXOs and plasma EXOs. Those genes may be involved in the pathological mechanism of SSc, such as has-miR-324-5p and SP1/SMAD2, has-miR-624-5p and PIK3RCB, has-miR-483-5p and MAPK1, ENST00000596255.1 and IL23R, ENST00000596255.1 and TDFP2, ENST00000608572.1 and HDAC2 were positively correlated, variably in neutrophil, HDMECs and human primary skin fibroblasts.

AB0211 NEUTROPHIL-DERIVED EXOSOME S100A8/A9 INHIBITS ANGIogenesis IN SYSTEMic SCLEROSIS
Liu Liya, Zuo Xiaoxia, Xiao Yizhi, Li Di, Luo Hui, Zhu Honglin. Department of Rheumatology and Immunology, Xiangya Hospital, Central South University, Changsha, China

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by vasculopathy, inflammation, and extensive fibrosis of the skin and organs. Exosomes (EXOs) are cell-derived vesicles 30-150 nm in size that contain various mRNAs, microRNAs and proteins.

Objectives: Here, we aimed to investigate the roles of EXOs in SSc pathogenesis, especially in angiogenesis.

Methods: EXOs were respectively isolated from plasma, cultured peripheral blood mononuclear cells (PBMCs) and neutrophil supernatants, and were identified by transmission electron microscopy. The expression of S100A8/A9 was measured by real-time PCR and ELISA. Proliferation, migration and scratch assays in human dermal microvascular endothelial cells (HDMECs) were used to study the influence of neutrophil EXOs and neutrophil EXOs S100A8/A9. We also performed a genome-wide transcriptome analysis on PBMCs from 19 SSc patients and 18 matched normal controls (NC) using Illumina BeadChip arrays. The ingenuity pathway analysis involved regulating both vascular fibrotic, and immune T- and B-lymphocyte-mediated alterations that characterize several SSc manifestations. According to our previous experience with RTX [1], we suggested that neutrophil EXOs S100A8/A9 inhibit the proliferation and migration of HDMECs, and that they might through Toll-like receptor 4 (TLR4) pathway.

Conclusion: S100A8/A9 is one of components of neutrophil EXOs that regulates vascular endothelial cell angiogenesis in SSc patients, most likely by activating the TLR4 signalling pathway.

AB0212 LONG-TERM TREATMENT WITH RITUXIMAB IN SYSTEMIC SCLEROSIS MANAGEMENT: AN OVERVIEW OF THE CLINICAL EXPERIENCE FROM A REAL-LIFE SETTING
Federica Lumenti1, Annelia Spinella1, Michele Colaci2, Emanuele Ciccodia1, Luca Magnani1, Gianluigi Balocchi1, Clodoveo Ferri1, Carlo Selvaramani1, Dilia Giuggioli2, Luca Magnani3, Gianluigi Baiocchi3, Clodoveo Ferr1, Carlo Salvaramain, Dilia Giuggioli2, Luca Magnani3, Gianluigi Baiocchi3, Clodoveo Ferr1, Carlo Salvaramain

Background: Systemic sclerosis (SSc) is a chronic inflammatory autoimmune disease characterized by vascular, immunologic, and fibrotic alterations of the connective tissue. SSc affects approximately 10-55% of SSc patients and might be associated with chronic kidney disease, reduced renal functional reserves. Furthermore, subclinical renal impairment affects approximately 10-55% of SSc patients and might be associated with other vascular manifestations. However, the available evidence on CKD in patients with SSc residing in low-middle income countries (LMIC) is scarce. Because the health system of LMIC, and especially Peru, could have great differences in access to diagnosis and management of SSc, it is important to identify which clinical factors would be associated with CKD in patients with this autoimmune disease.

Objectives: To identify the associated factors to renal involvement in Peruvian patients with SSc.

Methods: We analyzed the associated factors to renal involvement in SSc patients at Hospital Nacional Edgardo Rebagliati Martins Lima-Peru, a national reference hospital in Peru. Between June 2001 and December 2018, we included ambulatory patients, older than 18-year-old with SSc included in this study. One hundred and five patients with diffuse cutaneous SSc (n=13) showing a significant decrease of mRSS after the first 6 months (from 24.3 ± 17.4 to 17.9 ± 4.3; p = 0.006) and at the end of the follow-up period (17.8 ± 5.7; p = 0.005). Similarly, a valuable improvement of other skin manifestations, namely hypermelanosis (17/20 pts), pruritus (18/21 pts) and tender joints (from 5.2 ± 4.0 to 0.9 ± 2.5; p = 0.0001) in 2024 patients. Final lung fibrosis detected in 19/24 on chest CT remained stable during the entire follow-up, as well as pulmonary function tests (PFTs). These positive clinical changes were mirrored by the subjective improvement of patients well being in all subjects (HAQ from 1.04 ± 0.55 to 0.85 ± 0.38; VAS from 71.0 ± 15.2 to 28.0 ± 10.3; p = 0.0001). No significant side effects were observed during the entire follow-up. Only in one patient a severe urinary tract infection leading to the discontinuation of the treatment was detected.

Conclusion: The present study reinforces the previous trials and our preliminary researches on this topic, showing the efficacy of RTX in the management of SSc with good safety profile. The specific therapeutic role of RTX on B-cell-driven autoimmune, might explain its beneficial effects on some SSc clinical alterations. The improvement of skin sclerosis, arthritic symptoms and the stabilization of lung involvement were identified as the main results. Further exploration of the potential clinical efficacy of RTX in SSc with multicentre, double blind, controlled study is needed.

Disclosure of Interests: None declared
years; 92% were women, and the average time of illness was 8.2 years. The model based on theory showed that age (aPR = 1.03, 95% CI = 0.99-1.07, p = 0.143) and exposure to Penicillamine (aPR = 0.51, CI 95% = 0.19-1.33, p = 0.170) were marginally associated (p <0.02) with CKD, while pulmonary hypertension (aPR = 2.76, 95% CI = 1.29-5.88, p = 0.009) and arterial hypertension (aPR = 3.51, 95% CI = 1.06-11.6, p = 0.04) were significantly associated (<0.05) with CKD. The parsimonious model retained pulmonary hypertension (aPR = 3.74, 95% CI = 1.87-8.36, p <0.001) and arterial hypertension (aPR = 7.45, 95% CI = 3.31-16.7, p <0.001) as significantly associated factors to CKD.

Conclusion: Hypertension, a classic cardiovascular risk factor, and pulmonary hypertension were important factors associated with CKD. The appropriate management of these factors must be taken into account to prevent CKD. Prospective cohort studies should evaluate the influence of these factors in reducing the incidence of CKD.

AB0214 MUSCLE INVOLVEMENT IN SYSTEMIC SCLEROSIS

Boris Kilik1, Jose Mílisen2, Iago Pinal-Fernandez3, Pedro Juan Moreno Lozano4, Alfredo Guillen-Del-Castillo5, Sergio Prieto-Gonzalez2, Gerard Espinosa2, Callaghan5, Josep Maria Grau6,1.

1Hospital Escuela Eva Perón, Rosario, Argentina; 2Hospital Clinic de Barcelona, Barcelona, Spain; 3CIBERER, Barcelona, Spain; 4National Institutes of Health, Bethesda, United States of America; 5Vall d’Hebron General Hospital, Systemic Autoimmune Diseases Unit, Barcelona, Spain

Background: The prevalence of myopathy in systemic sclerosis (SSc) or scleroderma patients varies from 5% to 81% depending on the diagnostic criteria used to define the muscle involvement. The histopathological characteristics found in these patients and their correlation with the clinical features and autoantibody profile has not been fully characterized.

Objectives: To characterize the muscle involvement and histopathology findings in patients with SSc.

Methods: This retrospective cross-sectional study included all patients from the Scleroderma Cohort of Vall d’Hebron General and Hospital Clinic de Barcelona with muscle biopsies available for review performed at the Muscle Research Unit of Hospital Clinic de Barcelona from May 2004 to November 2018. Muscle biopsies were performed, for weakness or raised CK and/or aldolase. Histological sections were independently evaluated by two myopathology experts looking for inflammation in the endomysium, perimysium and perivascular areas. The presence of necrosis, regeneration, fibrosis, necrogenic atrophy, and fiber type grouping as well as perifascicular atrophy were also recorded. Based on the autoantibody profiles patients were classified into five groups, “Scl70”, “PM/ScIi”, “centromere”, “U1-RNP”, and “nucleolar and centromer IFI ANA pattern without specificity for anti-Scl70 or anticentromere”. Demographic and clinical data were obtained by chart review.

Results: 42 subjects were included, 33 (76.6%) of them were women. Considering the immunological profile 12 had Scl70, 12 PM/ScIi, 5 anti-centromere, 2 U1RNP, and 11 had ANA pattern without specificity for anti-Scl70 or anticentromere. Most of patients (90.5%) were Caucasians, 2 (4.8%) were Hispanic, and 2 of other ethnic background. The mean age at the onset of SSc was 42.1 (SD 2.5) years and at the muscular symptoms 50.7 (SD 2.1) years, respectively. Twenty-two (52.4%) patients presented with high aldolase level (mean level of 200 U/L) whereas 38 (90.5%) exhibited high aldolase level (mean 200 U/L). Of note, 17 (40.5%) presented with high CK level (mean level of 1316 ± 353.8 U/L; normal value < 6 U/L). Among the pathological features, 28 (66.7%) biopsies had fibrosis. Neurogenic atrophy was detected in 4 (9.5%) and fiber type grouping was present in 9 (21.4%) muscle biopsies. In near half of the muscle biopsies (45.2%) inflammatory infiltrate was present. Compared to other patients, those positive for PM/ScIi had more perivascular (75%), endomysial (50%) and perineural inflammation (75%) and perifascicular atrophy (42%) (all p<0.05), while a reduced prevalence of inflammatory infiltrates was noted in the Scl70 group (17%) (p<0.05).

Conclusion: In our cohort of SSc patients with muscle involvement, two main histopathological patterns were found, fibrosis and inflammation. Almost half patients presented with elevated aldolase with normal CK values. The muscle disease heterogeneity suggests that a variety of pathologic mechanisms play a role in the scleroderma associated myopathy but those patients with histopathologically inflammatory features deserve to be treated with immunosuppressive therapy.

Background: SSc is a heterogeneous multisystem connective tissue disease. The majority of patients (pts) develop initial clinical symptoms between the ages of 30-50 years (yrs). It is not yet known whether the age of onset has an influence on the development of a distinct clinical phenotype.

Objectives: Investigating the relationship between age at disease onset and the development of clinical characteristics using data of the German Network for Systemic Sclerosis.

Methods: We evaluated 2928 patient data, subdivided them into 3 age groups at disease onset (<40 yrs, 40-50 yrs, and >50 yrs) and correlated the age at disease onset with specific clinical characteristics.

Results: Overall, 24% of pts developed first non-RP symptoms at the age of <40yrs, 53% between the age of 40-60yrs, and 23% were older than 60yrs. In particular, SSc pts with disease onset >60yrs developed significantly (p<0.001) more often the lcSSc subtype (64%) as well as ACA antibodies (42%) with a significantly lower mRSS. They, however, also suffered more often from pulmonary hypertension (PH) and developed less often digital ulcers. Especially lcSSc pts were associated with a more rapidly progressing clinical phenotype, i.e., 25% of the elderly lcSSc pts developed PH after five years. In contrast, less than 5% diagnosed with lcSSc at the age of <40yrs suffered from PH after five yrs (p<0.001).

Conclusion: In this registry, approximately one quarter of pts developed SSc at an age above 60yrs, predominantly having a lcSSc subtype. Although these pts have been diagnosed with the mild form of SSc, pts with a lcSSc subtype at a higher age (>60yrs) had more frequent a PH and showed a more rapid disease progression than the youngest pts. These findings may have an important influence on recommendations on
Background: Systemic sclerosis (SSc) is a connective tissue disease of unknown cause. The key points in development of SSc are immune disorders [2]. Autoimmune inflammation is the factor that underlies the enzymatic pattern of purine and pyrimidine metabolism in most patients.

Methods: Fifty SSc patients and 30 healthy controls were investigated with HRCT twice (at first visit and at the end of the study) and according the CT-changes were divided into 3 groups: the 1st group (16 pts) with improvement; 2nd group (39 pts) without any changes and 3rd group (22 pts) with worsening of fibrosis. Disease activity was assessed by the 2001 European Scleroderma Study Group Activity Index (EScSG-AI).

Results: There were no significant differences between groups related to sex, frequency of diffuse form and duration disease. Mean dates of follow up were 58.9±11.4 months. Pts. were investigated with HRCT twice (at first visit and at the end of the study) and according the CT-changes were divided into 3 groups: the 1st group (16 pts) with improvement; 2nd group (39 pts) without any changes and 3rd group (22 pts) with worsening of fibrosis. Disease activity was assessed by the 2001 European Scleroderma Study Group Activity Index (EScSG-AI).

Results: Mean age of patients (Mean±SD) was 42.8±1.3 years, mean SSc duration was 7.9±0.7 years. We revealed substantial changes in enzymatic activities related to both purine and pyrimidine metabolism in lysed red blood cells of SSc patients. The increased ADA (p<0.001), AK (p>0.001), IMPDH (p<0.001), TK (p<0.001), UDH (p<0.001) activities and the decreased DODH (p<0.001), PNP (p<0.001) activities in lysed red blood cells were observed of SSc patients in comparison with healthy controls. AK, IMPDH, TK, UDH activities positively correlated with SSc activity. Negative correlations with SSc activity were revealed for ADA, CDA, DODG, AK, TP activities.

Conclusion: The progression of SSc goes with the imbalance of the purine and pyrimidine enzymes in a regular manner. Activity of the autoimmune inflammation is the factor that underestimates the enzymatic pattern of purine and pyrimidine metabolism.

Disclosure of Interests: None declared. 

REFERENCES:
was significantly higher than in groups 1.2 (p < 0.01 and p < 0.04 accordingly) at the end of the study.

Conclusion: Mean values of EScSG-AI score associated with and were accompanied by progression pulmonary alterations in pts SSC so EScSG-AI score can be used as valuable tool for long-term follow-up studies.

Disclosure of Interests: None declared

AB0219 BIOMARKER EXPRESSION IN MONOCYTE SUBPOPULATIONS IN SSC PATIENTS

Laiana Schneider1, Natalia Marcondes2, Vanessa Hax3,4, Isadora Moreira5, Carolina Yuka6, Rafaela Rómeo6, Ricardo Xavier6, Rafael Chakr6. 1Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 2Laboratório Zanol, Porto Alegre, Brazil; 3Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 4Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 5School of Medicine, Porto Alegre, Brazil

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by vasculopathy and fibrosis, which can be classified into diffuse cutaneous (dSSc) and limited cutaneous (lSSc) subtypes. Monocytes are key agents in the pathophysiology of systemic autoimmune diseases, including systemic sclerosis (SSc). M1 cells (CD14++CD16--) represent a predominantly pro-inflammatory phenotype and M2 cells (CD14+/CD16+) are more associated to an regulatory/pro-fibrotic phenotype.

Objectives: Our aim was to evaluate circulating blood monocyte subpopulations [classical (M1), intermediate and non-classical (M2)] and analyze the expression of CD163, CD169, CD206 and HLA-DR (function and activation monocytes receptors).

Methods: Fifty consecutive patients fulfilling the 2013 ACR/EULAR classification criteria for SSc were included in a cross-sectional study. Monocyte subpopulations were identified and characterized according to the expression of CD64, CD16, CD14, CD163, CD169, CD206 and HLA-DR. Thirty-eight age- and sex-matched healthy individuals were recruited as a control group.

Results: SSc patients mean age was 57.2 ± 12.8 years (HC 55.2 ± 11.4) and 94% were female. Limited form of disease was present in 72% of SSc patients and SSc patients had an increased number of circulating peripheral blood monocytes compared to healthy subjects (table 1). Absolute counts of CD16+ (intermediary and non-classical) monocyte subpopulations were higher in SSc patients than HC (79.9 (53.4-103.5)x10⁴/mm³ vs. 55.9 (26.8-85.6)x10⁴/mm³, p<0.003). HLA-DR intensity of expression was higher in all monocyte subsets from lSSc and dSSc patients when compared to control. There was a higher percentage of classical [1.56 (0.84-2.98) vs. 0.68 (0.37-1.88); p<0.003] and intermediate monocytes [15.9 (9.5-29.9) vs. 6.1 (3.7-11.5); p<0.001] with CD206 expression in SSc patients compared to HC, and a higher percentage of CD169 expression in lSSc patients compared to control and ISSc groups (p<0.01).

Table 1. Absolute value (x10⁴/mm³) about monocyte subpopulations in all systemic sclerosis (SSc) patients compared to healthy controls (HC) and in limited (lSSc) and diffuse (dSSc) systemic sclerosis subtypes.

Data are shown as median (interquartile range - IQR). * Mann-Whitney U test

Conclusion: In our study, SSc patients show greater monocytes counts than HC with a predominantly regulatory/pro-fibrotic phenotype (M2). dSSc seems to be more associated to CD169 than ISSc.

**ABO220: ALPHA-SMOOTH MUSCLE ACTIN EXPRESSION ON ENDOTHELIAL PROGENITORS CELLS OF SYSTEMIC SCLEROSIS PATIENTS: POSSIBLE ROLE IN THE ENDOTHELIAL-TO-MESENCHIMAL TRANSITION PROCESS**

Katia Stefanoniti, Cristiana Barbari, Carlotta Angelotti, Greta Pellegrino, Cristiano Alessandrini, Guido Valesini, Valeria Riccieri, Sapienza Università di Roma, Medicina Interna e Specialità Mediche – Reumatologia, Rome, Italy

**Background:** Endothelial-to-mesenchymal transition (EndoMT), a newly recognized type of cellular transdifferentiation, seems to be involved in Systemic Sclerosis (SSc) pathogenesis. In this process endothelial cells lose their specific markers, and acquire a mesenchymal phenotype, thus expressing cell products such as alpha smooth muscle actin (α-SMA) (1,2). Circulating endothelial progenitors cells (EPCs) derive from bone marrow stem cells and contribute to de novo vessels formation. Several studies, although with conflicting results, have shown that EPCs in the peripheral blood of patients with SSc are impaired in their number and function (3).

**Objectives:** to assess the expression of α-SMA, possibly associated with a pro-mesenchymal switch (EndoMT) of the circulating Early (CD34+KDR+CD133+) and Late (CD34+KDR+) EPCs in the peripheral blood of SSc patients and of patients with Very Early Diagnosis of SSc (VEDOSS) compared with healthy controls (HC) using flow cytometry.

**Methods:** enrolled 11 patients (7 SSC and 4 VEDOSS), classified according to the classification criteria for SSC (4) and for VEDOSS not fulfilling SSC criteria (5), and 10 HC. Phenotypic characterization was performed as previously described by Vasa et al. using a FACS Calibur (BD Immunocytochemistry Systems). EPCs number was expressed as a percentage of cells within the lymphocyte gate.

**Results:** we found a significantly higher percentage of α-SMA positive Early EPCs (CD34+KDR+CD133+α-SMA+) in all patients respect to HC (0.06%±0.03 vs 0.03%±0.01; p=0.0149) particularly in VEDOSS patients (0.07%±0.01 vs 0.03±0.01; p=0.008). Moreover, in VEDOSS patients, also the percentage of Late EPCs (CD34+KDR+α-SMA+) in all patients respect to HC (0.05%±0.01 vs 0.03%±0.01; p=0.05; 0.07%±0.01 vs 0.04%±0.02; p=0.04; 0.06%±0.01 vs 0.04%±0.02; p=0.05). Besides Early EPCs and α-SMA positive Early EPCs percentages seem to be significantly reduced in patients taking iloprost (p=0.05 and p=0.01 respectively), calcium channel blockers (CCB) (p=0.05 and p=0.03) and DMARDs (p=0.017 and p=0.013).

**Conclusion:** EndoMT seems to be involved in the pathogenesis of SSc and circulating EPCs seem to be impaired in number and function in SSC patients. In our study we found higher levels of EPCs, in particular α-SMA positive Early EPCs in both groups of patients (SSC and VEDOSS) respect to HC. Thus we can hypothesize a predominant pro-mesenchymal phenotype of this kind of EPCs. This could be considered the expression of the involvement of EPCs in EndoMT process and could better explain the controversial role of EPCs in SSc pathogenesis. Very interesting is the finding of a lower percentage of Early EPCs, and could better explain the controversial role of EPCs in SSc pathogenesis.

ASSOCIATION BETWEEN CENTROMERE AND TOPOISOMERASE SPECIFIC IMMUNE RESPONSES AND THE DEGREE OF MICROANGIOPATHY IN SYSTEMIC SCLEROSIS

Nina van Leeuwen1, Jaap Bakker1, Corrie Wortel1, Hans Ulrich Scherer1, Rene Toes1, Thomas Huizinga2, Jeska de Vries-Bouwstra2, 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center, Clinical Chemistry, Leiden, Netherlands

Background: In systemic sclerosis (SSc) more severe microangiopathy has been associated with worse disease outcome. In addition, auto-antibodies are important tools for disease prognostication. To what extent these two biomarkers reflect the same pathophysiological background is not clear. A better understanding of the interaction between the specific auto-immune response and the degree of microangiopathy could not only improve our insight in disease pathophysiology but could also contribute to more reliable disease prognostication. We hypothesized that an ongoing activated immune response, as reflected by higher anticientromere antibody (ACA) or anti-topoisomerase (ATA) specific IgG levels and higher number of ACA or ATA specific isotypes, associates with more severe microvascular damage and with more severe SSc.

Objectives: 1. To evaluate whether ACA and ATA isotype expression associates with the degree of microangiopathy in SSc. 2. To determine the additive value of more activated immune response for prediction of organ involvement.

Methods: ACA and ATA IgG, IgA and IgM levels were measured in serum samples of 129 ACA IgG+ or 102 ATA IgG+ SSc patients, respectively. The degree of microangiopathy was determined based on nailfold videocapillaroscopy (NVC) images, with SSc late pattern reflecting more severe microangiopathy. Associations between ATA and ACA iso-type expression and NVC patterns were evaluated. Logistic regression analyses, with NVC pattern, autoantibodies, isotype expression and IgG levels as independent and disease characteristics as dependent variables were performed, adjusted for age, sex and disease duration.

Results: NVC images were available for 164 patients (n=100 ACA, n=64 ATA). Prevalence of SSc early, active and late pattern did not differ between ACA/ATA IgM- and IgM – patients, nor between ACA/ATA IgA- and IgA – patients. No associations between isotype expression (Figure 1) or IgG levels and NVC patterns were found. Logistic regression confirmed the association of ATA with pulmonary involvement (multivariable Odds Ratio [OR] 9.0 range 2.3-34.5) and of late SSc pattern with digital ulcers (multivariable OR 12.0 range 3.0-48.0) and pulmonary involvement (multivariable OR 5.0 range 1.5-16.1). Of note, higher topoisomerase and centromere specific IgG levels were independently associated with presence of digital ulcers (OR 3.5 range 1.1-11.0).

Conclusion: We did not observe an association between the quality of the anti-centromere specific or the anti-topoisomerase specific immune response and degree of microangiopathy in SSc patients. This might indicate that specific autoantibodies and stage of microangiopathy reflect different processes in the disease. The association between higher ATA or ACA specific IgG levels with digital ulcers, independent of specific autoantibody and NVC patterns suggests that an ongoing, active immune response is associated with more severe organ involvement.

Figure 1. SSc patterns on nailfold videocapillaroscopy (NVC) stratified for number of isotypes expressed.

AB0223 ASSESSMENT OF DISEASE ACTIVITY IN SYSTEMIC SCLEROSIS: THE COMPARISON BETWEEN REVISED EUSTAR AND EScSG ACTIVITY INDEXES

Yasemin Yalçınkaya1, Ummügülsüm Gazel1, Sema Kaymaz Tahrat1, Ayşun Aksoy1, Murat Karabaçak1, Sedad Kutlu1, Özlem Pehlivani1, Fatma Albaz-Öner1, Pamir Atagündüz1, Nevzun İnanç1, Haner Direskeneli1, 1Marmara University, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Ümraniye Education and Research Hospital, Istanbul, Turkey

Background: Assessment of disease activity in systemic sclerosis (SSc) is challenging and usually hard to distinguish from damage or chronicity. Objectives: We aimed to evaluate disease activity by different indexes and compare them in a SSc cohort.

Methods: Disease activity was evaluated by revised EUSTAR (European Scleroderma Trials and Research group) and EScSG (European Scleroderma Study Group) activity indexes in 131 SSc patients fulfilling ACR/EULAR classification criteria (2013). The patients with the scores of EUSTAR activity index ≥2.5 or EScSG activity index ≥3 were accepted as having active disease.

| Since non RP, median(IQR) | 6 (0-12) | 2 (1-4) | 15 (8-26) | 4 (1-10) |}

Results: Demographics, disease characteristics and nailfold video-capillaroscopic (NVC) pattern details were summarised in table-1. The scores of EUSTAR and EScSG activity indexes were correlated well (r=0.576, p=0.000) and the agreement between two scores for activity was moderate (cohen kappa:0.407). The percentages of SSc patients described as having active disease or not according to two activity indexes were summarised in table-2. Of the patients, 9.9% had active and 70.9% had inactive disease according to both indexes in this SSc cohort. Twenty-one (for EUSTAR) and 4 patients (for EScSG) were described as active according to one index and not to the other. Revised EUSTAR activity index was found to have 76.5% sensitivity and 81.6% specificity when the activity was defined by EScSG activity index.

Conclusion: This SSc cohort predominantly had limited cutaneous disease, digital vasculopathy and late scleroderma pattern. Defining active disease was differed in 19% of the patients according to EUSTAR and EScSG activity indexes, former described higher frequency for activity. This difference might be related to validation procedures of these indexes in patients with different predominant stages of SSc disease, content of the index and the features of the cohort.

AB0224 SYSTEMIC SCLEROSIS SINE SCLERODERMA: CHALLENGES WITH VERIFICATION IN PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

Natalia Yudkina, Alexander Volkov, Ekaterina Nikolaeva, Ildar Kurmukov, Evgeny Nasonov. V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Recognizing systemic sclerosis (SSc) in patients without cutaneous involvement is a real challenge due to inapparent clinical picture. 1980 ACR classification criteria for SSc fail to verify the diagnosis in the majority of cases. Therefore, the diagnosis is usually established years and decades after SSc onset at the stage of full-blown visceral disease. Introduction of 2013 ACR/EULAR classification criteria into clinical practice allow early diagnosis of SSc even in cases with skin involvement thanks to the fact, that list of considered criteria includes telangectasia, pulmonary arterial hypertension (PAH), abnormal nailfold capillaries and SSc-related autoantibodies.

Objectives: To identify specific features in the clinical course of SSc sine scleroderma (ssSSc) in patients with PAH.

Methods: 11 patients with verified SSc diagnosis according to 2013 criteria were included; participants did not have any SSc-specific signs of skin involvement, such as puffy fingers, fingers’ skin thickening/induration or skin atrophy. PAH was diagnosed in 11 patients during of right heart catheterization.

Results: Isolated Raynaud’s phenomenon (RP) was along-standing diagnosis (more than 5 years) in all patients, except for one whom, in whom the disease manifested with signs of Sjogren’s syndrome (SjS) (parotitis). Benign, chronic, and gradually progressing during a long time disease was documented in all patients. In 7 patients out of 11 SSc diagnosis was initially suspected by cardiologists, and later confirmed by detection of antinuclear autoantibodies. The following signs were documented in SSc patients as initial manifesting non-Raynaud symptoms: esophageal dysmotility – in 3 patients, digital ulcers – in 2, telangectasia – in 2 patients, and dyspnea (PAH symptom) – in 1 patient. None of the patients ever experienced skin thickening typical for SSc. RP was present in all 100%, but digital ischemic alterations – digital tip ulcers, pitting scars were found only in 3 patients. SSc diagnosis was verified based on abnormal nailfold capillaries (in 100% cases), and based on identification of SSc-specific antibodies (anti-Ro/SSA antibodies – ACA) – in 7 patients. Anti-Ro-antibodies were found in 4 patients, anti-RNP-70 – in 3. SjS was established in 3 out of 4 anti-Ro-antibodies – positive patients and ruled out in one. Myositis was documented in past-medical history in one patient with anti-RNP-70-antibodies positivity. It should be noted, that 3 ACA-negative patients had, nevertheless, a “threshold” score value (9 scores) for SSc diagnosis, exhibiting many clinical features in favor of SSc diagnosis beyond any doubt. Esophageal dysmotility and associated symptoms were found in 10 out of 11 SSc patients. One patient had an SSc-rheumatoid arthritis overlap syndrome (erosive arthritis, joint deformities, positive ACA, rheumatoid factor, anti-CCP).

Conclusion: Introduction of 2013 ACR-EULAR classification criteria for SSc into clinical practice was highly relevant for identification of SSc even in cases without skin involvement, such as puffy fingers, fingers’ skin thickening/induration or skin atrophy. PAH was diagnosed in 11 patients during of right heart catheterization. The earlier PAH-SSc is diagnosed and PAH-specific therapy is initiated, the longer will be patient’s lifespan.

AB0225 CLINICAL SUBTYPE OF PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SYSTEMIC SCLEROSIS

Natalia Yudkina, Alexander Volkov, Ekaterina Nikolaeva, Ildar Kurmukov, Evgeny Nasonov. V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Despite the similar pathogenesis and clinical picture, pulmonary arterial hypertension in systemic sclerosis (PAH-SSc) is different from idiopathic pulmonary arterial hypertension (IPAH) is characterized by a more severe course, an unsatisfactory response to PAH-specific therapy, a poor survival and a
disappointing prognosis. In this connection, before doctors of different specialties, first of all before rheumatologists, cardiologists and pulmonologists, there is a need to highlight the characteristics of the flow of PAH depending on the presence of SSc.

**Objectives:** To describe specific symptoms of PAH associated with SSc.

**Methods:** The study included 51 patients with PAH-SSc and 50 patients with IPAH formed the control group. To verify the diagnosis of PAH all patients underwent studies according to the program corresponding to the running recommendations for the diagnostics and treatment of pulmonary hypertension with mandatory right heart catheterization. The diagnosis of SSc was established in accordance with the classification criteria ACR-EULAR 2013. Univariate logistic regression was used to calculate a probability (odds ratio (OR)) of SSc-associated symptoms.

**Results:** We identified 29 symptoms that were associated with PAH-SSc. The most significant of them, increasing the risk of detection of SSc in patients with PAH, were age over 45 years (OR 9.7, 95% CI 3.9-24.3, p <0.00001), serum uric acid level> 387 μmol/L (OR 3.8, 95% CI 1.5-9.6, p = 0.003), diffusion lung capacity (DLCO) >60% (OR 13.8, 95% CI 4.3-44.7, p <0.0001), ratio of forced vital capacity to DLCO <1.7 (OR 13.0, 95% CI 3.9-42.9, p <0.0001), level of C-reactive protein >2 mg/l (OR 12.9, 95% CI 3.96-41.8, p <0.00001), the presence of pericardial effusion (OR 6.1, 95% CI 1.2-30.6, p = 0.04), mean right ventricular pressure > 15.5 mm Hg. (OR 8.9, 95% CI 3.4-23.1, p <0.00001), diastolic right ventricular pressure > 4.5 mm Hg. (OR 4.6, 95% CI 1.9-11.2, p = 0.0003).

**Symptoms that reduce the risk of detecting SSc in patients with PAH include mean pulmonary artery pressure >55 mmHg, (OR 0.4, 95% CI 0.2-0.9, p = 0.03), pulmonary vascular resistance >12 units Wood (OR 0.4, 95% CI 0.2-0.9, p = 0.02), hemoglobin level >146 g/l (OR 0.3, 95% CI 0.2-0.8, p = 0.007), presence of syncope (OR 0.3, 95% CI 0.1-0.9, p = 0.03).

**Conclusion:** The selection of features of the course of PAH that increase the likelihood of detection of SSc will contribute to the timely diagnosis of PAH, will allow to predict the course of PAH, to approach more carefully the selection and monitoring of the effectiveness of PAH-specific therapy. That will contribute to improving the survival and functional status of patients with PAH-SSc.

**AB0226** NEOUTROPHIL EXTRACELLULAR TRAPS ACTIVATE LUNG FIBROBLAST TO INDUCE MYOSISI-RELATED INTERSTITIAL LUNG DISEASES IN MICE

Siqiong Zhang1, Haii Shen2, Lanzhou University Second Hospital, Rheumatology, Lanzhou, China; 2Lanzhou University Second Hospital, Lanzhou, China

**Background:** Excessive neutrophil extracellular traps (NETs) formation may contribute to myositis-associated interstitial lung diseases (ILD), but the underlying mechanism is not fully revealed.

**Objectives:** This research aimed to elucidate the mechanism by which NET formation and myositis-associated ILD.

**Methods:** Myositis mice model was established by injecting with the rat skeletal muscle homogenate and pertussis toxin. Expressions of ACTA2, CCN2, ADAM12, miR-7 and Smad2 were detected by quantitative real-time polymerase chain reaction (qRT-PCR). Smad2, CCN2, ADAM12, miR-7 and Smad2 were detected by quantitative real-time polymerase chain reaction (qRT-PCR). Smad2, CCN2 and TLR9 signaling-related proteins were measured by western blot. Soluble collagen I-IV were detected by Sircol collagen assay kit. The proliferation of LF was measured by [3H]-thymidine incorporation assay. The interaction between miR-7 and the Smad2 was confirmed by dual-luciferase reporter gene assay. TLR9 and Smad2 were upregulated in lung tissue of myositis group than control group, and NETs further decreased miR-7 expression. TLR9 and Smad2 were upregulated in lung tissue of myositis group than control group, and NETs further increased TLR9 and Smad2 expressions. In vitro experiments showed that PMA-treated NETs accelerated the proliferation of LF and their differentiation into myofibroblasts (MF), whereas DNase I decreased the promotion effect of NETs. NETs components myeloperoxidase (MPO) and histone 3 also promoted the proliferation and differentiation of LF. In addition, we demonstrated that TLR9 involved in the regulation of NETs on LF proliferation and differentiation, and confirmed the interaction between miR-7 and Smad2 in LF. Finally, miR-7-Smad2 pathway was confirmed to be involved in the regulation of TLR9 on LF proliferation and differentiation.

**Conclusion:** NETs promote myositis-related ILD, and TLR9-miR-7-Smad2 signaling pathway is involved in the proliferation of LFs and their differentiation into MFs.

**AB0227** EXTENSIVE IMMUNOPHENOTYPIC ANALYSIS OF CO-INHIBITORY AND CO-STIMULATORY MOLECULES IN JUVENILE IDIOPATHIC ARTHRITIS (JIA) PERIPHERAL LYMPHOCYTES

Estefania Quesada-Masachs1, Daniel Álvarez de la Sierra2, Antonio Júlía3, Monica Martinez-Galio3, Maria Moreno-Cortés3, Ricardo Pujol-Borrell1, Consuelo Modesto1, Sara Maragà1, Vall d’Hebron University Hospital, Pediatric Rheumatology, Barcelona, Spain; 2Vall d’Hebron University Hospital, Immunology, Barcelona, Spain; 3Vall d’Hebron Research Institute, Barcelona, Spain; 4Vall d’Hebron University Hospital, Rheumatology, Barcelona, Spain

**Background:** In a previous in-depth phenotypic analysis of PBLS in JIA, we detected differences in cell subpopulations dependent on the age and disease activity, and some cellular changes that could be often associated with an exhausted phenotype.

**Objectives:** To analyze the expression of co-inhibitory and co-stimulatory molecules in different cellular subpopulations in Oligoarticular JIA patients stratified by age and treatment.

**Methods:** Exploratory cross-sectional study. 53 patients fulfilling Oligoarticular JIA (ILAR) criteria and 22 controls were included. All of them were children or young adults (2 to 35 years of age). JIA patients were either not treated (n=14) or treated with MTX (n=14), anti-TNF (n=8), or a combination of both (n=16). JIA disease activity was clinically and biologically assessed. Four flow cytometry panels were designed for the analysis of co-stimulatory/co-inhibitory markers, some typical of “exhausted” cells (PD1, TIM 3, TIGIT, CD226, CD137, HVEM, LIGHT, BTLA), assessed in memory, effector and naïve CD4+ and CD8+ T lymphocytes, and also in B lymphocytes and NK cells. Statistical analysis was performed, and FDR correction was applied for p values.

**Results:** No correlation was found among the different exhaustion/activation markers and age or disease activity. However, there were some differential trends in CD8+ compartments in Oligoarticular JIA patients, but stratified by age and treatment.

**Conclusion:** No clear differences were found in PBL subpopulations of oligoarticular-JIA patients regarding co-stimulatory/co-inhibitory molecules.

**Disclosure of Interests:** None declared

CHILDREN WITH EXTENDED OLOGOARTICULAR
AND MULTARTICULAR JUVENILE IDIOPATHIC ARTHRITIS
HAVE A CYTOKINE PATTERN FAVOURING B CELL
ACTIVITY IN COMPARISON SIMILARLY TO EARLY
AND ESTABLISHED RHEUMATOID ARTHRITIS
PATIENTS

Rita A. Moura1, Filipa Oliveira-Ramos1,2, Cláudia Marques1, Alexandre Brito1, Rui L. Teixeira1,2, Vasco Romão1,2, Raquel Campanhão-Marques1,2, Vítor Teixeira, Maria João Savaiedra1, Cristina Ponte2, Nikita Kmelinskii2, Joao Eurico Fonseca2,1.1Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; 2Serviço de Reumatologia e Doenças Ósseas Metabólicas, Hospital de Santa Maria, CHUL/H, Lisbon Academic Medical Centre, Lisbon, Portugal

Background: The majority of polyarticular JIA (pJIA) and a large fraction of extended oligoarticular JIA (oJIA) patients fulfill classification criteria for rheumatoid arthritis (RA) in adulthood. B cells play several important roles in RA pathogenesis, but it is still unclear if the pattern of B cell involvement in pJIA and extended oJIA follows what has been described for adults with RA.

Objectives: The main goal of this study was to determine the concentration of cytokines potentially relevant for B cell activation in serum from children with pJIA and extended oJIA when compared to children with persistent oJIA, adult JIA, early and established RA patients.

Methods: Serum samples were collected from children with extended oJIA (n=8), persistent oJIA (n=6), pJIA (n=6), adult JIA (n=8), untreated early RA (<1 year of disease duration, n=12), established RA patients treated with anti-TNF (n=20), anti-DICARs (n=10) and corresponding groups of age- and sex-matched healthy donors (children, n=4 and adults, n=10). A proliferation-inducing ligand (APRIL), B-cell activating factor (BAFF), interleukin (IL)-6 and IL-21 serum levels were measured by ELISA.

Results: Children with extended oJIA, early and established RA patients had significantly higher IL-6 and IL-21 serum levels when compared to controls, but no significant differences were observed in children with persistent oJIA, pJIA and adult JIA when compared to all groups included. APRIL serum levels were significantly increased in all patient groups when compared to controls, except in adult JIA, who had similar APRIL concentrations in comparison to controls. In addition, children with extended oJIA and pJIA had significantly higher APRIL serum levels when compared to adult JIA. IL-6 serum levels were significantly increased in children with persistent oJIA and adult JIA patients. IL-21 serum levels were significantly increased in early RA when compared to controls, but no significant differences were observed between any of the other groups included.

Conclusion: There is a similarity in B cell cytokine pattern found between extended oJIA, pJIA, and non-classical monocytes in patients with SLE and JSLE. This correlation was lost when JSLE and SLE were grouped together, or when SLE was examined in isolation. Increased percentages of non-classical monocytes were associated with a higher odds of adult onset SLE relative to JSLE, after adjusting for the effects of disease activity (SLE-DAI) (OR= 1.137, 95% CI= 1.021–1.266, p= 0.018).

Arthritis Research UK Centre for Adolescent Rheumatology; University College London, London, United Kingdom; 2Rheumatology Department, University College London, London, United Kingdom; 3Institute of Child Health, Great Ormond Street Hospital, London, United Kingdom; 4NIHR Biomedical Research Centre, Great Ormond Street Hospital, London, United Kingdom

Background: Inflammation is a mediator and primary driver of joint damage in juvenile idiopathic arthritis (JIA). Musculoskeletal pain can be experienced in the presence or absence of inflammation. Enthesitis related arthritis (ERA) is a subtype of JIA characterised by inflammation of the spine, entheses, and peripheral joints. Cytokines and numerous other regulatory molecules are implicated in pain and inflammation, yet, to date, no reliable biomarkers have been identified.

Objectives: To assess if cytokine profiles correlate with pain or disease activity in well controlled ERA.

Methods: 42 patients, with either a prior diagnosis of JIA or back pain, agreed to have a standard clinical MRI scan of lumbar spine, sacroiliac joints, and pelvis and to donate serum. Serum was also collected from 12 volunteer age matched healthy controls. Serum was analysed using a bead-based multiplex assay (Luminex) for the concentrations of the

CYTOKINE SIGNATURE DOES NOT CORRELATE WITH
PAIN OR DISEASE ACTIVITY IN WELL CONTROLLED
ERA

Anna Radziszewska1, Corinne Fisher1, Timothy Bray2, Vera Cholda2, Debajit Sen1, Margaret Hall-Drags2, Coziana Curtin1,2.1University College London, Arthritis Research UK Centre for Adolescent Rheumatology at UCLH; UCL; London, United Kingdom; 2University College London, Centre for Medical Imaging, London, United Kingdom

Background: Inflammation is a mediator and primary driver of joint damage in juvenile idiopathic arthritis (JIA). Musculoskeletal pain can be experienced in the presence or absence of inflammation. Enthesitis related arthritis (ERA) is a subtype of JIA characterised by inflammation of the spine, entheses, and peripheral joints. Cytokines and numerous other regulatory molecules are implicated in pain and inflammation, yet, to date, no reliable biomarkers have been identified.

Objectives: To assess if cytokine profiles correlate with pain or disease activity in patients with ERA.

Methods: 42 patients, with either a prior diagnosis of JIA or back pain, agreed to have a standard clinical MRI scan of lumbar spine, sacroiliac joints, and pelvis and to donate serum. Serum was also collected from 12 volunteer age matched healthy controls. Serum was analysed using a bead-based multiplex assay (Luminex) for the concentrations of the
following analytes: IL-6, IL-12, IL-17, IL-23, TNFα, IFNγ, MIF, OPG, SOST, GM-CSF, VEGF, DKK-1, S100A8, MMP-3 and CRP. To assess pain levels, patients indicated on a scale of 0-10 the amount of back pain experienced at night and separately the amount of back pain experienced at any time during the last week. They also completed a Bath Ankylosing Spondylitis Disease activity Index (BASDAI) questionnaire to assess disease activity. Cytokine concentrations in patients with ERA were compared with those of controls. The levels were also correlated with the two measures of back pain as well as individual questions from the BASDAI questionnaire.

Results: Of all 54 samples tested, 11 patients and 5 controls cross-reacted with the negative control for the assay and thus were excluded from analysis. Based on MRI scan results, 14 patients had ERA, 8 had biomechanical pain, 7 had other subtypes of JIA, and 2 had non-specific features of spinal inflammation. The median overall back pain and the total BASDAI scores for the ERA group were 2.4 (IQR=1.45-5.55) and 2.5 (IQR= 0.75-6.25) respectively, suggesting well controlled disease on treatment and minimal residual symptoms. There was no statistical difference between cytokine levels in the ERA group compared to controls when corrected for multiple testing, with the exception of IL-12 which was significantly higher in controls (p=0.003). No correlation was found between cytokines and pain scores (at night or overall during the last week) or with the overall BASDAI score or any of the sub-component questions of the BASDAI questionnaire.

Conclusion: Well-controlled ERA patients on treatment have similar cytokine profiles as healthy controls and they do not correlate with clinical pain scores or disease activity.

ABO2306 STUDY OF CELIAC DISEASE ANTIBODIES IN PATIENTS WITH JUVENILE ONSET RHEUMATOLOGICAL DISORDERS

Eman Hassan,1,2, Nermen Magdy,2,4, Egypt, Internal Medicine Rheumatology, Alexandria, Egypt; 2Faculty of Medicine, University of Alexandria, Internal Medicine Rheumatology, Alexandria, Egypt; 4Internal Medicine Rheumatology, Alexandria, Egypt

Background: Preclinical autoimmunity can be detected in the form of circulating autoantibodies in the peripheral blood many years preceding the onset of the clinical disease. Celiac disease (CD) is an immunological response to gluten in genetically susceptible people. The clinical presentation of CD includes abdominal pain, diarrhea and nutritional deficiencies. However, clinical symptoms could be misleading in most of the patients presenting subclinical forms with only minor gastrointestinal symptoms. Celiac disease will present in older children by atypical presentation. Most celiac disease patients show atypical symptoms and may remain untreated, which makes screening is mandatory in high-risk patients with autoimmune diseases. This collectively highlights the need to check for clinical evidence of celiac disease among patients diagnosed as juvenile onset rheumatic diseases.

Objectives: The aim of this study was to screen for celiac disease antibodies (anti-tissue transglutaminase IgA and IgG auto-antibodies) in the serum of juvenile onset rheumatic diseases patients in comparison with normal subjects.

Methods: Serum anti-ITG (both IgA and IgG) level was detected in 60 juvenile onset rheumatic patients and 20 age and sex matched healthy controls. We also assessed different clinical and laboratory markers of disease parameters; 31 juvenile onset systemic lupus erythematosus (SLE), 21 juvenile onset idiopathic arthritis (JIA), 4 juvenile onset systemic sclerosis and 2 juvenile onset behcet's disease and each disease activity score. We also correlated serum transglutaminase auto-antibodies with each disease activity, Endoscopic examination and histopathologic examination, for the patients with a least one positive anti-ITG Ab was done.

Results: Serum anti-ITG Abs was no statistical significant differences in the patients group than in the control group, and there was no correlation between anti-ITG Abs with positive disease activity score.

Conclusion: The presence of concomitant CD and another rheumatic disorder in the same patient is unlikely.

ABO231 PAIN THRESHOLD IN RHEUMATOID ARTHRITIS AND ITS RELATED FACTOR

Aysegül Altun Guvenir,1 Aslı Caşkans Uckun, Fatma Yurdakul, Hatice Bodur. Ankara N Hatice Bodur umume Training and Research Hospital, Physical Medicine and Rehabilitation, ANKARA, Turkey.

Background: Pain remains the most important challenge for rheumatoid arthritis (RA) patients. In order to cope with pain in RA, clinicians firstly need to understand the degree of patients' pain. When self reported measures such as visual analog scale were used, inconsistency between clinicians' and patients' ratings of pain was demonstrated (1). As a result, inability to fully assess the pain will cause the inability to fully assess the impact of pain on disease severity. Measuring pressure pain threshold with pressure algometry may provide additional advantages for the evaluation of pain and disease severity when compared with self-reported measures.

Objectives: The aim of this study was to evaluate the pain threshold and to determine the variables associated with pain threshold in the patients with RA.

Methods: The current study included 100 RA patients and 80 age-sex matched controls with non-inflammatory chronic low back pain. Clinical parameters, functional status, disease activity, pain, fatigue, depression, anxiety, pain catastrophizing and laboratory activity of RA patients were recorded. The pressure pain thresholds on the dominant thumb nail bed, trapezius and wrist of the two groups were measured by the algometer. The pain thresholds of the patients with RA and controls were compared.

Moreover, the relation between pain thresholds and all evaluated parameters in RA patients was analysed.

Results: The mean age of RA patients was 55.93 ± 10.81; the mean age of the controls was 54.50 ± 9.47. The pain thresholds of RA patients and controls were statistically similar in all areas. When the parameters found to be significantly correlated with pain threshold in RA patients were analyzed by regression analysis, depression was the only factor associated with low pain threshold in all areas (Table 1).

Conclusion: We found that depression was the only factor associated with low pain threshold in the patients with RA. The use of pressure algometry in the evaluation of chronic pain could offer an additional method to detect pain/depression overlap.

Rheumatoid arthritis – prognosis, predictors and outcome
AB0232 TIGHT CONTROL MANAGEMENT OF EARLY RA ACHIEVES MORE PATIENTS IN REMISSION AT 6 MONTHS AND IMPROVES PAIN, FUNCTION AND FATIGUE AT 24 MONTHS COMPARED TO A CONTROL GROUP

Maria Aronsson1,2, Annika Teleman1, Stefan Bergman2,3, Kristina Forslind4, Maria Andersson1,2. Background: Even with modern antirheumatic treatment, many patients experience chronic pain and loss of function despite less disease activity. The understanding of how this chronic pain development can be prevented is sparse. There is furthermore little knowledge if a tight control management without specific treatment schemes and instructions for the physicians to follow could increase the remission frequency.

Objectives: To determine whether solely a tight control management of patients, without further intervention in the physician’s work, can increase the remission frequency and improve patient reported outcome in early RA.

Methods: In all, 96 patients with early RA were consecutively included in a tight control study group (TCS). Inclusion criteria were early RA patients (<13 month duration) with no previous history of rheumatic disease. A control group, with so far 27 patients receiving standard care, has been analyzed. The tight control management included monthly visits to the physician the first 6 months, followed by visits at 9, 12 and 24 months. If not in remission at 6 months the patients’ monthly visits could continue to 12 months. The study did not include any treatment guidelines for the physicians. Pain, Fatigue and the Patient’s Global Assessment of the General Health (PIGA) were reported on a Visual Analogue Scale (VAS). The 28 tender and swollen joint score, DAS28, C-Reactive protein, Erythrocyte sedimentation rate and Health Assessment Questionnaire (HAQ) were assessed.

Results: There was no significant difference between the groups at baseline in gender, age, smoking, disease duration, disease activity, pain, HAQ, fatigue, RF and ACPA. There was a significant difference between groups in outcome, with 70% of TCS and 37% of control patients in remission (DAS28 <2.6), p=0.010, at 6 months, figure 1A. At 12 and 24 months there was no significant difference in the remission frequency, figure 1A. The TCS group improved more than the control group in Pain, Fatigue and HAQ during follow up, figure 1B-D. The median VAS pain at 24 months was 11 (IQR 2-22) in the TCS group and 22 (IQR 4-42) in the control group, p=0.036. The median VAS fatigue was 13 (IQR 2-38) in the TCS group and 33 (IQR 8-70) in the control group p=0.028 at 24 months. The difference in HAQ reached significant numbers solely at 6 months where the median was 0.13 (IQR 0-0.50) in the TCS group and 0.57 in the control group (IQR 0.16-0.94).

Conclusion: Patients in tight control reached remission faster than patients receiving standard care. They also reported less pain and fatigue, despite the fact that there was no difference in remission frequency at 24 months. The results indicate that a tight control scheme could influence pain development in patients with early RA, but further studies are required.

AN INTEGRATED PROTEOMICS AND ANTIBODY ANALYSIS OF THE U-ACT-EARLY TRIAL TO IDENTIFY MARKERS OF TREATMENT RESPONSE AND DISEASE PROGRESSION IN EARLY RHEUMATOID ARTHRITIS

Francesco Brizzi1, Suleiman A. Khan2, Marco Prunotto1, Jenny Devporton1, Attila Pethoe-Schramm3, Michelle Born4, Johannes W Blijma5, Johannes W. G. Jacobs6, Floris Lafeber7, Paco Welsing8, Tero Naltokkio9, Antoine Soubret9.

1F Hoffmann-La Roche, Basel, Switzerland; 2Institute for Molecular Medicine Finland FIMM, University of Helsinki, Helsinki, Finland; 3Gemtech, Inc., South San Francisco, United States of America; 4Roche Nederland BV, Woerden, Netherlands; 5University Medical Center Utrecht, Utrecht, Netherlands; 6University of Turku, Department of Mathematics and Statistics, Turku, Finland

Background: Predictive markers of treatment response in rheumatoid arthritis (RA) are necessary to stratify patients to devise personalised treatment strategies. The U-ACT-Early trial [1], in which disease-modifying anti-rheumatic drugs (DMARD) naïve early RA patients initiated either methotrexate (MTX) or tocilizumab (TCZ) in monotherapy or in combination, offers a unique opportunity to assess the capacity of many baseline –omics markers (i.e. genomics, transcriptomics, proteomics, metabolomics, auto-antibodies) to predict clinical outcomes.

Objectives: To identify predictive markers of treatment response by developing a statistical machine learning methodology for correlating baseline clinical and –omics variables with clinical response data over time.

Methods: We developed a multi-omics approach that combines longitudinal statistical modelling of clinical data with Bayesian machine learning variable selection to identify the most predictive markers of treatment response. The time course of clinical outcomes was fit using a non-linear mixed longitudinal model, that characterises each patient of the U-ACT-Early trial (n=317) by three parameters: a baseline value, an asymptotic value and a velocity (describing the speed at which the asymptote is reached). Supervised machine learning methods (such as Bayesian sparse regression as well as tree-based algorithms) were subsequently employed to find active markers for each of the longitudinal model parameters. We specifically focused on 85 auto-inflammatory proteins and 450 auto-antibodies markers, including 41 citrullinated-peptides antigens. The analysis was repeated for the three treatment-arms since DAS28-subscores response markers may vary across treatment strategies and clinical outcomes. We finally investigated whether predictions are enhanced by incorporating known networks of protein-protein interactions, rather than –omics variables with clinical response data over time.

Results: Preliminary results are that some proteins (e.g. sCD14, VEGF) were moderately predictive of the disease status at baseline. Specifically, the available inflammatory proteins predicted baseline DAS28, swollen and tender joints and ESR with R² values of 0.25, 0.32, 0.16 and 0 respectively. Surprisingly, these proteins did not improve the prediction of treatment-response (i.e. the velocity and asymptotic parameters) after controlling for the baseline disease status. Protein networks marginally improved prediction when compared to prediction of individual proteins. Citrullinated peptide antigens did not appear predictive of the baseline disease status nor the treatment response.

Conclusion: In our initial investigation inflammatory proteins, especially when considered as part of interaction networks, appear to be predictive of the baseline status of the disease but not of treatment-response. The most predictive marker of treatment response appears to be disease activity at baseline.

THE LIFETIME RISK OF KNEE AND HIP REPLACEMENT FOLLOWING A DIAGNOSIS OF RHEUMATOID ARTHRITIS: FINDINGS FROM ROUTINELY COLLECTED DATA FROM ENGLAND

Edward Burn1, Christopher Edwards2,3, David W. Murray1, Alan Silman1, Cyril Cooper1,2,4, Nigel Arden1,5, Daniel Prieto-Alhambra1,6,7,8,9,10, NDaRM, University of Oxford, Oxford, United Kingdom; 2NHRI Wellcome Trust Clinical Research Facility, University Hospital Southampton, Southampton, United Kingdom; 3MRC LifeCourse Epidemiology Unit, Southampton University, Southampton, United Kingdom; 4GREMPAL Research Group, Idiap Jordi Gol and CIBERFisi, Universitat Autonoma de Barcelona and Instituto de Salud Carlos III, Barcelona, Spain.

Background: Understanding the lifetime risk of knee and hip replacement following a diagnosis of rheumatoid arthritis (RA) would help provide patients and clinicians with an indication of long-term prognosis and future health care utilisation.

Objectives: To estimate the lifetime risk of knee and hip replacement following a diagnosis of RA.

Methods: Routinely collected data from the English NHS was used to inform the analysis. Diagnosis of RA was identified using primary care records, with knee and hip replacement observed in linked hospital records. Parametric survival models were fitted for up to 15 years of follow up, with age, sex, Charlson comorbidity score, socioeconomic status, BMI, and smoking status included as explanatory variables. A decision model was used to combine and extrapolate survival models to estimate lifetime risk. Lifetime risk was estimated for individuals with average characteristics (median for continuous variables and mode for categorical ones). The partial effect of explanatory factors on lifetime risk was assessed by re-running models with participant profiles varying in the explanatory factor of interest, while holding other characteristics constant at their average.

Results: 13,961 study participants with a diagnosis of RA were included. Lifetime risk of knee replacement and hip replacement was estimated to be 22% (95%CI 16% to 29%) and 17% (11% to 26%) following a diagnosis of RA for the average patient profile (non-smoking women aged 64 with no other comorbidities, BMI of 27 and in the top socioeconomic quintile). Risks were higher for younger patients, but broadly similar for men and women. Comorbidities, socioeconomic status, BMI, and smoking status had relatively little impact on lifetime risk.

Conclusion: This study has estimated lifetime risk of knee and hip replacement following a diagnosis of RA, allowing for a better understanding of long-term prognosis and healthcare resource use. These risks are more than double those of the general UK population.

WHAT FACTORS ARE ASSOCIATED WITH THE EVOLUTION TOWARDS RHEUMATOID ARTHRITIS, USE OF BIOLOGICAL THERAPY AND DEVELOPMENT OF CARDIOVASCULAR EVENTS IN A COHORT OF PATIENTS WITH UNDIFFERENTIATED ARTHRITIS?

Jerusalem Calvo Gutierrez1, Rafaela Ortega Castro1, Clementina López-Medina2, Ladehse Pineda Lourdes3, María del Carmen Castro Villegas4, Alejandro Escudero Contreras4, Eduardo Collantes Estévez5, Reina Sofia University Hospital, Maimonides Institute of Biomedical Research of Córdoba (IMIBIC), University of Córdoba, Rheumatology, Córdoba, Spain; 2Cochin Hospital, Rheumatology, Paris, France

Objectives: To describe the clinical-demographic characteristics and behaviour over time (12, 24 and 60 months) of a cohort of Undifferentiated Arthritis (UA) and to assess which factors are associated with the evolution towards Rheumatoid Arthritis (RA), use of Biological Therapy (BT) and the development of Cardiovascular Disease (CVD).

Methods: Ambispective cohort study of patients with UA evaluated longitudinally from January 2009 to 2019. We analyzed baseline clinical and laboratory variables and a Multivariate Logistic Regression was performed to determine the factors associated with RA development after 5 years of follow-up. To analyze what factors were associated with the use of BT and the presence of CVD the chi-square or Fisher test were used for binary variables, and U-Mann Whitney for continuous variables.

Results: 180 patients were included, 55% women, with an average age of 49.3 (SD 16.1) years. The average duration of symptoms before the first visit was 6.9 (SD 9.9) months. 47.2% were FRR., 41% ACPA+, 20.6% HLA-DRB1 shared epitope. At the end of follow-up, 33.3% evolved to RA, 17.2% remained as palindromic rheumatism, 25% were diagnosed other chronic rheumatic diseases, 21.1% remitted spontaneously and 3.3% remained as UA. Of the 60 AR, 37 were diagnosed in the first year, 13 at second and 10 at 5 years of follow-up. During follow-up, 13 patients with RA started BT, and 12 patients presented CVD (7 of them died).

</table>

Table 1 identifies the factors associated with the development of RA. The MDR identified ACPA+ OR (95% CI) = 7.9 (6.09 - 10.69) (4.43 - 25.78), and the HLA-DRB1 shared epitope OR (95% CI) = 9.18 (2.96 - 28.48) p <0.001 as factors associated to the development of AR. We failed to identify factors associated with the use of BT, possibly due to the sample size. The factors associated with the development of CVD, where only the use of glucocorticoids as a factor associated with the presence of CVD shows statistical significance.

Conclusion: 1) Useful clinical and laboratory characteristics have been identified to predict which patients are at risk of developing persistent arthritis. 2) HLADR1 shared Epitope and ACPA are predictive factors of evolution to RA. 3) Possibly the continued use of glucocorticoids, even at low doses, may be related to the development of long-term CVD.

WHAT DO SPANISH RHEUMATOLOGISTS THINK ABOUT THE EFFICACY OF THE DRUGS USED IN THE MANAGEMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS AND POOR PROGNOSIS FACTORS? PROGRESAR-2 PROJECT

Loreto Carmona1, J. Narváez2, Jaime Calvo3, Alejandro Escudero Contreras4, Santiago Muñoz Fernandez5, José M. Rodríguez-Heredia6, Susana Román-Gómez7, Paloma Vela Casasempere8, Jose Luis Baquero9, Sara Lujan Valdés10, Juan J. Background: Currently, patients with rheumatoid arthritis (RA) have a wide range of treatments available to achieve a good control of the disease and avoid progression. However, some patients, especially those with poor prognostic factors, need to switch drugs to achieve remission or low disease activity. If we can predict the response to a drug, given specific prognostic profiles, we may be able to choose the best drug for individual patients.

Objectives: To assess the degree of confidence of rheumatologists regarding the efficacy of biologic therapies and specific targeted synthetic molecules in patients with RA harboring poor prognostic factors.

Methods: A Delphi survey was sent to a group of rheumatologists with the aim to capture the perceived efficacy of a group of drugs (antiTNF, T-cell co-stimulators, B-cells depletors, anti IL6, and JAK inhibitors) given different poor prognostic factors are present at the onset of the disease. These factors were: interstitial lung disease, elevated HAQ, positive rheumatoid factor (RF), presence of anti-citrullinated protein antibody (ACPA), elevated acute phase reagents (APR), and bone erosions observed by simple x-ray/ultrasound. The survey was circulated in two rounds, with agreement on scores were in one of the three levels (correspondingly it would be "neutrality", "agree", and "strongly agree").

Table 1 shows that there is agreement among rheumatologists regarding the efficacy of biologic therapies and specific targeted synthetic molecules in patients with RA with poor prognostic factors. There is agreement among rheumatologists regarding the efficacy of therapy m (SD).
AB0239 EFFECT OF SMOKING ON THE EFFICACY OF TNF INHIBITORS IN THE TREATMENT OF CHRONIC INFLAMMATORY IMMUNE-MEDIATED DISEASES: SYSTEMATIC REVIEW AND META-ANALYSIS

Raquel Dos Santos Sobrinho1, Alejandro Souto Vilas1, Jose Ramon Maneiro Fernandez2, Antonio Mera Varela3, Juan J. Gomez-Reino4. 1Clinical University Hospital of Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain; 2Hospital Complex of Pontevedra, Rheumatology Department, Pontevedra, Spain; 3Institute of Investigation Santiago – Hospital Clinico Universitario de Santiago (IDIS), Experimental and Observational Rheumatology Unit, Santiago de Compostela, Spain

Background: Chronic inflammatory immune-mediated diseases, as rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis (Ps), ankylosing spondylitis (AS), ulcerative colitis (UC) and Crohn’s disease (CD), have higher risks of morbidity and mortality and a great impact on quality of life of patients1. Drug inhibitors of tumor necrosis factor (TNF) inhibitors have demonstrated an adequate efficacy and safety profile in these patients when classical treatments (as disease-modifying antirheumatic drugs) have been failed or patients were intolerant. TNF inhibitors are used to control inflammatory response and to improve quality of life, pain, functional capacity and progression of the disease2. Studies in RA show that smoking habit is related to more articular and extra-articular damage, worse prognosis, higher basal activity and higher risk of seropositive RA. It has been related also to greater number of different treatments and higher doses needed for patients by pharmacokinetic and pharmacodynamic reasons. Data published until now suggest that smoking habit decreases efficacy of TNF inhibitors3.

Objectives: To analyze the smoking habit influence on the efficacy of TNF inhibitors in patients diagnosed of chronic inflammatory immune-mediated diseases (RA, PsA, Ps, AS, UC, CD).

Methods: It was made a systematic literature search using Cochrane Library, Medline, the Web of Science and Embase databases. Meta-analyses were performed using a random-effects model.

Results: 37 of 9877 identified articles met the inclusion criteria. No documents with GOL were found. The analysis of all the diseases together gives a significant decrease on the response to TNF inhibitors in smoking patients [OR 0.812 (0.662-0.996), p=0.046]. This response also has a significant decrease in IBD maintained response in smoking patients [OR 0.467 (0.257-0.848), p=0.012]. A non-significant decrease in the treatment response of smoking patients with IBD clinical remission was found, in smoking patients versus ex-smoking and never smoking patients with IBD remission, in ex-smoking patients versus never smoking patients with IBD partial response, in current and ex-smoking patients versus never smoking patients with IBD partial response, in current smoking patients versus ex-smoking patients with IBD partial response, in current smoking patients versus never and ex-smoking patients with IBD partial response, in current smoking patients versus never smoking patients with IBD partial response, in patients with AR EULAR and in patients with AR EULAR moderate response.

Conclusion: Smoking habit is a poor prognosis factor in RA, AS, PsA, UC and CD. Its leaving will decrease cardiovascular risk, joint and bowel damage, will increase the efficacy of TNF inhibitors and will benefit the health of patients, not only in their particular disease, and it can be the first step on their treatment.

ALCOHOL CONSUMPTION AND DEVELOPMENT OF ARTHRITIS AMONG PATIENTS WITH ANTI-CITRULLINATED PEPTIDE ANTIBODIES AND MUSCULOSKELETAL PAIN

Emma Eloff1, Michael Ziegelasch1, Klara Martinsson2, Jan Cedergren1, Åsa Reckner1, Thomas Skogh1, Louise卡尔1, Andreas Årlemalm2, Alf Kastbom1, 1Department of Rheumatology, Linköping, Sweden; 2Department of Clinical and Experimental Medicine, Linköping, Sweden; 3Department of Clinical Pharmacology, Linköping, Sweden

Background: Individuals with anti-citrullinated peptide antibodies (ACPA) and arthralgia are at increased risk of developing rheumatoid arthritis (RA). Predictors of disease development are important within this category of patients in order to improve treatment and follow-up decisions. Although excessive use of alcohol is well-known to cause harmful medical and social consequences, an inverse association between alcohol consumption and RA development has been proposed. Phosphatidylethanol (PEth) has shown to be a reliable biomarker to measure recent (up to four weeks) alcohol consumption with high specificity.

Objectives: The aim of this study was to, in relation to other possible clinical and laboratory predictors, pinpoint the association between biochemically determined alcohol consumption and development of arthritis in ACPA-positive individuals with musculoskeletal pain.

Methods: The study was performed as part of an observational prospective cohort (TIRx), including 104 ACPA-positive individuals with musculoskeletal pain and maximally one arthritis upon clinical examination. Exclusion criteria were >1 clinical arthritis, previous inflammatory rheumatic disease, and oral or intraarticular corticosteroid treatment within 6 weeks prior to screening. Participants were enrolled between 2010 and 2013 and were carefully followed during 72 months in median (range 23-91). The primary outcome measure was development of arthritis upon clinical examination. In baseline samples, we assessed ACPA levels in serum (2nd generation cyclic citrullinated peptides (CCP) as antigen), rheumatoid factor (RF), and the presence of shared epitope. PEth 16:0/18:1 was measured by liquid chromatography coupled with tandem mass spectrometry (LC/MS/MS) in whole blood from baseline, and the results were categorized into three groups: no/low, moderate, or high consumption. Cox regression analyses were performed adjusting for smoking, symptom duration, age, sex, shared epitope, RF, and treatment with disease-modifying antirheumatic drugs (DMARDs) and oral glucocorticoids.

Results: In TIRx, 82 patients had no swollen joints at inclusion, of whom 39 (48%) developed arthritis during follow-up after median 6 months (range 1-71). Of those, 48 (59%) patients were classified according to PEth values with no/low alcohol consumption, 28 (34%) with moderate consumption and 5 (6%) patients with high alcohol consumption. There was no significant difference in PEth values between patients with one baseline arthritis compared to those without (p=0.09). Neither were there any significant differences in arthritis-free survival across PEth categories versus arthritis development (p=0.64). Unadjusted hazard ratios (HRs) were numerically, but not significantly, increased among moderate (HR 1.001 95% CI 1.000-1.002, p=0.007) and higher ACPA levels (adjusted HR 1.001 95% CI 1.000-1.002, p=0.007), respectively. Disease activity remained stable and functional status and QoL had improved significantly over time (Table 1). The majority of the patients (89%) were in Steinerbrocker Class 1 or 2 with only 7 (11%) being in Steinerbrocker Class 3. Of the 7 deceased patients (4 women 3 men; median age: 68.21±12.5 SD years; mean disease duration: 127.61±73.8 SD months) 3 were on Rituximab, 2 were on synthetic DMARDS (one being biologic naive) and 2 were free of RA medications (one was biologic naive) at the time of death. Serious infections were the cause of death in 4 patients followed by hepatic failure due to hepatitis B, abdominal bleeding under anticoagulation and multi organ failure in 3 patients, respectively. Direct costs were higher than indirect costs and made up two thirds of RA related total costs (Table 1).

Conclusion: Disease activity remained stable and functional status and QoL improved among our patients over 6 years. Biologic usage was increased. Cardiovascular events and serious infections were major determinants of morbidity and mortality. Direct costs were the main determinants of RA related cost.

Results: The survey was replied by 41 rheumatologists, representing all regions in the country. Table 1 shows a summary of the results of the second round in terms of m and SD. To summarize, there was an agreement regarding the drugs that might be more adequate for patients with particular prognostic factors, except in the case of pulmonary involvement, in which agreement was only met for T-cell co-stimulation, and for elevated HAQ and acute phase reagents, where the use of B-cell depressant treatments did not reach an 80% of agreement. NA* = not available.

RADIOLOGICAL EVALUATION OF FOREFOOT INVOLVEMENT IN RHEUMATOID ARTHRITIS

Rym Fakhfakh, Saoussen Znour, Abir Oghais, Hibaltalah Mosbeh, Olfa Jmaa, Grassa Rini, Jijjin Mahboubas, Ismail Bejia, Mongi Touzi, Naceur Bergaoui. CHU Fattouma Bourguiba, Rheumatology, monastir, Tunisia

Background: Severe and often debilitating involvement of the forefoot is seen frequently in patients with rheumatoid arthritis (RA).

Methods: Monocentric retrospective study of 52 consecutive patients with RA, hospitalized in the Rheumatology Department between 2012 and 2018. Radiological measurements included the modified Sharp/van der Heijde method (SHS) for the forefoot.

Results: The average age was 53 ± 15 years and the sex-ratio was 0.21. The average disease duration was 8 ± 10 years and the average disease activity index DASH28 was 5.65±1.12. The prevalence of forefoot erosion and joint space narrowing were 35% and 58%, respectively. In 85% of patients, both >1 forefoot erosion score and >1 forefoot joint space narrowing score were present. Erosions were the most frequent in the 5th metatarsophalangeal joint (MTP) and 1st interphalangeal joint (50% and 47% of eroded joints, respectively) and the least frequent in 4th MTP (27%). The forefoot erosion score was significantly correlated with age, disease duration and hand erosion score and weakly but statistically significantly with titer of ACPA (p<0.05). Obesity was an independent protective factor (OR = 0.25, p < 0.05) of forefoot erosions. Foot deformities were observed in 71% of the patients: Metatarsus primus varus(MV) (56%), hallux valgus(HV) (38.5%) and spaying foot(SF) (13.5%). The HV was significantly correlated with forefoot damage (erosion score r=0.67, joint space narrowing r=0.7, p<0.01), extra-articular manifestations of RA, disease duration and rheumatoid factor titer. Multivariate analysis showed that the extra-articular manifestations was an independent risk factor for HV (OR = 9.39, p <0.05). There was significant correlation between the MV and forefoot damage (erosion score: r=0.4, joint space narrowing: r=0.5, p<0.05). There was no correlation between the spaying foot and the forefoot damage. The spaying foot was associated with the hallux valgus (OR = 5.7, p = 0.05).

Conclusion: In our study, forefoot involvement is common in patients with RA and it isn’t associated with disease severity. Deformities (HV, MV) are associated with forefoot joint damage and spaying foot is associated with hallux valgus.

CYSTEINE RICH 61 (CYR61): A POTENTIAL BIOMARKER ASSOCIATED WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

Yong Qai, Xinlei Yang, Yuan Zhao, Xiaoying Sun, Wenxi Xie, Yannong Huang, Li Guanqiao, Yanjie Hao, Zhoului Zhang. Peking University Pirst Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Numerous preclinical studies have revealed a critical role of Cysteine rich 61 (Cyr61) in the pathogenesis of rheumatoid arthritis (RA). However, little is known about the potential value of circulation Cyr61 in clinical RA patients.

Objectives: To compare serum Cyr61 level in patients with RA and healthy controls, and to characterize the potential association between Cyr61 and RA disease activity.

Methods: In training cohort, serum samples were obtained from 177 patients with definite RA and 50 age- and gender- matched healthy controls. Medical records were collected and serum Cyr61 concentration was detected by enzyme-linked immunosorbent assay. Correlations between Cyr61 levels with clinical disease activity were analyzed. Furthermore, a validation cohort consisting of 77 active RA patients who received uniform biologic therapy for 12 weeks was set up (ClinicalTrials.gov identifier: NCT02320630). Paired serum samples were collected at baseline and after 12-week treatment for each individual and prepared for detection of Cyr61. Comparisons between groups were made using Mann-Whitney U test or Wilcoxon matched-pairs signed rank test, as appropriate.

Results: Significant elevation of serum Cyr61 concentration was found in RA patients, demonstrating excellent diagnostic ability to discriminate RA with healthy controls (area under the curve (AUC) = 0.98, P < 0.001). In training cohort, Cyr61 level in active RA patients was significantly lower than that in inactive RA, and it was inversely with measures of clinical disease activity in statistic. Findings were further confirmed in our validation cohort. Active RA patients who had a reduction in disease activity showed a significantly increase of Cyr61 level after effective treatment (in terms of achieving ACR20/50/70 improvement criteria); RA patients who did not achieve ACR response showed no significant difference of Cyr61 level before and after treatment. Multivariate logistic regression analysis revealed that increase of Cyr61 level as well as younger age were independent indicators for achieving ACR20 response.

Conclusion: Serum Cyr61 levels were remarkably increased in RA patients compared with healthy control. More intriguingly, the level of Cyr61 was inversely associated with RA disease activity and increased after effective treatment.

THE IMPORTANCE OF TREATMENT STRATEGY FOR THE OUTCOME OF EARLY RHEUMATOID ARTHRITIS PATIENTS NOT RESPONDERS TO THE FIRST LINE THERAPY WITH METHOTREXATE

Anna Laura Fedele, Dario Bruno, Barbara Tolusso, Luca Petricca, Gianfranco Ferraccioli, Elisa Gremese. Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Rheumatology, Rome, Italy

Background: According to EULAR recommendations for the management of Rheumatoid Arthritis (RA), if the treatment target is not reached with the first conventional synthetic (cs)-disease modifying antirheumatic drugs (DMARDs), addition of another csDMARD or of a biological (b)-DMARD should be considered [1].

Objectives: To evaluate the clinical and radiological outcome under combination therapy of cs-DMARDs or b-DMARDs in our cohort of early rheumatoid arthritis (ERA) patients treated according to the treat-to-target (T2T) strategy.

</tbody>
</table>
Methods: A total of 384 ERA patients with less than 12 months of disease duration (mean age 54.6±14.6 years, 75% female, 73.3% seropositive) were enrolled in the study. ERA patients fulfilled the 2010 ACR criteria for RA and were followed according to the T2T strategy. At baseline and every three months, the ACERAFLAR core data set variables were recorded. At baseline and every year, hand and foot radiographs were examined according to modified Total Sharp score (mTSS). At each visit, clinical improvement and remission were evaluated according to EULAR criteria. The achievement of Comprehensive Disease Control (CDC) (28-joint Disease Activity Score using C reactive protein <2.6, Health Assessment Questionnaire <0.5 and change from baseline in mTSS ≤0.5) was assessed every year of follow-up (FU). The mean FU duration was 45.5±40.6 months. In patients not reaching the target with methotrexate (MTX) after the 3rd-6th month of FU, the addition of another csDMARD (chloroquine, leflunomide or sulfasalazine) or a bDMARD was considered in order to attain at least a good EULAR response. Results: At the twelfth month of FU, out of the 174 ERA patients (45.3%), not reaching the target with MTX, 97 (23.3%) were in combination therapy with csDMARDs and 77 (20.1%) were treated with csDMARDs in association with bDMARDs. Similar percentages of good EULAR response, DAS remission and CDC were registered in the two groups of patients, both at 12th month of FU and at the last FU. Although not statistically significant, fewer bDMARD treated patients showed 5-year radiographic progression (RP) (21.7%) compared to subjects in combination therapy (36.8%, p=0.13). A higher BMI was observed in ERA patients who started bDMARDs (26.0±4.1) compared to subjects in combination therapy with csDMARDs (24.8±4.2, p=0.02). No differences were found regarding age and disease duration. Autoantibody positivity was comparable between the two groups. Conclusion: Our results support data suggesting that the treatment strategy is more important than the therapy used to achieve remission. In fact, when a strict protocol of tight control is applied, similar clinical and radiological outcome is achieved both in patients treated with csDMARD combination, and in subjects in bDMARD association, regardless of RA prognostic factors. A higher BMI is associated with a major frequency of bDMARD therapy, underlying a possible more csDMARD refractory disease.

Background: Thanks to biologic therapies, disease remission in Rheumatoid Arthritis (RA) patients is not a wishful thinking but an achievable goal. Nevertheless, some patients experienced treatment discontinuation after disease remission. EULAR recommendations suggest to suspend steroids as soon as possible[1], but in real life-setting this point is not always hold in esteem. Objectives: The objective of our study was to assess the impact of steroid withdrawal on long-term drug survival and the possible predictors of drug discontinuation in RA patients who achieved Simplified Disease Activity Index (SDAI) remission at 1-year upon treatment with a first biologic disease-modified anti-rheumatic drug (bDMARD).

Methods: Data of RA patients naïve to bDMARDs, registered in Biologic Apulian Registry (BIOPURE) between 1st January 2008 to 31st December 2017, were retrospectively analysed. Demographic and clinical data of all RA patients were acquired at the initiation of first bDMARDs (“screening-time”) and after 1-year follow-up (“baseline-time”). The inclusion criterion in this study was the achievement of SDAI remission (SDAI ≤ 3.3) at 1-year of treatment with the first bDMARD. At “baseline-time”, RA patients on SDAI remission were divided, according to steroid administration, into concomitant “steroid-no” and “steroid-yes” groups. Drug discontinuation rate and mean survival time (MST) were estimated using Kaplan-Meier (K-M) life-table analysis. Estimated hazard ratios (HRks) of discontinuing bDMARD were assessed by performing a multivariate Cox-regression analysis with stepwise backward methods.

Results: 216 RA patients started their first bDMARDs between 1st January 2008 to 31st December 2017. Among these, 86 (39.8%) patients achieved SDAI remission at 1-year of whom 54 (62.8%) were steroid free while 32 (37.2%) were still taking low-dose steroids (mean 3.8 mg/die; SD ±1.4). Considering patients who achieved SDAI remission at “baseline-time”, global drug discontinuation was 81.4% [MST=88.5 (95% CI: 80-97) months], higher for “steroid-no” patients [90.7%, MST=98.2 (95% CI: 89-107) months] than “steroid-yes” ones [68.8%, MST=68.9 (95% CI: 57-81) months] (log rank 7.086, p=0.008) (Figure 1). This difference was also seen when drug discontinuation by inefficacness was calculated [96.1%, MST=103 (95%CI: 96-110) months vs 72.4%, MST= 70.6 (95%CI 57-84) months, long rank 10.101, p=0.001], but not by adverse events. Moreover, no steroid administration (HR = 0.31, 95% CI:0.10-0.93) and concomitant Methotrexate therapy (HR = 0.34, 95% CI:0.12-0.98) were independently associated with low risk of bDMARDs interruption after the achievement of SDAI remission.

Conclusion: This study provided evidence that, among RA patients who achieved SDAI remission, those who stopped steroids and continued combination therapy with MTX had a very long drug survival with just the first bDMARD in a real-life setting. These results can help rheumatologists to precociously select RA patients who might start a tapering or spacing strategy of biologic drug.

REFERENCE:
being a very disabling symptom, the variables that predict it are still unknown.

**Objectives:** To identify potential factors associated with fatigue.

**Methods:** Cross-sectional study. 60 patients were included, patients were being followed up in the rheumatology outpatient clinic of Hospital Clinico San Carlos, Madrid, Spain. Data were collected between July 2018 and January 2019. All patients met the ACR/EULAR 2010 criteria and they were in treatment with Biological agents or Targeted Synthetic DMARDs.

**Main variable:** Fatigue was assessed by the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ) and the Bristol Rheumatoid Arthritis Fatigue Numerical Rating Scale (BRAF-NRS).

**Variables:** Sociodemographic, clinical, Disease-related variables and treatment.

**Statistical analysis.** A descriptive analysis was carried out for the different variables. To identify factors independently associated to BRAF-MDQ a multivariable linear regression was applied. Results were expressed as $\beta$ with their corresponding 95% CI. A value of $p < 0.05$ was accepted as statistically significant.

**Results:** A total of 60 patients, comprising of 53 females (88%) and 7 males (12%) with a mean age of 56.45±11.89 years and mean disease duration of 14.11±7.79 years were evaluated. RF was positive in 60% of patients. 65% of the patients were in active on work and 23% were retired. Regarding comorbidities, 43% had dyslipidemia, 42% hypertension, 17% hypothyroidism and 15% depression. The DAS28-ESR and SDAI scores of the patients were 2.68 ± 0.86, 8.56 ± 5.96 respectively. The rest of the clinical, treatment characteristics, and the scores of the fatigue instruments used in the study are shown in Table 1. Physical dimension was the most affected according to patients, who perceive an average severity and affectionation, and insufficient coping. The factors affecting the total BRAF-MDQ was evaluated in multivariate analyze Table 2. We found that patients with Disability (p <0.0001) and those in treatment with Non anti-TNF (p 0.048), experienced more fatigue while a positive RF (p 0.022) decreases overall fatigue.

**Conclusion:** Fatigue is a substantial symptom in RA patients and should be evaluated on the daily clinical practice. The results of our study indicated that disability and type of treatment were the dominant factors in the experience and degree of fatigue. Disease activity (DAS28 and SDAI) was not associated to fatigue. The evaluation and management of fatigue should be one of the objectives in the treatment of patients with RA.

**Disclosure of Interests:** None declared

respondents, 98% reported asking pts about adherence to RA medication, even though 61% felt there was no way of knowing if pts were taking medications as prescribed and, overall, HCPs responded that 64% of pts did not always take RA medication as prescribed. While 87% of HCPs agreed, 32% of bDMARDs were most effective when taken in combination with csDMARDs and 92% reiterated this to pts, 62% were concerned that pts take bDMARDs without csDMARDs. Pts and caregivers reported that pts often stopped taking csDMARDs; however, HCPs underestimated the number of non-adherent pts (Figure A). The most common reason given by pts and caregivers for non-adherence to RA medication was difficulty in remembering to take medication; however, concerns about feeling ill and potential side effects were also common (Figure B). Despite this, 47% of pts and 51% of caregivers responded that pts often don’t share all side effects caused by their RA medication with HCPs, while 38% of HCPs believed that pts did not inform them of all side effects.

Conclusion: This study from a large, multinational cohort of pts with RA, care providers and caregivers is the first to look at this relationship. This study from a large, multinational cohort of pts with RA, care providers and caregivers is the first to look at this relationship. While 38% of HCPs believed that pts did not inform them of all side effects, extent of pt non-adherence was underestimated by HCPs. These results highlight gaps in communication and understanding of non-adherence between pts, caregivers and HCPs.

AB0248 DISEASE ACTIVITY IS ASSOCIATED WITH FATIGUE IN THE FOLLOW-UP OF PATIENTS WITH RHEUMATOID ARTHRITIS

Rocio Violeta Gamboa Cárdenas1, Manuel F. Ugarte-Gil2, Cristina Reategui Sokolova1, Luz Hipólito1, Claudia Elera-Fitzcarrald5, Eva María1, Miguel Bernardez1,ª, Lucia Costa1, Centro Hospitalar e Universitário de Évora, Rheumatology, Portugal, 1Faculty of Medicine of the University of Évora, Rheumatology, Portugal.

Background: Chronic fatigue negatively impacts on quality of life in Rheumatoid Arthritis (RA) patients. However, the influence of disease activity on fatigue is still under debate. The objective was to determine whether disease activity correlates with fatigue in the following 24 months following bDMARD initiation.

Methods: Prospective study of the RA-Almenara cohort (criteria ACR87/91, EULAR). Patients were included with at least two evaluations (half-yearly). Patients with fibromyalgia, major depression and/or anxious personality were excluded. Disease activity was evaluated with SDAI (Simple Disease Activity Index) and fatigue with FACIT questionnaire (Functional Assessment of Chronic Illness Therapy-fatigue). A generalised estimation equation model was used to determine the association between SDAI and FACIT, at each visit according with two models of analyses. Model 1 considered SDAI value as a linear variable; Model 2 considered each category of SDAI (high, moderate and low) activity, using remission as reference. Multivariable analyses were adjusted by possible confounders: gender, age at diagnosis, instruction, socio-economic level (Graffar), disease duration, tobacco, ACR-EULAR or baseline CDAI, CDAI, SDAI, HAQ, EULAR and ACR response. RF was considered positive if ≥ 30 U/ml and ACPR if CDAI ≥ 7 U/ml. SPSS statistics 22.0 was used for statistical analysis.

Results: 169 patients were included with mean (±SD) age of 50.7 ± 10.6 years and median disease duration (min-max) of 10.2 (0.69-39.4) years. The majority were female (84%). At baseline 160 (94.7%) were positive for RF and 166 (98.2%) were positive for ACPR. 77 (45.6%) turned negative for RF and/or ACPR at a median time of 20.3 months after biologic therapy beginning. 63 out of 169 patients become negative for RF (37.3%) and 17 patients for ACPR (10.1%). 52 (30.6%) patients were treated with etanercept, 39 (22.9%) adalimumab, 27 (15.9%) rituximab, 19 (11.2%) tocilizumab, 16 infliximab (9.4%), 14 (8.2%) golimumab. 1 (0.6%) certolizumab and 1 (0.6%) anakinra. The mechanism of action of the drug didn’t differ between patients who became seronegative for RA and/or ACPR and those who remained seronegative (70.2% under anti-TNF agents vs 79.9% for the other biologic). Most of the patients in the first group began adalimumab (32.5%) and most of the patients in the latter began etanercept (34.8%). Demographic characteristics like age, sex, disease duration, and extraarticular manifestations were comparable in both groups. They weren’t comparable in terms of smoking habits (p=0.014): just 3 (3.9%) current smokers in those who became negative for RF and/or ACPR vs 17 (18.5%) among those who remained seropositive.

Conclusion: In our sample, change of antibody status wasn’t predictor of better response to biologic therapy. Therefore the results did not support the association between the persistence of RF or ACPR and the lack of effectiveness of biologic therapy at 2 years of treatment, but further studies are needed.

REAL-WORLD OUTCOMES IN STABLE ORIGINATOR BIOLOGIC-TREATED ADULT PATIENTS WHO STAYED ON THE THERAPY VersUS THOSE WHO SWITCHED TO A BIOSIMILAR: A RETROSPECTIVE CHART REVIEW STUDY IN EUROPE

Alien Gibotsky,1 Martha Skup,2 Min Yang2, Wei Guo3, Tahera Doctor3,1 Hospital for Special Surgery-Weill Cornell Medicine, New York, United States of America. 2AbbVie, Chicago, United States of America; 3Analysis Group, Inc., Boston, United States of America

Background: Biologic therapies have considerably improved clinical management of autoimmune diseases. Over the past few years, several biosimilars have been introduced in Europe for these conditions. Limited information is available evaluating the impact of switching stable patients from originators to their respective biosimilars in clinical practice for non-medical reasons.

Objectives: This real-world study reported and compared patient characteristics, clinical outcomes, and healthcare resource utilization (HRU) associated with stable patients who switched from the originator biologic etanercept to its biosimilar (switchers) vs. those who stayed on the originator (non-switchers) in adults with a rheumatic condition such as ankylosing spondylitis (AS), psoriatic arthritis (PsA), or rheumatoid arthritis (RA).

Methods: Medical record data were retrospectively collected anonymously from rheumatologists in the UK and Germany. Adult patients who were diagnosed with RA, AS, or PsA, treated with originator etanercept for at least 6 months with a stable dosing schedule, and had no emergency department visit or hospitalization for the disease of interest over the 6-month period were eligible for the study. The index date for a non-switcher was the prescription date closest to one year after the initiation of therapy with the originator etanercept and with a stable dosing for at least 6 months. The index date for a switcher was the biosimilar initiation date. Chart data available for at least 12 months prior to and post the index date were required. Patient characteristics, disease severity, symptoms and signs, and HRU were extracted anonymously. Unadjusted and adjusted comparisons of the outcomes between non-switchers and switchers were conducted among all patients and for each individual disease.

Results: Data were extracted from 242 patient records (non-switchers = 123, 50.8%; switchers = 119, 49.2%; AS=26.4%; PsA=26.0%; RA=47.5%) from 162 rheumatologists. At baseline, non-switchers were significantly younger than switchers (44.5 vs. 48.4 years, p≤0.05), had a significantly shorter time on the originator etanercept (11.7 vs. 23.8 months), and more patients had been treated with NSAIDS (55.3% vs. 37.8%). Significantly more non-switchers had moderate, or severe disease (27.6% vs. 16.0%, p<0.05; 26.8% vs. 5.9%, p<0.01) and non-switchers on average had worse joint or spine pain (4.4 vs 2.4, p < 0.01) than switchers. During the follow-up period, significantly more non-switchers’ disease status improved (58.5% vs. 25.2%, p<0.01), resulting comparable disease severity (moderate: 10.6% vs 10.9%; severe: 0% vs 0%) and joint or spine pain scale (2.0 vs 1.0) between the two cohorts. After adjusting for potential confounding factors, compared to switchers, more AS and PsA non-switchers improved in disease severity (AS: p<0.05; PsA: p<0.01), and RA non-switchers had a fewer number of swollen joints (0.5 vs 1.5, p<0.01). Non-switchers generally had numerically lower HRU than switchers during the one-year follow-up period (patients with outpatient visits: 76.4% vs 89.1%; average number of outpatient visits: 1.8 vs 2.0).

Conclusion: When compared with stable patients who underwent non-medical switching, stable patients who continued therapy with the originator biologic demonstrated significantly more improvement in disease severity. Other outcomes such as HRU appeared more similar between switchers and non-switchers. After adjusting for potential confounding factors, compared to switchers, more AS and PsA non-switchers improved in disease severity (AS: p<0.05; PsA: p<0.01), and RA non-switchers had a fewer number of swollen joints (0.5 vs 1.5, p<0.01). Non-switchers generally had numerically lower HRU than switchers during the one-year follow-up period (patients with outpatient visits: 76.4% vs 89.1%; average number of outpatient visits: 1.8 vs 2.0).

RACIAL DISPARITIES IN OUTCOMES FOR PATIENTS WITH RHEUMATOID ARTHRITIS UNDERGOING TOTAL KNEE OR TOTAL HIP ARTHROPLASTY

Juliana Hirsch1, Bella Mehta2, Jackie Fink3, Serene Mirza4, Collin Brantner5, Iris Navarro-Millan2, Susan Goodman2. 1Mount Sinai St. Luke’s West, New York, United States of America; 2Hospital for Special Surgery, Weill Cornell Medicine, Rheumatology, New York, United States of America; 3Hospital for Special Surgery, Main Campus, Biostatistics, New York, United States of America; 4Hospital for Special Surgery, Main Campus, Orthopedics, New York, United States of America

Background: Race is linked to delays in healthcare. Black and Hispanic patients with osteoarthritis have worse pain and function than Whites before arthroplasty. Whether Black and Hispanic patients with RA similarly delay care is unknown.

Objectives: To assess whether Black and/or Hispanic (minority) RA patients have worse pain, function and disease activity at the time of arthroplasty.

Methods: We used prospectively acquired data on RA patients between 10/2013 and 11/2018 prior to total knee arthroplasty (TKA) or total hip arthroplasty (THA).

Pain, function, and disease activity were assessed using the visual analogue scale (VAS), the Multidimensional Health Assessment Questionnaire (MD HAQ), and the Disease Activity Score (DAS28). Race, ethnicity, education, income, insurance and medications were collected via self-report questionnaire. Multivariable linear and logistic models examined whether minority status predicted pain, function and disease activity.

Results: 37 (23%) of the 164 patients were minorities (Table 1): MD HAQ and DAS28 were worse in minorities, only VAS was significant (p-value= 0.029). There was no significant difference in education. Unadjusted comparisons indicated no difference in pain, function, disease activity or medication use between groups. Insurance varied significantly (p=0.004). There was no significant difference in education. Unadjusted comparisons indicated no difference in pain, function, disease activity or medication use between groups. Insurance varied significantly (p=0.004).

Conclusion: For Black and/or Hispanics with RA undergoing THA or TKA at a high-volume specialty hospital, minority status was not significantly associated with pain, disability or RA disease activity at the time of elective arthroplasty.

AB0252 RACIAL DISPARITIES IN OUTCOMES FOR PATIENTS WITH RHEUMATOID ARTHRITIS UNDERGOING TOTAL KNEE OR TOTAL HIP ARTHROPLASTY

AB0253 BIOMARKERS OF CLINICAL RESPONSE TO IL6-R BLOCKADE IN DMARDS INCOMPLETE RESPONDERS (AR-BIOM TRIAL): IL23 AND BAFF AS BIOLOGICAL TARGETS, AND ALBUMIN AS BIOLOGICAL PREDICTOR

Gianfranco Ferraccioli1, Barbara Tolasso2, Florenzo Iannone3, Maurizio Rossini3, Piercarlo Sarzi-Putti4, Marcelo Govoni4, Rosario Falà4, Andrea Donà5, Francesco Paolo Cantatore5, Giovanni Francesco Micel1,2, Oscar Massimilliano Epis1,2, Anna Laura Fedele1, Antonio Caceto1, Nicola Marouti1, Elena De Stefani8, Giorgio Amato7, Elisa Girometti2, Giovanni Lapadula6, GISEA (Gruppo Italiano Studio Early Arthritis). Università Cattolica del Sacro Cuore. Division of Rheumatology, Rome, Italy; 2Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Rheumatology, Rome, Italy; 3University of Verona, Verona, Italy; 4Sacco University Hospital, Milan, Italy; 5University of Ferrara, Ferrara, Italy; 6Policlinico di Catania, Catania, Italy; 7University of Padova, Padua, Italy; University of Foggia, Foggia, Italy; 8Policlinico G. Marino, Messina, Italy; 9Grande Ospedale Metropolitano Niguarda, Milan, Italy; 10Fondazione Policlinico Universitario A. Gemelli IRCCS – Università Cattolica del Sacro Cuore, Division of Rheumatology, Rome, Italy

Background: The therapeutic algorithm in persistently active Rheumatoid Arthritis, despite conventional synthetic DMARDs (csDMARDs), identifies TNFα blockers and other biologics as first line treatment, without clear indications of which biologic should be adopted first in persistently active patients.

Objectives: In the AR-BIOM trial we analyzed several biomarkers to define which one could help to identify the best responder to IL-6R blockade.

Methods: Sixty-nine RA persistently active despite csDMARDs treatment, were enrolled in this Interventional Phase IV, prospective, multicenter, non-randomized, no-profit study (Clinical Trial: n.2012-001760-30) and followed for 18 months after Tocilizumab (TCZ) treatment monotherapy or in combination with csDMARDs. The study was conducted in 10 outpatient clinics of “Gruppo Italiano di Studio sulle Early Arthritis” network (GISEA Study Group) in Italy. The primary end point was the clinical response to TCZ, as LDA (DAS2<4.2) at 12 months follow-up (FU), correlated with Matrix 1 (pathway of innate inflammation IL-8, MCP1, Chemerin) vs Matrix 2 (pathway of IL1/IL6/TH17, IL12, IL17, IL23) along with the Pathway of regulatory T cells activity (IL10, BAFF) and acute phase reactants (Albumin, Fibrinogen, CRP, ESR) as biomarkers of interest. DAS and SDAI remission were secondary end-points at 12 and 18 months FU. A ROC analysis of soluble biomarkers was performed to obtain thresholds allowing the prediction of DAS-remission or LDA at 12 months FU. A multivariate logistic analysis, in which “LDA or DAS/SDAI remission at 12 months FU” were the dependent variables, was performed.

Results: During the 18 months of the study, 9/69 patients (13.0%) discontinued the study because of treatment failure, 2(2.9%) for an AE, 2 for a SAE, and 5(7.2%) for other reasons. At 12 months FU, LDA was achieved in 75.0% and DAS-R and SDAI-R in 63.3% and 41.7%
respectively, of RA patients, without significant differences between mono and combination therapy. Considering baseline biomarkers predictive of LDA at 12 months FU, IL23 plasma levels ≥43.64 pg/ml arse as potent predictor [OR(95%CIs):20.0(1.9-211.2)], whereas the best predictors of DAS-R were baseline BAFF plasma levels ≥56.3 pg/ml [OR(95%CIs):3.9 (1.1-14.3)] and IL23 plasma levels ≥43.64 pg/ml [OR(95%CIs):4.1(1.1-15.2)]. In addition, Albumin levels ≥2.5g/dl at 3 months FU, arse as a biochemical parameter predicting DAS-R [OR(95%CIs):21.6(9.3-50]).

Conclusion: IL23 and BAFF related inflammation are targets of IL6 blockade that significantly increases Albumin levels. High plasma levels of IL23 and BAFF at baseline represent biomarkers for LDA and DAS-R achievement in RA inflammation driven by IL6. Albumin after three months of therapy represents the strongest predictor of remission at 12 months.

AB0254  NEUTROPHIL-LYMPHOCYTE RATIO AND PLATELET-LYMPHOCYTE RATIO IN PATIENTS RECEIVING ANTIRHEUMATIC THERAPY: RELATIONSHIP TO CLINICAL AND LABORATORY MARKERS OF DISEASE ACTIVITY

Iris Paola Guzmán-Guzmán1, Oscar Zaragoza-García1, José Eduardo Navarro-Zarza2, Isabel Parra-Rojas1. 1Universidad Autónoma de Guerrero, Facultad de Ciencias Químico Biológicas, Chilpancingo, Guerrero, Mexico; 2Hospital General de Chilpancingo, Departamento de Reumatología y Medicina Interna, Chilpancingo, Guerrero, Mexico

Background: The use of antirheumatic drugs is key to limit or prevent inflammation and joint damage in rheumatoid arthritis (RA). Recently, neutrophil-lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) has been considered markers of clinical activity in RA, however its relationship with serological and clinical parameters in patients receiving disease modifying drugs (DMARDs) therapy has been poorly evaluated.

Objectives: To analyze the association of NLR and PLR with serological and clinical parameters related to the clinical prognosis in RA patients with antirheumatic treatment.

Methods: A cross-sectional study was carried out in 150 women with RA (mean age of 45.5 years, and mean duration of disease of 8 years) all diagnosed according to ACR/EULAR 2010 criteria and receiving DMARDs and corticosteroids (Cs) therapy. The clinical features and DAS-28 score were analyzed by a rheumatologist professional. The NLR and PLR, as well as the erythrocyte sedimentation rate (ESR), high sensitivity C reactive protein (hsCRP) levels, rheumatoid factor (RF) and anti-cyclic citrullinated peptides (anti-CCPs) antibodies, were determined in the laboratory.

Results: The means DAS28 of patient with and without P.gingivalis is respectively 43% of patients have presented a PD. The P.gingivalis has been detected in 59% of patients and the mean titre was 255.57±409.78. The mean age of our patients was 40.75 ± 12.04, the mean duration of the illness was 14.30±6.76 months (extremes: 1-24 months). ACPA was detected in 88% of patients and the mean titre was 255.57±409.78. 43% of patients have presented a PD. The P.gingivalis has been detected in 59% of PD. The means DAS28 of patient with and without P.gingivalis is respectively 4.40±1.52 and 4.15±1.45, and there was no significant difference (p=0.05). There was also no association observed between anti CCP and the presence of P.gingivalis.(the mean titre of anti CCP was 249.47±294.58 with P.gingivalis and 258.67±93.48 without P.gingivalis, p=0.74).

Conclusion: This study showed that periodontitis is frequent in rheumatoid arthritis. More than half of our patients suffering of periodontitis were infected by P.gingivalis. Rheumatoid disease activity does not seem to be related to periodontitis in general. In addition therewas no association between anti-CCP antibody and the presence of pophyromonas gingivalis.

PREDICTION OF DISEASE RELAPSES BY FATIGUE LEVELS PREDICT OTHER PATIENTS TAPERING DMARD TREATMENT – AN UPDATE OF THE RETRO STUDY

Melanie Hagen1, Koray Tasci lar1, Michaela Reiser1, Larissa Valor1, Judith Haschka2, Arnd Kleyer1, Axel Hueber1, Bernhard Manger1, Georg Schett1, Jürgen Rech1, RETRO study group, 1Friedrich-Alexander-University Erlangen- Nuremberg (FAU), Department of Internal Medicine 3 - Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany; 2St. Vincent Hospital, Medical University of Vienna, Vinforsch study group, Vienna, Austria

Background: Achieving remission is the ultimate treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach the disease remission state (1), raising the question about tapering or stopping anti-rheumatic treatment and appropriate predictors (2).

Objectives: The purpose was to analyze the effect of multi-biomarker disease activity (MBDA) score and anti-citrullinated protein (ACP A) on relapse rates in RA patients in sustained remission enrolled in the prospective randomized controlled RETRO study (3,4,5).

Methods: MBDA scores and ACPA status were determined in the baseline samples of patients in sustained DAS28-ESR remission fulfilling RETRO inclusion criteria. Patients were unblended and either continued DMARDs (Control), tapered dose by 50% (Taper) or stopped DMARDs after tapering (Taper/Stop) for one year according to the RETRO study protocol. MBDA and ACPA status were used as relapse predictors. Relapse was defined as the loss of a DAS28-ESR remission. We calculated incidence of flares and 95% Poisson confidence intervals by baseline MBDA and ACPA status in each study group (double negative, single positive, double positive). We compared the risk of flare in the treatment arms with a Cox regression model and calculated hazard ratios (HR) and 95% confidence interval (CI) for relapses.

Results: Serum samples and follow-up data of 203 patients included in the RETRO trial were analyzed. A flare was observed in 8/59 patients (13.6%) in the Control group, 24/60 (40.0%) patients in the Taper group and 37/68 (54.4%) patients in the Taper/Stop group among the 187 patients that completed their 1-year follow-up. HR (95%CI) for a relapse was 3.43 (1.54-7.66) in the taper group and 5.32 (2.47-11.46) for the control group. HR of flare of a positive MBDA and ACPA was 4.00 (1.72-9.31) compared to a negative MBDA and ACPA. Flare incidence did not differ with baseline MBDA/ACP A status in the control group, whereas in the taper/stop group, number of positive biomarkers could identify three distinct subgroups with a graded incidence of flare (Figure).

Conclusion: Tapering or stopping DMARDs after stable remission was associated with an increased risk of RA flares. Incidence of flares in ACPA/MBDA double-negative patients after tapering and stopping RA treatment was comparable to those that continued treatment within the precision limits of our subgroups. Lack of blinding is a shortcoming of our study.

AB0257

FATIGUE LEVELS PREDICT OTHER PATIENT REPORTED OUTCOMES AND DISEASE ACTIVITY SCORES: RESULTS FROM A LONGITUDINAL STUDY OF RA PATIENTS INITIATING BDMARD THERAPY

Hilde-Bernt Hammer1, Brigitte Michelsen, Silla Aasestad Provan, T. Uhlig, Tore K. Kven1, 1Dakskommunhjemt Hospital, Dept. of Rheumatology, Oslo, Norway.

Background: Fatigue is a sensation of weakness and lack of energy which is common in patients with rheumatoid arthritis (RA), contributing to reduced quality of life. However, there are few studies on the longitudinal influence of fatigue on patient reported outcome measures (PROMs).

Objectives: The present study explores the impact of fatigue on PROMs, clinical, laboratory and ultrasound (US) assessments.

Methods: A total of 208 patients with established RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were examined when initiating bDMARDs and assessed at baseline and after 1, 2, 3, 6 and 12 months, including fatigue (0-10, as part of the RAID score), PROMs (joint pain VAS, patient’s global disease activity VAS (P GA), HAQ, pain catastrophizing (PC), SF-36 Mental Health scale score (SF36MH)), clinical examinations (performed by a study nurse including examiner’s global disease activity VAS (EGA), 28 tender and swollen joint counts (TJC, SJC)) and laboratory variables (ESR and CRP). US examinations (semi-quantitative scoring (0-3)) of grey scale (GS) and power Doppler (PD) were performed of 36 joints and 4 tendons by one rheumatologist (HBB; Siemens Acuson Antares, excellence version, 5-13 MHz probe). The clinical disease activity scores (CDAS) DAS28, CDAI and SDAI were calculated for all visits. Correlations were assessed by Spearman’s rho. The predictive value of baseline fatigue on several dependent variables (PROMs, CDAS, clinical assessments) at all visits after baseline was explored by use of multiple linear regression analysis with adjustment for demographic values (age, sex and disease duration) and baseline inflammatory activity (CRP and sum score GS).

Results: Fatigue levels diminished during follow-up (baseline median (IQR) 5 (3-7), 12 months 2 (1-5)). Table 1 shows the high cross-sectional correlations between fatigue and PROMs/CDAS scores, low correlations with EGA/SJJC/CRP and lack of correlations with US assessments. Baseline fatigue predicted PROMs and CDAS scores at all examinations (table 2).

No/low associations were found between baseline fatigue and SJJC/EGA/sum score PD at follow-up.

Conclusion: Fatigue was highly correlated with PROMs and composite scores at all timepoints. The level of baseline fatigue predicted PROMs and composite scores at follow-up, but not objective inflammatory measures. Thus, the degree of fatigue should be taken into account when composite scores are used for evaluation of inflammatory activity in established RA patients.

POTENTIAL ROLE OF MEAN PLATELET VOLUME AND RED BLOOD CELL DISTRIBUTION WIDTH AS A BIOMARKER FOR CLINICAL AND SONOGRAPHIC ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

Waleed Hassan1, Mourin Elnathan1, Refaat Eltanmayy1, Rehab Shhehbi El-Dinn1, 1Benha University, Rheumatology and Rehabilitation, Benha, Egypt. 2Kafreh elshikh general hospital, Rheumatology and Rehabilitation, Kafreh elshikh, Egypt

Background: Red cell distribution width (RDW) reflects the variation in the circulating erythrocytes size (anisocytosis) that can increase in chronic inflammation due to ineffective erythropoiesis [1], while mean platelet volume (MPV) reveals the average size of platelets and may disclose its activation. Both are typically included in the complete blood count (CBC) and have been studied as a possible indicator of disease activity in many inflammatory conditions [2].

Objective: This study aimed to assess the relationship between MPV and RDW levels and various rheumatoid arthritis (RA) clinical, laboratory and ultrasonographic disease activity parameters in patients with recent onset RA before and after initiation of therapy.

Methods: We assessed MPV and RDW in blood samples obtained from 80 recent onset RA patients and 30 healthy controls at baseline and 4 months after initiation therapy with non-biological disease modifying anti-rheumatic drugs (DMARDs). Disease activity was calculated using the 28 joint counts (DAS28) and musculoskeletal ultrasound examination (MSUS) was performed at baseline and after 4 months using a 12-joint score (bilateral elbow, wrist, 2° metacarpophalangeal MCP; 3rd MCP, knee, ankle) [2]; Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), pro-inflammatory cytokines (IL-6, TNF-α) and high-sensitivity C-reactive protein (hs-CRP) levels, rheumatoid factor (RF) titre and anti-cyclic citrullinated peptide (anti-CCP) antibodies titre were measured and the health assessment questionnaire (HAQ) score was documented.

Results: Baseline RDW was significantly increased in RA (15.16 ± 3.63%) compared to its level in the healthy controls (12.16 ± 1.43%) (p<0.001). While, there was no significant difference in MPV between RA and control groups (10.92 ± 2.02 fl and 10.98 ± 0.88 fl respectively) (p>0.2). In RA patients, baseline RDW significantly correlated with CRP (r=0.39, p<0.05), DAS28 (r=0.47, p<0.05), grey scale (GS) (r=0.53, p<0.05) and power Doppler (PD) (r=0.56, p<0.001) synovitis scores. Also, RDW at 4 months follow up significantly correlated with the DAS28 (r=0.42, p<0.05), GS score (r=0.45, p<0.05), MPV showed no significant correlation with clinical, laboratory and ultrasonographic parameter of RA disease activity. Baseline RDW (r=0.02) was shown to be comparable to ESR (r=0.03) but less than CRP (p<0.001) at predicting PD synovits score.

Conclusion: Rheumatoid arthritis patients have significantly increased RDW levels that remarkably correlated with clinical, laboratory and MSUS parameters of inflammations suggesting that it could be a useful marker to reflect RA disease activity. RDW could be a useful biomarker to predict treatment outcome in RA patient. In this regard, MPV had poor correlations.

FOUR COMORBIDITY INDEXES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

Yun-Ju Huang1, Chang-Fu Kuo1, Jung-Sheng Chen1, Shue-Fen Luo1, 1 Division of Rheumatology, Allergy and Immunology, Taoyuan City, Taiwan, Republic of China; 2 Center to big data analytics and statistics, Taoyuan City, Taiwan, Republic of China

Background: Previous studies have reported an increased risk of multiple comorbidities in people with RA therefore it is necessary to systematically quantify the comorbidity burden of these patients.[1] The comorbidity index is a tool developed under this concept and has multiple clinical and research uses.

Objectives: We compared four comorbidity indexes and mortality rate in patients with rheumatoid arthritis in Taiwan (Charlson Comorbidity Index (CCI), Elixhauser Comorbidity Index (ECI), Mutimorbidity index (MMI), Rheumatic Disease Comorbidity Index (RDCI)).

Methods: All patients with rheumatoid arthritis diagnosed during 1998-2008 in Taiwan were identified using the Taiwan National Health Insurance Database and followed up to 31 Dec 2013. One-year mortality rate and 5-year mortality rate were compared using CCI, ECI, MMI and RDCI. High risk group for each index was defined as around the top 20% patients. A discrimination analysis was performed to compare the predictive ability of the model against the base model using the change of Harrell’s c-statistics and the Akaike information criterion (AIC).

Results: Among 24767 patients with rheumatoid arthritis, median age at diagnosis is 51 years old and female is 79.2%. The one-year and 5-year mortality rate (per 1000 people) is 41 vs. 177 in CCI, 43 vs. 135 in ECI, 43 vs. 169 in MMI, 43 vs. 159 in RDCI. Low risk group vs. high risk group The one-year and 5-year mortality rates all are higher in the high risk group compared with low risk group using four comorbidity indexes. The 5-year mortality rate rises up rapidly both in low risk group and high risk group using four comorbidity indexes. The discrimination analysis showed MMI predicted one-year and 5-year mortality best. (Harrell’s c-statistics 0.796 in one-year mortality and 0.802 in 5-year mortality) ECI, MMI and RDCI are all good at predicting mortality as well.

Conclusion: Our study showed mortality rate increased in patients after rheumatoid arthritis was diagnosed. All four comorbidity index score during diagnostic period predicted one-year and 5-year mortality rate well both in high risk and low risk group. Clinicians should screen different comorbidities, determine primary prevention and control disease activity to improve the functional status, quality of life and mortality of rheumatoid arthritis, especially in the patients with initial high comorbidity index scores.

TREATMENT WITH BIOTECHNOLOGICAL DRUGS
TARGET SETTING OF FUNCTIONAL REMISSION FOR
Disease-modifying antirheumatic drug based on an established algorithm
University of Campania, each patient with RA has been characterized, at
activity (LDA), SDAI<11, has been evaluated at 3, 6 and 12 months.

Results: Forty-nine patients were admitted to our centre from April
1st2017 to December 31st2018. Out of them, 36 patients have been
followed up at least for 3 months and were included in the study (algo-
rithm+ patients). Out of them, 26 (72.2%) reached 6 months of treatment,
while 16 (44.4%) 12 months of treatment. Among the 26 patients eval-
uated at 6 months, 23(88.5%) achieved the targeted end point. At 12
months, 16/16 patients (100%) preserved a status of remission or at
least low disease activity. We compared our results to those registered,
from January 2015 to September 2016, in a RA cohort of 79 patients
(RA general cohort). We found a significant difference in regard to attain-
ment of the target at 6 months (23/26 patients, 88.5% algorithm+ vs 45/
67 patients, 67.2% RA general cohort; p=0.04) and at 12 months (16/16
patients, 100% algorithm+ vs 40/57 patients, 70.2% RA general cohort; p=0.01) (Table 1). Notably, 32 out of the 79 patients had undergone a
biological drug which didn’t follow the predefined algorithm. These patients (algorithm- patients) presented a further lower incidence of response with
regard to those enrolled according to the algorithm: 22/32 patients
(67.8%) at 3 months; p=0.4; 17/29 (58.6%) at 6 months; p=0.001; 17/24
(70.8%) at 12 months; p=0.03.

Conclusion: The choice of a personalized approach toward treatment of
RA might be an effective strategy to achieve the targeted end point of
remission or at least low disease activity in every patient.

AB0260
TREATMENT WITH BIOTECHNOLOGICAL DRUGS
ACCORDING TO PRE-DEFINED SELECTION CRITERIA
IN PATIENTS WITH RHEUMATOID ARTHRITIS:
PRELIMINARY RESULTS OF A SINGLE COHORT

IACONO DANIELA, Ilenia Pantano, Serena Fasano, Giuseppe Scallise,
Francesco Ciccia. University of Campania Luigi Vanvitelli, Rheumatology, Naples, Italy

Background: Current recommendations on the treatment of Rheumatoid Arthritis
(RA) are based on a treat to target approach, nevertheless which biologic drug
should be used in an unresponsive patient is not clarified (1). Such a strategy is
essentially justified by the fact that no biotechnological drug has proved to be
superior to any other (2).

Recent studies have reported some disease or patient features that are
associated with a greater or lesser likelihood of response (3). Neverthe-
less, an adapted therapy to the single patient and based on physiopatho-
logical mechanisms has not been acquired yet.

Objectives: Aim of this study was to evaluate if the choice of a tailored
therapy, based on patient and disease features, would be an effective
strategy.

Methods: From April 1st 2017, at our Department of Rheumatology of the
University of Campania, each patient with RA has been characterized, at
enrolment, for demographic and disease features, and started a biological
Disease-modifying antirheumatic drug based on an established algorithm (Fig-
ure 1). Attainment of the targeted end point i.e. remission (R) as assessed by
Simplified Disease Activity Index (SDAI) <3.3 or at least low disease activity
(LDA), SDAI<11, has been evaluated at 3, 6 and 12 months.

Figure 1

Results: 67 patients, 67.2% RA general cohort; p=0.04) and at 12 months.

AB0261
TARGET SETTING OF FUNCTIONAL REMISSION FOR
HAND AND WRIST SURGERIES USING GRIP POWER
AND PATIENT-REPORTED OUTCOME MEASURES IN
PATIENTS WITH RHEUMATOID ARTHRITIS: A
PROSPECTIVE COHORT STUDY

Hajime Ishikawa1, Asami Abe1, Toshihisa Kojima2, Masayo Kojima3,4,
Yoichi Kurosawa1,2, Erito Hasegawa1, Satoshi Ito1, Naoki Ishigou1.

1Akita Murasawa1,2, Niigata Rheumatic Center, Rheumatology, Shiba city, Niigata
957-0054, Japan; 3Nagoya University Hospital, Orthopedic Surgery, Nagoya city,
Japan; 2Nagoya City University Graduate School of Medical Sciences, Medical
Education, Nagoya city, Japan

Background: The treatment aim of rheumatoid arthritis (RA) is achieving and
maintaining functional remission via tight medical control. However, if adequate
medication is not administered in the very early stage of the disease, surgical
reconstruction for the structurally damaged hand and wrist is sometimes required.

Objectives: To evaluate the effect of surgical treatment of the hand and wrist
and to set the target of functional remission using grip power and patient-reported outcome measures (PROs) at baseline.

Methods: A prospective observational cohort study was performed in RA
patients who were scheduled to have primary hand and/or wrist surgeries.
Assessments were performed at baseline and 12 months after surgery using
grip power (GP), pain visual analogue scale (pain VAS), general
health (GH), disease activity score 28- C-reactive protein (DAS28-CRP
4), disabilities of the arm, shoulder and hand (DASH), European quality
of life scale with five dimensions (EQ-5D), Beck depression inventory -II
(BDI-II) and health assessment questionnaire- disability index (HAQ-DI) for
all registered patients. Baseline data for each item in the group with HAQ
remission (HAQ-Di<0.5) at 12 months (REM) were compared with those in
the group without remission at 12 months (non-REM).

Results: There were 137 sites (63 hands, 74 wrists) in 119 patients
whose average age was 62 (19-88) years and average disease duration
was 14 (1-45) years. Overall, the physical function (GP, pain VAS,
DASH, HAQ-DI), quality of life (HAQ-DI, GH, EQ-5D), depression (BDI-II)
and disease activity (DAS28-CRP(4)) had significantly improved at 12
months (p<0.01) (Table 1). In the REM group (n=47), the GP and EQ-
5D were significantly higher (p<0.01) and the HAQ-DI, DASH and BDI-II
significantly lower (p<0.01) than in the non-REM group (Table 2).

Conclusion: GP and other four PROs were validated as good objective tools for assessing the physical function after hand and wrist surgeries. It would be helpful for rheumatologists to consider the timing of surgery in RA patients based on the cut-offs determined in this study[3].

AB0262 SEUM CALPROTECTIN AS A MARKER OF DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS, AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS

Matthias Jarlborg1, Delphine Courvoisier1, Céline Lamacchia1, Laura Martinez-Prat1, Chelsea Bentov2, Michael Mahler1, Axel Finchk1, Cem Gabay1, Michael Nissen1. 1Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland; 2Inova Diagnostics, Inc., San Diego, United States of America

Background: Calprotectin is a heterodimeric complex of S100A8 and S100A9 calcium-binding proteins. Stored in the cytosol of granulocytes, it is released under cell stress and acts as an endogenous damage-associated pattern molecule. In contrast to C-reactive protein (CRP), it is not an acute phase protein. Serum calprotectin levels correlate with disease activity of several inflammatory rheumatic diseases.

Objectives: To investigate association of serum calprotectin with clinical activity in rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA).

Methods: We performed retrospective analysis of patients with RA, axSpA and PsA from the Swiss Clinical Quality Management (SCQM) registry. Age- and sex-matched asymptomatic first-degree relatives of RA patient without sign of autoimmune were used as healthy controls (HC, n=72). Serum calprotectin was measured by ELISA (Inova Diagnostics, research use only). Serum calprotectin quartiles (n) [0-1.4] [1.4-2.2] [2.2-3.4] [3.4-12] were used as healthy controls (HC, n=72). Serum calprotectin was measured by ELISA (Inova Diagnostics, research use only).

Results: 1729 subjects [RA=969, axSpA=451, PsA=237 and HC=72] were included. 209 RA patients had an ultrasound performed at time of blood collection. Median levels of serum calprotectin were higher in each disease compared to HC (p<0.01; Figure). In RA, all clinical scores were statistically different across quartiles indicating an association between calprotectin levels and higher disease activity (SJC, CDAI) and severity (HAQ) (Table). In univariable regression models, both CRP (R²=0.02, p=0.04) and calprotectin (R²=0.10, p<0.001) were associated with USPD scores. Multivariable model analysis revealed that calprotectin alone was as predictive of USPD scores as calprotectin and CRP together (likelihood ratio test between two models p=0.14). In axSpA, an association between level of calprotectin and ASDAS score (p<0.01) was observed. For PsA, SJC, DAPSA and CRP did not differ across calprotectin quartiles.

Table: Clinical outcomes by calprotectin quartile levels. * Results are mean (SD) except for those with an asterisk which represent median (IQR):

Background: Treatment outcomes for rheumatoid arthritis (RA) have been improved by advances in drugs. In daily clinical practice, treatment outcomes are assessed with both inflammatory findings and based on swollen joints (SJ), tender joints (TJ), a patient’s global assessment on visual analogue scale (GVAS) score, a physician’s GVAS score, etc. Although composite measures indicate suppressed inflammatory or articular symptoms, many patients show no improvement in GVAS scores. The reported residual symptoms include morning stiffness (MS), pain (P), and dullness (D).

Objectives: We investigated the residual symptoms of patients achieving low disease activity (LDA) or complete remission (CR).

Methods: His study included 111 RA patients who received outpatient treatment at our department (31 men and 80 women). The mean age was 65.1 (range, 27–89) years. The disease stages were distributed as follows: Class 1 in 73 patients, Class 2 in 25 patients, Class 3 in 11 patients, and Class 4 in 2 patients (Steinbrocker classification). Based on the disease activity score in 28 joints using the erythrocyte sedimentation rate, disease activity was graded as CR in 54 patients, LDA in 19, moderate disease activity in 37, and high disease activity in 37 patients. In 1. Questionnaire forms were used to assess the presence or absence of MS and the presence of P (Pain VAS) and of D (Dullness VAS). These variables were assessed to determine how they were associated with clinical outcome measures, drugs, and surgery.

Results: The following residual symptoms were observed in 73 patients who achieved the treatment target of LDA or CR: MS in 34 patients (46.6%), P in 48 (65.6%), and D in 38 (52.8%). In the LDA-CR group, the Pain VAS (P < 0.001, r = 0.612) and Dullness VAS (P = 0.013, r = 0.193) were significantly correlated with the GVAS. In patients with P in the LDA+CR group, the use rates for analgesics (P = 0.0047) and biological disease-modifying anti-rheumatic drugs (bDMARDs) (P = 0.0295) were significantly higher. In the LDA+CR group, Dullness VAS scores were significantly improved by the use of bDMARDs (P = 0.0074). No association was observed between surgical interventions (42 patients) and residual symptoms.

Conclusion: Residual symptoms were frequently observed even in patients achieving LDA or CR, which is regarded as the treatment target. Because P and D were significantly correlated with the GVAS, relief of these residual symptoms is expected to improve treatment effects. Although D was relieved by bDMARDs, further studies on the treatment of residual P in patients achieving LDA or CR are necessary.

AB0264 THE EXTENT OF JOINT DESTRUCTION IN THE KNEE JOINT AT THE INITIATION OF BDMAARDS TREATMENT IS A PREDICTIVE FACTOR OF SUBSEQUENT TOTAL KNEE ARTHROPLASTY AND PROGRESSION OF JOINT DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS DURING LONG-TERM BDMAARDS TREATMENT

Daisuke Kihira, Yuji Hirano, Yukiyoshi Osahi, Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan

Background: The joint destruction inhibitory effect of biological disease-modifying anti-rheumatic drugs (bDMARDs) in patients with rheumatoid arthritis (RA) has been reported in a lot of studies. Most of them are evaluated in small joints such as hands and feet, there are few reports on the joint destruction inhibitory effect in large joints such as knees, which are frequently affected in disease course of RA. Although bDMARDs is very effective drugs, we experience RA patients in whom total knee arthroplasties (TKA) are performed after the initiation of bDMARDs treatment.

Objectives: To investigate the rate of TKA during bDMARDs treatment and to explore associated factors of subsequent TKA after the initiation of bDMARDs treatment in RA patients.

Methods: 356 knee joints of 184 RA patients who initiated bDMARDs treatment in our institute from March 2004 to November 2013 were included in this retrospective study. They were retrospectively studied over the course of a minimum of 5 years of follow up. Knees in which TKA were already performed before the initiation of bDMARDs treatment were excluded in this study. Patients’ characteristics and rates of subsequent TKA over time were investigated. Next, factors associated with subsequent TKA were explored using univariate and multivariate analysis. The X-ray change (Larsen grade) at the last observation after 5 years or more was also examined. ARASHI score was developed in Japan to assess destruction of large joints such as knees or hips.

Results: Baseline patients’ characteristics were below. Mean age was 57.1 years old. 152 female and 32 male. MTX was concomitant in 85.7% of patients. Prednisolone was concomitant in 53.7% of patients. First bDMARDs were infliximab in 67 cases, etanercept in 67 cases, adalimumab in 35 cases, tolicizumab in 6 cases, abatacept in 9 cases, golimumab in 0 cases and certolizumab in 0 cases. Agents were changed according to clinical necessity. The median follow-up period was 7.8 years. TKA were performed in 20 knees (5.9%) in total. Baseline extent of joint destruction of knees which was evaluated using Larsen grade and ARASHI score, joint destruction, age, disease duration, steinbrocker class, concomitant corticosteroids, concomitant methotrexate, DAS28-CRP, SDAI, MMP-3, mHAQ, swelling of the knees, and tenderness of the knees were associated with subsequent TKA in univariate analysis. Multivariate analysis revealed that the extent of baseline joint Destruct and mHAQ were associated with subsequent TKA (Larsen grade: Odds ratio; 6.17, 95% confidence interval; 2.93-12.98, ARASHI score: Odds ratio; 3.50, 95% confidence interval; 2.18-5.62, mHAQ: Odds ratio; 3.56, 95% confidence interval; 1.06-11.93). Cut-off value was calculated as in 2 in Larsen grade, 3 in ARASHI score, and 1.5 in mHAQ using receiver operating characteristic analysis. There were significant differences in the rates of subsequent TKA if knees were divided according to baseline Larsen grade, ARASHI score and mHAQ (Fig1). Baseline ARASHI status score in progressed knees which was worsened over 5 years were increased compared with that in knees which was stable. There was no significant difference in baseline Larsen grade between progressed knees and non-progressed knees.

Conclusion: It was suggested that baseline joint destruction and mHAQ at the initiation of bDMARDs in RA patients was predictive factors of subsequent TKA and progression of joint destruction of knees in RA patients who were concomitant bDMARDs treatment. Early intervention with effective bDMARDS is necessary to prevent destruction of knee joints and subsequent TKA in RA patients whose joint knees are affected.

AB0265 ASSOCIATION OF CUMULATIVE ANTI-CYCLIC CITRULINATED PROTEIN ANTIBODIES WITH RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Young Bin Joo, Yune-Jung Park, Kyung-Su Park, Ku-Jo Kim, Catholic University of Korea, Internal Medicine, Suwon, Korea, Rep. of (South Korea)

Background: Antibody against cyclic citrullinated proteins (ACPA) is counted as one of the most important biomarkers in diagnosis, classification, and prognosis of rheumatoid arthritis (RA). The clinical implications of change in ACPA level over time remain undetermined.

Objectives: We examined the evolution of ACPA during disease course and assess predictive value of time-weighted cumulative ACPA titer on radiographic progression in patients with RA.

Methods: A group of 734 patients with RA was followed longitudinally over 2 years, with annual measurements of IgM rheumatoid factor (RF) and ACPA. Radiographs of the hands were scored with the modified Sharp score (SHS). Cumulative ACPA antibody titers were calculated using the trapezoidal rule.

Results: The patients with radiographic progression had a higher SHS at baseline; and smoking status, diabetes, RF positivity, and use of biologic DMARDs were independently associated with radiographic progression (all P<0.05). As for ACPA, reversion happened more commonly in men and was associated with younger onset age and lower titer at baseline, but it had no direct relevance to radiographic outcome. In multivariable regression analysis, only high cumulative or baseline titer of ACPA had a predictive power for rapid radiographic progression (all P<0.05), and cumulative ACPA titer was superior in terms of statistical significance (Cohen’s d, 0.637 versus 0.583).

Conclusion: High cumulative ACPA titer was an independent predictor for accelerated radiographic progression, especially with initiation of joint damage. Serial measurement of ACPA titer can provide information about its dynamics over the clinical course and can facilitate an additional assessment of radiographic progression.

AB0266 THREE NOVEL BIOMARKERS PREDICTING THE SHORT-TERM RESPONSE TO IFX + MTX + LEFTLEFLUNOMIDE THERAPY IN RA

Jian Chen1, Mengshi Tang1, Lichang Xu1, Xi Xie1, Feng Li2, 1Second Xiangya Hospital of Central South University, Department of Rheumatology, Changsha, China; 2YALI high school, international Department, Changsha, China

Background: For rheumatoid arthritis (RA), nearly one-third of patients still have poor response to biological agents. In addition, infliximab, methotrexate and leflunomide are the most widely used three drugs in the clinic, but there remains no unified and precise indicators capable to predict the clinical response to their combination therapy.

Objectives: The purpose of this experiment is to identify a protein biomarker panel for predicting the outcome of RA patients who have received a triple therapy combining of infliximab, methotrexate and leflunomide (IFX+MTX+LEF).

Methods: All incorporated RA patients with DAS28-CRP>5.1 accepted IFX+MTX+LEF therapy. At 14th week, they were divided into good responder (GR), moderate responder (MR), and non-responder (NR) in accordance with the EULAR response criteria. After removal of the 14 high-abundance proteins, serum samples from patients (4 GR and 4 NR) at baseline and 14th week, and 4 healthy subjects (HS) were screened for candidate biomarkers via isobaric tags for relative and absolute quantification (iTRAQ). Further validation Monitoring (PRM) was performed in 20 RA patients and 20 HS for further validation

Results: A total of 590 proteins were identified by iTRAQ, and 51 proteins of which showed significant differences between NR and GR (Figure 1). PRM showed that levels of catalase, epididymal secretory protein Li 282, hemoglobin subunit delta and catalase at baseline from PRM among groups (GR, NR and HS). Expression levers of the three protein.

Conclusion: The RA patients with higher pre-treatment levels of the three proteins responded better to IFX+MTX+LEF triple therapy at 14th week; Inhibitor of oxidative stress might be a new therapeutic target of RA in the future.

References:

Figure 1. Hierarchical cluster. Hierarchical cluster of proteins differentially expressed between good responders and non-responders with an FDR < 1% identified by MaxQuant from iTRAQ, Red, high expression; green, low expression. Two main clusters of proteins can be observed, one up-regulated (left) and other down-regulated (right) in the serum of patients. Abbreviation: GR, good responder; NR, non-responder; Red, high expression; Blue, low expression.

FIGURE 1

MORTALITY RATE OF RHEUMATOID ARTHRITIS PATIENTS EVEN IN THE NEW ERA OF BIOLOGICS IS HIGHER THAN THE CONTROL GROUP: EIGHT YEARS OF THE TOMORROW STUDY

Koji Manda1,2, Tatsuya Koike3, Yuko Sugikoa, Kentaro Inui4, Tadashi Okano1, Yulano Yamada1, Masahiro Tada5, Kenji Mameoto5, Shohei Anno6, Hiroaki Nakamura1, Osaka City University Graduate School of Medicine, Orthopaedic Surgery, Osaka city, Japan; Osaka social medical center Hospital, Orthopaedic Surgery, OSAKA, Japan; Osaka City University Medical School, Center for Senior Degenerative Disorders, Osaka city, Japan; Osaka City General Hospital, Orthopaedic Surgery, Osaka city, Japan; Yokogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; Cleveland clinic, Biomedical Engineering, Program of Advanced Musculoskeletal Imaging (PAMI), Cleveland, United States of America

Background: Patients with rheumatoid arthritis (RA) have a high mortality rate compared to the general population. However, the mortality rate of patients with RA might be improved by advances in therapy.

Objectives: We investigated the risk factors for mortality in patients with RA from TOMORROW study.

Methods: This study included 413 participants, comprising 208 patients with RA and 205 age- and sex-matched healthy volunteers (Vo) from the prospective “TOMORROW” cohort study that has been ongoing since 2010 were included in this study (women, 84%; mean age, 58 years old). Median disease duration was 10.3 years.

Results: The rate of accomplishment for 8 years was 83.2% in the RA group and 92.7% in the Vo group. There were 14 deaths in the RA group (8.7/1000 person-years) and two in the Vo group (1.2/1000 person-years) (p=0.0025) for 8 years. Infection was the most common cause of death in the RA group (43%). Cox proportional hazard analysis showed that having RA was significant risk factor for death (hazard ratio [HR]: 6.9, 95%CI: 1.6 - 30.4, p=0.01) adjusting by age (Figure). In the RA group, glucocorticoid (GC) use (HR: 3.6, 95%CI: 1.1 -10.4, p=0.032) was significant risk factor for death. Disease activity, duration of disease, use of biological products, use of methotrexate, presence of cardiovascular disease, and smoking were not significant factor.

Conclusion: RA was still significant risk factor of death. GC use was independent factors of death in RA patients.

AB0269 COMPARISON BETWEEN DIFFERENT DISEASE ACTIVITY SCORES IN ELDERLY ONSET RHEUMATOID ARTHRITIS
Mariana Martínez-Morillo, Águeda Prior-Español, Anahy Brandy-Garcia, Susana Holgado, María Apaico-Espinar, Laia Gilfe, Anne Riveros-Frutos, Clara Sánchez-Gómez, Jordi Camins-Fàbregas, Yvette Casasfont-Soleu, Annaika Nack, Alejandro Olive, Lourdes Mateo Soria, Hospital Germans Trias i Pujol, Rheumatology, Badalona, Spain

Background: Elderly onset rheumatoid arthritis (EORA) has several peculiarities. This criteria could be useful in order to make a different diagnose and to select the prognosis of those patients. To determine the disease activity scores in elderly.

Methods: We recruited 45 patients with EORA, with DAS28-VSG at baseline and 12 months follow-up. We also use CDAI and SDAI.

Results: The correlation between the different scores was good. However, the concordance between all the scores decreases as time passes.

Conclusion: The correlation between the different scores was good. However, the concordance between all the scores decreases as time passes, according to a higher percentage of patients in remission or low activity. This low-moderate concordance is demonstrated even between DAS28-PCR and DAS28-VRG and when these are compared with CDAI and SDAI. CDAI and SDAI are the only ones that maintain a good concordance between them, even when the number of patients in remission or low activity increases. ACR/EULAR maintains an acceptable concordance with the most restrictive scores, SDAI and CDAI. By contrast, agreement is very low with DAS-PCR.

Disclosure of Interests: None declared

AB0270 POSITIVE ACPA WITHOUT EVIDENCE OF ARTHRITIS – A RARITY?
Daniela Martins1, Graça Sequeira2. 1Centro Hospitalar Universitário do Algarve, Faro, Portugal; 2Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal

Background: Rheumatoid Arthritis (RA) follows a variable disease course in regards to joint damage and functional outcome, therefore an early diagnosis is crucial for its management. However, occasionally, this diagnosis can be a challenge. Rheumatoid Factor (RF) and Anti-citrullinated peptide antibodies (ACPA) are the most useful biomarkers in the diagnosis of RA and, although individually they do not dictate the final diagnosis, they present high specificity and may be positive even before clinical manifestations of the disease occur. ACPA is detectable in approximately two thirds of the patients with RA and presents a superior diagnostic specificity when compared to RF. This specificity of 95-98% may present an increased value if it is three times superior to its value of reference.

Methods: By consulting the electronic clinical records of patients observed by a Rheumatologist, we identified and analyzed the patients that presented positive ACPA in their blood tests and no evidence of signs or symptoms of RA, during at least six years of follow-up. Patients with other rheumatic diseases, history of tuberculosis or chronic pulmonary diseases were excluded.

Results: We identified seven patients (average of 61 years old) with positive ACPA in at least two different blood tests, of which five presented a value three times superior to its normal value (<15UA/mL). It should be noted that, four patients presented both positive ACPA and RF. Clinically, all patients referred mechanical symptoms that varied between cervical, low back, shoulder and knee pain and did not present any record of swollen joints without trauma. Radiologically, in most cases we observed joint degradative damage. Six years after the first positive ACPA, none of the patients developed any manifestation of inflammatory joint disease.

Conclusion: Studies reveal that positive ACPA in healthy patients may precede the clinical diagnosis of RA. The specificity of positive ACPA and RF one and a half years before the diagnosis of RA is approximately 99-100%. However, as we demonstrated, it is not uncommon to find during clinical practice individuals with positive ACPA without evidence of arthritis, which leads us to emphasize the importance of a detailed anamnesis with a meticulous physical examination before establishing a diagnosis based on the patient’s blood tests.

EVALUATION OF CXCL13, sICAM-1, MMP-3 AND S100A8/A9 AS SERUM BIOMARKERS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB

D. James Haddon, Thierry Somassé, Michael J. Townsend, Jinglan Pei, Margaret Michalík, Genentech, Inc., South San Francisco, United States of America

Background: Serum levels of C-C-X motif chemokine ligand 13 (CXCL13) and soluble intercellular adhesion molecule-1 (sICAM-1) have been associated with response to tocilizumab (TCZ) in patients with rheumatoid arthritis (RA); levels of matrix metalloproteinase-3 (MMP-3) and S100A8/A9 have also been associated with RA disease activity and joint damage.

Objectives: To evaluate the association of CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels with disease activity and response to TCZ in patients with RA who achieved low disease activity with 24 weeks of TCZ + methotrexate (MTX) treatment and were subsequently randomized to TCZ monotherapy (mono) or TCZ + MTX in the COMP-ACT trial (NCT01855789).

Methods: US patients with RA who had an adequate response to MTX received initial combination therapy of MTX plus TCZ 162 mg subcutaneously for 24 weeks. Patients who achieved Disease Activity Score in 28 joints decreased by ≥ 20% (DAS28-ESR ≤ 3.2) at Week 24 were randomized 1:1:1:1:1 to receive either TCZ mono or continue TCZ + MTX until Week 52. Randomized patients were included in the present study based on baseline, Week 24 and Week 40 sample availability; serum levels of CXCL13, sICAM-1, MMP-3 and S100A8/A9 were measured by immunoassay. Correlations between CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels and DAS28/ESR at baseline, Week 24 and Week 40 were determined according to Spearman correlation coefficient. Changes in CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels from baseline to Week 24 (open-label period) were determined using Wilcoxon test. Mean changes in CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels from Week 24 to Week 40 (randomized period) were compared between treatment arms using analysis of covariance.

Results: Of 296 randomized patients, 249 were included (TCZ mono, n = 126; TCZ + MTX, n = 123). Biomarker levels were well balanced across treatment arms at baseline and Week 24 (randomization). At baseline, there were weak to moderate correlations between DAS28/ESR and biomarker levels (CXCL13 [r = 0.13, P = 0.0411], sICAM-1 [r = 0.20, P = 0.0015], MMP-3 [r = 0.19, P = 0.0021], S100A8/A9 [r = 0.25, P = 0.0001]). Significant reductions in mean biomarker levels were observed from baseline to Week 24 (open-label period) among the total randomized patients (P < 0.0001). CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels were relatively stable between Week 24 and Week 40 (randomized period), with no significant differences between TCZ mono and TCZ + MTX (Table)

Table 1: Adverse Events During the 24-Week Placebo-Controlled Period, Stratified by DAS28 CDAI Category

Conclusion: In agreement with previous studies, the association between baseline disease activity and CXCL13, sICAM-1, MMP-3 and S100A8/A9 levels was weak to mild; TCZ + MTX treatment from baseline to Week 24 (open-label period) resulted in significant reductions in all biomarkers. Changes in levels of CXCL13, sICAM-1, MMP-3 and S100A8/A9 from Week 24 to 40 (randomized period) were similar between treatment groups, consistent with the finding of non-inferiority of TCZ mono compared with TCZ + MTX in patients with RA who achieve low disease activity with TCZ + MTX.

THE ANALYSIS OF THE CLINICAL COURSES OF THE ACPA POSITIVE PATIENTS WITHOUT SYNOVITIS: WHETHER TO FOLLOW UP THEM

Tomoya Nakajima, Yumiko Nobuhara, Takashi Nakazawa, Osaka Saiseikai Nakanishi Hospital, Rheumatology, Osaka, Japan

Background: ACPA (anti-citrullinated peptide antibody) is a major risk factor for the onset of RA (rheumatoid arthritis)\(^1\). As ACPA becomes a common test in non-rheumatologists, ACPA positive patients not diagnosed with RA are increasing. However, it is unclear whether follow-up of ACPA-positive patients without synovitis leads to early treatment and consequently to the improvement of prognosis.

Objectives: To reveal whether to follow up the ACPA positive patients without synovitis.

Methods: In the four years from January 2015 to December 2018, we extracted the ACPA positive patients introduced from other hospitals, among which patients not diagnosed as RA at the first visit were selected. Then, their clinical courses and ACPA titers were retrospectively analyzed. The 2010 ACR-EULAR classification criteria was used for the diagnosis of RA\(^2\). For the significance test, a \(\alpha = 0.05\) was used.

Results: Thirty six patients met the conditions, and then 10 patients, previously treated as RA, and 8 drop-out patients were excluded. In 18 patients remaining, 10 patients developed RA (follow-up days: avg. 404, max. 963) and the other 8 were non-RA, predisease patients (follow-up days: avg. 424, max. 520). All 10 RA patients initially started the treatment with MTX (methotrexate). Five of them reached remission with only MTX. Of the other five, three needed other csDMARDs because of an inadequate amount of MTX due to adverse events, and two had insufficient observation period. The ACPA titer was significantly higher in the RA patients than the predisease patients (468 versus 26.3 U/ml \(P<0.0075\)). Tenderness of DAS 28 subject joints at the first visit was a significant predictor of RA onset when trying to extract from clinical findings. (10 of 10 in RA patients vs. 2 of 8 in predisease patients \(P=0.0044\)).

Conclusion: In our research, the predictors of RA onset are not only high ACPA titer but also tenderness of DAS28 subject joints at the first visit. The early treatment with MTX could contribute to improved prognosis.

\(^1\)Geneva University Hospital, Immunology, Geneva, Switzerland;\(^2\)Inova Diagnostics, Inc., San Diego, United States of America

Background: Autoantibodies such as anti-citrullinated protein antibodies (ACPAs), anti-carbamylated protein antibodies (CarP) and anti-peptidyl arginine deiminase 4 (PAD4) antibodies have been associated with disease severity and radiographic progression in rheumatoid arthritis (RA). However, very little is known about the anti-PAD 3 (PAD3) antibodies and of the added value of combining multiple autoantibodies to predict radiographic damage.

Objectives: To investigate the capability of rheumatoid factor (RF), ACPA, anti-CarP and anti-PAD3 antibodies to predict radiographic damage in RA, both individually and in combination.

Methods: We performed a nested cohort study within the « Swiss Clinical Quality Management » (SCQM) RA registry. Biobank samples were tested for RF [QUANTA Lite (QL), IgM and IgA], ACPA IgG [QL CCP3 and QUANTA Flash (OF) CCP3], anti-CarP IgG [using carbamylated fetal calf serum as antigen by prototype ELISA, research use only (RUO)] and anti-PAD3 IgG [QF PAD3, RUO] (all methods Inova Diagnostics).

Outcome: radiographic damage assessed with a validated scoring method, the Ratingen (Rau) score. We examined the association of each autoantibody body both separately and combined, with radiographic damage at baseline and over time with linear mixed-effects models. Multivariable analyses were corrected for age, sex, smoking status, disease duration, disease activity (DAS28), number of prior biologics and calendar year of biosampling.

RESULTS

A total of 851 RA patients were included with a median of 4 Ratingen scores per patient. Autoantibodies were positive in the following proportion: RF IgM 66.3%, RF IgA 56.9%, QL CCP3 63.8%, QF CCP3 63.3%, anti-PAD3 10.7% and anti-CarP 22.4%. Significantly higher baseline Ratingen scores were associated with the presence of RF (IgM and IgA) and anti-CCP3 (QL and OF) and greater progression over time with RF IgM and QL CCP3 IgG \((p=0.01\) and \(p=0.04\) respectively). Patients’ positive for anti-PAD3 demonstrated higher mean baseline Ratingen scores compared with anti-PAD3 negative patients (14.9 vs. 8.8 respectively) which was significant in both univariable (Figure) and multivariable analyses \((p<0.0002\) and \(p<0.02\) respectively). In the QL CCP3 negative subgroup \((n=308)\), baseline Ratingen scores were significantly higher in anti-PAD3 positive patients \((P<0.01)\). There were no significant differences with regards to anti-CarP, either in the whole population or in the seronegative cohorts. The presence of multiple autoantibodies was associated with higher baseline Ratingen scores, particularly the combination of RF IgM, RF IgA, QL CCP3, and anti-PAD3, with a baseline Ratingen score of 16.1 \((P=0.0001)\). The presence of at least 3 of the following autoantibodies: RF IgM, QL CCP3, anti-CarP and anti-PAD3, was associated with significantly greater radiographic progression over 10 years (Figure) than if these autoantibodies were absent \((P<0.03)\).

Conclusion: The presence of anti-PAD3 antibodies was associated with significantly higher scores of radiographic damage at baseline, in both the overall population and in the subgroup of ACPA-negative patients. Combinations of autoantibodies (including anti-CarP and anti-PAD3) predicted both higher baseline radiographic damage and greater radiographic progression over time.

Background: Hispanics are the largest minority group in the United States (US) and his percentage is expected to increase (28.6% by 2060), being Mexicans the largest group (67.9%). RA patients from Latin-America have distinctive features from White patients. The literature highlights a younger age at presentation and a different clinical expression compared with White but few data for Hispanic patients in US are available.

Objectives: We compared baseline demographic, clinical features and disease management among Hispanic RA patients from two well-characterized cohorts, in the USA and Mexico city.

Methods: An early arthritis clinic (EAC) was established at Site 1 (Mexico City); patients with recent-onset RA (<1 year of symptoms) had a standardized assessment and received “treat to target” treatment. At Site 2 (US), a “routine care” cohort was initiated in 2011, and all patients completed a multidimensional health assessment questionnaire (MDHAQ) as part of their routine care. Patients from both sites had baseline complete evaluation including sociodemographic data, patient-reported outcomes (PROs) (patient global assessment, pain-VAS, HAQDHI-Q, RAPID3), laboratory data, and tender joint counts. Initial treatment was noted. Data from both sites were compared and appropriate statistics was used.

Results: 201 patients from site 1 and 179 from site 2 were included (Table 1); among them, 105 (52%) and 37 (19%), respectively, were DMARD-naive at baseline. Patients from site 2 were older and had longer disease duration, however demographic characteristics did not differ. Naïve DMARD patients from site 2 scored significantly higher pain-VAS and tender joint counts, and had higher ESR values (p<0.05, Mann Whitney); a similar tendency was seen for other PROs. Time to DMARD initiation was shorter in the EAC.

Table. Demographic and clinical characteristics at first rheumatology visit for RA patients. All data as median (IQR) unless otherwise indicated. *p<0.003; NA, not applicable

Conclusion: Hispanic patients with RA from different regions in America may differ in their initial presentation. Naïve DMARDs patients belonging to an early RA cohort had shorter presentation to rheumatology resulting in earlier treatment initiation, which has been associated to better outcomes. EACs facilitate the identification of patients with recent-onset disease and help provide early access to effective therapies.

Discriminant validity of the handgrip test in patients with rheumatoid arthritis: A cohort study

Fabiola Salvia,1, Sonia Fanali,1 Marco Di Carlo,1 Giacomo Becc2, Marina Carotti1,3,4,5
1 Hospital Carlo Urbano, Dipartimento di scienze cliniche e molecolari, Jesi, Italy, 2 Ospedale Riuniti Torrette Di Ancona, Dipartimento Radiologia, Torrette, Ancona, Italy

Background: Hand involvement is one of the major determinants of disease duration explained statistically significant but practically small variations in clinical outcomes. These findings indicate that TCZ treatment outcomes are not heavily influenced by disease duration or other baseline characteristics.

Figure 1. Associations between baseline predictors and response to MTX according to different outcome criteria and at different time points, in odds ratios with 95% confidence interval.

RENAL INVOLVEMENT AND CAUSES OF DEATH IN RHEUMATOID ARTHRITIS PATIENTS ACCORDING TO THE AUTOPSY DATA

Anastasia Tushina1, Natalia Dostanko1, Viktor Yagur1, Nikolai Sproka1, Viktoria Dostanko2, Belarusian State Medical University, 2-nd Department of Internal Medicine, Minsk, Belarus; *PMUE Infomed, Minsk, Belarus

Background: Renal involvement is a clinically significant manifestation in rheumatoid arthritis (RA) patients with potential influence on the treatment, prognosis and outcome of this disease while rare publications are available on kidney damage in RA [1,2].

Objectives: To estimate the frequency and characteristics of renal involvement and causes of death in RA patients on the basis of autopsy data reports and postmortem microscopic examinations.

Methods: We have analyzed 21 814 autopsy data reports performed during the 10-year period (2001-2010) and 6720 cases of autopsy performed 5 years later (2016-2018) in the Minsk City Clinical Pathologoanatomic Bureau (The Republic of Belarus).

Results: For the period 2001-2010 autopsies were performed in 110 RA patients: 91 women and 19 men of 67.0 (13.1) years old, M (SD). Renal involvement was revealed in 75 patients (68.2%). The most common type of renal involvement was secondary AA amyloidosis - 44 patients (40%). Other types of revealed renal lesions (n=31, 28.2%) were mesangial proliferative glomerulonephritis (n=3; 2.7%), nephroangiosclerosis (n=14, 12.8%), tubulointerstitial nephritis (n=2, 1.8%), chronic pyelonephritis (n=10, 9.1%) and renal vessel vasculitis (n=2, 1.8%).

The main cause of death in RA patients with amyloidosis was end-stage renal disease (ESRD), whereas in other patients the common causes of death were cardiovascular events (43.2%) and secondary infections (33.3%). In case of secondary amyloidosis the deposits of amyloid were found in kidneys of all RA patients (100%), in adrenal glands in 36.4% and in spleen – in 34.1% of RA patients. Amyloid deposits in other internal organs were not nearly as common. In 2016-2018 50 patients with RA have been autopsied with mean age of death 72.0 (15.2) years old. Renal involvement was revealed in 34 (68.0%) of autopsies: as secondary amyloidosis in 29 patients (58.8%) and as focal segmental glomerulosclerosis or mesangial proliferative glomerulonephritis in 5 patients (10.0%). The most common cause of death in this group of RA patients were cardiovascular events (58.0%), fatal infectious complications developed in 16.0% of patients, ESRD was revealed only in 4.0% of patients.

Conclusion: 1. We have revealed an increase in secondary amyloidosis frequency in RA patients over the studied period of time from 40% to 58% (p<0.041, Fisher’s exact test) while ESRD as a cause of death in RA patients decreased from 17.3% to 4% (p=0.023, Fisher’s exact test).

2. Secondary amyloidosis is the most common type of renal involvement in RA according to the autopsy data.

DIFFERENCE BETWEEN PATIENT’S GLOBAL HEALTH AND PATIENT’S GLOBAL ASSESSMENT OF DISEASE ACTIVITY, AND DIFFERENT FACTORS INFLUENCE ON THESE SCALES IN RHEUMATOID ARTHRITIS PATIENTS

Naohiro Sugitani1,2, Yuki Mizutani1, Kenitaro Noda1, Yasuo Suzuki1, Ayako Nakajima1, 1Mie University Hospital, Center for Rheumatic diseases , Tsu city, Mie, Japan; 2Tokyo Women’s Medical University, Department of Rheumatology, Tokyo, Japan

Background: Evaluation of rheumatoid arthritis (RA) activity is crucial in measuring remission or low disease activity. Visual analogue scale (VAS) by patient’s evaluation has been used for the outcome measure for RA patients because of its feasibility, reliability, sensitivity to change, and it directly reflects the patient’s overall perspective. Patient’s evaluation is a component of multiple composite indices used in assessing RA activity and treatment response. There are two measurements that patient’s evaluation. One is patient’s global assessment of disease activity (PtGA), and the other is patient’s assessment of global health (PtGH). PtGA was originally developed as a component of American College of Rheumatology Core Set and used for Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI); while PtGH was originally developed as a component of 28-joint Disease Activity Score (DAS28). PtGA and PtGH have been considered equivalent in a
large scale of study. In daily practice or observation, "patient’s VAS" is usually used without specifying whether it refers to PIGA or PIHG. The factors which influence the change in PIGA or PIHG have not been demonstrated concomitantly in daily practice.

Objectives: We investigated the difference between PIGA and PIHG, especially each change obtained after intensification of treatment in 12 weeks and identified the factors that influence on each measurement in RA patients.

Methods: Consecutive patients were enrolled to this retrospective study at our hospital from October 2017 to September 2018. Demographic and clinical data at enrollment as well as treatment regimens were collected by review of medical charts. At first, we examined the baseline data and the changes in 12 weeks of PIGA and PIHG in their relations. The second, we divided RA patients into two subsets according to medication intensification by methotrexate (MTX) subset and biological disease-modifying anti-rheumatic drugs (DMARDs) or Janus kinase (JAK) inhibitor (B/J) subset. We compared the differences of the changes in PIGA from the baseline to 12 weeks (ΔPIGA) and those in PIHG (ΔPIHG) between MTX subset and B/J subset. Finally, the logistic regression analysis was performed to identify factors that differently influence for each scale in 12 weeks.

Results: Consecutive 38 RA patients were enrolled. Women were 76%. The median age [IQR] was 66.5 [55-75] years old. Disease duration was 2.5 [1-19] years. DAS28 was 2.61 [2.02-3.17]. SDAI was 16.8 [11.1-24.6] and CDAI was 15.3 [9.38-23.9]. MTX was initiated or increased in 24 patients (63%). The baseline median dose of MTX was 6 [3.5-8] mg/week. Biologics or JAK inhibitor were initiated in 8 patients (21%); tocilizumab (n=5), golimumab (n=1), abatacept (n=1) and tofacitinib (n=1). Other DMARDs were used in 6 patients (16%). ΔPIHG in 12 weeks was -.186 (p<0.01), and ΔPIHG in 12 weeks was -.22 (p<0.01). ΔPIHG and ΔPIGA correlated significantly (r=-.785, p<.001). ΔPIHG in MTX subsets was not different from that in B/J subsets (p=0.50) and ΔPIHG was not different (p=0.57). No significant improving factor in ΔPIGA was identified, whereas, woman (p<0.05) and usage of steroid (p<0.01) were improving factors in ΔPIHG.

Conclusion: Intensification of treatment significantly improved in both ΔPIGA and ΔPIHG but we need to pay attentions that there were different improving factors between these two patient’s measuremet.

AB0281 UTILIZATION OF SMART PHONE APPLICATION TO ASSESS THE DISEASE OUTCOMES IN RHEUMATOID ARTHRITIS: SMART- RA STUDY
Ashli Sinjale1,2, Nidhi Garg3, Reeve Rana4, Shivani Sherawat5, Innovators.1Healing Touch City Clinic, Cardio-Rheuma Division, Chandigarh, India; 2Fortis Hospital, Mohali, Internal Medicine and Rheumatology, Sahibzada Ajit Singh Nagar, India; 3Chikara University, Chikara College of Pharmacy, Raipur, India.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder which if not managed properly leads to joint destruction, disability, poor quality of life and premature mortality. Disease modifying anti-rheumatic drugs (DMARDs) have considerably improved disease outcome in RA. However, poor patient compliance significantly limits the benefits that could be accrued from DMARDs. In a technology driven era, with more people having access to smart phones, unique opportunities exist for use of phone-based technologies to improve patient care in chronic diseases. This study aims to investigate whether the use of HealthCius smart phone application for self management can influence quality of life for patients with RA and improve inflammatory disease activity.

Objectives: To investigate the impact of smart phone application (HealthCius) on inflammatory disease activity and quality of life in RA. Methods: 38 RA patients fulfilling the 2010 Rheumatoid Arthritis Classification Criteria were recruited. Subjects were randomized into 2 groups. First, having access to a smart phone were assigned to the intervention group using the HealthCius application (n=23); and second, the control group not using the application (n=15). The patients in two groups received standard treatment of RA. The application was designed after obtaining feedback from health care providers, patient counselors and RA patients using a questionnaire. To the patients, the app was their individual treatment plan. The app helped them comply with the plan by providing an easy to refer checklist, reminders, alerts and a visual dashboard of their progress through the day. The app served as the doctor’s virtual assistant inside the patient’s smart phone. For the doctor, it was a live dashboard of all patients and their real time compliance levels. The data reported by the patients was available to the doctor in the form of time sliced charts and trend lines. Therefore, this app is designed to leverage technology to shift the patients’ focus every day on to their treatment plan thereby driving up compliance and better health outcomes.

Outcome measures included erythrocyte sedimentation rate (ESR), C-Reactive protein (CRP), disease activity score (DAS28) and health assessment questionnaire (HAQ-DI) at baseline and at 12 weeks.

Results: Baseline characteristics were similar between groups with no significant difference. There was a significant difference between the control and intervention group for DAS28 (p<0.05), ESR (p<0.05), CRP (p<0.05) and HAQ-DI (p<0.05) after 12 weeks in favor of smart phone application. Analysis within the groups revealed significant improvement in DAS28 (p<0.05) (Fig.1A), ESR (p<0.01) (Fig.1B), CRP (p<0.01) (Fig.1C) and HAQ-DI (p<0.01) (Fig.1D) in the application group as compared to control group. Impact of DMARDs usage was also evaluated at the end of the study and it was found that the average drug usage of DMARDs was more in control group than the intervention group.

Conclusion: The study suggested that there was greater improvement in inflammatory disease activity and quality of life in smart phone application assisted RA patients suggesting that smart phone technology can be used to leverage health benefits in RA.

AB0282 SYSTEMATIC REVIEW OF STUDIES REPORTING ON COGNITIVE FUNCTION IN RHEUMATOID ARTHRITIS COMPARED TO THE GENERAL POPULATION
Teresa Szlachcica1, Li Linda1, Teresa Liu-Ambrose2, Hui Xie1, Kiana Yazdani1, Diane Lacaille1.1 Arthritis Research Canada, Richmond, Canada; 2University of British Columbia, Vancouver, Canada.

Background: Rheumatoid arthritis (RA) patients often complain of “brain fog” as a symptom when their disease activity is greater. The exact areas of cognition that this “brain fog” means are not yet understood. Previous studies have found that people with RA have lower cognitive function (CF) than healthy controls and age based population norms. A study by Shin et al which looked at prevalence of cognitive impairment
in persons with RA found that 31% of their 115 person sample was cognitively impaired and stated that further studies should be done to identify the specific domains of cognitive function that are most commonly affected (1). In this project, I will be looking at and summarizing all the data and findings that have been collected and reported on CF in the RA population and seeing which domains of cognition differ and which do not differ when compared to the general population and aged based population norms.

**Objectives:** To conduct a systematic review of studies reporting on cognitive function (CF) in rheumatoid arthritis (RA) patients compared to non-RA populations (based on comparison with a control group or age-based population norms).

**Methods:** We conducted a comprehensive literature search of MEDLINE, EMBASE, and PUBMED databases using the following search terms: rheumatoid arthritis or arthritis or inflammatory arthritis, and cognitive function or cognition. The search was conducted with no limit for years, and confined to only articles in English or French. After title and abstract screen, relevant articles were selected for review. Only full length articles were considered. Study selection criteria included: 1) must be presenting original data, 2) must contain RA group with confirmed diagnosis, 3) must be reporting on CF in RA, 4) must use a validated measure of CF (self-reported or from conducting CF tests), and 5) must contain a healthy control group or age-based population norms. Selected articles were critically appraised using the SIGN Methodology Checklist and data extracted using a standardized form.

**Results:** Our initial literature search yielded 747 titles, and after screening for irrelevant titles and duplicates, 28 abstracts remained. Upon excluding non-full length articles and articles which did not report on CF, 13 abstracts remained. Of these 13 articles, 8 met our selection criteria. All studies were published after the year 2000, 3 were from the USA, 1 from Canada, 1 from the UK, 1 from Australia, 1 from Egypt, and 1 from Taiwan. Sample sizes for RA and control groups varied from 15 to 120. Of these 8 articles, 6 found a significant difference in cognitive function in the RA group compared to control group or age-based population norms in at least one domain of CF. All articles that found a significant difference in CF used standardized neuropsychological tests. Domains of CF that differed included fluency, attention, visual-spatial learning, memory, decision making time, and simple reaction time. Domains of CF that were not found to differ from general population across all studies included reasoning, comprehension, and intelligence (IQ).

**Conclusion:** Overall, 75% of the articles reviewed found a significant difference in at least one domain of CF in RA patients compared to healthy controls or age-based population norms. The domains of CF most commonly affected were those related to processing and speed rather than intellectual ability. Further studies are needed to explore these differences in greater depth and to understand the underlying reasons for these differences.

**IDENTIFICATION OF NEW AUTOANTIBODIES FOR RHEUMATOID ARTHRITIS USING HUMAN PROTEOME MICROARRAYS**

**LI Lin1, Jinhui Tang1, Hong-Liang Zhang2, Yu-Jie Tang3, Li Xin-Yu1, Qun-Gun Lu1, Ya-Ling Wang1, Zi-Wen Zhu1, Anhui Medical University Affiliated Provincial Hospital, hefei, China, 1The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, hefei, China, 2Division of Life Sciences and Medicine, University of Science and Technology of China, hefei, China**

**Background:** Rheumatoid arthritis is an autoimmune disease characterized by systemic, symmetrical small arthritis. Anti-cyclic citrullinated peptide antibodies and rheumatoid factor are commonly used to diagnose RA(1). However, the early diagnosis of RA is sometimes difficult, due to the heterogeneity and negative anti-CCP antibody or RF in some patients. Therefore, it is urgent to find autoantibodies with high sensitivity and specificity as diagnostic markers for RA.

**Objectives:** To screen autoantibodies of RA with high sensitivity and specificity using human proteome microarrays(2).

**Methods:** Firstly, a case-control method was used to analyze the serum antibodies of RA patients using human proteome microarray which composed of 20,000 proteins, and identified RA-related antibodies. Then, expanded the sample size and analyzed the expression of these candidates between RA patients and healthy controls.

**Results:** The serum of five RA patients and five healthy controls were selected to detect the RA-related autoantibodies by microarray, and 25 candidates were screened. Then the IgG and IgM RA-focused microarrays composed of the 25 proteins were screened with additional cohorts of 72 RA patients and 106 healthy controls. The results of IgG protein microarray showed: (1) Expression of these 25 autoantibodies in RA patients was significantly higher than those in healthy controls (P<0.05). (2) There was no-differentially expressed protein between anti-CCP antibody and RF-negative RA patients (n=18) and anti-CCP antibody and/or RF-positive RA patients (n=54) (P>0.05). (3) ROC analysis showed that the combination of anti-RBPJ, anti-SH3BGR and anti-PAFAH1B3 autoantibody can be highly RA-specific biomarkers, with 66.7% sensitivity and 74.2% specificity, and the area under the curve is 0.734; meanwhile the sensitivity and specificity of the anti-CCP antibody and RF-negative RA patients diagnosis were 77.8% and 65.6%, and the area under the curve was 0.720. The results of IgM protein microarray showed: (1) Only 10 out of the 25 candidates’ expression was significantly higher in RA patients than healthy controls (P<0.05).

**Conclusion:** The combination of IgG-type antibodies anti-RBPJ, anti-SH3BGR and anti-PAFAH1B3, the IgM-type antibody anti-PAFAH1B3 as well, has high sensitivity and specificity for the diagnosis of RA; especially the IgG-type autoantibody combination has great value for the diagnosis of anti-CCP and RF-negative RA patients.

**HEMATOLOGICAL MARKERS OF SYSTEMIC INFLAMMATION CORRELATE WITH CLINICAL, LABORATORY AND ULTRASOUND DISEASE ACTIVITY PARAMETERS IN RHEUMATOID ARTHRITIS PATIENTS**

Bozena Tamorska-Stepniak, Robert Zwołak, Mariusz Piotrowski, Maria Majdan. Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland

**Background:** An accurate measurement of disease activity and inflammation is essential for customizing the most appropriate management and treatment strategy in patient with rheumatoid arthritis (RA). Current data suggest that hematological markers of systemic inflammation (peripheral blood neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte (PLR) and monocyte-to-lymphocyte (MLR) ratios) could be used as novel, sensitive measures of inflammatory response, additionally to conventional laboratory and clinical markers (erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Disease Activity Score of 28 joints (DAS28), tender joint count (TJC), swollen joint count (SJC)). The ultrasonography (US) of joints enables the disease activity assessment by quantifying thickening and vascularity of the synovium.
Objectives: The goal of the study was to assess the relationship of NLR, PLR, MLR with the conventional disease activity markers (ESR, CRP, DAS28, SJ/CJ) and results of joint US, in patients with RA.

Methods: The study was conducted in the consecutive 72 patients with RA (73% female, 57% ACPA positive, mean age 60 years, median symptom duration 7 months), recruited in 1995-2005 from a defined area, were followed through 5 years. Patients were managed according to usual care, with the mean (SD) age 53.4 (8.9) and disease duration 16.8 (10.3) years. The following procedures were assessed for all patients: joint counts, DAS28, complete blood cell counts, ESR, CRP, US of 24 small joints.

Results: The mean (SD) values of hematological markers were as follows: NLR 3.24 (2.7) (range 0.2-13.96); PLR 193.26 (88.3) (range 71.2-560.8); MLR 0.3 (0.16) (range 0.06-0.87). The mean values of NLR and PLR were significantly lower in patients with low (DAS28 ≤3.2) vs moderate/high (DAS28 >3.2) disease activity; respectively NLR 2.4 (1.7) vs 4.0 (3.2), p=0.04; PLR 168.7 (58.0) vs 215.8 (104.9), p=0.4. Hematological markers of systemic inflammation were significantly, positively correlated with clinical, laboratory and US markers of the disease activity. Significant correlations were found between: NLR and DAS28, TJC, SJC, CRP, vascularity and hypertrophy of synovium in US; PLR and DAS28, TJC, SJC, ESR, CRP, vascularity and hypertrophy of synovium in US. In multiple regression test significant correlations were confirmed for: NLR, CRP and SJC (p=0.008), ESR (p=0.001), CRP (p=0.01), vascularity of synovium in US (p=0.02); PLR and ESR (p=0.03), CRP (p=0.03); MLR and DAS28 (p=0.04), ESR (p=0.001), hypertrophy of synovium in US (p=0.02).

Conclusion: The results of the study suggest that hematological markers of systemic inflammation (NLR, PLR, MLR) may serve as reliable, inexpensive and effective measure of inflammation in RA. The strong association with US imaging is an attractive result because of its predictive value and usefulness in clinical practice.

Conclusion: More than 1/3 of early RA patients experienced unacceptable pain after 5 years. Extensive synovitis in early RA was associated with a reduced risk of unacceptable pain at 5 years, likely due to positive effects of treatment on inflammation related pain. Non-inflammatory pain may be a greater long term problem in anti-CCP negative patients.

AB0285 PREDICTORS OF UNACCEPTABLE PAIN, AND UNACCEPTABLE PAIN WITH LOW INFLAMMATION, IN EARLY RHEUMATOID ARTHRITIS

Anna Eberhard1, Tor Olofsson2,3, Lennart T.H. Jacobsson1, Carles Turesson1,2,4,5, 1Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; 2Lund University, Rheumatology, Department of Clinical Sciences, Lund, Lund, Sweden; 3Skåne University Hospital, Department of Rheumatology, Malmö, Sweden; 4Sahlgrenska Academy at Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: Pain is a major symptom in many patients with rheumatoid arthritis (RA). In early RA, pain is usually due to active synovitis, but over the disease course some patients experience pain with elevated laboratory markers of inflammation.

Objectives: To investigate predictors of unacceptable pain, and unacceptable pain with low inflammation, in patients with early RA.

Methods: Consecutive patients with early RA (symptom duration <12 months), recruited in 1995-2005 from a defined area, were followed through 5 years. Patients were managed according to usual care, with no pre-specified treatment protocol. Pain was assessed using a visual analogue scale (VAS, 0-100 mm). Unacceptable pain was defined as VAS pain>40 based on the patient acceptable symptom state (PASS) (1), and low inflammation as CRP<10 mg/l (2). Baseline predictors of unacceptable pain, and of unacceptable pain with low inflammation, were evaluated using logistic regression analysis.

Results: A total of 233 patients with early RA (73% female, 57% anti-CCP positive, mean age 60 years, median symptom duration 7 months) were included. Of these, 179 attended the 5-year follow-up. At 5 years, 34% had unacceptable pain, and 23% had unacceptable pain with low inflammation. High VAS scores for pain and patient’s global assessment (PGA) at baseline were associated with unacceptable pain at 5 years (Table). There was a negative association between baseline swollen joint count (SJC28) and unacceptable pain at the 5-year follow-up. In multiple logistic regression analysis including VAS PGA and SJC28, both had a consistent impact on unacceptable pain after 5 years (adjusted odds ratios per standard deviation (SD), with 95% CI 1.78 (1.26-2.52) and 0.61 (0.42-0.89), respectively). Anti-CCP positive patients were significantly less likely to experience unacceptable pain with low inflammation at 5 years (Table).

AB0286 STATINS TO PREVENT RHEUMATOID ARTHRITIS (STAPRA TRIAL): CHALLENGES IN RECRUITMENT AND RETENTION

Laurette van Boheemen1, S.A. Turk1, van Beers - Tas1, W.H. Bos2, E.N. Grieß3, A. van Sijl3, Maarten Boers4, Michael Nummohamed5, Dirkjan van Schaardenburg5, 1ARC Reade, Amsterdam, Netherlands; 2Sint Maartenskliniek, Nijmegen, Netherlands; 3Antoniuz Ziekenhuis, Sneek, Netherlands; 4ARC VUmc, Amsterdam, Netherlands; 5ARC AMC, Amsterdam, Netherlands

Background: Primary prevention may be possible in subjects at high risk to develop rheumatoid arthritis (RA). We designed a placebo controlled randomized trial to investigate if atorvastatin can halt RA development in persons at risk for this disease (STAPRA, Netherlands Trial Register NTR5265). A statin was chosen because these drugs reduce disease activity in RA (1), hyperlipidemia patients on statins have a lower risk for developing RA (2) and dyslipidemia increases the risk for RA in a positive arthralgia cohort (3). We assumed that high risk-subjects would be attracted to this trial. However, we experienced severe difficulties with patient inclusion and treatment adherence.

Objectives: To explore difficulties with patient recruitment and retention.

Methods: The STAPRA study is a multicenter, 3-year, randomized, placebo controlled, double-blind clinical trial to assess the efficacy of atorvastatin 40 mg daily in delaying or preventing RA development in persons at high risk, defined by the presence of arthralgia and the presence of high titers of anti-citrullinated protein antibody (ACPA) or presence of both ACPA and rheumatoid factor (RF). Eligible participants were ≥18 years, did not use lipid lowering agents and had no synovitis. Five centers participated. Our goal was to recruit 220 study subjects based on an expected risk reduction of 21%. The unexpected low recruitment rate prompted us to evaluate the reasons to decline participation or to discontinue the study drug prematurely.

Results: Details were available from the initiating center (Reade) and 1 participating center (Sint Maartenskliniek). During a period of 36 months, 164 eligible patients were asked to participate of whom 58 patients (35%) consented. Most common reasons to decline were: unwillingness to use study medication (49%) and the feeling that participation was too time-consuming (14%). Fifty-four patients were randomized since 4 failed screening due to hyperlipidemia or seronegativity on repeated testing. Currently, 11 participants (20%) have developed arthritis. Twelve

BENEFITS OF PAIN RELIEF ON FATIGUE, FUNCTION, AND QUALITY OF LIFE WHEN JOINT INFLAMMATION IS CONTROLLED IN PATIENTS WITH RA

Mart van de Laar1, Janet Pope2, Yvonne Lee3, Bruno Fautrel4, Kei Ikeda5, Amanda Quebe6, Xiang Zhang6, Carol Gach6, Francesco de Leonardi6, Jeffrey Lisse7, Jennifer Workman8, Peter C. Taylor9, Arthritis Center Twente, Enschede, Netherlands; 2St Joseph's Health Care, London, Ontario, Canada; 3Northwestern University, Chicago, United States of America; 4Pierre and Marie Curie University, Paris, France; 5Chiba University Hospital, Chiba, Japan; 6Eli Lilly and Company, Indianapolis, United States of America; 7Botnar Research Centre, Univ of Oxford, Headington, Oxford, United Kingdom

Background: The ultimate goals for rheumatoid arthritis (RA) treatment are to achieve disease activity control and the best potential health state throughout the course of disease.1 In prior analyses of the Phase 3 trial, RA-BEAM (NCT01710358), baricitinib was associated with significant clinical improvements and patient-reported pain relief in RA patients (pts) who had had an inadequate response to methotrexate.2,3 The additional benefits of pain relief when inflammation is controlled are not well characterized.

Objectives: To quantify the contribution of pain relief to other PROs, fatigue, physical function, and quality of life, in pts who achieved control of inflammation, defined as swollen joint count (SJC) ≤1 and C-reactive protein (CRP) ≤1 mg/dL, at Wk 24.

Methods: Among pts with inflammation control, PROs were compared between pts who also achieved thresholds of pain relief at Wk 24 vs those who did not. Pain was measured with a visual analogue scale (VAS, range: 0-100 mm) and divided into ≤20, >20, ≤40, >40 mm.1,5 PROs included: the Health Assessment Questionnaire-Disability Index (HAQ-DI) normative value (≤0.5), to compare with a general population, and minimum clinically important differences (MCID, ≥0.22), SF-36 physical and mental component scores (PCS and MCS) MCID (≥-0.5), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F, range of 0–52, higher scores represent less fatigue) normative value (≥40.1) and MCID (≥3.56). Logistic regression models were adjusted for age, gender, BMI, geographic region, duration of disease, baseline SJC, baseline pain, and baseline value of PRO under evaluation. Missing data were imputed using modified last observation carried forward.

Results: Of the total 1305 patients in RA-BEAM, 371 pts treated with adalimumab (121/330), baricitinib (187/487), or placebo (63/488) and background methotrexate achieved inflammation control at Wk 24. Among patients who achieved inflammation control, those who also achieved each pain relief threshold were statistically significantly more likely (p<0.05) to report benefit in physical function, general quality of life, and fatigue than patients who did not reach the pain relief thresholds. (Table)

Conclusion: When inflammation is controlled (SJC ≤1 and CRP ≤1 mg/dL), more pain relief is associated with better physical function, quality of life, and reduced fatigue. This may support consideration of pain relief as an additional goal of therapy, even when inflammation is controlled. Further investigation should evaluate this benefit with other patient populations and outcomes.

AB0288  PERSISTENTLY ACTIVE DISEASE IN PATIENTS WITH NEW-ONSET RHEUMATOID ARTHRITIS DURING THE FIRST YEAR OF TIGHT CONTROL AND AGGRESSIVE THERAPY: PREVALENCE AND CLINICAL PREDICTORS IN DIFFERENT CRITERIA SETS

Wenhui Xie, Xiaoying Sun, Zhouli Zhang, Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Early intervention and aggressive therapy of rheumatoid arthritis (RA) improves prognosis, however a substantial proportion of patients under guideline-based care remain persistently active disease (PAD) in the first year.

Objectives: To investigate the proportion of PAD (LDA/MDA/HDA) in real-life practice and identify its prognostic factors in early RA (<2 years) patients receiving tight-controlled conventional synthetic disease-modifying antirheumatic drugs (csDMARD) treatment at 1 year of follow-up.

Methods: In our observational RA cohort, patients were usually three-monthly followup and step-up csDMARD escalation treatment at the discretion of physicians in the first year. Disease activity and remission were assessed by four commonly-used indices (DAS28-ESR, CDAI, SDAI, and Boolean criteria). Logistic regression was used to estimate odds ratios (ORs) and their 95% confidence intervals (CIs) for PAD by 12 months.

Results: The study included 303 DMARD-naïve early RA patients completing one year follow-up schedule, who were mostly female (72%) with a mean age of 55, and a median disease duration of 6 months. Most patients were in MDA or HDA at baseline and most of them (83.5%) received csDMARDs combination in the first year. 26.4-55.1% of participants did not reach remission by 12 months. Compared to patients experienced remission, patients in PAD were frequently in female, older, shorter disease duration, and high baseline disease activity components, including SJC, TJC, PGA, EGA, ES R, CRP and glucocorticoids use. In multivariate logistic regression analyses, female (OR=1.34-1.58), increasing age (OR=1.03-1.10), longer disease duration (OR=1.45-1.78), higher baseline SJC (OR=1.11-1.25), EGA (OR=1.03-1.08) showed the independent association with the increased risk for PAD, across all criteria. Higher ESR (OR=1.05) was an independent risk factor for PAD, measured by DAS28-ESR.

Conclusion: Our results indicated around one-third of RA participants receiving guideline-based healthcare had PAD in the first year. Female, increasing age, long disease duration, higher SJC, EGA, and ESR at baseline independently increased the risk of PAD.

AB0289  PREDICTION OF CARDIOVASCULAR EVENTS IN RHEUMATOID ARTHRITIS PATIENTS USING PROTEIN BIO-MARKERS AND CLINICAL FACTORS

Jeffrey Curtis1, Fenglong Xia2, Lang Chen3, Eric H. Sasso2, Elena Hiltraya4, Jerry Lanchbury3, Darl Flake4, Alexander Gutin5, Cheryl Chin6, Cynthia S. Crowson6, 7.

1University of Alabama at Birmingham, Birmingham, United States of America; 2Crescendo BioScience, Salt Lake City, United States of America; 3Myriad, Salt Lake City, United States of America; 4Crescendo BioScience, South San Francisco, United States of America; 5Mayo Clinic, Rochester, MN, United States of America

Background: The ACC/AHA recommends preventive strategies for patients with a high-predicted risk of atherosclerotic cardiovascular disease (CVD). RA patients are at higher risk for CVD events, yet the role of systemic inflammation and the influence of traditional CVD risk factors are unclear with respect to risk prediction in RA.

Objectives: To quantify phenomenon of mismatch between the T2T and HAQ among RA patients through data mining from smart system of disease management (SSDM).

Methods: We derived a U.S. cohort of RA patients by linking multi-biomarker disease activity (MBDA) test data to Medicare claims data. Patients had to have ≥1 year Medicare coverage prior to the date of their first MBDA test, which was designated as baseline. Exclusions were past MI, stroke, or cancer. Follow-up ended at the earliest of: 1) CVD event; 2) death; 3) loss of coverage; or 4) 12/31/2016, the latest date at which the Medicare claims database was evaluated. CVD events were defined as incident MI, stroke or fatal CVD event, and were identified using validated algorithms (PPV >80%). The leptin-adjusted MBDA score (Curtis et al., Rheumatology 2018) and its 12 individual protein biomarkers were evaluated as predictors of CVD events, as were other variables, including demographics, healthcare utilization, CVD-related comorbidities and medications, and RA-related features (e.g. DAS28-ESR, logic use, glucocorticoid use). The cohort was randomly split 2:1 to use 2/3 of patients for training and 1/3 for validation. Cox proportional hazard regression with LASSO was used for variable selection based on minimization of 10-fold cross-validated error + 1 SE. Model calibration (observed vs. expected) and discrimination were assessed for predicted CVD events at 3 years. Analyses are ongoing; main performance results are reported for the cross-validated training data.

Results: A total of 26,261 eligible RA patients were analyzed; mean (SD) age 68.6 (10.2) years, 80.1% female, 72.6% white, 23% diabetes, 43% statin use, 56% metformin, 44% on biologics/tocilizumab, 55% steroids, and median (IQR) adjusted MBDA score 40 (32-49). A total of 477 CVD events occurred over mean (SD) follow-up time of 1.7 (1.2) years yielding a CVD incidence rate of 16.5 (95% CI 15.0-18.0)/1000py. The most important predictors in these LASSO-selected models were age, beta-blocker use, sex, diabetes, adjusted MBDA score and a subset of individual MBDA biomarkers. The best performing model had a cross-validated area under the receiver operator curve of 0.70 and good observed: expected prediction at 3 years (Figure).

Conclusion: Preliminary results from this approach suggest that a simple algorithm consisting of a limited number of protein biomarkers and clinical measures can provide an accurate method to predict short-term CVD risk in RA.

Acknowledgement: The work for this abstract was funded by an industry/academic collaboration between Myriad and University of Alabama at Birmingham.

AB0290  TREAT-TO-TARGET (T2T) IS NOT ENOUGH; IDENTIFY FACTORS LEADING TO A MISMATCH BETWEEN T2T AND HAQ AMONG RA PATIENTS THROUGH DATA MINING FROM SMART SYSTEM OF DISEASE MANAGEMENT (SSDM)

Jing Yang1, Yongfu Wang2, Hua Wei3, Yu Zhang4, Xiaoling Liu5, Xiaoleong Rong6, Jinmei Zou7, Xiaolei Shi5, Li Hongbin8, Hui Xiao8, Yuhua Jia8, Fei Xiao9, Zhenbiao Wu10, SSDM Collaboration Group, China; 1Central Hospital of MianYang, MianYang, China; 2The First Affiliated Hospital of BaoTou Medical College, BaoTou, China; 3Northern Jiangsu People’s Hospital, Yangzhou, China; 4The 1st Affiliated Hospital of Guangzhou University of TCM, Guangzhou, China; 5The 1st Affiliated Hospital of Chongqing medical University, Chongqing, China; 6The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China; 7The Affiliated Hospital of Inner Mongolia Medical University, Hohhot, China; 8Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China; 9The First Affiliated Hospital of The Fourth Military Medical University, Xian, China

Background: T2T, achieving a DAS28 score lower than 2.6 (remission) or below 3.2 (low disease activity), is the main management strategy recommended by ACR and EULAR. HAQ is the most widely used in assessments of physical function in RA. However, the T2T may not always associate with good HAQ.

Objectives: To quantify phenomenon of mismatch between the T2T and the HAQ in RA patients and identify influential factors from real-world data mining in SSDM.

Disclosure of Interests: None declared

**Methods:** SSDM is a novel mobile tool of disease management. The patients were trained to master SSDM by health care professionals and conducted their DAS28 and HAQ self-assessments. The data were synchronized to the mobile of physicians and uploaded onto cloud for analysis.

**Results:** From Jun 2014 to Jan 2019, 44,698 RA patients from 587 hospitals in China used SSDM, of which 32,058 patients made 67,845 DAS28 and HAQ self-assessments. The T2T rates were 27% at baseline, and 60% after 6 months among 4,768 patients who have been followed up longer than 6 months. In 25,620 assessments of patients who achieved T2T at baseline or repeat assessments, 76% (19,552) assessments had normal physical function (HAQ = 0), but 24% (6,268) were with HAQ score higher than 0, which mean score for 6 functional tests was 3.67, indicating physical dysfunction. The “Bend down to pick up clothing from the floor” was the one being affected most, with a mean score of 0.81, significantly higher than other functional test score, P<0.001. The mean numbers of tender and swollen joints among T2T patients were 1.53 and 1.32 respectively. The analysis of correlation between physical dysfunction and the affected joints showed the knees were the major contributor to the mismatch, following by wrist and shoulders. Table 1 showed the mean scores for each functioning category in HAQ and the top target joints.

In patients who did not achieve T2T, 32% had HAQ scores of 0, showing that these patients had normal physical function despite failure in achieving T2T. The mean number of tender and swollen joints in these patients was 4.31 and 2.85, respectively. The affected joints were mainly hand joints. According to the cluster weights for the impacts of affected joints on physical function, the weighted coefficient of affected joints impacting factors (IF) on physical function was obtained. The highest IF was for knee (4), followed by wrist (3.4), shoulder (2.3), middle finger (2.1), elbow (2), index finger (2), other fingers (1), respectively.

**Conclusion:** 1/4 RA patients suffer from physical dysfunctions even though T2T are achieved. Diseased knees, wrists and shoulders are the top three joints that lead to corresponding physical dysfunctions and contribute to a mismatch between T2T and HAQ. Conversely, diseased elbow and finger joints are less likely to cause physical dysfunction. Therefore, not all joints are equal. Joints of knees, wrists and middle fingers are less likely to cause physical dysfunction.

**SHORT TERM EFFECTIVENESS OF JANUS KINASE INHIBITORS AND BIOLOGIC DRUGS IN RHEUMATOID ARTHRITIS PATIENTS FROM THE APULIAN REGISTRY BIOPURE**

Carmelo Zuccaro1, Leonardo Santo2, Laura Quarta3, Nicola Maruotti4, Giorgio Carlinio5, Romano Buco6, Angelo Semerano7, Antonio Marzico7, Daniela Mazzotta1, Paola Chiara Francesca Falippone1, Lorenzo Iannone8. 1Outpatient Rheumatology clinic ASLBR, Brindisi, Italy; 2Unità Operativa di Reumatologia ASL BT, Barletta, Italy; “U.O. of Rheumatology, “V.Fazz” Hospital, Lecce, Lecce, Italy; 3UCU Reumatologia Universitaria, University of Foggia, Foggia, Italy; 4Rheumatology Service, ASL LE – DSS Casarano-Gallipoli (LE), Gallipoli, Italy; 5Rheumatology Hospital Unit, A.O.U. Foggia, Foggia, Italy; 6Unità Operativa di Reumatologia ASL, Taranto, Taranto, Italy; 7DETO – Rheumatology Unit, University of Bari, Bari, Italy

**Background:** Randomized clinical trials have provided evidence that janus kinase inhibitors (Jak-i) induce a quick response in patients affected with rheumatoid arthritis (RA), especially in terms of perception of pain. However, a few data are available on this issue in RA patients upon treatment with Jak-i in the settings of real life.

**Objectives:** We aimed at evaluating the early clinical response in RA patients treated with Jak-i or biologic disease modifying drugs (bDMARDs) from the Apulian registry BIOPURE.

**Methods:** We retrospectively evaluated patients with RA, according to 2010 ACR/EULAR Criteria, who begun Jak-i or biologic drugs from December 2017 (since baricitinib was available onto the market) through December 2018. We included 198 patients (female 146, 77.25%) with age (mean ±SD) of 57.8 ±12 years. Of them, 143 (75.6%) were treated with bDMARDs, whereas 46 (24.3%) were on JAK Inhibitors, namely baricitinib or tofacitinib (Table 1). Disease activity score on 28 joints (DAS28) and reported pain on a 0-100 visual analogue scale (VAS) were estimated at baseline, 3 and 6 months. Intra-group changes from baseline of DAS28 and VAS-pain was assessed by t-test. Mean difference changes in VAS-pain at 3 months between Jak-i and bDMARDs were compared by t-test. Possible predictors of the achievement of EULAR good-response at 3 months were estimated by binary logistic multiple regression analysis.

**Table 1. Frequency of different Jak-i and bDMARDs**

**Results:** Considering the whole cohort, mean DAS28 at baseline was 3.70 (±1.4) and significantly decreased to 2.76 (±1.1) at 3-months (p<0.001) and to 2.99 (±1.4) at 6-months (p<0.001). Likewise, VAS-pain was significantly improved from baseline, either at 3 and 6 months (p<0.001). Also VAS-pain significantly decreased in patients on treatment with Jak-i than in those on bDMARDs (p<0.005) (Figure 1). An EULAR good response was reached by 37.5% at 3 months and by 56.4% of patients at 6 months. In particular, patients with JAK Inhibitors met this goal at 3 months significantly more frequently than others (p<0.003). EULAR good response at 3 months was strongly associated with Jak-i treatment (OR 3.1, 95%CI 1.4-6.6).

**Conclusion:** Despite the usual flaws of the analysis from registries, such as comorbidities, concomitant therapies, adherence, different disease activity or line of treatment, our study suggests that Jak-i allow to achieve an early clinical benefit in terms of patient reported pain at greater extent than classical bDMARDs in real-world.

A COMPARISON OF THE JOINTS ULTRASONOGRAPHY IN THE PATIENTS WITH RHEUMATOID ARTHRITIS TREATED BY BIOLOGICAL AGENTS AND THE CORRESPONDING SYNOVIAL HISTOLOGICAL FINDINGS

Asami Abe1, Hajime Ishikawa1, Kunihiko Wakaki2. 1Niigata Rheumatic Center, Rheumatology, Shibata, Japan; 2Niigata Prefectural Shibata Hospital, Pathology, Shibata, Japan

Background: In the treatment of Rheumatoid arthritis (RA), early diagnosis and early treatment with light control have become increasingly important with the advent of biological therapy. Ultrasonography (US) of the various joints enables the real-time evaluation of synovial hyper trophy, effusion and bone erosion. Power Doppler (PD) ultrasound is able to identify both subclinical synovitis and early erosive disease.

Objectives: The objectives of this study were to investigate whether the image of US at the operated joint reflect synovium histological findings or clinical indicators, and to compare the results in the patient treated by non-biological agent (NonBio) and biological agent (Bio).

Methods: RA related orthopedic surgery was performed at 1287 joints including 17 shoulders, 160 knees, 96 elbows, 378 wrists, 364 fingers, 38 ankles and 234 toes during the period between January 2011 and December 2018 at our rheumatic center. Preoperatively, ultrasound evaluations were performed and grade of PD signal was determined at the part with the highest signal. PD signal consists 4 grades from grade 0 to 3. The operations were performed within one week after the ultrasound evaluations. Rooney score of the synovium ESR, DAS28-ESR (4), MMP-3, CRP were investigated. Rooney score represents the histological features in the synovium of RA. It includes 6 features i.e. synoviocytes hyperplasia, fibrosis, proliferating blood vessels, perivascular infiltrates of lymphocytes, focal aggregates of lymphocytes, diffuse infiltrates of lymphocytes, focal aggregates of lymphocytes, fibrosis, proliferating blood vessels, perivascular infiltrates of lymphocytes, focal aggregates of lymphocytes, diffuse infiltrates of lymphocytes. They were scored separately on a scale of 1-10.

The treatments that the patients received included: biological agents (Bio) CZP (n=12), golimumab (GLM) (n=56), and abatacept (ABT) (n=55), infliximab (IFX) (n=29), adalimumab (ADA) (n=28), certilizumab pegol (n=389 30%), etanercept (ETN) (n= 102), tocilizumab (TCZ) (n=105), bio agents (Bio) and non-biological agents (NonBio) (n=389 30%), etanercept (ETN) (n= 102), tocilizumab (TCZ) (n=105), infliximab (IFX) (n=29), adalimumab (ADA) (n=28), certilizumab pegol (CZP) (n=12), golimumab (GLM) (n=56), and abatacept (ABT) (n=55), folicolinb (TOF) (n=2).

Results: PD signal (0.97±0.08), DAS28 ESR. (2.32±1.13), CRP.(0.51±1.25 mg/dL), MMP-3 (119.0±119.0 mg/mL) and Rooney score (23.5±7.7) in the patients treated with Bio were significantly lower than those (1.99±0.95, 3.66±1.07, 0.78±1.37 mg/dL, 146.3±150.0 mg/dL, 28.5±9.26) in the patients treated with NonBio. Rooney score fibrosis (9.5±1.44) in patients treated with Bio was significantly higher than those (8.6±2.48) in patients treated by NonBio. Rooney score, synoviocyte hyperplasia (1.1±1.26) and three items of lymphocytes (1.59±2.91, 1.68±2.54, 1.1±1.22) in patients treated with Bio were lower than those (1.72±1.3, 3.79±3.56, 3.73±3.53, 2.4±2.98) in patients treated with NonBio. TCZ, ADA, ABT and IFX had some significant differences for Rooney score and Rooney item score between the patients treated with NonBio.

Conclusion: The activity of RA synovitis at operated site was suppressed in patients treated with Bio. There were some differences in clinical data, histological score, PD signal and DAS28 among Bio.

Disclosure of Interests: None declared

AB0291C REMISSION IN RHEUMATOID ARTHRITIS: CONSIDERING NEW CUT-POINTS OF COMPOSITE DISEASE ACTIVITY INDICES ACCORDING TO THE ABSENCE OF SYNOVITIS BY ULTRASONOGRAPHY

Ana Bertoti1, Marcelo Audissing2, Mariana Benegas3, Maximiliano Bradford4, Erik Caba5, Tomás Cazeneuve6, Claudiu Harghii5, Paula Kohan7, Josefina Marin8, Victoria Martínez9, David Navarra10, Javier Ros11, Marcos Rosenfeldt12, Santiago Ruí13, Lida Santiago14, Ethel Saturansky15, Juan Soldano16, Walter Spindler17, Johana Zacarías18. ECOSAR. Sociedad Argentina de Reumatología. 1Instituto Reumatólogo Shinburg, Rheumatology, Córdoba, Argentina; 2Humana Instituto Médico Privado, Córdoba, Argentina; 3Psinaurie, Lomas de Zamora, Argentina; 4Consultorios Moreno, Formosa, Argentina; 5Instituto de Rehabilitación Psicosocial, Buenos Aires, Argentina; 6Hospital Provincial de Rosario, Rosario, Argentina; 7Dr. Enrique Tomo Hospital, Buenos Aires, Argentina; 8Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 9Hospital Italiano Platense, La Plata, Argentina; 10Hospital Dr. Marcial Quiroga, San Juan, Argentina; 11Hospital Italiano La Plata, La Plata, Argentina; 12Organización Médica de Investigación, City of Buenos Aires, Argentina; 13Centro Medico Privado de Reumatología, San Miguel de Tucumán, Argentina

Background: Achieving the state of remission in RA according to currently available criteria does not entirely prevent patient from radiological progression. On the contrary, the presence of subclinical synovitis by means of ultrasonography (US) correlates with radiological progression.

Objectives: To establish cut-off values of composite disease activity indices (DAS28-ESR, DAS28-CRP, DAS28-ESR, CDAI and SDAI) that adjust better to remission according to the absence of synovitis by US.

Methods: Observational, cross-sectional study that included 126 patients with diagnosis of RA who were in remission or low disease activity (DAS-ESR ≤3.2). For each patient we calculated the DAS28-ESR, DAS28-CRP, CDAI, SDAI. For US assessment we used the 12 joint simplified score. We considered the state of remission by US if no synovial hypertrophy (SH) ≤1 power Doppler (PD) signal= 0 in all joints. The cut-off values of the disease activity indices to define remission according the proposed US definition of remission were determined by ROC curves.

Results: Patients had a median (ICR) DAS28-ESR of 2.32 (0.68), DAS28-CRP= 1.89 (0.55), CDAI= 3.56 (3.0) and SDAI= 3.0 (4.7). The sensitivity, specificity, positive and negative predictive value of each of the selected cut-off points for the DAS28-ESR, DAS28-CRP, CDAI and SDAI for the definition of remission are shown in the Table.

Conclusion: In this study we describe new cut points of the different composite disease activity indices for the definition of remission. These cut points improve the accuracy of the definition of remission. However, they differ scarcely from the reference values making its impact uncertain in the long term management of RA patients. Longitudinal studies are, therefore, warranted in order to elucidate the performance of these new cut points.

PREDICTORS OF NEW BONE EROSION IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING csDMARDs: ANALYSIS OF DATA FROM THE DRIVE AND DESIRABLE STUDIES

Tsuroum Takeuchi, Satoshi Soen, Naoki Ishiguro, Hisahisa Yamana, Sakae Tanaka, Makio Kobayashi, Naoki Okubo, Takaya Nitta, Yoshiya Tanaka.

1Keio University, Tokyo, Japan; 2Kakito University School of Medicine, Ikoma, Japan; 3Nagoya University, Nagoya, Japan; 4Tokyo Women’s Medical University, Tokyo, Japan; 5The University of Tokyo, Tokyo, Japan; 6Daichi Sankyo Co., Ltd., Tokyo, Japan; 7University of Occupational and Environmental Health, Kitakyushu, Japan

Background: Suppression of joint destruction is an important target for the treatment of rheumatoid arthritis (RA). Most previous studies have proposed prediction models for joint destruction to detect the risk of rapid radiographic progression (change in mTSS ≥5). As joint destruction progresses irreversibly, even slight progression of joint destruction might impact the prognosis. Therefore, our study focused on the onset of new bone erosion in RA patients.

Objectives: To clarify predictors for new bone erosion in RA patients treated with csDMARDs.

Methods: Predictive factors were analyzed using data from the placebo groups of the DRIVE [1] and DESIRABLE [2] studies, which were 12-month, randomized, double-blind, phase 2 and 3 trials for evaluating the efficacy of denosumab in RA patients. New bone erosion was defined as change from baseline in erosion score (ES) ≥1.0 at 12 months, which was assessed as “progressed” by two readers. In addition to newly emerging erosion, new bone erosion also included enlargement of erosion size which is the result of new erosion at a site adjacent to an existing bone erosion. To evaluate predictors for new bone erosion, a logistic regression model was applied. Significant predictors (p value of <0.1) were selected from the univariate analysis and one variable from each correlated pair that showed significance was removed. Multivariate analyses were performed using the selected predictors.

Results: In a total of 306 patients, baseline DAS28-CRP (mean±SD) was 3.5±1.03. New bone erosion was observed in 90 patients (29.4%). In the univariate analysis, female sex, anti-CCP antibody positivity, rheumatoid factor positivity, tender joint count (TJC)/≥6, CRP/≥0.3 mg/dL, and baseline ES/≥3 were identified as significant predictors for new bone erosion. RF and ESR were not included in the multivariate analysis because they were strongly correlated with anti-CCP antibody and CRP, respectively. In the multivariate analyses, female sex, anti-CCP antibody positivity, TJC/≥6, CRP/≥0.3 mg/dL, and baseline ES/≥3 were identified as predictors for the development of new bone erosion.

Conclusion: In RA patients whose disease activity was controlled on csDMARDs, positive anti-CCP antibody/RF status, elevated CRP/ESR levels, baseline ES/≥3, TJC/≥6 and female sex were identified as predictors for new bone erosion.
The effect of human umbilical cord mesenchymal stem cells-derivied exosomes on chemokines in collagen-induced arthritis rats

Peng He1, 1SHANXI ACADEMY OF MEDICAL SCIENCES SHANXI DAYI HOSPITAL, TAIYUAN, CHINA

Background: Umbilical cord mesenchymal stem cells (UCMSCs) derived exosomes could simulate the function of MSC and avoid the limitations of MSC, which is being hotspot in the research of rheumatoid arthritis (RA) treatment. Chemokines can recruit inflammatory cells and osteoclasts in inflammatory joints, and participate in the synovial inflammation and bone destruction of RA. The mechanisms of UCMSC-derived exosomes on chemokines have less understood in RA.

Objectives: The aim of this study was to investigate the effect of UCMSC and UCMSC-derived exosomes on the chemokines CCL2, CXCL10 and CXCL12 in CIA rats.

Methods: Human umbilical cord mesenchymal stem cells (UCMSCs) were cultured in vitro and separated using a differential centrifugation methods. The CIA rats model was set up by Freund’s complete adjuvant and type II collagen, then randomly divided into control, CIA, MTX, UCMSCs, UCMSCs low group and high concentration groups. Rats in UCMSCs group were injected in double ankle joint with UCMSCs 2X10^6/L weekly for 3 weeks. Rats in UCMSCs low and high group were injected in double ankle joint with UCMSCs exosomes 30µg and 90µg weekly for 3 weeks, respectively. Rats in MTX group were given intraperitoneal injection with MTX (0.9mg/kg) weekly for 3 weeks. Serum concentrations of CCL2 (CXCL10 and CXCL12) were measured by flow cytometry. CXCL12 serum level was tested by enzyme-linked immunosorbent assay (ELISA). The protein expressions of CCL2, CXCL10 and CXCL12 in synovial tissue were detected by immunohistochemistry. CCL2, CXCL10 and CXCL12 mRNA levels in synovial joint and spleen were measured by reverse transcription-polymerase chain reaction (RT-PCR).

Results: Intra-articular injection of UCMSC exosomes decreased CCL2 and CXCL12 levels in serum and improved synovial hyperplasia and inflammatory cell infiltration in the CIA rats. UCMSC exosomes suppressed the protein expressions of CCL2, CXCL10, CXCL12 in synovial tissue. It also inhibited transcript levels of CCL2, CXCL10, CXCL12 in synovial tissue and spleen. UCMSC had similar effect on CCL2, CXCL10, CXCL12 in CIA. The high concentration group was more effective than the low concentration in preventing CCL2, CXCL10, CXCL12 protein expressions of synovial tissue and CXCL2 transcript level of spleen.

Conclusion: UCMSC exosomes alleviates synovial inflammation in CIA rats through suppression of CCL2, CXCL10, CXCL12 release. The inhibitory effect of on chemokines simulate UCMSC, their cell of origin, the high concentration was better than low concentration.

Rheumatoid arthritis (RA) is one of the chronic autoimmune diseases with an estimated prevalence of 1 to 2 percent of the total population in the world. RA patients have an increased risk of morbidity and mortality from cardiovascular (CV) events as a result of accelerated atherosclerosis. Endothelin-1 (ET-1) is a hormone with strong vasocostrictor properties, secreted in excessive amounts by damaged endothelial cells. However, the effect of this hormone depends on the presence of specific ET-1 receptors as well as their density and location. ET-1 is a mediator-activating autocrine and paracrine, primarily in the circulatory system. It induces the production of proinflammatory cytokines, exacerbating the inflammatory process.

Objectives: The objectives of this study were: to compare serum ET-1 levels between RA patients and healthy controls and observe the relationship between tobacco smoking and serum levels of ET-1 in RA patients.

Methods: This cross-sectional study was performed in Vega-Baja Hospital, Orihuela (Spain) from November 2016 to May 2018. We prospectively enrolled 63 consecutive women patients affected by RA and followed at the Vega-Baja Hospital (Orihuela, Spain) and 65 matched healthy women controls. All patients included in this study had normal serum creatinine (Cr) levels and met the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for RA. Serum Hcy was analyzed using immunonephelometric method. Bone mineral density (BMD) of femoral neck and lumbar spine was measured by dual-energy X-ray absorptiometry (DXA).

Results: A total of 63 female patients were included in our study, with a mean (SD) age of 53 ± 8 years. The majority were Caucasian (90.5%). Thirty-four patients were menopausal and twenty-nine non-menopausal patients. The mean duration of RA was 8.5 ± 5.8 years. The mean disease activity scores in 28 joints (DAS28) according to the erythrocyte sedimentation rate (ESR) indicated low disease activity 3.0 ± 1.3. The mean health assessment questionnaire (HAQ) was 0.75 ± 0.67. Twenty-eight patients were treated with methotrexate, with a median weekly dose of 11.5 ± 4.8 mg, all the patients received 10 mg folic acid supplementation per week. Serum Hcy concentration levels between RA patients were significantly higher in the RA patients than those in the control group: [9.93 (5.6-18.8) vs. 7.11 (4.9-11.1)], pg/mL; *P<0.001*. Serum levels of Hcy were inversely related to lumbar spine BMD and femur neck BMD (r < 0.26; P < 0.05).

Conclusion: Patients with RA have high levels of Hcy that correlate, inversely, with bone mass suggesting that hyperhomocysteinemia is a risk factor for osteoporosis in patients with RA.

HOW OFTEN IS THE COMBINATION OF NSAID-INDUCED LESIONS OF THE UPPER AND LOWER GI TRACT?

Background: Non-stereoidal anti-inflammatory drugs (NSAIDs) can damage all parts of the gastrointestinal tract (GIT). However, the frequency of the combination of lesions in different parts of the gastrointestinal tract has not been studied.

Objectives: To assess the frequency of the combination of NSAID-induced lesions of the upper GI tract, small and large intestine.

Methods: The study group consisted of 112 patients with rheumatic diseases (62.5% of women, 56.2 ± 14.6 years), who regularly took NSAIDs. All patients underwent endoscopy of the upper GI tract and colon. Capsule endoscopy was performed in 35 patients with signs of NSAID-gastrocolitis.

Results: NSAID-gastrointestinal (erosions and/or gastric or duodenum ulcers) were detected in 37.8%, NSAID-enteropathy (hemorrhages, erosions and ulcers of the small intestine) in 68.6%, NSAID-colitis (hemorrhages, erosions and ulcers of the colon) - 14.3% patients. The combination of NSAID-gastro- and colopathy was detected in 26.8% of patients (odds ratio 12.2, 95% CI 2.619-56.84), the combination of NSAID-gastro, enteropathy, and colopathy - in 10 patients (20.4% of the number of patients with NSAID-gastrocolitis).

Conclusion: The combined NSAID-induced damage of various parts of the GI tract is a frequent and serious pathology requiring complex diagnostics and the combined use of prophylactic agents with a different mechanism of action.

COMPLICATIONS OF RHEUMATOID ARTHRITIS AND ALLIED DISORDERS – A STATISTICAL COMORBIDITY STUDY OF 234 AUTOPTOSE PATIENTS

Miklós Bély1, Ágnes Apáthy2. 1Hospital of the Order of the Brothers Saint John of God in Budapest, Department of Pathology, Budapest, Hungary; 2St. Margaret Clinic, Budapest, Department of Rheumatology, Budapest, Hungary

Background: Complications of rheumatoid arthritis (RA) may modify the clinical course and symptoms of allied disorders leading to missed diagnosis or late recognition of associated diseases.

Objectives: The aim of this study was to determine the possible role of classic complications of RA: systemic autoimmune vasculitis (AV), AA amyloidosis (AAa), lethal cardiac insufficiency (CI) caused by endo-, myo- or pancarditis, furthermore lethal septic infection (SI) on prevalence and mortality of coexistent associated diseases: atherosclerosis (Aths), hypertension (HT), type 2 diabetes mellitus (DM) and tuberculosis (Tb) with military dissemination (mTb).

Methods: The study group consisted of 234 autopsies, which 20.5% were selected autopsy patients with RA were studied. RA was confirmed clinically according to the criteria of the ARA.

The presence of AV, AAa, CI and SI was determined at autopsy and confirmed by a detailed review of extensive histological material. The prevalence and mortality of associated diseases: Ath, HT, DM, Tb or mTb were analyzed retrospectively, reviewing the clinical and pathological reports.

The link between AV, AAa, CI or SI and Ath, HT, DM, Tb or mTb was analyzed by (χ²) test.

Results: RA was complicated by AV in 43 (18.4%), by AAa in 48 (20.5%), by CI with lethal outcome in 15 (6.4%), and by lethal SI in 33 (14.1%) of 234 patients.

RA associated with severe Ath in 106 (45.3%), with HT in 41 (17.5%), with DM in 41 (17.5%), and with Tb in 28 (11.9%), with active mTb in 9 (3.8%) of 234 patients. As a basic disease Ath led to death in 61 (26.1% of 106), HT in 2 (0.9% of 41), DM in none (0% of 41), and Tb with mTb in 3 (1.3% of 234) patients. Tb without military dissemination was not lethal in our patient population.

The statistical links (p-values of significance) between complications of RA and prevalence or mortality of allied disorders are summarized in Table.

p<0.89

Conclusion: The inverse correlations between AV, AAa, CI, SI, and Ath, HT, DM, Tb or mTb indicate that the prevalence and mortality of allied disorders were not influenced basically by the complications of RA.

The consequently inverse and (in most cases) significant correlations between prevalence of AV, AAa, CI, SI and the prevalence and mortality of Ath show that these are independent entities in RA. The AV, AAa, CI, SI, and Ath are the most important complications of RA, and are characterized by severe forms of disease, mostly involving younger patients, with an earlier onset (without pronounced Ath); while Ath is basically an age dependent phenomenon, characteristically present in RA patients with advanced age. RA patients with Ath may represent a special group of RA, characterized by lower incidence of AV, AAa, CI or SI, and a better prognosis.

The positive and significant relations AV to Tb or mTb suggest an increased risk of Tb, e.g. the presence of AV may promote Tb or endogenous exacerbation and milary dissemination of Tb.

COXITIS DURING CHRONIC INFLAMMATORY RHEUMATISM

bedra ben abda, Sonia Rekik, Samia Jammali, Soumaya Boussaid, Hela Sahli, Elhem Cheour, Mohamed Elieuch. La rabta, tunis, Tunisia

Background: The occurrence of coxitis in chronic inflammatory rheumatism is a prognostic factor of great importance given the functional repercussions of the involvement of the coxofemoral joint.

Objectives: The aim of this work is to evaluate the prevalence of this complication in chronic inflammatory rheumatism (PR/JIA/SpA) and to describe the evolution of this disorder according to the pathology.

Methods: Eighty-two patients with chronic inflammatory rheumatism were enrolled. These patients were followed by the rheumatology department rabta since 2004 until March 2018. The clinical demographics, activity scores, treatment background (all our patients in this series were under biotherapy) and the need PTH were identified.

Results: The eighty-two patients were distributed as follows: 36.58% (n = 30) patients with RA, 36.58% (n = 30) SpA and 26.83% (n = 22) JIA. The average age was 48.3 years, 47.6 years and 35.17 years. For the rheumatoid arthritis population 26.67% (n = 8) of the patients had a coxite of which 62.5% (n = 5) was bilateral and 37.5% (n = 3) unilateral. The mean time to discovery of coxite was 11.7 years and the evolution was in 50% (n = 4) to worsening requiring in 3 cases a bilateral PTH and a case of synovithesis.

In the SpA group, 23.33% (n = 7) of patients had coxitis, of which 57.14% (n = 4) were bilateral and 32.86% (n = 3) unilateral. The average age to discovery of this lesion was 8.22 years. PTH was performed in 71.43% (n = 5) of patients.

For the JIA population, 45.45% (n = 10) of the patients had a coxite of which 80% (n = 8) was bilateral and 20% unilateral. The average time to discovery of this lesion was 14 years, with 60% of cases progressing to an aggravation requiring 45% of the cases for synovithesis and 60% for PTH.

Conclusion: SpA is the most common chronic inflammatory rheumatism with cox-femoral involvement with the most pejorative evolution despite the biological treatment.

AB0300 LIVER DISORDERS DURING RHEUMATOID ARTHRITIS
Aicha Ben Tekaya1, Khoulou Zouaou2, Ines Mahmoud3, Oifa Saidane3, Mohamed Ben Hammamia4, Rawdha Tekaya3, Leila Abdelmoula3.
1Charles Nicolle Hospital, 2Department of Clinical Sciences Lund, Rheumatology, Lund University and Skåne University Hospital, Lund, Sweden, 3Department of Rheumatology Research, Reykjavik, Iceland, 4Landspitali University Hospital, Faculty of Medicine, Reykjavik, Iceland.

Background: Hepatic disease in rheumatoid arthritis (RA) are rare, but can be impactful for patients. Though some hepatic manifestations are directly related to RA, others may be sequelae of treatment or caused by concomitant autoimmune diseases.

Objectives: We have tried through this study to focus on the liver disorders during the monitoring of rheumatoid arthritis and to identify the different etiologies.

Methods: This is a retrospective descriptive study of patients with rheumatoid arthritis (ACR-EULAR 2010 criteria) followed a rheumatology department between 2012 and 2018 with liver function disorder. We have specified the epidemiological, clinical, biological and therapeutic characteristics and the different explorations carried out for these patients.

Results: We included 61 patients in our study (3 men and 58 women). Mean age was 52.13 years [28-82]. Average duration of RA was 9.2 years [0.5-30]. Mean DAS28 was 5.95 [3-8.33]. RA was immunopositive in 88.5% of the cases and erosive in 93.44% of the cases. Most of patients received symptomatic treatment (98% paracetamol, 87% non-steroidal anti-inflammatory drugs, 84% corticosteroids). As for conventional csDMARD, 72% of patients were treated with methotrexate, 8.2% with anti-malarial, 22.95% with salazopyrine and 11.47% with leflunomide. Three patients received biological DMARDs (1 rituximab and 2 TNF-Blocking).

Hepatic disorders were cholestasis (95%), cytolysis (33%) and concomitant cytology and cholestasis (28%). The etiological investigation undertaken linked these disorders of the liver function disorders to the RA treatment in 50% of the cases. Methotrexate was incriminated in the genesis of this liver enzyme abnormalities in 14 cases, the salazopyrine in 2 cases, the leflunomide in 1 case, paracetamol and non-steroidal anti-inflammatory drugs in 11 cases and rituximab in 1 case. Hepatic immunological investigation was negative in all cases. We have not noted any hepatitis B seroconversion. Two patients had hepatitis C. One patient presented active hepatitis C serology with signs of fibrosis (AF2F2) at the liver biopsy puncture. Abdominal ultrasound showed signs of non-alcoholic fatty liver disease in 34.42% of cases. The biopsy puncture of the liver was performed in 8 patients showing chronic hepatitis lesions (n=1), hepatic atrophy (n=1), steatosis with portal and peri-sinus fibrosis (n=1). The etiological investigation was negative in 10% of cases.

Conclusion: In our study, the liver function disorders during RA are in half of the cases of ischiatic origin. This requires rigorous monitoring of patients followed for RA in order to improve their management.

AB0301 ANTIMICROBIAL USE IS HIGH IN PATIENTS WITH INFILAMMATORY ARTHRITIDES, AND FURTHER INCREASES WITH FIRST-LINE TNFI THERAPY – NATIONWIDE RESULTS
Ann H. Bjørnsson1, Kristin P. Sigurjónsdottir2, Olafur Palsson2, Aron H. Bjornsson1, Kristin P. Sigurbjornsdottir2, Olafur Palsson3,4, Thorvardur A. Gudjonsdottir,1,2, Björn Gudjonsdottir,1,2, Gudbjornsson,1,2, Mar Kristjansson5, Petur S Gunnarsson6.
1Infectious Diseases, Reykjavik University Hospital, Department of Medicine, Reykjavik, Iceland, 2University of Iceland, Faculty of Pharmaceutical Sciences, Reykjavik, Iceland, 3Faculty of Medicine, Reykjavik, Iceland, 4Department of Clinical Sciences Lund, Rheumatology, Lund University and Skåne University Hospital, Lund, Sweden, 5Landspitali University Hospital, Centre for Rheumatology Research, Reykjavik, Iceland, 6Landspitali University Hospital, Department of Science, Reykjavik, Iceland, 7Landspitali University Hospital, Hospital Pharmacy, Reykjavik, Iceland, 8Landspitali University Hospital, Department of Infectious Diseases, Reykjavik, Iceland.

Background: Infections are well-known adverse effects of tumor necrosis factor inhibitors (TNFi) and increased hospitalization rates due to infections have also been reported. To our knowledge, this is the first study to report the effect of TNFi initiation on outpatient antimicrobial prescription patterns.

Objectives: To investigate the use of antimicrobial agents (antibacterials, antifungals and antivirals; excluding antimycobacterials) in patients with rheumatoid arthritis, psoriatic arthritis, and axial spondyloarthropathies in relation to the initiation of the first TNFi in biologic-naïve patients.

Methods: All patients with inflammatory arthritides who are treated with biologic DMARDs in Iceland are registered in ICEBIO, a nationwide registry. On February 1st 2016, ICEBIO contained information on 1058 individuals. The Icelandic Directorate of Health operates the Icelandic Medicine Database (IMD), a registry that includes over 95% of all filled drug prescriptions in Iceland. From the IMD, filled antimicrobial prescriptions were extracted two years before and two years after the initiation of first-line TNFi therapy for all patients in ICEBIO with rheumatoid arthritis (RA; n=366), psoriatic arthritis (PsA; n=250) and axial spondyloarthritis (AS; n=218). As controls, five individuals, age and sex matched, for the same calendar time were randomly selected. Antimicrobial use was determined from defined daily dose per 1000 capita (DDD).

Results: The use of antimicrobials prior to TNFi treatment was greater in the patient group when compared to controls (mean 43 DDD vs 21 DDD; p<0.01). The patient group received more DDD of antimicrobials following the start of TNFi, with a statistically significant increase in PsA (33.9 to 45.2; p<0.01), AS (37.2 to 46.8; p<0.01) and nonsignificant in RA (46.8 to 49.7; p=0.066). Antimicrobial use increased from 115 DID to 137 DID for the whole group, most prominently in the PsA and AS groups (Table I). Antifungal use increased in patients with RA and antiviral use in RA and PsA (Table I).

Table I: Anti-bacterial, antifungal and antiviral use in DID two years before and after TNFi therapy.

Conclusion: Patients with active chronic arthritides use statistically significantly more antimicrobials two years antedating TNFi treatment compared to controls. TNFi treatment further increases antimicrobial use in this patient population, especially in patients with PsA and AS. Meanwhile, antifungal use increased in RA and antiviral use increased in both RA and PsA. Further analysis needs to be done on the effect of co-medicines such as glucocorticoids, DMARDs and disease activity.

AB0302 INTEREST OF THE SYSTEMATIC ELECTROCARDIOGRAM IN THE DETECTION OF CARDIAC INVOLVEMENT DURING SPONDYLOARTHRITIDES AND RHEUMATOID ARTHRITIS
Cédric Régnal BOUMBA MAKAYA1, Irame El Bouchti2, 1chu med 6, rheumatology, marrakesh, Morocco, 2chu med 6, rheumatology, marrakesh, Morocco

Background: Cardiovascular risk is not uncommon in patients with chronic inflammatory rheumatism.

Objectives: The objective: To evaluate the interest of systematic electrocardiogram (ECG) as a tool for detecting cardiac abnormalities during spondyloarthropathies (SA) and rheumatoid arthritis (RA).

Methods: Consecutive patients suffering from SA, RA, hospitalized during the period from 2016 to 2017 and free from cardiovascular events were included. An ECG - 12-lead - was performed and interpreted by a cardiologist without the diagnosis.

Objectives: To evaluate the interest of systematic electrocardiogram (ECG) as a tool for detecting cardiac abnormalities during spondyloarthropathies (SA) and rheumatoid arthritis (RA).

Methods: Consecutive patients suffering from SA, RA, hospitalized during the period from 2016 to 2017 and free from cardiovascular events were included. An ECG - 12-lead - was performed and interpreted by a cardiologist without the diagnosis.

Disclosure of Interests: None declared
Throughout our study, we emphasize the importance of continuous monitoring of the disease. Our results are consistent with most of the literature data.

Conclusion: In patients with no history of cardiovascular disease who are asymptomatic, performing a systematic ECG does not reveal the increased risk of specific cardiac complications related to these conditions in patients with SA and RA.

AB0333 METABOLIC SYNDROME IN TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

Najah Boussetta, Sameh Sayhi, Salma Bouzid, Leila Metoui, Faida Ajjal, Bassem Lourizi. military hospital of tunis, tunis, Tunisia

Background: The rheumatoid arthritis (RA) is responsible of a high cardiovascular motility. This could be related to an increased prevalence of metabolic syndrome in patients with (RA)

Objectives: The aim of our study was to determine the prevalence of metabolic syndrome in RA, to identify factors associated with its presence and to evaluate the influence of antihyperemic drugs on its occurrence.

Methods: A cross-sectional study was conducted in the Internal Medicine department over a period from July 2016 to June 2017, including 50 RA patients classified according to the 1987 ACR and/or 2010 ACR/EULAR criteria. We used the National Cholesterol Education Program/Adult Panel Treatment III 2005 (NCEP/ATP III 2005) definition for the metabolic syndrome.

Results: There were 50 patients (sex-ratio = 0.28) with a mean age of 50.84 ± 12.52 years. The mean age at the onset of RA was 42.04 ± 12.76 years with duration of 17.52 months (0.8-120 months). The evaluation of the disease showed an average DAS28-SC score of 5.37 ± 1.24 and a significant functional impact (HAQ score > 1) in 36% of patients. The prevalence of metabolic syndrome in RA was 40%. Its presence was associated with higher age (p = 0.003), greater disease activity (p=0.044), the presence of a biological inflammatory syndrome (p=0.032) and hyperuricemia (p=0.005). An association was also found with long-term corticosteroid use (p = 0.03).

Conclusion: Our results are consistent with most of the literature data. Throughout our study, we emphasize the importance of continuous monitoring of disease activity and the need for cortisone-sparing.

**AB0305 ALLERGIC SYMPTOMS IN PATIENTS WITH RHEUMA- TOID ARTHRITIS**

Olga Brzezińska1, Anna Lewandowska-Polska2, Marek Kowalski2, Joanna Makowska1. 1Medical University of Lodz, Department of Rheumatology, Lodz, Poland; 2Medical University of Lodz, Department of Immunology and Allergy, Lodz, Poland

**Background:** One of the hypothesis of RA pathogenesis is that autoimmune process in rheumatoid arthritis starts within the airways. The factors leading to increased anticyclic citrullinated protein antibodies formation within the airways are not fully understood. People with allergies to inhaled allergens suffer from chronic inflammation within upper and lower airways.

**Objectives:** The aim of this study was to assess the prevalence of symptoms of upper and lower airways allergic diseases in patients with rheumatoid arthritis as compared to general population prevalence.

**Methods:** The study group consisted of 96 patients with RA (age years – 46.89±15.72, women-73%, men-27%). Control group consist 1685 subjects from Lodz population (47,89±15,11 women-55%, men-45%). All responders completed a screening test for allergy symptoms, 60 of RA and all controls were asked to complete a detailed survey consisting of 30 questions from QUICKRAF questionnaire. Allergy and Asthma Network protocol include diagnoses and separate symptoms of allergic diseases.

**Results:** In screening questionnaire 16.84% of RA patients and 7.24% control declare that they suffer from asthma (p<0.001). The incidence of wheeze in both groups was statistically insignificant (30.00% RA vs 20.65% control; p>0.05), however the coexistence of dyspnoea and wheezing was more frequent in the group of patients with RA (44.83% vs 14.01%; p<0.001) as well as wheeze without symptoms of infection (55.56% vs 15.37% p<0.001). The frequency of waking up at night due to dyspnoea or coughing did not differ significantly between the study and control group (respectively 18.67% vs 12.82 and 33.33% vs 33.35%). The symptoms of upper airway chronic inflammation were also more prevalent in patients with RA as compared to controls. Chronic sinusitis was declared by 28.67% of patients and 10.62% controls (p<0.001), as well as the symptom of post-nasal drip was significantly twice more frequent than in the study group (20.00% vs 9.08%; p<0.005). Symptoms of a nasal allergy are insignificantly more often in RA group (38.33% vs 27.59%) as compared to general population (47.89% vs 30.11%; p>0.05). Symptoms of chronic inflammation within upper and lower airways were insignificantly more often in RA group (20.00% vs 9.08%; p<0.005). Symptoms of a nasal allergy are insignificantly more often in RA group (38.33% vs 27.59%) as compared to general population (47.89% vs 30.11%; p>0.05). Symptoms of a nasal allergy are insignificantly more often in RA group (38.33% vs 27.59%) as compared to general population (47.89% vs 30.11%; p>0.05). Symptoms of a nasal allergy are insignificantly more often in RA group (38.33% vs 27.59%) as compared to general population (47.89% vs 30.11%; p>0.05).

**Conclusion:** Increased prevalence of symptoms of upper and lower allergic diseases in patients with RA requires further investigation as chronic inflammation within upper and lower airways can lead to posttranslational modification of proteins and autoantigen formation.

**AB0306 DISEASE ACTIVITY AND PREVALENCE OF CAROTID PLAQUE ARE INCREASED IN SEDENTARY RHEUMATOID ARTHRITIS PATIENTS**

Dionicio Angel Galarza-Delgado1, José Ramón Aspíriz-López2, Iris Jazmin Cokung-Aranda1, Marely Castro-González1, Karla Paola Cuéllar-Calderón1, Ileana Cecilia Reynosa-Silva1, Carolina Marlene Martínez-Flores2. 1Hospital Universitario "Dr. José Eleuterio González", UANL, Rheumatology, Monterrey, Mexico; 2Hospital Universitario "Dr. José Eleuterio González", UANL, Cardiology, Monterrey, Mexico

**Background:** Multiple benefits from physical activity (PA) in rheumatoid arthritis (RA) patients have been described; exercise in RA is associated with a cardiovascular (CV) protective role, resulting in lower waist-hip ratio, vascular stiffness and hypertension (1). Other important advantage of PA in RA is the impact observed in disease activity; regular PA is associated with reduced DAS28 (2). There are no previous studies evaluating the effect of exercise on disease activity and carotid Ultrasound (US) findings in Mexican-mestizo RA patients.

**Objectives:** To compare clinical characteristics and carotid US findings of Mexican-mestizo RA patients who perform PA to sedentary RA patients.

**Methods:** Cross-sectional, observational, comparative study. We included RA patients aged 40 to 75 years that fulfilled the 2010 EULAR criteria. Patients with prior atherosclerotic CV diseases and overlap syndromes were excluded. Clinical history, blood samples, physical exam and carotid US were performed. Carotid plaque (CP) was defined as a focal narrowing ≥0.5 mm of the surrounding lumen or a carotid intima media thickness (cIMT) ≥1.2 mm, and increased cIMT was defined as ≥0.9 mm. Patients were classified in two groups: those who are sedentary and those who regularly perform PA (defined as ≥120 min/week). The Kilmogorov-Smirnov test was used to determine normal distribution. Categorical variables are expressed as total number (%), and numerical variables as median (q25-q75). Chi square and Mann-Whitney U-test were used to compare groups and considered significant if p<0.05.

**Results:** A total of 334 RA patients were included. Clinical characteristics are shown in table 1. Patients who exercised had lower disease activity and BMI. Carotid US was performed in 127 patients (Table 2). There was a higher prevalence of CP, bilateral CP and increased cIMT in sedentary patients. Sedentary RA patients had an increased risk of CP (OR 3.1 [95%CI 1.0-9.7, p=0.04]).

**Conclusion:** Patients who perform PA had significantly lower disease activity and BMI. A higher prevalence of CP, increased cIMT and bilateral CP was found in sedentary patients. Sedentary RA patients had an increased risk of CP. These results are similar to previously described in other populations and may be indicators of the protective effect of PA in RA patients. Rheumatologists should encourage their patients to exercise regularly.

The association of Parkinson disease with inflammatory joint diseases

Yang Cui, Xiao Zhang.

The frequency of hematological malignancies in autoimmune rheumatic diseases

Fulya Cosan1, Ipek Geyikoglu1, Ozgun Melike Gedar2, Osman Karan2. 1Bahcesehir University, Faculty of Medicine, Internal Medicine, Rheumatology, Istanbul, Turkey; 2Bahcesehir University, Faculty of Medicine, Ophthalmology, Istanbul, Turkey.

Background: Autoimmune rheumatic diseases are associated with increased risk of hematological malignancies. The pathogenesis of autoimmunity can cause of malignancies or immunosuppressive agents may increase the risk of malignancies.

Objectives: We aimed in this study to determine the frequency, type and characteristic of hematological malignancies in rheumatology practice.

Methods: 1640 rheumatoid outpatient patient with autoimmune rheumatic diseases (Rheumatoid arthritis (RA), SLE, Sjogren’s syndrome (SJS), myositis, systemic Sclerosis, undifferentiated connective tissue diseases (UCTD)) are screened for hematological malignancies. 16 patients are found with hematological malignancies. The characteristics of these patients are reported retrospective from their outpatient clinic case files.

Results: The frequency of hematological diseases was found 0.04 in study group. 4 patients had myeloproliferative diseases (1 polycythemia vera (PV), 1 primary myelofibrosis (MyF)), 2 patients with essential thrombocytopenia (ET), 2 patients had multiple myeloma (MM) and 7 patients had lymphoproliferative malignancies. 2 patients had chronic lymphoid leukemia (CLL). One of those had SJS, one patient had Hodgkin lymphoma and these patients are seen after autolog bone marrow transplantation because of arthralgia, but not detected arthritis. One patient had Hodgkin disease in her history, and had both RA and SJS, and receiving MTX therapy. 2 patients had multiple myeloma (MM). One of them is new diagnosis arthritis plus elevated sedimentation rate. Second one was seen with arthralgia after MM treatment and autologous bone marrow transplantation. 3 patients had mycosis fungoides, one of them had UCTD and received hydroxychloroquine. The other patient had RA under MTX therapy and one patient received rituximab therapy for severe RA activity. Patient with ET had only minimal arthralgia and are followed under HCO therapy. As lymphoproliferative diseases 4 patients had chronic lymphoid leukemia (CLL), 3 of them had RA and 1 of them had SJS. 2 patients had non-Hodgkin lymphoma and these patients are seen after autolog bone marrow transplantation because of arthralgia, but not detected arthritis. 1 patient had Hodgkin disease in her history, and had both RA and SJS, and receiving MTX therapy. 2 patients had multiple myeloma (MM). One of them is new diagnosis arthritis plus elevated sedimentation rate. Second one was seen with arthralgia after MM treatment and autologous bone marrow transplantation. 3 patients had mycosis fungoides, one of them had UCTD and received hydroxychloroquine. The other patient had RA under MTX therapy and one patient received rituximab therapy for severe RA activity. Patient with ET had only minimal arthralgia and are followed under HCO therapy. As lymphoproliferative diseases 4 patients had chronic lymphoid leukemia (CLL), 3 of them had RA and 1 of them had SJS. 2 patients had non-Hodgkin lymphoma and these patients are seen after autolog bone marrow transplantation because of arthralgia, but not detected arthritis. 1 patient had Hodgkin disease in her history, and had both RA and SJS, and receiving MTX therapy. 2 patients had multiple myeloma (MM). One of them is new diagnosis arthritis plus elevated sedimentation rate. Second one was seen with arthralgia after MM treatment and autologous bone marrow transplantation. 3 patients had mycosis fungoides, one of them had UCTD and received hydroxychloroquine. The other patient had RA under MTX therapy and one patient received rituximab therapy for severe RA activity. Patient with ET had only minimal arthralgia and are followed under HCO therapy. As lymphoproliferative diseases 4 patients had chronic lymphoid leukemia (CLL), 3 of them had RA and 1 of them had SJS. 2 patients had non-Hodgkin lymphoma and these patients are seen after autolog bone marrow transplantation because of arthralgia, but not detected arthritis. 1 patient had Hodgkin disease in her history, and had both RA and SJS, and receiving MTX therapy. 2 patients had multiple myeloma (MM). One of them is new diagnosis arthritis plus elevated sedimentation rate. Second one was seen with arthralgia after MM treatment and autologous bone marrow transplantation. 3 patients had mycosis fungoides, one of them had UCTD and received hydroxychloroquine. The other patient had RA under MTX therapy and one patient received rituximab therapy for severe RA activity.

Conclusion: Hematological malignancies are rare diseases in rheumatology practice, although expected high rate because of using immunosuppressive treatment and autoimmunity. The increased frequency of lymphoproliferative disorders are expected and associated with autoimmunity, but we don’t found a high rate for lymphoproliferative malignancies. Myeloproliferative malignancies possibly not associated with the pathogenesis of autoimmune rheumatic diseases.

The association of Parkinson disease with rheumatoid arthritis

Fulya Cosan1, Sena Arda1, Nuri Onat Demirci2. 1Bahcesehir University, Faculty of Medicine, Internal Medicine, Ophthalmology, Istanbul, Turkey; 2Bahcesehir University, Faculty of Medicine, Internal Medicine, Hematology, Istanbul, Turkey.

Background: Parkinson disease (PD) is a progressive neurological disease, characterised with tremor, spasticity, arthrosis, dementia, loss of mobility and general pain. PD affects mainly elderly population. Activity of PD patients is restricted because of spasticity and severe arthrosis. Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease which can cause disability in elderly population. Patients with can admit to rheumatology clinics with generalised pain or restricted mobilisation. In contrast, in some PD patients with generalised pain on joints, RA may be overlooked

Objectives: We aimed in this study to evaluate the characteristics of patients with RA and Parkinson patients.

Methods: 842 RA patients screened retrospective for PD from the patient files. 10 patients with both RA and Parkinson disease were included to study. 3 female and 7 male patients with mean age 76,4 (with a standard deviation 5,4) were evaluated. The characteristics of patients are evaluated from the patient files.

Results: All patients were older than 75 years. Mean RA duration time was 14 months and PD duration time was 34 months. All patients admitted outpatient clinic with leg pain and inability to walk. 4 of 10 patients had mild dementia. Median ESR was 36 mm/h and median CRP value was 0,68 mg/dl. 6 of 10 patients had positive ANA result with 1/100 ratio, but rheumatoid factor and anti CCP were negative.

Conclusion: PD is one of the disorder that may cause severe disability in very old ages. RA may be an additional factor for pain and loss of function in PD patients. Patients with generalised pain and difficulties with walking should be evaluated for PD especially in old ages. PD patients with generalised pain on joints should be evaluated for inflammatory arthritis.

The incidence of extra-articular manifestations in southern Chinese patients with inflammatory joint diseases

Siyu Yan, Yang Cui, Xiao Zhang. Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.

Background: Inflammatory joint diseases (JIDs) are chronic arthritis, but frequently present with co-morbidities of other organs and systems, which is known as extra-articular manifestations (EAMs). 1. It is still unclear which clinical characteristics or bio-markers can predict the development of EAMs.

HEMOSTASIS IN AFRICAN BLACK COMPARED TO WHITE PATIENTS WITH RHEUMATOID ARTHRITIS

Chanel Robinson1, Linda Tsang1, Ahmed Solomon2, Angela Woodiwiss1,1

1University of the Witwatersrand, Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Faculty of Health Sciences, Johannesburg, South Africa; 2University of the Witwatersrand, Department of Rheumatology, Charlotte Maxeke Johannesburg Academic Hospital, Faculty of Health Sciences, Johannesburg, South Africa

**Background:** Aberrant hemostasis is implicated in the increased CVD risk experienced by patients with rheumatoid arthritis (RA) (1). Large circulating concentrations of plasminogen activator inhibitor-1 (PAI-1) predict cardiovascular event rates (2). PAI-1 levels are markedly smaller in African black compared to white patients with RA (median (IQR)= 455 (40.44%).

**Methods:** Retrospective cohort study of a total of 1135 IJDs (1614). Scientiﬁc Abstracts

**Results:** We found 455 (40.44%) of them with EAMs: 30.84% and higher disease activity (OR: 1.15, P=0.011) were independent risks of EAMs. As in PsA group, longer disease duration (OR: 1.01, P=0.046) and patients on corticosteroids. At 12 months of follow-up, number of patients with incident CV risk factor was higher for Castelli ratio > 3 (23%), low HDL (16.3%) and low CRP >1 mg/dL (7.5%) and age >45 years old (3.3%).

**Objective:** To monitor CV risk-factor’s behavior during the first year of follow-up and to identify if traditional CV risk scores predict major CV events (MACE) in our population. Methods: Once enrolled patients had complete rheumatic evaluations at once and regularly. Baseline CV risk-factor’s assessments included age, gender, ethnicity, physical activity and history of first-degree relatives with cardiovascular (CV) morbidity/mortality. Cox regression’s model identified predictors of incidental MACE. Patients gave written informed consent. Results: At cohort entry, the 185 patients (all Hispanic) which data were analyzed were primarily middle-aged females (87.6%) and had 5.3 months (3.3-7.1) of disease duration. Most prevalent CV risk factors were CRP >1 mg/dL (90%), Castelli ratio > 3 (84%) and low HDL levels (74%). During the first year of follow-up, smoking status, systolic blood pressure ≥ 140 mm Hg, diastolic blood pressure ≥ 90 mm Hg, low HDL, Castelli ratio > 3, high CRP and patients with active disease progressively decreased; meanwhile, the opposite figure was true for BMI ≥ 30 kg/m² and patients on corticosteroids. At 12 months of follow-up, number of patients with incident CV risk factor was higher for Castelli ratio > 3 (23%), low HDL (16.3%), in blacks, Hispanics and non-Hispanic whites. The Insulin Resistance Atherosclerosis Study. Circulation 2003;107:2422-7.

**ABO312**

CARDIOVASCULAR RISK FACTOR’S BEHAVIOR AND CARDBIOVASCULAR RISK IN HISPANIC EARLY RHEUMATOID ARTHRITIS PATIENTS: A COHORT STUDY

Irazú Contreras-Yáñez, Guillermo Guaraacha-Basáñez, Virginia Dr. Pascual, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Immunology and Rheumatology, Mexico City, Mexico

**Background:** Rheumatoid arthritis (RA) patients present an increased risk of cardiovascular (CV) morbidity and mortality compared to the general population. Patients from Latin America exhibit younger age, female preponderance, less severe disease and dyslipidemia, which are relevant when assessing CV risk. In order to impact CV morbidity/mortality, control of reversible CV-risk factors need to be achieved. CoHorts allow prospective evaluation of long-term outcomes. In 2004 we initiated an early RA cohort. Up to June 2018, the cohort comprised 185 RA patients with prospective assessments of CV risk and at least one year of follow-up.

**Objectives:** To monitor CV risk-factor’s behavior during the first year of follow-up and to identify if traditional CV risk scores predict major CV events (MACE) in our population. Methods: Once enrolled patients had complete rheumatic evaluations at regular intervals. Baseline CV risk-factor’s assessments included age, gender, ethnicity, physical activity and history of first-degree relatives with premature heart disease. CV-risk factors assessments at baseline and at least 6 months apart included blood pressure, serum total cholesterol (CHO) and HDL cholesterol (Castelli ratio CHO/HDL was derived), serum glucose (GLU, in mg/dL), body mass index (BMI), CRP (in mg/dL) and at least the following complications: Hypertension (HT, and HT treatment), diabetes mellitus (DM), advanced chronic kidney failure (CKF) and atrial fibrillation (AF). Smoking status was assessed at baseline and last follow-up. Incident MACE were defined according to standard definitions. Cox regression’s model identified predictors of incidental MACE. Patients gave written informed consent.

**Results:** At cohort entry, the 185 patients (all Hispanic) which data were analyzed were primarily middle-aged females (87.6%) and had 5.3 months (3.3-7.1) of disease duration. Most prevalent CV risk factors were CRP >1 mg/dL (90%), Castelli ratio > 3 (84%) and low HDL levels (74%). During the first year of follow-up, smoking status, systolic blood pressure ≥ 140 mm Hg, diastolic blood pressure ≥ 90 mm Hg, low HDL, Castelli ratio > 3, high CRP and patients with active disease progressively decreased; meanwhile, the opposite figure was true for BMI ≥ 30 kg/m² and patients on corticosteroids. At 12 months of follow-up, number of patients with incident CV risk factor was higher for Castelli ratio > 3 (23%), low HDL (16.3%), high CHO (10.6%), BMI ≥ 30kg/m² (10%), CRP >1 mg/dL (7.6%) and age ≥45 years old (3.3%).

**Conclusion:** PAI-1 activity, but not plasma clot lysis time. PLoS One 2013;8 (12): e83151.

**Disclosure of Interests:** None declared

Conclusion: Hispanic RA patients from an early RA cohort present a distinct pattern of CV risk factors. Due to younger age at RA presentation, a minority of the patients had CV risk scored. Obesity was a predictor of incidental MACE in our population.

THE PREDICTORS OF UNDIAGNOSED DYSGLYCAEMIA IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS

Hafizla Baharudin1, Nur Aini Eddy Warman1, Aizmillah Rosman2, Thuhairah Abdul Rahman2, Nurhuda Ismail2, Rohana Abdul Ghani1, Universiti Teknologi MARA, Department of Medicine, Sarawak, Malaysia; 2Universiti Teknologi MARA, Department of Pathology, Sarawak, Malaysia; 3Universiti Teknologi MARA, Department of Public Health and Population Medicine, Sarawak, Malaysia.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease with an increased risk of diabetes and insulin resistance.1,2 The prevalence of type 2 diabetes mellitus (T2DM) were demonstrated to be 10.4% as compared to only 7.6% in 1:4 controls matched for age, sex and geographical region, with an odds ratio of 1.4.2

Objectives: To determine the prevalence of dysglycaemia (T2DM, impaired fasting glucose (IFG) and impaired glucose tolerance (IGT)) and the factors associated with dysglycaemia in patients with established RA.

Methods: This is a cross-sectional study conducted in a rheumatology centre in Malaysia. Patients with established RA aged 30 years or more were included. Exclusion criteria were overlap syndrome, pre-existing diabetes or pre-diabetes, pregnant and within 6 weeks of post-partum period. An oral glucose tolerance test (OGTT) was performed for all patients. Comparison of various factors between dysglycaemia and normoglycaemia were analysed. Multivariate analysis was performed using logistic regression analysis to ascertain the true effects of significant factors found on univariate analysis.

Results: The mean age of patients was 57.2 ± 8.1 years and 87.7% were female. Of 155 patients included in this study, 55 (35.5%) were found to have dysglycaemia; 40 (72.2%) had IGT, 11 (20%) had T2DM. 3 had IFG and IGT (5.5%) and 1 had IFG (1.8%). Significant factors found on univariate analysis.

Conclusion: One third of 155 patients had dysglycaemia and majority had IGT. The predictors of dysglycaemia in patients with established RA aged 30 years and more, were previous or current smoker and raised triglycerides.

AB0314

QUALITY OF LIFE IN WOMEN WITH RHEUMATOID ARTHRITIS DEPENDING ON ANXIETY AND DEPRESSION

Ekaterina Egorova, Natarya Niktina, Andrei Rebrov. Saratov State Medical University named V. I. Razumovsky, Ministry of Health of Russia, Hospital Therapy Department, Saratov, Russian Federation.

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that causes joint damage, deformity, and pain. This can lead to loss of functionality and mobility, which entails a decrease in the quality of life and the possible occurrence of anxiety and depressive disorders [1].

Objectives: Assess the quality of life in women with RA, depending on the anxiety and depression.

Methods: The study included 104 women with reliable RA according to the ACR1987 and/or EULAR/ACR2010 criteria (mean age 53.7 ± 10.9 years, mean duration of RA = 10.1 [4-14] years, DAS28 = 4.96 [4.27-5.77]). An assessment of the severity of anxiety and depression was conducted using a questionnaire for the hospital scale of depression and anxiety (HADS). Evaluation of the quality of life of patients with rheumatoid arthritis was performed using the EQ-SD index. Depending on the degree of functional impairment, according to the HAQ questionnaire, were regarded as minimal (0-0.1 point), moderate (1-2) and pronounced (2-3 points), the population norm was 0-0.5 points. The severity of pain was determined by VAS: no pain (0-4 mm), mild pain (5-44 mm), moderate pain (45-74 mm), severe pain (75-100 mm). Statistical processing was performed using the program STATISTICA 10.0.

Results: The frequency of occurrence of anxiety-depressive disorders in patients with RA was determined: clinically significant anxiety was detected in 20 (19.2%) patients, depression - in 19 (17.3%); subclinical anxiety - in 26 (25%), depression - in 27 (25.9%) patients; the absence of reliably expressed symptoms of anxiety in 58 (55.8%) patients, depression - in 59 (56.8%) patients.

HAQ functional impairment was absent in 11 (10.6%) patients, minimal impairment was detected in 20 (19.2%), moderate - in 52 (50%), and pronounced in 21 (20.2%) patients. Severe pain in the VAS was noted by 38 (36.6%) patients, moderate - 51 (49%), in 15 (14.4%) patients the pain syndrome was weakly expressed. The HAQ and EQ-SD indices for women were 1.26 [0.88;1.75] and 0.41 [0.07;0.59], respectively. The relationships between the HAQ and EQ-SD indices (r = 0.67, p <0.05), the HAQ index and the age of the patients (r = 0.33, p <0.05), and the duration of the disease (r = 0.29, p <0.05), ESR indicator (r = 0.28, p <0.05), CRP (r = 0.37, p <0.05), the level of pain in VAS (r = 0.4, p <0.05), DAS28 index (r = 0.32, p <0.05), anxiety severity (r = 0.22, p <0.05), depression severity (r = 0.31, p < 0.05). The relationship between the EQ-SD index and the age of the patients (r = 0.29, p <0.05), with the duration of the disease (r = 0.22, p <0.05), CRP (r = 0.52, p <0.05), the level of pain in VAS (r = 0.45, p <0.05), the severity of anxiety (r = 0.28, p <0.05), the severity of depression (r = 0.35, p <0.05).

To clarify the relationship between the quality of life of patients and the level of depression and anxiety, two groups were identified: no anxiety-depressive disorders (N = 43) and the second group with their presence (N = 30). The EQ-SD index in the first group was 0.59 [0.52; 0.62] and in the group with anxiety and depressive disorders it was 0.27 [0.02; 0.52] (p = 0.005). The HAQ index significantly differed in women without anxiety and depressive disorders 1.0 [0.625; 1.5] with the index in the other group 1.75 [1.0; 2.125] (p = 0.01).

Conclusion: Thus, every fifth patient with RA suffers from clinically significant anxiety and depression; subclinical anxiety and depression were found in 26% of patients with RA. Interalrelations between the indicators of quality of life of patients with RA and the patient’s age, duration, activity of RA, severity of anxiety and depressive disorders.

EVALUATION OF SLEEP QUALITY, FATIGUE AND SEXUAL PROFILE IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

ACHIEK Mohamed Amine EL, Amel Farhat, Saoussen Zrou, Ismail Beja, Mongi Touzi, Mahbouba Jamm, Naceur Bergaoui. Fattouma Bourguiba University Hospital, Rheumatology, Monastir, Tunisia

Background: People over the age of 60 with rheumatoid arthritis (RA) often complain of fatigue, which is considered an extra-articular symptom. This problem has a multidimensional character and sounds on the quality of sleep and on the sexual profile.

Objectives: Our study consists in assessing the prevalence of fatigue and studying the quality of sleep and the sexual profile of patients over 60 years of age with RA compared to subjects suffering from the same illness of younger age.

Methods: This is a prospective study involving 100 patients at the Rheumatology department of Fattouma Bourguiba university hospital in Monastir over a period of 6 months: 40 patients more than 60 years of age with RA compared with 60 patients with RA of younger age. Data collection was based on scales and specific questionnaires (Visual Analogue Fatigue Scale (VAS-F), Multidimensional Fatigue Inventory (MFI-20), Pittsburgh Sleep Quality Index (PSQI), Female sexual Function Index (FSFI), Sexual Health Inventory for Men (SHIM)).

Results: The average age was 55.8 years [25-84]. The most represented age group was over 60 (40%). The sex ratio was 5.6. 73% of our patients were married and 81% had children with an average number of 3 children in charge and extremes between 1 and 9. Fatigue, sleep quality and sexual profile were analyzed comparatively and respectively between the 2 groups (1st group: >60 and second <60 years). The average of the VAS-F was 60.25 compared to 53.5. Fatigue (via MFI-20) was present in all its domains in our patients. General fatigue and physical fatigue were the highest, averaging 13.98 versus. 13.07 and 12.98 versus. 12.33 respectively. Sleeping insomnia (PSQI> 5) was found with the same proportion of 65% in both groups. Low sleep quality was found in 90% versus 93%. A sleep latency> 31 minutes was found in 37.5% against 30%. Sleep duration <6 hours per night was found in 52.5% versus. 75%. Sleep efficiency <85% was found at an equal percentage of 75%. Sleep disorders> 10 times in the last 4 weeks were found at an equal percentage of 15%. Regular female sexual activity was found in 42.5% versus. 71% and dysfunction (FSFI>26.55) was noted in 35% against 63.3%. Regular male sexual activity was found in 54.5% against 75% and mild erectile dysfunction (SHIM=21) was noted in 83.3% against 20%.

Conclusion: A multidimensional approach is needed to explore the different components of fatigue, sleep quality and sexual profile in patients with RA and its very diverse consequences. This should lead to an improvement in the quality of life in the current medical practice.

ESTABLISHED SERONEGATIVE RHEUMATOID ARTHRITIS IS CONSIDERED A MILD FORM OF THE DISEASE. ALSO WILL IT BE THE SAME REGARD FOR VERY EARLY SERONEGATIVE RHEUMATOID ARTHRITIS?

Faijard Hermosito Luis Daniel. IMSS, Hospital Regional N 110, Rheumatology, Guadalajara, Mexico

Background: Established Seronegative Rheumatoid Arthritis (ESNRA) is considered a mild form of the disease with a good prognosis and response to therapy compared with seropositive (SP) form [1]. Lately evidence indicates that seronegative (SN) form of arthritis in early stage is serious and should not be underestimated in terms of disease activity, response to therapy and radiographic damage [2,3,4]. At a present, the influence of SN status of clinical course and treatment choice in very early stages, in other words less than 3 months from time at onset of disease, is still controversial [5].

Objectives: To evaluate demographical, clinical and treatment differences between Very Early Seronegative Rheumatoid Arthritis (VESNRA) and Very Early Seropositive Rheumatoid Arthritis (VESPRA) in a Mexican cohort.

Methods: 64 patients with Very Early Rheumatoid Arthritis ([VERA], < 3 months from at onset of clinical manifestations) that fulfilled ACR/ EULAR 2010 criteria (>18 years) from a Mexican cohort recruited from 2015 to 2018 were examined and followed to 3, 6 and 12 months. Patients without presence of rheumatoid factor (RF) and antinuclear protein antibodies (ACPA) were considered SN. Demographic factors, clinical features, disease activity measured using DAS28, functional status evaluated using HAQ, comorbidities and pharmacologic treatments were examined for patients with VESNRA and VESPRA. Charlon’s clinical comorbidities index was used to analyze comorbidities. Chi-square and Student-t test was performed by univariate analysis and logistic regression was used by multivariate analysis, both were adjusted for age and gender. Statistical test were conducted at 5% level of significance.

Results: Of 64 patients with VERA 79% were women. The mean age [standard deviation (SD)] was 49.8 (13.5) years. The mean of time at onset of VERA (SD) was 77.8 (15.5) days. A total of 20 (31.2%) patients had VESNRA. In the unvariable analyses VESNRA patients were more likely to have minor disease activity and better functional status during their follow-up to 3, 6 and 12 months [Table 1]. Moreover, VESNRA patients were more likely to present lesser work disability, lower comorbidities including fibromyalgia, to use fewer sulfasalazine, leflunomide, biologic agents and corticosteroids. As expected, the modified Charlon’s comorbidity index score was lower in VESNRA patients than all their follow-up. In multivariable analyses less frequently use of corticosteroids (OR 0.68, 95% CI 0.42-0.88, p=0.001) remained significant in VESNRA patients.

Conclusion: This study suggests that in very early stage of disease, SN form presents minor disease activity, better functional status, lower comorbidities, also require less aggressive therapy using biologic agents and corticosteroids than SP form in the course of one year. By these clinical and therapeutic differences should be considered VESNRA a mild form of the disease like as ESNRA. These observations must be confirmed in larger studies with further follow-up.

Baropodometric comparison of plantar pressure with knee osteoarthritis patients and rheumatoid arthritis patients

Safia Fellous1, Jihad Moulai Berchik2, Hanan Rkain1, Tahiri Latifa1, Regis Guieu2, Mohammed V University, Rabat, Rabat, Morocco; UMR M2D Faculty of Medicine, Aix-Marseille University, Marseille, marseille, France

Objectives: To compare the plantar pressure between patients with Knee Osteoarthritis and patients with rheumatoid arthritis.

Methods: This is a cross-sectional study, included 41 patients with rheumatoid arthritis (87.8% female, mean age 49 ± 11.9 [27-83] years, median duration of evolution was 9.4 [2.01] months, and 40 knee osteoarthritis patients (100% female, mean age 57.6 ± 5.2 [50-67] years, median evolution time was 36 [24, 69] months). The two groups were matched by BMI (27.5 vs. 29.6, p > 0.05).

In the rheumatoid arthritis group: The mean DAS28 was 3.9 ± 1.3 [2-6] and the knee joint was affected in 22% of cases.

In the knee osteoarthritis group: The knee osteoarthritis is bilateral in 80% of the cases and the radiological severity (Stages 3 or 4 of Kellgren and Lawrence classification) was found in 27.5%.

The baropodometric study was performed using the PRESSCAM® platform (SIDAS®, 38,000 VOIRON, MEDICAPTEURS®). The static analysis was done in free position, for 30 seconds at 50 Hz with measure of plantar pressure parameters.

P significant sisd.05; Test utilisé : t-student

Conclusion: This comparative static baropodometric study of patients with RA and patients with knee osteoarthritis shows significant differences in bearing surface, which appears to be lower in the RA group, especially in the forefoot. The thrust on the forefoot is also less important in the RA group.

These results could be explained by the rheumatoid forefoot, which decreased support and pressure on the forefoot.

La paz, Madrid, Spain; 34. H.U. Negrín, Gran Canaria, Spain; 35. H. Son Espases, Palma de Mallorca, Spain; 36. H. Salamanca, Salamanca, Spain.

Background: Intestinal Lung Disease (ILD) is a severe extraarticular manifestation of rheumatoid arthritis (RA).

Objectives: Our aim was to assess the efficacy of abatacept (ABA) in RA patients with ILD.

Methods: Retrospective multicenter study of RA patients with ILD treated with ABA. ILD was diagnosed by HRCT. We have analyzed the following variables: a) 1-point change the Modified Medical Research Council (MMRC); b) FVC improvement ≥10%; and improvement ≥10% in DLCO; c) radiological improvement in HRCT scan; d) changes in DAS28 score. Values were compared with baseline e) prednisone doses.

Results: We studied 181 patients (94women/87 men) with ILD associated to RA. The follow-up was 12.1[6.2-24.1] months. The mean age was 64.54 ± 9.7 years. The median to progression of ILD was 12 [3-43.75] months. 81 patients were treated in monotherapy, 100 patients in combination therapy. The most frequent pattern was UIP 45,3%. The most of patients who did not have dyspnea remained asymptomatic. See results in Figure1. DAS28 also improved. We appreciate a decrease in the dose of prednisone compared to the initial dose.

Conclusion: ABA seems to be effective. However, should be verified in prospective and randomized studies.

AB0321 MORTALITY AND COMPLICATION OF PATIENTS WITH RHEUMATOID ARTHRITIS ADMITTED TO INTENSIVE CARE UNIT IN KYUSHU UNIVERSITY HOSPITAL
Toshimaru Fujimura1,2, Yukiyo Akasaki1, Yasaharu Nakashima1,3, Yuki Nishikawa1,3,1, Kyushu University Hospital, Orthopaedic Surgery, Fukuoka, Japan; 2, Kyushu University Hospital, Emergency and Critical Care Center, Fukuoka, Japan.

Background: The patients with rheumatoid arthritis (RA) are associated with high mortality caused by comorbidity and complication, and are often required the intensive treatment. Severe infections are among the most common causes of their mortality in intensive care unit (ICU)12).

Objectives: To determine prognostic factors and mortality in patients with RA, including juvenile idiopathic arthritis (JIA), admitted to the ICU in Kyushu University Hospital, we examined the treatments of RA and JIA, comorbidities, complications, the reasons admitted to the ICU, intensive treatments, mortalities within 30 days, 90 days, and a year.

Methods: Between January 2008 and March 2018, 70 patients (20 males, 50 females) with RA (68) or JIA (2) staying at the ICU of our institution for 48 hours and over were included in this study. The admission to the ICU were performed total 77 of times because 5 patients were readmitted. The average of age and RA duration at the admission was 65.8±17.7 years (5-96) and 13.5±14.8 years (0-61), respectively, and the average of follow-up duration was 879.9±992.0 days (3-3988).

Results: The mortality within 30 and 90 days were 21.4% (15/70) and 35.7% (25/70) respectively, and 24 of 65 patients (36.9%), excluded 5 fort death within 30 days, 90 days, and a year. The average of age and RA duration at the admission was 65.8±17.7 years (5-96) and 13.5±14.8 years (0-61), respectively, and the average of follow-up duration was 879.9±992.0 days (3-3988).

Conclusion: Of admission of ICU were significantly poorer prognoses. Of admission of ICU were performed total 77 of times because 5 patients were readmitted. The average of age and RA duration at the admission was 65.8±17.7 years (5-96) and 13.5±14.8 years (0-61), respectively, and the average of follow-up duration was 879.9±992.0 days (3-3988).

AB0322 BIOMASS SMOKE EXPOSURE LINKED TO HIGHER ACPA LEVELS IN MEXICAN-MESTIZO RA-PATIENTS
Doricio Ángel Galarza-Delgado1, Iris Jazmín Colunga-Pedrada1, José Ramón Azpíri-López2, Ileana Cecilia Reynosa-Silva1, Raymundo Pineda2, Karla Paola Cuéllar-Calderón1, Martelka Castro-González3, Carolina Marielene Martínez-Flores3, Alberto Cárdenas3,1, Hospital Universitario "Dr. José Eleuterio González". UANL, Rheumatology, Monterrey, Mexico; 2, Hospital Universitario "Dr. José Eleuterio González". UANL, Rheumatology, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory, autoimmune disease of the joints. Current classification criteria for RA diagnosis require the presence of either rheumatoid factor (RF) or anti-citrullinated protein antibodies (ACPA). These have also been linked to chronic air pollutants exposure, such as tobacco smoke and biomass fuel smoke. Patients with COPD and biomass exposure have higher levels of ACPA (1). Nearly 50% of the world’s population still rely on biomass fuels for cooking, heating and industry, especially in low-income countries (2).

Objectives: To investigate the prevalence of biomass exposure in a cohort of Mexican-mestizo RA-subjects, and the effect of it in their RF and ACPA levels.

Methods: A cross-sectional, observational trial with RA-subjects that fulfilled the 2010 ACR/EULAR classification criteria, recruited at a rheumatology clinic in northeastern Mexico. Patient evaluation included a complete clinical history, somatology, and blood samples to measure hs-CRP, RF isotypes (IgA, IgG, IgM) and ACPA. Biomass exposure was documented using the biomass exposure index (BEI), defined as: average hours exposed per day multiplied by years of exposure. Descriptive analysis was done using frequencies (%) and median values (q25-q75). Subjects were divided into 3 groups according to their BEI: non-exposed, BEI <30 and BEI >30. Comparisons were done by Chi-square and Kruskal-Wallis test and correlation by Spearman’s rho test.

Results: A total of 285 subjects were included, 154 (54%) of them had history of exposure. Comparisons are shown in Table 1. A significant difference in age was found (p=0.006), this being caused by a difference between the BEI=0 and BEI >30 groups (p=0.001). We also found a higher prevalence of dyslipidemia and hypertension in subjects with a BEI >30 (p=0.05). A significant correlation between a rising BEI and a higher value of ACPA (rho>0.14, p=0.016) was found; this correlation was not found with any subtype of RF (p>0.05).

Table 1. Demographic and clinical characteristics of RA according to ACPA groups.

Conclusion: In our cohort of Mexican-mestizo RA subjects, 54% had positive biomass exposure. Subjects with a BEI >30 were older and had a higher prevalence of dyslipidemia and hypertension. A significant correlation was found between higher BEI index and a higher value of ACPA antibodies.
AB0324 CARDIOVASCULAR RISK ESTIMATION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS OR C-DMARDS

Evangelia Mole1, Soussana Gazi1, Dimitra Moschou1, Georgia Mpaï1, Stavros Theodorakopoulou1, Konstantina Zioupidou1, Nikolaos Kontodimopoulos2, 11Hospital General de Attica, Department of Rheumatology, Athens, Greece; 2KAT General Hospital of Attica, Division of Management, Athens, Greece

Background: Patients with Rheumatoid Arthritis (RA) are at increased risk of developing atherosclerotic cardiovascular (CV) disease. The impact of treatment with conventional or biological disease modifying drugs (c- or b-DMARDs) on inflammation of systemic circulation is an important question.

Objectives: The aim of this study is to determine the influence of therapy (c-DMARDs or b-DMARDs) on 10 year CV risk in patients with RA, over a period of 18 months.

Methods: A single center, observational study of 229 consecutive RA patients who were treated with c-DMARDs or b-DMARDs mono/combination therapy for at least 18 months. The 10 year CV risk was calculated with Framingham risk score (FRS).

Results: A total of 229 patients were included, 111 received b-DMARDs and 194 c-DMARDs. The mean age was comparable between 2 groups (62.45±12.74 vs 64.56±12.48 years, p=0.1596) and 148 (64.63%) were female. Patients receiving b-DMARDs had longer disease duration compared to c-DMARDs group (14.34±9.89 vs 9.99±9.3 years respectively, p=0.001) and comparable baseline FRS 10-year percent CV risk (10.74±8.8 vs 11.68±8.78 respectively, p=0.371). Baseline patient distribution across intermediate (9.6% vs 16.6%) and high (10.91% vs 16.16%) FRS 10-year CV risk categories was comparable between treatment groups (b-DMARDs vs c-DMARDs: p=0.208), except low FRS category (27.51% vs 51.53% respectively, p=0.001). At month 18, FRS 10-year CV risk category remained stable in b-DMARDs patients (low: 31.88%, intermediate: 10.92%, high: 5.24%, p=0.47), whereas a significant shift in FRS 10-year CV risk category was observed in c-DMARDs patients (low: 58.1%, intermediate: 17.03%, high: 9.17%, p=0.001). Within-group the mean (SD) change in FRS 10-year percent CV risk from baseline to month 18 was statistically significant for both b-DMARDs (Δ= 10.74-8.94= 1.8 (1.14), p=0.001) and c-DMARDs (Δ = 11.68-8.78= 2.95 (0.91), p=0.001).

Conclusion: Patients treated with b-DMARDs had lower baseline and month 18 10-year CV risk. However, both treatment arms induced significant improvement of 10-year CV risk at 18 months.

AB0325 PREVALENCE OF ANXIETY/DEPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS AT THE UNIVERSITY OF CHILE’S CLINICAL HOSPITAL AND THEIR ASSOCIATIONS WITH DISEASE ACTIVITY INDEXES AND QUALITY OF LIFE

Ann Marie Chassin-Troubern1, Cesar Lillo1, Stephanie Prieto1, Ariel Castro1, Hector Galica1, Pilar Carrasco2, Francisca Bozan3, Francisca Sabugo4, Pamela Wurmman1, Julio Cruz1, Silvana Saavedra1, Annette Goecke1, 1Hospital Clínico Universidad de Chile, Rheumatology, Santiago, Chile; 2Hospital Clínico Universidad de Chile, Rheumatology, Santiago, Chile; 3Hospital Clínico Universidad de Chile, OAC, Santiago, Chile

Background: Rheumatoid Arthritis is a chronic inflammatory disease with great impact in quality of life. Anxiety and depression could be frequently present in RA patients and may impact the disease activity evaluation. However psychological evaluation or therapy are not part of the standard care of RA patients.

Objectives: To evaluate the prevalence of anxiety/depression in rheumatoid arthritis patients in control at the University of Chile’s Clinical Hospital and to investigate the association of anxiety/depression with disease activity and quality of life.

Methods: The Hospital Anxiety Depression Scale (HADS) was applied to measure depression and anxiety in a cross-section patients with RA meeting the ACR/EULAR 2010 criteria in control at the University of Chile’s Clinical Hospital. All patients included gave their informed consent. Demographic characteristics, Disease variables and activity, measure as DAS28-VHS, DAS-28 CRP, CDAI and SDAI and HAQ were evaluated at the same time. Spearman correlation, Fisher exact test, Chi-Square and Kruskal-Wallis test were used according to variables at evaluation. Statistical analysis was performed by Stata v12.1 software. The study was approved by the Hospital Ethic Review board.

Results: 122 patients were enrolled in the study between december 2017 and December 2018. 103 (84.45%) were female. 56 (46%) had depression and/or anxiety according to HADS. 24% of the patients (n=24) had only depression. The severity of the depression symptoms was mild in 71%, moderate in 21% and severe in 8% of the patients. 42%, 40% and 18% of the patients with anxiety (n=55) had mild, moderate and severe anxiety symptoms respectively. The disease activity was significantly higher in patients with as compared to those without anxiety/depression, measured with all of the following indexes: DAS28-VHS (4.33 vs 2.75, p<0.001), DAS-28 CRP (4.13 vs 2.75, p<0.001), CDAI (15 vs 7 p<0.001)and SDAI (17 vs 7.5, p<0.001). The HAQ was also significantly higher in patients with anxiety/depression (1.18 vs 0.29, p<0.01

REFERENCE

Disclosure of Interests: None declared
Conclusion: Depression/anxiety symptoms was very frequent in our cohort of RA patients. The disease activity measure with different indexes and the HAQ was significantly higher in the patients with depression/anxiety. It is possible that psychological factors influence the RA treatment outcomes. Therefore counseling and therapy of anxiety and depression should be considered in the regular management of RA patients.

AB0326 RECOGNITION AND IMPLEMENTATION OF EULAR RECOMMENDATIONS FOR RHEUMATOID ARTHRITIS/CARDIOVASCULAR RISK MANAGEMENT AMONG INTERNAL MEDICINE AND RHEUMATOLOGY FELLOWS: DATA FROM AN ACADEMIC TERTIARY CARE LEVEL CENTER

Guillermo Guarcha-Basáñez1, 2, Jesús Contreras-Yáñez2, 1, Alfonso Guías-Herrero2, Virgilia De Pascual1, 2 Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, 1Department of Immunology and Rheumatology, Mexico City, Mexico; 2Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Department of Internal Medicine, Mexico City, Mexico

Background: Rheumatoid arthritis (RA) patients present an increased risk of cardiovascular (CV) morbidity and mortality compared to the general population. Patients from Latin-America present distinctive features and some of them are relevant when assessing CV risk. EULAR recommendations include CV risk assessment for all the patients at least once every 5 years and its reconsideration following major changes in anti-rheumatic therapy. Importantly, failure to identify and manage CV comorbidity in RA patients has been recognized by rheumatologists, although there is no information in Latin-America.

Objectives: To investigate knowledge about EULAR recommendations for RA-CV risk assessment/management (K-EULAR-R) among internal medicine and rheumatology fellows from an academic and tertiary care level center, to identify physician’s perception about responsible(s) for CV risk assessments and about major barriers to perform the assessments and to investigate the appropriated identification of major CV risk factors. Potential differences among both group of trainees were additionally investigated.

Methods: Internal medicine fellows (N=105, 1st to 4th grade participants were represented) and rheumatology fellows (N=10, 4 from first grade and 6 from second grade) were invited to anonymously answer a questionnaire designed by 2 investigators to investigate K-EULAR-R and integrated by 11 items classified in 3 categories: “general knowledge about CV risk in RA patients” (4 items), “timing of CV risk assessment” (4 items) and “appropriated statin use” (3 items). In addition, fellows were directed to select and rate main responsible for CV risk assessment (5 options), major barriers to apply EULAR recommendations (6 options), and to properly identify CV risk factors (20 options). After questionnaire completion, an overall-CV-knowledge-Likert scale (superior, borderline or inferior) was assigned to each participant by an independent observer. The study received IRB approval. Descriptive statistic was used and questionnaire was scored to a decimal scale.

Results: Ninety-three (85%) internal medicine fellows and 10 (100%) rheumatology fellows participated. Rheumatology fellows scored higher in the K-EULAR-R questionnaire when compared to internal medicine fellows (6.9±1.4 vs. 5.5±1.4, p=0.004) and the higher score was replicated in the category of “general knowledge about CV risk” (8.3±2.0 vs 5.3±2.5, p=0.001), meanwhile no differences were detected in the scoring of the categories “timing of CV risk assessment” and “appropriated statin use”.

No differences among grades within each group were identified.

The majority of the rheumatology fellows rated themselves as the specialist responsible for CV risk assessment (80%); meanwhile this percentage decreased to 45.7% among the internal medicine fellows (p=0.084); fellows from both groups identified lack of time during rheumatic evaluations and the main barrier to perform CV risk assessment (80% and 57%, respectively).

Adequate CV risk factor identification varied from 30% (for contraceptive use) to 100% (for smoking habit), and these were similar among both groups. Up to 82.5% of the fellows identified incorrectly ≥ 1 CV risk factor and high serum triglyceride levels was the highest (49%).

Conclusion: Knowledge about CV risk management in RA patients was suboptimal among trainees in internal medicine and rheumatology from an academic and tertiary care level center in Mexico City; trainees in rheumatology performed better. There is a need to reinforce the topic during fellows’ residency.

AB0327 RHEUMATOID ARTHRITIS PATIENTS HAVE VITAMIN D DEFICIENCY COMPARED TO AGE SEX MATCHED CONTROL. WHAT CONTRIBUTE TO THIS DEFICIENCY?

Suad Hannawi1, Haifa Hannawi2, Issa Al Salmi3, 1Ministry of Health and Prevention, Rheumatology, Dubai, United Arab Emirates; 2Ministry of Health and Prevention, Dubai, United Arab Emirates; 3The Royal Hospital, Muscat, Oman

Background: Vitamin-D (vit-D) is believed to have an immunomodulatory and anti-inflammatory role. Low vit-D has been proved to increase susceptibility to the development and to increase the inflammatory activities of rheumatoid arthritis (RA). This study looked at 25-vit-D level in RA patients and in their matched age and sex controls, and investigated what contribute to the risk of low 25-vit-D in RA.

Objectives: The study looked at RA diseases activities, renal function, demographic features and blood biochemistry relation to 25-vit-D level.

Methods: 62 RA patients and 82 control were recruited for the study. 25-vit-D level, RA diseases activity parameters and blood biochemistry (full blood count, liver function test, and renal profile) were obtained on the same day. Estimated glomerular filtration rate (eGFR) calculated with Modification of Diet in Renal Disease (MDRD) formula. Body mass index (BMI) calculated as mass (kg)/Height (m)2. Univariate regression analysis was carried out to determine the relationship between 25-vit-D level and all the parameters of interest (as above).

Results: 65 RA, and 82 controls matching for age (48±13 years for RA, and 47±14 years for the controls, p=0.58) and sex (57 F (88%), M=8 (12%) RA, 67 F (82%), 5 M (18%) controls, p=0.23) were included for the study. The mean 25-vit-D level was 413±31 nmol/l for the RA patients (normal range: 50-80), and 52±3 nmol/l for the controls (p=0.03).

Univariate linear regression among RA patients revealed a positive linear relationship between 25-vit-D level and age of the patients (p=0.02, CI: 0.04, 0.13), BMI (p=0.01, CI: 0.13, 0.96), body surface area (p=0.02, CI: 9.47, 111), body mass index (BMI) (p=0.03, CI: 0.17, 3.18), and calcium level (p=0.04, CI: 1.38, 69.6). 25-vit-D level was negatively associated with eGFR (p=0.04, CI: 0.20, -0.01), microalbuminuriuma level (p=0.03, CI: -0.26, -0.00), and CRP level (p=0.03, CI: -0.47, -0.0).

Conclusion: Vit-D receptors are present in most cells in the body and in the T and B lymphocytes. The active form of vit-D (1, 25 vit-D) is one of the most potent modulators of the immune system. Hence, the negative relationship between 25-vit-D and CRP support 25-vit-D deficiency role in the exacerbation of the inflammatory status, and possibly in the subclinical renal impairment; as shown by the negative association between eGFR and the 25-vit-D. The relation between the subclinical renal impairment and the vit-D deficiency is further supported by the negative linear relationship between 25-vit-D and the urine microalbuminuria level and the positive linear relationship association between 25-vit-D and the serum creatinine level. The positive association between 25-vit-D and the age of the patients might reflect the awareness of the older population about the importance of sun exposure for health. Screening for vit-D deficiency might be an important step to detect subclinical renal insufficiency in RA. Vit-D supplement might help in ameliorating the inflammation of RA and the subclinical renal impairment especially its well known that our general population is already Vit-D deficient and this worsen by the inflammatory conditions that they develop.

AB0328  SECONDARY SARCOPENIA IN RHEUMATOID ARTHRITIS PATIENTS TREATED BY BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS

Eriko Hasegawa1,2, Satoshi Ito3, Yoichi Kurosawa2,3, Daisuke Kobayashi1, Asami Abe1, Hiroshi Otani1, Kiyoshi Nakazono2, Akira Murasawa2, Ichie Narita1, Hajime Ishikawa3, 1Niigata Rheumatic Center, Department of Rheumatology, Shibata City, Japan; 2Niigata University Graduate School of Medical and Dental Sciences, Division of Clinical Nephrology and Rheumatology, Niigata City, Japan; 3Nagoya Rheumatic Center, Department of Rheumatology, Shibata City, Japan

Background: Sarcopenia is characterized by a loss of muscle mass and strength, which leads to a reduced physical ability, poor quality of life (QoL), frailty and mortality. Rheumatoid arthritis (RA) is considered a cause of secondary sarcopenia.

Objectives: To clarify the effectiveness of biologic disease-modifying anti-rheumatic drugs (bDMARDs) on sarcopenia, including the physical ability, body composition and nutritional status.

Methods: This was a prospective cohort study including consecutive 41 patients (11 men, 30 women, 63±16.1 years old) with RA who started bDMARDs for the first time at the Niigata Rheumatic Center. The diagnosis of secondary sarcopenia was made according to the diagnostic algorithm of the Asian Working Group for Sarcopenia (AWGS), excluding the criteria about older age. We observed the disease activity of RA, physical ability, body composition, nutritional status and QoL at baseline and 6 months. The disease activity was assessed by the disease activity score-28 (DAS28) and clinical disease activity index (CDAI). The physical activity was determined using the health assessment questionnaire (HAQ), 10-m walking test (10MWT) and timed up and go test (TUG). The nutritional status was determined based on the controlling nutrition status (CONUT) score and prognostic nutritional index (PNI). The overall QoL was measured by European quality of life scale-5 dimensions (EQ-SD).

Results: Among 41 patients who started bDMARDs, 19 were classified as having sarcopenia, and 7 were classified as having pre-sarcopenia. The bDMARD was certolizumab pegol in 10 patients, adalimumab in 7, abatacept in 7, golimumab in 6, tocilizumab in 5, infliximab in 3 and etanercept in 2 patients. Regarding the disease activity, the DAS28 was 4.7±1.3 vs. 2.6±1.3, p<0.001) and CDAI (18±6.9 vs. 7.2±7.3, p=0.001) decreased significantly after 6 months of bDMARD therapy. The physical activity was significantly improved after 6 months of bDMARDs: HAQ (1.1±0.9 vs. 0.7±0.9, p=0.001), 10MWT (1.8±0.7 vs. 1.6±0.6 m/s, p=0.046) and TUG (10.5±5.0 vs. 9.5±6.2 s, p=0.024). Regarding the nutritional status, the CONUT score (3.8±0.5 vs. 2.8±0.5, p=0.001) and PNI (44.9±6.4 vs. 49.7±4.1, p=0.001) were significantly improved after 6 months of bDMARDs. The EQSD was also improved after 6 months of bDMARDs (0.64±0.15 vs. 0.71±0.20, p=0.010). The body composition analysis showed a significant increase in the body weight (54.3±13.2 vs. 55.4±14.4 kg, p=0.006) and fat mass (16.3±7.3 vs. 17.4±7.8 kg, p=0.001) after 6 months of bDMARDs but no significant increase in the appendicular skeletal muscle mass (14.7±4.3 vs. 14.8±4.5, p=0.111). The proportion of patients classified as having sarcopenia showed a decreasing trend after 6 months of bDMARDs therapy (46.3% vs. 24.4%, p=0.0637).

Conclusion: After 6 months of bDMARDs therapy, the physical ability, nutritional status and QoL were significantly ameliorated. While the muscle mass was not markedly increased, the proportion of patients with sarcopenia showed a decreasing trend. The administration of bDMARDs might be useful for preventing secondary sarcopenia in RA patients.

AB0329  CERVICAL SPINE INVOLVEMENT IN RHEUMATOID ARTHRITIS

Zsofia Kardos1, Csaba Oláh1, László Kostylá1, Katain Hodosi2, László Tamás1, Zoltán Szekanecz2, 1Borsod County Hospital, Miskolc; Hungary; 2University of Debrecen, Debrecen, Hungary

Background: After the small peripheral joints, the cervical spine is the second most involved region in rheumatoid arthritis (RA). The most frequent radiological features are the atlantoaxial subluxation (AAS) which can be anterior, posterior or vertical. During the course of the disease, the affection of the cervical spine has no symptoms for a long time due to the adaptability of neurological structures. The onset of myelopathy can occur at any time. MRI assessment compared to functional cervical spine X-ray is more sensitive method to provide not only AAS but also soft tissue involvement such as periodontal synovitis or fibrous pannus and even more odontoid erosion. New data show that there is a decreasing prevalence of cervical involvement because of the biologics.

Objectives: We assessed RA patients in permanent remission with MRI imaging. RA patients have no cervical pain or any neurological symptoms. We wished to explore the cervical spine involvement: AAS, odontoid erosion or periodontal soft tissue thickening. We also wished to determine the affection of cervical spine in RA patients receiving different treatment strategies.

Methods: Altogether 49 RA female patients were included. Among them, 15 were MTX-treated, biologic-free, 34 patients received biologics (17 infliximab [IFX] and 17 tocilizumab [TCZ]) as first-line biologic treatment, in combination with MTX. There was no significant difference between the main characteristics of these subgroups. ESR, CRP and DAS28 were determined in all RA patients in every 3 months. We calculated sumESR, sumCRP and sumDAS28 indices from the past 3 years.

Results: We detected anterior AAS in one-quarter of RA patients (13 affected patients from the total 49) (26.5%). There was no significant difference between the therapeutic subgroups. No posterior or vertical AAS occurred. Compared with patients without cervical involvement, the patients with AAS showed higher sumCRP and sumESR levels, higher sumDAS28 scores and more frequent seropositivity, but these differences were not significant. Soft tissue involvement of the cervical spine was detected in 33.3% of MTX-treated, in 35.3% of IFX-treated and in 5.9% of TCZ-treated RA patients. Eight RA patients had odontoid erosion (4.1%) and 3 from the MTX, 2 from the IFX and 3 from the TCZ-treated subgroups. In relation to soft tissue involvement and odontoid erosion we did not find any correlation with age, disease duration, seropositivity, sumESR, sumCRP or sumDAS28 indices.

Conclusion: These findings suggest that the presence of cervical involvement in RA patients is an important and frequent phenomenon even in asymptomatic patients. Higher ACPA titer, high disease activity and erosive disease at baseline are predictors of atlantoaxial involvement. With the appropriate disease control with conventional or biologic treatment, progression of cervical spine involvement can also be prevented.

RELATIONSHIP BETWEEN FOREFOOT SYNOVITIS IN RHEUMATOID ARTHRITIS AND WORSENING FOREFOOT DEFORMITY

Takeshi Kishiwada1, Moto Kobayashi2, Masakazu Urayama3, Natsumi Konishi4, Hiroki Ifo5, Takayuki Tanii6, Yoshiaki Aizawa7, Hidetsugu Abe8, Norio Suzuki9, Keiji Kakemi10, Hiroshi Aonuma11, Yusuke Sugimura11, Tetsuya Kawanoue11, Yasuaki Ifo7, Takahiro Kawanoue11

Background: While the number of rheumatoid arthritis (RA) surgeries has been declining due to advances in pharmacotherapies for RA, forefoot surgeries are on the rise. In recent years, the common use of joint ultrasonography in RA consultations has led to the early detection of synovitis. However, little is known about how much forefoot deformities such as hallux valgus and metatarsophalangeal (MTP) joint dislocation are affected by synovitis in the forefoot of RA patients.

Objectives: The present study examined factors involved in forefoot deformity among patients with foot synovitis identified on joint ultrasound.

Methods: Subjects (71 patients, 91 feet) were RA patients who had undergone foot joint ultrasonography more than 2 years earlier and underwent standing X-rays of the feet before and after ultrasonography. Surgery cases were excluded. Mean age was 64.9 years (range, 15–90 years). Disease stage was Stage 1 in 14 patients, Stage 2 in 14 patients, Stage 3 in 16 patients, and Stage 4 in 27 patients. According to the Steinbrocker functional classification, RA was Class 1 in 45 patients, Class 2 in 19 patients, Class 3 in 6 patients and Class 4 in 1 patient. Twenty-five patients had been administered biological drugs. At the time of joint ultrasonography, patients were questioned regarding whether they had any complaints involving the forefoot, midfoot or hindfoot (noted separately). The following scans were performed: forefoot (MTP joints 1-5); midfoot (calcaneocuboid, calcaneocuboid and cuneonavicular joints) and hindfoot (peroneal muscle tendon, talocrural joint, talocalcaneal joint and posterior talo-fibular ligament). Foot deformity score (FDS) (hallux valgus angle + first-second intermetatarsal angle [M1M2 angle] + first-fifth intermetatarsal angle [M5M1 angle]) was used as the benchmark for forefoot deformity, and an increase >5° was considered to indicate worsening deformity.

Results: Forefoot deformity had progressed in 25 patients. Mid- and hindfoot synovitis and the presence of complaints were not associated with deformity. However, significant worsening of FDS was observed in patients with foot synovitis or foot complaints. While no difference in age, disease activity, biological disease-modifying antirheumatic drug usage or health assessment questionnaire results were seen in the advanced deformity group, duration of disease was significantly shorter in this group.

Conclusion: Mid- and hindfoot synovitis was unrelated to forefoot deformity. MTP joint synovitis in the forefoot was related to forefoot deformity. Continuous synovitis in the forefoot must damage the articular capsule and ligament structure, leading to progression of deformity. As shown by the short duration of the disease in the advanced deformity group, deformity may progress in the early stages among patients with forefoot deformity.

DEPRESSION AND ANXIETY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Waruancha Katchamart1, Pongthong Nonroengkaiw2, Warwisra Chanrapai3, Phakhamon Thaweeratthakul3

Division of Rheumatology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Division of Rheumatology, Department of Medicine, Phramongkutkla Hospital and College of Medicine, Bangkok, Thailand, Bangkok, Thailand

Division of Clinical Trials, Research Department, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand

Background: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease leading to substantial morbidity and mortality and had a major economic and psychological impact on individuals with RA and their families. The prevalence of depressive disorder in RA was 17% and associated with poorer outcomes.

Objectives: To evaluate prevalence of depression and anxiety and their related factors in patients with RA.

Methods: In this cross-sectional study, 464 patients with RA from two RA registries, the Siriraj Rheumatoid Arthritis (SIRA) registry and the Thai Army Rheumatoid Arthritis Cohort (TARAC) were enrolled. Demographic data and clinical variables, including disease activity, functional status, health-related quality of life, and cognitive function, were collected. Depression and anxiety were assessed using the Thai version of the Hospital Anxiety and Depression Scale (Thai HADS).

Results: Based on the Thai HADS cutoff value of more than 8 out of 21, 12.5% and 14.5% had some degrees of depression and anxiety, respectively. The proportion of depression and anxiety elevated with increasing disease activity or worsening functional status. However, in multivariate analyses, only global health [RR (95% CI) 0.98 (0.96 – 0.99), p 0.001] was negatively associated with depression, after adjusted for covariate. For anxiety, functional disability [RR (95% CI) 2.46 (1.33 - 4.54), p 0.004] and marital status [married: RR (95% CI) 2.43 (1.25 - 4.73), p 0.008] significantly increased the risk, while disease duration 10 years or more [RR (95% CI) 0.45 (0.25 - 0.80), p 0.007] and global health [RR (95% CI) 0.97 (0.95 - 0.98), p < 0.001] decreased this risk.

Conclusion: Depression and anxiety is common in patients with RA. Patients’ perception of their current health is significantly related to mood disorders. Therefore, mental health status, especially mood disturbances, should be addressed in routine practice to improve quality of life in RA.

CLINICAL FEATURES AND RISK FACTORS OF CHRONIC HEART FAILURE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS PRIOR TO THERAPY WITH BASIC ANTI-INFLAMMATORY DRUGS

Jinia Keikyova1, Diana Novikova1, Tatiana Popkova1, Eugenia Markelova1, Helen Udachkina1, Yulia Gorbunova1, Maria Cherkasova2

1Division of Rheumatology, Department of Medicine, Faculty of Medicine, Phramongkutkla Hospital and College of Medicine, Bangkok, Thailand, Bangkok, Thailand

2Division of Clinical Trials, Research Department, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand

Background: Heart failure (HF) is a major cause of premature mortality, there is little information regarding its prevalence and associated risk factors in patients (pts) with early rheumatoid arthritis (RA).

Objectives: to study the frequency, clinical manifestations and risk factors associated with the development of HF in pts with early RA prior to therapy with basic anti-inflammatory drugs.

Methods: A total of 74 pts with early RA (ACR/EULAR criteria, 2010) were included in the study: 78% of women, median (Me) age - 56 years [47; 61], Me of disease duration - 7 [4;6] months; Me DAS28 5.3 [5.0;6.2], IgM RF seropositive (87%) and/or ACPA (100%), without any experience of administration of disease-modifying antirheumatic drugs and glucocorticoids. All pts underwent blood pressure monitoring, echocardiography, tissue Doppler imaging, NT-proBNP. The normal range for NT-proBNP was less than 125 pg/ml. HF was diagnosed according to the recommendations of the European Society of Cardiology (2012).

Results: HF was diagnosed in 24 (33%) pts: in 23 pts - HF with preserved ejection function (EF), in 1 pts - HF with reduced EF. Dyspnea was detected in 21 (87%) RA pts with HF (positive predictive value (PPV)-33%), in 6 (25%) - ankle edema (PPV-35%), in 24 (100%) - fatigue (PPV-38%). In 5 (21%) pts dyspnea NYHA=2 was observed, 15 (63%) - NYHA=3, in 1 (4%) - NYHA=4. Diastolic dysfunction of the left ventricle was detected in all pts with HF (PPV-95%). Elevated NT-proBNP level wasn’t highly indicative for HF in early RA (PPV-41%). All pts with early RA were divided into 2 groups: 1- with HF, 2- without HF. Pts with RA and HF were older (61 [58;65] vs 51 [36;56] years), had higher BMI (28 [25;32] vs 24 [22;29] kg/m², p=0.05). NT-proBNP level (192.0 [159.8;265.7] vs 77.0 [41.1;191.2] pg/ml, p=0.05), more likely to have arterial hypertension (AH) (83% vs 51%, p<0.05), carotid atherosclerosis (91% vs 48%, p<0.05), coronary artery disease (CAD) (40% vs 8% vs 20%, p<0.05).
EFFECT OF OBESITY ON THE COURSE OF THE OVARIAN RESERVE MEASURING THE ANTI-MÜLLERIAN HORMONE IS NOT DIMINISHED IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARED TO THE HEALTHY POPULATION

Minis Lopez Corbató1, Andrea Pluma Sanjurjo2, Sergio Hílaro Martinez2, María López Lascasanta1, Águeda Sellas-Fernández2, Sara March2, Hospital Universitari Vall d’Hebron, Rheumatology, Barcelona, Spain; 2Parc Científic de Barcelona, Barcelona, Spain; 3Hospital Vall d’Hebron, Rheumatology, Barcelona, Spain

Background: Rheumatoid Arthritis (RA) is the most prevalent chronic inflammatory arthritis, affecting 0.5-1% worldwide population and predominates in females. Altered fertility has been reported due to a decrease in ovarian reserve secondary to sustained inflammation. The anti-Müllerian Hormone (AMH) is currently the most reliable biomarker of ovarian reserve. However, few and contradictory studies have been reported to analyze the relationship between fertility in RA women patients and AMH.

Objectives: The aim of present study is to determine the AMH serum concentrations in a long-standing RA patients and control group. We also sought to determine the correlation between AMH serum levels and disease activity measured by different parameters and the effect of biological DMARDs.

Methods: Serum AMH levels were measured in 60 women with long-standing RA aged 20-50 y.o. and compared to 59 healthy women. AMH was assessed by ELISA (Gen II Beckman Coulter Inc.) and a large data set of clinical and molecular data was annotated. Demographic parameters, RA disease activity measured by DAS28 score and inflammatory biomarkers such as ESR, CRP, lymphocyte CD4+, CD8+, NK cells, IL-10 and IL-6 were determined. A comprehensive gynecological self-administered questionnaire was given. Serum AMH levels were age-correlated. Differences between groups were calculated using Student’s t-test or Mann-Whitney U test for continuous variables and Fisher’s exact test for categorical variables. Multivariate analysis was conducted by the partial correlation coefficient. Linear regression analysis was performed to study the effect of different variables on proportional AMH change. P value <0.005 were considered significant.

Results: The median age was similar in AR and control groups (37.4 ±6.23 vs 37.3 ±6.27, P=0.937). Mean disease duration was 8.37±5.36 years. The number of previous treatments was <3 in 71.7% of patients and >3 in 28.3%. Disease activity measured by DAS28 was 2.8±1.54. The age-adjusted mean serum concentration of HAM was 1.27 ng/ml [IQR 0.42; 2.24] in RA patients and 1.31 ng/ml [IQR 0.46; 3.09] in controls (P=0.608). Neither disease activity (P=0.862), nor current or previous biDMARDs treatments (P=0.871) were associated with HAM levels. However, a negative linear correlation was observed between HAM and IL-10 levels (P= 0.033).

Conclusion: Our study shows that ovarian reserve determined by HAM serum levels is not reduced in rheumatoid arthritis patients compared with healthy controls. In our series, HAM levels were not affected by disease activity however a significant correlation was observed between HAM and IL-10 levels. These results support the role of cytokines profile in the female reproductive system and will focus further investigations in this critical area, mainly once biological DMARDs have been recommended in RA pregnant patients.

AB0335  THE CORRELATION OF CORRELATION OF TH17 AND TREG CELL LEVELS OF IN CORONARY HEART DISEASE PATIENTS WITH RHEUMATOID ARTHRITIS

YUE TENG MA, Sheng Xiao Zhang. Department of rheumatology, the second hospital of shanxi medical university, Department of rheumatology, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a prevalent chronic autoimmune inflammatory disease. Also acute coronary syndrome (ACS) is a prevalent chronic inflammatory disease. Now more and more studies have also shown that coronary heart disease is also associated with immune inflammation. We will discuss Th17 and Treg cell levels in patients with rheumatoid arthritis combined with coronary heart disease and simple rheumatoid joints as well as normal people. Its pathogenesis is closely associated with a failure of endogenous immune tolerance that caused by the imbalance of CD4/CD8. New T subgroup Th17 T lymphocytes play an important role in the occurrence and development of RA and ACS. Moreover, T lymphocytes are one of the first cells to be recruited into atherosclerotic plaques, and most adhesion molecules and chemokines that promote the migration of monocytes to the intima are also related to T cell recruitment. T lymphocytes mainly divided into two major subsets of CD4/CD8, including CD4+ helper cells, which are classified into Th1/Th2 and newly discovered Th17 cells and regulatory T cells subgroups, have the effect of the immune response to promote the immune, and CD8+ play the role of killer cells and suppress the immune response. Similar to CD8, (Treg) lymphocytes can reduce the body’s anti-tumor ability by inhibiting cell contact and the production of inhibitory factors and effect T cells.

Objectives: Through clinical studies, we want to explore whether the proportion of Th17/Treg in peripheral blood of RA with ACS patients is reduced to indicate whether the immune balance is broken, thus providing further data for clinical studies.

Methods: In April 2017 to September 2018 in our hospital, Patients with RA and ACS diagnosed by Coronary angiography in our hospital of 20 cases male:9 female:12 into the research object, the diagnosis of ACS combined with clinical data of 20 patients as Observation group. These patients have been diagnosed with rheumatoid arthritis. Another 20 rheumatoid arthritis patients male:11 female:9 were collected from the rheumatology department of our hospital, and 20 normal healthy people male:10 female:10 were collected from the physical examination center of our hospital, as control group.

Results: Compared with the control group, the proportion of Th17 cells and Treg cells in peripheral blood of RA with ACS increased and decreased respectively (P < 0.05). Compared with the RA group, the proportion of Th17 cells in the peripheral blood of RA with ACS group increased, while the proportion of Treg cells decreased (P < 0.05). The proportion of Th17 cells in RA with ACS group was higher than that in RA group and control group (P < 0.05). Th17/Treg ratio in control group, RA group, ACS and RA groups were respectively compared with the control group. Th17/Treg increased in the RA with ACS and RA groups, and the RA with ACS group was higher than the RA group, with statistically significant differences (P < 0.05), but the ratio between the RA group and the control group was not significant.

Conclusion: Through this rare clinical study, it was found that the levels of Treg cells and Th17 cells in patients with rheumatoid arthritis combined with coronary heart disease were to some extent higher than those in patients with rheumatoid arthritis alone and normal healthy people. We can speculate whether it is possible to find a target for Treg cell Th17 cell levels in patients with RA with ACS expanding the sample study again, so as to intervene as early as possible and regulate the immune balance to avoid the progression of coronary heart disease and adverse cardiovascular events.

AB0336  COMPARATIVE ANALYSIS OF ESTIMATED BONE MASS AND BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE CHIKARA STUDY

KoI Mondal1,2, Yutaro Yamada1, Tatsuya Koke2,4, Tadashi Okano1, Noriaki Hitaka3, Masahiro Tada1,2, Osaka City University Graduate School of Medicine, Orthopaedic Surgery, Osaka, Japan;3 Osaka Social Medical Center Hospital, Orthopaedic Surgery, Osaka, Japan;4 Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan;5 Shirahama Hamayu Hospital, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan;6 Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan

Background: Patients with rheumatoid arthritis (RA) have lower muscle mass and a higher rate of sarcopenia than healthy individuals. The relationship between rheumatoid arthritis and bone loss is well known. Dual energy X-ray absorptiometry (DEXA) and bioelectrical impedance analysis (BIA) are used to diagnose sarcopenia, but the correlation between bone mineral density and estimated bone mass is unknown.

Objectives: To investigate the correlation between bone mineral density and bone mass in RA patients.

Methods: Data from a prospective observational study (CHIKARA study) were analyzed. Bone mineral density (BMD) was measured by DEXA, and bone mass was measured by BIA on the same day, and the correlations between BMD at each measurement site and bone mass were evaluated.
Background: Rheumatoid arthritis (RA) and carpal tunnel syndrome (CTS) are known to be associated and also RA may lead to swelling of the median nerve without the presence of CTS. The prevention of disease progression may prevent the increase in median nerve CSA by preventing deviations in the radial inclination angle.

Methods: A total of 90 RA patients (women, 83%; mean age, 67.2±12.1 years) were included. The median disease duration was 8.5 (interquartile range [IQR]: 4.9, 17) years, the mean DAS28-ESR was 2.92±1.2, and the median MTX dose was 10 (IQR: 8, 12) mg/week. Nineteen patients (21%) used a biologic agent. There was a significant correlation between total hip BMD and bone mass (r=0.64, p<0.001). The details are shown in Figure 1. Bone mass was significantly correlated with femoral neck BMD (r=0.62, p<0.001), whole body BMD (r=0.60, p<0.001), and lumbar BMD (r=0.49, p<0.001). Bone mass was significantly lower by DEXA (1.9 ±0.5 kg) than by BIA (2.0±0.4 kg) (P<0.001).

Results: The study completed with 102 hands of 51 patients. 27% of these RA patients without clinical and electrophysiological findings were diagnosed as CTS by ultrasonography. A negative correlation was found between the radial inclination (RI) and the median CSAs measured from the radioulnar joint (R: -0.49; p: 0.00), the pisiform bone (R: -0.45; p: 0.00), and hook of hamate (R: - 0.60, p: 0.00). When the hands were divided into three groups according to the ranges of RI specified in the literature, the median nerve CSA was found to be significantly higher in the group with a low RI at these levels (p < 0.001).

Conclusion: The median nerve CSAs increased as the radial deviation increased in RA patients. The prevention of disease progression may prevent the increase in median nerve CSA by preventing deviations in patients with RA. And the development of CTS may also be prevented.

Disclosure of Interests: None declared

ELDERLY ONSET RHEUMATOID ARTHRITIS AND POLYMYALGIA RHEUMATICA: COMPARATIVE CLINICAL STUDY

Melania Martínez-Morillo, Águeda Prior-Espinol, Anaíy Brandy-García, Susana Holgado Pérez, María Aparicio-Espinar, Laia Gilfe, Anne Rivers-Frutos, Clara Sangüesa-Gómez, Jordi Camins-Fàbregas, Ivette Casañ-Sorribes, Annika Nack, Alejandro Olive, Lourdes Mateo Soria. Hospital Universitari Germans Trias i Pujol, Rheumatology, Badalona, Spain

Background: Polyarthritis at the elderly people usually has a similar onset with an acute inflammatory character and scapular girdle involvement. Differenitling elderly onset rheumatoid arthritis (EORA) and polymyalgia rheumatica (PMR) can be a diagnostic challenge.

Objectives: To analyse the clinical and analytical differences between EORA and PMR.

Methods: Longitudinal observational study of patients older than 60 years newly diagnosed with EORA (ACR/EULAR 2010) and PMR (ACR/EULAR 2012). Inclusion: consecutive and voluntary. Follow-up time: 12 months. A single rheumatologist made all follow-up visits. The clinical-epidemiological and analytical characteristics were collected. The statistical study was performed with Stata 15.1.

Results: 45 EORA were recruited (53% women; mean age 74.8 ± 7.5) and 20 PMR (85% women; mean age 76.6±5.0). 75% of EORA had scapular girdle involvement, but only 44% of the pelvic girdle. All had peripheral arthritis, and the small joints of the hands were involved in 93.3%, with edema in 46.7%. Forty percent of EORA patients were seropositive (RF> 20 IU/mL and/or ACPA> 20 U/mL): 33% RF positive (132.8 ± 12 IU/mL), 28.9% for ACPA (2 cases [15.4%] from 100 to 250 U/mL and 11 cases [84.6%] above 250 U/mL) and in 10 patients [22.2%] double positive. All patients with PMR patients had shoulder girdle involvement and 90% of the pelvic girdle. None of them had peripheral arthritis. RF was positive in one patient (73 IU/mL) and ACPA in 2 patients (titers between 20-40 U/mL). No patient was double positive. Table 1 and 2.

IS THE RADIAL DEVIATION ASSOCIATED WITH MEDIAN NERVE SWELLING IN PATIENTS WITH RHEUMATOID ARTHRITIS?

Basak Mansiz-Kaplan1, Seçil Vural2, Figen Ayyan1. 1University of Health Sciences, Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey; 2University of Health Sciences, Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey

Background: Ultrasonography, the median nerve cross-sectional areas (CSAs) of the patients were measured from the four levels of the distal 1/3 of the forearm, radioulnar joint, pisiform bone and hook of hamate, and the ulnar nerve CSAs were measured from the pisiform bone.

Results: The study completed with 102 hands of 51 patients. 27% of these RA patients without clinical and electrophysiological findings were diagnosed as CTS by ultrasonography. A negative correlation was found between the radial inclination (RI) and the median CSAs measured from the radioulnar joint (R: -0.49; p: 0.00), the pisiform bone (R: -0.45; p: 0.00), and hook of hamate (R: -0.60, p: 0.00). When the hands were divided into three groups according to the ranges of RI specified in the literature, the median nerve CSA was found to be significantly higher in the group with a low RI at these levels (p < 0.001).

Conclusion: The median nerve CSAs increased as the radial deviation increased in RA patients. The prevention of disease progression may prevent the increase in median nerve CSA by preventing deviations in patients with RA. And the development of CTS may also be prevented.

REFERENCES

Disclosure of Interests: None declared

Background: Rheumatoid arthritis (RA) is a known cause of cardiovascular disease (CVD). Several studies suggest that serum uric acid (SUA) is associated with RA disease activity and functional capacity in patients with RA. Previous studies have revealed different results, mainly regarding the role of DMARDs in lowering SUA levels.

Objectives: The aim of the present study is to determine the prevalence of hyperuricemia in RA patients and to evaluate whether disease modifying anti-rheumatic drugs (DMARDs) have a hypouricemic effect.

Methods: We have conducted a cross-sectional study over four months (DMARDs) have a hypouricemic effect.

Results: The mean age was 51.76±12.84 and the mean age at RA diagnosis was 42.5±15.23. Fourteen patients (6.9%) had hyperuricemia and the average rate of SUA was 41.99±11.85 mg/L. All patients were taking Methotrexate, 34% received also Sulfasalazine, 6.4% Hydroxychloroquine and 77% steroids. Males and post-menopausal women had the average rate of SUA was 42.5±15.23. Fourteen patients (6.9%) had hyperuricemia and the average rate of SUA was 41.99±11.85 mg/L. All patients were taking Methotrexate, 34% received also Sulfasalazine, 6.4% Hydroxychloroquine and 77% steroids. Males and post-menopausal women had significantly higher SUA levels (p<0.001 and p=0.0001, respectively).

Univariate analysis showed a positive relationship between SUA levels and age (p=0.004), gender (p=0.002), age at RA diagnosis (p=0.03), smoking (p=0.046), use of alcohol (p=0.025), high body mass index (BMI) (p=0.012), elevated blood pressure (p=0.0001), dyslipidemia (p=0.001) and high doses of steroids (p=0.001). The association between RA and gout was noted in one case. We found no correlation between inflammation, DMARDs, CVD and SUA. In multivariate regression analysis adjusted for age, gender, BMI and steroids maintained a significant correlation with SUA.

Conclusion: The prevalence of hyperuricemia is low in our RA patients and similarly gout remains infrequent. However, RA patients must be screened for hyperuricemia. There is growing evidence that higher doses of steroids can cause hyperuricemia. Practitioners should be aware that these patients are at risk of having high SUA levels as well as more traditional cardiovascular risk factors. Thus, appropriate preventive interventions in these patients should be introduced.

AB0341 REASONS FOR DROP-OUT IN RHEUMATOLOGY SPECIALTY CARE OF ELDERLY RHEUMATOID ARTHRITIS PATIENTS

Shinich Mizuki 1, Matsuyama Red Cross Hospital, The Center for Rheumatic Diseases, Matsuyama, Japan

Background: The difference between total and healthy life expectancies were 12.3 and 8.8 years for women and men respectively in 2016, in Japan. Rheumatoid arthritis (RA) not only reduces daily living activities due to joint symptoms but also deteriorates the life prognosis due to systemic inflammation. That is, patients with RA are short for both total and healthy life expectancy. In recent years, the need for rheumatologist to provide specialty medical care to elderly patients with RA has been expanding. However, some elderly patients drop out of specialty treatment and care. To date, there are little information concerning background of patients who drop out.

Objectives: To investigate reasons and characteristics of elderly RA patients who drop out from rheumatology specialty medical care.

Methods: Of RA patients who had been visited our rheumatology specialty facility in 2016, we defined as drop-out when the patients did not return to the hospital in 2017. We surveyed age, gender, disease activity, and reason for drop-out retrospectively from medical records and questionnaires.

Results: Of 2,092 patients with RA who visited to our department, 156 patients (7.5%, 95% confidential interval: 6.4 – 8.6%) dropped out. Among drop-out patients, 101 patients were older than 65. 37 patients (37%) dropped out due to comorbidities including death (group C), 32 (32%) patients were introduced certified rheumatologists near the patients’ residences (group R). Twenty-two patients were due to unknown reasons, nine were due to remission, and one patient moved out to other area. Average age of both group C and R were eighty years old. Glucocorticoid user rate (C: 89%, R: 71%) and dose (C: 5.6 mg, R: 5.7 mg) were similar in the both two groups. Patients in group C showed less use of methotrexate (C: 19% vs R: 58%, P < 0.01) compared with group R patients. Simple disease activity index was similar, however, higher modified health assessment questionnaire was observed in group C patients (C: 1.13 vs R: 0.25, p=0.01).

Conclusion: Some elderly RA patients, especially may drop out from rheumatology specialty care due to comorbidities. Regional co-management should be constructed so that elderly patients could continue receiving RA specialized care.

Disclosure of Interests: None declared.

AB0342 DEPRESSION ON PATIENTS WITH RHEUMATOID ARTHRITIS

Simeon Monova 1, Russka Shumalneva 2, Elena Mloshova 3, Daniela Monova 4.
1Medical University – Sofia, Department of Rheumatology, Sofia, Bulgaria; 2Medical University – Sofia, Department of Rheumatology, Sofia, Bulgaria; 3Medical Institute, Department of Internal Diseases, Sofia, Bulgaria; 4Medical Institute, Medical University – Sofia, Department of Internal Diseases, Sofia, Bulgaria

Background: Rheumatoid arthritis (RA) is a chronic representative inflammatory autoimmune disease. The association of disease activity and pro-inflammatory cytokines with depression has not been sufficiently investigated.

Objectives: The aim of this study is to analyze the association between disease activity and depression using Patient Help Questionnaire (PHQ-9) in patients with rheumatoid arthritis (RA). We also examined the outcome of intervention on depression score and determined the prevalence of depression and risk factors for depression and deterioration of depressive symptoms in RA patients.

Methods: 146 RA patients with a mean age of 51±12.2 years were included in the study. Demographic and laboratory data were examined. Disease activity score 28-joint count C-reactive protein (DAS 28-CRP) was performed to assess disease activity of RA. PHQ-9 scores were collected at each clinic visit. Physicians assessed corresponding disease activity using Clinical Disease Activity Index (CDAI). Patients with at least moderate depression (PHQ-9 _10) were offered depression intervention, counseling or medications. PHQ-9 was re-administered after intervention.

Results: 119 of RA patients were females, the average disease duration was 6.8 ± 5.9 years. Depression was diagnosed in 36 of RA patients: 18 - mild, 13 - moderate and 7 - moderately severe. Severity of depression positively correlated with disease activity in RA patients (p <0.05). RA patients with moderate/high CDAI had significantly higher PHQ-9 than those with low CDAI (p<0.001). Of 7 patients who met criteria for depression intervention, 6 were treated and 1 - declined. With treatment 5 patients had improved PHQ-9 scores, 1 patient worsened, and 1 patient had no change in score. The risk of developing a depressive disorder is highest between 5 and 10 years of onset of the disease and depression is a better predictor of work disability than disease activity and response to treatment. Depression is associated with more pain, fatigue and impaired quality of life. Therefore, the risk to develop a depression is increased with impaired function as measured by the health assessment questionnaire (HAQ). Increased disease activity increases the risk for depression in RA. The severity of disease activity of RA, DAS 28-CRP [OR 1.75, 95% CI 1.08-2.64] and severity of fatigue [OR 1.32 95% CI 1.12-1.27] were associated with depression and deterioration of depressive symptoms in the multivariate analysis. Among the components of DAS 28-CRP, patient assessment for global health and abilities for daily performance were more related to depression. Depression unfavorably influences the response to therapy, the rate of remission is lower and the mortality is increased in RA patients. Taken together, this indicates that it is necessary to detect a depression in patients with RA as early as possible in order to initiate appropriate treatment of depression in such cases.

Conclusion: Our study shows depression in 19.18% of patients. Correlation between disease activity and depression score is found in RA patients. Depression intervention resulted in PHQ-9 improvement in some patients, supporting the benefit of depression screening and treatment in rheumatology practice. Depression was related with the level of fatigue and high RA disease activity, which was associated with impaired ability to perform activities of daily life. Strict control of fatigue and disease activity to improve one’s capacity to perform daily life activities would be important to regulate depression. Depression is common and associated with worse outcomes among patients with RA.

AB0343 ANTIRHEUMATIC THERAPY IS NOT ASSOCIATED WITH CHANGES IN CIRCULATING N-TERMAL PRO-BRAIN NATRIURETIC PEPTIDE (N-PROBNP) LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Thao Nguyen 1, Gia Deyabo 2, Morten Fagerland 3, Stefan Agewall 4, Geo Ellertsen 5, Mark Feiring 6, Knut Mikkelsen 2, Øystein Farne 2, Irina Holli1 7, Lietherammer Hospital for Rheumatic Disease, Lillehammer, Norway; 2Inlandet Hospital Trust, Department of Medical Biochemistry, Lillehammer, Norway; 3Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway; 4Oslo University Hospital University, Utslev, Department of Cardiology, Oslo, Norway; 5The Artic University of Norway, Department of Rheumatology, Tromso, Norway; 6Harvard Medical School, Boston, United States of America; 7Bingham and Women’s Hospital, Department of Cardiology, Boston, United States of America; 8University of Oslo, Oslo, Norway

Background: Patients with rheumatoid arthritis (RA) are predisposed to impaired cardiac function and heart failure (HF). While the pathophysiology has not been fully elucidated yet, inflammation is suspected to play an important role. However, the impact of disease-modifying antirheumatic drugs on cardiac dysfunction in RA remains controversial. Although anti-inflammatory drugs might have protective effects, some of them, i.e. tumour necrosis factor inhibitors (anti-TNF), might also negatively influence cardiac function. Serum NT-proBNP (n-NT-proBNP) is used as a biomarker of cardiac function, and levels ≤125 ng/L with high probability exclude HF.

Objectives: To examine effects of methotrexate (MTX) and anti-TNF regimens on s-NT-proBNP in patients with active RA, and to assess associations between s-NT-proBNP and endothelial function (EndoF).

DISCLOSURE OF INTERESTS

Mark Feiring: None declared. 7. Knut Mikkelsen: None declared. 8. Øystein Farne: None declared. 9. Irina Holli: None declared. 10. Lietherammer Hospital for Rheumatic Disease, Lillehammer, Norway: None declared. 11. Inlandet Hospital Trust, Department of Medical Biochemistry, Lillehammer, Norway: None declared. 12. Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway: None declared. 13. Oslo University Hospital, Utslev, Department of Cardiology, Oslo, Norway: None declared. 14. The Artic University of Norway, Department of Rheumatology, Tromso, Norway: None declared. 15. Harvard Medical School, Boston, United States of America: None declared. 16. Bingham and Women’s Hospital, Department of Cardiology, Boston, United States of America: None declared. 17. University of Oslo, Oslo, Norway: None declared.
Methods: From the observational PSARA study, we examined 64 RA patients starting with MTX monotherapy (n=34) or anti-TNF with MTX co-medication (n=30) due to active disease. All patients starting with anti-TNF regimens had been previously unsuccessfully treated with MTX, s-NT-proBNP levels (ELISA). EndoF (measured by finger plethysmography), and other laboratory and clinical parameters were evaluated at baseline and after 6 weeks and 6 months of treatment. Results: Median age was 57 years (range 26-78), and 73% were women. 17 (27%) patients had CVD (history of angina, MI, heart surgery, PTA, cerebrovascular disease, thromboembolism, aortic aneurysm, peripheral artery disease). None of the patients had known symptomatic HF. There were no statistically significant differences between s-NT-proBNP levels at baseline (median 2241 ng/L [IQR 9002]) and after 6 weeks (median 2300 ng/L, [IQR 8690]) and 6 months (median 2358 ng/L, [IQR 7770]) of anti-inflammatory therapy (p=0.992 and p=0.528, respectively). There were no significant differences in the effects of MTX monotherapy and anti-TNF regimens on s-NT-proBNP levels (Baseline-D0: -7.97, Baseline-D6: -4.21). At baseline, 57 (89%) patients had s-NT-proBNP>125 ng/L, and 44 (69%) had high s-NT-proBNP levels (s-NT-proBNP>450 ng/L in patients <50 years old and >900 ng/L in patients ≥50 years old), and these frequencies did not significantly change with anti-inflammatory treatment. s-NT-proBNP was not related to EndoF. Conclusion: A large proportion of RA patients without known HF had elevated s-NT-proBNP levels, which might indicate subclinical impairment of cardiac function. s-NT-proBNP levels were not influenced by six-month MTX and/or anti-TNF treatment. Thus, in contrast to some previous studies, our data does not support the notion that anti-inflammatory treatment protects against HF, and that anti-TNF treatment has negative effect on cardiac function in RA. Nevertheless, definitive conclusions cannot be drawn by our study, e.g. due to limitations of s-NT-proBNP as surrogate marker of HF. Cardiac function in terms of s-NT-proBNP levels was not related to EndoF.

COMPARATIVE ANALYSIS OF SIDE EFFECTS BETWEEN PATIENTS TREATED WITH AND WITHOUT CORTICOSTEROID AT DMARDS-STARTING POINT. SINGLE CENTER RETROSPECTIVE REAL WORLD DATA ANALYSIS

Michihiro Ogasawara,1 Yosuke Shimada2, Yoshiyuki Abe1, Ken Yamaji1, Satoshi Hori1, Naoto Tamura1,1 Juntendo University Graduate School of Medicine, Department of Internal Medicine and Rheumatology, Tokyo, Japan; 2SECOM Co., Ltd., Intelligent Systems Laboratory, Tokyo, Japan; 3Juntendo University Graduate School, Medical Informatics Department, Tokyo, Japan

Background: In the EULAR recommendation on rheumatoid arthritis (RA) treatment, short-term steroid combination should be considered at the start of DMARDS treatment. In this study, we analyzed the present condition of steroid combined use in Japan and the actual situation of side effects in recent years.

Objectives: RA patients who started treatment with DMARDS at our hospital during July 2008 to April 2018.

Methods: A new incidence of hypertension (HTN), diabetes (DB), dyslipidemia (HLP), infection (INF) were compared between the two groups of steroid combined use group (D_PSL) and noncombined group (D_nonPSL) and analyzed by Cox regression analysis. The cases had there complications before the start of RA treatment were excluded from the analysis.

Results: The number of cases of analysis was 573 (D_PSL = 216, D_nonPSL = 357, average observation period: 5.2±2.70 year), and the new incidence of each complication was INF 50/561 (D_PSL 16/245 vs. D_nonPSL 4.46%[16/351], p=0.00094), HTN 48/527 (19.8% [23/122] vs. 11.8% [40/340], p=0.018). The incidence of INF was high in D_PSL group in both groups over 65 and under 65 years old (p = 0.0065, p = 0.0027), HTN was high in D_PSL group only in group over 65 years old (p=0.0279, p=0.0554). Average starting amount of steroids was 6.07±10.2 mg, cases of non-withdrawal of steroid at 1, 2, 3 years later is 79.7%, 72.2% and 66.3% respectively.

Conclusion: Combined use of steroid at the start of DMARDS increased the rate of mortality of infection requiring hospitalization and hypertension.

More than half of them were difficult cases of withdrawal of steroids. From the viewpoint of side effect, it is necessary to study the optimization of steroid therapy in the future.

AB0345

A PILOT ATTEMPT TO USE THE CONSTANT GENETIC MARKERS IN CARDIOVASCULAR RISK STRATIFICATION IN RHEUMATOID ARTHRITIS

Vitaly Omekhenko1, Elena Letyagina1, Tatjana Pospelova2, Maxim Korolev1

1RICEl – Branch of Canso GB RAS, Novosibirsk, Russian Federation; 2NSMPL, Department of Therapy, Hematology and Transfusionology, Novosibirsk, Russian Federation

Background: Rheumatoid arthritis (RA) is associated with early atherosclerosis and high mortality. Routine riskometers developed for a common population usually underestimate a true cardiovascular (CV) risk in RA-patients. For early prevention additional criteria is needed to evaluate CV risk in RA-patients. It’s known, that early CV accidents in relatives relate to elevated risk. Nevertheless, specific constant genetic markers don’t use in risk stratification. Single nucleotide polymorphisms in regulatory regions of genes, participating in immune interaction, can potentially play a role in progression atherosclerosis and used in CV-prevention algorithms.

Objectives: to develop the model for cardiovascular risk stratification in RA-patients including constant genetic markers.

Methods: Two hundred and twelve Caucasian patients with RA (age – 58.0 yrs [48.3; 65.0]; DAS28 4.96 [3.86; 5.85]) were included in our study. Patients had American College of Rheumatology (ACR)-defined RA (1987 classification criteria). All patients gave written informed consent before enrollment. Traditional and “non-traditional” (e.g. RA-associated factors) were analyzed [1]. Carotid atherosclerotic plaques had been found by ultrasonography. Single nucleotide polymorphisms were determined by restriction fragment length polymorphism (TNFA G-308A; TNFA C-863A; IL6 G-174C; MMP9 -1562T; MMP9 5-1171 6A; IL1B T-31C; IL1B -592A; IL4 C-590T; VEGFA C-2578A; IL10 C-8198T; TNFA G-308A; VEGFA G-1193C). Descriptive statistics, Chi-squared test, logistic regression with Wald statistics were used for data analysis. Results are presented as median and 25th/75th percentiles (Me [25th percentile; 75th percentile]).

Results: Atherosclerotic plaques (AP) were found in 59 (27.8%) patients. API revealed were strongly associated with age (66.0 yrs [59.0; 73.0]) with API vs 55.0 yrs [42.0; 61.0] without API, p<0.001 and sex (51.6% for man vs 23.8% for woman, p<0.001). Then, a logistic regression was performed to determine which variables analyzed are predictors of a carotid atherosclerosis lesion. Regression results had demonstrated that the model was statistically reliable in distinguishing between patients with API and without [-2 Log Likelihood = 146.53, p<0.001]. The model correctly classified 85.3% of cases. The Wald statistics showed that at least 6 parameters were principal – age (B=0.123, p<0.001), hypertension (B=3.114, p<0.001), smoke (B=2.167, p<0.001), positive rheumatoid factor (B=1.674, p=0.038), body mass index (B=0.098, 0.199) and depressive allele in TNFA C-863A (B=1.338, p<0.005). Using parameters obtained the ROC-curve was constructed. Area under ROC curve were 0.900 (SE 0.022; 95%CI 0.857-0.942, p<0.001). Sensitivity and specificity calculated by Youden’s Index were 79.7% and 87.5% respectively.

Conclusion: Age, hypertension, smoke, positive rheumatoid factor, low body mass index and depressive allele in TNFA C-863A were associated with carotid atherosclerosis.

REFERENCES
Background: Ascending aorta has an increased stiffness (AoSI) in rheumatoid arthritis (RA) patients due to their chronic inflammatory status. We assessed prevalence and modification of AoSI during a follow up period and its prognostic role on cardiovascular events (CVE) in a large cohort of RA patients.

Objectives: Prognostic role of AoSI and its modification over time on CVE.

Methods: We prospectively followed 146 RA patients without overt cardiac disease with periodic echocardiographic examination. Abnormally high AoSI was diagnosed if AoSI > 6.07% (95th percentile of the AoSI detected in our reference healthy population). AoSI was assessed at the level of the aortic root by two-dimensional guided M-mode evaluation as part of a thorough echocardiography performed in all patients. CVE information were collected during follow up.

Results: Of our 146 RA patients, 89 had a normal AoSI at baseline, in the remaining 57 it was abnormally high. After a mean follow up of 27 months: among patients with normal baseline AoSI it stayed normal in 64 (6 to 5.6%) and in 25 raised to an abnormal high AoSI (from 3.7 to 11.9%); of the 57 patients with high baseline AoSI, 33 went back to normal values (9.4 to 3.1%) and in 24 it remained high. Of these 4 groups divided by AoSI trend over time the group with de novo high AoSI showed the highest prevalence of new CVE (33%), together with the group with persistent high AoSI (16%). Much lower prevalence was observed in the other two groups (persistent normal 5%, normalized at follow up 6%).

Conclusion: Abnormally high AoSI is common in RA patients, rapid increase through time or persistent high AoSI identify those patients that are more prone to develop CVE. On the contrary, patients that showed a normalization of AoSI demonstrated to have a similar low incidence of CVE as patients who ever had a normal AoSI.

AB0348 PREVALENCE AND SAFETY OF BIOLOGIC THERAPY IN A CHILEAN COHORT OF RHEUMATOID ARTHRITIS PATIENT, A RETROSPECTIVE STUDY

Silviana Saavedra1, Felipe Reyes2, Claudia Hernandez2, Karen Vergara2, Maria Luisa Molina3, Annelise Goecke1, Hospital Clinico Universidad de Chile, Rheumatology, Santiago, Chile,1Hospital Clinico Universidad de Chile, Pulmonary, Santiago, Chile,2Hospital Clinico Universidad de Chile, pulmonology, Santiago, Chile

Background: Interstitial lung disease (ILD) is a common extra-articular condition in rheumatoid arthritis (RA). New-onset ILD or ILD worsening has also been reported as a possible consequence of biologic therapy. These associations are based on case reports. The present study evaluated ILD prevalence and exacerbation among users of abatacept (T-cell inhibitor), rituximab (B-cell inhibitor), and anti-TNFα agents in a cohort of adult RA patients.

Objectives: In the present study, we aimed to assess the safety of biologic therapy in patients with ILD associated to RA and patients without a history of ILD.

Methods: Data from RA patients beneficiaries of the Ley Ricarte Soto (LRS) program, at the Hospital Clinico de La Universidad de Chile, who received abatacept, rituximab, or anti-TNFα agents for at least a year, were reviewed.

Results: Seventy four patients were reviewed retrospectively between January 2016 and December 2018 (55 female; mean disease duration, 7 years; mean age, 55 years). Mean (SD) DAS28 ESR was 6.9 (±0.1) previously to initiate therapy. RA was seropositive in 65 patients (97.8%). Eighteen patients (24.3%) had been previously diagnosed with ILD, with a median duration of 4 years. Most common patterns of RA-associated ILD were UIP (n=5 [40%]) and CPFE (n=3 [23.1%]). Patients with ILD at baseline as compared to patients without history of ILD were more frequently males (27.8% vs 7.5%, p < 0.05), had an older age (64±12 vs 52±13, p < 0.005), a higher positivity of anti-cyclic citrullinated protein antibodies (CCP) (87.5% vs 80%, p < 0.005) and a more frequent history of smoking (50% vs 28%, p < 0.005). The treatment received by patients with RA-associated ILD previously to start biologics under LRS program were: methotrexate (MTX) (n=5), leflunomide (LEF) (n=14),

AB0349 DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS AND RISK OF LUNG INVOLVEMENT

Olfa Saiad1, Leila Gatl1, Hana Sah1, Ahica Ben Tekaya1, Rawdha Tekaya1, Ines Mahfoud1, Leila Abdelselou1, Charles Nicole Hospital, Rheumatology Department, Tunis, Tunisia. Polyclinic El Omrane, Rheumatology Department, Tunis, Tunisia.

Background: Rheumatoid arthritis (RA) is a common inflammatory disease developing within joints but extra-articular organs such as the lung could be involved.

Objectives: To determine the relationship between disease activity and lung involvement in rheumatoid arthritis (RA) Tunisian patients.

Methods: We performed a retrospective study of patients with RA diagnosed according to American College of Rheumatology-European League Against Rheumatism classification criteria for RA 2010 between 2014 and 2017 in a department of rheumatology in the north of Tunisia. The prevalence of pulmonary involvement was determined based on combined results from chest-X-ray, computed tomography of the chest and pulmonary functional tests. Disease activity was evaluated based on number of night waking, morning stiffness duration, painful joints number and swelling joints number, erythrocytes sedimentation rate (ESR) and C-reactive protein levels (CRP). Specific disease activity scores were also noted including the 28-joint Disease Activity Score Index (DAS28), Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI).

Results: Sixty five patients were collected. Mean age was 56 years ± 12.8 years and mean age of disease onset was 46.4 ± 13.8 years ranging from 17 to 75 years. Mean disease duration was 9.6 ± 10.1 years ranging from 1 to 38 years. Number of painful joints was 13.71 at mean and swelling joints number was 5.98. Morning stiffness duration was 1.03 hour at mean and number of night waking was 2.31. Concerning laboratory investigations, mean ESR was 49.7 mm ant mean CRP level was 13.6 mg/l. The average of DAS28 was 5.8. The overall frequency of lung involvement based on different lung investigations was 27.6% (18 patients). Interstitial lung disease was found in 7 cases, bronchiectasis was found in 5 cases, rheumatoid nodule in 4 cases and pleural disease in 2 cases. Patients with lung involvement had significantly higher painful joints number (p=0.004) and no difference was seen concerning swelling joints number. Number of night waking and morning stiffness duration had no impact in lung involvement (p=0.651, p=0.907 respectively). RA patients with lung involvement displayed higher ESR level (p=0.032) and no difference was seen concerning CRP level. No association was found between lung involvement and specific disease activity scores (DAS28, CDAI, SDAI).

Conclusion: Our study showed that only high level of ESR could be associated with lung involvement in RA Tunisian patients.

REFERENCES

[1] Pérez-Doramea R, Mejiaa M, Mateos-Toledoab H,Rojas-Serranob J.Rheumatoid arthritis-associated interstitial lung disease: Lung inflammation evaluated with high resolution computed tomography scan is correlated to a 1 year follow-up. RA patient without ILD who started biologic therapy did not had ILD at 1 year follow-up. Conclusion: There were no significant differences in the risk of complications between patients with a baseline history of ILD receiving different biologic agents. The present study found that male sex, older age, sero-positive RA and patients with a history of smoking, were at increased risk for developing ILD. These data are largely consistent with those of the existing literature. Patients without a history of ILD did not develop pulmonary complications, but these data may be affected by the short follow-up window. Further studies are needed to evaluate the risk of RA-associated ILD and its complications.

AB0350 RHEUMATOID ARTHRITIS MANAGEMENT IN SOUTHEAST TURKEY, EXPERIENCE FROM RURAL AREA

Senem Tekeoglu. Batman State Hospital, Batman, Turkey.

Background: Rheumatoid arthritis is a chronic disease affecting more commonly women in all age groups. Access to healthcare, taking part in decision making and compliance with the treatment are very important in management. In Turkey, after completion of their fellowships, rheumatologist work for a limited time in state hospitals mandatorily (especially in under-developed cities of the country). Batman city lies in the southeast of Turkey with a population of 585,000 people; 7% of whom is illiterate. Due to ethnic and cultural reasons women suffer more commonly in obtaining and maintaining education and healthcare.

Objectives: To define the clinical characteristics, adherence to follow-up appointments and treatments ever received in patients with rheumatoid arthritis in Batman State Hospital.

Methods: Hospital records between July 15th 2017 and January 1st 2019 were viewed retrospectively. Only 1 rheumatologist works in the hospital. Appointments were scheduled between 1-3 months intervals, patients were defined as 'lost to follow-up' if there was no clinical appointment in last 3 months. Patients were categorized as recently or formerly diagnosed and according to receiving conventional synthetic disease modifying agents (DMARDs) (methotrexate, leflunomide, hydroxy-chloroquine, sulfasalazine) or biologic DMARDs (adalimumab, etanercept, infliximab, golimumab, certolizumab pegol, rituximab, tocilizumab, abatacept, tofacitinib).

Most of the patients received low-dose steroids.

Results: Patient characteristics and treatments are displayed in the table. Follow-up duration for the patients who continued follow-ups was 8.9 months on average (max: 17 months). Average follow-up duration for patients who lost to follow-up was 2.8 months (min: 1 month, max:13 months). Seventy-one of 146 patients who lost to follow-up came to appointment only once. Route of administration was very important in biologic treatment decisions, oral treatments and intravenous administration in hospital were favored over subcutaneous administration especially for elderly illiterate patients.

Table: Patient characteristics, treatments

AB0437 CLINICAL AND LABORATORY FEATURES OF RHEUMATOID ARTHRITIS IN A RURAL TURKISH POPULATION

Erhan Salda1, Leila Gatl1, Hana Sah1, Ahica Ben Tekaya1, Rawdha Tekaya1, Ines Mahfoud1, Leila Abdelselou1, Charles Nicole Hospital, Rheumatology Department, Tunis, Tunisia.

Background: To define the clinical characteristics, adherence to follow-up appointments and treatments ever received in patients with rheumatoid arthritis (RA) Tunisian patients.

Methods: We performed a retrospective study of patients with RA diagnosed according to American College of Rheumatology-European League Against Rheumatism classification criteria for RA 2010 between 2014 and 2017 in a department of rheumatology in the north of Tunisia. The prevalence of pulmonary involvement was determined based on combined results from chest-X-ray, computed tomography of the chest and pulmonary functional tests. Disease activity was evaluated based on number of night waking, morning stiffness duration, painful joints number and swelling joints number, erythrocytes sedimentation rate (ESR) and C-reactive protein levels (CRP). Specific disease activity scores were also noted including the 28-joint Disease Activity Score Index (DAS28), Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI).

Results: Sixty five patients were collected. Mean age was 56 years ± 12.8 years and mean age of disease onset was 46.4 ± 13.8 years ranging from 17 to 75 years. Mean disease duration was 9.6 ± 10.1 years ranging from 1 to 38 years. Number of painful joints was 13.71 at mean and swelling joints number was 5.98. Morning stiffness duration was 1.03 hour at mean and number of night waking was 2.31. Concerning laboratory investigations, mean ESR was 49.7 mm ant mean CRP level was 13.6 mg/l. The average of DAS28 was 5.8. The overall frequency of lung involvement based on different lung investigations was 27.6% (18 patients). Interstitial lung disease was found in 7 cases, bronchiectasis was found in 5 cases, rheumatoid nodule in 4 cases and pleural disease in 2 cases. Patients with lung involvement had significantly higher painful joints number (p=0.004) and no difference was seen concerning swelling joints number. Number of night waking and morning stiffness duration had no impact in lung involvement (p=0.651, p=0.907 respectively). RA patients with lung involvement displayed higher ESR level (p=0.032) and no difference was seen concerning CRP level. No association was found between lung involvement and specific disease activity scores (DAS28, CDAI, SDAI).

Conclusion: Our study showed that only high level of ESR could be associated with lung involvement in RA Tunisian patients.
Conclusion: Even though management goal is directed at remission induction in the earliest stages of rheumatoid arthritis with molecular targeted therapies in most of the developed countries, in rural parts of the developing countries low rate of adherence to follow-up appointments and medications is still an important difficulty in management.

Patients receiving biologic DMARDs have higher adherence to treatment. Awareness and education of patients in rheumatoid arthritis, as well as in all chronic diseases, is most important aspect of management.

AB0351
ELDERLY-ONSET RHEUMATOID ARTHRITIS (EORA): DIFFERENCES ACCORDING TO CLINICAL DEBUT AND SEROLOGICAL POSITIVITY

María Andreina Terán Tinedo, Cristina Pijoan Moratalla, Jose Renato Quiñones Torres. Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: In patients with Elderly-onset Rheumatoid Arthritis (EORA) has been described a clinical debut mimicking polymyalgia rheumatica with rhizomelic pseudopoliarthritis, in contrast with the classical profile of patients with Rheumatoid Arthritis similar to younger patients. We compare in our study these two profiles of the disease.

Objectives: To describe and compare the differences according to clinical debut, serological positivity and its implications in terms of treatment and prognostic factors in patients with Elderly-onset Rheumatoid Arthritis (EORA).

Methods: Patients with a diagnosis of RA over 65 years of age according to ACR/EULAR 2010 criteria were included. A database was created including the age of onset, the presence of polymyalgia-like symptoms (rhizomelic pseudopoliarthritis), the positivity of rheumatoid factor (RF) and anti-citullinated protein antibodies (ACPAs), elevation of acute phase reactants (APR), the presence of erosions and the treatment required.

Finally, data was analyzed according to clinical debut, serological positivity and prognostic factors.

Results: 83 patients diagnosed of EORA were included, with an average age of 73.8 years. 71.25% had positive RF (58.75% high titers) and 62.5% had positive ACPA (52.3% high titers). 24/83 patients (29%) debuted with a polymyalgia-like symptoms. 47.5% had persistent APR elevation during follow-up. Regarding treatment, 15% were treated only with corticosteroids, 81.5% required treatment with DMARDs and 15% were receiving biological treatment. 42/83 patients (50%) had erosions on plain X-rays. Of those patients with a polymyalgia-like profile, 52.2% (43/83) had positive RF but most of them had low titers (61%). On the other hand, patients without polymyalgia-like symptoms had positive RF in 78% of the cases and most of them at high titers (66%, p = 0.01).

In the first group there was less positivity for ACPAs (26%, p = 0.009) and half of them had low titers. Erosions were observed in only 30% of the patients with polymyalgia-like symptoms, while they were not observed in all the cases. Patients with positive RF and ACPAs had high APR elevation during follow-up. 24/83 patients (29%) debuted with a polymyalgia-like symptoms.

Conclusion: Patients with EORA with polymyalgia-like symptoms tend to have less erosions and a higher prevalence of negative RF and ACPA or at low titers. These patients usually require less DMARDs and biological treatments to control the disease unlike patients with non-polymyalgia symptoms. On the other hand, patients with high RF and ACPA titers have more erosions and elevated APR during follow-up but do not usually experience polymyalgia-like symptoms.

HIGH PREVALENCE OF ANTICIPATORY AND ASSOCIATIVE SYMPTOMS OF METHOTREXATE INTOLERANCE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Rawdha Tekaya, Walid Taki, Aicha Ben Tekaya, Olfa Saidane, Ines Mahmoud, Louda Abdelmoula, R.Tekaya, W. Triki, A. Ben Tekaya, Oo.Saidane, L. Abdelmoula, Charles Nicole Hospital, Rheumatology, Tunis, Tunisia

Background: Methotrexate (MTX) is the most widely used anti-rheumatic drug in the treatment of Rheumatoid Arthritis (RA) due to low costs, efficacy and an acceptable safety profile. However MTX has certain side effects. The most common side effects include the gastrointestinal tract not only after taking MTX, but also before MTX intake (anticipatory) and when thinking of MTX (associative).

Objectives: The aim of this study was to assess the prevalence of MTX intolerance and particularly the anticipatory and associative symptoms using the validated methotrexate intolerance Severity Score (MISS) (1).

Methods: We performed a cross-sectional descriptive study that involved patients with RA and treated by MTX for more than 3 months, compiled from Charles Nicole hospital’s rheumatologic department. The tolerance of MTX was assessed by the MISS questionnaire. The MISS Questionnaire includes five elements: abdominal pain, nausea, vomiting, fatigue, and behavioral symptoms of restlessness, crying, irritability and drug refusal.

Each symptom is evaluated after intake of MTX, before taking MTX (anticipatory) and on thinking about MTX (associative). MTX intolerance was defined as >6 points on the MISS, with at least 1 point on anticipatory, associative or behavioral adverse effects.

Results: A total of 100 RA patients (87 women and 13 men) with a mean age of 53.5 years. The MTX was administrated by oral route in 91% of patients; the other 9% received it by intramuscular way. The average MTX weekly dose was 15,4mg. The average MTX duration was 76,7 months. All patients received folic acid with an average of 7,6 mg a week. MTX intolerance was found in 36% of patients. Abdominal pain was the most common symptom occurring in 55% of patients and up to 91.66% in MTX-intolerant patients, followed by nausea in 51% of patients and in 86,11% of MTX-intolerant patients and vomiting in 16% of patients and in 44,44% of MTX intolerant-patients. Anticipatory and associative abdominal pain affected 72,2% and 69,4% of intolerant-patients respectively. Anticipatory and associative nausea were found in 58,3% and 59% of intolerant-patients respectively. Anticipatory vomiting occurred in 16,6% of intolerant-patients. Overall, behavioral symptoms occurred in 75% of intolerant-patients, of whom 19,4% refused MTX. Older age was significantly correlated with better tolerance to MTX (p=0,02). There was no correlation between the dose of MTX, the duration of MTX intake and the route of MTX and the MISS score (respectively p=0,7, p=0,07and p=0,2). Also, the use of other disease modifying drugs didn’t worsen the tolerance of MTX.

Conclusion: To conclude intolerance to MTX is frequently seen in RA. In addition to gastrointestinal symptoms after taking MTX, RA patients can suffer from anticipatory and associative gastrointestinal symptoms. We should screen these symptoms earlier using MISS questionnaire in order to improve MTX compliance.

WORSE OFFICE AND 24-HOUR BRACHIAL AND CENTRAL AORTIC BLOOD PRESSURE MONITORING PROFILE IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARED TO CONTROLS

Elena Troitskaya1, Sergei Velimkin1, Svetlana Villevalde2, Zhanna Kobalava1.
1Peoples’ Friendship University of Russia (RUDN University), Internal diseases, Moscow, Russian Federation; 2Almazov National Medical Research Centre, St. Petersburg, Russian Federation; 1Peoples’ Friendship University of Russia (RUDN University), Moscow, Russian Federation

Background: Hypertension (HTN) contributes to increased cardio-vascular (CV) morbidity and mortality in RA. Recent European guidelines on the management of HTN encourage wider use of ambulatory blood pressure monitoring.
CAN CANCER TRIGGER AUTOIMMUNITY DISEASE?

CANCER and AUTOIMMUNITY DISEASE

The relationship between cancer and autoimmune diseases is complex and multifaceted. While the exact mechanisms are not fully understood, several studies have suggested that cancer can trigger autoimmune diseases, and vice versa. Here, we briefly review some of the key findings and related research.

Aim: To understand the potential mechanisms linking cancer and autoimmune diseases.

Methods: A comprehensive literature review was conducted to identify relevant studies. Relevant databases were searched for publications from 2010 to 2020.

Results: A total of 12 studies were included in the final analysis. The results showed a significant association between cancer and autoimmune diseases, with a risk ratio of 2.75 (95% CI 1.23-5.27).

Conclusion: Cancer can trigger autoimmune diseases, and vice versa. Understanding the underlying mechanisms could lead to new therapeutic strategies for both cancer and autoimmune diseases.

AB0355 CANCER TRIGGER AUTOIMMUNITY DISEASE? FEATURES OF AUTOIMMUNE DISORDER OF CANCER PATIENTS

Sayaka Tsuzuki, Hideyuki Takahashi, Fangyi Chen, Keigo Setoguchi. Tokyo Metropolitan cancer and disease center Komagome hospital. Department of systemic immunological disease, Tokyo, Bunkyo-ku, Japan

Background: Association between cancer and autoimmune diseases are reconsidered by frequent use of immune checkpoint inhibitor and its adverse effects. In addition, the childhood cancer patients have the higher possibility of developing autoimmune disease than general population in previous research, though this may be related to cancer therapy. Furthermore the development of sclerodema in cancer patients harboring the iPOLAR3A mutation suggests that cancer can directly induce autoimmune disease.

Objective: We examine the features of autoimmune diseases in the patient with pre-existing cancer.

Methods: Date on clinical characteristics, laboratory features, and treatment response from patients with autoimmune disease in our hospital were analyzed retrospectively. We included patients who had diagnosed cancer more than 5 years ago, who use immune check point inhibitor, whose symptom became clear by the drug toxicities and endocrine dis- ease, and who had no symptoms but only test abnormalities.

Results: 149 patients consulted our department and 111 patients were included; their median duration of follow-up was 39 months. The median period of diagnosing cancer from autoimmune disease was 17 months, and median age of the patients with autoimmune diseases at diagnosis was 68 years. Baseline manifestations included rheumatoid arthritis (RA) 42%, polymyalgia rheumatica (PMR) 20%, systemic sclerosis (SSc) 10%, Sjogren syndrome (SjS) 7.3%, IgG4-related disease 6.3%, vasculitis 5.5%, polynonititis and dermatomyositis 5.5%, interstitial pulmonary 2.7%.

In patients with RA, 53% were positive for both rheumatoid factor (RF) and anti-CCP antibody (median RF 155IU/mL, anti-CCP antibody 380U/ mL). This median age of diagnosis was 68 years, and 52% were female. The average serum C-reactive protein (CRP) was 1.7mg/dL. Patients who experienced only operation for previous cancer therapy was 44%. 39% patients developed RA symptoms with in half year. As a treatment, MTX was used in 44%, SASP in 26%, PSL alone in 11%. The response to therapy was 70% overall. One patient who used MTX developed MTX-LPD (DLBCL) after 10 months.

In PMR, all cases were seronegative. The median age of diagnosis was 71 years, and 63% were female. The average CRP was 5.4mg/dL. 41% of patients had operation for previous cancer therapy and 32% had oper- ation and chemotherapy. All cases started using PSL (15-40mg) and responded to treatment. They all tapered PSL.

In SSc, all cases were female and mean age was 63 year old. 33% of them had breast cancer. 82% had centromere antibody and the median titer of the antibody were 1280. Interestingly, even in SjS patients, the same antibody was positive in 38%.

In myositis, 4 out of 6 patients had ARS antibodies and their main symptom was interstitial pneumonia. No patients were positive for TIF-1.

Conclusion: Patients with cancer developed autoimmune diseases, and had different characteristics from primary autoimmune disease. This suggest that cancer itself and it’s therapy somehow influence to our immune systems.

Disclosure of Interests: None declared

n = 5). Non-target lipid levels were detected in 44.7% of low-risk patients, in 83% of medium risk patients, in 78.6% of high risk patients, in 100% of very high risk patient. Absolute indications for statin therapy were detected in 17.4%.

Hemodynamically insignificant carotid plaques (stenosis <50%) was detected in 56.5% of patients with RA: in 23.7% of low risk category, in 74.3% of medium risk patients, in 85.7% of high risk patients, in 100% of very high risk patients. A sever calcification of the coronary arteries was detected in 25% (the coronary index is more than 300 U or > 75 percentile of the age- and sex-related reference values, in accordance to MESA): in 5.3% of low risk patients, in 37% of medium risk patients, in 28.6% of high risk patients, in 80% of very high risk.

After carotid ultrasound 38% (34/92) of RA patients were reclassified from the category of low and medium cardiovascular risk on the mSCORE scale to the high risk category. The proportion of patients with high cardiovascular risk increased in 3.5 times (53.2%, p <0.001). There were 42 patients with non-target lipid levels in the high risk category. The proportion of patients with absolute indications for statins increased in 2.9 times compared with the results of the mSCORE evaluation (n = 47/92; 51%; p <0.001).

After MDCT assessment of coronary calcification 16.3% (15/92) of RA patients were reclassified from the category of low and medium cardiovascular risk on the mSCORE scale to the high risk category. The proportion of patients with high cardiovascular risk increased in 2.1 times (31.5%, p <0.001). There were 24 patients with non-target lipid levels in the high risk category. The proportion of patients with indications for statins increased in 1.8 times compared with the results of the mSCORE evaluation (n = 29/92; 31.5%; p <0.001). Carotid ultrasound more often reveals indications for statin therapy, p <0.001.

Conclusion: The use of the mSCORE scale is not sensitive enough for stratification of cardiovascular risk in RA patients due to the high incidence of subclinical atherosclerosis in this population. The use of carotid ultrasound and the MDCT assessment of coronary calcification significantly improve the stratification of cardiovascular risk in patients with RA, which helps to identify patients requiring intensive prevention of cardiovascular complications. The frequency of identifying patients with absolute indications for statin therapy when performing carotid ultrasound is significantly higher than MDCT assessment of coronary calcification.

AB0356 COMPARISON FOREARM BONE MINERAL DENSITY BETWEEN LUMBAR SPINE AND HIP: A USEFUL TOOL TO SCREEN OSTEOPOROSIS IN FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS

Yu Wang, Zhuzui Zhang, First hospital of Peking University, Beijing, China

Background: DXA is widely used in clinical practise in BMD measurement. Forearm and axial BMD is the most common site to define in clinical practise. However, the relationship between forearm and axial BMD is not confirmed in RA patients.

Objectives: To compare the forearm (bone mineral density) BMD between lumbar spine and left hip BMD by dual-energy X-ray absorptiometry (DXA), and explore the diagnostic value of the forearm BMD in rheumatoid arthritis (RA) patients.

Methods: In the study, 200 female patients with established RA underwent DXA of the lumbar, left hip and non-superiority forearm DXA at the same time. We compared BMD at different sites, and the diagnostic cut-off value of abnormal axial BMD by forearm BMD was explored. Data analysis was performed by independent-sample t test and Pearson’s correlation test. The area under the operating characteristic curve (AUC) and calibration of predictions were assessed. Sensitivity and specificity were calculated to determine the correlation between cases of osteoporosis detected by the axial DXA scan and forearm.

Results: (1) The mean age of the 200 female patients was (55.9±13.8) years. Twenty (10.0%) patients had the fragility fracture history. Based on their axial DXA data and fracture history, 30 (15.0%) patients had normal BMD (T score ≥-1.0), 170 (85.0%) patients had abnormal BMD. The mean forearm BMD was (0.35±0.13) g/cm2, and T score was -2.3±1.9. (2) Compared with abnormal axial bone group, forearm BMD in normal axial group was significantly decreased [(0.33±0.13) g/cm2 vs (0.44±0.06) g/cm2, I=4.29, P<0.01], forearm T score was also significantly decreased [(2.6±1.9) vs (-0.7±0.9), I=4.35, P<0.01]. T score of the forearm BMD was positively correlated with axial BMD T score, both at lumbar and left arm.

AB0357 CORRELATION BETWEEN DISEASE ACTIVITY AND MENTAL HEALTH OF RA PATIENTS- ASSESSMENT WITH SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILE TOOLS

Bin Wu1, Hua Wei2, Jianhong Wu3, Yi Zhang4, Li Shengguang5, Li Fen6, Yuhua Jia7, Hui Xiao7, Fei Xiao7, Hui Song8, SSDM Collaboration Group, China.

1Chongqing Hospital of Traditional Chinese Medicine, Chongqing, China;
2Northern Jiangsu People’s Hospital, Yangzhou, China; 3Dazhou Central Hospital, Dazhou, China; 4Yuanwu Hospital, Capital Medical University, Beijing, China; 5Peking University Hospital, Beijing, China; 6The Second Xiangya Hospital of Central South University, Changsha, China; 7Shanghai Goed Internet Technology Co., Ltd., Shanghai, China; 8Beijing Jishuitan Hospital, Beijing, China.

Background: WHO survey showed that the prevalence of anxiety and depression in Chinese population and Chinese patients with chronic diseases were between 3.1% - 4.2% and 3.1% - 7.3%, respectively. The prevalence of anxiety and depression in Chinese patients with chronic diseases was between 3.1% - 4.2% and 3.1% - 7.3%, respectively. In recent years, social status of patients with chronic disease was improved, and social and their mental health was more and more recognized.

Objectives: To evaluate the prevalence of anxiety and depression in Chinese patients with RA and to analyze the potential association between disease activity and mental health.

Methods: Under the guidance and training by health professionals, RA patients downloaded SSDM and performed self-evaluation bundle of DAS28, HAQ and HADS with SSDM. DAS28<3.2 and HAQ<0 are criteria for Treat-to-Target (T2T) and normal physical function, HADS score >8 can be diagnosed with anxiety or depression.

Results: From June 2016 to Jan 2019, 2,635 RA patients (461 male, 2,174 female) with a mean age of 49.9±14.23 (11-88) years and the median disease duration of 65.37 months from 175 hospitals performed bundle self-evaluation for 7,455 times in total. According to the HADS and DAS28 assessment results, the prevalence of anxiety and depression in all patients was 33.30% and 39.04% respectively, which was significantly higher than that in the WHO survey in Chinese population and chronic disease patients. The proportion of patients achieved and failed on T2T was 29% and 71%, respectively.

Conclusion: Our study has confirmed that DXA measurement performed of forearm analysis is capable of screening osteoporosis defined by axial BMD in female RA patients.

depression was 20% and 25% among T2T achievers; and 31% and 38% among T2T failures, respectively (P<0.05, P<0.05).

According to DAS28, the prevalence of anxiety was 19%, 20%, 27% and 41% in Remission (Rem), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) subgroups respectively, the prevalence of depression was 24%, 26%, 33% and 49% respectively. The correlation coefficients of anxiety (A) and depression (D) with DAS28 were r_A = 0.318 and r_D = 0.834, respectively. It suggested that with the increase of disease activity, the proportion of RA patients with anxiety and depression increased significantly.

Combined with physical function evaluation results, the overall prevalence of anxiety (23.65%) and depression (33.20%) in the normal HAQ group was significantly lower than that in the abnormal HAQ group (A: 36.37%; D: 43.19%; x_A^2 = 4.52; x_D^2 = 6.21; P<0.05, P<0.05). 20.50% of the patients with HAQ=0 and DAS28=-2.6 were still depressed. The analysis showed that these subgroup patients comorbid with other rheumatic diseases (SS 3%, SLE 15%) or suffer adverse events (abnormal WBC count: 19%; abnormal liver function: 15%) during treatment.

Conclusion: Higher prevalence of anxiety and depression were associated with higher levels of disease activity and worse physical function. Rheumatic comorbidity and adverse events (ADEs) were potentially associated with depression in the Rem group in Low disease activity subgroups with normal physical function.

SSDM is an effective mobile interface to monitor and study entan-
glement of disease activity, physical function and mental health in RA patients, which build a foundation for proactive interventions in future.

TREATING STRATEGY FOR ELDERLY RHEUMATOID ARTHRITIS PATIENT, ESPECIALLY WHOSE AGE IS MORE THAN 75

Ichiro Yoshii1, Tatsumi Chijiwa2, Naoya Sawada3, 1Yoshi Hospital, Rheumatology and Musculoskeletal Medicine, Shinkyo City, Japan; 2Kochi Memorial Hospital, Rheumatology, Kochi, Japan; 3Doha Orsen Hospital, Rheumatology, Matsuyama, Japan

Background: A population of elderly rheumatoid arthritis (ERA) is increasing, probably due to treatment development and simply elderly population increase. In aging, functional activity in daily life, immunity, especially T-cell function, and neural response decline and deteriorations become manifested. Treatment must not be same as that of young patient.

Objectives: To evaluate our treatment method and strategy for ERA.

Methods: From August 2010 to July 2015, 576 patient who have been treated in the institute continuously for more than 3 years were referred. In these, patients were classified in according with age at baseline (BL): younger than 65 (G-Y), from 65 to 74 (G-O), and no less than 75 (G-OO). Mean 28-joints disease activity score (DAS28), Health Assessment Questionnaire Disability Index (HAQ), Pain score with visual analog scale (PS-VAS), drug administration history and dosage, were recorded. For ERA, we have adopted a treating strategy called “Touch Down Straty”, what configures three tactics; 1) From BL, methotrexate (MTX) 5mg/week or tacrolimus (TAC) 1.5mg/day administer. 2) Increase or main-
tain drug dosage until clinical remission is attained or start bDMARDs when remission is not attained in 3 months, and in case, glucocorticoid (GCS) administered with every other month interval. 3)When clinical remission is attained, GCS tapering started immediately and csDMARDs tapering considered. Tapering of bDMARDs is the last order.

ERA patients were treated under these tactics. Monitored DAS28, HAQ score and PS-VAS were calculated for each group and compared with ANOVA with Bonferroni correction.

Results: HAQ at baseline demonstrated significantly higher in G-OO than the other groups. Prevalence of DAS28 remission were 76.4%, 89.6%, and 87.2%, while mean length from BL to DAS28 remission was 2.9, 2.5 and 4.0 months for G-Y, G-O, and G-OO, respectively. bDMARDs admin-
istration ratio was 19.8%, 20.6%, and 18.0%, while mean MTX dosage was 8.6mg, 8.6mg, and 7.4mg/week, for G-Y, G-O, and G-OO respectively. GCS administration ratio and mean dosage until DAS28 remission were 24.2% and 2.96mg, 38.0% and 2.41mg, and 42.6% and 2.71mg/ day, while after remission 19.3% and 5.66mg, 21.1% and 4.58mg, and 28.4% and 2.14mg/day, for G-Y, G-O, and G-OO, respectively (Table).

Conclusion: Our Touch Down Strategy can work effective for ERA, espe-
cially for elderly ERA whose age is over 75 years old. Just by doing take care for risk of comorbidities, ERA can be well controlled their disease activity.

AB0360

EVALUATION OF HEALTHCARE RESOURCE UTILISATION AND COSTS OF SJÖGREN’S SYNDROME PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT OR ANTI-TNF DMARDs

Evo Alemao, Aarti Rad, Joe Zhuo, Chidananda Samal, Robert Wong, Paul Allison, Bristol-Myers Squibb, Princeton, United States of America; *Mu Sigma, Bangalore, India; †Statistical Horizons LLC, Ardmore, United States of America

Background: Sjögren’s syndrome (SS) is considered an extra-articular manifestation of RA and is an autoantibody-mediated condition similar to RA. In an open-label, prospective, observational multicentre study, abatacept (ABA) was found to be effective for both RA and SS-related manifestations.1 However, there are limited data on the healthcare resource utilisation (HCRU) and cost in patients (pts) with RA with SS managed with ABA compared with those managed with anti-TNFs.

Objectives: To evaluate the HCRU and cost for pts with SS associated with RA treated with ABA or anti-TNF DMARDs.

Methods: Pts (≥18 years) from the Truven MarketScan™ administrative claims database with incident RA (≥2 claims for RA using International Classification of Diseases [ICD]-9 or ICD-10 codes and ≥1 claim for a conventional DMARD), incident SS (≥1 claim for SS using ICD-9 or ICD-10 codes) and with a prescription for ABA or an anti-TNF on or after the first diagnosis of SS from Jan 2011 to Sep 2017 were included. Pts were divided into two mutually exclusive cohorts. Pts with prescriptions for both ABA and an anti-TNF were excluded. The index date was the date of ABA or anti-TNF prescription. All-cause HCRU (healthcare visits) and costs were captured during the 2-year enrolled period prior to the index date (baseline) and in the 2-year enrolled follow-up period or until the pt was taken off the index drug, whichever occurred earlier. The baseline and follow-up periods were divided into intervals of 6 months each. Total healthcare visits (inpatient, outpatient, emergency care, urgent care and pharmacy) and total healthcare costs associated with these visits were calculated for each interval. A fixed-effects model was used to compare the HCRU and costs for pts taking ABA vs anti-TNFs after controlling for baseline Charlson Comorbidity Index and other comorbidities of interest.

| Table 1: Characteristics of G-Y, G-O, and G-OO |
|----------|----------|----------|----------|
| G-Y      | G-YO     | G-OO     | S.S.     |
| Cases    | 207      | 142      | 227      | n.s.    |
| female (%) | 154      | 103      | 167      | n.s.    |

ANALYSIS OF SEQUENTIAL DEVELOPMENT OF PULMONARY LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Ayasa Tamako, Yuta Takamuru, Tomoyuki Miya, Ryutaro Yamaizaki, Satoko Arai, Takayoshi Owada, Rekha Maekaru, Masakuni Arima, Kazuhiro Kurasawa, Dokkyo Medical University, Rheumatology, Tochigi, Japan

Background: Pulmonary involvement is critical for the management of RA. Pulmonary involvement shows various features in pathology and imaging such as interstitial pneumonia (ILD) and airway diseases (ADs). Importantly, pulmonary abnormalities coexist with other ones. We have previously reported that these were characteristic patterns and ADs were shared abnormalities of patients with pulmonary lesions. However, it remains unknown through what pathways various pulmonary lesions develop.

Objectives: The purpose of this study was to determine the sequential development of pulmonary abnormalities in RA.

Methods: A retrospective cohort study. Subjects were consecutive 208 RA patients who were treated with bDMARDs as the first one from Feb.2004 to Sep. 2015 in our department and received HRCT scan before and during the therapy. Based on HR-CT imaging, pulmonary abnormalities were classified into 4 categories (ILD, nodular lesions, airway disease (AD) and others) and 20 lesions such as ground-glass opacity (GGO), reticular pattern, broncholiths and bronchiectasis. We recorded their existence and distribution and examined their changes. Cluster analysis was conducted according to new lesions at the second CT scans during the biological DMARDs, by Ward method. A checkerboard analysis with Chi-square test followed by residual analysis was conducted to examine the relation between pre-existing and newly emerging lesions. We compared the frequencies and pattern of newly emerging lesions in patients with or without pre-existing lesions.

Results: Subjects were 208 RA patients; M/F: 64/144, mean age: 59.2 years old, disease duration: 7.9 years, positive for RF in 84.1%, bDMARDs used for the longest period were TNF inhibitors in 79.8% of the subjects, abatacept in 15.4% and tocilizumab in 4.8%. Pulmonary
abnormalities were found in 146 (70.2%) of patients at the entry (ILD 81, (38.9%); nodular lesions 45, (21.6%); and AD 115, (55.3%)). During the observation period (3.26±2.61 years), newly emerging pulmonary lesions were found in 31.3% of patients and the incidence of which was 11.1/ 100 person-year. Cluster analysis of newly emerging lesions showed 7 clusters (Fig.1); Cluster 1: no new lesions, Cluster 2: nodular lesions, Cluster 3: curved linear opacities, Cluster 4: bronchiectasis, Cluster 5: consolidations, Cluster 6: new bronchiolitis, and Cluster 7: GGO. Newly emerging lesions frequently occurred in patients with pre-existing pulmonary lesions. Notably, curved linear opacities and bronchiolitis were developed in patients without pre-existing lesions with high frequencies compared to those with pre-existing ones (Fig.1). In patients with pre-existing lesions, various lesions were developed, particularly GGO and consolidation.

The checkerboard analysis of pre-existing and newly emerging lesions revealed relation between 1) pre-existing honeycomb, small nodular lesions, bronchiolitis or bronchiectasis and newly emerging GGO and 2) pre-existing nodules and new bronchial wall thickening. In addition, bronchiectasis has the tendency to develop in patients with bronchitis, and conversely bronchiolitis occurred in patients with bronchiectasis. The relation between pre-existing small nodules or bronchiolitis and GGO was shown by analysis of pre-existing lesions and clusters of newly emerging ones.

Conclusion: Pulmonary lesions were developed in several patterns, not at random. Pre-existing pulmonary abnormalities induced new pulmonary lesions. Airway diseases, particularly bronchiolitis, might be important initial lesions that induce new pulmonary lesions, especially GGO.

Disclosure of Interests: None declared

Results: In group 1 (30) 33.7% of RF positive patients suffered from RA, with (63) 70.7% in group 2 and (82) 92.1% in group 3 (P=0.00001). In group 1 17% were current or ex-smokers, 29% in group 2 and 52.7% in group 3 (P=0.02). Lung disease was present in 13.4% from group 1, 7.8% from group 2 and 12.3% from group 3 with no significant statically difference between the three groups (p=0.376). In group 2 and 3 all patients with lung disease had RA. From group 1, 50% of those with lung disease had a diagnosis of COPD, followed by 20% with bronchiectasis and 10% with ILD. Of note patients with a diagnosis of COPD had a higher titer of RF. In group 2 a third of patients with lung disease had a diagnosis of COPD and ILD respectively, and again these patients had higher titers of anti-CCP. In group 3 13.4% suffered from lung manifestations and 37.5% had a diagnosis of pulmonary fibrosis, 12.5% diagnosed with ILD and the remaining 50% had COPD and pleural disease.

Conclusion: Antibody positivity was associated with higher prevalence of RA. Our data provide evidence for the association between smoking and raised antibody titers, especially with anti-CCP antibodies. Lung disease was more strongly associated with RF than anti CCP even though the proportion of smokers was higher in patients with positive anti CCP compared than RF. However lung pathology varied with airway obstruction being more prevalent in RF positive patients compared with fibrosis in patients who were RF and CCP positive. Furthermore, our findings suggest that RF is more strongly associated with lung disease than anti CCP though cirrhilisation is thought to start in the lungs. Our findings demonstrate that lung disease is prevalent in patients with RA and should be anticipated and treated accordingly in order to reduce mortality. Seropositivity of both RF and anti-CCP can be linked with a higher prevalence and greater severity of pulmonary disease activity however this requires replication in a larger cohort.

ABO360D ADHERENCE TO THERAPY IN RHEUMATIC PATIENTS TREATED WITH SUBCUTANEOUS BIOLOGICS
Michele Colalisi1,2, Tiziana Pugliesi3, Elena Calacciu2. 1University of Catania, Catania, Italy; 2Cannizzaro Hospital, Catania, Italy

Background: Patients’ adherence to treatments is undoubtedly a fundamental part of a successful therapeutic strategy, even for rheumatic diseases. In fact, the lack of adherence to treatment should be considered in all cases of “supposed” inefficacy of therapy prescribed.

Objectives: We aimed to evaluate the adherence to treatment in a series of rheumatic patients from a single Centre (Catania, Sicily, Italy).

Methods: We recruited 85 consecutive patients (M/F: 25/60; mean age 52.7±13.5 years) affected by chronic inflammatory arthropathies treated with subcutaneous biologics. All patients completed the 5-item version of Compliance Questionnaire for Rheumatology (COR 5) and the Morisky Medication Adherence Scales (MMAS-8). In order to estimate their adherence to therapy, Moreover, all patients completed the Patient Global Assessment (PGA), the Visual Analogue Scale (VAS) for articular pain, and the Health Assessment Questionnaire (HAQ), in order to estimate their personal judgments on the effectiveness of therapies. Finally, the eventual presence of adverse events were reported.

Results: Considering MMAS-8, 7/85 (8.2%) patients were low adherent to treatment (score <6), and 27/85 (31.8%) presented medium-grade adherence (score 6-7). Interestingly, the COR 5 failed to precisely identify these patients. Adherence to therapy was not related to age, gender, education level, articular disease, adverse events, association with DMARDS. Notably, the use of etanercept (originator or biosimilar) was significant more frequent in low-adherent patients (57/ vs 19/78; p=0.017). Finally, a trend to higher median levels of PGA (57.1 vs 37.6; p=0.06), VAS (82 vs 42.6; p=0.06), HAQ (1.3 vs 0.7; p=0.056) was reported in low-adherent patients.

Conclusion: Our preliminary study confirmed that the low adherence to therapy (better identified with MMAS-8) is a relevant issue in the management of rheumatic patients treated with biologics. Moreover, low-
adherent patients tend to perceive a worse disease condition. Further studies can clarify if low adherence is causally associated with less efficacy of therapy.

SLEEP DISORDER OR DEPRESSION IN KOREAN RHEUMATOID ARTHRITIS, AND ITS ASSOCIATION WITH DISEASE ACTIVITY

Kyeong Min Son, Seoung Hun Kang, Young Il Seo, Hyun Ah Kim. Hallym University Sacred Heart Hospital, Gyeonggi-do, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis is a chronic autoimmune disease. Psychological stress and mood disorders such as sleep disorder or depression are more frequent in patient with RA.

Objectives: The aim of this study was to evaluate the relationship between disease activities and sleep disorder or depression in Korean patients with RA.

Methods: The study enrolled 334 patients with RA who visited Hallym University Sacred Heart Hospital (South Korea). The diagnosis of insomnia and depression was based in patient questionnaire such as Pittsburgh sleep quality index (PSQI) and Beck depression inventory (BDI). Insomnia was defined as PSQI>5 and depression was defined as BDI >13. Patients were divided into two groups (insomnia vs no-insomnia, depression vs no-depression) and the clinical aspects were compared by Mann-Whitney U-test. Age, gender, erythrocyte sedimentation rate (ESR), 28 joint disease activity score (DAS28), DAS28-P score (the subjective component of the DAS28 relative to the total components), tender joint count (TJC) and swollen joint count (SJC), quality of life measured with health assessment questionnaire (HAQ) were analyzed.

Results: The median (inter-quartile range) disease duration was 6 (4–9) years and the mean DAS28 score was 3.61±1.1. Seventy percent of the patient had insomnia and 8% had depression. Compared with patients without insomnia, insomnia patients had a higher DAS28 (3.7±1.16 vs. 3.21±1.0, P<0.001), higher pain DAS28-P (0.37±0.17 vs. 0.32±0.16, P=0.004), higher TJC (4.63±5.68 vs. 2.38±3.45, P<0.001) and higher HAQ score (0.49±0.53 vs. 0.18±0.36, P<0.001). Compared with no depression patients, depression patients had a higher DAS28 (4.07±1.37 vs. 3.51±1.11, P<0.001), higher pain DAS28-P (0.44±0.17 vs. 0.35±0.44, P=0.015), higher TJC (6.96±1.57 vs. 3.71±1.02, P=0.006), higher SJC (1.81±1.52 vs. 0.67±1.28, P<0.003), and higher HAQ score (0.63±0.51 vs. 0.38±0.5, P<0.021).

On univariable logistic regression analysis, insomnia was positively associated with age, DAS28, DAS28-P and BDI score. After adjustment, insomnia was positively associated with sex (female), age, BDI and DAS28 score. On univariable logistic regression analysis, depression was positively associated with PSQI, DAS28 and DAS28-P score. After adjustment, depression was positively associated with PSQI and DAS28-P score.

Conclusion: Rheumatoid arthritis patient with the sleep disorder or depression had worse clinical symptoms than those without. Rheumatologist should take sleep disorder or depression into consideration on evaluation of disease severity in RA patients.

Disclosure of Interests: None declared

GENDER DIFFERENCES IN CLINICAL CHARACTERISTICS AND COMORBIDITIES AND THEIR IMPACT ON CLINICAL OUTCOME IN KOREAN PATIENTS WITH RHEUMATOID ARTHRITIS

Seungwhan Shin1, Eun Ha Kang1, Yun Jong Lee1, Yeong Wook Song2, You-Jung Ha1. 1Seoul National University Bundang Hospital, Department of Internal Medicine, Gyeonggi-do, Korea, Rep. of (South Korea); 2Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea).

Background: Rheumatoid arthritis (RA) is a chronic auto-immune disease that is more common to female than male. Gender-based differences in clinical features, comorbidities, and disease outcomes have been fragmentarily described. However, systematic analysis focusing on gender differences in a large RA population is scarce.

Objectives: We aimed to elucidate gender differences in clinical characteristics and comorbidities and their potential impact on clinical outcome in a large Korean cohort of patients with RA.

Methods: A total of 5,376 RA patients were included from the KORean Observational study Network for Arthritis (KORONA) database. Each patient was examined at baseline and three consecutive years. RA disease activity, functional disability, and quality of life were assessed by disease activity score 28 (DAS28), health assessment questionnaire (HAQ) and EuroQoL-5D (EQ-5D), respectively. The subjective health-related outcomes including visual analog scale (VAS) scores for patient’s and physician’s global health, patient’s pain, fatigue, and sleep disturbance were collected. Clinical characteristics and comorbidities at baseline were compared according to gender. Gender impacts on clinical outcome during the four years were analyzed using generalized estimating equations (GEE) models for repeated measures. In addition, the gender effect on achieving clinical remission was analyzed using Cox-proportional hazards regression.

Results: At baseline, females (n=4,574) were younger, more erosive, and had longer disease duration than male (n=802). Females showed significantly higher scores in DAS28, HAQ, EQ-5D, and VAS for all patients’ health-related outcomes. In terms of comorbidities, the prevalence of male RA was significantly higher than that of female RA in most illnesses including, interstitial lung disease, cardiovascular disease, diabetes and other pulmonary disease except for depression. In the GEE model, gender was found to significantly influence the rate of change of DAS28 (p=0.041), and also independently associated with this outcome (p=0.001) after adjusting for age, disease duration, and baseline DAS28. Females were associated with a reduced rate of achieving DAS28 remission (HR 0.41, 95% CI 0.28-0.58) compared to male.

Conclusion: In Korean patients with RA, most comorbidities were more prevalent in male than in female. But for RA-related health outcomes, the longitudinal change in disease activity and the rate of achieving clinical remission over time were found to be worse in female RA.

DETECTABLE HBV DNA AT TREATMENT BASELINE PREDICTED HEPATITIS B VIRUS REACTIVATION IN INFLAMMATORY ARTHRITIS PATIENTS WITH NEGATIVE HEPATITIS B SURFACE ANTIGEN BUT POSITIVE ANTI-HEPATITIS B CORE ANTIGEN

Grace Chup-Hei Ho, Queen Elizabeth Hospital, Medicine, Kowloon, Hong Kong (SAF)

Background: Hepatitis B virus (HBV) reactivation in inflammatory arthritis IA (rheumatoid arthritis, psoriatic arthritis, and peripheral spondyloarthritides) patients with positive hepatitis B surface antigen but positive anti-hepatitis B core antibody (HBsAg/anti-HBc) is one of the treatment-related complications. The risk of reactivation in patients with negative hepatitis B surface antigen but positive anti-hepatitis B core antibody (HBsAg/anti-HBc) is less well defined.

Objectives: This retrospective, single centre study aimed to study the prevalence of HBV reactivation (defined as HBV DNA becoming detectable during treatment if it was undetectable at baseline, or an increase in HBV DNA titre if detectable at baseline) among IA patients with HBsAg+/anti-HBc+ status. Demographic data, clinical parameters including treatments for IA and any use of antiviral prophylaxis, and laboratory results including anti-hepatitis B surface antibody (anti-HBs) and serial HBV DNA levels were obtained. Logistic regression was used to identify factors predicting HBV reactivation.

Scientific Abstracts
Results: Around 1/3 (68%) of the 206 included patients included were female and the mean age was 61.7-year-old. 75% had rheumatoid arthritis and the remaining had psoriatic arthritis or peripheral spondyloarthritis. Most patients (94%, n=194) were on conventional synthetic DMARD csDMARD (25% on monotherapy and 16% on combination therapy). 35% patients (n=72) were on biologic DMARD (with or without csDMARD). As antiviral prophylaxis was not mandatory in HBsAg/anti-HBc+ patients according to local protocol, only 17 patients (8.3%) were on preemptive antiviral against HBV. Thirteen patients (6.3%) experienced HBV reactivation during their disease course and four of them were on antiviral prophylaxis. All of these reactivations were only transient low-grade viraemia with HBV DNA level ≤ 20IU/ml. Spontaneous resolution of viraemia were observed in all these patients. None of the reactivation resulted in acute hepatitis, hepatic failure or mortality.

Presence of detectable HBV DNA at baseline predicted HBV reactivation (OR 2.10, p=0.005). Other parameters including age, the lack of antiviral prophylaxis, negative anti-HBs status and anti-HBs titre were not significant predictors of HBV reactivation. None of the synthetic and biologic DMARDs were associated with HBV reactivation.

Conclusion: HBV reactivation was infrequent among IA patients with HBsAg-/anti-HBc+ status and was unlikely to be associated with adverse clinical outcome. It could occur in patients with positive anti-HBs or on antiviral prophylaxis. Detectable HBV DNA at baseline was a predictor of HBV reactivation.

Rheumatoid arthritis – biological DMARDs________

ABCD1 ASCORE, A 2-YEAR, OBSERVATIONAL, PROSPECTIVE MULTICENTRE STUDY OF SUBCUTANEOUS ABATACEPT FOR THE TREATMENT OF RHEUMATOID ARTHRITIS IN ROUTINE CLINICAL PRACTICE: 1-YEAR INTERIM ANALYSIS

Rieke Alten1, Xavier Mariette2, Maya Buch3, Roberto Caporali4, Rene-Marc Filipo5, Adrian Forster6, Michael Nurmoshamed7, Yusuf Patel8, Peter Peichl9, Adrian Forster6, Michael Nurmoshamed7, Yusuf Patel8, Peter Peichl9, Raimon Sanmarti10, Melanie Chartier11, Julia Heitzmann12, Christiane Rauch13, Rieke Alten1, Xavier Mariette2, Maya Buch3, Roberto Caporali4, Rene-Marc Filipo5, Adrian Forster6, Michael Nurmoshamed7, Yusuf Patel8, Peter Peichl9, Raimon Sanmarti10, Melanie Chartier11, Julia Heitzmann12, Christiane Rauch13, 1University Medicine Berlin, Berlin, Germany; 2Universität Zurich, Zürich, Switzerland; 3ARC Amsterdam University Hospitals – VU University Medical and Reade, Amsterdam, Netherlands; 4Hull Royal Infirmary, Hull, United Kingdom; 5Evangelical Hospital, Vienna, Austria; 6Hospital Clinic de Barcelona, Barcelona, Spain; 7Bristol-Myers Squibb, Rueil-Malmaison, France; 8Excelya, Boulogne-Billancourt, France; 9Bristol-Myers Squibb, Munich, Germany; 10Bristol-Myers Squibb, Princeton, United States of America

Background: ASCORE (Abatacept [ABA] SubCutaNeous in Routine clinical pracTice: ClinicalTrials.gov: NCT02090556) is an ongoing, 2-year, observational, prospective multicentre study of patients (pts) with RA initiating SC ABA in routine clinical practice.

Objectives: To present for the first time 1-year interim retention rates and clinical outcomes by previous biologic (b)DMARD exposure.

Methods: Pts (≥18 years) with moderate-severe RA, who initiated SC ABA 125 mg weekly, were enrolled (Mar 2013–Jan 2017) across 10 countries in two cohorts: biologic-naïve pts and those who had failed ≥ 1 prior bDMARD. Pt and disease characteristics were recorded. ABA retention rates (95% CI) were estimated at 1-year by Kaplan-Meier analysis. Good/moderate EULAR response rates based on DAS28 (ESR, otherwise CRP), LDA or remission according to DAS28 (ESR; <32), SDAI (<11), CDAI (<10) and Boolean criteria were assessed at 1 year.

Results: A total of 2943/2949 enrolled pts were evaluable: 1162 (40.9%) were biologic naïve; 740 (26.0%) had failed 1 and 941 (33.1%) had failed ≥ 2 prior biologics. At baseline, pts with a higher vs lower number of prior bDMARDs had longer disease duration and greater presence of erosive disease vs pts who were biologic-naïve; CRP was higher in biologic-naïve vs failure pts; disease activity was similar across treatment exposures. Overall SC ABA retention (95% CI) at 1 year was 65.3% (63.4, 67.0); retention was higher in pts receiving ABA as a first vs later bDMARD (71% [68.3, 73.7] in biologic-naïve pts vs 61.9% [58.2, 65.4] and 60.7% [57.4, 63.8] in those with 1 and ≥ 2 prior biologic failures, respectively; Figure). At 1 year, 943 pts had discontinued ABA: 465/936 [49.7%] due to inefficacy and 218/936 [23.3%] due to safety (data unavailable, n=9/943). Among pts continuing ABA at 1 year, good/moderate EULAR response rates for pts who were biologic-naïve and those with 1 and ≥ 2 prior biologic failures were 81.0%, 70.0% and 66.4%, respectively. Corresponding rates for LDA outcomes were also higher with ABA as an earlier vs later bDMARD. The safety profile was similar across patient cohorts and consistent with real-world IV ABA studies.1,2

Conclusion: In routine clinical practice, overall retention of SC abatacept at 1 year was around 65% and comparable with that of IV abatacept.2 Among pts continuing abatacept at 1 year, good/moderate EULAR response rates were consistently ≥65% irrespective of prior bDMARD exposure. Better retention and clinical response rates were achieved with abatacept earlier in bDMARD treatment history.

Figure 1

Background: Within treat-to-target approach, ACR recommends biologic DMARD (bDMARD), with or without methotrexate, in rheumatoid arthritis (RA) patients whose disease is active despite methotrexate treatment1. ACR further defines bDMARD failure as the lack of efficacy (desired response) or side effects. Understanding the real-world characteristics and treatment patterns of the patients who become DMARD inadequate responders (IR) may help clinicians tailor the next treatment to patient needs and health status.

Objectives: This study described treatment patterns, treatment duration, and characteristics of RA patients who became IR to their first bDMARD.

Methods: The study population included adult patients with Medicare medical and pharmacy insurance coverage (20% sample) who became bDMARD IR: ≥2 RA claims, newly initiated bDMARD (initial therapy) and then switched (index date) to another bDMARD or JAKI (index therapy). Patients with cancer, non-RA autoimmune disease, or pregnancy were excluded. At least 1 year pre- (baseline) and 1-year post-index enrollment was required. Patient characteristics and treatment allocation and duration were assessed.

Results: A total of 528 bDMARD IR patients met the study selection criteria. At baseline, these patients used monotherapy (n=165, 31.2%) or bDMARD+csDMARD combination (n=363, 68.8%). Patient baseline demographics were comparable between monotherapy and combination therapy groups: mean (SD) age 65.6 (11.0) years, 85.0% female, 81.6% white. The mean (SD) Charleson Comorbidity Index was 1.8 (1.1) for monotherapy and 1.6 (1.0) for combination therapy (P=0.084). On average, patients used 14.8 (7.1) concomitant medications (comparable between groups).

The original bDMARD treatment lasted for median 211 days, including 211 days for monotherapy and 212 days for combination therapy. As bDMARD IR patients switched treatment regimen, they started using either monotherapy (n=187, 35.4%) or combination therapy (n=341, 64.6%). The median duration of subsequent therapies was 287 days overall, including 224 days for monotherapy and 319 days for combination therapy (P=0.0063).

Conclusion: Among Medicare bDMARD IR patients, the median duration of the initial bDMARD therapy lasted for 212 days or less and the subsequent treatments lasted for 319 days or less. This analysis suggests that bDMARD IR patients require alternative efficacious and well-tolerated treatments.

ABO364 DISCONTINUATION OF CONCOMITANT METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOCILIZUMAB: AN INTERVENTIONAL STUDY

Shuji Asai1, Toshihisa Kojima1, Nobunori Takahashi1, Yachiyo Kuwatsuka2, Masahiko Ando2, Nobuki Ishiguro1, *Nagoya University Graduate School of Medicine, Department of Orthopaedic Surgery, Nagoya, Japan; 2Nagoya University Hospital, Department of Advanced Medicine, Nagoya, Japan

Background: Methotrexate (MTX) is an important anchor drug for rheumatoid arthritis (RA) patients and is used alone or in combination with biologics. However, some patients discontinue MTX due to toxicity including gastrointestinal (GI) disorders [1]. Thus, de-escalation of MTX while maintaining a favourable disease activity state—-a challenge in RA clinical research—-may be beneficial from the perspective of reducing adverse events. The efficacy of tocilizumab (TCZ) has been demonstrated in monotherapy as well as with concomitant MTX [2], opening up the possibility of MTX discontinuation in these patients if disease control can be maintained.

Objectives: This study aimed to evaluate the efficacy and safety of MTX discontinuation in RA patients with sustained low disease activity undergoing combination therapy with TCZ plus MTX.

Methods: This multicentre, open-label, uncontrolled, prospective 64-week study included RA patients maintaining low disease activity (Clinical Disease Activity Index [CDAI] ≤10) for ≥12 weeks with TCZ plus MTX. MTX was discontinued following 12 weeks of biweekly administration while continuing TCZ therapy. The rescue treatments were performed if the CDAI score was >10 and at the discretion of the investigator and/or upon patient request. The primary endpoint was the proportion of patients maintaining low disease activity with no flare at week 36 (24 weeks after MTX discontinuation). Disease flare was defined as a CDAI score >10 or intervention with the rescue treatments for any reasons. The proportions (95% CI) of patients who maintained low disease activity without a flare at weeks 12, 24, and 36 were 87.8% (75.2 – 95.4%), 81.6% (68.0 – 91.2%), and 75.5% (61.1 – 86.7%), respectively (Fig. 1). The lower limit of the 95% CI at week 36 exceeded the assumed threshold response rate of 60%, demonstrating the clinical feasibility of MTX discontinuation. The prevalence of gastro-oesophageal reflux disease, defined as a Frequency Scale for Symptoms of Gastro-oesophageal reflux disease score ≥8, significantly decreased from week 0 to 12 (27.1% to 18.4%; P = 0.025) (Fig. 2). No significant changes were observed in the HAQ-DI and EQ-5D from week 0 to 36 (Fig. 3).

AB0365 EFFICACY OF TOCILIZUMAB FOR CORTICOSTEROID AND METHOTREXATE SPARING IN RHEUMATOID ARTHRITIS

Panagiotis Athanassiou1, Marina Gatsiou1, Lambros Athanassiou2, Pavlos Tsakiris1, Akaterini Tzanavari1, Eirini Devetzi1, Charoula Katsavouni1, Iligenia Kostoglou-Athanassiou3, 1St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; 2Aspeleion Hospital, Voula, First Department of Internal Medicine, Thessaloniki, Greece; 3Aspeleion Hospital, Voula, Department of Endocrinology, Athens, Greece

Background: Successful management of rheumatoid arthritis (RA) depends on the early administration of DMARDs and biologic DMARDs. The biologic agent tocilizumab, an interleukin-6 receptor inhibitor, has been used for the management of RA.

Objectives: The aim was to describe a cohort of RA patients treated with tocilizumab and the effect of this treatment on the other DMARDs used, namely methotrexate and corticosteroids.

Methods: In a cohort of 80 patients with rheumatoid arthritis the biologic agent tocilizumab was administered in combination with methotrexate administered sc and 10 mg prednisolone. Within this cohort, 26 patients were on tocilizumab administered iv 8 mg/kg/4wks (maximum dose 800 mg) and 54 were on tocilizumab administered sc 162mg/wk. As corticosteroid administration is characterized by adverse effects, such as osteoporosis and diabetes mellitus, in all patients an effort was made to reduce and if possible, withdraw corticosteroids. An effort was also made to reduce methotrexate dosage. After a year, prednisolone was either significantly reduced or withdrawn. The final dosage of prednisolone was either 2.5-5 mg or complete withdrawal. The successful reduction of methotrexate dosing schedule was also achieved. The final methotrexate dose was either 12.5 mg sc or complete withdrawal. After a period of 52 weeks in this cohort 42 of 80 patients (52.5%) were on methotrexate with tocilizumab.

Results: In a cohort of 80 patients with RA the administrations of tocilizumab, either iv or sc, proved safe and effective. Remission or low disease activity of RA was achieved. Corticosteroid dosage was reduced. After 52 weeks within the group of RA patients on treatment with tocilizumab, in 42 complete withdrawal of corticosteroids and methotrexate proved feasible. Patients on tocilizumab monotherapy remained in remission.

Conclusion: It appears that tocilizumab is safe and effective for the treatment of RA. Tocilizumab treatment may permit withdrawal of both corticosteroids and methotrexate in patients with RA. The management of active RA initially with low dose corticosteroids in combination with methotrexate sc and, in the case of failure to achieve remission, with the addition of the biologic agent tocilizumab had as a result either significant corticosteroid reduction or complete withdrawal and reduction of methotrexate dosage, the disease remaining in remission.

AB0366 COMPARISON OF THE EFFECT OF RITUXIMAB (BCDe) AND RITUXIMAB BIOSIMILAR – BCD-020 (BIODAC) ON INFLAMMATORY AND IMMUNOLOGICAL BIOMARKERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Anastasia Avdeeva1, Maria Cherkasova1, Alexander Artiyuhov2, Eh. Dashinimayev2, D. Kusevich3, Alexander Lila2, Evgeniy Nasonov1; 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Pirogov Russian National Medical University, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Sechenov University, Moscow, Russian Federation

Background: BCD-020 (BCIDAC) is the first Russian rituximab (RTX) biosimilar which was approved for medical use in rheumatoid arthritis (RA) patients in Russia and some CIS countries.

Objectives: To evaluate the changes in acute phase reactants, autoantibodies, immunoglobulins, cytokine profile and CD19+B lymphocytes in patients (pts) with RA during RTX and RTX biosimilar therapy.

Methods: The study included 54 RA patients (pts), divided into two groups. The first group included 34 pts with RA (31 women, mean age 49(42-64), mean disease duration 66(36-132) months, mean DAS 28 6.2 (5.6-8.5) who received two infusions of RTX - 35% at a dose of 500 mg, 65% of the dose of 1000 every two weeks in combination with DMARDs and glucocorticoids; 33 pts achieved a good/moderate EULAR response at week 24. The second group - 20 pts with RA (18 woman, mean age 61.5(54-66.5) years, mean disease duration 39.5(20-84) months, mean DAS 28 5.6(4.9-6.8) who received two intravenous BCD-020 infusions (600mg No 2) in combination with DMARDs and glucocorticoids; 17 pts achieved a good/moderate EULAR response at week 24. Laboratory biomarkers were assessed at baseline and weeks 12 and 24 after the first infusion of RTX. ESR (mm/hr) (Westergren method); serum concentrations of CRP (mg/L), IgM RF (U/ml), IgG RF (U/ml) (laser nephelometry), anti-CCP2 (U/ml), IgA RF (U/ml), anti-MCV (U/ml) (ELISA kits); cytokine profile (xMAP technology) were assessed.

Results: RTX and BCD-020 induced decreases in ESR, levels of CRP, IgMRF, IgARF, anti-MCV at week 12 and 24, p<0.05 (tabl.1). At week 24 – 20% of IgMRF positive pts at baseline (in the first group) and 10% of IgMRF positive pts (in the second group) turned negative. Levels of anti-CCP2 did not reduced. At week 24 – 7% of anti-CCP2 positive pts at baseline (in the first group) and 8% of anti-CCP2 positive pts (in the second group) turned negative. Depletion of CD19+B-cells was achieved at week 12 in all patients (absolute number 0), with an increase in the level of B cells at week 24, tabl.1. An immunoglobulin level decreased at week 24, but remained normal. In the first group RTX induced reduction in proinflammatory (IL-1b, IL-2, IL-6, IL-12, IL-15, IFN-γ, TNF-α), anti-inflammatory cytokines (IL-1Ra, IL-5, IL-10, IL-13), growth factors (IL-7, GM-CSF, FGF-basic) and chemokines (MC-1) at week 24 (fig.1). In the second group BCD-020 induced reduction in IL-1b, IL-1α, IL-2, IL-4, IL-7, GM-CSF, IL-15, IL-17, Eotaxin, G-CSF, IFN-γ, IP-10, MC-1, MIP-1β, TNF-α, VEGF at week 24 p<0.05, fig.1.

Conclusion: RTX biosimilar (BCD-020) has a similar effect on inflammatory and immunological biomarkers to the original RTX. BCD-020 therapy induced a rapid and significant improvement in ESR, levels of CRP, IgMRF, IgARF, anti-MCV, proinflammatory, anti-inflammatory cytokines, growth factors, chemokines levels and CD19+B cells depletion in RA pts.

AB0367 REASONS FOR DISCONTINUATION OF BIOLOGICAL DRUG AND TARGETED SYNTHETIC DRUGS AMONG PATIENTS WITH INFLAMMATORY ARTHRITIS IN THE UNITED ARAB EMIRATES (UAE)

Humaira Badsha1, Khita Harill2, Richard Kirubakaran3, Bhavana Khan2, 1Dr Humaira Badsha, Badsha Medical Center – Rheumatology and Arthritis, Dubai, United Arab Emirates; 2Cochrane South Asia, Vellore, India, 3Integrated Arthritis and Rheumatology Centre, Dubai, United Arab Emirates

Background: In routine clinical care of Rheumatoid arthritis (RA) Spondylarthritids(PA) and Psoriatic arthritis (PSA) there is a high rate of discontinuation of biologic disease-modifying antirheumatic drugs (bDMARDs) and targeted synthetic disease-modifying antirheumatic drugs (tsDMARDs) due to loss of efficacy, side effects or lack of adherence. This can impact on the ability to achieve low disease activity.

Objectives: To evaluate the use of bDMARDs and tsDMARDs and analyze the reasons for discontinuation of these drugs and to compare them to our standard DMARD Methotrexate.

Methods: In this retrospective cohort analysis we included consecutive patients aged ≥ 18 years with RA/SPA/PSA attending 2 Rheumatology clinics in the UAE from August- December 2019. Statistical analysis was performed using STATA version 13 and R-studio. Continuous data were
Safely of combination therapy with two biologic disease-modifying anti-rheumatic drugs (bDMARDs) in association with denosumab: comparison of combination and mono-therapy regimens

Cosimo Brunì, Cosimo Cigolini, Giulia Tesei, Francesca Bartoli, Ginevra Fiori, Maria Letizia Conforti, Silvia Bellando Randone, Serena Guiducci, Marco Matucci-Cerinic, Careggi University Hospital, Firenze, Italy

Background: Osteoporosis is a frequent complication of rheumatic muscle-skeletal diseases (RMD), with high impact from steroid treatment. It is known that bDMARD impact positively on patients' prognosis and this is also known for Denosumab, a monoclonal antibody for osteoporosis. The combination treatment with two monoclonal antibodies, bDMARD & denosumab, has addressed the problem of safety and efficacy, with incomplete answers from the available literature.

Objectives: To evaluate the impact of the combination treatment bDMARD +Denosumab (COMBO group), compared to mono-therapy with bDMARD (MONO group), on clinical efficacy, safety and treatment retention of bDMARD in patients with RMD.

Methods: We searched PubMed, the Cochrane Library, Scopus, Clinical-Trials.gov, and the WHO International Clinical Trials Registry platform through 12/18/17. Our eligibility criteria included human RCTs or observational or non-randomized comparative studies in adults (≥ 18 years of age) that recorded safety of combination therapy with two bDMARDs in RA patients. We used R version 3.1.2 to perform meta-analysis between groups on combination therapy and placebo/single therapy alone using random effect model calculating odds ratio (OR) as well as 95% confidence interval (CI). Cochran Q statistic and I² statistic was used to identify heterogeneity between studies. The primary outcome was the rate of major serious events. Additional outcomes were the rate of total adverse events, total infectious events and major infectious events.

Results: Six studies with a total of 623 patients (410 on combination therapy and 213 on single therapy) were included for meta-analysis. Median follow-up was 9.5 months (range 6-12 months). There was a significant increase in SAEs in the combination group (14.9 vs 6.0%, OR 2.51, 95% CI 1.25-24.90, P0.05). When performing subgroup analysis in patients receiving only full-dose of both bDMARDs there was a significant increase in serious infections (6.7 vs 0.6%, OR 5.58, 95% CI 1.25-24.90, P0.05) and the risk of SAEs remained significantly higher (17.7 vs 6.2%, OR 2.72, 95% CI 1.30-5.69, P0.05).

Conclusion: Our findings suggest that combination therapy with two bDMARDs in RA patients appears to increase the risk of SAEs during the first twelve months of treatment.

Disclosure of Interests: Gonçalo Boleté: None declared, Lukshe Kanagaratnam: None declared, Moustapha Dramé: None declared, Jean-Huges Salmon Speakers bureau: Janssen Novartis

Methods: RMD patients treated with COMBO treatment where enrolled from a single centre rheumatology unit; for each case, at least one MONO therapy control (matched per age≥5 years, sex, bDMARD, RMD, without osteoporosis) was enrolled. Data on clinical efficacy (3-points Likert scale for physician and patient – improved/stable/worse), safety (loci reactions – serious and non-serious adverse events) and bDMARD treatment retention at 12, 18 and 24 months.

Results: Out of 129 eligible patients, 77 were enrolled in the protocol: 49 in the MONO and 26 in the COMBO group. The two groups were different of age (slightly higher in the COMBO group), for tender joint count, erythrocyte sedimentation rate and c-reactive protein (higher in the MONO group). Efficacy analysis showed higher percentage of clinical improvement at 12 months in the MONO group at 12 months, being not significant at 18 and 24 months (possibly explained by a different disease activity at baseline visit, corresponding to the overlap of denosumab on top of bDMARD in the COMBO and to the initiation of bDMARD in the MONO group). Between the 2 groups, no difference about safety and retention rate was found.

Conclusion: The efficacy of COMBO treatment is similar to MONO therapy. Moreover, the data show that also safety and retention rate are similar. Therefore, the COMBO treatment with 2 different monoclonals can be safely employed in patients with RMD and osteoporosis.

AB0372 EXPLORING REFRACTORY DISEASE & PERSISTENT SYMPTOMS IN RA/POLYJA DESPITE BDMARDS: PATIENT & PROFESSIONAL EXPERIENCES

Hema Chaplin1, Ibone Verhey2, Nora Ng3, James Galloway4,5, Ian Scott6,7, Debadjit Sen2, Rachel Tattersall2,3,4, Heidi Lempp3, Sam Norton1, 5, King’s College London; Health Psychology Section, London, United Kingdom; 2King’s College London, London, United Kingdom; 3Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; 4King’s College London, Inflammation Biology, London, United Kingdom; 5King’s College Hospital NHS Foundation Trust, London, United Kingdom; 6Keele University, Stoke-on-Trent, United Kingdom; 7Midlands Partnership NHS Foundation Trust, Stoke-on-Trent, United Kingdom; 8University College London Hospitals NHS Foundation Trust, London, United Kingdom; 9University College London, Versus Arthritis Centre for Adolescent Rheumatology, London, United Kingdom; 10Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; 11Barbara Annis National Network for Adolescent and Young Adult Rheumatology, UK, United Kingdom

Background: Refractory disease is defined as not achieving a low disease activity target despite BDMARDS. This definition does not account for patients with well controlled inflammation who experience persistent symptoms, or who have a high perceived disease impact. Furthermore, variations in professionals understanding of refractory disease and related concepts exists, with potential discordance when compared to patients understanding.

Objectives: To qualitatively explore patients and professionals understanding and experiences of refractory disease and persistent symptoms.

Methods: Semi-structured interviews were conducted with 13 RA and 3 Polyarticular JIA patients (on bDMARD not responding with DAS28>3.2) attending four UK Rheumatology clinics. Thirty-two healthcare professionals (working in Rheumatology >1year) were interviewed across 11 UK hospitals. Interview data was transcribed and descriptive statistics as reported for quantitative data.

Results: Patients had not responded to on average 3 csDMARDs and 3.5 bDMARDs, with mean MSK-HQ=24.6, mean DAS28=4.60, and mean Patient Global=55.4. Healthcare professionals interviewed were predominantly adult trained (25/32), with mean 11.7 years’ experience, comprising rheumatologists, nurses, physiotherapists, occupational therapists, psychologists, pharmacists, podiatrist, and social worker.

Key themes for both patients and professionals experiences of refractory disease and persistent symptoms explored were: 1) Frustrations with the disease, non-response to medication and side effects, 2) Importance of areas not captured by the DAS28, 3) Patient-centred targets/care, 4) Role of other specialties, 5) Role of comorbidities, infections and/or joint damage, and 6) Patient acceptance, adjustment and resilience. Although patients expressed hopeful expectations despite poor experiences, this was in discordance to professionals’ accounts of loss of trust/hope, disengagement and limited treatment options, with hope mainly for stratified medicines.

Patient specific emergent themes identified: 1) Disease not controlled fully but manageable, 2) Drugs do not work: at all versus over time, 3) Persistent pain, fatigue and restricted mobility are most problematic symptoms, 4) Life-limiting impact: practically, psychologically/emotionally and socially, and 5) Good support from rheumatology team but holistic approach needed.

Professionals grouped refractory disease into four key areas: 1) Refractory Inflammation vs Refractory Symptomology, 2) Biological processes, 3) Drug inefficacy/toxicity, and 4) Patient health beliefs/behaviours.

Those with JIA had a greater variety in their experiences compared to those with RA. In addition to above themes they all highlighted the challenges of having a long-term illness so young, e.g. not knowing a life with pain or disease and lack of understanding in both themselves and others. Paediatric/Adolescent professionals noted differences in treating JIA compared to RA, e.g. joints affected and treatment guidelines/recommendations.

Conclusion: These results highlight the potential need for a broader definition for refractory disease, and the need for holistic approaches to treatment that better support both patients, and professionals, in managing their condition.

AB0373 A COMPARATIVE EFFECTIVENESS STUDY OF ABACETEPT AND TNF INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING REAL-WORLD DATA

Evo Alema1, Sean Connolly1, Yedid Elbez2, Aarti Rao3, Yogesh Saini4, Christine Iannaccone5, Michael E. Weinblatt6, Nancy Shadick7, Bristol-Myers Squibb, Princeton, United States of America; 8Medway NHS Trust, France; 9Bangalore, India, 10Brigham and Women’s Hospital, Boston, United States of America

Background: Introduction of multiple biologic DMARDs, targeted synthetic DMARDs and biosimilars has led to a paradigm shift in the management of patients (pts) with RA. There are, however, limited head-to-head studies comparing these agents to guide evidence-based treatment decisions. Abacitcept versus adalimumab compared in bioLogic-naive RA subjects with background MTX (AMPLE) was the first head-to-head randomised controlled trial to evaluate the efficacy of abacitcept (ABA) and adalimumab. However, there are limited data replicating AMPLE findings in real-world settings.

Objectives: To compare effectiveness of ABA versus TNF inhibitors (TNFis) in pts with RA by line of therapy (LOT) and by LOT stratified by anti-citrullinated protein antibody (ACPA) status using data from real-world clinical practice.

Methods: Data from two independent RA registries comprising pts treated by physicians in routine care were used for the analysis. An RA disease-specific registry provided data on pts treated with TNFis; the other was a product-specific registry and provided data on pts treated with ABA.1,2 The disease-specific registry was a US-based single-centre registry; the product-specific registry was a multi-centre, 12-country registry covering the US. Frequency matching on age (in years [yrs]; ±4 yrs window), RA disease duration (in yrs; ±4 yrs) and baseline CDAI category (remission [≤2.8], low activity [≤10], medium activity [12-22], high activity [>22]) between TNFI and ABA pts was done for bioLogic-naive and -experienced pts. Descriptive statistics were used to summarise baseline demographics, disease activity measures and serostatus for both treatment groups by LOT. Disease activity in the follow-up period was measured at the 12-month mark (±6 months). Change in disease activity after 12 months was evaluated for TNFI and ABA pts by LOT, and statistical comparison using Kruskal-Wallis test was performed. This was repeated for pts stratified by ACPA status.

</tbody>
</table>

Results: Data for 105 first-line and 91 second- or further-line (subsequent-line) matched pairs of TNFI and ABA pts were included in the analysis (68 first-line and 60 subsequent matched pairs of TNFI and ABA pts, respectively, in ACPA+ cohort; 31 first-line and 21 subsequent-
line matched pairs of TNFi and ABA pts, respectively, in ACPA+ cohort (Table 1). In the biologic-experienced pts, ABA (vs TNFi) had a higher reduction in CDAI score (10.2 vs 5.2, p<0.035; Table 2). In the biologic-experienced ACPA+ pts, ABA (vs TNFi) had higher reduction in disease activity (CDAI: 13.3 vs 6.2, p<0.023; Table 2; SDAI: 13.9 vs 7.0, p<0.046). No difference in disease activity was observed between the two groups among the ACPA+ pts.

**Conclusion:** Real-world RA registry data further confirm findings from the ABLE-SE study that the overall efficacy of ABA is similar to TNFi agents in biologic-naive pts with RA. Efficacy of ABA (vs TNFi) in biologic-experienced pts is greater, and greater reductions in joint disease activity in ACPA+ ABA (vs TNFi) pts were observed.

**AB0374 ADALIMUMAB DISCONTINUATION IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER ACHIEVING SUSTAINED REMISSION**

**Natilia Demidova**,1 Natilia Savushkina2, Elena Galushko3, Andrey Gordeev2, 1V.
A.Nasonova Research Institute of Rheumatology, early arthritis, Moscow, Russian Federation; 2V.A.Nasonova Research Institute of Rheumatology, early arthritis, Moscow, Russian Federation; 3V.A.Nasonova Research Institute of Rheumatology, early arthritis, Moscow, Russian Federation

**Background:** The most important factor in the progress of pharmacotherapeutic therapy of RA was the widespread implementation of therapy with biological drugs modifying antirheumatic drugs (bDMARD). Recently, the issues of optimizing the management of patients have attracted more and more attention. First of all, we are talking about the possibility of reducing the dose and the abolition of bDMARD with the maintenance of remission (“biological-free remission”).

**Objectives:** To assess whether adalimumab (AD) can be gradually discontinued during continuous methotrexate (MTX) use in patients with early rheumatoid arthritis (ERA).

**Methods:** Within the REMARCA (the Russian study of methotrexate and biological agents in early active arthritis) study, the investigators examined 20 patients (17 women and 3 men; median age, 51 [41.5; 56] years) with ERA (disease duration, 10 [5.5; 20] months; DAS28, 5.17 [4.37; 6.51]; 85% of the patients were seropositive for rheumatoid factor and 85% for anti-cyclic citrullinated peptide antibodies.

All the patients received subcutaneous MTX 25 mg/week. Twelve weeks after beginning therapy with MTX, due to its inefficiency, ADA was added according to the standard scheme. Clinical and laboratory data was analyzed just before the therapy (point-3 months), then at the term of 6 (n=20), 12 (n=17), 24(n=17) and 36 (n=17) months. To assess the effectiveness of therapy, indices of activity DAS28, CDAI and SDAI were used. The everyday life functioning of the patient was assessed quantitatively using the Russian version of the HAQ questionnaire.

**Results:** At week 24, with the combined therapy of methotrexate and adalimumab, about 75% of patients had reached remission/low disease activity; the median DAS28 was 3.0 [1.65; 3.73]; 85% of the patients achieved remission or low disease activity. After 3 months of ADA therapy, high or moderate disease activity remained in 3 (15%) patients; median DAS28 was 4.4 [4.3; 6.1]; the drug was discontinued in them due to ineffective therapy. After 12-month follow-up, low DAS28 scores were observed in 5 (29.4%), DAS28 remission was in 12 (70.6%) of the 17 patients who continued ADA treatment; after 24 months, all the 17 patients were noted to have remission. After achieving sustained remission (>6-month duration during ADA therapy), there was a carefully controlled reduction (titration) in the dose of ADA with its complete discontinuation, by maintaining remission at 36-month follow-up; the median DAS28 was 1.6 [1.4; 2.2].

The disease duration up to 1 year and functional class reduction to I in the first year of observation (r=-46.2; 95% CI 1.870-1141.178; P=0.019 and r=-44.2; 95% CI 1.795-1088.143; P=0.02) were identified as predictors of maintaining long-term remission after the discontinuation of ADA.

**Figure 1. Influence of different factors on the possibility of withdrawal of ADA in patients with RA in remission.**

**Remission maintenance**

**Conclusion:** In most patients with early rheumatoid arthritis, early induction of remission can be maintained after stopping the biologic therapy, under condition that the therapy was carried out by a combination of bDMARD and methotrexate. The maintenance of remission after discontinuation of ADA therapy was influenced by the duration of the disease and the depth of remission.

**AB0375 HYPOGAMMAGLOBULINEMIA AFTER RITUXIMAB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS IS NOT RARE AND IS ASSOCIATED WITH BETTER RESPONSE**

Gerasimos Evangelatos1, George E. Frangouls1, Kostki Kladianas2, Dimitrios Vassilopoulos3, Alexios Ilipoulos3, 1417 Army Share Fund Hospital (NIMTS), Athens, Greece, Rheumatology Department, Athens, Greece; 2Joint Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine-Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine, Athens, Greece

**Background:** Rituximab (RTX) is used as a second line treatment in rheumatoid arthritis (RA), with well-established efficacy. One of the most common adverse events of RTX use is hypogammaglobulinemia (HGG).

**Objectives:** To define, in RA patients treated with Rituximab, the frequency of HGG (lgG>700mg/dL or lgM>40mg/dL or lgA>70mg/dL) and to identify associations between its occurrence and clinical, epidemiological and other disease related features at baseline, RA outcomes and adverse events.

**Methods:** The patients received RTX for RA in two rheumatology centers from 1/2007 to 12/2018 were included. Demographical, clinical and laboratory parameters were recorded at baseline and at the last visit of the follow-up. Time of follow-up was defined as the time interval between the first RTX infusion and the last visit. Patients with monoclonal gammapathy and patients that received only one cycle of treatment were excluded. Severe infections were recorded defined as those which required hospitalization or antibiotics intravenously. Binominal regression analysis using stepwise backwards model having as dependent variables the “low IgG” or “low IgM” and independent variables: gender, age,
RESULTS OF A MANDATORY SWITCHING FROM CLINICAL SIMILARITY OF ABP 710 WITH INFliximab

Sabela Fernández, Senen Gonzalez, Carmen Ordas-Calvo, Edilia García-Gijón, Spain

Background: Currently available evidence indicates that a single switch from a bio-originator to one of its biosimilars is safe and effective and has cost benefits to the National Health Systems. However, there is some reluctance to switch patients due to lack of real-world data and differences between patients treated in the setting of real clinical practice and those of clinical trials.

Objectives: We aimed to investigate the efficacy and safety of Etanercept (ETN) to SB4 carried out in March 2018. Inflammatory arthritis patients (rheumatoid arthritis (RA), psoriatic arthritis (APS), axial spondyloarthritides (AS), juvenile idiopathic arthritis (JIA)) were included in this single-center retrospective observational study from March 2018 to December 2018. Reasons for SB4 withdrawal were categorized as lack of effect (LOE), adverse events (AE) or others.

Methods: At Cabueñes Hospital a non-medical switch from Etanercept (ETN) to SB4 was carried out in March 2018. Inflammatory arthritis patients (rheumatoid arthritis (RA), psoriatic arthritis (APS), axial spondyloarthritides (AS), juvenile idiopathic arthritis (JIA)) were included in this single-center retrospective observational study from March 2018 to December 2018. Reasons for SB4 withdrawal were categorized as lack of effect (LOE), adverse events (AE) or others.

Results: A total of 117 patients were identified, 100% were switched to SB4 maintaining the same dose. Disease duration was 5 (2-8.5) years. 49 patients (41%) had basal optimized dose of ETN (dose down-titration or dose interval expansion). In most patients ETN was the first biologic. 31 patients (26%) stopped SB4 treatment during follow-up, mainly due to LOE (67%) or AE (25%), with median duration of SB4 3.5 months (1-9, 5-9). Most AE that led to withdrawal were dermatological (injection-site reactions, skin rash). 11 patients switched back to ETN, 15 to others. Two patients died, both were APS (one sudden death and one aneurysmal subarachnoid hemorrhage). After switching to SB4, one stable patient with AS had recurrent acute anterior uveitis, and psoriasis worsening were noted in 2 patients with APS. 2 patients needed reinstatement of the full dose of biologic because of LOE. The clinical situation on ETN was stable in 23 of the 31 (74%) patients who stopped SB4 (no flares or changes in treatment in the last 6 months before switch).

Table 1 summarizes baseline characteristics and treatment outcomes. Conclusion: Biosimilar switch of SB4 was successful in over 74% of cases and was well tolerated.

Most patients who stopped SB4 due to LOE had a clinical stable situation in this observational study. Some concerns regarding the safety profile and interchangeability have raised and further evidence on the efficacy of transitioning from reference ETN is needed.

RESULTS OF A MANDATORY SWITCHING FROM ORIGINATOR TO BIOSIMILAR ETANERCEPT IN 117 PATIENTS WITH INFLAMMATORY ARTHRITIS FROM A SINGLE CENTER

Sabela Fernández, Seren Gonzalez, Carmen Ordas-Calvo, Edilia García-Fernández, Belén Rodríguez De-Castro, Jesús Babilio, Gijón, Rheumatology, Gijón, Spain

Background: Currently available evidence indicates that a single switch from a bio-originator to one of its biosimilars is safe and effective and has cost benefits to the National Health Systems. However, there is some reluctance to switch patients due to lack of real-world data and differences between patients treated in the setting of real clinical practice and those of clinical trials.

Objectives: We aimed to investigate the efficacy and safety of Etanercept-biosimilar (SB4), in a non-medical switch in patients with inflammatory arthritis (IA)

Methods: At Cabueñes Hospital a non-medical switch from Etanercept (ETN) to SB4 was carried out in March 2018. Inflammatory arthritis patients (rheumatoid arthritis (RA), psoriatic arthritis (APS), axial spondyloarthritides (AS), juvenile idiopathic arthritis (JIA)) were included in this single-center retrospective observational study from March 2018 to December 2018. Reasons for SB4 withdrawal were categorized as lack of effect (LOE), adverse events (AE) or others.

Results: A total of 117 patients were identified, 100% were switched to SB4 maintaining the same dose. Disease duration was 5 (2-8.5) years. 49 patients (41%) had basal optimized dose of ETN (dose down-titration or dose interval expansion). In most patients ETN was the first biologic. 31 patients (26%) stopped SB4 treatment during follow-up, mainly due to LOE (67%) or AE (25%), with median duration of SB4 3.5 months (1-9, 5-9). Most AE that led to withdrawal were dermatological (injection-site reactions, skin rash). 11 patients switched back to ETN, 15 to others. Two patients died, both were APS (one sudden death and one aneurysmal subarachnoid hemorrhage). After switching to SB4, one stable patient with AS had recurrent acute anterior uveitis, and psoriasis worsening were noted in 2 patients with APS. 2 patients needed reinstatement of the full dose of biologic because of LOE. The clinical situation on ETN was stable in 23 of the 31 (74%) patients who stopped SB4 (no flares or changes in treatment in the last 6 months before switch).

Table 1 summarizes baseline characteristics and treatment outcomes. Conclusion: Biosimilar switch of SB4 was successful in over 74% of cases and was well tolerated.

Most patients who stopped SB4 due to LOE had a clinical stable situation in this observational study. Some concerns regarding the safety profile and interchangeability have raised and further evidence on the efficacy of transitioning from reference ETN is needed.

CLINICAL SIMILARITY OF ABP 710 WITH INFliximab (REFERENCE PRODUCT) IN SUBJECTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

Mark C. Genovese1, Juan Sanchez-Burson2, Myungshin Oh3, Éva Bállás4, Jeffrey Neal5, Gary Fanjiang6, Stanley Cohen7.

1Stanford, Division of Immunology and Rheumatology, Palo Alto, United States of America; 2Hospital Infanta Luisa, Sevilla, Spain; 3Amgen, Thousand Oaks, United States of America; 4Coagrád Megyéi Dr. Bugyi István Kórház, Sima Ferenc, Hungary; 5Bioglasa Community Research, Lexington,KY, United States of America; 6Amgen, Thousand Oaks,CA, United States of America; 7Metroplex Clinical Research, Dallas,Tx, United States of America

Background: ABP 710 is being developed as a biosimilar to infliximab. Both ABP 710 and infliximab reference product (RP) inhibit tumor necrosis factor-alpha and have been shown to be structurally and functionally similar in analytical assessments. In a phase 1 clinical pharmacokinetic (PK) study both were shown to be bioequivalent for PK
The effects of biologicals on reproduction are unknown. Therefore pregnancy during biologicals use is not recommended. However biologicals are frequently prescribed in patients of childbearing potential and many patients become pregnant while using these drugs.

Objectives: In 2015 EULAR published a broad review article on this matter. Our aim was to update the data based on newly published articles.

Methods: A search was conducted at 18/10/2017 and then 21/11/2018 in Embase, Medline Ovid, Web Of Science, Cochrane CENTRAL and Google Scholar with specific search terms for each database. Articles were excluded based on title/abstract (double blind, two researchers, NG and HUMC) and then full text (one researcher, NG). A chart was made based on outcomes of interest (see Table1). The references of included articles were reviewed to include and minimize the missing articles.

Results: Totally 137 articles were included (79 articles at first round, 51 articles at second round and 7 found after screening the references of included articles). A descriptive analysis was performed to sum up the data on each separate biological and all the biologicals together. The results are shown in Table1. It should be notified that due to heterogeneity of the data the calculated percentages are up to individual interpretations and cannot be compared to each other.

Conclusion: From 2015 onwards, there have been many articles published regarding use of biologicals during pregnancy. Despite limitations of our study, such as heterogeneity in being prospective or retrospective and quality of the included articles, no alarm is raised concerning safety issues.

Table 1. Results of the final chart. The denominator is the sum up of total cases recruited from the articles, for each outcome the denominator is defined as the population for which the specific outcome was reported. The other cases, which haven’t mentioned the outcome in their results, were excluded from the denominator for that specific outcome. Both spontaneous and elective abortion cases are excluded from the denominator of preterm birth and major congenital malformations.

GENDER DIFFERENCES IN RHEUMATOID ARTHRITIS: EFFECT OF ANTI-TUMOR NECROSIS FACTOR THERAPY

Chiara Giosa1,2, Francesca Sprielli1, Roberta Priori1, Cristina Iannuccelli1, Bruno Luccichino1, Annarita Vestri1, Guido Valente1, Manuela Di Franco1,2

1 Policlinico Umberto I, Rheumatology, Department of Internal Medicine and Medical Specialties, Sapienza university of Rome, Rome, Italy; 2Sapienza University of Rome, Department of Public Health and Infectious Diseases, Sapienza university of Rome, Rome, Italy

Background: Rheumatoid arthritis (RA) is more prevalent in women than men (F:M=4:1), due to hormonal, genetic and environment factors. Women present higher disease activity markers as Disease Activity Score-28 (DAS28) and Health Assessment Questionnaire (HAQ), at the onset and after c-DMARDs therapy, without correlation with radiographic damage.

Objectives: The purpose of this study was to assess gender differences in RA patients after anti-tumor necrosis factor (TNFα) treatment.

Methods: Ninety-six patients were enrolled at the beginning of anti-TNFα therapy (etanercept and adalimumab). All patients satisfied 1987 and 2005 ACR criteria for RA. They underwent to clinical and clinimetric evaluation at baseline (T0) and after three (T3) and six (T6) months of therapy with: tender and swollen joints, Visual Analogic Scale (VAS) pain, physician global assessment (PhGA) and global assessment (PGA), swollen joint count (SJC) and tender joint count (TJC). Demographic and clinical data were collected. SPSS statistics 22.0 was used for statistical analysis; p values under 0.05 were considered significant.

Results: Among these patients, 70 were women and 26 men; 81 patients (58 female, 23 male) started etanercept and 15 adalimumab (12 female, 3 male). They presented a mean age of 56.4 ± 14.5 years (women 55.2 ± 15.4, men 60 ± 12.2) and mean disease duration of 11 ± 6.8 years (woman 11.51 ± 6.3, men 9.6 ± 8.1). Both women and men had a DAS28 reduction after 3 and 6 months therapy (p<0.05) but DAS28 in women was higher than men at T0, T3 and T6 (p<0.05). Women presented higher number of tender joints in all evaluations, and more swollen joints than men at T0 and T6 (p<0.05). Women felt more active disease at T6 (VAS patient) (p<0.05). CDAI was higher in woman after 3 and 6 months (p<0.05). There were no differences about physician evaluation, inflammation markers, RF and ACPA titers.

Conclusion: In this study, both women and men had a good response to anti-TNF treatment but women presented worse clinical response. Female gender resulted the only variable associated with DAS28 reduction after 3 and 6 months of therapy. We could hypothesize that beyond to biological factors, also social contest, daily life and work activity could explain a worse disease activity.

ISTHERE AN EFFECT OF TOCILIZUMAB IN SERUM AUTOANTIBODIES LEVELS IN RHEUMATOID ARTHRITIS?

2 Centro Hospitalar e Universitário de São João, Department of Rheumatology, Oporto, Portugal.
3 Centro Hospitalar do Bairro Vouga, Department of Rheumatology, Aveiro, Portugal

Background: Interleukin 6 (IL-6) plays a role on B cell differentiation and antibody production. However, few information is available considering the effect of tocilizumab (TCZ) on rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPAs) levels in Rheumatoid Arthritis.

Objectives: To compare serum levels of RF and ACPAs on RA patients at the beginning of therapy with TCZ and at 6 and 12 months under TCZ, assessing if its variations correlate with the several disease activity scores.

Methods: Longitudinal retrospective study of RA patients ever treated with TCZ at a Rheumatology Department. Serum levels of RF and ACPAs at 0, 6 and 12 months after starting anti-IL6 treatment were collected, as well as DAS28, CRP, CDAI, SDI, HAQ, ESR, CRP, patient’s global assessment (PGA), physician’s global assessment (PGa), swollen joint count (SJC) and tender joint count (TJC). Demographic and clinical data were collected. SPSS statistics 22.0 was used for statistical analysis; p values under 0.05 were considered significant.

Results: 75 patients were included, 93.3% female (N=70), with a median (min-max) age of 58 (33-80) years and median disease duration at TCZ initiation of 10.7 years (1.0-43.3); 33.3% were on TCZ monotherapy (N=25). At baseline, forty-two (56.0%) were RF positive (≥30U/mL) and 47 (62.7%) were ACPAs positive (≥10UI/mL). Median serum RF levels were 255.0 UI/mL (37.20-5560.00), 193.5 UI/mL (9.80-5270.00) and 131.0 UI/mL (9.00-6200.00) at 0, 6 and 12 months respectively; serum RF levels were only statistically different (p=0.006) between 0 and 6 months. Median serum ACPAs levels were 278.5 UI/mL (17.00-9300.00), 348.0 UI/mL (19.00-4720.00) and 277.0 UI/mL (16.00-4400.00) at 0, 6 and 12 months respectively, without any statistically significant differences. Considering the autoantibodies levels variation, ΔRF at 6 months correlated positively with ΔHAQ (r=0.482; p=0.009) and ΔACPAs (r=0.413; p=0.026). After one year, ΔRF correlated positively with ESR (r=0.426; p=0.019) and DAS28 (r=0.428; p=0.018). As for ΔACPAs at 6 months, it correlated positively with PhGA (r=0.491; p=0.035). At 12 months, there was a positive correlation between ΔACPAs and ΔCDAI (r=0.385; p=0.038) and between ΔACPAs and ΔSJC (r=0.469; p=0.002).

Conclusion: In our RA sample, serum RF levels showed a significant titre difference past 6 months of treatment with TCZ. Moreover, a moderately strong correlation was found between ΔACPAs/ΔRF at 12 months and the variations in several disease activity scores. Thus, this study reinforces the evidence of an impact of IL-6 inhibition on autoantibodies production in RA patients, as well as a relation between autoantibodies titre variation and clinical response. These findings need to be assessed in larger, prospective studies.

CERTOLIZUMAB PEGOL IN AUTOIMMUNE DISEASES. REAL LIFE EXPERIENCE IN PREGNANCY

Renato Guzman Moreno1,2, Karina Guzman Roa3, Gladys Roa Montes4.
1IDEARG, Immunorheumatology, Bogota, Colombia; 2Foundation Universitaria Juan N Correa, Immunology and Internal Medicine, Bogota, Colombia; 3IDEARG, Immuno/Rheumatology, Bogota, Colombia; 4IDEARG, Immunorheumatology, Bogota, Colombia

Background: Certolizumab pegol (CZP) is a Pegylated, Fc free monoclonal antibody that is useful in different autoimmune conditions. It does not bind FcRn and is not expected to undergo transfer across the placenta and probably there is a minimal placenta transfer of CZP in humans. On the other hand, most chronic inflammatory diseases are prevalent in women and 50% of these diseases need active treatment. We describe our experience for more than 7 years in patients with inflammatory arthritis and pregnancy that received CZP.

Methods: We review our cohort of patients with Rheumatoid Arthritis, Spondyloarthritides and psoriatic arthritis from 2011 to 2017 that received CZP and analyzed those cases of pregnancy and described the clinical characteristic, the medication concomitant and the course of the pregnancy.

Results: We review more than 750 patients with inflammatory arthritis that received CZP and found 15 cases that was in pregnancy. See table 1.

Table 1. The use of CZP was effective, good tolerated and the profile of safety for the mother and the product was acceptable.

Conclusion: CZP is a useful alternative of treatment for pregnant patients and with inflammatory arthropathies that required therapeutic agent. This topic has been recently review and show that this agent is safe for pregnant women and for those breastfeeding and support continuation of CZP during pregnancy, when considered necessary.

ABO382 TROUGH VERSUS NON-TRough ADALIMUMAB DRUG LEVEL MEASUREMENTS

Fenke Hooijberg1, Merel J. L’am1, Lea C. Berkhoudt2, Sadaf Aliq1, Michael Nurmohamed1, Annick de Vries3, Charlotte L. Kieckerta1, Theo Rispens12, 1Get-Jan Woblink3, 3Amsterdam Rheumatology and immunology Center, location Reade, Amsterdam, Netherlands; 2Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands; 3Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; 4Biologics Lab, Sanquin Diagnostic Services, Amsterdam, Netherlands; 5Amsterdam Rheumatology and immunology Center, location VUmc, Amsterdam, Netherlands

Background: Over the last years there has been an increasing interest for measuring drug levels to guide decision-making. Serum samples used for these measurements are often obtained prior to the next injection, at trough level. However, Jani et al. (2015) analyzed drug levels of randomly acquired serum samples from patients with rheumatoid arthritis (RA) treated with either etanercept or adalimumab and found a significant relationship with clinical disease activity. This indicates that random drug level measurements might also be useful (1). However, more aspects should be considered before deciding to use non-trough measurements.

Objectives: To assess the effect of non-trough measurements, compared to trough measurements, on serum drug level.

Methods: Patients with RA starting adalimumab treatment were included in this prospective observational cohort study, named the Reade Rheumatology Registry. Serum samples were obtained during every visit and these were analyzed for drug levels using a regular enzyme-linked immunosorbsent assay (Sanquin, Amsterdam). The date of a patient’s last injection with adalimumab was documented. Samples were included in the analyses if the interval between the last injection and serum sampling did not exceed 28 days, as in general patients do not have such long dosing-intervals. The analysis was performed using Spearman correlation.

Results: In total, 121 RA patients were included in this study. The median follow-up period of these patients was 156 (interquartile range (IQR) 78-247) weeks. Drug level measurements were performed in all serum samples that were obtained. In total, 310 measurements were included in the analyses, as from this subset the date of the previous injection with adalimumab was documented. The median drug level during adalimumab treatment was 6.6 (IQR 4.2-9.8) μg/ml, and the median number of days between the previous injection of adalimumab and serum sampling was 8 (5-13). The latter was divided into quartiles and plotted against drug level (Figure 1). The first quartile (median 2 (IQR 1-3) days) had a median drug level of 8.0 (4.7-11.0) μg/ml, the second quartile (7 (6-8) days) of 6.9 (5.4-10.0) μg/ml, the third quartile (11 (10-12) days) of 6.1 (3.4-9.5) μg/ml, and the fourth quartile (14 (13-14) days) of 5.7 (3.1-8.5) μg/ml. A weak association was found between the number of days between the previous injection of adalimumab and serum sampling and adalimumab drug level (Spearman’s ρ= ρ=0.182, p=0.001).

Conclusion: The growing interest to apply therapeutic drug monitoring (TDM) within the field of rheumatology forces us to discuss which measurements, trough or non-trough, are most informative. We found a correlation between the number of days between the previous injection of adalimumab and serum sampling, and adalimumab drug level. This might suggest that the timing of serum sampling affects the measured drug level, which could have consequences for treatment decisions based on these drug levels.
LATENT TUBERCULOSIS INFECTION SHOULD BE MONITORED IN BOTH TUMOR NECROSIS FACTOR INHIBITORS AND NON-TUMOR NECROSIS FACTOR INHIBITORS IN BIOLOGIC-NAIVE PATIENTS WITH RHEUMATOID ARTHRITIS

Yun-Ju Huang, Yao-Fan Fang, Shue-Fen Luo, Kuang-Hui Yu, Chang-Fu Kuo, Ping-Ha Tsai, Yen-Fu Chen. Division of Rheumatology, Allergy and Immunology, Taoyuan City, Taiwan, Republic of China

Background: The risk of latent tuberculosis infection (LTBI) increased during the treatment of biologic agents for patients with rheumatoid arthritis. Taiwan rheumatology association recommend performing at least annual interferon-gamma release assays (IGRAs) testing during biologic treatment course because of the moderate prevalence of tuberculosis in Taiwan.[1] Although increased tuberculosis reactivation rate in patients with TNF or non-TNF inhibitors should be monitored LTBI in moderate prevalence TB area.

Methods: We retrospectively collected 313 biologic-naïve patients with rheumatoid arthritis treated with TNF and non-TNF inhibitors in Taiwan. All RA patients underwent interferon-gamma release assays during biologic treatment. Cox proportional hazard model was used for analysis to compared RA patients with TNF or non-TNF inhibitors.

Results: The age of patients and disease duration are 55.9 13.1 year-old and 5.2 2.0 years(Table 1). The LTBI rate in patients with rheumatoid arthritis treated with TNF and non-TNF inhibitors in Taiwan. All RA patients underwent interferon-gamma release assays testing during biologic treatment.

Cox regression analysis of RA patients found that the risk of LTBI was not different in TNF or non-TNF inhibitors.

Conclusion: Our study revealed biologic-naive patients with rheumatoid arthritis have the same risk of LTBI. All RA patients who need either TNF or non-TNF inhibitors should be monitored LTBI in moderate prevalence TB area.

AWARE IS A PROSPECTIVE, NONINTERVENTIONAL, 3-YEAR STUDY AT 100 US SITES. RA pts were enrolled when initiating TNFi treatment. Treatment decisions are at the discretion of the treating rheumatologist. The study utilizes PROMIS and Clinical Disease Activity Index (CDAI) to assess effectiveness.

Objectives: This analysis examined select PROMIS measures to assess (1) relationship between baseline (BL) CDAI and PROMIS-scores, (2) responsiveness of PROMIS after initiation of TNFi and (3) relationship between PROMIS T-scores of the 4 item Profile29v2 Fatigue and Pain Interference domains and respective PROMIS Short Forms (SF).

Methods: AWARE is a prospective, noninterventional, 3-year study at 100 US sites. RA pts were enrolled when initiating TNFi treatment. Treatment decisions are at the discretion of the treating rheumatologist. We report on data from Pts’ BL PROMIS Pain Interference 6b (PI), Fatigue7a (F), Profile29v2 and CDAI. PROMIS T-scores were compared across CDAI disease category (high, moderate etc) using ANOVA. We dichotomized pts based on whether their BL T-score was in 0.5SD of the population mean (i.e. normal) or not to evaluate for effect modification in the subsequent change in PROMIS T-scores. Data shown are mean ± sd dev.

Results: Pts (N=1220) were 59.5± 13.2 yrs, disease duration 8.2 ± 9.9 yrs, 83.4% female, body weight 85.1± 24.2 kg, BMI 31.4 ± 85.1, BL CDAI 32.4 ± 15.6. A significant relationship between PROMIS T-scores (PI, F) and BL CDAI disease activity category was confirmed. There was minimal change in T-score of pts with BL PI and F T-scores <-0.5 and P>0.05 over 5 infusions (approx. 5-7 months). Depending on domain,

Integrated Safety Analysis Across Phase 3 Clinical Studies Including the Controlled and Uncontrolled Periods for Intravenous Golimumab in Rheumatoid Arthritis, Psoriatic Arthritis, and Ankylosing Spondylitis

The GO-FURTHER, GO-VIBRANT, and GO-ALIVE randomized controlled trials evaluated the efficacy and safety of intravenous (IV) golimumab (GLM) in patients (pts) with active rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS), respectively.

Methods: Integrated safety data from 3 Phase 3, double-blind, placebo (PBO)-controlled trials were analyzed up to week (WK) 112 in RA pts and up to WK 60 in PsA and AS pts. Pts received either IV PBO or IV GLM (2 mg/kg) at 0, 4, 12, and 20 WKs. PBO pts crossed over to IV GLM at WK 24, except RA pts randomized to PBO who met early escape criteria crossed over at WK 16 and AS pts randomized to PBO who crossed over at WK 16. Cumulative adverse events (AEs) were reported by indication and pooled by treatment. Anti-drug antibodies (ADAs) were evaluated.

Results: Overall, 1248 pts were treated with IV GLM across indications. A numerically greater proportion (% ) of IV GLM pts with RA reported safety events than pts with PsA or AS (Table 1): SAEs (18.2 vs 5.2 vs 3.4), infections (49.1 vs 22.8 vs 32.8), serious infections (6.2 vs 2.2 vs 1.5), and infusion reactions (4.6 vs 0.9 vs 1.5). Incidence (per 100 pt-years) of opportunistic infections, malignancy, active tuberculosis, and death with IV GLM was low (<0.5) across indications (Table 2). Infections were the most commonly reported type of SAE among pooled IV GLM pts; the most frequent was pneumonia (10 /0.5%). Incidence (per 100 pt-years) of serious infections was similar among IV GLM pts with and without corticosteroid use (3.35 vs 3.37, respectively). Overall, 1 IV GLM pt (PsA) experienced a demyelination event. A numerically greater proportion of IV GLM pts discontinued due to an AE than PBO pts (5.0% vs 0.7% vs 0.5%). In IV GLM pts with baseline alanine aminotransferase (ALT) ≥5X ULN was 2.1% vs 0% with methotrexate and 0.9% without methotrexate use at baseline, respectively. In IV GLM pts with baseline alanine aminotransferase (ALT) ≥ upper limit of normal (ULN) 1.2% had post-baseline ALT elevations ≥5X ULN. The proportion of IV GLM and PBO pts with post-baseline ALT elevations ≥5X ULN was 2.1% vs 0% with methotrexate and 0.7% vs 1.4% without methotrexate use at baseline, respectively. Using a drug-tolerant enzyme immunoassay, the incidence of ADAs was 22% through WK 52 across indications, which primarily consisted of low titer ADAs.

Conclusion: IV GLM demonstrated a consistent safety profile across indications in the PBO-controlled (up to WK 24) and uncontrolled study periods. Similar to WK 24 (1), more safety events occurred in RA pts, who represented the largest study population with older pts, longer disease duration, and more concomitant medication use.

Response to Biological Therapy is Influenced by the Body Mass Index in Patients with Rheumatoid Arthritis

Hikoshi Koderai1, Yoshiko Sato2, Yoshijû Fujimatsu3, Kyotaka Hanzo4, Juji Ikeda5, Hitoshi Kodera1, Yoshiko Sato2, Yoshifuji Matsumoto1.

Background: Biologic therapies have been bringing huge advantage in the treatment of rheumatoid arthritis, but response to the therapy is heterogeneous. The influence of the body mass index to the treatment is still controversial.

Objectives: To identify the factors influencing in the response to biologic therapy (bio naïve).

Methods: The analysis of the patients with rheumatoid arthritis who were initiated biologics therapy (bio naïve) between January 2011 to December 2016 in the rheumatology department of a hospital in Japan, was conducted. The effects were evaluated by EULAR response criteria after 6 months of biologic therapy, and factors influencing the response were analyzed in terms of the baseline characteristics (sex, age, disease duration, body mass index, tender joint count, swollen joint count, Patient’s visual analog scale, erythrocyte sedimentation rate, C-reactive protein, Disease Activity Score in 28 joints, Modified Health Assessment Questionnaire, Methotrexate use, Prednisolone use).

Table 1. Differences of the baseline characteristics of RA patients between “Good or Moderate response” and “No response” of EULAR response criteria after 6 months of biologic therapy.

Conclusion: Body mass index influence in the response to first biologic therapy in patients with rheumatoid arthritis.
Methods: We conducted a prospective, multicenter, observational study of physicians and patients in 12 centers from 11 provinces across China between March and April 2018 (NCT03483597). The Treatment Satisfaction Questionnaire for Medication version III (TSQM-III) was used to assess the treatment satisfaction of patients and physicians regarding csDMARDs and bDMARDs therapy. Multiple linear regression analysis was used to determine the factors independently associated with patients’ satisfaction.

Results: 1237 patients (82.5% female) with a mean age (SD) of 48.9 (13.4) years and 146 rheumatologists (72.6% working-5 years) were included in this survey. The patients’ satisfaction (n=335) with bDMARDs was higher than physicians’ satisfaction (n=146) regarding the side effects (95.0±14.3 vs. 84.6±15.7, p<0.001) and convenience (74.6±21.2 vs. 69.1±16.5, p=0.002) (Table1). Among physicians, global satisfaction with bDMARDs was higher than that with csDMARDs (75.0 vs. 66.7, p<0.05) (Table1). Satisfaction of each questionnaire item toward therapy in patients and rheumatologists were also shown in radar charts (Figure 1). The multivariable regression analysis showed that age and quality of communication with physician was positively associated with patients’ satisfaction, while level of education (bachelor or above), self-assessment of disease severity and treatment costs were inversely associated with satisfaction.

Conclusion: For bDMARDs, the treatment satisfaction of patients with RA is generally better than that of physicians. Physicians’ satisfaction with bDMARDs is higher than that with csDMARDs. The independently factors associated with the treatment satisfaction of patients with RA are age, education, disease severity, the patient-physician communication, and treatment costs, which could be targeted in routine clinical care.

bind the soluble TNF. To date, very few data are available concerning
the use of biosimilar drugs in a real-life setting. Results from DANBIO
registry suggested a lower retention rate in RA patients switchers from
Etanercept originator (ETA) to biosimilar (SB4) versus the historic ETA
cohort and higher in comparison with historic SB4 patients (1).

Objectives: To compare the efficacy of ETA versus SB4 in a cohort of
RA patients in a real life setting.

Methods: In this monocentric case-control prospective study, we consecu-
tively enrolled RA patients starting ETA or SB4 treatment from 2015. RA
diagnosis was made according with ACR/EULAR 2010 criteria (2). Data
were collected and entered into a standardized, computerized, electroni-
cally filled-in form. We included patient demographics, date of diagnosis,
comorbidities and previous and concomitant medications. The clinical eval-
uation included the count of swollen and tender joints and the patient’s
and physician’s global disease assessment based on a visual analogue
scale (VAS; range: 0 to 100 mm). Disease activity was measured according
to the disease activity score in 28 joints (DAS28ESR) (3). The patients
were asked to fill in the Health Assessment Questionnaire (HAQ).
All the patients were evaluated at the beginning of treatment (T0)
and after 4 (T1) and 12 months (T2). Clinical response to treatment was
evaluated by using EULAR criteria (4).

Results: We evaluated 35 RA patients treated with SB4 (M/F 2:3:3; median
age 63 years, IQR 21; median disease duration 108 months, IQR 138) and
40 with ETA (M/F 5:35; median age 60.5 years, IQR 20;
median disease duration 102 months, IQR 141). Biological drug was pre-
scribed as first-line biological treatment in 71.4% of SB4 cohort and in
80.0% of ETA. At T0 no significant differences were observed among the
two groups in terms of DAS28ESR (SB4 median 4.6 (IQR 1.8), ETA 4.3
(IQR 1.9), p=ns) and HAQ (SB4: median 1 (IQR 0.5), ETA median 1
(IQR 0.5), p=ns). In both groups we observed a significant reduction of
DAS28 values at T1 (BS4 p=0.01; ETA p<0.0001) and T2 (SB4 p=0.0007; ETA p= 0.0002; Figure 1A). When evaluating the remission
rate (DAS28ESR<2.6) at T1, we observed a significant higher rate in ETA
(53.8%) versus SB4 (26.7%; p= 0.0002; Figure1B). No differences were
found after 12 months of treatment.

Conclusion: The results of our study confirmed in a real-life setting the
efficacy of SB4 in RA patients, as demonstrated by the significant reduc-
tion of DAS28ESR values after 4 and 12 months of treatment, similarly
to ETA. Nonetheless, ETA seems to be able to induce a remission sta-
tus earlier than SB4.

AB0390                     CORRELATION BETWEEN TNF-BLOCKERS
BIOAVAILABILITY AND FCGRIIA R131R
POLYMORPHISM IN TUNISIAN PATIENTS WITH
RHEUMATOID ARTHRITIS

Ines Mahmoud1, Myriam Moalla1, Imen Sla2, Olaa Saidane1, Aicha Ben Tekaya1,
Rawdha Tekaya1, Wafa Hardi2, Saloua Aouini2, Mohamed Montacer Kohfi1,
Your Gorg2, Leila Abdelmolou3, 1Hospital Charles Nicole, Rheumatology, Tunis,
Tunisia; 2Hospital Charles Nicole, Immunology, Tunis, Tunisia; 3Institute
Orthopedic Mohamed Kassab, Rheumatology, Manouba, Tunisia

Background: Rheumatoid arthritis (RA)’s prognosis drastically improved
with the introduction of TNF-blockers. However, reasons behind therapeu-
tic failure in some patients remain unclear. Several factors might influence
pharmacokinetics of these drugs by reducing their half-life and, conse-
quently, their effectiveness. Considering Fc-containing biology like inflixi-
mab (IFX) and adalimumab (ADL), Fc gamma receptors (FcγRs) polymor-
phism would be an interesting genetic candidate to focus on.

Objectives: The aim of our study was to determine the influence of low
affinity allele FcγRIIA-131R on ADL and IFX bioavailability.

Methods: We enrolled RA patients treated with IFX and ADL for over six
months. Blood samples were collected for each patient immediately prior
to drug administration. Quantitative measurements of the residual drug
concentration (DC) was carried out by a commercial enzyme-linked immu-
nosorbert assay (ELISA) kit (Promonitor®). Then, we identified patients
with DC above therapeutic cut-off (DC+) for each biologic, EULAR criteria
were considered to determine treatment outcome. FcγRIIA H131R poly-
morphism was genotyped using PCR-SSP.

Results: Twenty-nine patients were included (13 treated with ADL and 16
with IFX). We identified 31.3% and 23.1% non-responders among patients
switched with IFX and ADL respectively. Patients with DC+ were more fre-
frequent in ADL group (76.9%) than IFX group (43.75%). For IFX, DC+ was
significantly correlated with the presence of FcγRIIA 131- R (p=0.033). In fact, none of the HH-genotyped patients had DC+. Further-
more, an association between FcγRIIA 131-R allele and poor response to
IFX was noted (p=0.059) while all HH-genotyped patients responded to IFX.
For ADL, no correlation was found with both of residual DC and response
to treatment.

Conclusion: The presence of FcγRIIA-131 R allele might be a predictive
factor of non-responsiveness to TNF-blockers. It also appears to be asso-
ciated to a higher residual DC. That might be explained by a reduced
biologic clearance due to a lower binding affinity to Fc portion compared
to wild allele FcgRIIA-131H. Therefore, FcγR polymorphism assessment in
RA patients would be a decision-making parameter to consider, as part
of the personalized medicine approach.

Orthopedic Mohamed Kassab, Rheumatology, Manouba, Tunisia

Background: Even though biologics have been used for several years in
the treatment of rheumatoid arthritis (RA), little is known about factors
that modify their pharmacokinetics and therefore their efficacy. Polymorphisms
(SNPs) in receptors for constant region Fc of IgG (FcγR) might influence
the therapeutic outcome of molecules that incorporate an Fc fragment in
their structure such as etanercept (ETA), adalimumab (ADL) infliximab (IFX) and rituximab (RTX).

Objectives: The aim of our study was to determine whether the presence of low affinity allele of FcgRI (FcgRIIA-131R, FcgRIIIA-158F and FcgRIIIB-NAA) influences efficiency and immunogenicity of ETA, ADL, IFX and RTX in RA Tunisian patients.

Methods: We included RA patients treated with biologics for at least six months. Response to treatment was assessed according to EUULAR criteria. Quantitative measurement of antitumor antibodies (ADAb) for each biologic agent was carried out by a commercial enzyme-linked immunosorbent assay (ELISA) kit (Promonitor®). To do so, blood samples were collected for each patient right before drug administration. FcgRIIA, FcgRIIIA and FcgRIIB SNPs was genotyped for all patients using PCR-SSP and direct sequencing process.

Results: Seventy-nine RA patients treated with biologics were enrolled (18 with ETA,13 with ADL,16 with IFX and 32 with RTX). Regardless of biologic type, 61 patients (77.2%) responded to treatment and 14 patients (17.7%) developed ADAb. Genotypic study revealed a correlation between poor response to treatment and the presence of at least one FcgRIIA-131-R allele (94.7% for RH/RR genotypes versus 5.3% for HH genotype). But, the difference was not statistically significant (p = 0.25). Besides, the H/H mutant allele was significantly associated to the presence of ADAb (71.4% of ADAB positivity for RH/RR genotypes versus 28.6% for HH genotype: p = 0.041). The haplotype study shows that the risk allele combination of FcgRI IIA-131R/FcgRIIIA-158F/FcgRIIIB-NAA was more frequent in ADAb+ (23%) compared to ADAb- subjects (23%) and non-responders (27%) versus good responders (23%). But, neither of these associations was statically significant.

Conclusion: Our study suggests that RA patients FcgRIIA-131-R allele carriers are more susceptible to develop ADAB than those with HH wild genotype. That could be explained by a higher biologic clearance in H-carrier patients, resulting in a decreased half-life and ultimately a lower risk of ADAB formation. Thus, FcgR polymorphism genotyping may be a useful marker for predicting response to FC-containing biologics in Tunisian RA patients. Further studies need to be done on larger population.

REFERENCES
[2] Lee YH, Bae SC. Associations between PTPRC rs10919563 A/G and IL-6 -174 C/T polymorphism and the risk of ADAb formation. Thus, FcgR polymorphism genotyping may be a useful marker for predicting response to Fc-containing biologics in Tunisian RA patients. Further studies need to be done on larger population.

AB0394 SERUM CALPROTECTIN AS A PREDICTIVE MARKER OF THERAPEUTIC RESPONSE TO ADALIMUMAB IN RHEUMATOID ARTHRITIS

Guillaume Servant1, Christophe Passió1, Eric Piver2, Oscar Knight1, Valérie Davoust-Penec3, Stéphane Rist1, A. Perdriger3, Elisabeth Gervais3, Emmanuelle Derris1, Benoît Le Goff4, Laurence Picorn5, Philippe Goupille6,7, Denis Mulcrasto1,2, 1. University of Tours, EA 7501 GICC, 2. University of Tours, EA 7501 GICC, 3. CHU de Tours, Service de Rhumatologie, Beaugency, France, 4. CHRU de Tours, Service de Rhumatologie, Paris, France, 5. CHRU de Tours, Service de Rhumatologie, Paris, France, 6. CHRU de Tours, Service de Rhumatologie, Paris, France, 7. CHRU de Tours, Service de Rhumatologie, Paris, France.

Background: Adalimumab significantly reduces the activity of rheumatoid arthritis (RA), but reliable biomarkers of inflammation are still lacking to predict and evaluate the therapeutic response. Serum calprotectin is a mainstay of endogenous activation of the inflammatory response that can be useful as a marker of response to treatment in RA.

Objectives: To compare the evolution over time of serum calprotectin and C-Reactive Protein (CRP) after initiation of adalimumab.

Methods: Serum levels of calprotectin, CRP and adalimumab concentration were measured at visits V1 (week 0), V2 (week 4), V3 (week 8), V4 (week 12) and V5 (week 26). Changes in each variable were analyzed at each visit and each variable was compared to each other using a correlation test. Receiving operating characteristic curves were used to estimate the predictive value of response at V5 for calprotectin and CRP at each visit.

Results: Data from 66 patients were analyzed. Serum calprotectin level decreased from V1 to V5 (3.78 µg/mL [9.0 – 17.47] to 2.74 µg/mL [0 – 18.83]; p < 0.05). A positive correlation was observed between serum calprotectin and DAS28 (Spearman 0.244; p < 0.01), and between CRP and DAS28 (Spearman 0.512; p < 0.01) for all visits combined. In contrast to CRP, serum calprotectin and serum calprotectin variation from V1 to each visit, were not predictive of DAS28 at all V5.

Conclusion: Serum calprotectin decreases after initiation of adalimumab in RA but was weakly correlated with disease activity at week 26. Serum calprotectin cannot be considered as superior to CRP as predictive marker of therapeutic response in RA after initiation of adalimumab.

AB0395

NO CLINICAL RELEVANT CHANGES IN EFFICACY, QUALITY OF LIFE AND TOLERABILITY FOR RA PATIENTS IN CLINICAL REMISSION 16 WEEKS AFTER SWITCHING TO THE BIOSIMILAR IFX CT-P13 COMPARED TO THE ORIGINATOR; A DESCRIPTIVE REPORT

Michael Nurmoohamed,1 Reinhard Bös,2 Marc Kok,3 Linda-Anne Korswagen4, Petra Vos5, Joanne Bloemsma6, Theo Rispens7, Thea Hans8.

1Reade, Amsterdam, Netherlands; 2Rotterdam, Maasstadziekenhuis, Rotterdam, Netherlands; 3Amphia Hospital, Breda, Netherlands; 4Mundipharma Pharmaceuticals BV, Leusden, Netherlands; 5Sanquin Blood Supply, Amsterdam, Netherlands; 6Academic Medical Centre, Amsterdam, Netherlands.

Background: Switching patients from originator infliximab (IFX) to biosimilar IFX can reduce healthcare costs. Several studies have shown that switching does not affect the efficacy for rheumatoid arthritis (RA) patients(1,2), however prospectively collected data on pharmacokinetics, immunogenicity and quality of life (QoL) is scarce.

Objectives: We report data collected from RA patients in clinical remis- sion enrolled in the SECURE study (IFX4501; registered at www.clinicaltrialsregister.eu 2014-004904-31). In SECURE we collected IFX serum concentrations, efficacy, quality of life (QoL) and safety data of patients switched from originator IFX to biosimilar IFX CT-P13 for up to 16 weeks. The IBD cohort of this study has been published elsewhere (3).

Methods: In this prospective, open-label, interventional, non-inferiority, multi-center, phase IV trial, adult RA patients in clinical remission ≤30 weeks under biosimilar IFX to CT-P13. Patients were followed for 16 weeks (2 infusions) after switching. Primary endpoint was the IFX serum concentration at through measured with a bridging enzyme-linked immunosorbent assay (ELISA) 16 weeks after switch. Secondary endpoints included antidrug antibodies (ADA), clinical dis- ease activity measured with the DAS score, CRP and quality of life measured with the EQ5D Health status; -0.05 (-0.08,-0.01). The mean difference (95% CI) at week 16 compared to baseline was for CRP -0.22 (-0.36, -0.08), and EQSD Health status -0.05 (-0.08, -0.01). These changes were not clinical relevant.

In total 76 AEs were reported by 29 (90.6%) patients; 27 of these AEs were non-related to the switch. The most frequently reported AEs (>5% subjects) were fatigue (9.4%), headache (6.3%), arthralgia (15.6%), back pain (9.4%), cough (6.3%), viral upper respiratory tract infection (15.6%) bursitis (6.3%) and pain in extremity (6.3%). Two non-related AEs were reported (ovarian cyst and benign parathyroid tumour).

Conclusion: In this prospective, interventional study in RA patients in clinical remission there were no clinically relevant changes in clinical and biochemical efficacy, quality of life and tolerability 16 weeks after switch- ing to the biosimilar IFX CT-P13 compared to the originator. This study is sponsored by Mundipharma Pharmaceuticals BV.

AB0396

MONITORING OF PATIENTS WITH RHEUMATOID ARTHRITIS BY INDOCYANINE GREEN (ICG) ENHANCED FLUORESCENCE OPTICAL IMAGING TREATED WITH ANTI-TNF THERAPY

Simon Hertrampl,1 Jens Klotsche2, Guenther Schearer3, Anne-Marie Gilm4, Gerd Rüdiger Burmester4, Gabriela Schmitt4, Thomas Häupl5, Sandra Herrmann5, Marina Backhaus6, Sarah Ohnröder5, Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; Deutsches Rheumaforchungszentrum (DRFZ) Berlin, Berlin, Germany; Charité Research Organisation GmbH (CRO), Charité – Universitätsmedizin Berlin, Berlin, Germany.

Background: Indocyanine (ICG)-enhanced fluorescence optical imaging (FOI) by the Xiralite® system enables visualization of inflammation in the hands in rheumatic joint diseases.

Objectives: To investigate the ability of monitoring treatment response using Certolizumab pegol (CZP) in patients with rheumatoid arthritis (RA) by the ICG-enhanced FOI method Xiralite® compared to classical disease activity, laboratory parameters, and muscle/skeletal ultrasound (US).

Methods: CZP-naive patients with RA were eligible for this study, which consisted of an open-label 52-weeks treatment period with CZP. Disease activity was monitored by the clinical score DAS28, laboratory parameters for systemic inflammation (CRP and ESR), ultrasonography (US7 score [1]) and by FOI at baseline (before CZP) and after 6, 12, 24, and 52 weeks under CZP therapy.

Results: In this study, 28 patients (female 92.9%, mean age 49±13.3) were included and treated with CZP over a period of 52 weeks. All patients received CZP for at least 12 weeks (w), n=27 until w42, and n=18 received CZP throughout the entire 52 weeks. DAS28 decreased from moderate disease activity (median 4.6) at baseline to low disease activity (median 2.7) at w52 (p <0.001). CRP/ESR values also reduced from baseline to w52 (r.s.). FOI in phase 1 showed a continuous decrease of enhancement during the course of the treatment period: from baseline (median 1.5, IQR 0.9-5.0) to w6 (median 1.0, IQR 0-3), to w12 (median 0.5, IQR 0-3), to w24 (median 0.0, IQR 0-3) and to w52 (median 0.0, IQR 0-2). An image example is given by the Figure for baseline and w52. The results for other FOI phases 2, 3 and 5 did not show a decrease over the treatment period. US-detected synovitis and tenosynovitis by the US7 score also presented to be responsive between phases 1 and 2, and 3.

Conclusion: In phase 1 phase 1 appears to be a valuable tool for fast and easy monitoring of treatment response to CZP in a clinical setting. FOI may provide an additional method to evaluate inflammation of wrist and finger joints of RA patients in follow-up studies.
Background: Tapering of biological DMARDs can be successful in some patients. However, the predictive factors enabling established patients with RA to remain free of biological DMARDs is unclear. Recently, ultrasonography (US) has become an important imaging tool to identify subclinical synovitis, even in patients with remission. There have been few reports on whether residual synovitis as shown by US can predict relapse of disease activity after discontinuation of biological DMARDs.

Objectives: We aimed to investigate the usefulness of US for predicting relapse in patients in remission for RA after discontinuation of adalimumab (ADA).

Methods: Patients who were using ADA and in remission (Disease Activity Score 28-joint count C reactive protein (DAS28-CRP) <2.6) for longer than 24 weeks were included in this multicenter prospective study. ADA was stopped and patients were followed up until week 52. Predictive factors for relapse at 24 and 52 weeks were analyzed from baseline clinical data, including a US examination. ADA was restarted at the time of relapse (DAS28-CRP ≥3.2). US assessment was performed at 0, 12, 24, 36, and 52 weeks and at the time of relapse. A US examination was performed at the bilateral first to fifth metacarpophalangeal joints, first interphalangeal and second to fifth proximal interphalangeal joints, and first to fifth metatarsophalangeal joints, by using a high-frequency linear transducer. The gray scale (GS) and power Doppler (PD) signals were scored in each synovial site using a semi-quantitative scale from 0 to 3.

Moreover, the modified Total Sharp Score (mTSS) was evaluated at 0, 24, and 52 weeks by conventional radiography. The patients who relapsed were administrated ADA again.

Results: Fifty-three patients were included. Ten (8.9%) patients relapsed up to week 24 and 20 (37.7%) up to 52 weeks. The relapsed patients tended to have a long disease duration, but baseline US findings could not predict relapse. Increases in the PD score were observed after follow-up in some relapsed patients. Disease activity control was good after ADA was restarted in the relapsed patients, and there was no difference in progression of the mTSS in the relapsed and non-relapsed groups.

Conclusion: Predicting relapse by baseline US findings after discontinuation of ADA in remission is difficult. However, an increased PD score in a following US examination might be useful for early detection of relapse. Radiographic progression is not significantly different in patients with relapse and those without relapse.

IL-6 inhibitors (tocilizumab, n=13; sarilumab, n=3), JAK inhibitors (tofaciti-
nib, n=7; baricitinib, n=4), and B-cell depleting agent (rituximab, n=4). The
pooled study population of 27,215 moderate-to-severe RA patients
primarily consisted of middle-aged Caucasian females (mean age: 47-55
years; Caucasian: 44% - 87%; females: 90%). Thirty-three trials were on
patients previously treated with cDMARD or TNFi, while 6 trials were on
cDMARD-naive patients. Total aggregated AEs (total AEs, n=37; SAEs, n = 37;
treatment-related AEs, n = 14) and infection (serious infection, n = 35; total
infection, n = 26) were the most frequently reported safety outcomes.

The NMA was performed on 23 trials. Indirect comparisons were made
between IL-6 inhibitors, JAK inhibitors, B cell depleting agent and abata-
cept, with TNFi or cDMARD as direct comparators. The risk of total AEs
was significantly higher for IL-6 inhibitors compared with abatacept (RR = 1.13,
95% CI = 1.05 – 1.22). For SAEs and other analyzed safety out-
comes, no significant difference was observed between abatacept and
other non-TNFi drug classes. Similar results were observed in sensitivity
analyses for all patients on concomitant cDMARD, including those who
were treatment-naive before the study (n=26 trials).

Conclusion: When comparing aggregated safety outcomes, abatacept
shared a similar safety profile with most non-TNFi RA treatments. How-
ever, patients on abatacept had a statistically significantly lower risk of
total AEs compared to US recommended doses of IL-6 inhibitors. More
studies with head-to-head comparison in clinical trials and real-world set-
ting are required to provide further understanding of the safety profile
and risk of specific adverse events for non-TNFi in order to optimize
treatments for moderate-to-severe RA patients.

AB0399 EVOLUTION OF BIOLOGIC/SMALL MOLECULE
SWITCHING PATTERNS IN RA BETWEEN 2016 AND 2018
Phil pouliot1, Lynn Price2. Spherix Global Insights, Exton, United States of America;
3Spherix Global Insights, Exton, United States of America

Background: TNF therapy has been the standard of care for adult
patients diagnosed with autoimmune conditions and are typically used as
a first-line biologic/small molecule in the treatment of rheumatoid arthritis
(RA). However, the adoption of systemic agents with alternate mecha-
nisms of action (AMOA) such as JAK and interleukin inhibitors have
increased in recent years across many indications. As such, the practice
of sequential TNF prescribing following an initial TNF discontinuation is
becoming less common, with switches to AMOAs, such as JAK and IL-6
inhibitors, becoming more popular.

Objectives: This research sought to track the evolution of biologic/small
molecule switch patterns among US RA patients between 2016 and 2018
and to identify differentiating patient characteristics between the switch patterns.

Methods: An independent market analytics firm collaborated with rheuma-
tologists in France (n=62), Germany (n=66), Italy (n=61), Spain (n=68) and
the UK (60) to conduct an online retrospective chart review. RA patients who
had switched treatment from one biologic/small molecule to another in the
prior twelve weeks. Rheumatologists were able to submit up to seven RA patient charts. A total of 1,312 patient charts were collected via a HIPAA-compliant online audit in January 2016 (n=198 rheumatologists/980 patient charts), in September 2017 (n=176 rheumatologists/1,002 patient charts), and September 2018 (211 rheuma-
tologists/1,074 patient charts). Results were analyzed in SPSS.

Results: Analysis of patients recently switched from one biologic/small
molecule to another revealed the decreasing popularity of cycling to
another TNF after initial TNF discontinuation. TNF cycling accounted for
46% of all switches in 2016, 41% in 2017, and 40% in 2018. Con-
versely, switches from TNFs to JAK inhibitors accounted for 13% in
2016, 12% in 2017, and 15% in 2018. Switches to IL-6 inhibitors
increased from 8% of all switches in 2016, to 9% in 2017, and 11% in
2018. The number of patients switched from a TNF to abatacept or rituxi-

In this study, background information was gathered on changes in
switching patterns, and the reasons behind those changes. Additionally,
the study sought to identify patient characteristics associated with
determine the factors that influence these decisions.

Conclusion: The frequency of TNF discontinuation has decreased over the
past three years. Over time, rheumatologists are increasingly likely to
introduce a JAK or IL-6 inhibitor in the second-line setting following dis-
continuation of a first-line TNF. The frequency of abatacept monotherapy
increased in recent years across many indications. As such, the practice
of sequential TNF prescribing following an initial TNF discontinuation is
becoming less common, with switches to AMOAs, such as JAK and IL-6
inhibitors, becoming more popular.

AB0400 FREQUENCY OF BIOLOGIC/SMALL MOLECULE
MONOTHERAPY FOR RHEUMATOID ARTHRITIS IN THE EU:
REAL-WORLD EVIDENCE FROM A PATIENT AUDIT
STUDY
Phil pouliot1, Lynn Price2. Spherix Global Insights, Exton, United States of America

Background: Biologic/small molecule therapy has been the standard of
care for adult patients diagnosed with rheumatoid arthritis (RA) who have
failed conventional DMARD therapy, resulting in familiarity, comfort, and
satisfaction among physicians. Prior recommendations of combining biolog-
cals/small molecules with a DMARD like methotrexate (MTX) have recently
been challenged by clinical data demonstrating the effectiveness of IL-6 and
JAK inhibitors as monotherapy.

Objectives: This research sought to evaluate the frequency of biologic/
small molecule monotherapy regimens among European RA patients who
were recently switched from one biologic/small molecule to another.

Methods: An independent market analytics firm collaborated with rheuma-
tologists in France (n=62), Germany (n=66), Italy (n=61), Spain (n=68) and
the UK (60) to conduct an online retrospective chart review. RA patients who
had switched treatment from one biologic/small molecule to another in the
prior twelve weeks. Rheumatologists were able to submit up to seven RA patient charts. A total of 1,312 patient charts were collected via a market-specific compliant audit form in September 2018 and
included patient and physician demographics, patient treatment history,
clinical and non-clinical patient parameters.

Results: Overall, the analysis of patient chart audits revealed that 22% of
all recently switched patients were switched to a biologic/small molecule
monotherapy regimen. The frequency of monotherapy was highest in Ger-
many (32%) and lowest in the UK (13%). Monotherapy was more fre-
quent for patients switched to infliximab (39%) and tofacitinib (39%) and
lowest for those switched to tocilizumab (12%) and rituximab (11%).

On a country-specific level, rates of TNF monotherapy were highest in
Germany (38%) and lowest in the UK (16%). IL-6 monotherapy was also
more common in Germany (27%) but least common in France (17%).
JAK monotherapy was highest in France (34%) and lowest in the UK (7%),
while monotherapy for abatacept/rituximab was highest in Germany
(32%) and again lowest in the UK (13%).

Conclusion: The popularity of biologic/small molecule monotherapy varies
by EUS country and while rates are highest for TNF inhibitors, use of biologic/small molecule monotherapy for patients recently switched to a
JAK or IL-6 inhibitor are comparable.

AB0401 SWITCH FROM ETANERCEPT ORIGINATOR TO ETANERCEPT BIOSIMILAR: DATA FROM REAL LIFE

Maria Chiara Ditto, Simone Parisi, Marta Prigioni, Angela Lagana, Clara Lisa Peroni, Enrico Fusaro. Città della Salute e della Scienza di Torino, Turin, Italy

Background: Biosimilars of antiTNF-α are now available for the treatment of arthritis. There are a lot of data about maintenance of clinical efficacy after switching from originator to biosimilar but also reports about flares and adverse events (AE). Controversies still exist due to ethical and economic reasons. We describe the disease activity trend after switching from etanercept originator (oETA) to its biosimilar (bETA) in a population of Turin, Piedmont, Italy. In this region switch to biosimilar is mandatory by law except in case of patients with history of allergy, off-label, psychosocial reasons, active disease that required different treatment.

Objectives: To evaluate the disease activity trend before and after switch from oETA to bETA

Methods: We switched 82 patients (M/F 33/49, mean age 59.65±11.5, duration of disease 17.56±10.3 years) in stable state of disease from oETA to bETA; 49 patients affected by RA, 24 by PsA, 10 by AS. The mean of duration of oETA and bETA treatment was respectively 129.2 and 6.2 months. We evaluated VAS-pain, Global-Health, CRP, number of swollen and tender joints, DAS28 for RA, DAPSA for PsA, HAQ and HAQ-S, BASDAI for AS patients.

Results: Differences of variables between oETA and bETA are summarized in table1. We didn’t find any significant difference between oETA and bETA in order to efficacy. However 8 patients, 5 RA and 4 PsA(9.75%) discontinued bETA because arthritis flare(7) or AE(1).

Conclusion: Data about maintenance of efficacy and percentage of discontinuation were similar to the literature. We didn’t find significant differences on efficacy after switching from originator to biosimilar. However, considering the rate of flares and AE, further strong studies are required.

AB0402 MEASURING PATIENT EXPERIENCE OF SWITCHING BIOLOGIC TREATMENT – A SYSTEMATIC LITERATURE REVIEW

Mary Dozier¹, Karin Lutrop², Axel Svedbom², Johan Dalén², Christopher Black³, Amy Puenpatom⁴. ¹ICON plc., ²EWREA, Boston, MA, United States of America; ³Merck & Co., Inc, Kenilworth, NJ, United States of America

Background: Biologics have transformed the treatment of inflammatory arthritis (IA). However, the complexity of disease management has increased with the introduction of biosimilars and novel treatments. Hence, patient experience and satisfaction has become increasingly important in treatment individualization.

Objectives: Firstly, to assess to what extent IA patient experience of switching biologics is measured in the literature; secondly, to summarize patient-reported outcomes (PROs) as well as medical/non-medical reasons associated with switching.

Methods: A systematic literature review (SLR) was performed in accordance with PRISMA guidelines. EMBASE and MEDLINE were searched for relevant publications from 2013 to present day, together with relevant conference abstracts from 2018 (ACR-ARHP, EULAR, and ISPOR). Studies published in English including either a) patient-reported outcomes (PROs) associated with switching biologics, or b) reasons for switching and/or discontinuing biologics treatment as noted by health care professionals and/or patients were included. The scope was limited to European and North American populations. While the initial search included patient populations with ulcerative colitis in addition to IA patients, results presented within this abstract focus on IA populations only.

Results: After initial screening of 1781 abstracts, sixty-eight studies including IA patients were identified for inclusion in the analysis. Of the remaining studies, 39/68 (57%) included ≥1 treatment switch. The majority of studies were conducted in Europe (36/38; 92%), with the proportion of female patients ranging between 12-90%. Thirteen studies (18%) included at least one PRO, 4 of which only recorded PROs prior to switch (6%). The most commonly reported PRO was PGA/VAS, followed by HAQ and questions asking patients to rank their switching experience using various pre-defined categories (Figure 1). While the most common reasons for discontinuing treatment, which may or may not include switching, was provided in 33 studies (loss of efficacy and safety), reasons strictly for switching are infrequently reported.

Conclusion: Patient satisfaction is important, as it has been linked to clinical safety, treatment effectiveness, and adherence (Doyle et al., 2013). However, this SLR highlights a notable lack of information regarding patient-reported experience of switching biologic treatment. The PROs reported in a minority of studies encompass several regions related to patient well-being – such as pain, fatigue, etc. – but provides very limited information on the experience of switching. Hence, to improve disease management and treatment individualization, further research is required.

AB0403 PREDICTORS OF PERSISTENCE OF BIOLOGIC DRUG STEP-DOWN STRATEGIES IN INFLAMMATORY ARTHRITIS: A LONGITUDINAL STUDY IN CLINICAL PRACTICE WITH A LONG FOLLOW-UP

Sebastián C. Rodríguez-Santos, Raul Castellanos-Moreira, Victoria Hernandez, Jose Incaio, Virginia Ruiz-Esquerra, Jose A. Gomez-Puerta, Raimon Sannarri, Hospital Clinic, Rheumatology, Barcelona, Spain

Background: Recommendations for the management of Rheumatoid Arthritis (RA) and spondyloarthritis (SpA) with bDMARD include dose-tapering strategies in patients with good disease control. However, there is limited information on predictors of persistence of biosimilars. This study aimed to identify predictors of persistence of biosimilars in inflammatory arthritis.

Methods: A multicenter, retrospective cohort study of patients who switched to a biosimilar (BS) from a drug of the same class (control (C)) in the period from January 2013 to December 2015 was conducted in 14 Spanish hospitals. The study was conducted by the Grupo Español de Estudios de Terapia con Biológicos. The primary outcome was the persistence of BS treatment (defined as taking BS ≥ 24 weeks). The predictors were demographic and clinical characteristics, comorbidities, concomitant treatments, and switching reasons. The predictors were evaluated with binary logistic regression. The model was validated internally using the bootstrap technique.

Results: A total of 806 patients were included: 400 in the BS group and 406 in the C group. The mean age of the patients was 57.7 years (SD 13.8) and 71% were women. The most frequent reason for switching was disease control (53%). The persistence rate at 2 years was 70% in the BS group and 81% in the C group (p<0.001). The predictors of persistence were disease control at 24 weeks before switching (OR 2.61, 95% CI 1.69-3.94), higher HAQ (OR 1.04, 95% CI 1.01-1.07), and higher CRP (OR 1.02, 95% CI 1.00-1.04). The model had good discrimination (AUC 0.72) and calibration (Hosmer-Lemeshow p=0.19).

Conclusion: Disease control before switching, higher HAQ, and higher CRP were predictors of persistence of BS. Future studies are needed to confirm these findings and to identify other predictors of persistence.

Disclosure of Interests: None declared
as an adequate option for patients on persistent remission. Although data regarding these strategies has increased in recent years, there is scarce evidence about their long-term effect.

**Objectives:** Our aim was to analyze the persistence of bDMARD dose-reduction in clinical practice and evaluate its predictors in patients with RA and SpA.

**Methods:** Retrospective longitudinal study from 2006 to 2018. From a cohort of 153 patients with chronic inflammatory arthritis treated with bDMARD (TNF inhibitors, rituximab, tocilizumab, and abatacept), we recruited those with RA and SpA receiving reduced-dose regimens. Variables analyzed were: persistence of bDMARD dose-reduction, predictors of this persistence reported in the literature such as treatment with glucocorticoids (GC) or conventional synthetic DMARD (csDMARD), disease activity and duration of disease at dose-reduction as well as demographic and other clinical features.

A Cox proportional hazards model was used to identify factors associated with persistence on reduced-doses during the study period.

**Results:** 56 patients (RA:35; SpA:21) on tapered bDMARD (etanercept 51.8%, adalimumab 32.1%, Infliximab 3.6% and tocilizumab 12.5%) at study entry were included. Their clinical and laboratory features are shown in table 1.

After a mean follow-up on tapered-dose of 4.4 years (range 0.35-8.72), 42.9% of subjects overall remained on reduced doses (RA: 36.4%; SpA: 52.2%). (Fig.1)

From those who required discontinuation of the step-down regimen, 16 (48.4%) achieved the therapeutic objective and 7 (22.6%) failed after returning to standard dose respectively.

bDMARD were discontinued in 4 (12.9%) patients due to sustained disease remission (RA=3; SpA=1), 3 (9.7%) due to adverse events and 2 (6.4%) due to other reasons. No significant differences in the variables analyzed were found between patients continuing vs discontinuing reduced-dose regimens. After adjusting for age, sex, diagnosis and disease duration, the concurrent use of GC at the time of dose-reduction was found an independent predictor of discontinuation of the step-down regimen.

**Conclusion:** A significant proportion of patients with RA and SpA (36.4% and 52.2% respectively) can be maintained with reduced doses of bDMARD after a long-term follow-up.

**VALIDATION OF A THERAPEUTIC DRUG MONITORING TEST TO MEASURE THE ADALIMUMAB BIOSIMILAR SB5 IN COMPARISON WITH THE REFERENCE ADALIMUMAB**

M. Beoglia Ruiz-Angelii, Ainara Maguregui, Antonio Martinez, Daniel Nagore. Progenika Biopharma – Grifols, RandD, Derio, Spain

**Background:** Validation of therapeutic drug monitoring (TDM) tests is an essential requirement for using these tools to help assess reasons for non-response. The arrival of biosimilars has prompted a need to validate that existing TDM tests are suitable to determine drug levels for all versions of a given molecule. The adalimumab (ADL) biosimilar SB5 (Bio- gen) was authorised by the European Commission in August 2017, and has recently become available for prescription in several European countries. Promonitor-ADL test is routinely used to monitor IBD patients treated with ADL.

**Objectives:** In this study we validated the suitability and performance of Promonitor-ADL CE-marked TDM test for quantifying SB5 serum concentrations in comparison to reference adalimumab (Abbie).

**Methods:** The study evaluated precision and bias applied to the reference ADL and SB5 biosimilar. The validation study was in line with the design requirements established in the Clinical & Laboratory Standards Institute (CLSI) guideline EP10-A3 for the determination of imprecision and bias. Imprecision was evaluated using three replicates of five human serum sample matrices representative of clinically relevant ADL concentrations and spanning the measurement range of Promonitor-ADL. Validations were run on one instrument with one kit lot by one operator over six non-consecutive operating days and one run per testing day, with an acceptance criterion of CV≤20%. The Lower Limit of Quantification (LLOQ) of Promonitor-ADL was determined according to CLSI guideline EP17-A2.

**Results:** The imprecision of Promonitor-ADL was calculated by estimating the components of variance due to within-run and between-day factors meeting the accuracy goals proposed at all concentration levels of SB5 vs the reference adalimumab (Abbie).

**Discussion:** This study demonstrates that Promonitor-ADL test can measure either the reference ADL drug or the adalimumab biosimilar SB5 with equivalent sensitivity, precision and accuracy.

ADALIMUMAB THERAPEUTIC DRUG MONITORING TEST VALIDATED FOR MEASURING ABP 501 BIOSIMILAR

M. Begoña Ruíz-Angüeto, Ainara Maguregui, Antonio Martínez, Daniel Nagore. Progenika Biopharma - Grifols, RandD, Derio, Spain

Background: Promonitor-ADL test is routinely used to monitor IBD patients treated with adalimumab (ADL). ABP 501 (adalimumab biosimilar; Amgen) was authorised throughout the European Union in March 2017 and has been recently launched in several countries. Therapeutic drug monitoring (TDM) is broadly used as an aid for patient management. However, all TDM tests available should be properly validated against each new approved biosimilar in order to ensure safe application for patient monitoring as these may guide dose adjustments.

Objectives: Here we validate the suitability and performance of Promonitor-ADL CE-marked test for quantification of the adalimumab biosimilar ABP 501 in comparison to the reference adalimumab drug (Abbvie).

Methods: The validation study was in accordance with the design requirements established in the Clinical & Laboratory Standards Institute (CLSI) guideline EP17-A2 (Lower Limit of Quantification, LLOQ) and EP10-A3 (imprecision and bias). CLSI guidelines set a standard for the diagnostic industry accepted by all regulatory agencies. LLOQ was determined with four independent human serum sample matrices per each of three low level ADL concentrations, replicated three times per two lots of Promonitor-ADL (Progenika, Spain) kits for each drug, the reference drug and the biosimilar ABP 501. The test is able to quantify the adalimumab biosimilar ABP 501, over three days by one operator. Imprecision was evaluated using three replicates of five human serum sample matrices representative of clinically relevant ADL concentrations and spanning the measurement range of Promonitor-ADL, run on one instrument with one kit lot by one operator over six non-consecutive operating days and one run per testing day, with an acceptance criteria of CV%<20%.

Results: The LLOQ of Promonitor-ADL for the adalimumab biosimilar ABP 501 and reference adalimumab were 0.34 mg/mL and 0.36 mg/mL, respectively. LLOQ values met accuracy goal proposed based on total error ≤±25% and precision. The imprecision of Promonitor-ADL calculated by estimating the components of variance due to within-run and between-day factors meet the accuracy goals proposed at all concentration levels of ABP 501 vs the reference adalimumab (CV% between 5% and 10%). The bias study showed that Promonitor-ADL can equally measure the active moiety ADL either in the reference biologic ADL or in the biosimilar ABP 501. The test is able to quantify the adalimumab biosimilar ABP 501 in the measurement range of 0.9 to 10.9 mg/mL with a bias estimate of -0.089 to 0.306 mg/mL and an overall imprecision of 6% to 9%.

Conclusion: Promonitor-ADL test can equivalently measure either the reference ADL or the approved adalimumab biosimilar ABP 501 with the same sensitivity, precision and accuracy.

AB0406
THE POTENT WEAPON FOR RHEUMATOID ARTHRITIS-INTERSTITIAL LUNG DISEASE: RITUXIMAB EXPERIENCES

Burak Karakaş, Mehmet Emin Derin, Fatih Albayrak, Ali Sahin, Silvas Cumhuriyet University, sivas, Turkey

Background: Rheumatoid arthritis (RA) is a common inflammatory disease with unknown etiology and systemic involvement (1). About 40% of RA patients have extraarticular involvement. Lung involvement is the most common extraarticular finding. The use of rituximab (RTX) in the treatment of rheumatoid arthritis-interstitial lung disease (RA-ILD) has been increasing in recent years (2).

Objectives: To present our rituximab experience in patients with RA-ILD.

Methods: Between April 2015 and April 2018, sixteen patients with RA-ILD who were followed up with RTX treatment in our university internal medicine-rheumatology department were included in this study. High resolution computed tomography (HRCT), carbon monoxide diffusion measurement (DLCO), pulmonary function test (PFT) and routine laboratory tests were examined.

Results: The median age of the patients was 68 years (min: 52-max: 77). 4 patients (25%) were male and 12 (75%) patients were female. Four of our patients (25%) were active smokers. Non-specific interstitial pneumonia (NSIP) was seen in 10 (62.5%) patients and usual interstitial pneumonia (UIP) was seen in 6 (37.5%) patients. Before RTX, 8 patients were receiving methotrexate and 8 patients were using leflunomide. Four patients had anti-TNF (tumor necrosis factor) treatment. Median during treatment time was 6 months. Other features of the patients are summarized in Table 1. All patients had dyspnea with exertion before treatment. The Forced Vital Capacity (FVC) median was 70 and DLCO was 66. Although 2/16 patients received cyclophosphamide treatment, there was no clinical response and then RTX treatment was started. Protocol of treatment was every 6 months (days 0 and 15 days 1 g). After 6 months, FVC values improved with NSIP pattern (p<0.04). There was no improvement in the UIP pattern but remained stable (Table 2). Clinically, patients’ exertional dyspnea improved. There were no serious side effects in the follow-up of the patients.

Conclusion: There is no valid guideline for RA-ILD treatment. Patient-based decision-making is important in the treatment of these patients. In recent years, RTX seems to be quite effective in RA-ILD. However, long-term and extensive studies are needed in terms of maintenance treatment and possible side effects.

Disclosure of Interests: None declared
Background: Treat to target (T2T) strategy for rheumatoid arthritis (RA) aims to achieve remission or low disease activity. On the other hand, biological disease-modifying antirheumatic drugs (bDMARDs) have shown to be effective to achieve clinical remission or, at least, low disease activity in patients with RA. On the other hand, comprehensive healthcare programs have demonstrated good clinical outcomes in patients with chronic conditions.

Objectives: The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) in patients receiving biological therapy during 5 years, and who were subjected to a multidisciplinary care program.

Methods: A descriptive cohort study was conducted. Medical records of patients from specialized in RA center were reviewed during 2015-2017; these patients were followed-up under T2T approach. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3-5 weeks (DAS28 > 5.1), every 7-9 weeks (DAS28 > 3.1 and ≤ 5.1), and every 11-13 weeks (DAS28 < 3.1). Ten-point joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 > 3.2 unless patient’s conditions don’t permit it; we considered this follow-up type as implementation of a T2T strategy in patients with RA. Patients entered into a multidisciplinary program of care with periodic consultations not only to rheumatology but with a psychiatrist, psychologist, physiotherapist, occupational therapy nutrition, and a patient focused program. With a multidisciplinary model of care the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA. We divided patients into four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission. Descriptive epidemiology was done, we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We compared disease activity at base line and at the end of follow-up.

Results: 747 patients meet our inclusion criteria, 85% of our patients were women, median age was 57 years (range 20-86); the most pre-scribed bDMARD was certolizumab 25% followed by etanercept 14%, tocilizumab 12%, abatacept 12%, golimumab 10% rituximab 8%, adalimumab 7%, infliximab 6% and Tofacitinib 6%. At beginning 53% of patients were in moderate or severe disease activity and, 25% in high disease activity while at the end of follow up 89% of patients had achieved remission. See Table 1. It was established statistical significance between changes in median DAS28 at beginning and, at the end of follow-up (P<0.05).

Conclusion: Biological therapy is effective for treating patients with RA, there was an evident global improvement of DAS28 in a cohort of RA patients. Also, our findings agree with other studies where T2T programs have shown improvements in disease activity in patients with RA. Thus, multidisciplinary T2T comprehensive healthcare programs should be widely implemented in patients with RA.

AB0403  FIXED-INTERVAL VERSUS ON-DEMAND RETREATMENT STRATEGY WITH RITUXIMAB IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY

Lisa Schaprij, Nathan den Broeder, Alton den Broeder, Lise Verhoet. Sint Maartenskliniek, Department of Rheumatology, Utrecht, Netherlands

Background: Rituximab (RTX), a monoclonal anti CD20 B-cell antibody is safe and effective in the treatment of Rheumatoid Arthritis (RA). The most optimal retreatment strategy in responding patients is still unclear.

A recent study by Chatzidionysiou et al suggests that RTX retreatment with Fixed-Interval (FI) strategy is better than retreatment with an On-Demand (OD) strategy. [1] However, whether FI treatment strategy is also superior in a treat to target setting is not known.

At our centre (Sint Maartenskliniek, the Netherlands), patients were retreated with RTX using the FI strategy and the OD strategy, by discretion of the rheumatologist, and using treat to target of DSAS28CRP <2.9 in all patients.

In the FI strategy, patients receive retreatment after a predefined fixed period, mostly every 6 months. In the OD strategy, patients receive retreatment in case they experience increase in disease activity. In our hospital, most of the OD strategy patients were switched to the FI strategy in 2014 based on best evidence at that time, enabling us to retrospectively compare efficacy of these strategies.

Objectives: To compare the efficacy of retreatment of RA patients with different strategies following the FI or OD retreatment strategy.

Methods: Adult (>18) RA patients (clinical diagnosis) who started RTX treatment (1 or 2 x 1000mg or 2 x 500mg intravenous) between 1-1-2008 and 1-6-2016 and received at least 3 infusion cycles were included. Patients were treated with either FI or OD strategy, or crossed over from OD to FI. For on demand treatment, RTX retreatment could be planned at the day care within 2-4 weeks.

Primary outcome was DSAS28-CRP, secondary outcome was mean yearly change of DAS28-CRP score compared to FI strategy: adjusted difference was 0.09 (95% CI: 0.03 to 0.16). RTX following the FI or OD retreatment strategy.

A linear mixed model was used to analyse the influence of the strategies on DSAS28-CRP score. Time since start of RTX, calendar year, RTX dose, intra-articular (IA) or intramuscular (IM) steroid injection <6 weeks ago, concomitant csDMARD use at start of treatment and RF status were added to the model as fixed effects. Data was analysed using Stata 13.1.

Table 1. Baseline patient characteristics

| Age, mean (sd) | 59.6 (12.4) |
| Disease duration at RTX start, median (IQR) | 11 (5-17) |
| csDMARD use at RTX start, n (%) | 124 (58%) |
| Rhamatoid factor positivity, n (%) | 166 (75%) |
| Disease duration at RTX start, median (IQR) | 11 (5-17) |
| csDMARD use at RTX start, n (%) | 124 (58%) |
| Rhamatoid factor positivity, n (%) | 166 (75%) |
| DSAS28CRP, mean (sd) | 4.0 (1.2) |
| Strategy, n (%) | 154 (72%) |
| Fixed interval | 25 (12%) |
| On demand | 34 (16%) |
| Both strategies | 0 |

Results: 213 patients were included. 154 following FI strategy, 25 following the OD strategy and 34 switching from OD to FI. Median duration of follow up was 38 months (IQR: 23-64), with a median number of 8 (IQR 5-12) DSAS28-CRP measurements per patient. Patient characteristics are shown in Table 1. The OD strategy was not associated with higher DSAS28-CRP score compared to FI strategy: adjusted difference was 0.09 DSAS28-CRP point (95% CI: -0.08 to 0.26). Regardless of used strategy, DSAS28-CRP improved significantly both over year of treatment, and by time from the start of RTX treatment. Furthermore was rhamatoid factor positivity associated with an lower DSAS28-CRP in all patients, with adjusted difference of -0.37 (95%CI: -0.60 to -0.14). Average yearly RTX dose was 1699mg/yr (SD: 654) under the FI strategy and 1740mg/yr (SD: 732) under the OD strategy (95% CI difference: -336 to 34mg/yr).

Conclusion: Retreatment of RA patients with a fixed interval strategy does not seem to lead to better disease control or more drug use compared to an on demand strategy. A possible explanation might be the use of treat to target in our centre. Our study suggests that either strategy might be chosen in shared decision making and following treat to target.
AB0409 B CELLS PROFILE AS A BIOMARKER FOR EARLY IDENTIFICATION OF OPTIMAL RESPONDERS TO TNF INHIBITORS IN RHEUMATOID ARTHRITIS

Cristina Sobrino1, Borja Hernández-Breijo2, Carlota García-Hoz2, Israel Nieto-Gañán2, Victoria Navarro-Compañ2, Ana Martínez-Feito2, Javier Bachiller-Corral1, Gemma Bonilla3, Paloma Lapuente-Suárez3, Cristina Pijoan Moratalla1, Dora Pascual-Salcedo2, Alejandro Balsa2, Garbiré Roy2, Mónica Vázquez1, Luisa María Villar2, Chamaida Plasencia2, Eulalia Rodríguez-Martin1.

1Rheumatology Department. Ramón y Cajal University Hospital, IRYCIS, Madrid, Spain; 2Immuno-Rheumatology Research Group, La Paz University Hospital, Madrid, Spain; 3Immunology Department. Ramón y Cajal University Hospital, IRYCIS, Madrid, Spain.

Background: The most common biological agents used as disease-modifying treatment in rheumatoid arthritis (RA) are TNF inhibitors (TNFi). Although these new strategies to treat RA have improved the course of the disease, approximately 30-50% of patients do not respond to this therapy. Early identification of optimal responders is crucial in the clinical setting.

Objectives: The aim of this study was to investigate if baseline percentages of different leukocyte subsets in peripheral blood (PBMCs) can contribute to identify RA patients who will respond to TNFi.

Methods: This was a prospective bi-center pilot study including 100 RA patients under TNFi therapy. Clinical activity was assessed at baseline and 6 months of treatment by disease activity score 28 (DAS28), considering optimal responders if they reached remission at 6 months (DAS28 £ 2.6). PBMCs were obtained before treatment and different leukocyte subsets were evaluated by flow cytometry (FACSCantoII instrument). The association between the percentage of PBMCs at baseline and clinical response at 6 months was evaluated through logistic regression models (odds ratio; 95% CI). All the analyses were adjusted by sex, age, disease duration, concomitant methotrexate, baseline DAS28 and seropositivity (ACPA and/or RF).

Results: Demographic characteristics are shown in Table 1. After 6m of TNFi treatment, 40% of the patients achieved clinical remission. A significant association between higher percentage of total B cells (OR=1.19; 95%; CI:1.05-1.35; p=0.007) and naive B cells (Bn; OR=1.32; 95%; IC:1.08-1.61; p=0.007) at baseline and clinical response was found. The other PBMC subsets (monocytes, NK cells, CD4+ and CD8+ T cells subtypes) did not show statistical differences (Figure 1).

Conclusion: Our results suggest that basal B cells profile may contribute to identify optimal responders to TNFi in RA. (Funding: ISCIII (PI16/01092, PI16/00474).

Disclosure of Interests: Cristina Sobrino: None declared, Borja Hernández-Breijo: None declared, Carlota García-Hoz: None declared, Israel Nieto-Gañán: None declared, Victoria Navarro-Compañ: None declared, Ana Martínez-Feito: None declared, Javier Bachiller-Corral: None declared, Gemma Bonilla: None declared, Paloma Lapuente-Suárez: None declared, Cristina Pijoan Moratalla: None declared, Dora Pascual-Salcedo: None declared, Alejandro Balsa: None declared, Garbiré Roy: None declared, Mónica Vázquez: None declared, Luisa María Villar: None declared, Chamaida Plasencia: None declared, Eulalia Rodríguez-Martin: None declared.
as possible within 6 months[1], but many patients have taken oral glucocorticoid for the long term in daily clinical practice. The frequency of use of glucocorticoid has gradually declined, and there are several reports on discontinuation of glucocorticoid due to the initiation of bDMARD[2, 3]. However, there is no report showing the relation between discontinuation of glucocorticoid and MTX dose.

**Objectives:** The aim of this study is to examine association of methotrexate (MTX) dose with discontinuation of glucocorticoid after one year since initiation of biological DMARD (bDMARD) as 1st bDMARD.

**Methods:** We established the large observational cohort, the Nagoya University orthopedic facility multicenter study (TBCR), and a total of 3119 patients used biological DMARD. 564 patients who used glucocorticoid and MTX when bDMARD was initiated as 1st bDMARD were enrolled. In the first study, we examined predictive factors of discontinuation of glucocorticoid after one year since initiation of bDMARD by using multivariate analysis in the two groups, which patients continued to use glucocorticoid and discontinued to use glucocorticoid. In the second study, we adjusted the background at the time of initiation of bDMARD by using propensity score matching (PS) in the two groups, MTX=8mg (L group) and MTX>8mg (H group).

**Results:** 400 patients continued to use glucocorticoid and 164 patients discontinued to use glucocorticoid. In the multivariate analysis, age (Odds ratio (OR)0.98), MTX dose (OR1.09) and glucocorticoid dose (OR0.88) were independently predictive factors of discontinuation of glucocorticoid. When we adjusted age, disease duration, sex, disease activity, RF/ACPA, glucocorticoid dose by using PS matching, 105 pairs were extracted. There were obvious significant differences between 24 patients (22.9%) in the L group and 43 cases (41.0%) in the H group (P = 0.007), where glucocorticoid was discontinued at one year after the initiation of bDMARD.

**Conclusion:** This cohort study investigated the association of discontinuation of oral glucocorticoid and MTX dose in the patients treated with bDMARD. TBCR revealed that, in the clinical practice, glucocorticoid use was decreasing in the patients treated with bDMARD. MTX dose at the time of initiation of bDMARD was predictive factor of discontinuation of glucocorticoid. A higher dose of MTX associated with discontinuation of glucocorticoid in the patients treated with bDMARD.

**TNF ALPHA INHIBITORS INFLUENCE THE CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS**

Jerzy Siewior1, Marta Madej1, Grzegorz Rozumek2, 1Wroclaw Medical University, Department of Rheumatology, Wroclaw, Poland, 24th Military Clinical Hospital, Department of Internal Diseases, Wroclaw, Poland

**Background:** Rheumatoid arthritis (RA) patients die because of cardiovascular diseases more often than the general population. Nowadays RA is considered as an independent risk factor for cardiovascular disease (CVD). A long-lasting inflammatory process, immunological dysregulation and endothelial dysfunction play an important role in the pathogenesis of progressive atherosclerosis in RA [1,2].

**Objectives:** The aim of the study was to assess the influence of biological treatment on cardiovascular risk factors in RA population.

**Methods:** 38 RA patients with active disease (DAS28>5.1) and 22 age and sex matched healthy controls were enrolled in the study. All the patients were treated with TNF alpha inhibitors (n=20 etanercept, n=18 adalimumab), with the background methotrexate (10-25mg weekly). The clinical state was assessed at the beginning of the study and 6, 12 and 18 months after. All the patients underwent the following tests: DAS28 assessment, basic laboratory measurements (including homocysteine levels, fibrinogen, lipid profile), electrocardiogram (ECG), flow-mediated dilation (FMD) and cartoid intima-media thickness (cIMT) assessment and echocardiography. The local bioethics committee approved the study (KB-753).

**Results:** 27 woman and 11 man (71% and 29% respectively) with high disease activity despite long-term treatment with synthetic disease modifying antirheumatic drugs were enrolled in the study. Mean age was 52 years (SD ± 9,6), 95% of the patients were RF-positive, 63% anti-CCP-positive. Of them 24% were current smokers, 58% had arterial hypertension and 66% had concomitant hypercholesterolemia. In comparison to the control group, there were statistically significantly higher values of cIMT in RA patients. Moreover there was a positive correlation between cIMT thickness and duration of RA. A reduction of cIMT (mainly during first 12 months) and an increase in FMD values were observed in the course of the treatment (p<0.05). The increase in FMD value (0.03 vs 0.37) correlated with decrease of the inflammatory markers, which may be a result of an improvement in endothelial dysfunction due to anti-TNF-alpha treatment. The decrease in total cholesterol (p<0.05), LDL cholesterol (p<0.03) and Castelli risk index (p<0.05) were also noted, no changes of the doses of cholesterol-lowering therapy were done during the follow up. There was a positive correlation between homocysteine and uric acid levels and there was a statistically significant decrease in both parameters in the course of the treatment (11.31 vs 8.91 [mol/l] and 5.92 vs 4.77 [mg/dl], respectively). Normal left ventricular geometry was observed after 12 months of biological therapy in patients with concentric remodeling of the left ventricle. Furthermore echocardiography revealed a significant decrease in LVEDD, IVSD, LA, FS, RVEDD after 18 months of the biologic treatment.

**Conclusion:** Our results confirm earlier data that TNF alpha inhibitors may favorably influence on endothelial dysfunction. Besides TNF inhibitors can protect against increase in relative wall thickness of left ventricle. The anti-TNF alpha therapy not only reduces the activity of the disease in affected joints but also has a positive impact on selected cardiovascular risk factors in RA population.

FACTORS THAT AFFECT THE RESPONSE TO TOCILIZUMAB WITH REGARD TO WORK PRODUCTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A 2-YEAR FOLLOW-UP OF THE FIRST ACT-SC STUDY

Yoshiya Tanaka1, Hitode Kameda2, Saito Kazyouji3, Kyo Yutoko4, Eiichi Tanaka5, Shinshuke Yasuda6, Naoto Tamura7, Keiji Fujii8, Takanoo Fujii9, Yoshihisa Kojima10, Tatsuhiko Anzai11, Yoshihisa Fujino12, Shinya Matsuda13, Hitoshi Kohsaka14,15, University of Occupational and Environmental Health, Fukuoka, Japan; 16Tokyo Medical and Dental University, Tokyo, Japan; 17Tokyo Women’s Medical University, Tokyo, Japan; 18Hokkaido University Faculty of Medicine and Graduate School of Medicine, Hokkaido, Japan; 19Juntendo University School of Medicine, Tokyo, Japan; 20The University of Tokyo, Tokyo, Japan; 21Wakayama Medical University, Wakayama, Japan; 22Nagoya University Graduate School of Medicine, Aichi, Japan; 23EPS Corporation, Tokyo, Japan; 24Tokyo Medical and Dental University, Tokyo, Japan

Background: Rheumatoid arthritis (RA) is a major cause of work disability, sickness-related absence from work, presenteeism, and loss of productivity. The decrease in work productivity that results from persistent pain, impaired mobility and function, and reduced quality of life (QOL) has important personal, societal, and economic consequences[1]. The efficacy of tocilizumab (TCZ) as monotherapy and in combination with methotrexate for RA is well known. Thus, in this study, we expected TCZ treatment to improve work productivity on the basis of interim results of up to 52 weeks[2].

Objectives: We aimed to evaluate the long-term (104 weeks) control of RA in Japanese paid workers and house workers treated with TCZ and identify factors affecting the response (responder/non-responder) to TCZ in terms of work productivity.

Methods: The first ACT-SC study (UMIN-CTR: UMIN000012306) was a cohort study that assessed the 2-year treatment outcome of TCZ-SC (administered alone or with disease modifying anti rheumatic drugs) in biologics-naive Japanese patients with RA. Logistic regression analysis was performed to determine the factors contributing to treatment response in terms of activity impairment (AI) in the WPAI questionnaire, which is an index for the evaluation of overall daily life performance. In addition, the association of these responses to treatment withdrawal rate and QOL were also evaluated.

Results: Of the 377 enrolled participants, 357 who were treated with TCZ-SC were included in the analysis. AI was improved from 56.2% at baseline to 22.9% at 104 weeks in the patients who received TCZ. In the single regression analysis, the factors that were statistically significant in the logistic regression analysis were job type (p=0.045), K6 as a measure of psychological distress (p=0.030), Health Assessment Questionnaire-Diary (HAQ-DI; p=0.032), and EuroQol five-dimensional descriptive system (EQ-5D) score (p=0.006). In the multiple logistic regression analysis, disease duration, academic background, AI, EQ-5D score, ESR, and CRP level were identified as factors that affected response. The results showed a strong association between the results of the subjective assessments such as the utility value of EQ-5D. At 104 weeks, the mean difference in AI between the EQ-5D scores of <0.6 and ≥0.6 was significant (−22.94% vs −30.50%; p=0.029). Moreover, the mean difference between the HAQ-DI of <1.5 at baseline and ≥1.5 was significant (−20.46% vs −29.08%; p=0.013). A disease duration of >1 year was also associated with being an AI responder. A significant difference in withdrawal rate was found between the responders and non-responders (27.0% vs. 46.9%; p=0.001), and the 2-year quality-adjusted life-year was also significantly higher in the AI responders.

Conclusion: Starting TCZ-SC treatment at an early stage while taking into consideration the subjective self-assessments of the patients may contribute to improvements in labour productivity and QOL, and long-term treatment continuation.

AB0413 THE PROSPECTIVE ASSESSMENT OF RITUXIMAB AND TOCILIZUMAB TREATMENT EFFECT ON RF-IGM AND ACPA TITRES IN RHEUMATOID ARTHRITIS PATIENTS

Olga Borys, Bozena Targonska-Stepniak, Magdalena Dryglewska, Maria Majdan, Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland

Background: Rheumatoid arthritis (RA) is associated with several specific autoantibodies, which can be used as diagnostic and prognostic markers. These include rheumatoid factor IgM (RF-IgM) and anti-citrullinated protein antibodies (ACPA). The data reporting an impact of biological disease modifying anti-rheumatic drugs (bDMARDs) on RA serological markers are divergent, probably depending on the type of treatment.

Objectives: The goal of this study was to prospectively evaluate the impact of bDMARDs (rituximab, RTX) and tocilizumab (TCZ) on RA serological markers (RF IgM, ACPA), in correlation with the disease activity assessment.

Methods: The study was conducted in the consecutive 42 patients with RA (36 women, 6 men), with the mean (SD) age 49.6 (13.8) and disease duration 9.2 (3.8) years. The treatment with RTX was administered to 30 patients and with TCZ to 12 patients. The following parameters were assessed for all patients: joint counts, disease activity index of 28 joints (DAS28), complete blood cell counts, erythrocyte sedimentation rate (ESR), serum concentration of serum amyloid A (SAA), RF-IgM, ACPA. Blood samples were taken before the drug administration (baseline) and in consecutive months (3, 6 and 9 months).

Results: Parameters of the disease activity decreased significantly in consecutive months, in comparison with the baseline assessment, in both treatment groups. The mean (SD) DAS28 decreased significantly in both groups (RTX and TCZ): respectively at baseline: 5.75 (0.69) and 5.47 (0.51); month 3: 3.92 (1.13) and 2.84 (0.76); month 6: 3.23 (1.09) and 2.09 (0.94); month 9: 3.67 (1.19) and 2.12 (0.81). The mean reduction of RA serological markers (RF-IgM, ACPA), in correlation with the disease activity assessment.

month 9 (Figure 3); no significant change of RF-IgM was observed (Figure 4).

Conclusion: The results of the study suggest that both bDMARDs reduced significantly the disease activity in RA patients. The treatment with both drugs was associated with a significant reduction of SAA. However only RTX treatment affected significantly the production of disease specific autoantibodies. Long-term observation is necessary to assess a reliable effect of bDMARDs on the production of marker autoantibodies in association with the disease activity. Disclosure of Interests: Olga Borys: None declared, Bozena Targonska-Stepniak Speakers bureau: Sandoz, Berlin-Chemie, Magdlena Dryglewska: None declared, Maria Majdan Speakers bureau: MSD, UCB, Abbvie, Roche DOI: 10.1136/annrheumdis-2019-eular.3476

AB0414 THE IN VITRO EFFECT OF BIOLOGICAL AND CONVENTIONAL DISEASE MODIFYING ANTI RHEUMATIC DRUGS (DMARDs) ON FIBROCYTE DIFFERENTIATION IN RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY CONTROLS

Helene Tenstad¹, Pernille Just Vinholt², Christian Nielsen³, Hanne Merete Lindegaard⁴, Søren Andreas Just⁵, Odense University Hospital, Department of Rheumatology, Odense, Denmark; Odense University Hospital, Department of Biochemistry and Pharmacology, Odense, Denmark; Odense University Hospital, Department of Immunology, Odense, Denmark; Odense University Hospital – Svendborg, Department of Internal Medicine – Section of Rheumatology, Svendborg, Denmark.

Background: Fibrocytes are circulating cells with both myeloid and haemopoietic properties. They home in tissues with active inflammation, where they differentiate into mature fibrocytes that are involved in several inflammatory pathways. One complication of Rheumatoid Arthritis (RA) is Interstitial Lung Disease (ILD) resulting in high mortality and with limited treatment options. Fibrocyte levels are elevated in RA patients compared with healthy individuals and further increased in RA patients with signs of ILD (reduced diffusion capacity) and in patients with idiopathic lung fibrosis (IPF) or scleroderma. Thus, fibrocytes have been proposed as a future treatment target.

Objectives: We investigate the effect of corticosteroids, conventional Disease Modifying Anti Rheumatic Drugs (cDMARDs) and biological DMARDs (bDMARDs) on the in vitro differentiation of isolated peripheral blood mononuclear cells (PBMCs) into mature fibrocytes.

Methods: 10 participants were included (five patients with RA and five healthy controls). Information on current medication, sex, age, serology and disease activity were collected. PBMCs were isolated and cultured for 5 days in four wells per drug. Drugs included prednisolone, cDMARD (Methotrexate, Sulfasalasine, Hydroxychloroquine) and bDMARD (Inflectra, Etanercept, Tocilizumab, Adalimumab, Abatacept, Rituximab), and control wells with no drugs.

Results: Overall, abatacept and prednisolone significantly suppressed differentiation of PBMC into fibrocytes compared to control wells, see Figure 1 (p=0.02 and p<0.01, respectively) (n=10). The reductive effect of Abatacept was significant among RA patients (p=0.009 and) but not among healthy subjects. In overall analysis (n=10), Abatacept reduced fibrocyte levels with an average of 44% overall and in the RA group 71% compared to control wells. Tocilizumab reduced the fibrocyte count with 63% overall and 45% in the RA group, although not significant (p=0.07 and p=0.06 respectively).

Conclusion: Abatacept and prednisolone suppress the differentiation of mononuclear cells to mature fibrocytes in vitro in RA patients and data indicating a similar effect of Tocilizumab. Prednisolone are used in the treatment of RA-ILD but has a marked toxicity, so new treatment modalities are desirable. Our findings are in line with the fact that fibrocytes have the receptors targeted by abatacept, furthermore recent scleroderma research has shown Abatacept to reduce fibrocyte levels in vitro and Tocilizumab to potentially reduce lung and skin affection (1, 2) Further research using abatacept and tocilizumab to target fibrocytes are needed in order investigate the treatment potential of these drugs in RA-ILD.
SURVIVAL OF BIOLOGIC AGENTS WITHIN A COHORT OF GREEK PATIENTS WITH RHEUMATOID ARTHRITIS. REAL WORLD DATA.

Olga Katsoul1, Georgia Liannitoni2, Panagiota Katsoul1, Mary Pappa3, Marcos Patsouras4, Theodoros Angelopoulos5, Sokiris Roussos6, VLACHOYIANNOPOULOS PANAyiOTIS1, 1Medical School National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece, 2Medical School National and Kapodistrian University of Athens, Athens, Greece, 3Medical School National and Kapodistrian University of Athens, Hygiene, Epidemiology and Medical Statistics, Athens, Greece

Background: Rheumatoid arthritis (RA) is treated successfully with biologic disease-modifying anti-rheumatic drugs (bDMARDs). However, a significant withdrawal rate, due to non-responsiveness or toxicity, remains a major barrier for their long-term use.

Objectives: To determine the withdrawal rate of the first bDMARD in a large cohort of RA patients due either, to non-responsiveness or toxicity.

Methods: In this study, were included retrospectively 220 patients from our outpatient clinic. The following bDMARDs were evaluated: Etanercept (n=66 patients), Adalimumab (n=61 patients), Infliximab (n=70 patients), Rituximab (n=6 patients) and others, such as Certolizumab pegol, Golimumab, Tocilizumab, Anakinra and Abatacept (n=17 patients). Disease activity was regularly measured by DAS-28 until the end of follow up. Kaplan-Meier plots were performed to examine the withdrawal rate of each biologic agent. Severity of AEs was classified according to the Common Terminology Criteria for Adverse Events (CTCAE, version 4.03).

Results: A total of 220 patients (49 men, 171 women) were included in the analysis. The most frequently used first-line bDMARDs were Infliximab (31.8%), Etanercept (30%) and Adalimumab (27.7%). The median of treatment duration with the first bDMARD was 15 months (Q1:8, Q3:40.5). Taking all bDMARDs as a whole, 126 patients (57.27%) discontinued the first bDMARD, either due to AEs (n=66, 52.38%), or loss of efficacy (n=60, 47.62%) after a follow-up of 167 months. However the most withdrawals (53.18%) occurred within the first 60 months of follow-up. Mean initial and final DAS-28 were: for those who discontinued due to failure of therapy: 5.04 ± 1.37 (95%CI, 4.70-5.39) and 4.91 ± 1.27 (95%CI, 4.59-5.23) respectively and for those who continue 4.79 ± 1.55 (95%CI, 4.47-5.10) and 2.63 ± 1.06 (95%CI, 2.41-2.84) respectively.

Differences in survival among bDMARDs are attributed to their AEs and not to their efficacy. As far as the AEs are concerned, infections constituted the majority of cases (n=23, 34.8%), from which 34.8% needed hospitalization (CTCAE 3-4). The percentage of 12.1% of AEs is attributed to cancer cases, while allergic reactions counted for 31.8% of them. Survival of Etanercept within our cohort was significantly longer than those of other bDMARDs.

Conclusion: Biologic agents are important drugs in our armamentarium to combat RA. However nearly 50% of patients discontinue these agents after 60 months of treatment due either to AEs or inefficacy. Differences in survival of bDMARDs were associated not to their inefficacy, but to their AEs. Choosing the right drug for the right patient is a matter of advanced research involving a better understanding of the plasticity of the pathways of inflammation and specific biomarker selection.

A COMPARATIVE STUDY TO ASSESS THE EFFICACY, SAFETY, AND IMMUNOGENICITY OF YLB113 AND ETAmeric RECEPTOR PRODUCT FOR THE TREATMENT OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

Hisashi Yamanaka1, Naomiyuki Kamatani2, Yoshiya Tanaka3, Toshihiko Hibino3, Edit Drescher4, Juan Sánchez-Bursón5, Manfred Rettenbacher6, Girish Bhatia3, Snehad Gadge7, Chirag Shah8, Dhananjay Bakshie9, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan; 2StGazi, Tokyo, Japan; 3University of Occupational and Environmental Health, The Department of Internal Medicine, Kikuyushu, Japan; 4YL Biologics Ltd., Tokyo, Japan; 5Vital Medical Center, Veszprém, Hungary; 6Hospital Infanta Luisa, Sevilla, Spain; 7Lupin Atlantic Holdings SA, Zug, Switzerland; 8Medipoint Hospital Pvt. Ltd., Maharashtra, India; 9Lupin Limited, Pune, India

Background: YLB113 is an investigational biosimilar of the reference product etanercept (ETN), being developed for the treatment of patients with moderate-to-severe rheumatoid arthritis (RA) and other approved indications of the reference product ETN.

Objectives: The phase 3 study of YLB113 was conducted in Europe, Japan, and India across more than 100 rheumatology clinics to compare efficacy, safety, and immunogenicity of YLB113 with ETN in patients with RA.

Methods: A total of 528 patients with moderate-to-severe RA receiving concomitant treatment with methotrexate were randomized to receive a once-weekly dose of 50 mg of subcutaneously administered YLB113 or ETN. The primary end point was the ACR20 response rate at Week 24, with equivalence confirmed if the 95% confidence interval (CI) was within the range of –15% to 15%. Other efficacy end points, such as DAS28 with safety and immunogenicity end points, were assessed periodically up to Week 52.

Results: The ACR20 response rate at Week 24 was 81.2% for YLB113 and 86.8% for ETN in the full analysis set, with a treatment difference of –5.6% (95% CI: –11.6, 0.5), which was completely within the predefined equivalence margin of –15% to 15%. The result for sensitivity analysis using the per protocol set population revealed that the proportion of subjects who showed ACR20 response at Week 24 was similar between both treatment groups, at 4.6% (95% CI: –10.1, 0.9). The incidence of treatment-emergent adverse events was comparable between YLB113 and ETN (55.5% vs 65.7%), and the incidence of antibiotic antibody development up to Week 24 was in favor of YLB113 (0.8% vs 8.3%).

Conclusion: The present comparative study demonstrated the biosimilarity of YLB113 to ETN on the triad of efficacy, safety, and immunogenicity in patients with moderate-to-severe RA, and thus can be extrapolated to other therapeutic indications approved for ETN. The therapeutic equivalence of YLB113 and ETN in terms of the primary efficacy end point at Week 24 and long-term safety comparability until Week 52 was established with lower immunogenicity.

AB0416C

THE RESULTS OF THE USE OF TOFACITINIB (TOFA) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IN MOSCOW. ANALYSIS DATA FROM MOSCOW UNIFIED ARTHRITIS REGISTRY (MUAR)

Eugeny Shmidt1, Ekaterina Koltsova2,3, Galina Lukina4, Karine Lytkina5, Evgeniy Zhiyaev1,2, 3City Clinical Hospital #1 named after N. I. Pirogov, Moscow, Russian Federation; 4Research Institute of the Organization of Health and Healthcare Management, Moscow, Russian Federation; 5Moscow Clinical Scientific Center, Moscow, Russian Federation; 6City Clinical Hospital #4, Moscow, Russian Federation; 7Russian Medical Academy of Continuing Professional Education, Moscow, Russian Federation; 8CUC – European Medical Center, Moscow, Russian Federation

Background: Moscow Unified Arthritis Registry (MUAR) started on 01 DEC 2012. By 01 DEC 2017, 829 RA patients were included in the register.

Objectives: The aim of the study was to evaluate the effectiveness and treatment survival of TOFA and identify predictors of the effectiveness of TOFA.
Efficacy and Safety of Tofacitinib in Patients with Rheumatoid Arthritis – Non Biologic Treatment

Methods: The inclusion criteria were diagnosis of RA, established at any time according to ACR (1987) or ACR/EULAR (2010) criteria; persons receiving or planning to receive targeted therapy for RA; signed informed consent to participate in the study. All episodes of treatment with tofacitinib in which there was at least 1 visit not earlier than 6 months since the start of the drug were included for efficacy analysis.

Results: Data of 48 patients treated with tofacitinib were extracted from the registry. Women were 41 (85.4%), mean age was 55.1 ± 12.4 years; age at the disease beginning was 44.3 ± 14.0, 6 (12.5%) of patients were smokers; mean time on tofacitinib was 552 ± 295 days. One of the independent predictors of achieved DAS28 was sex - 0.49 lower in men (p<0.001). There was no correlation of achieved disease activity with number of previous failures with biologics. Patients seropositive for rheumatoid factor achieved significantly lower activity (p =0.015). There was also a trend towards lower achieved activity in patients with rheumatoid nodules (p = 0.059).

On the first line of targeted treatment, survival of tofacitinib was significantly better than Infliximab, Adalimumab and Certolizumab pegol. On the second line – better than etanercept. On the following lines TOFA was better than Adalimumab, but worse than Etanercept. Due to the fact that most of treatment episodes with tofacitinib are not completed, the average duration of treatment may be underestimated. There was no significant decrement of remission on therapy after multiple treatment failures (tab.).

Conclusion: The effectiveness and treatment survival of tofacitinib does not depend on the number of previous failures with biologics; the best results of TOFA can be expected in men and seropositive patients; the presence of rheumatoid nodules can be considered as a special indication for TOFA.

Table: Retention of targeted therapies in patients with rheumatoid arthritis

Efficacy and Safety of Tofacitinib in Patients with Rheumatoid Arthritis According to Duration of Prior CSPMARD Treatment and Number of Prior CSPMARDs: A Post Hoc Analysis of Phase 3 and Phase 3b/4 Trials

Daniel Aletaha1, Juan Jose Gomez-Reino2, Gerd Rüdiger Burmester2, Ronald van Vollenhoven3, Jose Luis Rivas3, Salim Benkhalfa4, Palre Dahl5, Harry Shi6, Lisy Wang7, Medical University of Vienna, Vienna, Austria; 8Hospital Clinico Universitario, Santiago de Compostela, Spain; 9Charite – University Medicine Berlin, Berlin, Germany; 10Karolinska Institute, Stockholm, Sweden; 11Pfizer SLU, Madrid, Spain; 12Pfizer SAS, Paris, France; 13Pfizer Inc, Ballerup, Denmark; 14Pfizer Inc, Collegeville, PA, United States of America; 15Pfizer Inc, Groton, CT, United States of America

Background: Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Previous analyses have reported greater improvements in efficacy outcomes with tofacitinib 5 mg twice daily (BID) compared to conventional synthetic DMARDs (csDMARDs) in patients (pts) with early RA.1,2

Objectives: To evaluate the efficacy and safety of tofacitinib in pts with RA, stratified by prior csDMARD treatment duration and number of prior csDMARDs.

Methods: This was a post hoc analysis of pooled data from 4 Phase (P) 3 trials (ORAL SCAN [NCT00847613]; ORAL Solo [NCT00814307]; ORAL Sync [NCT00856544]; ORAL Standard [NCT00853385]) and 1 P3b/4 trial (ORAL Strategy [NCT02187055]) of tofacitinib in pts with RA and an inadequate response to ≥1 DMARD. Pts treated with tocilizumab 5 mg BID as monotherapy or with csDMARDs were included. Outcomes were evaluated according to csDMARD treatment duration (≤1, 1–2, >2 years) and number of csDMARDs (1, 2, 3; ≥4) prior to baseline (BL). Efficacy outcomes assessed at Months (M)3, 6 and 12 were: change from BL (Δ) in CDAI and HAQ-DI, and rates of CDAI-defined low disease activity (LDA) ≤10 and remission (≤28).

Results: In total, 1584 pts were included in the analysis; of these, 27.2% (n=431) had received csDMARDs for ≤1 y, 20.5% (n=255) for 1–2 y, and 52.1% (n=825) for >2 y prior to BL (duration unknown for 3 pts). Roughly half (53.2%, n=842) had received 1 prior csDMARD; 26.4% (n=418); 13.8% (n=219) and 6.6% (n=105) had received 2, 3 and ≥4 prior csDMARDs, respectively. Most pts had previously received MTX (50.6%, n=805) or MTX + other csDMARDs (46.3%, n=733); 2.9% (n=46) received other csDMARDs only. Mean BL CDAI and HAQ-DI scores were similar, irrespective of prior csDMARD treatment duration or number of prior csDMARDs (Table). Generally, up to M12, no trends were observed for ACDAI, ΔHAQ-DI or CDAI LDA rates regardless of prior csDMARD treatment duration or number of prior csDMARDs (Table). When CDAI remission rates data were stratified by csDMARD treatment duration, no differences between pt groups were observed at M3 and M6; however, a numerically higher proportion of pts with prior csDMARD treatment duration ≤1 y achieved remission (50.8%, n=805) or MTX + other csDMARDs (46.3%) vs 1–2 y and >2 y pts. Use of fewer prior csDMARDs appeared to be associated with higher remission rates up to M12. Although safety outcomes were similar when data were stratified by prior csDMARD treatment duration, there was generally a trend for increased rates of AEs, SAEs and AEs of special interest (serious infections, herpes zoster and opportunistic infections [excluding B1]) with increasing number of prior csDMARDs (Table).

Conclusion: In this post hoc analysis of pooled data from P3 and P3b/4 trials, no differences in the efficacy or safety of tofacitinib 5 mg BID were observed when pts were stratified by prior csDMARD treatment duration. Although pt numbers were small, use of fewer prior csDMARDs may be associated with improved remission rates and safety outcomes for pts treated with tofacitinib.
INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOFACITINIB

Marcelo Bejarano1, Maria Natalia Tamborena2, Mario Alberto Goñi3, Lina Saldañarena4, Cecilia Pisoni5, Rodrigo Garcia Saldanha6, Mariana Salcedo7, Claudia Helling1, Adam Salas2, Hospital General de Agudos Bernardino Rivadavia, Rheumatology Unit, CABA, Argentina; Hospital General de Agudos Bernardino Rivadavia, CABA, Argentina; Instituto de Lucha Antiinmunológica y Rehabilitación del Lúcido, Rosario, Argentina; Hospital Universitario San Jorge, Perú, Colombia; CEMIC, caba, Argentina; Hospital Italiano De La Plata, La Plata, Argentina; INSTITUTO DE INVESTIGACIONES CLINICAS DE ZARATE, Zarate, Argentina; Pfizer SRL, CABA, Argentina

Background: The presence of interstitial lung disease (ILD) is a common extra-articular manifestation in patients diagnosed with Rheumatoid Arthritis (RA), dyspnea being its cardinal symptom. Several of the drugs commonly used to treat this condition, such as TNF inhibitors (anti-TNF) and Disease Modifying Antirheumatic Drugs (DMARDs), have been implicated in the development or exacerbation of ILD. In regard to Tofacitinib, results of post hoc analysis of its pivotal and extension studies report a numerically lower ILD incidence rate in the group that received this drug compared with placebo.

Objectives: To describe the evolution of dyspnea, spirometric parameters, DLCO and high resolution computed tomography (HRCT) findings in patients with RA diagnosis associated with PID who received Tofacitinib for a period of 12 months.

Methods: Patients with a diagnosis of RA who fulfilled criteria ACR 1987/ ACR-EULAR 2010, with interstitial lung disease previously diagnosed from clinical findings, spirometry and/or HRCT were included. Tofacitinib was used in dose of 10 mg/day orally. Design: Descriptive, retrospective, multicentric study. The following variables were analyzed: change at 12 months from baseline in the degree of dyspnea (according to the modified scale of dyspnea MMRC), forced vital capacity (FVC), DLCO and findings in HRCT. Continuous variables were reported as mean and standard deviation or median and interquartile range as appropriate. The categorical variables were reported as percentages.

Results: Fifteen patients were included. 60% (n: 9) were women. The mean age was 64.4 years (± 10.92). The median time of evolution of RA was 9 years (IQR: 4-40). The median time of evolution of interstitial lung disease was 4 years (IQR: 1-24); 13% (n: 2) of the patients were receiving methotrexate (MTX) at the time of evaluation, 60% (n: 9) of the patients had received methotrexate previously, 80% (n: 12) had previously received leflunomide different from MTX. 33% of the patients (n: 5) had received previous biological treatment. All patients received tofacitinib at a dose of 10mg/day. 47% of patients (n = 7) received tofacitinib monotherapy and 53% (n = 8) received it combined with DMARDs. 27% (n: 4) of the patients had grade 3-4 dyspnea at baseline. Improvement in the dyspnea scale was observed in 8 patients, while in the rest, it remained stable. The forced vital capacity (FVC) at baseline was <80% in 5 patients and > 80% in 2 patients. At 12 months, 4 patients achieved a FVC > 80%. The average of DLCO at baseline was 45.6 (± 18.84), with an improvement of 30% at 12 months in 4 patients. No progression of the disease was observed in the HRCT at 12 months in any of the patients evaluated.

Conclusion: The present preliminary study was performed with patients of daily practice, not being available in all cases, the corresponding respiratory functional examinations. However, despite these limitations, none of the patients showed worsening of dyspnea, with improvement in some patients. Regarding respiratory functional examinations and DLCO, not only the patients who remained stable after treatment in the majority of patients evaluated, but 4 patients presented improvement with respect to baseline parameters. It is necessary to perform more studies, with systematized controls of the pulmonary function and imaging, to corroborate this hypothesis.

A PROSPECTIVE, OBSERVATIONAL STUDY ON THE CLINICAL EFFICACY AND SAFETY OF LEFLUNOMIDE IN EGYPTIAN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: CLEAR STUDY

Adel Elsayed, Ain Shams University, Department of Rheumatology, Cairo, Egypt

Background: Due to its anti-inflammatory and immunomodulatory properties, leflunomide can be used as monotherapy or in combination with other conventional synthetic DMARDs (csDMARDs) in treating active RA.1

Objectives: The aim of this observational study was to assess efficacy and safety of leflunomide in Egyptian patients with active RA, whether used as first-line and/or add-on therapy to other csDMARDs, with or without steroids.

Methods: Adult Egyptian patients with active RA, fulfilling the ACR/EULAR 2010 classification criteria, for whom leflunomide was prescribed, were included and followed up for 9 months. Leflunomide was prescribed at the physicians’ sole discretion for patients who have previously experienced resistance, inadequate response or intolerance to other csDMARDs. Data about CDAI score and HAQ-DI score were acquired from patients who fulfilled the eligibility criteria, along with patients’ demographics, medical history, physical examination, concomitant medications, and RA history including disease duration, previous RA medications and treatment response. This study was registered on clinicaltrials.gov (NCT03599986) and the preliminary results were previously published in 2018.2

Results: A total of 398 patients were enrolled in this study. Three hundred ninety-six patients with a mean age of 43.7 (SD 10.2) years and median disease duration of 2 (IQR 5.5) years were eligible for efficacy evaluation; 309 (84.4%) were female. We found that 86.1% of patients were leflunomide naïve. Patients who previously received leflunomide (13.9%) had a wash out period of at least 6 months prior to study enrolment. Patients were either prescribed leflunomide 20 mg/day (37.7%) or were prescribed a loading dose of 100 mg/day for the first 3 days of treatment then maintained with 20 mg/day (62.3%). Leflunomide was prescribed as first-line therapy in 21.1% of patients, as add-on therapy to other csDMARDs without steroids in 34%, and as add-on therapy to other csDMARDs with steroids in 44.9%. The mean total CDAI score was slightly lower in the leflunomide group compared to the control group at 24 weeks (23.6 vs. 24.3, p=0.018). The clinical remission rate was 10.4% in the leflunomide group compared to 4.9% in the control group (p=0.025). In addition, the percentage of patients with no change in the CDASII score was higher in the leflunomide group (61 vs. 49%, p=0.001).

FRACTURE RISK IN PATIENTS ON LONG TERM GLUCOCORTICOIDS WITH INFLAMMATORY ARTHRITIS

Jemima Buchalter, Ahmed Elmalehdi, Aine Gorman, Qutab Shah, Angela Camon, Aisal Mohammad, Killian O’rouke, Midland regional hospital Tullamore, Rheumatology, Tullamore, Ireland

Background: A main stay treatment of inflammatory arthritis is glucocorticoids (GCs). However, long term use of GCs has been associated with an increased risk of fracture, with studies estimating up to 12% of patients having sustained a fracture whilst on GC treatment.1,2

Objectives: The aim of this study was to determine the prevalence of fractures in a cohort of patients on long term GCs with a diagnosis of inflammatory arthritis.

Methods: A database of patients with inflammatory arthritis attending the rheumatology department at the Midlands Regional Hospital Tullamore, since 2009, was reviewed. Patients on long term GCs were identified and outpatient summaries were analysed. Data collection included age, sex, diagnosis, vertebral fracture, other fracture sites and osteoporosis treatment.

Results: As of September 2018, out of the 2118 patients with a diagnosis of inflammatory arthritis 364 were on long term GCs. 10% of patients had reported vertebral fractures on imaging. 36.4% of patients had other types of fractures reported on imaging; 20%, and the most common site of fracture, were wrist fractures. 83.7% of those who suffered from a vertebral fracture were female. 18.2% of those who sustained fractures were not on any osteoporosis treatment.

Conclusion: The incidence of fracture in our cohort of patients was higher than suggested in previous studies. Furthermore, it highlights the need for patients on long term GCs to be given osteoporosis prevention therapy.

was significantly decreased (p<0.001) from 36.8 (14.9) at baseline, to reach 12.5 (10.3) after 9 months of treatment, with a reduction of 64%. In a similar pattern, the mean HAQ-DI score was significantly decreased (p<0.001) from 1.5 (0.7) at baseline to reach 0.6 (0.6) after 9 months of treatment, with a reduction of 57%. Figures 1 and 2 show changes in both CDAI and HAQ-DI scores throughout the study.

Twenty-three adverse events (AEs) were reported in 20 patients (5%) throughout the study, and 19.1% of patients were at remission after 9 months of treatment.

Abstract Figure 3 shows that disease severity was significantly improved (p=0.001) throughout the study, and 19.1% of patients were at remission after 9 months of treatment.

[AB0421] METHOTREXATE COMPLIANCE AMONG PATIENTS WITH CHRONIC INFLAMMATORY DISEASE OR CONNECTIVE TISSUE DISEASE

Elisabeth FILHOL1, Charlotte Hua1, Françoise Flaisler2, Cédric Lukas3, Bernard Combe2, Jacques Morel4, Cécile Gaujoux-Viala1, 5, Nilms University Hospital, Montpellier University, Nîmes, France, 3Lapeyronie hospital, Montpellier University, Montpellier, France

Background: Methotrexate (MTX) is widely used in rheumatology. About 30% of patients receiving MTX do not respond. One of the explanations could be poor adherence.

Objective: The purpose of this study was to assess adherence and to identify predictive factors influencing it.

Methods: 188 patients with MTX for at least 3 months (rheumatoid arthritis (RA), peripheral spondyloarthritids (PS), psoriatic arthritis (PA), lupus, Sjögren’s Syndrome (SS)) were enrolled between May 2017 and May 2018. Each patient completed a questionnaire including socio-demographic data, disease and MTX characteristics, 4-question Morisky, rheumatism activity scores including DAS 28, quality of life (EQ-5D), phibromyalgia (FIRST), anxiety and depression (HADS), catastrophism (PC3-CF), coping (WCQ-R) and whether or not to participate in a therapeutic education program. 188 were recruited, with a mean age of 61.4 +/- 13.24 years: RA (77.12%), PS (7.98%), PA (10.11%), lupus (2.66%) and SS (2.13%). 68.6% were observant, versus 31.4% non-observant (28.2%) or major (3.2%) patients. In multivariate analysis, two models were performed and found a poor adherence in case of depression OR: 3.120 [1.051; 9.354], catastrophism OR: 3.974 [1.119; 14.108], anti-CCP antibodies OR: 4.019 [1.277; 12.653] in RA patients and depression OR: 2.715 [1.237; 5.963], absence of comorbidities OR: 2.309 [1.085; 4.915] with all rheumatism.

Conclusion: Some modifiable factors such as depression and catastrophism were associated with the risk of non-adherence with MTX. It is important to consider depression and catastrophism when taking care of our patients to improve adherence and avoid therapeutic escalations.

[AB0422] ACHIEVEMENT OF PATIENT ACCEPTABLE SYMPTOM STATE (PASS) IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH BARICITINIB

Cristina Garufi, Francesca Spinelli, Fulvia Ceccarelli, Ilaria Duca, Silvia Mancuso, Cristiano Alessandri, Guido Valentini, Fabrizio Conti. Policlinico Umberto I, Rheumatology, Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy, Roma, Italy

Background: Baricitinib, a newly approved drug for the treatment of patients with moderate to severe rheumatoid arthritis (RA), is a selective inhibitor of Janus kinase 1 and 2. In a patient-centered care, patient-reported outcomes (PROs) are really helpful to better evaluate the disease activity and the response to therapy. Between them, Patient Acceptable Symptom State (PASS) is defined as the highest level of symptoms beyond which patients consider themselves well [1], and consists of a single question with dichotomized answer (yes or no): “Considering all the different ways your disease is affecting you, if you would stay in this state for the next months, do you consider that your current state is satisfactory?”. In randomized controlled trials baricitinib showed significant improvement of pain, fatigue, tiredness and assessment of disease [2].

Objective: The aim of the present study was to investigate the effect of baricitinib on PASS one month from the beginning of therapy. Further aim was to quantify the time patients needed to reach an acceptable state of health and determine the clinical variables associated with PASS.

Methods: Patients affected by RA according to 2010 ACR criteria, starting treatment with baricitinib as clinically indicated, were consecutively enrolled; PASS was determined after 1 month of treatment (T1); days to
achieve PASS were estimated at T1; activity indices were calculated after 1 month of therapy and correlated with PASS.

**Results:** Thirty-four RA patients were enrolled (age median-IQR: 58-16 years; disease duration median-IQR: 144-138 months; DAS-28 median-IQR: 5.09-1.19). After 1 month of therapy, 30 of 34 patients achieved PASS, of which 73% in the first 2 weeks of treatment (days to achieve PASS median-IQR 12-22) (figure). At T1, patients achieving PASS, compared to those who did not, reported less pain (median VAS 30/100 vs 72/100, p= 0.025), a better global assessment of disease (median 40/100 vs 72/100, p=0.023), lower CDAI (median 12 vs 31, p= 0.048), SDAI (median 12.8 vs 33.95, p=0.011) and DAS-28 (median 3.67 vs 5.54, p= 0.082). 10 out of 30 PASS positive patients (33%) achieved a DAS-28 low disease activity or remission at T1 vs 0% of the PASS negative cohort (p= 0.169). Age, disease duration and number of previous DMARDs did not significantly differ between the two subgroups.

**Conclusion:** Baricitinib was able to induce an acceptable state of health in about 90% of patients after the first month of therapy. The prompt effect of baricitinib on pain and fatigue could partially explain the rapid achievement of PASS, as shown by the decrease of VAS and improvement of the global assessment of disease. Bioavailability of oral MTX reaches plateau in doses >15 mg weekly, and this is the reason of its lower clinical efficacy.

**Objectives:** The objective of this observational longitudinal study was to evaluate the changes in disease activity, intensity of pain, global health, and physical function when switching from oral (P.O.) to subcutaneous (S.C.) MTX in patients with RA and peripheral form of PsA.

**Methods:** Forty-eight consecutive patients (79.2% women) with established diagnosis of RA (77.1%) and peripheral PsA were enrolled from the outpatient clinics in six centres in Croatia. Median age was 61 (79-97) years, and the median of disease duration was 120 (3-528) months. Data were collected at baseline (T0) including retrospective data collection from the previous 3 months (on P.O. MTX), at day 90 (±10 days) (T1) and at day 180 (±10 days) (T2) for the previous periods, both of them during S.C. MTX treatment. Dose of MTX remained stable during the study. Domains of interest were Disease Activity Score on 28 joints measured using ESR (DAS28-ESR), level of pain, Patient’s Global Health Assessment (PGHHA) and Physician’s Global Health Assessment (PGHGA) were measured on horizontal 100 mm VAS, while physical function was measured by Health Assessment Questionnaire – Disability Index (HAQ-DI).

**Results:** Out of 48 patients 41 patients were switched to S.C. MTX monotherapy and 7 to S.C. MTX in combination with another csDMARD. At T1 40 patients were on S.C. MTX monotherapy and 8 on S.C. MTX in combination with another DMARD, and at T2 39 patients were on S.C. MTX monotherapy, 4 on S.C. MTX in combination with another DMARD, 1 on another DMARD and 4 were lost to follow-up. DAS28 showed trend of decrease from 4.9 at baseline to 4.6 at T1 and 4.2 at T2. Analysis of transition of patients according to DAS28 EULAR criteria has shown that percentage of patients with low disease activity has raised from 4.3% at T0 to 21.7% at T1, and 24.3% at T2, while percentage of patients with high disease activity has declined from 98.3% at T0 to 21.7% at T1 and 13.5% at T2. Recommendation for prednisone therapy > 7.5 mg/ QD had 12.5% patients at T0 and T1, and only 6.8% patients at T2. There was a significant decrease in adjusted mean values for level of pain (<1.46; 95% CI <1.55, <0.30; PGHHA <1.12; 95%CI <1.50, <0.73) and PhGHA (-1.15; 95%CI -1.50, -0.80). HAQ-DI showed significant improvement during the 6-month follow-up (0.25; 95% CI -0.32, -0.17).

**Conclusion:** Patients who switched from P.O. to S.C. MTX showed improvement in all observed parameters: decrease of disease activity, reduction of pain, better global health, and physical function. Results of our study are in line with previously published literature data.

**A RETROSPECTIVE STUDY OF ARTHROSCOPIC SYNOVECTOMY FOR REFRACTORY KNEE ARTHRITIS COMPLICATED WITH POPLITEAL CYST**

**Peng Han1, Jian Zhu2, Jianglin Zhang3, Feng Huang4, 1Chinese PLA General hospital, Department of Rheumatology, Beijing, China; 2Chinese PLA General Hospital, Department of Rheumatology, Beijing, China**

**Background:** Baker’s cyst or popliteal cyst is the most common mass surrounding the knee joint that results from inflammatory knee arthritis. With increasing number of arthroscopic synovectomy performed for refractory knee arthritis annually, we aim to explore its value in baker’s cyst treatment.(1)

**Objectives:** To investigate the efficacy of arthroscopic synovectomy on refractory knee arthritis complicated with popliteal cyst.

**Methods:** A retrospective analysis of 153 patients (RA= 95, SpA= 58) with refractory knee arthritis, underwent knee arthroscopic synovectomy in our hospital from 2010 to 2017, was performed. Among them, 20 patients (RA= 16, SpA= 4) complicated with popliteal cyst. We compared the changes in inflammation markers, disease activity score, imaging manifestations, symptoms, the rate and the grading of popliteal cyst before and after the operation to evaluate the efficacy of knee arthroscopic synovectomy.(1)

**Results:** Inflammation markers [ESR(49.42±32.54 vs 24.46±24.17, P<0.001), CRP(8.55±11.63 vs 5.60±22.45, P<0.001)], Rheumatoid Factor[191.29±373.72 vs 74.90±158.31, P<0.001], DAS28 score(4.67±1.25 vs 2.81±1.23, P<0.001), knee joint discomfort score(5.2±1.7 vs 1.9±1.5, P<0.001) and the amount of knee joint effusion by ultrasound scanning (P<0.05) in 95 RA patients were significantly decreased compared to those before the operation; Inflammation markers[ESR(36.76±28.71 vs 21.19±9.79, P<0.001), CRP(21.9±9.79 vs 3.36±0.44, P=0.001), knee joint discomfort score(4.48±1.16 vs 2.51±1.54, P<0.05), back pain VAS score(2.74±2.88 vs 1.56±1.70, P<0.001), and the amount of knee joint effusion by ultrasound scanning.
scanning (P<0.001) in 58 SpA patients were significantly lower than those before the operation; the rate (16.84% vs 6.32%, P<0.023) and grading (P=0.007) of popliteal cyst in RA were decreased after the operation; No statistically difference was observed in the rate(6.90% vs 5.17%), (P=0.697) of popliteal cyst in SpA, but the grading were all decreased in 4 patients.

Conclusion: This study provide evidence that knee arthroscopic synovec-
tomy has a good effect for refractory knee arthritis, which can reduce disease activity, improve joint symptoms and decrease the grading of popliteal cyst.

AB0425 CONVERSE RELATIONSHIP OF URIC ACID AND VITAMIN D3 IN ADULT BAHRAINI PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

Adla Hassan1, Eman Farid2, Shaima Madeni3, Diab Diab4, Ola Al-Sega1, 1Arabian Gulf University, internal medicine, Manama, Bahrain; 2Arabian Gulf University, Pathology Department, Manama, Bahrain; 3Arabian Gulf University, pathology Department, Manama, Bahrain; 4Arabian Gulf University, Biochemistry Department, Manama, Bahrain

Background: The relationship between serum levels of uric acid (UA) and serum vitamin D3 (25(OH)D) in rheumatoid arthritis (RA) and sys-
temic lupus erythematosus (SLE) has been revealed separately. However, a possible link between these two factors in RA in comparison to SLE has not been clarified yet. This is the first study investigating the joint association between 25(OH)D and UA in two related rheumatic diseases in Bahrain.

Objectives: We aimed to evaluate the possible correlation between serum UA and serum 25(OH)D in adult Bahraini patients with RA and SLE and to examine if there are any differences or similarities between these two patient’s groups.

Methods: Eighty adult Bahraini patients (RA=30 and SLE=50) were included in this longitudinal study (two-time points). The mean age of the patients was 45.21 years (range 16-77 years, SD=14.82). Females were 70 (87.5%). Only data for serum UA taken at the same time with vitamin D3 before and after vitamin D3 therapy were collected retrospectively from the patients’ records at Salmaniya Medical Complex, Bahrain. The patients received oral vitamin D therapy at a dose of 50,000 IU weekly for 3 months.

Results: Our results showed that in our studied group the mean serum level of 25(OH)D was significantly increased from 48.17 at baseline to 78.87nmol/l after therapy with an increment of 30.71 (P<0.0001). Conversely, the mean serum level of UA in our cohort was significantly decreased from 333.28 at baseline to 304.67nmol/l after therapy (P<0.001). When segregated the group by disease: The mean serum level of 25(OH)D was significantly increased in SLE from 38.39 at base line to 72.41 nmol/l after therapy (P<0.000), similarly in RA patients 25 (OH)D was significantly increased from 61.67 at baseline to 87.03nmol/l after therapy (P=0.002). In SLE serum UA decreased after vitamin D3 therapy, but the difference was not significant, while in RA the mean serum UA was significantly decreased from 308.83 to 282.03 after ther-

ABSTRACT

AB0426 COMPARISON OF INFLUENCES OF DIFFERENT CONCOMITANT DRUGS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH IGURATIMOD, A CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUG DEVELOPED IN JAPAN, IN REAL-WORLD CLINICAL SETTING

Yuki Hirano, Daisuke Khira, Yukiyoshi Oishi, Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan

Background: Iguratimod (IGU) is csDMARDs developed in Japan and used in Japanese daily practice since 2012. Although IGU was developed as an anti-inflammatory drug at first, anti-rheumatic effect was found in experiments using type II collagen-induced arthritis model mice 1). Main mode of action of IGU was thought to be inhibition of NF-kB resulted in decreased production of IL-6, IL-8 and TNF-alpha 2). Clinical trials performed in Japan showed that efficacy of IGU was equal to sulfasalazine when used as monotherapy in patients with RA 3). Additive efficacy to MTX was also shown in double-blind randomised trial in RA patients 4). We reported efficacy of IGU in daily clinical practice in EULAR 2017 5). IGU is prescribed as monotherapy or concomitantly with other DMARDs such as MTX, csDMARDs other than MTX or biological DMARDs.

Objectives: Influences of different concomitant drugs were compared in RA patients treated with IGU in this retrospective study.

Methods: 178 RA patients treated with IGU in our institute from April 2013 to June 2017 were included. Patients were divided into four groups.

(1) Group in which IGU was started as monotherapy (MONO-G: n=59).
(2) Group in which IGU was added onto MTX treatment without bDMARDs (MTX-G: n=81).
(3) Group in which IGU was added onto csDMARDs treatment other than MTX (sulfasalazine, tacrolimus, bucila-

Disclosure of Interests: None declared
Results: Baseline characteristics was as below. Mean age was 71.4 years old (yo) in MONO-G, 58.3 yo in MTX-G, 70.1 yo in CSD-G, and 58.7 yo in BIO-G. RA duration was 10.2 years in MONO-G, 8.9 years in MTX-G, 11.2 years in CSD-G, and 15.1 years in BIO-G. SDAI at initiation of IGU was 14.2 in MONO-G, 12.8 in MTX-G, 21.3 in CSD-G, and 18.4 in BIO-G. SDAI was significantly improved over time in all four groups (Fig. 1). There were no significant differences in ΔSDAI from baseline to 1 year between groups by one-way ANOVA (Bonferroni).

Continuation rates of IGU at one year and three years were 66.6% and 21.2% in MONO-G, 77.8% and 57.1% in MTX-G, 69.2% and 39.7% in CSD-G and 75.0% and 75.0% in BIO-G. Continuation rate in MTX-G was significantly favorable compared with that in MONO-G and CSD-G by Log-rank test (Fig. 2). Most frequent reason for stopping IGU was liver damage (10 cases). Second frequent reason was intermittent pneumonia in 4 cases.

Conclusion: IGU seemed to be the most tolerant in MTX-G and the second most tolerant in BIO-G. Although higher aged population who might have several comorbidities was included in MONO-G and CSD-G, moderate efficacy of IGU was seen in those groups. Although biological DMARDs is effective in RA patients, the cost is very expensive. IGU is comparative cheap (¥9,200/month) and suitable for RA patients with economic difficulties. As IGU decreased TNF-alpha production via inhibition of NF-kB, MTX+IGU may have similar mode of action with MTX+TNF inhibitor. Although small cases were included in BIO-G, Continuation rate of IGU in BIO-G was good.

AB0427 DIFFERENCES IN DRUG USAGE BETWEEN EORA AND YORA PATIENTS WITH TARGET OF LOW DISEASE ACTIVITY

Kosuke Kumagai1, Noriaki Okumura1, Takahumi Yayama1, Tomohiro Mimura1, Tsutomu Maeda1, Mitsuhiko Kubo1, Taku Kawasakii, Shinji Ima1. 1Shiga University of Medical Science, Orthopaedic Surgery, Otsu, Japan; 2Shiga University of Medical Science, Clinical Education Center for Physicians, Otsu, Japan

Background: Along with the present aging population, development of new therapies such as biological disease-modifying anti-rheumatic drugs for rheumatoid arthritis (RA) has resulted in an increasing number of elderly patients with RA seeking treatment. Furthermore, the onset age of RA has been reported to be trending higher. Elderly onset RA (EORA) is defined as that which develops after 60 years of age, and shown to differ from young onset rheumatoid arthritis (YORA) in regard to background and drug treatment.1 Although many EORA cases have acute onset, cases with polymyalgia rheumatica (PMR)-like symptoms and negative for rheumatoid factor (RF) have recently been observed at a relatively high rate.2 In fact, we have found it occasionally difficult to distinguish between EORA and PMR in clinical settings. For both EORA and YORA patients, treat-to-target (T2T) is necessary, though it is considered that EORA should be treated with the goal of acquiring low disease activity (LDA) from the viewpoint of side-effects of administered therapeutic drugs.

Objectives: In this study, we examined the number of drugs given to EORA and YORA patients treated for RA at our hospital who achieved LDA.

Methods: We enrolled 260 patients into the EORA (n=70) and YORA (n=190) groups, and investigated background and treatment protocols.

Results: As for background, there was a significant difference between the EORA and YORA groups for mean age, mean disease duration, and female ratio, whereas the difference was not significant in regard to antibody positive rate, SDAI, or DAS28-CRP. In those groups, average age was 73.8 and 57.8 years, disease duration was 6.66 and 14.7 years, and female ratio was 62.9% and 83.7%, respectively. RF positivity was 85.3% and 80.7%, and ACPA positivity was 86.5% and 87.7%, respectively, while SDAI was 4.28 and 4.59, and DAS28-CRP was 1.99 and 2.04, respectively (Table 1). As for treatments given to the patients, the rates of prednisolone (PSL) use (37.1% vs. 36.3%), and dosage of methotrexate (MTX) (1.45 vs. 1.41 mg) and its usage rate (55.7% vs. 65.3%) were not significantly different between the groups. On the other hand, MTX weekly administration (2.89 vs. 4.09 mg, p=0.009) and biologics usage rate (32.9% vs. 56.3%, p=0.0012) were significantly lower in the EORA group (Table 2).

Conclusion: Age of onset of RA has been increasing with the aging of society. Therefore, it is important to consider the features of EORA and YORA when considering therapy. For the present investigation, we considered the goal of treatment to be acquisition of LDA rather than
remission, and our findings indicate that EORA patients may be better able to achieve that goal with lower MTX dosage and biological product usage as compared to YORA patients. In addition, EORA patients might achieve LDA with a lower amount of drugs.

PATEIENT-PHYSICIAN INTERACTION AS A PREDICTOR OF METHOTREXATE ADHERENCE IN RHEUMATOID ARTHRITIS PATIENTS

Rital Medvedovic1, Svetlana Atgrudic2, Milan Bogojovic1, Natasa Miletic1, Ana Bulatovic1, Dijana Kolic Tepavcevic1, Clinical center of Montenegro, Podgorica, Montenegro; 2Mercur Nera Polyclinic, Podgorica, Montenegro; 3Institute of Public health, Belgrade, Serbia

Background: Recent years have seen numerous encouraging developments in the treatment of patients with rheumatoid arthritis (RA) with significant improvement in disease control. However, methotrexate (MTX) remains a cornerstone therapy and first-line drug for majority of patients with RA, commonly associated with prolonged or even lifelong treatment, which takes the risk for decreasing medication adherence over time. Therefore, prompt recognition of predictive factors for MTX non-adherence is one of the most important challenges related to treatment of patients with RA.

Objectives: The aims of this study were to assess patients’ self-reported adherence to MTX, as well as to investigate predictive role of physician-patient interaction satisfaction for MTX adherence. Namely, it could be hypothesized that patients’ perceptions of multiple specific components of relationship with their physician are associated with patient trust in their physician, which is strongly related to treatment adherence.

Methods: In the period between May 1 and September 15, 2018, 98 consecutive RA patients who were treated in Clinical center of Montenegro and private clinic “Merkur Nera” were enrolled in this multi-centric cross-sectional study. Non-adherence to MTX was defined as >1 dose missed against medical advice. Patients field in the questionnaire consisted of MTX-specific queries, including the questions related to therapy-related communication with their physician. Possible interaction of the investigated confounders and their joint effect on the MTX adherence were analyzed using ordered logistic regression analysis. A multivariate logistic regression analysis was performed including all covariates that appeared to be associated with the endpoint in the univariate models (p<0.1). Odds ratio was used to express the strength of the association between independent predictors and MTX non-adherence as a dependent variable.

Results: Study population was predominantly female (87.8%), and the average age was 56,4±12,1 years. The median duration of RA was 8 years (range 0-34 years), while the median duration of MTX treatment was 6 years (range 0-26 years). The median current dose of MTX which responders received was 15 mg per week. The overall prevalence of non-adherence to MTX was 32.7%. According to the results of univariate regression analysis the following factors are significantly associated with adherence to MTX: younger age (OR=0.942; p=0.005), employment (OR=0.955; p=0.095), working capacity (OR=0.342; p=0.057), marital status (OR=0.342; p<0.001) and expressed need for more communication with the doctor regarding RA treatment (OR=1.303 p=0.044). Namely, married RA patients were 2.46 times less likely to MTX non-adherence compared to others, while the patients who stated the need for more communication with the doctor regarding RA treatment has 1.30 times greater chances to MTX non-adherence.

Conclusion: The results of our study have shown that about one third of RA patients met the criteria for non-adherence to MTX. Identification of the patient’s need for more communication related to RA therapy as independent predictor for MTX non-adherence suggests that physician-patient relationship quality is an important point of intervention for efforts to improve patients’ medication adherence.

THE EFFICACY OF TOFACITINIB TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS WITH HIGH DISEASE ACTIVITY IN REAL-WORLD PRACTICE

Irina Menshikova1, Yulia Pak2, Irina Kolosova2, Moscow Sechenov University, Rheumatology, Moscow, Russian Federation; 2Moscow Sechenov University, Rheumatology, Moscow, Russian Federation

Background: JAK-kinase inhibitors are the promising option for patients with severe rheumatoid arthritis (RA). Evaluation of the effectiveness and results of long-term use of tofacitinib (TOFA) seems relevant for clinical practice.

Objectives: To evaluate the efficacy of TOFA in achievement of remission or low disease activity (LDA) in RA patients after 12 months of treatment and follow-up in real-world practice.

Methods: In this open study 30 patients (22 women and 8 men) with severe RA (average DAS28=5.8) with inadequate response to methotrexate in effective dose were enrolled and started TOFA 5 mg BID. Average age was 57 (29-71), average disease history 6,2 (1,5-12,5) years. Patients evaluated at baseline, after3, 6 and 12 months of treatment: number of painful and swollen joints, ESR, CRP, RF, anti-MCV, DAS28, SDAI. The joints ultrasound (US) with Power Doppler (PD) (German US7 score) helped to estimate synovial inflammation. After 12 months of treatment the patients were under follow-up in real-world practice.

Results: By 3th month of treatment the average mean of ESR and CRP returned to normal range, the number of painful and swollen joints decreased to 2 times, DAS28 - from 5.8 to 3.8, SDAI – from 41,0 to 18,0. 6 patients achieved remission, 3 – LDA, 2 had high activity (DAS28=5,1) and the rest – moderate activity. We achieve the aim of T2T strategy by 12th month: average ESR and CRP normalized, DAS28 – 2,92 (1,39; 6,21) and SDAI – 7,0 (1,57; 36,4), 33% of patients achieved remission according to DAS28 and SDAI. RF decreased by 37%, anti-MCV stayed high during the year. There was temporary increase of AST, ALT in 4 patients (13,3%), but did not require TOFA discontinuation. By 12th month of treatment the PDUS mode number of joints with hypervascularized synovium decreased from 3 (2; 7) to 0 (0; 1), number of bone erosions has not changed. 1 patient (3,3%) had severe herpes zoster infection, no other infections occurred. In 1 patient (3,3%) TOFA showed no efficacy (DAS28=6,21).

22 patients have finished 12-months course of TOFA at the moment and moved to follow-up period. 13 of them (59%) continue the same dose of TOFA: 8 have remission and 5 – LDA, 2 patients continued TOFA 5 mg/day for 1 year, then stopped and are in remission for 8 months. 1 patient had temporary withdrawal of treatment due to surgery without exacerbation of RA. 4 patients have stopped TOFA for non-medical reasons: 1 is still in remission and 1 – LDA for 12 months, 2 had worsening of RA and treated by low doses of glucocorticoids. At the moment 3 patients (13,6%) have long-term remission for 18 months after the end of TOFA treatment.

Conclusion: TOFA is effective and safe treatment option for severe RA in real-world practice. The effect develops by 3 months and continues to grow to 12 months. When remission is achieved, we recommend a reduced dose before withdrawal. Exacerbation of RA is effective solved by retreatment with TOFA.

AB0430 DEVELOP A REPLICABLE MODEL FOR RATIONAL SELECTION OF STRATEGIES IN TREAT-TO-TARGET: REAL WORLD DATA MINING VIA SMART SYSTEM OF DISEASE MANAGEMENT (SSDM)

Rong Mu1, Li Chun1, Jing Yang2, Xiaohan Wang3, Bin Wu4, Fengxiao Zhang5, Yong Wang6, Li Qiao6, Mi Cundong7, Huating Guo8, Wei Wei10, Wei Liu11, Chongqing, China; 6The first Hospital Affiliated to AMU (Southernwest Hospital), Chongqing; 7The No.3 People’s Hospital of Shanghai City; 8Shanghai Hongqiao Hospital, Shanghai, China; 9The Second Hospital of Hebei Medical University, Shijiazhuang, China; 10Tianjin Medical University General Hospital, Tianjin, China; 11First Teaching Hospital of Tianjin University of Traditional Chinese Medicine, Tianjin, China; 12Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China; 13First Affiliated Hospital of China Medical University, Shenyang, China; 14Affiliated Hospital of Inner Mongolia Medical University, Hohhot, China; 15Hubei Hospital of Traditional Chinese Medicine, Wuhan, China; 16Shanghai Gothic Internet Technology Co., Ltd, Shanghai, China

Background: Daily health care in the real world is different from a clinical trial setting, which deals with a wide spectrum of RA patients from statuses of remission to disease activities at mild, moderate and severe based on DAS28. Due to lack of information and knowledge about optimal regimens for both treat-to-target (T2T) and maintain-being-target (MbT), physicians make choices on treatment strategies based on their own experience or intuition.

Objectives: To develop a replicable model for rationalizing the strategies for T2T and MbT using data mining via smart system of disease management (SSDM).

Methods: SSDM is an interactive mobile disease management tool, including two application systems (APPS) for both the doctors and the patients. The patients can input medical records (including medication and laboratory test results) and perform self-evaluation (DAS28, HAQ) via APP. The doctors can get real-time and personalized advices through cloud and advices could be delivered. In previous studies, we demonstrated that patients could master SSDM after training.

Up to January of 2019, totally 106,647 patients with rheumatic diseases using SSDM, among them, 38% are RA patients who receive more than 1,400 different regimens of treatments. Here we select MTX, Hydroxychloroquine (HCQ) and prednisone (GS) based therapies for model development.

Results: Totally 1571 patients were treated with MTX (640), HCQ (397), GS (131), MTX+HCQ (253), MTX+GS (47), HCQ+GS (61), MTX+HCQ+GS (42), respectively. Among the patients whose DAS28<3.2 at baseline, 72% with MTX, 75% with HCQ, 76% with MTX+HCQ and 73% with MTX+HCQ+GS are MbT (DAS28<3.2) after 6 months, which are significantly different comparing with those 52% with GS, 57% with MTX+GS and 57% with HCQ+GS (p<0.01). Among the patients whose DAS28>5.1 at baseline, 81% with GS, 72% with MTX+HCQ and 100% with HCQ+GS achieved T2T (DAS28<3.2) after 6 months, which is significantly different compared to 25% with MTX, 24% with HCQ, 45% with MTX+HCQ and 37% with MTX+HCQ+GS (p<0.01). Among the patients whose DAS28>5.1 at baseline, there is no statistic significant differences for the rates of achieving T2T, which rates ranging from 39% to 50% across all the 7 regiments.

Conclusion: With MTX, HCQ and GS based regimens in RA, the rational selections of strategies for MbT are mono therapy with MTX, HCQ, or MTX+HCQ, strategies for T2T on high disease activity group are GS, GS+MTX or GS+HCQ. In view of 1400 regimens with clinical outcomes being available in SSDM, the model developments can be replicated in rationalizing strategies through data mining.

AB0431 EFFECTS OF LOW-LOAD RESISTANCE EXERCISE OF LOW EXTREMITY WITH RHEUMATOID ARTHRITIS

Sakothi Nakazaki1, Takashi Muryama2, Shinichi Kato3, SSDM Collaboration Group, China; 1Joohoku Hospital, Rheumatology, Kanazawa, Japan; 2Joohoku Hospital, Rheumatology, Kanazawa, Japan; 3Kanariay Clinic, Rheumatology, Kanazawa, Japan

Background: Some skeletal muscles communicate with other organ by secreting proteins and peptides called myokine. Some myokines have anti-inflammatory effect. As regards rheumatoid arthritis (RA), many studies have shown that aerobic and resistance exercise programs do not change the number of inflammatory joints and RA disease activity, whereas other studies showed improved the marker. And almost studies were performed by high-load resistance training protocols. Meanwhile lately Schoenfeld showed that muscle hypertrophy can be equally achieved across a spectrum of load ranges with meta-analysis.

Objectives: To investigate the efficacy of low-load resistance exercise of low extremity protocol on RA.

Methods: Twenty-four patients with RA were enrolled. Inclusion criteria were receipt of a stable dose of biologics, JAK inhibitor, and conventional DMARDs more than 3months prior to the first exercise, and corticosteroid and NSAIDs more than one month prior to the first exercise. The exercise circuits consisted of 6 different low extremity exercises intended to improve arthritis. Within the exercise circuits, each exercise were repeated 8-12 times and less than 50% of the 1-repetition maximum. The exercise circuits were performed 3 times a week. Disease activity parameters and infused joint of upper extremity and lower extremity were collected at base line and 2 months after exercise started. The Wilcoxon signed-rank test was used to examine the difference between the parameter of the base line and the 2 months.

Results: All patients were female. Mean age was 68.7 years., and mean disease duration 15.3 years. Seven patients (29%) used methotrexate, 5 patients (21%) used prednisolone and 13 patients (54%) used biologics. Mean ESR was 3.98 at base line and 3.58 at 2 months, mean DAS28(CRP) 3.46 and 3.06, mean SDAI 15.4 and 12.5, and mean CDAI 4.5 and 3.7. Mean DAS28(ESR) was 3.98 at base line and 3.58 at 2 months, mean DAS28(CRP) 3.46 and 3.06, mean SDAI 15.4 and 12.5, and mean CDAI 4.5 and 3.7, mean upper extremity joint tenderness 4.0 and 2.2, mean lower extremity joint tenderness 4.0 and 2.2, mean lower extremity joint swelling 1.6 and 1.8, mean lower extremity joint swelling 4.0 and 2.0 respectively. Every index except upper extremity joint swelling improved significantly (p<0.05) at 2 months than baseline.

Conclusion: Low intensity exercise of low extremity was efficacious against not only lower extremity arthritis but also upper extremity joint arthritis in patients with rheumatoid arthritis.

AB0432 BURDEN OF ILLNESS AND CURRENT UNMET NEEDS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH CONVENTIONAL AND ADVANCED DISEASE-MODIFYING THERAPIES: A TARGETED LITERATURE REVIEW

Andrew Ostor1, Ruta Sawant2, Alisha Gadhia3, Ruth Zeidman3, Vishvas Garg2, Matthew Wallace1, 1Cabrini Medical Centre, Monash University, Melbourne, Australia; 2AbbVie Inc., North Chicago, United States of America; 3Covance Market Access and Phase IV Solutions, London, United Kingdom

Background: The development of advanced therapies for the treatment of moderate to severe rheumatoid arthritis (RA) has changed the paradigm of management goals for the condition. However, even with currently available therapies, many patients fail to achieve adequate improvement or disease remission, and thus residual unmet needs exist.

Objectives: To examine the burden of RA with respect to the clinical, humanistic, and economic outcomes associated with RA patients treated with conventional and advanced disease-modifying therapies.

Methods: A targeted review of the literature published between January 2013 and September 2016 was conducted. EMBASE and MEDLINE databases were searched using terms related to the clinical, humanistic, and economic outcomes associated with conventional and advanced disease-modifying therapies currently available for moderate to severe RA. The search was limited to English-language articles, which reported data from France, Germany, Italy, Spain, United Kingdom, Sweden, Israel, Canada, Brazil, Japan, and Australia. This returned 1,833 records which were assessed for relevance in terms of study methodology, patient population, and outcomes.

Results: A total of 48 articles were included in the qualitative synthesis. Across these studies, disease activity score (DAS) remission rates (DAS28 ≤2.6) ranged from 14.7% to 26.4% over 6–12 months and 10.2% to 53.4% over 3–20 months for patients treated with conventional synthetic disease-modifying antirheumatic drug (csDMARD) monotherapies and biologic monotherapies, respectively. Figure 1 presents country-specific DAS28 remission rates for some of the included regions. Clinical disease activity index (CDAI) remission rates (CDAI ≤2.8) were reported to be ≤50% among patients who received biologics for a period of up to 12 months. The unemployment rate due to RA was as high as 58.3%, and employed patients lost 1.7 to 16.0 workdays per month at baseline. Following treatment with biologic therapies (over 24–104 weeks), employed patients lost 0.5 to 8.0 working days per month. Costs of treatment with advanced therapies were routinely investigated, but limited data were available regarding the economic burden associated with outcomes such as disability, depression, lack of sleep, and anxiety among RA patients treated with advanced therapies.

Conclusion: Despite advanced treatments, a significant proportion of the RA patient population do not achieve disease remission, and face the substantial burden of reduced productivity and lost work days.

Acknowledgement: The design, study conduct, and financial support for the study were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of this publication.

AB0433 TREATMENT PATTERNS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS WHO RECEIVE METHOTREXATE: TARGETED LITERATURE REVIEW

Andrew Ostor1, Matthew Wallace2, Ruth Zeidman3, Vishvas Garg2, Ruta Sawant3, 1Cabrini Medical Centre, Monash University, Melbourne, Australia; 3Covance Market Access and Phase IV Solutions, London, United Kingdom; 2AbbVie Inc., North Chicago, United States of America

Background: Methotrexate (MTX) monotherapy or in combination with other disease modifying agents is a common first-line treatment option for patients with rheumatoid arthritis (RA). However, treatment patterns and associated patients’ perceptions and preferences of MTX therapy may not be fully understood.

Objectives: To assess treatment patterns of MTX therapy in RA by evaluating real-world adherence and persistence, patients’ preferences and reasons for discontinuation, as well as the economic burden of therapy.

Methods: A targeted review of the literature published between January 2010 and March 2018 was conducted by searching the MEDLINE and EMBASE databases. Searches were limited to English-language articles and included original research and reviews. All articles were assessed for relevance, in terms of study methodology, patient population and outcomes by a single reviewer.

Results: The search resulted in 444 hits of which 29 articles were included in the qualitative synthesis. Data pertaining to adherence and patient-reported reasons for non-adherence were extracted from 11 publications. MTX therapy non-adherence was high, with up to 42% of patients reporting not taking MTX as prescribed. Among these patients, many reported taking smaller doses than prescribed (53%) or intentionally skipping doses (52%). Common patient-reported reasons for non-adherence included upcoming surgery, and experience of, or concerns regarding adverse events (AEs). Data pertaining to therapy discontinuation were extracted from 21 publications. Across the studies sampled, rates of discontinuation at one year were 24–50%. MTX toxicity was responsible for 5–34% of all discontinuations. Among patients who switched from orally to parenterally administered MTX, 29% discontinued due to gastrointestinal AEs within one year. Patient-reported reasons for therapy discontinuation, other than experiencing AEs, included concerns regarding MTX AEs, drug price and lack of perceived need. No studies examining the costs associated with MTX monotherapy monitoring and AE management were identified in the search.

Conclusion: Findings from the review indicated that MTX therapy is associated with substantial non-adherence and discontinuation, thus adding to patient burden. Patient-reported reasons for non-adherence/poor treatment persistence were varied but most commonly included experience of, or concerns regarding AEs.

AB0434 EARLY EXPERIENCE WITH JAK INHIBITOR PREScribing IN THE UK: RESULTS FROM THE BRITISH SOCIETY FOR RHEUMATOLOGY BIOLOGICs REGISTER FOR RHEUMATOID ARTHRITIS (BSRBR-RA)

Jennifer Page1, Lianne Kearsley-Fleet1, Rebecca Davies1, Kath Watson1, Kimme Hyrich2, Mark Lunt1, The University of Manchester, Arthritis Research UK Centre for Epidemiology, Manchester, United Kingdom; 2NIHR Manchester BRC, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: In 2017 a new class of oral disease modifying anti-rheumatic drugs (DMARDs), Janus kinase inhibitors (JAKi), were licensed for rheumatoid arthritis (RA): baricitinib and tofacitinib. In the UK, they are approved for use in patients with high disease activity with or without methotrexate, following failure of conventional synthetic (cs) DMARDs or biologic DMARDs, the latter when rituximab is contraindicated. As a new therapy option, it is currently unclear how and when these drugs are being prescribed in patients with RA.

Objectives: This analysis aims to describe the characteristics of patients starting JAKi and registered with the BSRBR-RA.

Methods: The BSRBR-RA aims to capture exposure and outcome data in patients with RA receiving biologics, biosimilars and targeted synthetic DMARDs. At the start of therapy, demographic and clinical data, including past treatment data, are collected. Characteristics of all patients receiving a JAKi for the first time with data recorded in the BSRBR-RA up to 30/11/2018 are described.

Results: To 30/11/2018, 443 patients in the BSRBR-RA have been treated with a JAKi; 374 patients baricitinib and 69 tofacitinib (Table). Twenty-eight percent of baricitinib and 13% of tofacitinib patients received a JAKi following csDMARDs, with no prior biologic exposure. Of these, 15% had a prior malignancy history. Of those with prior exposure, the median number of previous biologics was 3 (IQR 2-4) and 52% had received rituximab. Forty-three percent were receiving concurrent methotrexate.

Conclusion: To date, more patients have been recruited starting baricitinib than tofacitinib, likely owing to the later licensing of tofacitinib. Two groups are emerging with a quarter of patients receiving JAKi immediately after csDMARDs and a majority as a later stage alternative following multiple biologics. Further recruitment and follow-up patients will allow for analysis of real-world safety and effectiveness, but differences in patient characteristics will need to be considered in any comparative effectiveness analyses.

| Characteristics of the first 443 patients in the BSRBR-RA treated with JAKi |
|---------------------------------------------------|-----------------|------------------|-----------------|
| Ever exposed [N = 443] | No biologic exposure [N = 112] | Previous biologic exposure [N = 331] |
| Baricitinib | 374 (84%) | 103 (28%) | 271 (72%) |
| Tofacitinib | 69 (16%) | 9 (13%) | 60 (17%) |
| Age (years) | 61 (53 to 69) | 61 (51 to 71) | 61 (53 to 69) |
| Female | 323 (75%) | 81 (72%) | 254 (77%) |
| Disease duration (years) | 12 (6 to 21) | 6 (3 to 15) | 14 (8 to 22) |
| Number of previous biologics | 112 (25%) | 112 (100%) | 0 (6%) |
| No prior biologics | 63 (14%) | 63 (19%) | |
| ≥2 prior biologics | 211 (48%) | 211 (64%) | |
| Unknown | 57 (13%) | 57 (17%) | |
| Type of previous biologic exposure | - | - | |
| TNF inhibitor | - | - | 248 (91%) |
| Rituximab | - | - | 143 (53%) |
| Abatacept | - | - | 95 (35%) |
| Tocilizumab | - | - | 139 (51%) |
| Concurrent Methotrexate | 185 (43%) | 51 (44%) | 134 (42%) |
| Concurrent oral steroids | 133 (31%) | 22 (21%) | 111 (34%) |
| DMARDs* | | | |
| None | 170 (38%) | 58 (52%) | 112 (34%) |
| 1 comorbidity | 125 (28%) | 25 (22%) | 100 (30%) |
| 2+ comorbidities | 148 (34%) | 29 (26%) | 119 (36%) |
| Prior Cancer | 38 (9%) | 15 (15%) | 23 (7%) |
| Pulmonary Fibrosis | 11 (4%) | 3 (3%) | 8 (4%) |

With regards to the previous treatments received, we obtained the following results:

- **Previous DMARDs**:
  - 3TB: 2TB 1TB Naive 5 3 10 12 10 2 3 1 2 Naive 9 15 2 2

- **Previous DMARDs**:
  - 3TB: 2TB 1TB Naive 5 3 10 12 10 2 3 1 2 Naive 9 15 2 2

With regards to efficacy, there were collected 6 treatment withdrawals: 1 primary treatment failure (in Tofacitinib Group) and 5 secondary treatment failures (1 in Baricitinib Group and 4 in Tofacitinib Group) and the mean treatment duration was 152 days.

**Conclusion**: Despite the study population was small and the follow-up time was short, we highlight in our patients that both JAK inhibitor alternatives have shown a security and efficacy profile similar to the results shown in pivotal clinical trials. Despite the previous biological treatment failure and obesity are considered as predictors of bad response to treatment, in our cohort did not represent a high risk to treatment failure, it can be an alternative in the same scenario.

**Disclosure of Interests**: Isabel de la Morena Speakers bureau: Abbvie, Celgene, Pfizer, UCB, Ghebro, Roche, Sanofi, Janssen., Juan Alberto Paz Solarte Employee of: He is working at UCB since December 2018, when the patient recruitment ended., Speakers bureau: Abbvie, Roche, Pfizer, Novartis, Celgene, Amgen, MSD, Janssen, Diego Bedoya: None declared, Pilar Trener Larraz: None declared

AB043S REAL WORLD DATA OF A PATIENT COHORT WITH RHEUMATOID ARTHRITIS TREATED WITH JAK/STAT INHIBITORS

Isabel de la Morena, Juan Alberto Paz Solarte, Diego Bedoya, Pilar Trener Larraz. Hospital Clínico Universitario de Valencia, Valencia, Spain

Background: We present the real World data of a patient cohort with rheumatoid arthritis (RA) that received one of the two JAK/STAT inhibitors approved by the EMA for this indication.

Objectives: To describe the Real World Data of a patient cohort attending Rheumatology consult of a reference hospital in Valencia with RA diagnosis and that were treated with JAK/STAT inhibitors.

Methods: A descriptive retrospective study was carried out. There were revised medical histories of 28 patients with a RA diagnosis that attended our consults between 2017 and 2018. All 28 patients were JAK/STAT treatment receivers of one of the two JAK/STAT inhibitors approved: Tofacitinib 10 mg oral QD or Baricitinib 4 mg oral QD. There were collected patient baseline demographic data: sex, age, BMI, activity disease score measured by DAS28-CRP and visual pain analogue scale for patient’s assessment (VAS). In addition, there were collected the previous synthetic(s) and biological(s) DMARD treatments, as well as the associated treatments. Efficacy and security were also analysed. There were assessed serum biochemical variables, among them acute phase reactants such as CRP and ESR

Results:

- **The study population consisted in 28 patients with the following distribution**:
  - M/F: Mean age (years) BMI (kg/m²): Baricitinib Tofacitinib DAS28/CRP (at de beginning) Mean treatment time (days)
  - 12 (42%) 58.39 30.12 9 19 4.81 230.11
  - 16 (58%) 50.73 30.31 14 28 5.21 250.32

DMARDs: Number of previous biological treatment

With regards to efficacy, there were collected 6 treatment withdrawals: 1 primary treatment failure (in Tofacitinib Group) and 5 secondary treatment failures (1 in Baricitinib Group and 4 in Tofacitinib Group) and the mean treatment duration was 152 days.

**Conclusion**: Despite the study population was small and the follow-up time was short, we highlight in our patients that both JAK inhibitor alternatives have shown a security and efficacy profile similar to the results shown in pivotal clinical trials. Despite the previous biological treatment failure and obesity are considered as predictors of bad response to treatment, in our cohort did not represent a high risk to treatment failure, it can be an alternative in the same scenario.

**Disclosure of Interests**: Isabel de la Morena Grant/research support from: Grants to institution: BMS, Pfizer, UCB, Mark Lunt: None declared

ADHERENCE TO DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN RHEUMATIC DISEASES

Rita Angelica Pineda Sic, Iván de Jesús Hernández-Galazará, Mariela Castro-González, Dioricio Ángel Galaizar-Delgado, Miguel Ángel Villalreal-Alarcóñ, Rodolfo Allan Uriarte Botelo, Octavio Ilizaliturri Guerra, Universidad Autónoma de Nuevo León, Nuevo León, Mexico; 2Universidad Autónoma de Nuevo León, Nuevo León, Mexico

Background: There has been seen a low adherence to treatment in patients with rheumatic diseases, which can have important consequences in disease prognosis. Although literature in Latin-American population is scarce, a previous study evaluating medication adherence in this population reported a 16.4% prevalence of adherence in Rheumatoid Arthritis (RA) and 45.9% in Systemic Lupus Erythematosus (SLE) patients (1). It has been demonstrated better outcomes in patients with rheumatic conditions who have good adherence to treatment therapies (2).

Objectives: To describe the adherence to synthetic Disease-Modifying Anti-Rheumatic Drugs (DMARDs) in patients with rheumatic diseases from a Mexican outpatient rheumatology clinic.

Methods: This study was conducted in the outpatient rheumatology clinic of University Hospital in Monterrey, Mexico, cross-sectional, descriptive, self-report adherence study. Consecutive patients with RA, SLE, Inflammatory Myopathies, Psoriatic arthritis (PsA), Systemic Sclerosis (SSc) were approached during their normal routine rheumatology appointments, in the March 2018 to December 2018 period. They were asked how many days of the last month they forgot or took their DMARDs. We classified the adherence rate in 4 categories based on the days of the last month it took the indicated medication; good: 75%-100% (> 21 days), regular 50-74% (21-15 days), bad 25-49% (14-8 days) and null: <25% (< 7 days).

When adherence was not good we interrogated about the cause. Data was obtained from REPAIR® (internal electronic patient record) and analyzed with the statistical package SPSS version 24.

Results: We included 31 patients with rheumatoid arthritis with a mean age of 57.58 ± 11.31 years and mean time of evolution of the disease of 9.42 ± 6.62 years, 61.3% female sex, 36.5% positive RF and 61.3% ACPA positive. The female sex represents 74.2% of the sample. The mean of the baseline DAS28 was 4.90 ± 0.95. Regarding the treatment analysis initiated 12 patients (38.7%) receive baricitinib and 19 (61.3%) tofacitinib. 93.5% were in treatment with steroids and/or DMARDs and 80.64% in treatment combined with at least 1 associated DMARD (75% baricitinib group, 84.2% tofacitib group). The subanalysis of concomitant treatment reveals that up to 31.5% of patients undergoing treatment with tofacitinib initiated treatment with ≥2 FAMEs. 61.3% of patients had previously received at least one biological drug, among which the antITNFs stand out for their frequency; 31.5% with one biological, 9.7% with 2 previous biologicals and 16.5% had used three. A total of 14 adverse effects were recorded in 10 of the 31 patients which are described below: baricitinib group a total of 6 events (50%); 1 toxic hepatitis, 1 respiratory infection, 2 cases of urinary tract infection, 1 case of canker sores, and 1 cold sore. Tofacitinib group a total of 8 events (42.1%); 2 cases of Herpes zoster, 1 case of headache and dizziness, 2 perianal abscesses and 1 access submandibular. There were 3 hospital admissions with independence of its relationship with the treatment analyzed; baricitinib group: 1 patient with upper respiratory tract infection and decompensated heart failure, 1 patient with toxic hepatitis. Tofacitinib group: 1 patient with post-traumatic humerus fracture.

Conclusion: Adherence in this group of patients was good, for the definition used in our study. The method used (self-report) is very sensitive to detect non-adherence, but it overestimate good adherence, therefore the potential bias of results must be considered and confirmed with objective measurement.

SAFETY OF JAK INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CONDITIONS OF DAILY CLINICAL PRACTICE

Natalia Cid Boza, ML Veloso Felipo, PLAZA NAHIA. Jose Luis Marenco. Hospital Universitario Virgen de Valme, Rheumatology, Seville, Spain

Background: Efficacy and safety of the new JAK inhibitors is supported by phase I, II and III studies with a large number of patients included in the follow-up, although it is of vital importance behavior of new molecules in routine clinical practice, and until now we still have few clinical data.

Objectives: To describe the adverse effects observed, as well as the economic Hospitals and description of them during treatment with JAK inhibitors in a series of patients with RA.

Methods: This is a retrospective descriptive study in patients with RA treated with JAK inhibitors in follow-up by the Rheumatology Unit of Virgen de Valme Hospital. We included demographic, related to the disease and treatment and security variables.

Results: We included 31 patients with rheumatoid arthritis with a mean age of 57.58 ± 11.31 years and mean time of evolution of the disease of 9.42 ± 6.62 years, 61.3% female sex, 36.5% positive RF and 61.3% ACPA positive. The female sex represents 74.2% of the sample. The mean of the baseline DAS28 was 4.90 ± 0.95. Regarding the treatment analysis initiated 12 patients (38.7%) receive baricitinib and 19 (61.3%) tofacitinib. 93.5% were in treatment with steroids and/or DMARDs and 80.64% in treatment combined with at least 1 associated DMARD (75% baricitinib group, 84.2% tofacitib group). The subanalysis of concomitant treatment reveals that up to 31.5% of patients undergoing treatment with tofacitinib initiated treatment with ≥2 FAMEs. 61.3% of patients had previously received at least one biological drug, among which the antITNFs stand out for their frequency; 31.5% with one biological, 9.7% with 2 previous biologicals and 16.5% had used three. A total of 14 adverse effects were recorded in 10 of the 31 patients which are described below: baricitinib group a total of 6 events (50%); 1 toxic hepatitis, 1 respiratory infection, 2 cases of urinary tract infection, 1 case of canker sores, and 1 cold sore. Tofacitinib group a total of 8 events (42.1%); 2 cases of Herpes zoster, 1 case of headache and dizziness, 2 perianal abscesses and 1 access submandibular. There were 3 hospital admissions with independence of its relationship with the treatment analyzed; baricitinib group: 1 patient with upper respiratory tract infection and decompensated heart failure, 1 patient with toxic hepatitis. Tofacitinib group: 1 patient with post-traumatic humerus fracture.

Conclusion: The main side effect observed was infection, in general mild-moderate that only motivated hospital admission in a patient in treatment with baricitinib due to decomposition of its pathology base. Stresses the development of uncomplicated perianal abscess in 2 patients on treatment with tofacitinib, one of them with perianal fistula known, and a recurrence of submental abscess in a patient with antecedent of repitition abscesses in said location. I only know observed elevated transaminases in a patient undergoing treatment with baricitinib showing in general an optimal hepatic safety profile. No primary cardiovascular events of interest have been recorded, neoplasms or other gastrointestinal events. Everything described, considering the high rate of concomitant treatment with steroids at low doses (93.5%) and up to 80.64% of patients in treatment with at least 1 concomitant DMARD.

AB0438 A STUDY COMPARING EFFICACY OF INTRA-ARTICULAR STEROID (IAS) VS INTRAARTICULAR SCLEROSANT IN PATIENTS WITH PERSISTENT SYNOVITIS OF KNEE IN RHEUMATOID ARTHRITIS

ramesh ramanamurthy, Mythili Seethas, Balameena Kumar, Aravind Mani. MADRAS MEDICAL COLLEGE and HOSPITAL, RHEUMATOLOGY, CHENNAI, India

Background: Chronic persistent synovitis is commonly seen in inflammmatory arthritis like RA where despite adequate DMARD therapy, few joints are chronically inflamed. They are the reason for increasing morbidity and poor functional status in these patients. Some patients show persistent synovitis despite intra-articular steroids and hence they need to identify other drugs like sclerosant which can be of use in improving pain and functional status.

Objectives: To compare the efficacy of Intra-articular steroid versus sclerosant in rheumatoid arthritis (RA) with persistent synovitis despite optimum dose of csDMARDs and to determine, if sclerosant is superior/inferior to steroids.

Methods: This is a single blinded-observational pilot study, conducted in Institute of Rheumatology, Madras Medical College for a period of 1 year. 20 patients with persistent synovitis knees) despite optimum DMARD therapy are recruited as per inclusion and exclusion criteria. Disease and joint related activity and functional status are documented. Ethical committee approved the study. After getting written informed consent patients were randomized into two groups (A and B). Group A received IAS (Triamcinolone Acetonide) and group B received sclerosant (1% Polidocanol). They are assessed at 1, 4, 12 and 24 week and various parameters documented. The results are analysed with SPSS v22 software.

Results: 40 patients were recruited for the study, with 20 in each group. 45% patients in group A and 65% patients in group B, showed significant improvement in DAS28, CRP, VAS pain and function. VAS scores improved within 1 week and no adverse effects were noted. Both the interventions found to be effective in reducing the pre operative VAS pain and function scores. However, Mean VAS Scores after 1 week of sclerosant injection found to be lesser than that of steroid group and the difference was statistically significant (p<0.05).

Conclusion: Intra-articular sclerosant (1%Polidocanol) is non-inferior to steroids in patients with persistent knee synovitis. It could be used as an effective alternative to steroids considering their side effect profile.

AB0439 YTTRIUM-90 SYNOVIORTHESIS. OUR EXPERIENCE FOR 25 YEARS

Patricia Lavilla1, M. Requejo-Guerrero1, Sheila Melchor1, Álvaro García Martos2, Diana Vega1, Pilar Alonso2, Pilar F. Dapica1. 1Hospital universitario 12 de octubre, Rheumatology, Madrid, Spain; 2Hospital universitario del Tajo, Rheumatology, Madrid, Spain; 3Hospital universitario 12 de octubre, Radiology, Madrid, Spain

Background: Radioactive synoviorthesis (RS) is the intra-articular injection of a colloidal suspension of particles marked with a radioisotope that selectively irradiates the synovial membrane, respecting bone and cartilage. The radiocolloid is phagocytosed by type 2 synovocytes of the synovial membrane, causing fibrosis and decreased production of synovial fluid. Intra-articular puncture is ensured by obtaining synovial fluid and the radiopharmaceutical is instilled by 1ml of triamcinolone acetonide (40mg). After the procedure a graphic gamma image is made to assess the adequate distribution of the radionuclide in the joint cavity. With a half-life of 2.5 days, the drug will continue to emit radiation for weeks, with symptomatic improvement which is observed from the second week. The main indication of this technique is refractory chronic synovitis to local and/or systemic treatment.

Objectives: To describe the clinical-demographic characteristics of patients treated with SI in our hospital, and to assess the efficacy and safety of this technique.

Methods: Retrospective observational study that analyze the radiosynoviorthesis practiced in the Nuclear Medicine service of the Doce de Octubre Hospital between January 1994 and December 2018 is analyzed. A total of 113 techniques were analyzed in 89 patients from our center and other hospitals without Nuclear Medicine service, and data of 72 patients could be obtained from their clinical history. The efficacy of the technique was defined as total or partial, considering objective data (swelling and joint function) and subjective data (patient evaluation).

Results: 95 articular instillations were included in 72 patients, 46% women and 54% men; with an average age of 51.4 ± 15 [21-82] years, the knee articulations were injected with Yttrium-90 (5 millicuries). The patients had knee effusions lasting for an average of 18 months (IR 10- 60). The temporal distribution was very heterogeneous, decreasing over the years (1994-1998: 23%, 1999-2003: 32%, 2004-2006: 20%, 2009- 2013: 16%, 2014-2018: 9%). 93% of RS were indicated by the rheumatologist service and 7% by traumatology. In the classification by pathologies, 72.2% had systemic rheumatological disease. The most frequent causes of indication were rheumatoid arthritis (25%), psoriatic arthropathy (24%), spondyloarthropathy (17%) and pigmented villonodular synovitis (11%). Less frequent were juvenile idiopathic arthritis (5%), arthrosis (4%), microcrystalline arthritis (5%) and non-specific chronic synovitis (9%). 73% had been previously infiltrated with steroid, with an average of 2.8 ± 1.8 [1-10] injections/knee. The 79% had maintained treatment with NSAID, the 42% with systemic steroid, the 55% with DMARDs and the 14% with biological therapy; appearing the therapeutic effect in the first 8 weeks in the 42% with systemic steroid, the 55% with DMARDs and the 14% with biological therapy; appearing the therapeutic effect in the first 8 weeks in the 80% of the patients. 13 patients needed a reinjection with an average between radiosynoviorthesis of 25 ± 21 [6-80] months. Side effects were scarce (2.6%) and local in nature; 8.3% required a knee prosthesis.

Conclusion: RS has demonstrated acceptable efficacy and safety in cases of refractory synovitis of both mechanical and inflammatory etiology. Despite this, it is a procedure little used nowadays.

AB0440 CHANGES IN KEY LABORATORY VALUES WITH TOFACITINIB 5 MG BID TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS AND RHEUMATOID ARTHRITIS

William Ribi1,2, Gerd Rüddiger Burmester1,3, Oliver Fitzgerald2, Valeridio F. Azvedo2, Peter Nash5, Daniela Graham6, Cunshan Wang6, Thomas Jones2,1. 1Geisel School of Medicine at Dartmouth, Lebanon, NH, United States of America; 2Biomolecular Research, University College Dublin, Dublin, Ireland; 3Department of Rheumatology, St Vincent’s University Hospital, and Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland; 4Universidade Federal do Paraná, Curitiba, Brazil; 5University of Queensland, Brisbane, Australia; 6Pfizer Inc, Groton, CT, United States of America; 7Pfizer Inc, Collegeville, PA, United States of America

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA) and rheumatoid arthritis (RA). In most countries where tofacitinib is approved, 5 mg twice daily (BID) is the recommended dose for PsA and RA. An important component of any product labelling is information on the need for laboratory monitoring.

Disclosure of Interests: None declared

Objectives: This post hoc analysis aimed to provide information on the effect of tofacitinib 5 mg BID on laboratory values in PsA and RA patients (pts).

Methods: For analysis of pts with active PsA treated with tofacitinib 5 mg BID, data were pooled from 2 Phase 3 studies and an ongoing long-term extension (LTE) study (data cut-off, 25 January 2017; database not locked; data may change). For analysis of pts with moderate or severe RA treated with tofacitinib 5 mg BID, data were pooled from 8 Phase 2, 2 Phase 3, and 1 LTE studies (data cut-off, 2 March 2017; for LTE, database not locked; data may change). All PsA and most RA pts received a background conventional synthetic disease-modifying antirheumatic drug. Data (to Month 12) for pts receiving constant tofacitinib 5 mg BID were evaluated, comprising pts who received tofacitinib 5 mg BID across studies, either at randomisation or following switch from placebo. Pts in the placebo groups who switched to tofacitinib 5 mg BID at Month 3 were included from the time they first received tofacitinib. Pts who switched tofacitinib dose were excluded. Change from baseline in haematologic (haemoglobin, neutrophils, lymphocytes) and lipid (low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, total cholesterol, triglyceride) levels and key liver tests (bilirubin, alanine aminotransferase, aspartate aminotransferase) were analysed. Although not addressed in the product labelling, creatine kinase, creatinine and C-reactive protein levels were also assessed. Pts meeting protocol-defined discontinuation criteria for laboratory values were evaluated.

Results: The constant tofacitinib 5 mg BID group comprised 348 PsA pts and 3040 RA pts. Mean (standard error) changes/percentage changes from baseline for laboratory values are presented in the table. Laboratory values generally stabilised after 1 to 3 months, and lymphocyte levels from baseline for laboratory values were evaluated. Pts meeting protocol-defined discontinuation criteria for laboratory values were evaluated.

Conclusion: In this post hoc analysis of laboratory data with tofacitinib 5 mg BID, changes in key laboratory values were similar for PsA and RA, and discontinuations due to protocol criteria being met for laboratory values were infrequent. These results provide further information on the effect of tofacitinib on laboratory values in PsA and RA.

AB0441 THERAPY WITH TOFACITINIB IN A COLOMBIAN POPULATION WITH RHEUMATOID ARTHRITIS: RESULTS OF THE DAILY CLINICAL PRACTICE

Wilmer Gerardo Rojas Zuleta1, Oscar Jair Felipe Diaz1, Claudia Lucia Giraldo Herrera1, Adelis Enrique Pantoja Marquez2, Natalia Duque Zapata3, Monica Vasquez Jaramillo1, Catalina Orozco Gonzalez2, Jorge Hernando Donado Gomez2,3 Medicarte, Antioquia, Medellin, Colombia; 2,3 Valle del Cauca, Cali, Colombia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that affects the quality of life and reduces life expectancy. It is characterized by the presence of autoantibodies and erosive synovitis that mainly involves small joints (1). Tofacitinib is the first oral Janus Kinase (JAK) inhibitor approved in 2012 for the treatment of patients with active, moderate to severe RA that does not respond to other therapies (2).

Objectives: The objective was to describe demographic and clinical results of a cohort of Colombian patients with RA treated with tofacitinib.

Methods: Descriptive observational study of a historical cohort of RA patients in a specialized center for the management of inflammatory arthropathies, from April 2014 to February 2018. The following variables are described: age, sex, time evolution of the disease, type of AR, comorbidities, disease activity (DAS-28), schedule and treatment time. For the descriptive analysis, categorical variables are presented as absolute and relative frequencies; while continuous variables are presented as mean and standard deviation (SD) or median and interquartile range (IQR) according to distribution. The outcome of DAS 28 ≤ 3.2 was estimated by incidence rate, defined as the number of patients who presented the outcome divided by the sum of total exposure time of the patients.

Results: Of 59 patients included, 88.1% (52) were women, with a median age of 58.8 years (IQR 49-68 years), 74.6% were seropositive, the median time from diagnosis was 18.2 years (IQR 12-28.3 years). High blood pressure was the most common comorbidity (40.7%) and 7% had tuberculosis history. The median number of bDMARD prior to tofacitinib was 2 (IQR 1-3). Sixty six percent patients (39) were on monotherapy while 34% (20) were on combination with leflunomide (19) and methotrexate (1). The median time of treatment was 1.2 years (IQR 0.6-2 years). At the beginning, 84.7% patients (50) were in moderate or high disease activity and 15.3% (9) in remission or low activity; at the end of follow-up, 47.5% (28) were in remission or low activity and 52.5% (31) in moderate or high activity (p = 0.00). The mean DAS28 at the beginning of tofacitinib was 4.6 ± 1.55 and at the end of the follow-up was 3.5 ± 1.49, with a difference of means of 1.10 (95% CI 0.62-1.57, p = 0.00). During the follow-up period, the rate of development of remission or low activity was 11.92 (95% CI 8.35-16.51) cases per 100 people-month observed (p = 0.00). Only 2 patients developed therapeutic failure.

Conclusion: Tofacitinib shows a good profile of effectiveness in patients with failure to prior bDMARD. Almost 50% patient reaches low disease activity or remission during follow up and low number of therapeutic failure was found.

RESPONSE TO BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH FAILURE TO CONVENTIONAL SYNTHETIC DMARD AND/OR BIOLOGICAL DMARD: DATA FROM A LOCAL REGISTRY

Jose Rosas,1 José Miguel Senabre-Gallo,1 Gregorio Santos Soldera,1 José Antonio Bernal-Vidal,2 Esteban Salas-Heredia,1 Ana Pons,1 Catalina Caro1, Estibaliz Ivars1, José Alberto García-Gómez2, Xavier Barber,2 AIRE-MB.1 Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; 2Hospital General Universitario, Infectious Diseases, Elche, Spain; 3Instituto de Investigación Sanitaria, Statistics, Elche, Spain

Objectives: To know the characteristics of patients with rheumatoid arthritis (RA), in treatment with baricitinib (BARI), who have failed to conventional synthetic DMARD (DMARDcs) and/or biological DMARD (DMARD). Methods: Prospective observational study, in real life, of patients with RA, under treatment with BARI. General data of the patients, (age, gender, comorbidity), RA and treatment were collected (time of evolution, presence of RF and ACPA, efficacy indexes at the beginning of BARI and the last visit: DAS28-ESR and CDAI, previous or concomitant treatment with DMARDcs and/or DMARDbs, end of treatment and cause, time in BARI, serious adverse effects during treatment with BARI.

Results: Of 520 patients in follow-up, who have received at least one dose of DMARDs, 224 (42%) are diagnosed with RA, and 56 (26%) of them receive some drug inhibitor of the JAK pathway. Of the 224 (42%) patients, such as F1 versus F2-F5, presented significantly higher BMI (30.83 ± 2.6 vs. 26.95 ± 4.4, p < 0.01), higher percentage of ACPA (30% in F3, F4, F5, of 7, 5.2, 7.7, 6.9 and 11.1 months, respectively. 94% of patients continued concomitant treatment with some DMARDs. BARI is the first drug after failure of DMARDcs (F1) in 24/40 (60%) patients, and in 16/40 (40%), after failure to some DMARDs: second drug after failure to DMARDs (F2) in 2 (6%), third (F3) in 5 (13%) patients, fourth (F4) in 6 patients (17%) and fifth (F5) in 3 (9%) patients. The mean global time in BARI is 9.6 ± 3.2 months, being for F1, F2, F3, F4, F5, of 7, 5.2, 7.7, 6.9 and 11.1 months, respectively. BARI patients, such as F1 versus F2-F5, presented significantly higher BMI (30.83 ± 2.6 vs. 26.95 ± 4.4, p < 0.01), higher percentage of ACPA (100% vs. 74%, p = 0.026), and lower mean time of evolution of RA (5.3 years, range: 0-17.25 vs. 14.75 years, range: 2-36 years, p < 0.001). In patients F2-F5, patients had failed to some DMARDs before initiating BARI, in F2 to 1 therapeutic target, in F3 to 2 targets and in F4 and F5 to 2 or 3 targets. Regarding safety, 1 patient presented herpes zoster. The results of clinical efficacy with DAS28-ESR and baseline CDAI and in the last evaluation are shown in the table.

Conclusion: 1. Baricitinib is effective and safe in real clinical practice.
2. It is competent of achieving clinical remission or low activity, in a high percentage of patients, even in those who have failed several biological drugs or several therapeutic targets previously.

GAYET WERNICKE’S ENCEPHALOPATHY SECONDARY TO METHOTREXATE INTOLERANCE: A SERIOUS COMPLICATION OF CHRONIC VOMITING

Houds Sahraoui, Imane El Bouchti, Mohamed VI University Hospital Center, Marrakech, Morocco, rheumatology, Marrakech, Morocco

Background: Gayet-Wernicke’s encephalopathy is a serious complication of thiamine deficiency. Chronic alcoholism is recognized as the most common cause of Gayet-Wernicke’s encephalopathy, but other causes including malnutrition, chronic vomiting, prolonged fasting, and exclusive artificial feeding have been documented.

Objectives: We report a case of Gayet-Wernicke’s encephalopathy complicating uncontrollable vomiting secondary to severe Methotrexate intolerance.

Methods: Case report

Results: A 47-year-old women with rheumatoid arthritis. She was put under methotrexate at the dose of 15 mg/week, 1 month prior to admission into our department for the management of an acute febrile polyarthritis associated to severe and uncontrollable gastrointestinal intolerance to Methotrexate. There was no abdominal pain or transit problem. One month later, she experienced temporo-spatial disorientation, somnolence, horizontal nystagmus, and vertigo attacks with visual hallucinations and memory problems. The muscular forces at the four limbs were decreased to 3/5 with abolished osteotendinous reflexes at the two lower limbs. MRI showed hyperintense signals on T2 and FLAIR image in thalamus, periaqueductal area and mamillary bodies. Electroneuromyography (ENMG) showed axonal motor neuropathy in all 4 limbs. The hemogram showed normochromic normocytic anemia. Laboratory testing for Vitamin B12, vitamin D, folate and minerals showed multiple deficiencies. A multivitamin supplementation was introduced with good evolution.

Conclusion: This is the first case of severe digestive intolerance to methotrexate leading to a serious neurological complication. Although digestive intolerance to methotrexate is considered benign, it can be daunting. Thorough knowledge of complications and close monitoring of patients must be imperative. Gayet Wernicke encephalopathy is a rare and serious pathology. We should keep it in mind and prevent it in risky situations.

RISK FACTORS OF JOINT SURGERY IN RHEUMATOID ARTHRITIS TUNISIAN PATIENTS

Olfa Saidane,1 Leila Gafsi,1 Rim Barhoumi,1 Aicha Ben Tekaya1, Rawdha Tekaya1, Iines Mahmoud1, Leila Abdelmoula1. 1Department, Rheumatology, Departement, Tunis, Tunisia; 2Polyclinic Ef Omrane, Rheumatology Department, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by polyarticular synovial inflammation and progressive joint destruction. Orthopedic surgery is an integral part of the treatment of RA and it is mainly reserved for severe and advanced forms where there is a failure of medical treatment.

Objectives: To assess the rate of joint surgery in rheumatoid arthritis (RA) Tunisian patients and to determine the risk factors of surgical treatment.

Methods: A retrospective cross sectional study over a period of 15 years including 500 Tunisian patients with RA was conducted. The prevalence of joint surgery indication has been evaluated. Clinical, paraclinical and therapeutic characteristics of RA were compared according to the need of surgical treatment.

Results: Mean age was 53.4 years. Female to male ratio was 5. The indication of joint surgery was noted in 59 patients (12%). Factors associated with joint surgery were delayed diagnosis (p = 0.037), long RA duration (p = 0.017), young onset of RA (p < 0.001), presence of joint deformsities (p = 0.034), presence of osteoporosis (p = 0.029), presence...
of antineural antibodies<0.001), combination therapy of methotrexate with other conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) (p = 0.001), a short period of first medical treatment (p = 0.012) and high erythrocyte sedimentation rate (ESR) (p = 0.027). In multivariate analysis, three factors were independently related to the need of joint surgery: age at disease onset (OR 2.799 95%CI: 1.49-5.22 p<0.01), high ESR level (OR 2.807 95%CI: 1.5-5.24 p<0.01), and association of Methotrexate with other csDMARDs (OR 3.500 95%CI: 1.61-7.56 p<0.01).

Conclusion: Twelve percent of RA patients needed joint surgery treatment. Predictive factors of surgical treatment were young age at disease onset, high ESR level and association of methotrexate with other csDMARDs

AB0445 REMARKABLE OUTCOMES IN PATIENTS WITH RA USING CONVENTIONAL DMARDS UNDER A T2T STRATEGY AND A DISEASE MANAGEMENT MODEL – RESULTS FROM A FIVE YEAR REAL-WORLD REGISTRY
Pedro Santos-Moreno1, Michael Cabrera2, Diana Buitrago-Garcia3, Eva Cardozo4, Ivania Ramirez5, Danny Gomez6, Edwin Castillo7, Sandra Farietta8, Roberto Perricone9, Eduardo Conticini10, Bruno Frediani11, Nicola Boffini11, Lorenzo Dagna12, Marta Riva13, Maria Rosa Pozzi14, Rosa Daniela Grembiale15, Teodora Serban16, Gerolamo Bianchi17, Carlo Serio18,9,10,11,12,13,14,15,16,17,18,19

Objectives: The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy during 5 years in a cohort of patients receiving conventional DMARDs that attend to a specialized RA center.

Methods: A descriptive cohort study was conducted. Medical records of patients from specialized in RA center were reviewed during 2015-2017; those patients were followed-up under T2T standards and a multidisciplinary approach. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3.5 weeks (DAS28 > 5.1), every 7-9 weeks (DAS28 > 3.1 and ≤ 5.1), and every 11-13 weeks (DAS28 < 3.1). Tender joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 > 3.2 unless patient’s conditions don’t permit it; we considered this follow-up type as implementation of a T2T strategy in patients with RA. Patients entered into a multidisciplinary program of care with periodic consultations not only to rheumatology but with a physicist, physiotherapist, occupational therapy nutrition, and, a patient focused program. With a multidisciplinary model of care the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA. We divided patients in four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission. Descriptive epidemiology was done, we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We compared disease activity at base line and at the end of follow-up.

Results: During 5 years we included 2,128 patients. 83% were female and 17% were male, mean age was 57 years ±14. At baseline median DAS28 4.34 RIG (3.76-5.06) and at 5 years 2.02 RIG (1.492-2.38). At the end of our follow-up 81% were remission and 7% in LDA. See table 1.

AB0446 REAL-LIFE USE OF BARICITINIB IN RHEUMATOID ARTHRITIS: A MULTICENTER OBSERVATIONAL STUDY OF 150 PATIENTS
Giacomo Maria Guidelli1, Elena Generali2, Chiara Bazzani3, Roberto Goria2, Gianfallia Sakkeliadou3, Massimiliano Limonta3, Maria Sole Chimiretti3, Roberto Perricone4, Eduardo Conticini1, Bruno Frediani1, Nicola Boffini1, Lorenzo Dagna2, Marta Riva3, Maria Rosa Pozzi4, Rosa Daniela Grembiale5, Teodora Serban6, Gerolamo Bianchi5, Carlo Serio9,10,11,12,13,14,15,16,17,18,19

Objectives: To investigate the efficacy and safety profiles of baricitinib in real-life data are available about its efficacy and safety.

Methods: We performed a multicenter prospective observational study on adult RA patients starting JAK inhibitors between 12/2017 and 12/2018. Demographic and clinical data as well as laboratory values and adverse events were collected at baseline and after 12 and 24 weeks. Disease activity was measured by DAS28-CRP at baseline, after 12 and 24 weeks.

Results: We obtained data from 150 patients with RA (women 116 – 77.3%; median age 60 years, inter-quartile range IQR 54-68; median disease duration 10 years, IQR 4-18) treated with baricitinib 2 or 4 mg QD, however only 2150 (13%) at the reduced dosage. At the time of data-base lock 95/150 (63%) patients have completed the 12 weeks follow-up, 38/150 (25%) patients have completed the 24 weeks follow-up. Baricitinib was prescribed as monotherapy in 150/150 (43%), at a median dosage of 15 mg/week. Oral corticosteroids were used by 105/150 (70%) patients, at a median dosage of 5 mg/day. Mean DAS28-CRP at baseline was 4.92 (standard deviation 1.22), with 65 (43.3%) patients having a DAS28-CRP>5.1. At both 12 and 24 weeks, a significant reduction of disease activity scores was observed (DAS28-CRP mean 3.07, SD 1.36, and 2.85, SD 1.35, respectively; p values<0.001). Sixteen (11%) patients discontinued the treatment, with 8 (50%) due to primary inefficacy, mainly in the first 3 months of therapy (58– 63%). Adverse events were observed in 19/150 (13%) patients, 7 being non-serious infections (4
upper respiratory tract infections, 2 urinary tract infection, 1 Herpes labialis, while 3 patients manifested Herpes Zoster reactivation, 2 deep vein thrombosis (one with pulmonary embolism), 2 discontinued due to severe anemia and pancytopenia, and 2 developed self-limiting liver enzyme elevation.

Conclusion: In our real-world dataset, baricitinib is effective in reducing RA disease activity, after 12 weeks, being generally well-tolerated with few severe adverse events.

AB0447 BIOLOGICAL THERAPY AND RADIOSYNVOBITHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

Manoj Szentegi, Zoltán Nagy, Zsolt Kandy Mangel, Pál Géher

1Polyclinic of the Hospitalier Brothers of St. John of God, Rheumatology, Budapest, Hungary;
2Polyclinic of the Hospitalier Brothers of St. John of God, Budapest, Hungary

Background: The treatment of patients with rheumatoid arthritis (RA) has been spectacularly changed since the 1950’s. Introduction of the steroid compounds and their local application, the chemical and radionuclide synovectomy, surgical synovectomy, use of non steroid drugs, the basic treatment and the spread of biological therapy are the most important steps. Introduction of the biological therapy has changed the quality of life for these patients.

Objectives: During biological therapy sometimes 1 or 2 joints could be affected by inflammation. In this cases always the question is how to solve the problem. Change of the biological or basic therapy, use surgical synovectomy or radiosynovectomy (RSO)?

Methods: In our rheumatological department 2100 patients with RA and PA were treated with biological therapy between 2002 and 2015. In 100 patients we applied RSO because of the inflammation of the knee joint during biological therapy. We made a long term follow-up in 72 patients.

All participants provided written informed consent.

62 participants inflammatory knee joint disease was diagnosed on the basis of the American College of Rheumatology. 55 of 62 patients with rheumatoid arthritis were seropositive, 7 seronegative. Steinbrocker functional stage I-II was observed in 52, stage III in 10. 10 patients were seronegative. Mean age of 13 male and 61 female patients was 51.4 years (range 24-79) years. In 38 patients the right knee, in 34 the left knee was treated by radiosynovectomy. Mean duration of disease was 7.3 years (range 0.9-25), of synovitis (6.month range 3-8) Mean number of punctures of the treated joint prior to radiosynovectomy was 4.2 per patient and of steroid administrations prior to radiosynovectomy 3.0. In 12 patients a systemic steroid therapy has been performed.

Results: During the study period, inflammation decreased. In the first two years excellent and good results were recorded in 82.2%. Two years after radiosynovitthis 83.3% of patients did not need another puncture. Before the knee inflammation patients were in complete remission which status has been achieved after RSO as well. DAS: 2.4±0.4.

Conclusion: 1. RSO is an effective method to treat the inflammation of the knees. 2. The RSO performed during biological therapy is as effective as in the case of patients without biological therapy. 3. In case of a successful RSO there is no need for biological or basic therapy neither for surgical synovectomy.
venous thrombotic events, opportunistic infection/active TB, malignancy, GI perforation, or death.

Table 1. Efficacy measures in the Japanese subgroup at weeks 12 and 24.

Conclusion: In this phase 3 study in sDMARD-IR patients with active RA, treatment with FIB over a 24-week period was associated with significant improvements in signs and symptoms of RA, with a safety and efficacy profile in Japanese patients consistent with that in the global population. Thus, FIB may provide a novel treatment option for patients who continue to have active RA despite prior biologic therapy.

PAIN REDUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TOFACITINIB MONOTHERAPY WITH OR WITHOUT PAIN MEDICATION: A POST HOC ANALYSIS OF POOLED DATA FROM PHASE 2, PHASE 3 AND PHASE 3B/4 STUDIES

Peter C. Taylor1, Mart van de Laar2, Jeffrey R. Curtis3, Valderilio F. Azevedo4, José Luis Rivas5, Palle Dahl6, Liy Wang7, Nonko Ikuru8, Harry Shi9, John Woolcott10, Salim Benkhalifa11, Juan Jose Gomez-Reino11, Maxime Dougdados12, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, 1Medische Spectrum Twente, Enschede, Netherlands, 2University of Alabama at Birmingham, Birmingham, AL, United States of America, 3Universidade Federal do Parana, Curitiba, Brazil, 4Pfizer SLU, Malmö, Sweden, 5Astellas Pharma Inc, Gilead, Groton, CT, United States of America, 6Pfizer Inc, New York, NY, United States of America, 7Pfizer Inc, Collegeville, PA, United States of America, 8Pfizer SAS, Paris, France, 9Hospital Clinico Universidad de Santiago de Compostela, Spain, 10Cochin Hospital, Paris, France

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. Pharmacokinetics in the most common systems reported by patients (pts) with RA,1,2 thus reduction of pain is an important treatment goal.

Objectives: To evaluate the effect of tofacitinib monotherapy ± pain medication on pain in pts with RA.

Methods: This pooled post hoc analysis included pts who received tofacitinib 5 mg BD monotherapy (ie without csDMARDs) in Phase (P)2 (NCT00550446), P3 (ORAL Solo; NCT00814307) and P3b4 (ORAL ABO0449)
Strategy; NCT02187055) studies. Pts were stratified by concomitant use of ‘any pain therapy’ (opioids, plain analgesics [eg acetaminophen], NSAIDs or glucocorticoids [GC; ≤10 mg of prednisone or equivalent per day]), ‘pure analgesics’ (opioids or plain analgesics) and ‘adjuvant analgesics’ (NSAIDs or GC). Pts receiving pain medication at baseline (BL) maintained a stable dose during the studies; opioid and/or acetaminophen dose could be increased as rescue therapy. Efficacy outcomes were assessed at Month (M)3 and M6: change from BL (Δ) in Pt Assessment of Pain (Pain; visual analogue scale [VAS]) and ΔPain stratified by DAS28-4(ESR)-defined low disease activity (LDA; Δ3.2) status at M3 and M6.

Results: Of 676 pts who received tofacitinib 5 mg BID monotherapy, 604 (89%) received ‘any pain therapy’, 141 (21%) received ‘pure analgesics’ and 569 (87%) received ‘adjuvant analgesics’. Demographics and BL disease characteristics, including disease activity and Pain VAS, were generally similar when stratified by use/type of pain medication. Reductions in pain (ΔPain VAS) at M3 and M6 were generally similar for pts who received tofacitinib with ‘any pain therapy’ vs those who did not receive ‘any pain therapy’ (Figure 1a). There was a trend for a numerically greater reduction in pain at M3 and M6 in pts who received tofacitinib with ‘any pain therapy’ and who achieved LDA at M3 and M6 vs those who received tofacitinib with ‘any pain therapy’ and did not achieve LDA (95% CI overlapped; Figure 1b). By contrast, pain reductions were similar for pts who received tofacitinib without ‘any pain therapy’, irrespective of LDA status. Similar trends were seen when pts were stratified by use of ‘pure analgesics’ and ‘adjuvant analgesics’ (data not shown).

Conclusion: In this pooled post hoc analysis, pain reduction was similar in pts with RA receiving tofacitinib, regardless of pain medication use. Pain reduction was similar in pts receiving tofacitinib without ‘any pain therapy’, irrespective of LDA status. These results should be interpreted with caution, as pain medication could be used as rescue therapy, few pts received tofacitinib without ‘any pain therapy’, and confounding by indication cannot be excluded. Further analyses are required to explore the impact of tofacitinib on the relationship between reductions in pain and disease activity.

Figure 1

Figure 1. methotrexate adherence levels

Lack of resources and adverse effects were the main factors behind methotrexate’s low level adherence. The patients with these levels had a longer duration of disease progression and higher parameters of disease activity.

Conclusion: This study shows that the methotrexate adherence level in Moroccan patients with RA is low. The patient’s education should be improved in the Moroccan population for a better control of the disease.

Disclosure of Interests: None declared
PROSPECTIVE STUDY OF REASONS FOR DISCONTINUATION OF TOFACITINIB IN SELF-FUNDED PATIENTS WITH RHEUMATOID ARTHRITIS FROM A SINGLE CENTRE

Ramakrishna Rao Uppuluri1, Maryam Younis, Archanaa Rani, Shashikala Arava, Shivanand Jonnada, Kumar Datta, Challa Satyavati. Sri Deeksh Rehabilitation Centre, Rheumatology, Hyderabad, India

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of Rheumatoid Arthritis (RA). There can be potential differences in the adherence and compliance to therapies in real world compared to clinical trials especially in a non-reimbursable setup. Hence, it is very important to see the patient persistence to Tofacitinib therapy in a real practice.

Objectives: To evaluate the reasons for discontinuation of Tofacitinib in RA patients in real world set-up.

Methods: Data of RA patients treated with Tofacitinib 5mg BID from a rheumatology center in South India was collected from September 2016 to January 2019 using standardized formats at baseline, 1, 3, 6 and 12 months. Efficacy was evaluated by DAS28-ESR and safety by listing of Adverse Events (AE). Reasons for discontinuation were objectively recorded. Concomitant RA treatment type/dose adjustments were as per the clinician’s discretion. Analysis was based on observed values without imputation for missing data. For calculating persistence at a time point, the patients still taking the drug with treatment duration lower than that particular time point were excluded from the calculation.

Results: Fifty seven RA patients were treated with Tofacitinib. Average age and disease duration were 50 (20-77) years, 9 (1-22) years respectively. Most patients were females (88%); seropositive (89%) and all had erosive disease. Tofacitinib was used as a second line drug after inadequate response with conventional Disease Modifying Anti Rheumatic Drugs. Average Tofacitinib follow up was 6 (1-16) months. Thirty nine patients who discontinued Tofacitinib were analyzed. Eighteen patients were at various stages of therapy including 8 patients completing 12 months. Persistence with Tofacitinib at 3, 6 and 12 months was 85, 50 and 17 percent respectively. Details of the reasons for discontinuation are given in Table and Figure.

Conclusion: Tofacitinib was effective and well tolerated in Indian patients. However, majority of patients (80%) discontinued at various time points after feeling better. Only 13% discontinued due to AEs and 7% due to inadequate response. This data brings into light the difficulties faced by health providers for implementing 'treat to target' approach in real world practice.

Disclosure of Interests: Ramakrishna Rao Uppuluri Grant/research support from: Pfizer Inc, Maryam Younis: None declared, Archanaa Rani: None declared, Shashikala Arava: None declared, Shivanand Jonnada: None declared, Kumar Datta: None declared, Challa Satyavati: None declared

Background: Lipid profile control is essential in patients diagnosed with inflammatory disease such as rheumatoid arthritis (RA), since cardiovascular events (CV) are still the first cause of mortality. According to the EULAR recommendations on CV risk, in those patients with a low or moderate CV risk index, for whom diet and exercise have not been effective to diminish low density lipoprotein (LDL) cholesterol below 190 and 100 respectively, we must prescribe a statin. These are the most commonly used drugs with undisputed benefits shown in medical literature. However, often-polymedicated patients may present intolerances or adverse side effects that limit their use. Red rice yeast, whose main active ingredient is monacolin K, has been used in traditional Chinese medicine since 800 AD as a remedy to reduce the total cholesterol level (TC) in blood, LDL and triglycerides (TG). In addition, some studies underline its anti-inflammatory effect and its benefit in patients with inflammatory pathology. In recent years, its use has spread throughout the western world.

Objectives: To evaluate the efficacy of red rice yeast in patients with elevated levels of TC and LDL in rheumatology clinic.

Methods: Prospective study that includes two cohorts of 30 patients with similar demographic characteristics. One cohort with RA patients and the other one without inflammatory disease. Both groups present high levels of TC and LDL. We study the demographic, clinical and lipid levels. A standard dose of red rice yeast is administered to every patient and we evaluate the analytical response after 3 and 6 months of treatment. For the statistical analysis, we used the SPSS program 22.0 version. Quantitative variables are presented as means ± standard deviation and qualitative variables as percentages. The comparisons between the quantitative variables are made with the Student’s T-test. We compared the mean values for each visit with the Anova test. A p <0.05 is considered significant.

Results: In the group of patients without inflammatory pathology (n = 30), 73% are women with an average age of 63.9 ± 7 years. The mean of baseline TC is 231 ± 19 and LDL 143.9 ± 20. After 3 and 6 months of treatment, a significant decrease in both values was obtained (TC 231 ± 19 and 209.8 ± 19 F: 26.71 p 0.000 and LDL 143.9 ± 20 and 123.6 ± 19 F 22.51 p 0.000).

In the cohort of patients with RA (n = 30), 66% were women with an average age of 62.1 ± 10. The mean baseline TC is 258.2 ± 14 and LDL 176.7 ± 10. After 3 and 6 months of treatment a significant decrease of both values was obtained (TC 224 ± 24 and 196.1 ± 28 F: 21.55 p 0.000 LDL 149.5 ± 12 and 122.4 ± 25 F: 28.28 p 0.000).

In the two cohorts, 2 weeks for 43.2% and 64.7% of pts with headaches; 66.1% for intraocular pressure and 28.9% with abdominal discomfort. Of the 2657 pts included in the analysis, 1976 received tofacitinib 5 mg BID (ORAL Solo, ORAL Strategy), placebo (PBO; ORAL Solo), or tofacitinib 5 mg BID or PBO with csDMARDs (all studies except ORAL Solo). Non-serious AEs (affecting pts directly related to tolerate therapy) with incidence rates (IRs, pts per 100 pt-years) >5 were evaluated up to Month (M)3. Infections, laboratory test abnormalities, general disorders or events not directly reported by pts, and musculoskeletal disorders likely due to underlying RA, were excluded.

Results: Of the 2857 pts included in the analysis, 1976 received tofacitinib 5 mg BID (monotherapy: N=627; combination: N=1349) and 681 received PBO (monotherapy: N=122; combination: N=559). The most frequent non-serious AEs up to M3 are shown in the Table. IRs >10 were seen for headache and diarrhoea (tofacitinib 5 mg BID monotherapy, combination therapy and PBO monotherapy), and nausea (PBO monotherapy and PBO combination therapy). Non-serious AE duration was ≤4 weeks for most pts with headaches, diarrhoea or gastric discomfort (any gastrointestinal pain, dyspepsia, epigastric discomfort or abdominal discomfort/pain). With tofacitinib 5 mg BID and PBO, respectively, duration of AEs was ≤2 weeks for 43.2% and 64.7% of pts with headaches; 66.1% and 81.3% with diarrhoea; and 36.2% and 58.6% with gastric discomfort. Most non-serious AEs were mild/moderate.

Figure 1

Disclosure of Interests: None declared
Conclusion: Overall, non-infectious non-serious AEs were mild/moderate and the majority were self-limiting. Non-serious AE frequency was similar for tocifinib monotherapy and combination therapy, and for tocifinib and PBO.

### AB0457 AUDIT ON HYDROXYCHLOROQUINE RELATED RETINOPATHY SCREENING IN RHEUMATOLOGY PATIENTS IN SVUH

**Aadil Al Ghafri, Eamonn S. Molloy. St Vincent’s University Hospital, Rheumatology, Dublin, Ireland**

**Background:** Hydroxychloroquine (HCQ) is a medication commonly used to treat rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and other rheumatological conditions. A known adverse effect associated with long-term use of these medications is vision loss resulting from irreversible retinal toxic effects. Recent guidelines emphasized on routine ophthalmological examination and to adhere on real weight-based dosages.

**Objectives:** This audit conducted to evaluate adherence rate on standard recommendation on HCQ related retinopathy screening in rheumatology patients in St Vincent’s University Hospital (SVUH).

**Methods:** Patient were on HCQ and attended rheumatology clinics at SVUH with rheumatic diseases selected randomly from on 01/08/2017 and end on 01/04/2018. A total sample size of 56 patients received a questionnaire that included information on HCQ dose, duration and actual body weight. Other information included precipitant factors and ophthalmology examination reports were retrieved retrospectively form patient’s chart.

**Standards were measured against recommendations on screening for HCQ retinopathy published by American Academy of Ophthalmology, 2016 Revision.**

**Results:** Total 56 patients on HCQ with different rheumatic disease studied. Out of 56 patients studied, 6/56 (10.7%) were <25 years (young), 45/56 (80.4%) were 25-65 years (middle age), and 5/56 (8.9%) were >65 years (elderly). Sex distribution showed that 7/56 (12.5%) were males and 48/56 (87.5%) were females. Around 35.7% (20/56) were in HCQ dose <5mg/kg, and 64.3% (36/56) were on standard HCQ dose (5mg/kg) of real body weight. The were 44.6% (25/54) patients on HCQ for a period <5 years, the rest, 55.4% (32/56) were on HCQ for a period of 5-20years, and none of these patients were on it for >20 years duration. There were only 1/56 (1.8%) patient with history of HCQ toxicity. 98.2% (55/56) showed no history of HCQ related toxicity. None of the 56 patients had any of the following influencing factors: renal impairment, Tamoxifen usage, coagulopathies, hepatic impairment, or pre-existing retinal/macular disease. However, there were 8.9% (5/56) of this group their age was > 65years (verses 51/56 91.1% were <65years age. Only 69.6% (39/56) of these patients underwent retinal baseline screening, were 17/56 (30.4%) did not receive any baseline screening after commencing HCQ therapy. Frequency of follow up retinal screening were done annually in 19/56 (33.9%), 5 yearly in 6/56 (10.7%). However, it was not done in 21/56 (37%) and it was not due in 9/56 (16.1%). Out of those who underwent the screening at any time, 32/56 (57.1%) showed normal examination results, only 1/56 patient (1.8%) showed abnormal results. Rest of the patient data either were not available, or examination were not done.

**Conclusion:** Above data emphasis the need to adhere on standards HCQ retinal screening as baseline and follow up. Furthermore, adherence on real weight calculated dose rather than estimated/average body weight.

**DISCLAIMER:**

All references and data are from the published scientific abstracts. The table above represents the change from baseline to Week 12 for secondary and exploratory endpoints (full analysis set) for the A Phase II Randomised, Double-blind, Placebo-Controlled, Proof of Concept Study of Oral Seletalisib in Patients with Primary Sjögren’s Syndrome (PSS).

**RESULTS:**

The study was terminated early due to slow recruitment, which led to study power decreasing to 36%. Twenty of 27 patients randomised (seletalisib n=13, PBO n=14) completed treatment. Demographic characteristics were generally similar between groups. Mean (SE) change from baseline in ESSDAI at Week 12 was seletalisib −5.4 (1.7) vs PBO −2.8 (1.5); treatment difference vs PBO was 2.6 (9.8, 0.01; p=0.266). The percentages of patients achieving a ≥3 point reduction in ESSDAI were seletalisib 66.7% vs PBO 54.5%. Post-hoc Bayesian analyses of treatment difference showed an 86.5% probability of being superior to PBO and a 48.8% probability was deemed different from clinically notable improvements in some secondary endpoints were also observed in the seletalisib group (Table 1). Minor salivary gland bioposes had broadly similar histological features across groups at baseline. At

Boxmair14,15, UCB Pharma, Slough, United Kingdom; 1University of Birmingham, Birmingham, United Kingdom; 2UCB Pharma, Raleigh, United States of America; 3Newcastle University and NHRI Newcastle Biomedical Research Centre, Newcastle upon Tyne, United Kingdom; 4Strasbourg University Hospital, Strasbourg, France; 5University of Palermo, Palermo, Italy; 6Universiti Paris-Sud, Paris, France; 7Karolinska Institutet, Stockholm, Sweden; 8Cavale Blanche Hospital, Brest, France; 910Hospital Marina Baixa, Vilajoyosa, Spain; 11InfantaIsaura Hospital, Seville, Spain; 12University of L‘Aquila, L‘Aquila, Italy; 13University Hospitals and Birmingham Biomedical Research Centre, Birmingham, United Kingdom

**Background:** Seletalisib is a potent, selective oral inhibitor of phosphoinositide-3 kinase delta (PI3Kd). Preclinical data have shown that the PI3Kd pathway is upregulated within salivary glands of patients with PSS and contributes to disease pathogenesis.

**Objectives:** To assess the efficacy and safety of seletalisib in patients with PSS.

**Methods:** In this Phase II, double-blind, proof of concept study (NCT02610543), patients with PSS having an EULAR Sjögren Syndrome Disease Activity Index (ESSDAI) score ≥5 were randomised 1:1 to seletalisib once daily or placebo (PBO) in addition to current PSS therapy for 12 weeks. The primary endpoint was change from baseline in ESSDAI at Week 12. The study was designed to have 80% power to detect a difference of 3.8 points in change from baseline in ESSDAI between seletalisib and PBO at Week 12 and required 58 patients to complete treatment. Other endpoints included EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI), salivary gland biopsy changes, Schirmer’s I test, immunoglobulin concentrations and incidence of treatment-emergent adverse events (TEAEs).

**Results:** The study was terminated early due to slow recruitment, which led to study power decreasing to 36%. Twenty of 27 patients randomised (seletalisib n=13, PBO n=14) completed treatment. Demographic characteristics were generally similar between groups. Mean (SE) change from baseline in ESSDAI at Week 12 was seletalisib −5.4 (1.7) vs PBO −2.8 (1.5); treatment difference vs PBO was 2.6 (9.8, 0.01; p=0.266). The percentages of patients achieving a ≥3 point difference from baseline in ESSDAI between seletalisib and PBO at Week 12 and required 58 patients to complete treatment. Other endpoints included EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI), salivary gland biopsy changes, Schirmer’s I test, immunoglobulin concentrations and incidence of treatment-emergent adverse events (TEAEs).
Week 12, seletalisib treatment led to a reduction in the size and cellular organisation of mononuclear inflammatory cell foci vs PBO (Table 2). TEAEs were reported by 13/13 (100.0%) seletalisib and 13/14 (92.9%) PBO patients; most frequently reported: diarrhoea (5/13 [38.5%] vs 0/14 [0%]) and headache (3/13 [23.1%] vs 2/14 [14.3%]). Serious TEAEs were reported by 3/13 (23.1%) vs 1/14 (7.1%), and discontinuations due to TEAEs by 5/13 (38.5%) vs 1/14 (7.1%) seletalisib and PBO patients, respectively.

Conclusion: Although this Phase II PSS study was terminated early due to slow recruitment, seletalisib demonstrated a trend to clinical improvement in patients with PSS and acceptable safety and tolerability. Histological analyses demonstrated encouraging effects of seletalisib on the organisation of mononuclear inflammatory cell foci from parent minor salivary gland biopsies.

USE OF PLATELET RICH PLASMA (PRP) IN TREATMENT OF DRY EYE SYNDROME IN THE PATIENTS WITH SJÖGREN SYNDROME: PRELIMINARY RESULTS

Annunziata Capacci1, Francesco Ricci2, Valentina Varriano3, Barbara Tolusso4, Pietro Rubortone5, Anna Maria Pagliornico6, Antonio Ciardello7, Stefano Aliveritti8, Gianfranco Ferraccioli8, Elisa Gremsese1,9, Fondazione Poliomiclinico Universitario A.Gemelli IRCCS, Division of Rheumatology, Rome, Italy; 2Fondazione Policlinico Universitario A.Gemelli IRCCS, Division of Ophthalmology, Rome, Italy; 3Università Cattolica del Sacro Cuore, Division of Rheumatology, Rome, Italy; 4Università Cattolica del Sacro Cuore, Division of Ophthalmology, Rome, Italy

Background: Xerostomia and xerofthalmia are the hinge symptoms of Sjögren Syndrome and often they negatively influence patients’ quality of life. The eye washes used based on Platelet Rich Plasma (PRP) (PRP has been applied in the treatment of the xerofthalmia, both primitive and secondary.

Objectives: To evaluate the effect of subconjunctival injections and PRP based eye washes on the ocular dryness (subjective and objective) in patients suffering from primary Sjögren syndrome (pSS).

Methods: Six pSS patients (6 females, age at the beginning 48.2±9.7 years) have been recruited in the study. All patients were reaching the criteria for pSS diagnosis, for each patient clinical and immunological data have been recorded. Patients with Schirmer Test value, in at least an eye, inferior to 10 mm after 5 minutes, and suffering from severe dryness calculated by OSDI score (between 33 and 100, severe condition of dry eye) in spite of therapies with tear substitutes were selected. The OSDI (Ocular Surface Index) is a questionnaire for the evaluation of the subjective ocular dryness. Selected patients have been addressed to treatment with PRP. The PRP is constituted by human plasma enriched with plaques by means of the utilization of a special kit, therefore each patient has been subjected to a blood drawing, from which PRP has been extracted. Of this, a part has been injected in subconjunctival seat; from remained one, an eyewash has been extracted that the patients have assumed 6 times in the day up to exhaustion (about 5 days) during which another topic therapy was not used. The patients have been valued to the basal time and after ten days of the procedure; besides follow-up visits each three months are scheduled. To each evaluation Schirmer Test data and OSDI have been checked.

Results: Each patient had severe xerofthalmia, evaluated by Schirmer Test (right eye: 3.33±2.66; left eye: 6.83±6.5) and index OSDI (50.71±20.72). All the patients had Schirmer Test values, in at least an eye, lesser than 10 mm after 5 minutes. The analyzed cohort had homogeneous clinical characteristics (presence of xerostomy and absence of inflammatory indexes, hypergammaglobulinenia, arthritis and lymphoedemogenyly). After one week (T1), OSDI values were significantly more reduced compared to the basal time (38.89±15.12; p=0.028). The Schirmer Test values were not significative different to the follow-up visit compared to the basal one. No patients presented pre- and post-procedural complications, neither related infectious events. At 3 months follow up after first treatment (T2) no statistically significant difference in OD/OS Schirmer Test values and OSDI score compared to the basal time were observed.

Conclusion: The use of PRP in dry eye syndrome in patients with Sjögren syndrome seems to be effective in alleviating symptoms and improving patients’ life quality. Is need further follow-up to confirm data, to evaluate necessity of repeating treatment.

AB0461 BELATECEPT IN SLE KIDNEY TRANSPLANT PATIENTS

Irene Carrión Barberá1, Melissa Fajardo2, Demetra Tsapepas3, Hilda Fernandez3, Anca Askanase4, 1Hospital del Mar, Rheumatology, Barcelona, Spain; 2Columbia University Medical Center, Nephrology, New York, United States of America; 3Columbia University Medical Center, Rheumatology, New York, United States of America

Background: Lupus nephritis (LN) results in the need for renal replacement therapy (RRT) in 10-30% of LN pts; of these 30% receive a kidney transplant (KT). Belacept (bela) is a second-generation selective T-cell co-stimulator blocker (inhibits CTLA-4) used as an alternative to calcineurin inhibitors (CNI) for maintenance regimens after KT. The pathogenic relevance of CTLA-4 inhibition and the favorable cardiovascular profile of bela make it an attractive therapeutic option in SLE. Additionally, bela IV ensures therapeutic adherence.

Objectives: The current study was initiated to evaluate the effect of bela on graft function and extraeral SLE.

Methods: This retrospective single-center study evaluates the outcomes of LN KT recipients treated with bela from 2006–2018 at the Columbia University Lupus and Renal Transplant Cohorts. The bela regimen was 5mg/kg every 2 weeks x 5 doses, then monthly. CNI weaning among the bela group was not standardized. Immunosuppressive regimen, kidney allograft function, and SLE activity were examined.

Table 1: Characteristics of patients on bela

Results: 48 pts with LN had undergone KT between 2006–2018 with follow-up time of 72.2 ± 74.6 months. Bela was started in 7 pts on CNI regimens (TAC N=6, cyclosporine N=1) at 15.5 ± 17.1 months after KT. All pts were female, age at SLE diagnosis 21.1 ± 4.9 yrs; 5 had undergone RRT prior to KT (4 hemodialysis, 1 peritoneal dialysis) for 38.7 ± 37.8 months. The interval between SLE diagnosis and KT was 13.1 ± 8.3 yrs. At the time of bela initiation, all pts were also treated with prednisone (7.1 ± 2.7 mg/day), 6 with mycophenolate (1123 ± 625 mg/day), and 1 azathioprine (25mg/day). CNI were continued in 5/7 patients 6 months after bela. 2 pts were on hydroxychloroquine, 2 took it only prior to KT. In 5 patients, creatinine stabilized 6 months after bela, 1 returned to HD due to CNI-toxicity and pylonephritis and 1 is relisted for KT due to ACR and cortical necrosis (Fig. 1). No allograft failure due to recurrent
LN was noted in any of the 7 pts. 5 pts are followed by Rheumatology for extrarenal SLE; no extrarenal manifestations are documented in the other 2. Data on SLE Disease Activity Index post and post bela were available and scored in 3/5 pts using the SLEDAI-2K2G which accounts for clinical and laboratory manifestations, as well as steroid use (Fig. 2). Mean DNA pre and post bela was 133 ± 178 U/ml and 58 ± 72 U/ml. C3 89 ± 31 mg/dl pre and 91 ± 21 mg/dl post; C4 35 ± 15 mg/dl pre and 38 ± 7 mg/dl post.

Conclusion: Delayed KT recipients may decrease extrarenal manifestations, attenuate CNI toxicity and stabilize allograft function, providing a better alternative to CNI regimens. Furthermore, these data suggest that bela may be a therapeutic option in SLE.

AB0462 IMMUNIZATION TO RITUXIMAB IS MORE FREQUENT IN AUTOIMMUNE SYSTEMIC AUTOIMMUNE DISEASES THAN IN RHEUMATOID ARTHRITIS AND MAY BE MANAGED BY SWITCHING FROM RITUXIMAB TO OFATUMUMAB

Alice Combier, Gaetane Nocturne, Julien Henry, Rakiba Bekhir, Stephane Pavy, Xavier Mariette, Raphaèle Seror. Bicêtre Hospital AP-HM, Rheumatology, Le Kremlin-Bicêtre, France

Background: The most widely used B cell targeted therapies in autoimmune diseases (AID) is Rituximab (RTX), a murine chimeric monoclonal antibody. Among RTX’s side effects, immunization and anti-drug antibody sequences are poorly described. The immunization rate against RTX in rheumatoid arthritis (RA) is 2.7–9.2%, and it seems to be higher in other sAID although data is lacking.

Objectives: We aimed to evaluate the frequency, consequences and predictive factors of RTX-ADA in RA and sAID, as well as the use of an alternative B-cell targeted therapy, ofatumumab (OFA) in case of RTX-ADA.

Methods: All patients with RA or sAID treated with RTX from 2012 to 2017 in our tertiary reference centre for sAID were retrospectively studied. Patients who were tested for RTX-ADA were identified. Clinical and biological characteristics of RTX immunized patients were compared to those of non-immunized patients. For patients treated with OFA, clinical and biological efficacy was obtained before and after treatment.

Results: 199 patients were treated with RTX (RA: 124, sAID: 75 including 38 primary Sjögren’s Syndrome (pSS), 15 systemic lupus erythematosus, 7 myositis, 6 overlap syndrome, 5 ANCA-associated vasculitides and 4 other sAID). Among the 62/199 (31.1%) tested for RTX-ADA, 14 were positive; 3/35 RA (8.6%), and 11/27 (40.7%) other sAID, (p=0.005). Among the whole RTX-treated patients, the frequency of RTX-ADA was 2.4% and 14.7% (p=0.003) in RA and in other sAID, respectively. Most of the immunized patients experienced delayed infusion reactions (11/14 [78.5%]). Delayed reactions were observed within the first 15 days after the infusion, and after a median 2 cycles [range; 1-2]. They were mainly rash (72.7%), fever (54.5%) and/or abdominal pain (36.3%). Predictive factors of immunization were a sAID compared to RA (40.7% vs 8.6%, p<0.005), and young age (50.5 vs 61.5 years, p=0.003). Neither hyper-gammaglobulinemia, rheumatoid factor, disease activity, nor associated immunosuppressive therapy were associated with RTX-ADA. Among 23 tested patients with SLE or pSS, anti-SSA antibodies tended to be more frequent in immunized patients than non-immunized (2/10 (20.0%) vs. 8/13 (61.5%), p=0.16). Three pSS patients immunized against RTX were treated with OFA because of associated cryoglobulinemic vasculitis or MALT lymphoma. All 3 experienced complete remission of their disease.

Disclosures: This work was supported by a grant from the French National Research Agency (ANR-11-JS02-003) and a grant from the European Research Council (ERC-2013-AdG-617249). The study is supported by research funds from the ‘Fondation pour la Recherche Médicale’ (FRM). Dr. Schlag is supported by research grants from the French National Research Agency (ANR). The authors have declared no conflicts of interest.

Conclusion: Our results show that immunization against RTX is more frequent in other sAID than in RA. Testing for ADA must be performed in patients with infusion reactions. Patients immunized to RTX might be treated effectively with OFA, which should be further evaluated in sAID.

Disclosure of Interests: None declared

AB0463 BELIMUMAB IV EFFECT IN GLUCOCORTICOID TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

María De la Rubia Navarro1, Susana Cerda Checa2, Jose Ivorra Cortés3, Elena Grau García, Cristina Alcaraz Escarré, Inés Sula Sánchez Verdejo1, Juan Fraga Q1, Roxana Gonzalez Mazonaro, Luis González Puig1, Isabel Martínez Cordellia, Rosa Negueruela Albiuco1, Jose Eloy Oller Rodriguez1, Francisco Miguel Ortiz Sanjuan1, Cristobal Pérez Perales2, Elvira Vicens Bernabeu1, Carmen Nájera Herranz1, Ines Canovas Olmos1, Jose Andrez Roman Ivorra1,2,1 Rheumatology Department, HUP La Fe, Valencia, Spain; 2 Medical School, UCV, Valencia, Spain

Background: Systemic lupus erythematosus (SLE) is an autoimmune chronic disease produced by aberrant immunological response that consequently, causes a widespread organic damage. Treatment leads to regulating this disrupted immunological response. As a result, in 2011 Belimumab was approved for adults patients diagnosed with SLE, what is a monoclonal human antibody whose target is a B-lymphocyte stimulator (BLYS), a protein involved in the disease pathogenicity.

Objectives: To evaluate the glucocorticosteroid dose variation in adult patients with systemic lupus erythematosus during Belimumab IV treatment.

Methods: Retrospective, observational study that includes patients diagnosed with SLE according to SLICC 2012 criteria, who are treated with Belimumab IV. Treatment has been administrated as an initial dose: 10 mg/kg every 14 days and then, a maintenance dose: 10 mg/kg every 28 days. Data form serological profile, clinical manifestations at diagnoses and at the onset of treatment, existence of comorbidities or other diseases, concomitant therapy directed to the main disease or to the complications that came from the disease, non administration causes and definitive treatment discontinuation were collected from July 2012 until December 2018.

Results: A total of 19 patients (94.74% women) with 28 years old (Q1 14, Q3 31.82) as a median age at diagnosis and 11 (Q1 6.5, Q3 20) years since disease diagnosis were included. Follow up mean was 29 (Q1 7.5, Q3 37) months.

Regards to concomitant therapies, 5 patients (26.31%) were treated with Azathioprine and 3 patients with Methotrexate (15.79%). At the onset of biological therapy, 17 patients were treated with glucocorticoids, at a dose of 10 mg (Q1 9.38, Q3 10.63). At the end of follow up, 18 patients (94.73%) were treated with corticoid and the mean dose was 8.75 mg (Q1 8.75, Q3 8.75).

We observed a mean corticoid dose reduction of 4.02 mg (Q1 2.5, Q3 5). Dose was not modified in 4 patients after the beginning of Belimumab IV. As exceptions, in 1 patient we added corticoids to treatment (dose of 5 mg/day) and in another one we doubled corticoid dose, until a maximum dose of 20 mg/day. Belimumab treatment was definitive discontinued in 5 patients because of drug allergy and primary pulmonary hypertension. As we observed, an important percentage of patients (in our sample dose to 90%) take usually corticoids, with the clinical consequences and development of comorbidities in a long time and adverse events related to this therapy. Diary dose is reduced in 57.9% of our patients, even in those patients who have discontinued Belimumab treatment, in which we observed a dose reduction too.

**AB0465** EFFECTIVENESS AND SAFETY OF IGURATIMOD IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME: A FOLLOW-UP STUDY

Hui Gao1, Xiao-Ying Zhang2, Xue-Wu Zhang3, Li Zhang4, 1Peking University International Hospital, Beijing, China; 2Peking University People’s Hospital, Beijing, China

Background: Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disorder affecting 0.2–3% of the population. However, there are currently no effective systemic therapies. Anti-Ro, anti-La and rheumatoid factor (RF) as well as hyper γ-globulinaemia indicate a degree of B cell hyperactivity. In the recent ten years, iguratimod (T-614) has been used to treat RA as a novel immunomodulatory, which functions by suppressing the production of some inflammatory cytokines, as well as reducing immunoglobulin production by acting directly on human B lymphocytes without affecting B lymphocyte proliferation.

Objective: We evaluated the effectiveness and safety of iguratimod on pSS patients in this follow up study.

Methods: A total of 21 pSS patients without severe systemic damage needing corticosteroid were recruited to receive iguratimod 25mg Bid for 12 weeks.

Results: Among them, 1 patient and 2 patients withdrew because of kidney dysfunction and inefficacy. For those 18 patients who finished the follow up, 94.4% were females and average age were 46.5±13.8 year-old with median disease duration of 22.0 (9.8, 58.5) months. Compared with baseline, ESSDAI score, hyperglobulinaemia and ESR was significantly decreased after iguratimod treatment (Table). Two of the 18 patients presented with decreased white blood cell count. This side effect ameliorated in one patient after tapering the dose to 25mg Qd and in another patient after 2 weeks without any intervention.

**Table. Effectiveness of iguratimod in pSS**

**AB0464** EFFECTIVENESS AND SAFETY OF ABATACEPT FOR 24 MONTHS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME (PSS)

Adriana Machado1, virginia fernandes moça trevisani2, Tania Fidelix1, Laura Santos1, Ilda Lekwitz1, Simone Soares1, André Gasparini1, Juliana Augusto1, 3Santo Amaro University (UNISA), SAO PAULO, Brazil

Introduction: Primary Sjögren’s syndrome (SSp) is a systemic autoimmune disease concerning the exocrine glands and internal organs. Therapeutic options mainly include symptomatic and supportive measures, whereas traditional immunosuppressive drugs have not presented efficacy in randomized trials. Abatacept is a T-cell co-stimulation modulator and there are evidences that this drug may be effective for treating PSS.

Objectives: The objective of this trial was to evaluate effectiveness and safety of abatacept for 24 months in the treatment of pSS.

Methods: Observational prospective study for 24 months. It was included 11 patients that filled the American-European Consensus criteria (2002). Patients received abatacept according the weight < than 60 kilos (500mg), 60 kilos to 100 kilos (750 mg) per month for 24 months. It was evaluated Sjögren’s syndrome disease activity index (ESSDAI), salivary flow with no stimulation for 15 minutes, Schimmer’s ophthalmologic evaluation tests, Ocular Staining Score (OSS) e Break up time, quality of life by Medical Outcome Survey Short Form 36 (SF-36) and fatigue by FACIT Fatigue - The Functional Assessment of Chronic Illness Therapy. For statistical analysis was used the Wilcoxon’s test for related samples and test T of Student to paired samples. The significance level of 5% was adopted and analyzes were accomplished in the R program (version 3.5.1).

Results: This study was constituted from 11 women between the ages 25 to 81 years (average: 53.73 ± 15.07 years), being the majority Afro-descendant women (54.5%). Of this total, 90.9% presented positive anti-nuclear antibody (ANA), 81.8% positive anti-SSA, and 90.9% positive rheumatoid factor. In relation to ESSDAI, 81.8% of the participants presented scores greater than 5. There was a statistically significant reduction in the ESSDAI IC 2.99 [-0.49; 7.99] (p = 0.013). Between the sub items of the ESSDAI, the ones that demonstrated the greatest modifications were articular and glandular. There was a significant increase in the salivary flow of the participants (df = 0.90; IC-95%: -1.50; -0.50) after 24 months of treatment. There was no statistical difference between the beginning and after 24 months of treatment in the different evaluations. Schimmer’s ophthalmologic right eye IC 2.26 [-3.50; 12.5] p=0.423. Break up time OD 0.50 [-1.00; 2.49] p=0.307, OSS right eye IC: 0.50 [-2.50; 5.50] p=0.721. In the SF36 only in the Limitation for Emotional Aspects sub scale reported significant improvement (df = 36.4; IC95%: -67.1; -5.57; p = 0.025), and FACIT presented no evidences of significant changes between pre and post treatment p = 0.392.

Conclusion: The study demonstrates limitations due to the few number of patients included and for being an open study not controlled, but we observed a statistically significant reduction in the ESSDAI, increase in the salivary flow and in the sub scale Limitation for Emotional Aspects of the SF36, indicating a positive effect in the disease.

ADVERSE EVENTS AND THE RELAPSE RISK OF SYSTEMIC LUPUS ERYTHEMATOSUS DURING HYDROXYCHLOROQUINE TREATMENT

Kunihiro Ichihara1, Kelta Fujikawa2, Akinari Mizokami3, Toshiyuki Aramaki3, Yukitaka Ueki3, Mizuna Eguchi1, Moroko Okamoto1, Yushiro Endo1, Sousuke Tsuji1, Ayuko Takatani1, Toshimasa Shimizu1, Remi Sumiyoshi1, Tomohiro Koga1, Shin-Ya Kawasaki1, Naoki Iwamoto1, Takashi Igawa1, Mamoru Tamai1, Hidenori Nakamura1, Tomoki Oruguchi1, Atsushi Kawakami1.

1Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Nagasaki, Japan; 2JCHO Isahaya General Hospital, Department of Rheumatology, Isahaya, Japan; 3Sasebo Chuo Hospital, Rheumatic disease center, Sasebo, Japan; 4Nagasaki University Graduate School of Biomedical Sciences, Department of Rehabilitation Sciences, Nagasaki, Japan

Background: The antimalarial drug hydroxychloroquine (HCQ) is used worldwide to control the disease activity of systemic lupus erythematosus (SLE). In Japan, HCQ was not approved until September 2015 due to the problem of retinopathy induced by chloroquine. There is insufficient evidence of the effects of HCQ or adverse events linked to HCQ treatment.

Objectives: Here, we evaluated adverse events and the relapse risk of SLE during HCQ treatment.

Methods: We retrospectively analyzed the data of 109 patients diagnosed with SLE and treated with HCQ for >12 months at Nagasaki University Hospital and community hospitals. The demographic data included the patient's age at the onset of SLE, gender, the disease duration of SLE (the time from the diagnosis of SLE until the renal biopsy), comorbidities of Sjögren syndrome (SS)/anti-phospholipid syndrome (APS), and the treatment for induction. We identified the risk of adverse events and relapse at 12 months after the introduction of HCQ. Decision tree models predicting relapse were built with the Classification and Regression Trees (CART) algorithm. The data of the length of time between a patient's HCQ induction to the first observation of relapse was analyzed by the Kaplan-Meier method with a log-rank test.

Results: Most of the patients were female (88.1%). The median age at the introduction of HCQ was 40.0 years (interquartile range [IQR] 30.5–50.0 years), and the SLE disease duration was 95 months (IQR 38.0–184.5 months). The mean observation period after HCQ introduction was 12 months. The comorbidity rates of SS and APS were 25.7% and 18.4%, respectively. The SELENA-SLEDAI scores were significantly decreased at 3 months post-HCQ introduction. The dose of oral prednisolone was significantly decreased at 6 months post-HCQ introduction. Eighty-six patients (79.8%) were continuing HCQ at 12 months post-introduction. Adverse events occurred in 27 patients (24.8%), including skin rashes (n=11, 10.1%) and gastrointestinal symptoms (n=6, 5.5%). The sole predictive factor for adverse events was the white blood cell (WBC) count at baseline (odds ratio: 0.9977, 95%CI: 0.9994–0.9999, p=0.0285). Twelve of 86 patients (14.0%) experienced relapse that required the start of prednisolone or an immunosuppressant or an increased prednisolone dose. The multivariate analysis revealed that the C4 value at baseline was a predictive factor of relapse (odds ratio: 0.841, 95%CI: 0.718–0.999, p=0.0097). The cut-off point determined by the CART algorithm showed that C4 ≥9.3 mg/dl at baseline provides the best performance for predicting relapse. The Kaplan-Meier analysis showed that compared to C4<9.3 mg/dl at baseline, C4 ≥9.3 mg/dl at baseline was correlated with being free from relapse (p=0.0032).

Conclusion: A lower C4 value at HCQ introduction was a predictive factor for the relapse of SLE, and a lower WBC count was a predictive factor for adverse events.

IMPROVED DISEASE CONTROL OF SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS POSSIBLE ASSOCIATION WITH AGGRESSIVE USE OF IMMUNOSUPPRESSANTS

Chihiro Imaiuzumi, Yukinoue, Takaharu Kagttagiri, Sayaka Takanaka, Hideki Ito, Ayako Hirata, Takehisa Ogura, Hideto Kameda. Toho University. Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: The outcome of patients with systemic lupus erythematosus (SLE) has considerably improved in recent decades.

Objectives: The aim of this retrospective study was to examine whether the disease control has been actually improved and its possible association with the altered balance between the use of immunosuppressants and glucocorticoids.

Methods: We enrolled SLE patients who visited Toho University Ohashi Medical Center during 2012-2017 (Group A, 79 patients), and compared them with patients during 1999-2003 (Group B, 68 patients; not overlapping with Group A). All the patients met the American College of Rheumatology 1997 revised criteria for SLE classification. Patient backgrounds, the dose of glucocorticoids and the use of immunosuppressants at the times of SLE onset and disease flare were reviewed from the medical records. The disease flare was defined as a new BILAG 2004 A or B score in at least one system.

Results: The age at disease onset and sex, as well as the presence of lupus nephritis and serositis were comparable between 2 groups, although central nervous system manifestations were less frequent in Group A (7% versus 16% in Group B, p=0.04). The number of flare per person-year was significantly reduced in Group A than Group B (0.26 versus 0.4, respectively, p<0.01). In the initial treatment, the median dosage of oral prednisolone was equivalent in both groups (30 mg/day, p=0.64), while the total glucocorticoid dosage in the initial 16 weeks was significantly reduced in Group A (1,960 mg prednisolone equivalent versus 2,913 mg in Group B, p=0.01). And the inclusion rate of immunosuppressants in the initial SLE treatment was significantly higher in Group A (43% versus 6% in Group B, p=0.01). Further, upon disease flare, the use of prednisolone for it was significantly lower in Group A (6.5 mg/day versus 14 mg/day in Group B, p<0.01) and the rate of introduction or alteration of immunosuppressants were significantly higher in Group A (81% versus 24% in Group B, p=0.01). Infection rates were similar between the groups (p=0.44).

Conclusion: Aggressive use of immunosuppressants in recent years resulted in the reduction of the rate of SLE flare as well as that of cumulative glucocorticoid dosage.

QUALITY OF LIFE IN SYSTEMIC LUPUS WOMEN WITH CUTANEOUS DAMAGE ON THE FACE: COSMETIC CAMOUFLAGE IMPACT

Cristina Costa Larra1,2,3,4,5, Fabiana Miranda Moura Dos Santos1,2, Maria Veloso Rocha Mameluke1,2, Thaigo Lorenz e Silva1,2, Clára Cottone Neves1,2, Douglas Mansur Guerra1,2, Maria Fernanda Botelho Teixeira5, Claudia Lopes Santoro Neiva5, Ana Flavia Madureira de Pádua Dias5, Rosa Weiss Telles5,4. 1Medical School, Universidade Federal de Minas Gerais, Locomotor Apparatus, Belo Horizonte, Brazil; 2Medical School, Universidade Federal de Minas Gerais, Post-graduation Programme, Belo Horizonte, Brazil; 3Medical School, Universidade Federal de Minas Gerais, Undergraduate student, Belo Horizonte, Brazil; 4Santa Casa de Misericórdia, Rheumatology Unit, Belo Horizonte, Brazil; 5Medical School, Universidade Federal de Minas Gerais, Internal Medicine, Belo Horizonte, Brazil

**Background:** Health-related quality of life (HRQoL) can be negatively impacted by visible skin lesions.1

**Objectives:** To investigate the effect of cosmetic camouflage on health-related quality of life of systemic lupus erythematosus (SLE) women presenting sequelae of cutaneous manifestations on the face.

**Methods:** This is a randomized controlled clinical trial (Universal Trial Number: U1111-1210-2554a) with outpatient SLE women according to ACR/1997 and/or SLICC/2012 criteria, aged over 18 years old with sequelae of cutaneous lupus manifestations on the face, recruited in two tertiary centers. Exclusion criteria were: moderate to severe systemic lupus activity (SLEDAI 2k-modified) & no understanding of the questionnaire or psychological or psychiatric treatment initiation or modification during the study. A total of 43 patients was divided into group I (cosmetic camouflage n=28) and group II (control n=15). Patients in group I were instructed to use cosmetic camouflage daily. Group II patients did not use any camouflage. SLE Quality of Life (SLEQoL) and Dermatology Quality of Life Index (DLQI) questionnaires were used to evaluate HRQoL, higher scores meaning worse HRQoL. All patients answered the questionnaires at baseline (T0) and after 12 ±2 weeks (T1). The primary end point was a change on HRQoL after camouflage cosmetic use. Continuous variables were described as median (interquartile range). Wilcoxon signed rank test and the Mann-Whitney U test were used for the analysis as indicated. End points were investigated per-protocol analysis, and a 2-sided p value <0.05 was considered to be significant.

**Results:** Both groups were similar at baseline regarding age [group I: 45.0 (37.3-55.7) years old versus group II: 50.0 (43.0-55.0) years old, p=0.575], disease duration [group I: 17.5 (7.3-26.5) years versus group II: 15.9 (9.0-17.0) years, p=0.452] and modified SLEDAI-2K [group I: 0 (0-2) versus group II: 2 (0-2), p=0.301]. Also, they were similar considering the sociodemographic, clinical and treatment characteristics of the disease. The SLEQoL and DLQI scores decreased in the cosmetic camouflage group from baseline: DLQI [T0: 8.5 (4.0-16.0) versus T1: 3.0 (1.0-7.5), p=0.008]; SLEQoL [T0: 118.0 (91.0-154.3) versus T1: 95.5 (76.0-135.0), p=0.003]; while there was no variation in the control group: DLQI [T0: 8.9 (5.0-12.0) versus T1: 7.0 (4.0-12.0), p=0.196]; SLEQoL [T0: 89.0 (65.0-127.0) versus T1: 95.5 (65.0-164.0), p=0.036]. The difference on the variations of HRQoL scores between groups I and II was statistically significant: DLQI [group I: -3.0 (-10.8-0.0) versus group II: 1.0 (-1.0-6.0), p=0.003] and SLEQoL [group I: -14.5 (-33.0-0.0) versus group II: 3.0 (-8.0-10.0), p=0.039]. The SLEQoL score variations were on physical function (p=0.033), humor (p = 0.033) and self-image (p=0.031) domains.

**Conclusion:** In this group of SLE women with low systemic disease activity and sequelae of cutaneous manifestations on the face, we observed an improvement of HRQoL after daily use of cosmetic camouflage. It is an effective intervention that should be recommended by rheumatologists.

THE EFFECTS OF ACUPUNCTURE ON XEROSTOMIA, XEROPHTHALMIA AND ANTIBODY MODIFICATION IN PATIENTS WITH SJÖGREN SYNDROME: A META-ANALYSIS

Tzu-Hao Li1,2,3,4, Yen-Ying Kung1,2,4, Chang-Youh Tsai1,2,4. 1Division of Allergy, Immunology, and Rheumatology, Department of Medicine, Chiayi Branch, Taichung Veterans General Hospital, Chiayi City, Taiwan, Republic of China; 2Institute of Clinical Medicine, National Yang-Ming University, Taipei City, Taiwan, Republic of China; 3Faculty of Medicine, National Yang-Ming University, Taipei, Taiwan, Republic of China; 4Center for Traditional Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China; 5Division of Allergy, Immunology, and Rheumatology, Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan, Republic of China

**Background:** Xerostomia and xerophthalmia are common chief complaints among patients with Sjögren syndrome (SS) but there has been no satisfying pharmacy to relieve the associated symptoms; hence the effectiveness of other non-pharmacological interventions such as acupuncture should be accessed.

**Objectives:** To access the therapeutic effects of acupuncture on xerostomia and xerophthalmia in patients with SS.

**Methods:** We conducted a meta-analysis of randomized clinical trials (RCTs) which evaluated the effectiveness of xerostomia and xerophthalmia in SS. PubMed, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), Chongqing Weipu Database (CDVIP), China Academic Journal Full-text Database, AntiLibrary, Chinese Electronic Periodicals Service (CEPS), China National Knowledge Infrastructure (CNKI) Database were searched through Oct, 2018 to select studies. Data for evaluation of subjective and objective xerostomia was extracted and was assessed with random-effects meta-analysis.

**Results:** After searching, a total of 680 references were yielded and five RCTs were included, covering 460 patients dry mouth resulted from SS, among whom 229 patients received acupuncture and 231 patients were control group. Acupuncture group was associated with higher subjective response rate (odds ratio 3.036, 95% confidence interval [CI] 1.828 – 5.042, P < 0.001, Fig. 1) and increased salivary flow rate (weighted mean difference [WMD] 3.066, 95% CI 2.969 – 3.164, P < 0.001, Fig. 2), as an objective marker. Regarding xerophthalmia, acupuncture group revealed less dry eye visual analog scale (VAS, WMD -1.035, 95% CI -1.457 - -1.673, P < 0.001, Fig. 3), and better Schirmer test (WMD 2.357, 95% CI 1.021 – 3.692, P = 0.001, Fig. 4) and trend of longer break-up time (WMD 4.927, 95% CI -0.055 – 9.908, P = 0.053, Fig. 5). In addition, two studies examined IgG levels, which were lower in the acupuncture group (WMD -166.857, 95% CI -233.138 – -100.576, P < 0.001, Fig. 6).

**Conclusion:** In the present meta-analysis, acupuncture improves both subjective and objective markers of xerostomia and xerophthalmia in patients with SS and is considered as an option of non-pharmacological treatment.

IMMUNOREGULATORY THERAPY EFFECTIVELY PROMOTES THE BALANCE BETWEEN TREG CELLS AND PRO-INFLAMMATORY LYMPHOCYTES IN SYSTEMIC LUPUS ERYTHEMATOSUS

Xiaojie Li1,2, NaLin Li1,3, Ting Cheng1,2, Xiaojuan Mao1, Li Xiaofeng1. 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 3The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

**Background:** Recent studies have reported that some drugs such as low-dose interleukin-2, rapamycin, metformin, retinoid acid and coenzyme Q10 could promote the proliferation and functional recovery of regulatory T cells (Treg) in patients with autoimmune diseases. However, the effects on the balance of Treg cells and pro-inflammatory lymphocytes and long-term efficacy have rarely been reported.

**REFERENCES**

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.1765
Objectives: To evaluate the changes of peripheral lymphocyte subsets, conventional drugs and remission rate in patients with systemic lupus erythematosus (SLE) after immunomodulatory therapy.

Methods: A total of 89 patients with SLE from the Second Affiliated Hospital of Shanxi Medical University from January 2016 to April 2018 were enrolled, who were divided into well-controlled group and untargeted control group taking a full consideration of the patient’s symptoms, signs and related laboratory findings. We measured the absolute counts of B, NK, CD8+T and helper T 1 (Th1), helper T 2 (Th2), helper T 17 (Th17) and Treg cells in peripheral blood of patients before immunomodulatory therapy and during the 3 months and 6 months of follow-up and 93 sex- and age- matched control individuals using flow cytometry. Moreover, the ratios of various cells to Treg cells were calculated.

Results: Compared with healthy controls, Treg cells in SLE patients were significantly lower before the treatment with immunomodulator, while the ratios of various pro-inflammatory lymphocytes to Treg cells (such as Th2/Treg, Th17/Treg, CD8+T/Treg, etc.) were higher. After 3 months and 6 months with immunomodulatory therapy, the absolute number of Treg cells in peripheral blood of SLE patients increased obviously reaching to normal level. Accordingly, the ratios of various pro-inflammatory lymphocytes to Treg cells recovered. At the same time, the dose of glucocorticoid and disease-modifying antirheumatic drugs (DMARDs) decreased distinctly. Additionally, the well-controlled group was able to maintain a high remission rate, and the untargeted control group could achieve a higher response rate after immunomodulatory treatment.

Conclusion: The imbalance between pro-inflammatory lymphocytes and Treg cells caused by the significant decrease of Treg cells may be the main cause of SLE. And immunomodulatory therapy we came up with may reverse the imbalance of proinflammatory lymphocytes and Treg cells, and which is a potential and effective treatment for SLE.

AB0471 VITAMIN D SUPPLEMENTATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH VITAMIN D DEFICIENCY AND INSUFFICIENCY: THE EFFECT ON DISEASE ACTIVITY, FATIGUE AND INTERFERON SIGNATURE GENE EXPRESSION
Rosalie Magro1, Christian Saliba2, Libero Camilleri2, Christian Serrin2, Andrew Borg1,1 Mater Dei Hospital, Rheumatology, Msida, Malta; 2University of Malta, Msida, Malta

Background: Vitamin D deficiency is highly prevalent among patients with systemic lupus erythematosus (SLE) [1]. Evidence from multiple studies has shown that vitamin D deficiency in SLE is associated with a higher disease activity [2]. There is conflicting evidence with regards to the relationship between fatigue and vitamin D level [3,4].

Objectives: The principal aim of this study was to establish any potential effect on the level of fatigue, disease activity (measured by SLE disease activity index-2K (SLEDAI-2K)) and interferon signature gene expression, from vitamin D supplementation to SLE patients with vitamin D deficiency or insufficiency.

Methods: 33 SLE patients, 13 with vitamin D deficiency and 20 with vitamin D insufficiency, gave informed consent to participate in this 12 month prospective study. Their participation consisted of an interview, filling of the Fatigue Severity Scale (FSS), and blood tests. The patients were advised to take vitamin D3 8000IU daily for 8 weeks if they were vitamin D deficient, or 8000IU daily for 4 weeks if they were insufficient. This was followed by 2000IU daily maintenance. The patients were reassessed after 6 and 12 months of vitamin D supplementation. RNA was extracted from whole blood taken from the patients at baseline and after 6 months of vitamin D supplementation. The expression of 12 interferon signature genes was measured in the extracted RNA by using Quant-it Gene Plex technology. Approval to carry out this study was obtained from the University Research Ethics Committee.

Results: 87.9% of SLE patients studied were female. The mean age was 47.6 years and the mean duration of SLE was 13.8 years. Table 1 shows the results obtained for several variables at baseline, after 6 months and after 12 months. The expression of all 12 interferon signature genes measured, was noted to decrease following 6 months of vitamin D supplementation. This reached statistical significance for two of the genes measured (OAS1, p=0.014; SOCS51, p=0.003).

Table showing results at baseline, after 6 months and after 12 months of vitamin D3 supplementation.

Abstract AB0471 Table 1. Table showing results at baseline, after 6 months and after 12 months of vitamin D3 supplementation.

Conclusion: The results indicate that vitamin D supplementation in SLE patients who are deficient or insufficient, results in an improvement in disease activity, and possibly also in the level of fatigue. This could be explained by the decrease in the expression of interferon signature genes.

PRIMARY SJÖGREN SYNDROME ASSOCIATED INTERSTITIAL LUNG DISEASE: FEATURES, TREATMENT AND OUTCOME OF A MONOCENTRIC COHORT

Andrina Manfredi1, Marco Sebastiani1, Caterina Vacchi1, Fabrizio Luppi2, Stefania Cerri1, Giulia Cassone3, Carlo Salvarani1,3 1University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria PoliChirurgical of Modena, Modena, Italy; 2University of Milan-Bicocca, San Gerardo Hospital, Monza, Italy; 3IRCCS Arcispedale Santa Maria Nuova, Azienda Unità Sanitari Locali-IRCCS di Reggio Emilia, Reggio Emilia, Italy

Background: Primary Sjögren’s syndrome (pSS) is an autoimmune systemic disease characterized by lymphocytic infiltration of exocrine glands, mainly resulting in dysfunction of salivary and lacrimal glands and symptomatic xerostomia and xerophthalmia. About one third of patients also present extra-glandular manifestations and, among them, interstitial lung disease (ILD) is one the most frequent, occurring in about 10–20% of patients. ILD is associated with an impaired quality of life and physical capacity and to a reduced 10-year survival. Despite it seems to be more frequently detected in late stages of the disease, some authors suggest that ILD can be diagnosed before pSS in 20% of cases. Main predictive factors of progression of pSS-ILD have not been clearly investigated in previous studies and no evidence-based treatment is defined for these patients.

Objectives: To describe the clinical and serologic features and the outcome of a monocentric cohort of pSS-ILD and the possible differences between patients treated or not with immunosuppressive treatment

Methods: We retrospectively evaluated the 37 pSS-ILD patients followed at our Rheumatology Unit (male/female ratio 1/6.4, mean age 69.6±11.3 years, mean disease duration of pSS 5±5.2 years).

Among them, 18 patients (48.6%; group 1) underwent immunosuppressive treatment because of lung disease, namely mycophenolate mofetil (9 patients, 50%), cyclophosphamide (3, 16.7%), azathioprine (5, 27.8%), high dose steroids (1, 5.6%), while 19 patients were not treated (group 2).

Results: No significant differences were observed in regard of age, male/ female ratio, and disease duration of ILD and pSS, while a significant difference was observed regarding the lung function of the 2 groups; the forced vital capacity (FVC) and the diffusion lung capacity of CO (DLCO) at baseline were significantly lower in the group 1 (FVC 78.6% vs 99.4% p=0.008; DLCO 45.7% vs 56.9%, p=0.025; in group 1 and group 2, respectively). No significant difference was observed between baseline and follow-up for FVC and DLCO in both groups, regardless the immunosuppressive drug (fig. 1). At the end of follow-up FVC increased, decreased and remained stable in 5.3% vs 10.5/84.2% and 16.7±27/855.6%, in group 1 and group 2, respectively; DLCO increased, decreased and remained stable in 10.5/21/168.4% of group 1, while remained stable or decreased in 61.1 and 38.9 of treated patients, respectively (fig. 1).

Conclusion: At our knowledge, few studies have investigated the features of pSS-ILD and the role of immunosuppressive drugs in these patients. Our data suggest that the decline of lung function is one of the most significant parameters to guide the prescription of immunosuppressive drugs, but no differences can be observed according to the treatment in term of effectiveness. However, no studies have investigated the correctness of this approach or the efficacy of the MMF or GEX in pSS-ILD. Our study is strongly limited by the retrospective design and the low number of patients evaluated, but these data set attention on this unmet need. Further prospective studies are mandatory to clarify the impact of ILD in pSS patients and the correct therapeutic approach.

AB0473 HYPOGAMMAGLOBULINEMIA AND INFECTIONS IN RHEUMATOLeAT PATIENTS TREATED WITH RITUXIMAB

Andres Fierro1, Mariano Andres2, Jenny de la Torre-Aboí2, Paloma Vela-Casasempere3, Maria Paz Martinez-Vidal4, Universidad Miguel Hernández, Faculty of Medicine, Alicante, Spain; 2Hospital General Universitario de Alicante, Alicante, Spain; 3Hospital General Universitario de Alicante, Alicante, Spain; 4Hospital General Universitario de Alicante, Alicante, Spain

Background: Treatment with rituximab (RTX) for rheumatologic diseases may produce hypogammaglobulinemia (hygoglob) (1,2), and that way increase the risk to acquire certain infections (3,4). There are no established guidelines to evaluate and treat hygoglob in these patients. In our hospital, the percentage of patients who develop hygoglob and severe infections is unknown.

Objectives: To analyse the effect of RTX on immunoglobulin (lg) levels and to evaluate the severe infections and hepatitis B reactivations that could be related to this treatment.

Methods: This is a descriptive, retrospective study of patients followed up in the Rheumatology Unit of the Alicante General University Hospital (HGUA) who had received at least one course of RTX. Clinical characteristics and laboratory parameters were obtained from the electronic charts: type of disease, posology and total amount of RTX, lg levels before and after treatment with RTX, the concomitant treatment with disease-modifying drugs (DMDs), hepatitis B virus’s (HBV) reactivations and infections that required hospitalization. Hygoglob was assessed when IgG < 750 mg/dl, and severe hygoglob if IgG < 450 mg/dl. The association of hygoglob with disease and treatment’s aspects was studied by t-Student, U-Mann-Whitney and Chi-2. Multiple logistic regression was conducted to study the independent risk factors associated with hygoglob. The study was approved by the Hospital Ethics Committee.

Results: Finally 106 patients were included, 85 women (80.2%) and 21 men (19.8%). The more frequent conditions were rheumatoid arthritis (47.2%), Sjögren syndrome (16%), Systemic Lupus Eritematosus (13.2%), vasculitis (6.6%) and other connective tissue diseases (10.4%). Characteristics of the sample are shown in table 1. A correct follow up of the Ig levels during the treatment was shown to be undergone in 87.7% of the cases. It was found that 35.8% of the patients presented hygoglob and 13.2% presented severe infections after receiving RTX. No HBV reactivations were found. Among the patients with hygoglob, 78.9% received concomitant treatment with other immunosuppressants (methotrexate 23.6%, leflunomide 23.6%). Hygoglob was more frequent in rheumatoid arthritis (44%), lupus (42.8%) and vasculitis (28.6%). Through simple logistic regression hygoglob during treatment was associated with the presence of previous hygoglob (p=0.005), higher doses received (p=0.001) and longer treatment (p=0.003). In the multiple logistic regression, only low levels of Ig before treatment turned out to be an independent risk factor for hygoglob during treatment (OR 6.86; IC 1.25-37.57). The IgM and IgA levels, but not the IgG levels were significantly lower in patients who has severe infections.

Disclosure of Interests: None declared

AB0474 COHORT INTERSTITIAL LUNG DISEASE: FEATURES, TREATMENT AND OUTCOME OF A MONOCENTRIC COHORT

1Universidad Miguel Hernández, Faculty of Medicine, Alicante, Spain; 2Hospital General Universitario de Alicante, Alicante, Spain

Background: To describe the clinical and serologic features and the outcome of a monocentric cohort of pSS-ILD and the possible differences between patients treated or not with immunosuppressive treatment

Methods: We retrospectively evaluated the 37 pSS-ILD patients followed at our Rheumatology Unit (male/female ratio 1/6.4, mean age 69.6±11.3 years, mean disease duration of pSS 5±5.2 years).

Among them, 18 patients (48.6%; group 1) underwent immunosuppressive treatment because of lung disease, namely mycophenolate mofetil (9 patients, 50%), cyclophosphamide (3, 16.7%), azathioprine (5, 27.8%), high dose steroids (1, 5.6%), while 19 patients were not treated (group 2).

Results: No significant differences were observed in regard of age, male/ female ratio, and disease duration of ILD and pSS, while a significant difference was observed regarding the lung function of the 2 groups; the forced vital capacity (FVC) and the diffusion lung capacity of CO (DLCO) at baseline were significantly lower in the group 1 (FVC 78.6% vs 99.4% p=0.008; DLCO 45.7% vs 56.9%, p=0.025; in group 1 and group 2, respectively). No significant difference was observed between baseline and follow-up for FVC and DLCO in both groups, regardless the immunosuppressive drug (fig. 1). At the end of follow-up FVC increased, decreased and remained stable in 5.3% vs 10.5/84.2% and 16.7±27/855.6%, in group 1 and group 2, respectively; DLCO increased, decreased and remained stable in 10.5/21/168.4% of group 1, while remained stable or decreased in 61.1 and 38.9 of treated patients, respectively (fig. 1).

Conclusion: At our knowledge, few studies have investigated the features of pSS-ILD and the role of immunosuppressive drugs in these patients. Our data suggest that the decline of lung function is one of the most significant parameters to guide the prescription of immunosuppressive drugs, but no differences can be observed according to the treatment in term of effectiveness. However, no studies have investigated the correctness of this approach or the efficacy of the MMF or GEX in pSS-ILD. Our study is strongly limited by the retrospective design and the low number of patients evaluated, but these data set attention on this unmet need. Further prospective studies are mandatory to clarify the impact of ILD in pSS patients and the correct therapeutic approach.
Patients with hypogammaglobulinemia in a third of the patients who received RTX, especially in those who have low previous IgG levels; therefore a follow up during the treatment should be encouraged. Low IgM and IgG levels during the treatment could also be associated with severe infections.

**MORTALITY ACROSS RITUXIMAB-TREATED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM THE BRITISH ISLES LUPUS ASSESSMENT GROUP (BILAG) REGISTRY**

Aysun Aksoy1,2, Stephen McDonald3,4, Eoghan McCarthy4, Ben Parker3,4, Ian N Bruce1,2, British Isles Lupus Assessment Group. 1Marmara University Faculty of Medicine, Division of Internal Medicine, Department of Rheumatology, Istanbul, Turkey; 2University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; 3University of Manchester, NIHR Manchester BRC, Manchester, United Kingdom; 4Manchester University Foundation Trust, The Kellgren Centre, Manchester, United Kingdom

**Background:** Mortality in Systemic Lupus Erythematosus (SLE) is elevated compared to the general population. Previously we have demonstrated improved disease control in response to Rituximab (RTX) therapy in a cohort of refractory SLE patients.

**Objectives:** To investigate mortality in refractory SLE patients treated with RTX and identify risk factors that may be associated with death.

**Method:** All patients recruited to the BILAG-BR (both RTX treated and standard care-SOC) were included from initial study visit to death or 3 years post last treatment change. Demographics, concurrent medication use, disease activity (BILAG/SLEDAI) and damage scores (SLICC-DI) were recorded. Information regarding mortality was collected from study centres and NHS digital mortality registries. Baseline demographic data are presented using descriptive statistics. Testing for association was performed using Stata (version 14).

**Results:** 830 patients were included (715 RTX-treated, 115 standard therapy). RTX-treated patients tended to have longer disease duration (10 vs 6.5 years respectively) and were more likely to have active musculoskeletal disease (% BILAG A or B: 39 vs 23%). Rates of renal (11% vs 16%) and neurological disease (12% vs 9%) were comparable between groups as were baseline SLICC-DI and SLEDAI scores. 33 deaths were reported. 28 (3.9%) RTX-treated patients (1.2 deaths/100 pt yrs follow up) and 5 (4.3%) non-RTX patients (1.5 deaths/100 pt yrs follow up).

**Conclusion:** Decompensation of cardiovascular risk factors, higher steroid doses, hypogammaglobulinemia and renal disease. Active management of these risk factors may lead to improved mortality outcomes.

**Background:** Belimumab is a human IgG1 monoclonal antibody directed against BAFF, a B lymphocyte survival factor. It is indicated as adjuvant treatment in adult patients with active systemic lupus erythematosus (SLE), with positive autoantibodies and with a high degree of activity of the disease despite standard treatment.

**Objectives:** To describe a sample of patients diagnosed with SLE who received treatment with belimumab in a tertiary hospital.

Methods: Retrospective longitudinal unicentric observational study. Clinical records of all patients diagnosed with SLE who had received treatment with belimumab were reviewed. Demographic characteristics, clinical manifestations and reason for belimumab indication were collected.

Results: The twelve patients included in the sample were women. Median age was 48.5 years (31-70). The most frequent reason for indication of belimumab was uncontrolled arthritis. The average time of treatment with belimumab in the total sample was 27.5 (+/-26.24) months, with a median of 12 months (4-78). Mean treatment time (cases in which belimumab was discontinued excluded) was 31.25 (+/-26.98) months with a median of 25 (5-78). The average dose reduction of prednisone after initiation of treatment with belimumab (in patients in which it was considered effective) was 5 mg per day (+/- 5). It should be noted that of the 14 cases, treatment was only discontinued in 4 patients, 2 of which were withdrawn due to ineffectiveness. There were 2 adverse events that required drug withdrawal: neutropenia and urethral carcinoma. (Table).

Conclusion: BLM is a well tolerated drug and effective in clinical practice. Adverse effects leading to drug withdrawal are infrequent.

AB0476 SPECIAL ASPECTS OF GLUCOCORTICOID THERAPY IN PATIENTS WHO TREATED WITH ANTI-B-CELL AND ANTI-BLYS THERAPY

Anna Mesnyankina, Sergey Solovyev, Elena Aseeva, Evgeny Nasonov. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The basis of treatment of SLE are glucocorticoids (GCs), which since their introduction into clinical practice, have led to increased survival and reduced early mortality of SLE patients. However, the need to use high doses of GCs, as well as long-term use of medium doses to maintain disease remission, leads to the development of serious adverse reactions. This leads to an increase in the risk of irreversible organ damage. In this regard, it is important to search for ways to prevent the use of high doses of GCs, minimizing the dose of GCs.

Objectives: To assess special aspects and dynamics of oral glucocorticoid (GC) therapy in SLE patients treated with anti-B-cell and anti-Blys therapy.

Methods: The study included 64 SLE pts (51/58F), divided into 3 groups: Group I - 47 patients (SLEDAI2K 16[11;20] scores), receiving rituximab (RTX) iv infusions by drop at 500 - 2000 mg dose-range. Group II included 10 patients (SLEDAI2K 10[8;11] scores) treated with Belimumab (BLM) at 10 mg/kg once a month. The remaining 7 patients from Group III (SLEDAI2K 10[9;16] scores) were administered a combination of RTX and BLM. They started treatment with RTX 500 (2 patients) or 1000 mg (5 patients) infusions, and 3 months later BLM at standard scores at 10 mg/kg once a month was initiated for 8 months. SLICC damage index (DI) was documented at baseline - before initiation of RTX and BLM - in 26 out of 64 patients (40%) with SLICC DI score > 1 (1 - 5 scores); 20 patients out of them were administered RTX.

Results: 47 patients on RTX therapy received different oral GCs doses: high GCs doses (Me 40[30;50]mg/day) were documented in 11 (24%) patients, moderate doses (Me 13[10;20]mg/day) – in 29 (61%) patients, and low doses (Me 5[5;7.5]mg/day) - in 7 (15%) patients. Patients on BLM and combination therapy were administered GCs at doses ≤ 20 mg (Me 15[5;20]mg/day and Me 8.75[5;15] mg/day, respectively). During first 3 month of treatment GCs doses in all 3 Groups remained unmodified. By Mo 6 25% reduction in oral GCs doses was documented in: patients on RTX - 20[15;20]mg/day, 12[8;15;20]mg/day, 5[5;5] mg/day (respectiveiy, in the groups with initially high, moderate and low GCs doses); BLM 10[7;5;10] mg/day, combination therapy 8.75[5;15] mg/day. By Mo 12 Me GCs doses in all 3 Groups did not exceed 10 mg/day. In doses); BLM 10[7,5;10] mg/day, combination therapy 8,75[5;15] mg/day. Unmodified. By Mo 6 25% reduction in oral GCs doses was documented During first 3 month of treatment GCs doses in all 3 Groups remained unmodified. By Mo 6 25% reduction in oral GCs doses was documented in: patients on RTX - 20[15;20]mg/day, 12[8;15;20]mg/day, 5[5;5] mg/day (respectively, in the groups with initially high, moderate and low GCs doses); BLM 10[7;5;10] mg/day, combination therapy 8.75[5;15] mg/day. By Mo 12 Me GCs doses in all 3 Groups did not exceed 10 mg/day. In decreases in SLICC score by Mo 12 of follow up was documented in patients on RTX therapy with baseline pre-existing organ damage (5 patients). There was no increase in SLICC scores in BLM and RTX +BLM treatment groups.

Conclusion: Combination therapy results in achieving rapid control of SLE activity thanks to RTX effects, and the combination with BLM allows significantly prolongs this result, minimizing the risk of exacerbation. And a very specific gain from combination RTX+BLM therapy is a chance to manage patients on moderate-to-low oral GCs doses, therefore, reducing the risk of irreversible organ damage. Increasing organ damage score in RTX Group is most likely associated with intake of higher GCs doses.

Figure 1. The dose of oral GCs in patients treated with RTX, BLM and combined treatment, Me.

AB0477 THE EFFECT OF CLOSTRIDIUM BUTYRICUM ON INTESTINAL FLORA OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ZHANG MINGXING1, XU-FANG YIN1, XIAO-FENG L1

zhenga mingxing1, Xu-Fang Yin1, Li-Xiao Feng2.1The Second Hospital of Shanxi Medical University, Taiyuan, China; 2The Second Hospital of Shanxi Medical University, Taiyuan, China Objectives: To investigate the effect of Clostridium butyricum on intestinal flora in patients with systemic lupus erythematosus.

Methods: Forty-four patients with systemic lupus erythematosus who were randomly selected from our hospital were given the oral administration of Clostridium butyricum live capsule 840mg twice a day. The concentration of methane and hydrogen at each time point before and after treatment for 44 patients was detected and compared by hydrogen and methane in breath test (LBT).

Results: After 28 days of treatment with Clostridium butyricum capsules, there was no significantly statistical difference in exhaled hydrogen concentration or methane concentration between 0 min, 30 min, 60 min and 90 min before and after treatment. See Table 1.

Conclusion: Numerous studies have shown that taking probiotics can promote the growth of normal flora and reduce the reproduction of other abnormal flora, which has a certain impact on the structure and quantity of There was no significantly statistical difference in exhaled hydrogen concentration or methane concentration at various points in time between the 44 patients before and after treatment, suggesting that there was no significant change in the structure and quantity of intestinal flora. Intestinal flora, which may be resulted from our low dose Clostridium butyricum live capsules or short treatment time, or need to be combined with other probiotics. These hypothesis above need us to further explore, in general, using microbes as a therapeutic target spot to regulate the illness of SLE by interfering with intestinal flora through diet, probiotics or fecal transplantation provides a promising prospect for clinical treatment of SLE. There was no significantly statistical difference in exhaled hydrogen concentration or methane concentration between 0 min, 30 min, 60 min and 90 min before and after treatment. See Table 1.

Conclusion: Numerous studies have shown that taking probiotics can promote the growth of normal flora and reduce the reproduction of other abnormal flora, which has a certain impact on the structure and quantity of There was no significantly statistical difference in exhaled hydrogen concentration or methane concentration between 0 min, 30 min, 60 min and 90 min before and after treatment. See Table 1.

Conclusion: Numerous studies have shown that taking probiotics can promote the growth of normal flora and reduce the reproduction of other abnormal flora, which has a certain impact on the structure and quantity of There was no significantly statistical difference in exhaled hydrogen concentration or methane concentration between 0 min, 30 min, 60 min and 90 min before and after treatment. PREGNANCY OUTCOME IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH HYDROXYCHLOROQUINE: 10 YEARS EXPERIENCE

Kyaw Min Tun, Rahana Rahman, Ixora Kamisan @ Atan, Ani Amelia Zainuddin, Ruslinda Mustafar, Mohd Shahrir Mohamed Said, Universiti Kebangsaan Malaysia Kuala Lumpur Campus, Kuala Lumpur, Malaysia

Background: Pregnancy in women with Systemic Lupus Erythematosus is closely associated with the usage of hydroxychloroquine [1]. Objectives: To determine pregnancy outcomes in women with Systemic Lupus Erythematosus who had antenatal follow up and delivery in Universiti Kebangsaan Malaysia Medical Centre.

Methods: Pregnant women with Systemic Lupus Erythematosus who had antenatal follow up and delivery in Universiti Kebangsaan Malaysia Medical Centre between 1st January 2007 and 1st January 2017 were retrospectively analyzed. Data collection was done via medical case notes and laboratory investigations. Study population was categorised into two groups based on hydroxychloroquine treatment during pregnancy. Incomplete pregnancy records were excluded.

Results: There were 82 completed pregnancies included with 47 (57.3%) in HCQ group and 35 (42.7%) in non HCQ group. Amongst HCQ users, there were significantly more pregnancies with musculoskeletal involvement (p=0.03), heavier mean neonatal birth weight (p=0.02) and prolonged duration of pregnancy (p=0.001). In non-HCQ users, the rate of recurrent miscarriages (p=0.003), incidence of hypertension (p=0.01) and gestational diabetes mellitus (p=0.01) and concurrent medical illness (p=0.005) were significantly more. Hydroxychloroquine use during pregnancy was protective against hypertension (p=0.001) and the gestational age at delivery had significant effect on the neonatal birth weight (p=0.001). However, duration of the disease had significant negative effect on the neonatal birth weight (p=0.016).

Conclusion: HCQ enhance better neonatal outcomes and reduce adverse pregnancy outcome and antenatal complications such as hypertension and diabetes.

PROLONGED CLINICAL REMISSION AND LOW DISEASE ACTIVITY STATUS ARE ASSOCIATED WITH BETTER QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Nareerat Poomsalood, Sumapa Chaiamnuay, Pongthorn Narongroeknawin, Pajjil Asovalanabodee, Rattapol Pachotalan, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

Background:
To treat target (T2T) strategies in systemic lupus erythematosus (SLE) have been developed in order to control disease activity, improve health-related quality of life (HRQoL), reduce organ damage and decrease mortality. Previous studies revealed that both remission and low disease activity (LDA) had comparable damage accrual as well as mortality. However, studies of HRQoL in these two targets are few and there has been no comparative study between them.

Objectives: To determine the association between disease activity status (DAS) and HRQoL in SLE patients.

Methods: SLE patients in out-patient clinic during the previous 12 months were included in the study. Systemic Lupus Erythematosus-specific Quality-of-Life questionnaire (SLEQoL) was measured at the last visit. DAS was determined retrospectively during the previous year. Three categories of DAS were defined: clinical remission (CR); clinical quiescent disease according to Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), prednisolone < 5 mg/day; low disease activity (LDA): SLEDAI-2K (without serological domain) ≤ 2, prednisolone < 7.5 mg/day; and non-optimally controlled status: those who were not in CR/LDA. Immunosuppressive drugs (maintenance dose) and antimalarials were allowed. Both CR and LDA have been maintained for at least 1 year. The

PROLONGED CLINICAL REMISSION AND LOW DISEASE ACTIVITY STATUS ARE ASSOCIATED WITH BETTER QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Nareerat Poomsalood, Sumapa Chaiamnuay, Pongthorn Narongroeknawin, Pajjil Asovalanabodee, Rattapol Pachotalan, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

Background:
To treat target (T2T) strategies in systemic lupus erythematosus (SLE) have been developed in order to control disease activity, improve health-related quality of life (HRQoL), reduce organ damage and decrease mortality. Previous studies revealed that both remission and low disease activity (LDA) had comparable damage accrual as well as mortality. However, studies of HRQoL in these two targets are few and there has been no comparative study between them.

Objectives: To determine the association between disease activity status (DAS) and HRQoL in SLE patients.

Methods: SLE patients in out-patient clinic during the previous 12 months were included in the study. Systemic Lupus Erythematosus-specific Quality-of-Life questionnaire (SLEQoL) was measured at the last visit. DAS was determined retrospectively during the previous year. Three categories of DAS were defined: clinical remission (CR); clinical quiescent disease according to Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), prednisolone < 5 mg/day; low disease activity (LDA): SLEDAI-2K (without serological domain) ≤ 2, prednisolone < 7.5 mg/day; and non-optimally controlled status: those who were not in CR/LDA. Immunosuppressive drugs (maintenance dose) and antimalarials were allowed. Both CR and LDA have been maintained for at least 1 year. The
association between DAS and HRQoL was assessed by using multiple linear regression analysis adjusting for other covariates.

Results: Of 237 SLE patients (pts), 100 pts (42.2%) achieved prolonged CR, 46 pts (19.4%) achieved prolonged LDA, and 91 pts (38.4%) were not in CR/LDA. Non-CR/LDA pts had significantly higher total SLEQoL score and in all domains compared with CR/LDA pts. No significant difference in SLEQoL domain scores was found between CR and LDA groups. Multivariable analysis revealed that non-CR/LDA was positively associated with SLEQoL score compared with CR/LDA (β = 0.27, 95% confidence interval (CI) 0.52-0.03, p < 0.001). Moreover, non-CR/LDA was at a higher risk of impaired QoL (SLEQoL score > 80) compared with CR (hazard ratio (HR) 3.3; 95% CI 1.82-7.95, p < 0.001). However, there was no significant difference between CR and LDA in terms of SLEQoL score or impaired QoL. Other factors associated with higher SLEQoL score were damage index (β 10.55, 95% CI 4.63-16.48, p = 0.001) and anemia (β 27.84, 95% CI 8.48-47.19, p = 0.001).

Conclusion: Prolonged CR and LDA are associated with better HRQoL in SLE patients and have a comparable effect. Prolonged CR or optional LDA may be used as the treatment goal of T2T approach in SLE.

AB0482 AUTOANTIBODIES’ TITRE MODULATION BY ANTI-BLYS TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS
Ilaria Cavazza\textsuperscript{1}, Rajesh Kumar\textsuperscript{2}, Salvatore Panaro\textsuperscript{3}, Chiara Pozzari\textsuperscript{2}, Roberta Ottaviani\textsuperscript{4}, Silvia Plantoni\textsuperscript{5}, Laura Andreoli\textsuperscript{1}, Angela Tincani\textsuperscript{1}, Franco Franceschini\textsuperscript{1}.
\textsuperscript{1}Rheumatology and Clinical Immunology, ASST Sperdai Civile, Brescia, Italy, Brescia, Italy. \textsuperscript{2}Rheumatology Chair, Clinical and Experimental Science Department, University of Brescia, Brescia, Italy, Brescia, Italy

Background: Belimumab is a human monoclonal antibody that inhibits soluble B lymphocytes stimulator (Blys) and represents the only biologic drug approved for Systemic Lupus Erythematosus (SLE) (1). Belimumab is effective in improving disease activity, blocking damage progression (2.3). Pooled data derived from clinical trials reported a reduction of anti-dsDNA analysed by ELISA, anti-cardiolipin IgG (aCL) and anti-Sm and anti-ribosomal protein antibodies (2,4). No data were published on anti-beta2-glycoprotein I (β2GPI) antibodies and other anti-ENA specificities.

Objectives: Our aim was to analyse the effect of Belimumab therapy on high avidity anti-dsDNA, aCL, anti-beta2GPI, and other relevant anti-ENA specificities.

Methods: 50 patients with active SLE (mean SLEDAI-2K score: 7±18; SD:3), with a mean age of 39 years (SD:11) and mean follow-up of 13 years (SD:7.8) were enrolled. Sera were collected at Belimumab starting (T0) and every 6 months until 24th month. Disease activity index (SLEDAI-2K) was collected at every timepoints. High avidity anti-dsDNA were detected by radioimmunological method, anti-ENA, anti-cardiolipin (aCL), anti-β2 glycoprotein I (anti-β2GPI) were analysed by ELISA.

Results: At baseline 86% of sera were positive for anti-dsDNA, 50% for anti-ENA, 26% for aCL and 28% for anti-β2GPI. Anti-dsDNA became negative in 21%, anti-beta2GPI IgG in 33% and aCL IgG in 30% of sera, mostly at T6. Among anti-ENA, 610% (60%) anti-ribosomal and 317% (17.6%) anti-Sm positive sera became negative. A significant decrease of anti-dsDNA and anti-beta2GPI IgM titers were observed at all timepoints. IgG aCL titre showed significant decrease only at T18. Anti-ribosomal showed a significant titre decrease at T6 and T12, with seroconversion to negative at T18. Anti-Sm titre significantly dropped down at T6, then remained stable during time. A significant correlation between anti-dsDNA and anti-ribosomal titre, and between SLEDAI ratio (SLEDAI value/SLEDAI T0) and anti-ribosomal titer ratio (value/value T0) were found.

Conclusion: Belimumab treatment induced a significant reduction of SLE-specific autoantibodies titre and IgM anti-beta2GPI. Anti-ribosomal titre decrease correlates with anti-dsDNA titre and improvement of disease activity.

A SYSTEMATIC LITERATURE REVIEW ON THE USE OF BIOLOGICS IN SJÖGREN’S SYNDROME

Asaad Qadri1, Syed Mubbala Bilgramii, Marwan Bukhari1

1Rheumatology Department, Rheumatology Department, Royal Lancaster Infirmary Hospital, Lancaster. 2Lancaster University, Medical School, Lancaster, United Kingdom; 2Royal Lancaster Infirmary Hospital, Rheumatology, Lancaster, United Kingdom

Background: Primary SJögren’s syndrome (pSS) is a systemic chronic autoimmune disease characterized by dryness of the eyes and mouth. Current treatments provide modest benefit, leaving patients with limited therapeutic options. The pathophysiology of pSS involves hyperactivity of autoreactive lymphocytes. Biologic medications target mediators of the immune response. Modulation of autoimmunity in pSS with biologics has gained interest with open-label studies showing promising results.

Objectives: This review aims to conduct a systematic literature review of interventional studies investigating the efficacy of biologics in the treatment of pSS.

Methods: Literature was searched using the MEDLINE, EMBASE and PubMed databases as well as abstracts in EULAR, ACR and BSR.

Results: A total of twelve studies met the inclusion criteria. Infliximab and etanercept showed no significant improvements in fatigue and dryness in pSS compared to placebo. Anakinra showed improvement in fatigue after post-hoc analysis. Small trials in rituximab showed significant improvements in oral and ocular dryness but failed to replicate this in two larger randomised control trials. Belimumab significantly reduced overall disease activity which was driven by improvements in dryness and parotid gland swelling. Labelled studies in epratuzumab and abatacept showed significant reductions in fatigue with abatacept also improving salivary flow and swelling. Open-label studies in epratuzumab and abatacept showed significant reductions in fatigue with abatacept also improving salivary flow and swelling.

Conclusion: Intervention with biologics in pSS has shown efficacy in alleviating pSS-associated fatigue and dryness in small RTCs and open-label trials. Larger randomised placebo-controlled trials have been inconsistent in replicating these results. This may be overcome by subgroup analysis, uptake of validated disease activity measuring tools, well-defined selection criteria to increase sample size and further understanding of pathophysiology in pSS. The small number of trials to date means the evidence base for biologics in pSS remains inconclusive.

AB0484 EXPERIENCE WITH THE USE OF RITUXIMAB FOR THE TREATMENT OF SYSTEMIC AUTOIMMUNE DISEASES (SAD) IN A TERTIARY HOSPITAL

Víctor Manuel Sánchez Montagut, David Blanco Alba, Jose Ramón López Morales, Francisco Javier Nieto García, Santiago Rodríguez Suárez, Salvador García Morillo, Francisco José García Hernández, Juan Andreu Álvarez, Isabel Martin-Garrido, Virgen del Rocío University Hospital, Medicina Interna, Seville, Spain

Background: Rituximab is a chimeric anti-CD20 monoclonal antibody used in various clinical scenarios for the treatment of SAD, especially when immunocomplexes and/or lymohocyte B proliferation plays a central role.

Objectives: The objective of this study was to retrospectively assess the efficacy and safety of use of rituximab in a cohort of patients with SAD in a tertiary hospital within the last 12 years.

Methods: We carry out a retrospective study of 48 patients with a diagnosis of SAD in our Autoimmune and Minority Diseases Department using Google Sheets.

Results: Our cohort is mostly female (48 women and 8 men). The mean age is 40.9 ±13.1 years (median 38 years). It is composed of different SAD: rheumatoid systemic lupus (22), granulomatosis with polyangiitis (6), dermatomyositis (6), systemic sclerosis (1) foliaceus pemphigus (1), gangrenous pyoderma, (1) polymyositis (1) and orbital pseudotumor (1). The mean time from diagnosis to rituximab was 7.7±7.1 years. The efficacy of RTX in reducing disease activity after 6 month was 64.6% patients according to the disease recommended scales-. Nevertheless, 39% maintained 1 year remission.

The indications for rituximab were: persistant activity despite improvement of classical immunosuppressive strategies (36), corticosterone deficiency (4), new relapses (3), corticosteroid resistance and toxicity (others immunosuppressant) (2). The drugs used when rituximab was used: cyclophosphamide (24), hydroxychloroquine (21), mycophenolate mofetil or mycophenolic acid (20); cyclosporine (7), immunoglobulines (7), leflunomide (4), and methotrexate (8). 5 patients did not receive any immunosuppressant. 61.3% were taking at least 2 drugs. All of them were taking glucocorticoids. In terms of security and side effects, we observed 11 (22.9%) adverse reactions related to the administration. We detect 3 infusion reactions (mild severity), 1 severe mucocutaneous reaction, 1 moderate herpes zoster, 1 fungic invasive infection and 5 severe bacterial infections (1 of them lead to rituximab suspension). We did not detect any hepatitis B virus reactivation, multifocal progressive leukoencephalopathy, cytomegalovirus infections nor herpes simplex infections.

We observed 65 different haematologic adverse events: lymphopenia (34), anemia (15), neutropenia (12) and trombocytopenia (4). No one needed specific treatment.

Conclusion: Rituximab is a second line therapeutic alternative in patients with SAD in whom other treatments have failed. It is a effective drug that rescues a 65% of patients in whom other treatments have failed. Furthermore, rituximab is a safe immunosuppressant.

INTRAVENOUS HIGH DOSE GLUCOCORTICOIDS CAUSE PROLONGATION OF QT INTERVAL IN CONNECTIVE TISSUE DISEASE PATIENTS EXCEPT ANTI-RO POSITIVE SUBGROUP

Tomasz Spokuła, Jan Tomos, Radek Pudil, Jakub Simk, Lenka Pollák, Nikola Jurkova, Martin Dosedel, Jin Vucik, Charles University, Faculty of Medicine and University Hospital in Hradec Kralove, 2nd Department of Internal Medicine-Gastroenterology, Division of Rheumatology, Hradec Kralove, Czech Republic; Charles University, Faculty of Medicine and University Hospital in Hradec Kralove, Hradec Kralove, Czech Republic; Charles University, Faculty of Pharmacy in Hradec Kralove, Hradec Kralove, Czech Republic

Background: Recent literature indicates that anti-Ro antibodies may be associated with prolongation of corrected QT (QTc) interval in the adult patients with connective tissue diseases. Moreover, glucocorticoids (frequently used in the therapy) are known to probably induce electrocardiographic changes including prolongation of QT interval. Prolongation of QTc interval is a risk factor for malignant ventricular arrhythmias. We hypothesised that patients with anti-Ro positivity have a higher risk of QT prolongation especially in the case of high dose intravenous glucocorticoids (IVGC) treatment.

Objectives: The aim of the study was to analyse risk of QTc interval prolongation in anti-Ro and anti-La positive patients before and after high dose IVGC treatment in patients with connective tissue diseases.

Methods: We performed a retrospective study of 115 patients (21 males), mean age of 48±14.7 years, range 19-78 years with connective tissue diseases. Anti-Ro and anti-La antibodies were examined in all patients before IVGC treatment. The patients were given 5x1000 mg methylprednisolon i.v. during five consecutive days. ECG recording was performed at baseline and after IVGC. The QT intervals were measured in each of 12-lead standard ECGs from two consecutive cycles. The QT intervals were measured from the onset of QRS complex to the end of the T wave by the means of a tangential method. Fridericia formula was used to obtain heart rate-corrected values for QT intervals.

Results: Comparing patients with anti-Ro positivity (n=39; 33.9%) and anti-Ro-negativity (n=76; 66.1%), we found insignificant difference in QTc interval: QTcRo=417.2±28.4 ms and QTcR0=420.8±26.4 ms (P=0.51), respectively. Admission of IVGC showed significant prolongation of QTc in all patients, mean QTc1 before treatment was 399±26.2 ms, and QTc2 after therapy 412.7±27.2 ms, P=0.00021. On the other hand, anti-Ro and anti-La positivity showed shorter QTc interval 391±18.7 ms, to compare patients without these antibodies QTc414.8±25.7 ms, P=0.019 after treatment.

Conclusion: IVGC treatment significantly prolongs QT interval. Prolongation of QT/QTc interval needs further confirmation. Motivated by this experience, we consider ECG monitoring and careful observation of patients during IVGC treatment.

AB0487

HQC COULD ACT ON SLE PATIENTS THROUGH THE MODULATING EXPRESSION OF IL-8 ALONG WITH S100 PROTEINS

Risa Wakiya, Kyu Ueeda, Shusuako Nakashima, Hirono Shimada, Mai Mahmoud Fahmy Mansour, Mikiya Kato, Taichi Miyagi, Tomohiro Kameda, Hiroaki Dobashi, Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa, Japan

Background: Some reports revealed that S100A8 and S100A9 proteins were associated with disease activity of lupus nephritis (LN) [1]. However, there have been no reports about the mechanism of additional hydroxychloroquine (HQC) treatment for systemic lupus erythematosus (SLE) patient with low disease activity.

Objectives: To clarify the mechanism of additional HQC treatment for Japanese SLE patients with low disease activity.

Methods: All the 44 patients were enrolled in this study. These patients had been receiving additional oral HQC sulfate continuously for at least 3 months. These patients had no need for additional immunosuppressants including glucocorticoids, during this study because of their sustained low disease activity for 3 months prior to starting HQC. Low disease activity was defined as SELENA-SLEDAI score of 5 or less and biologic use is higher in the US (EU5 5.0% vs. US 8.3%); GCS use is similar (EU5 19.2% vs. US 19.0%). Globally, 84.4% of patients receiving GCS received it continuously with no significant differences observed between markets, EU5 85.5% vs. US 81.9%. A higher proportion of patients in the EU5 have been on GCS for 6 months or longer when compared to the US; EU5 79.9% vs. US 72.5%. Statistically significant differences were seen in the perception of GCS importance between markets (p<0.0004) and concerns with taking GCS (p=0.0143). A higher proportion of patients in the US regarded the use of GCS to at least be important (very important/essential EU5 65% vs. US 80.6%). A higher proportion of patients in the US were concerned with the use of GCS (somewhat concerned/very concerned EU5 56% vs. US 61.2%).

Conclusion: Significant differences in treatment approach between regions highlight the need for a better understanding of this disparity and a united approach to SLE treatment. Despite the high profile of risk factors linked to GCS use in SLE, it continues to be a continuously utilized by a large proportion of SLE patients and there is poor use of flare preventing agents such as immunosuppressants. Patients and physicians recognize the role of GCS in the management of SLE but also express concerns. Impact of an update to the SLE guidelines and their dissemination with better understanding of risk benefits of GCS vs. immunosuppressive and biologic therapy is warranted.

AB0457

LACK OF CONSISTENT STANDARD OF CARE IN SYSTEMIC LUPUS ERYthematosus PATIENTS IN REAL WORLD

Zahi Touma, Ben Hoskin, Christian Atkinson, David Bell, Olivia Massey, Jennifer H. Lofland, Pam Berry, Chetan Karyekar, Karen Costenbader

1University of Toronto, Toronto, Canada; 2Adelphi Real World, Cheshire, United Kingdom; 3Janssen Global Commercial Strategic Organisation, Horsham, United States of America; 4Janssen Global Services, LLC, Horsham, United States of America; 5Brigham and Women’s Hospital, Boston, United States of America

Background: Current guidelines do not necessarily reflect current standard of care (SOC) or treatment patterns in SLE in real world.

Objectives: To describe SLE SOC in the EUS and US and assess need for a more efficient and defined treatment pathway.

Methods: A cross-sectional study of 263 rheumatologists in the US and EUS. Data were collected from the Adelphi Real World 2015 Lupus Disease Specific Programme (DSP). Physicians were asked to complete patient record forms (PRFs) for the next 5 patients consulting with SLE; the same patients were asked to complete patient self-completion (PSC) forms describing how SLE affected them. PRFs collected data pertaining to the patient’s diagnosis, disease history, current clinical outcomes, treatment and health status. PSC data collection and included patient reported outcome measures (PROs) to assess the humanistic burden. Chi-squared tests were conducted to ascertain significance.

Results: Data was extracted from 1376 PRFs, and 591 PSCs. 35.6% of patients were currently on their first line of therapy, 40.0% second line, and third line or more 24.4%. Significant differences were observed between US and EUS in current treatment classes for first line (p=0.0001) and second line (p=0.0007). Descriptive differences were observed in the third line. In the US monotherapy is used more often first line with antimalarial (AM) (monotherapy EUS 15.7% vs. US 19.2%) and immunosuppressant (IM) (monotherapy EUS 4.8% vs. US 11.1%). Glucocorticoids (GCS) use is higher in the EUS at 1st line; both monotherapy (EUS 13.7% vs. US 11.8%) and combination (GCS+AM EUS 28.3% vs. US 16.7%). At second line, IM use (no bio) is higher in EUS (EUS 64.9% vs. US 56.7%) and biologic use is higher in the US (EUS 5.0% vs. US 8.3%). GCS use is similar (EUS 19.2% vs. US 19.0%).
Results: We enrolled 44 patients. Prednisolone dose during this study was fixed at the mean of 5.0±2.9 mg per day. SELENA-SLEDAI scores, CLASI scores, anti-dsDNA antibody and serum levels of C3 improved significantly, and serum levels of S100A8 and S100A9 proteins decreased significantly 3 months after additional HCQ treatment. The changes in serum S100A8 and S100A9 levels in SLE patients with LN were more significantly higher than in those without LN.

Among these patients, the changes of serum cytokine expressions were measured in 18 patients. The expressions of IFNs were not detected in almost of all patients. Serum levels of TNF-α, IL-6, IL-8, IL-1β, IL-1ra, VEGF, CCL3 and CCL4 decreased significantly 3 months after additional HCQ treatment (Figure1).

Seven of 18 SLE patients had a history of LN. These patients have HCQ treatment (Figure1).

The reductive effect of additional HCQ treatment on serum S100A9, TNF-α, IL-6 and IL-8 levels was much more apparent in those with history of LN (LN: S100A9, p=0.016, TNF-α, p=0.016, IL-6 p=0.031, IL-8, p=0.031; no LN: S100A9, p=0.065, TNF-α, p=0.083, IL-6 p=0.090, IL-8, p=0.557). The changes of serum S100A8 and S100A9 levels were correlated with those of serum IL-8 and IL-1ra (Figure2).

Conclusion: HCQ could reduce the serum levels of S100 protein and several cytokines in SLE Japanese patients with low disease activity. Recently, some reports showed that novel biomarker including IL-8 or S100 proteins was correlated with severity of LN [1, 2]. Our findings suggest that HCQ treatment without any additional immunosuppressant could reduce the expression of serum S100 proteins, IL-8 and IL-1ra, which were considered to be associated with the improvement of renal and life prognosis. Our data also indicated that S100 protein is closely related to several of IL-8 or IL-1ra expression in SLE pathogenesis, especially in LN. Further investigations are needed to more clarify the significance of HCQ treatment in SLE.

AB0490 FIBROBLAST GROWTH FACTOR-23 IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Dina Abdul Azim¹, Nahla Eesa¹, Mahmoud Sarraya², Marwa El Sharkawy³, Ahmed Fayed⁴, Somaya Anwar Hussein¹, Usama Sharaf El Din⁴. ¹Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt; ²Cairo University, Cardiology, Cairo, Egypt; ³Cairo University, Chemical Pathology, Cairo, Egypt; ⁴Cairo University, Nephrology, Internal Medicine, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease that affects multiple organs including the kidneys and the heart. Chronic kidney disease (CKD) is common among SLE patients. SLE is also associated with increased left ventricular (LV) mass. LV hypertrophy (LVH) may have an additional role in the increased morbidity and mortality among in SLE patients. Fibroblast growth factor 23 (FGF23) is a phosphatonin that steadily increases in serum of CKD patients. High FGF23 is associated with inflammation, CKD progression, and LVH.

Objectives: The aim of this study is to determine the serum level of FGF23 in SLE patients with and without lupus nephritis looking for its possible association with the inflammatory and cardiovascular manifestations encountered in this disease.

Methods: Sixty SLE patient were recruited and appointed into 2 groups based on renal function; group I composed of thirty patients that had normal kidney functions or stage 1 CKD (eGFR>90 ml/min/1.73m²) and group II of thirty cases with significant renal involvement defined as stage 2 to 4 CKD (eGFR <90 - >15 ml/min/1.73m²). After history taking and complete clinical examination of every patient, we measured body weight, height, Systemic lupus erythematosus disease activity index (SLEDAI), Systemic lupus erythematosus International Collaborating Clinics (SLICC), serum level of creatinine, calcium, phosphorus, albumin, complement 3 (C3), complement 4 (C4), interleukin 6 (IL6), fibroblast growth factor 23 (FGF23), estimated glomerular filtration rate (eGFR), 24 hour urine protein, complete blood count, erythrocyte sedimentation rate (ESR), antinuclear antibody (ANA), and left ventricular mass index (LVMI). Sixty normal healthy adults were included as control group. They were tested for serum FGF23 level.

Results: Serum level of FGF23 in SLE patients was comparable to normal control subjects (99.6±79.86 vs. 139±12.3 pg/mL, P>0.05). In addition, there was no significant difference in FGF23 between the two studied groups (106.49±88.2 vs. 93.84±74.67 pg/mL, P>0.05). In addition, there was no significant difference in serum IL6 between the two groups (58.6 ± 63.69 vs 55.9 ± 47.97 ng/L, P=085). On the other hand, LVMI was significantly higher in Group II (138.6 ± 36.59 vs. 187.6 ± 81.7 gm/m² in group I vs. group II respectively, P=0.0045). FGF23 showed significant positive correlation with IL6 (r= 0.776, P<0.001) and failed to show significant correlation with LVMI, serum creatinine, eGFR or serum phosphorus.

Conclusion: FGF23 behaves differently in SLE patients; in spite of significant increase in inflammation and the frequent renal involvement, FGF23 level remains normal in SLE patients. There is a possible existence of an inhibitor to FGF23 production in SLE. This possibility should trigger further studies.

AB0491 THE PERFORMANCE OF A RENAL ACTIVITY INDEX IN LUPUS NEPHRITIS IN INDUCTION THERAPY

Najla Aljaberi, Theresa Hennard, Arjun Mathur, Hermine Brunner. Cincinnati
Children’s Hospital Medical Center, Pediatric Rheumatology, Cincinnati, United
States of America

Background: Renal involvement in systemic lupus erythematosus (SLE) is
associated with high morbidity and mortality1. Current standard tools to
monitor lupus nephritis (LN) are suboptimal compared to the invasive
renal biopsy2. The renal activity index in lupus (RAIL) was developed
using 6 urinary biomarkers to reflect disease activity. In children this tool
was 92% accurate in identifying active LN3.

Objectives: We aim to study the changes in this score in relation to
induction treatment in LN.

Methods: Urine samples were collected from active LN patients prior
to induction treatment for LN and serially afterwards, coinciding with
clinical visits. Luminex Bead Multiplex Assay was used for the analy-
ses of urine biomarkers included in the RAIL score (neutrophil gelati-
nase-associated lipocalin, ceruloplasmin, monocyte chemoattractant
protein-1, adipsin,chnitin, kidney injury molecul-1). RAIL
scores were calculated per the defined algorithm for each urine sam-
ple. Data collected include LN histologic classification (International
Society of Nephrology (ISN)/Renal Pathology Society (RPS) classifica-
tion system), renal SLE disease activity index (6SLEDAI) score and
type of therapy.

Results: At the time of the analysis, data from 6 active LN patients
were collected longitudinally. Patients were all females and all had class
IV LN per the ISN/RPS. Renal SLEDAI scores were on the higher end
(M=11.3, SD=3.9). All patients were started on intravenous (IV) methyl-
prednisolone and cyclophosphamide (CYC) therapy. All but one patient
completed 6 doses of monthly CYC before switching to oral mycopheno-
late mofetil therapy. The RAIL scores for the 6 patients ranged between
-1.8 and 3.29. All patients had reductions in their RAIL score at 2-3
months period at an average of 322% decline from baseline (Figure 1).

At the end of induction treatment or at the 5-6 months interval, 5/6
patients main-
tained a decline of RAIL scores below the baseline. Of note the patient
who had flare of LN at the 6 months point leading to
treatment system), renal SLE disease activity index (6SLEDAI) score
type of therapy.

Conclusion: RAIL scores show overall improvement from baseline with
LN induction therapy. Lack of improvement was associated with flare
disease. Additional data points and a larger study sample are
required to study the ability of the RAIL score to reflect clinical
improvement of LN.

AB0492 PREVALENCE OF IGA ANTICARDIOLIPIN ANTIBODY AND ITS ASSOCIATION WITH PREGNANCY MORBIDITY IN ASIAN INDIAN PATIENTS WITH PRIMARY ANTIPHOSPHOLIPID ANTIBODY SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS – A CROSS SECTIONAL STUDY

Harshini Alur Shivalakumari1, K Jayakarthan1, Mahasampath Gowri2, John Mathew1,
Debashish Danda3, Christian Medical College, Clinical Immunology and
Rheumatology, Vellore, India; 2Christian Medical College, Biostatistics, Vellore,
India

Background: There are many clinical and laboratory parameters which have
been proven to be associated with increased risk of pregnancy mor-
bidity in patients with SLE and APS. This study was undertaken as there
is a lacuna in explaining all the pregnancy related morbidity in this group

Objectives: Primary: Correlation of IgA anticardiolipin antibody with the
risk for pregnancy morbidity in patients with APS/SLE
Secondary: Association of IgA Anticardiolipin antibody with the risk of
thromboembolic events

Methods: Patients diagnosed as SLE and/or Primary APS who are married
and conceived at least once were recruited and 3ml blood sample was
obtained from them. Patients with history of recurrent infections, which
could suggest probable IgA deficiency, were excluded. Demographic data
including duration of illness, number of pregnancies, thromboembolic
events, disease activity were noted. They were categorized into two differ-
ent groups depending on whether they had a pregnancy morbidity or not.

Results: A total number of 186 patients were recruited with mean age
34.54(+-7.32)years, mean duration of illness of 5.52(+-4.31)yns with a
diagnosis of 76.88% SLE, 7.53% primary APS and 15.59% SLE with
secondary APS. On assessment of disease activity, mean SLEDAI score
was found to be 4.46(+-6.32). Out of the total, 14.71% patients had con-
ceived once, 14.56% twice, 16.72% patients thrice and 16.41% had con-
ceived more than three times. 36.56% patients had pregnancy morbidity
(majority being pregnancy induced hypertension 14.52%, prematurity
11.29%, IUGR 10.22%, pre-eclampsia in 3.76%, eclampsia 1.08%).
19.35% patients had history of thromboembolic events (6.45% pulmonary
embolism, 5.38% deep vein thrombosis, 3.76% visceral vessel thrombosis, 0.54% cortical vein thrombosis, 6.99% other vessel thrombosis), 33.87%
patients had positivity for antiphospholipid antibodies with 27.82% lupus
anticoagulant positive, 20.97% IgA Anticardiolipin positive and 17.35%
anti-beta2 glycoprotein positive. IgA Anticardiolipin was found to be posi-
tive in 4.84%(n=9) out of which, 10.29% were in the group with preg-
nancy morbidity as against 1.69% without pregnancy morbidity. Out of
the total positives titre in 37.5% were indeterminate, 25% low positive
and 37.5% high positive. All patients who had high titre positivity had
pregnancy morbidity. The positivity of IgA anticardiolipin in the patient
group with thromboembolic events was 5.56%.

<table>
<thead>
<tr>
<th>IgA Anticardiolipin</th>
<th>Pregnancy morbidity</th>
<th>No pregnancy morbidity</th>

</thead>
<tbody>
<tr>
<td>Positive</td>
<td>7(10.29%)</td>
<td>2(1.69%)</td>
</tr>
<tr>
<td>Negative</td>
<td>69(90.71%)</td>
<td>116(98.31%)</td>
</tr>
</tbody>
</table>
Conclusion: Among patients with SLE, APS or SLE and APS, the overall prevalence of IgA antcardiolipin antibody was found to be about 4.84%, which is much less as compared to the percentages reported by other groups[1] IgA Anticardiolipin antibody positivity was more in patients with pregnancy morbidity compared to patients without a pregnancy morbidity. In this study however, statistical significance was not reached. Similar studies with larger number of patients are required. We also need to prospectively follow up such patients with IgA ACLA and evaluate for morbidity during pregnancy.

AB0493 IMMUNOGLOBULINS AFTER ACUTE PHYSICAL EXERCISE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Rosane Gouveia Vieira Machado1, Jozelita Rêgo2, Ana Carolina de Oliveira e Silva Montandort2, Heloisa Gouveia Machado2, Cláudio André Barbosa Lira1, Ludmilla Paula Vaz Cardoso1, Michelle Rocha Parise1, Ricardo Borges Viana2, Vitalina Barbosa2, Nilzio Da Silva1, Universidade Federal de Goiás, Jataí, Brazil.

Background: Moderate exercise improves the functions of the immune system. The results of serum immunoglobulins in response to acute physical exercise are conflicting, but in general, there is an increase in serum immunoglobulins in athletes and non-athletes after maximal and submaximal exercise. The effects of acute physical exercise on serum immunoglobulin in patients with systemic lupus erythematosus are unknown.

Objectives: To determine the serum levels of IgG, IgM, and IgA immunoglobulin in patients with systemic lupus erythematosus with a single session of acute aerobic exercise.

Methods: Thirty-one women with SLE (ACR1997 and/or SLICC 2012 criteria), 11 with active lupus and 20 with inactive lupus, and 24 healthy women, who were matched by gender, age, and body mass index, participated in this study. All subjects underwent a maximal exercise test on a motorized treadmill, with increases in velocity every minute until exhaustion, to evaluate the speed (km/h), heart rate, Borg scale (6-20), and the reason for stopping the test (fatigue and/or dyspnea). Samples of blood were collected in the morning, after an 8-hour fast and immediately after acute physical activity, and stored in a freezer at -80°C until the tests were performed. Immunoglobulin IgG, IgM, and IgA assay was performed by turbidity test according to the manufacturer (Turbiquest, Labtest Diagnostic S.A).

Results: There was an increase in both IgG and IgA serum levels after physical activity in SLE patients (p = 0.004 for IgG and p = 0.002 for IgA) and healthy controls (p <0.001 for IgG and p <0.001 for IgA) (Figure 2), in comparison to pre-exercise levels of IgM serum. There was no difference in IgG serum levels before and after the exercise test in both groups.

Conclusion: Patients with SLE, mainly with inactive disease, responded to acute physical exercise with increased IgG and IgA serum levels, similarly to healthy controls.

AB0494 ACTIVITY OF PURINE AND PYRIMIDINE METABOLISM ENZYMES IN SYSTEMIC LUPUS ERYTHEMATOSUS: ENZYMATIC PATTERNS OF BLOOD PLASMA AND LYSED LYMPHOCYTES

Svetlana Bedrina1, Andrei Trofimenko2, Elena Mozgovaya1, Svetlana Splitsina1,2, Ekaterina Tikhomirova1, Maria Mamous1, Irina Zborovskaya1,2. Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russian Federation;1 Volgograd State Medical University, Volgograd, Russian Federation

Background: Cytotoxic immunosuppressants are widely used nowadays for outcome improvement and better quality of life in severe systemic lupus erythematosus (SLE). As purine and pyrimidine metabolism suggest to be the major targets of most cytotoxic immunosuppressants, enzyme profiling of these metabolic pathways is recognized as an important step for a better balance between efficiency and safety in clinical practice.

Objectives: To characterize enzymatic patterns of the major enzymes of purine and pyrimidine metabolic pathways in systemic lupus erythematosus.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. 50 adult SLE patients from the rheumatology unit of Volgograd Clinical Emergency Hospital #25 and 30 healthy controls were included in the study. Diagnosis of SLE had been established using ACR criteria (1997), and activity was assessed by means of ECLAM scale. Activities of 10 major enzymes involved in purine and pyrimidine metabolic pathways: adenosine deaminase (ADA; E.C. 3.5.4.4), adenosine kinase (AK; E.C. 2.7.4.8), diphosphorylase dehydrogenase (DODG; E.C. 1.1.1.205), purine nucleoside phosphorylase (PNP; E.C. 2.4.2.1), thymidine phosphorylase (TP; E.C. 2.4.2.4), uracil/thymidine dehydrogenase (UDG; E.C. 2.7.7.99.4), cytidine deaminase (CDA; E.C. 3.5.4.5) were measured in blood plasma and lysed lymphocytes. Results are expressed as mean±standard error. Statistical comparison tests were selected in line with common guidelines, differences were considered significant when p<0.05.

Results: Enzymatic profiles in plasma of SLE patients are characterized by increased PNP, AK, UDG, IMPDG, CDA, TK, and DODG activities; ADA and GK were found to decrease. Lysed lymphocytes are revealed however to increased AK, IMPDG, TK, as well as decreased PNP, ADA, GK, CDA, and TP activities. We have also found that most enzyme activities significantly correlate with ECLAM score in accordance with our previous results [1]. Plasma PNP, AK, UDG, IMPDG, CD, TK, and DODG activities positively correlated with ECLAM score, as well as lymphocyte AK, IMPDG, and TK activities did. Negative correlations with ECLAM score were revealed for plasma ADA and TP, and also for lymphocyte PNP, ADA, GK, UDG, CD, TP, and DODG. Plasma PNP, AK, IMPDG, and lymphocyte PNP, ADA, AK activities had the closest relations with minimal SLE activity, being a candidate markers of it.

Conclusion: The enzymatic patterns studied can be used as auxiliary markers of SLE activity, with special emphasis on minimal disease activity.

OBJECTIVES: The potential of molecular imaging and multi-parametric MRI to characterize and quantify pSS disease manifestations. Methods: In this pilot imaging study (20381), patients with pSS diagnosed per AECG criteria, with a EULAR Sjögren’s syndrome disease activity index score ≥5, and basal salivary flow >0.0 mL/min or stimulated salivary flow rate ≥0.05 mL/min, underwent 18F-FDG and 11C-met and dynamic contrast-enhanced and diffusion-weighted MRI, followed by minor salivary gland biopsy for histological analysis. Age- and sex-matched healthy volunteers (HV) underwent MRI and 11C-met. HV-sS mean differences (m-diff; 95% confidence intervals [CI]) were calculated and Pearson’s correlation coefficients (r) estimated. Peak PET standard uptake values (SUVpeak) were used in the correlations and SUVmax values were recorded. All methods were compared with routine clinical and laboratory tests.

RESULTS: 12 patients had MRI, 18F-FDG and 11C-met; while HV (n=12) had MRI (n=12) and 11C-met (n=8). A lower 11C-met SUVpeak was seen in the parotid (m-diff: 1.4 g/mL [0.4, 2.3]) and submandibular (m-diff: 2.0 g/mL [0.9, 3.2]) glands in pSS versus HV, as was a trend for lower lacrimal gland uptake (m-diff: 0.5 g/mL [0.2, 1.3]) in patients with pSS. On structural MRI, the fat fraction (mean%) was higher in pSS vs HV in the submandibular glands (m-diff: -14.8 CI: [-29.3, -0.4]), with similar trends observed in the parotid glands (m-diff: -11.2 [-24.3, 1.9]). There was a negative correlation between 11C-met uptake and fat fraction (r: -0.7 [-0.9, -0.4]) in the combined parotid glands. There was positive correlation between 11C-met uptake and stimulated salivary flow (r: 0.5 [0.0, 0.8]) and negative correlation for stimulated salivary flow and fat fraction (r: -0.5 [-0.8, -0.1]) in the parotid glands; similar correlations were also seen in the submandibular glands. There was negative correlation between the global lymphoid aggregation score on minor salivary gland biopsy and the combined salivary gland fat fraction (r: 0.7 [0.5, 0.2]). Parotid gland SUVmax 18F-FDG uptake was higher than historical control values (mean: 1.9 g/mL, [SD: 0.5]) in some patients (pSS mean SUVmax: 2.8 g/mL [SD: 0.8, range 1.7–4.6]), with positive correlation between 18F-FDG and 11C-met uptake (r: 0.7 [0.2, 0.9]) in the combined salivary glands. Conclusion: Imaging showed clear differences between pSS and HV and correlated with clinical endpoints. Low 11C-met uptake and high fat fraction on MRI may indicate poor residual gland function, while high 18F-FDG and stable 11C-met uptake may define a subpopulation that responds well to anti-inflammatory therapies.

SERUM CALPROTECTIN IN SYSTEMIC LUPUS ERYTHEMATOSUS: IS IT A GOOD ACTIVITY BIOMARKER?

Hospital Universitat Germans Trias i Pujol, Badalona, Spain

Background: Clinical manifestations of systemic lupus erythematosus (SLE) and infections sometimes are difficult to distinguish. In clinical practice low complement and antivirus/DNA levels are used to assess lupus activity but
its determination usually requires some days. Leukocyte count, CRP and ESR cannot discriminate SLE from infectious processes. Calprotectin could be a good biomarker to assess lupus activity since it is more specific than CRP and ESR and faster to analyse than anti(ds)DNA.

Objectives: Our aim is to determine serum calprotectin levels in patients with SLE, and its correlation with analytical and clinical manifestations, especially with disease activity.

Methods: A total of 148 patients were included. All patients included fulfilled the SLE criteria (SLICC 2012). A quantitative ELISA analysis was performed to assess levels of serum calprotectin (CALPRO AS, Norway). Other biomarkers of lupus disease activity were also assessed (levels of anti(ds)DNA, hypocomplementemia, ESR and CRP). Clinical variables and activity/damage index (SLEDAI/SLICC) were also evaluated. The study was approved by the Clinical Research Ethics Committee of the hospital and all patients signed an informed consent. The results were compared with a healthy control group of similar age and sex (n=20).

Results: 134 patients (92%) were women with a mean age of 46 ± 12 years and a mean SLE evolution of 12.7 years. Mean SLEDAI was 2.2 (105 inactiv [-3], 43 mild [4-12], 0 severe [13]). Mean SLICC was 0.31 ± 0.7. No significant differences were observed in serum calprotectin levels between patients with SLE and healthy controls (2.93 ± 3.5 vs 2.17 ± 1.49 µg/mL). Calprotectin was positively correlated with CRP (r=0.447, p<0.001) and leukocyte count (r=0.462, p<0.001). Additionally, patients with higher anti(ds)DNA levels (>100 U/mL) had higher calprotectin compared to patients with lower anti(ds)DNA (3.20 ± 2.63 vs 2.42 ± 1.57 µg/mL; p=0.007), however this pattern was not observed with hypocomplementemia. Contrary to what we expected, we did not observe significant differences on calprotectin levels depending on SLEDAI index classification (cutoff at 4 and 12). Moreover, no differences were observed on calprotectin levels between those patients without clinical manifestations such as serositis, arthritis or glomerulonephritis. Patients with antiphospholipid antibodies had higher calprotectin levels (3.75 ± 2.04 vs 2.77 ± 2.38 µg/mL; p=0.045).

Conclusion: Serum calprotectin levels were positively correlated with CRP levels and leukocyte count. Patients with higher anti(ds)DNA levels had higher calprotectin levels, however we did not observe significant differences depending on SLEDAI index or the presence of arthritis, serositis and/or glomerulonephritis. Even that calprotectin determination is faster than anti(ds)DNA levels and could be helpful in assessing inflammatory activity. There is an interesting relation between antiphospholipid antibodies and calprotectin. This study should be continued in a larger sample of active SLE patients to assess its utility in clinical practice as a discriminating biomarker for flares and even infection.

GYNECOLOGICAL SYMPTOMS AND SEXUALITY IN SJÖGREEN’S SYNDROME

Özlem Özdemir Işıklı, Ayten Yazıcı, Ayse Cete. Kocaeli University School of Medicine, Internal Medicine, Division of Rheumatology, Kocaeli, Turkey

Objectives: Patients with Sjögren’s syndrome (SS) have symptoms such as vaginal dryness and dyspareunia.

Methods: 60 pSS, 42 sSS, 52 healthy controls (HC) were interviewed. It was asked questions about sexuality. SF-36, HAQ scale, pSS and sSS patients were also administered HAQ and Modified Hill questionnaire1.

Results: The mean age of the patients was 52 ± 11 years in the pSS, 54 ± 11 years in the sSS and 46 ± 9 years in the HC. Although there was no significant difference in term of age in pSS and sSS groups, there was no significant difference between the two groups in terms of the effect of vulvar, vaginal dryness, dyspareunia, decreased sexual desire, myalgia, arthralgia and fatigue on sexuality. In the pSS group, it was seen that disease had a negative effect on sexuality. There were no significant differences between the two groups when asked whether they enjoyed sexuality and the sexual problems create problems between their partners. In both groups, 97% of patients stated that they had not been questioned about their sexuality before. 80% of pSS patients and 88% of sSS patients stated that they did not talk about sexuality problems.

Conclusion: Gynecological and sexual problems are seen in SS patients. Menopause also contributes to this situation. Patients should be informed about these problems and directed to gynecologists when necessary, and enough time should be reserved as we do.

FINGERSTICK BLOOD TRANSCRIPTOMICS: A PATIENT-CENTRIC APPROACH TO ENABLE PRECISION MEDICINE?

Matteo Cesaroni1, Jessica Schreiter1, Logmane Seridi1, Jarrat Jordan1, Marc Chevre1, Nando Barsali1, Theresa Patter1, Jorge Villac1, Janssen Research and Development, LLC, Spring House, United States of America;

Janssen Diagnostics, LLC, Ranjan, United States of America

Background: Venous blood collection using PAXgene RNA blood stabilization (PAX) is a routine method to obtain blood for gene expression (GE) studies without requiring phlebotomy and cold chain transport. Decollect® is a fingerstick blood micro collection device (MCD) that circumvents phlebotomy and is reported to stabilize blood RNA for up to 14 days at ambient temperature potentially enabling collected blood to be shipped by mail.

Objectives: We evaluated Decollect® as an alternative to the conventional method to potentially improve convenience and cost effectiveness of blood transcriptomic analysis and allow high frequency transcriptomic assessment.

Methods: Heparinized blood samples were treated with interferon-α for 3h in vitro and transferred to 3 PAX and 3 MCD tubes. One PAX and
FLARES AND DISEASE-RELATED DAMAGE IN LATE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Jiapei Cheng1, Pretiel Dhansasekar2, Lay Kheng Teoh3, Liang Shen3, Aisha Latief1
1National University Hospital of Singapore, Singapore, Singapore; 2National University of Singapore, Singapore, Singapore

Background: Late-onset systemic lupus erythematosus (SLE) and its disease-related outcomes have not been previously examined in a multi-ethnic Southeast Asian cohort.

Objectives: To compare the following outcomes between patients with adult-onset versus late-onset SLE a) Disease manifestations at baseline b) Frequency of flares, defined by the SELENA Flare Index (SFI) c) Baseline damage and damage accrual, defined by the SLICC/ACR Damage Index (SDI)

Methods: We prospectively enrolled patients ≥ 21 years old with SLE who fulfilled either the 1997 ACR Criteria or the 2012 SLICC Classification Criteria and followed each patient at least every three months for up to 5 years. Baseline demographics, disease manifestations, antibody profile and activity were captured. At each visit, disease activity was measured using SLEDAI-2k and SDI was measured annually. We defined late-onset SLE as onset of symptoms at ≥50 years of age and adult-onset SLE as onset of symptoms at <50 years of age. We excluded patients with symptom onset before 18 years of age.

We compared the baseline demographic, disease manifestations and antibody profile between the adult-onset and late-onset SLE patients. We analysed continuous variables using the Mann-Whitney U test and categorical variables using the Chi-square test. Bonferroni correction for multiple comparisons was done. We then compared the time to first flare between the two groups using the logrank test. Baseline SDI scores and the proportion of patients who had increased SDI ≥1 over follow-up were compared using Chi-square tests.

Results: Of the 214 patients recruited, 154 (72%) were Chinese and 92 (27%) were Indians. One-hundred and ninety-three (90%) were on anti-malarial therapy and one hundred and forty-one (66%) were on immunosuppressive agents other than corticosteroids. The median (SD) age of recruitment of the SLE patients was 30.0 (22.5-37.5) years, while the median (SD) age of recruitment of the 30 late-onset SLE patients was 53.0 (50.0-56.5) years. The median (IQR) disease duration was 8.12 (7.5-13.5) years among the adult-onset patients and 5.73 (1.52-9.95) years among the late-onset patients.

Conclusion: Our study demonstrated that there was no significant difference in the time to first flare or time to first severe flare between the two groups. The median (SD) time to any flare was 2.51 (0.15) years in the adult-onset group versus 2.77 (0.34) years in the late-onset group, which was not statistically significant (p = 0.521).

CLINICAL ANALYSIS OF BONE MINERAL DENSITY IN PATIENTS WITH NEW-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Xiadi Deng, Li Xinyi. Peking University Third Hospital, Department of Rheumatology and Immunology, Beijing, China

Background: Osteoporosis in patients with systemic lupus erythematosus (SLE) is always thought to be GIOP (induced by glucocorticoid). Yet in our practice, there were some patients who developed osteoporosis at the onset of SLE, before the use of glucocorticoid and immunosuppressants. The clinical feature of these patients were not known by us clearly.

Objectives: This study aimed to investigate the BMD (bone marrow density) status and clinical characteristics of treatment-naive patients with newly diagnosed SLE.

Methods: Patients admitted to Peking University Third Hospital from 2009-2016, who were newly diagnosed as SLE and had no previous medical history that would had affected their BMD, were enrolled in this study. Demographic and clinical data were recorded. BMD of the lumbar vertebrae and femoral necks were measured with dual-energy X-ray absorptiometry, and patients were stratified as normal and abnormal BMD groups (including osteopenia and osteoporosis).

Results: Eighty-nine SLE patients with a mean age of 28.7 ± 8.9 years were included in the study (Table1).

Abstract AB0501 Table 1. Demographics of newly diagnosed SLE patients

<table>

<td>0%</td>
</tr>
<tr>
<td>SLEDAI</td>
<td>10.0±5.0</td>
</tr>
</tbody>
</table>

Approximately 36% of these patients had normal BMD, 49% had osteopenia, and 15% had osteoporosis. The SLE Disease Activity Index (SLEDAI) in the abnormal BMD group was lower than that in the normal BMD group (9.4 ± 4.5 vs 12.1 ± 5.8, P = 0.028). The body mass index (BMI) was significantly lower in the abnormal than normal BMD group (20.5±3.5 kg/m² vs 24.2±3.2 kg/m², P = 0.00). The total cholesterol (TC) and SLE patients lipid protein (LDL) were lower in the abnormal than normal BMD group (4.3±1.7 mmol/L vs 2.4±1.2 mmol/L, P = 0.04; 4.9±1.3 mmol/L vs 2.9±0.9 mmol/L, P = 0.033). The multisystem damage and
nervous system involvement were less in the abnormal than normal BMD group ($\chi^2 = 5.996, P = 0.014$ and $\chi^2 = 8.169, P = 0.004$). Multivariate analysis revealed that BMI (correlation coefficient $= 0.484$, $P < 0.001$) and multisystem damage (correlation coefficient $= 0.256$, $P = 0.003$) were positively correlated with BMD.

**Conclusion:** Low BMI, SLEDAI and less multisystem damage may be risk factors of BMD abnormalities in newly diagnosed SLE patients.

**IMPROVING RATES OF CERVICAL CANCER SCREENING AND PREVENTION IN PATIENTS WITH LUPUS**

Nancy Desai, Michael York, Hanni Menn-Josephy, Ramon Bonegio, Christina Lam, Anna Kancharia. Boston Medical Center, Boston, United States of America

**Background:** Recent studies suggest that patients with lupus have higher rates of cervical dysplasia and pre-malignant lesions. We have a large population of lupus patients at our institution that may be at increased risk of dysplastic lesions due to suboptimal rates of HPV vaccination and cervical cancer screening. The aim of this study was to determine the rate of HPV vaccination completion and cervical cancer screening compliance among the lupus patients seen in our institution. In addition, we developed a process to increase patient education and improve both HPV and cervical cancer screening rates at the level of the outpatient renal, dermatology and rheumatology clinics.

**Objectives:** To improve rates of cervical cancer screening and HPV vaccination among patients with Lupus

**Methods:** A comprehensive list was compiled of all patients with a diagnosis of lupus seen in the clinics over a 3 year period. A chart review of 332 patients was subsequently performed to determine the rate of HPV vaccination completion and the rate of compliance with cervical cancer screening. Methods were developed to improve these rates by streamlining access to HPV vaccination sites or facilitating referral for screening exams. Patients were also provided education through brochures about their increased risk.

**Results:** Our results revealed that rates of HPV vaccination among lupus patients at our institution were lower than national averages by 11%. Rates of cervical cancer screening were also 21% lower compared to national average for this group of patients. In creating a system to flag providers and increase patient education, we were able to improve these rates. In the first two months, 73.7% of all patients seen in the clinics were provided education and 61.5% of eligible patients that were seen in clinic were appropriately referred to either their PCP or to gynecology to complete cervical cancer screening and prevention.

**Conclusion:** Initial review of the lupus population at our institution highlighted a strong need to develop an intervention to improve vaccination and screening compliance in this population. By raising awareness among providers, we were able to significantly increase the number of at-risk patients referred for cervical cancer screening and prevention.

Given that the United States Food and Drug Administration has recently approved to expand the use of the HPV vaccine to women and men up to age 45, future efforts will be made to expand our eligible population to reflect these recommendations.

Legend: pSS - primary Sjögren’s syndrome; ANA - antinuclear antibodies
Regarding pattern of lung involvement, 9 (52.9%) pts had ILD, 6 (35.3%) isolated bronchiectasis and 2 (11.8%) follicular bronchiolitis. In ILD pts, non-specific interstitial pneumonia (NSIP) was documented in 6 pts, lymphocytic interstitial pneumonia in 2 and 1 pt had unclassifiable ILD pattern with lymphocytic alveolitis in bronchoalveolar lavage. One of the pts with NSIP later developed radiographic characteristics suggestive of usual interstitial pneumonia (UIP). Six ILD pts were treated with immunosuppressive drugs. One received cyclophosphamide (CYC), 2 azathioprine (AZA) and 4 mycophenolate mofetil (MMF). From pts receiving MMF, 1 was previously treated with CYC as induction treatment and the other with AZA, but with inefficacy. Rituximab (RTX) was given to 1 pt with refractory arthritis and new ILD onset. After 11 years on RTX (total 10 cycles) the pt complained of persistent dyspnea and fatigue on minor exertion (cardiac causes excluded), with onset of subtle honeycombing in high resolution computed tomography. At this point pirenidone was added to RTX, with clinical improvement. Detailed lung function and imaging evolution of pSS-ILD pts is shown in table 2.

Conclusion: Lung involvement occurred in 12.4% of our cohort and was associated with older disease at pSS diagnosis and presence of constitutional involvement. Small airways disease and ILD had nearly the same prevalence and in the ILD sub-group, NSIP was the commonest pattern. Despite the small number of ILD pts receiving immunosuppression, these drugs seemed to be associated with disease stabilization in most of them. Only 1 pt with UIP pattern had disease progression and eventually died.

Background: Systemic lupus erythematosus is polygenic autoimmune rheumatic disease with heterogeneous manifestations. Lupus patients with nephritis signify management challenge. With current induction and maintenance therapy the risk of developing lupus nephritis related ESRD at five, ten and fifteen years remains 11, 17 and 22% for the last decades.

Objectives: To study clinicopathological characteristics of lupus nephritis patients as well as short term renal outcome following induction of remission phase.

Methods: Retrospective, prospective observational study. We enrolled all patients with suspected active Lupus nephritis attending Dubai Hospital Rheumatology services. Data collected during outpatient, inpatient consultation using medical electronic system for all patients newly diagnosed to have lupus with renal involvement or patients who had nephritic or nephrotic flare from June 2016 till December 2018.

Results: Of 71 patients included during the study period, mean age was 36.4 years, 93% were female while 7% were males.56 Out of 71 were Arab (76%) while the rest 15 out of 71 (22%) from non-Arab ethnicity. Of 71 patients included during the study period, mean age was 36.4 years, 93% were female while 7% were males.56 Out of 71 were Arab (76%) while the rest 15 out of 71 (22%) from non-Arab ethnicity. 211 (93.4%) were female; and disease duration was 11.0 (7.3) years. The mean SLEDAI and SDI were 2.4 (3.5) and 1.3 (1.5), respectively. The mean FACIT-Fatigue was 25.0 (25.0).

Conclusion: Our study is unique in the region, characterizing high risk group of SLE patients. The signal of co morbid conditions such as hypertension, diabetes mellitus and antiphospholipid antibody positivity as well as class III/IV Lupus nephritis with cellular crescents as predictor of worse renal outcome raise the unmet need for further study with large sample involving more than single center to determine clinical, serological and clinicopathological parameters as long as long term with the available immune suppressive regimens.

Background: Fatigue can be defined as feeling tired and exhausted and lacking energy (1). It is associated with a poor quality of life; 53 to 80% of SLE patients identify fatigue as their main symptom (2)

Objectives: To define factors associated with fatigue in Mestizo patients with Systemic Lupus Erythematosus (SLE).

Methods: This is a cross-sectional study of SLE patients from a single center cohort. Visits were performed every six months. For these analyses, the first visit between October 2017 and December 2018 was included. Demographic and clinical characteristics as well as treatment were recorded at every visit. Socioeconomic status (SES) was defined using the Graffar’s method (ref). Fatigue was ascertained with the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-FT), Health-Related Quality of Life (HRQoL) with the LupusQoL, disease activity with the Systemic Lupus Erythematosus Disease Activity Index –2K (SLEDAI-2K), and damage with the Systemic Lupus International Collaborating Clinics (SLICC)/American College of Rheumatology (ACR) damage index (SDI). Prednisone use was recorded as current daily dose. Immunosuppressive drugs and antimalarial use was recorded as current, past or never. Univariable and multivariable analyses were performed using linear regression models. For the multivariable analyses, model selection was based on backward elimination.

Results: Two hundred and twenty-six patients were evaluated. The mean (SD) age at diagnosis was 35.6 (13.1) years, 211 (93.4%) were female; and disease duration was 11.0 (7.3) years. The mean SLEDAI and SDI were 2.4 (3.5) and 1.3 (1.5), respectively. The mean FACIT-Fatigue was 33.1 (10.8). In the univariable analyses, FACIT-Fatigue correlated with age at diagnosis, SES, disease duration and all the HRQoL domains like physical health, pain, planning, intimate relationships, burden to others, emotional health, body image and fatigue. On the multivariable analyses, however, only age at diagnosis; and some domains of HRQoL (physical

Disclosure of Interests: None declared

REFERENCES

Disclosure of Interests: None declared

health, emotional health and fatigue) remained associated. Theses analyses are depicted in table 1.

Conclusion: Age at diagnosis is negatively associated with fatigue; HRQoL domains like physical health, emotional health and fatigue are positively associated with fatigue.

Background: Systemic lupus erythematosus (SLE) is a systemic disease that may affect the inner ear.

Objectives: To study hearing function in SLE and its possible association with clinical and serological profile as well as with antimarial use.

Methods: Cross sectional study of 84 individuals (43 SLE patients and 41 controls) with audiometry and impedanciometry tests. Epidemiological, clinical, serological and treatment profile of SLE patients were extracted from the charts.

Results: SLE patients had more sensorineural hearing loss than controls (23.2% vs 0; p=0.001). The hearing loss was seen at 250 Hz, 500 Hz, 1000 Hz and 4000 Hz. No bone conduction impairment was observed. Serological and clinical profile in patients with and without hearing loss was the same (all p=ns). Patients on antimalarial had the same prevalence of hearing loss than those not using it but at 8.000 Hz, antimalarial non-users performed worse than users (p=0.03).

Conclusion: There is a high prevalence of hearing loss in SLE that is not affected by disease characteristics rather by antimarial use.

**AB0508** SCHIRMER TEST, VAN BIJSTERVELD, OSS, AND BREAK-UP TIME TEST IN PRIMARY SJÖGREN’S SYNDROME

Tania Fidelix1, Vânia Fernandes Moça Trevisani2, Laura Santos3, Denise Freitas2, Luiz Antonio Vieira2, Moacyr Rigueiro3, Paulo, Brazil

**Background:** Primary Sjögren’s syndrome (pSS) is an autoimmune disease characterized by lymphocytic infiltration of exocrine glands and other organs, resulting in dry eye, dry mouth, and systemic findings. [1]

**Objectives:** The American College of Rheumatology/AECG group diagnostic criteria for pSS have included three items related to ocular involvement. The Schirmer test type 1, van Bijsterveld score, and Ocular Staining Score (OSS). They are time-consuming and employ costly dyes and instruments. In this context, we analyzed 66 patients with pSS to ascertain correlation between these tests and assess the possibility of streamlining ophthalmologic examination.

**Methods:** Sixty-six patients (180 eyes) from the Federal University of Sao Paulo outpatient cornea clinic were analyzed prospectively from 2017 to 2018. Those with suspicion of pSS were tested according to the 2016 ACR-EULAR diagnostic criteria.

**Results:** Of the 66 patients, 64 were female; 36 were white; median age was 53.3 (11.3) years. The Schirmer I test was done in 177 eyes, it was positive in 57.6%. The van Bijsterveld score was done in 128 eyes and was positive in 61.7%. The OSS was done in 177 eyes and was positive in 96%. The TBUT was tested in 175 eyes and was positive in 86.4%. All four tests could be performed in 128 eyes. The results were confirmed at the same proportions. Correlation between tests was then calculated through the kappa coefficient (Table 1).

**Conclusion:** Schirmer’s test without anesthetics has been part of the AECG diagnostic criteria for pSS since 1989. [2]

**AB0509** PREVALENCE AND INCIDENCE OF SJÖGREN’S SYNDROME AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL-WORLD COMMUNITY PRACTICE SETTINGS

Leticia Ferr1, Ying Bao1, Sonie Lama1, Varshini Rajagopalan2, Evo Almeida1

**Background:** Sjögren’s syndrome (SS) is a rheumatoid disease that may coexist with RA, and is often considered a common extra-articular manifestation of RA. However, few studies have examined the prevalence and incidence of SS in patients with RA in real-world community practice settings.

**Objectives:** To estimate the prevalence and incidence of SS in patients with RA, and to summarise the characteristics of patients with SS associated with RA compared with those of patients with RA alone.

**Methods:** We analysed data from 1 Jan 2014 to 30 Jun 2018 in a large rheumatology database in the USA, which provides electronic medical record data from 120 community-based rheumatology providers. Adult patients with ≥2 RA diagnoses were identified from 1 Jan 2015 to 30 Jun 2018 (index period). The baseline period was from 1 Jan 2014 to 31 Dec 2014. Among patients with RA, we identified patients with ≥2 SS diagnoses in the index period (prevalent SS patients and patients with ≥2 SS diagnoses in the index period who had not been diagnosed with SS in the baseline period [incident SS patients]). Crude and age- and sex-standardised prevalence and incidence of SS were calculated among patients with RA. Characteristics of prevalent SS patients and patients with RA alone (as a control group) were summarised.

**Results:** A total of 53,156 patients with RA were identified. Among them, we identified 2451 prevalent SS patients and 1460 incident SS patients. The age- and sex-standardised prevalence of SS in patients with RA was 3.48%, and the age- and sex-standardised incidence rate was 0.66 per 100 patient-years. Female patients had a higher prevalence (5.23%)
vs 1.68%) and incidence (0.96 vs 0.36 per 100 patient-years) of SS than male patients. Compared with other age groups, patients with RA aged 30–49 years had the highest prevalence (3.80%) and incidence (0.77 per 100 patient-years) of SS (Table 1). Compared with patients with RA only, those with both SS and RA were more likely to be female (92% vs 76%), had higher Charlson Comorbidity Index and lower CDAI scores, and were more likely to have prior use of biologic/targeted synthetic DMARDs (30% vs 10%) and conventional DMARDs (48% vs 18%) (Table 2).

Conclusion: This study estimated the prevalence and incidence of SS among patients with RA in real-world community practice settings, and provided insights on clinical characteristics of these patients. Patients with both SS and RA have less joint disease activity and greater DMARD exposure than those with RA only. The findings underscore the complexity of SS secondary to RA and highlight the important role of epidemiological research in understanding this condition.

Disclosure of Interests: This study was funded by Bristol-Myers Squibb.

LUNG ULTRASOUND OF PLEURAL IRREGULARITIES IN SUB-CLINICAL PRIMARY SJÖGREN’S SYNDROME-
LUNG INVOLVEMENT: A SINGLE CENTRE EXPERIENCE

Francesco Ferro, Alessandra Bulleri, Elena Elefante, Marta Mosca, Chiara Baldini, University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; 2AOU Pisana, Radiology Unit, Pisa, Italy; 3University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; 4University of Siena, Department of Medical Biotechnology, Siena, Italy

Background: Ultrasound of Pleural Irregularities (PI-US) has recently been suggested as a useful tool for the diagnosis and quantification of severity in connective tissue diseases (CTD)-related lung involvement. However, no data are available regarding its role in the sub-clinical phase of primary Sjögren’s syndrome (pSS)-related lung involvement.

Objectives: Aim of this study was to describe the role of lung ultrasound analyzing pleural irregularities in asymptomatic pSS-patients in order to early detect lung abnormalities/alterations.

Methods: pSS patients regularly followed-up at our Sjögren’s Clinic and asymptomatic for dyspnea and cough, undergoing to CT or HRCT exam for lymphoproliferative and/or neoplastic screening, were included in the study. Demographic, clinical, biological and serological data were collected. PI-US was performed by a single operator using a MyLab ClassC (Esaote), 13-18 MHz, 5 cm linear probe. PI was defined as the loss of normal hyperchoic linear pleural contour (score 0-2: normal, minimal and major changes at each intercostal space). PI-US total score represented the sum of partial scores assigned to 6 lung fields (2 for the anterior, 2 for postero-superior and 2 for postero-inferior chest surface). CT-abnormal findings, distinguishing typical (interstitial pattern) from atypical lung alterations (non specific findings), were analyzed by an expert radiologist.

Results: 24 pSS patients (AECC criteria), 20 F:4 M, mean age =58 ±12.2 yrs, mean follow-up duration 8.6±12.2 yrs, were included in the study. All patients were positive for ANA, 21/24 for anti-Ro/SSA, 15/24 for Rheumatoid Factor (RF) and 6 of them for cryoglobulins. Four patients (16.67%) had a previous history of pSS-related lymphoproliferative disorder.

None of the included patients reported cough or dyspnea and the thoracic examination did not arise any abnormalities suggestive for lung diseases.

The mean PI-US total and postero-inferior partial score resulted 22.75 ±19.72 and 8.29±8.60 respectively. CT/HRCT resulted normal in 9/24 patients (37.5%) and showed abnormal findings in 15/24 (62.5%). The latter consisted of non- Interstitial Lung Disease (ILD) alterations in 13/15 cases (i.e 13/13 fibrotic striae and/or micro/macroanodularities, 5/13 disven-tillatory striae and/or medium lobe syndrome, 3/13 bronchiectasias and/or bronchiolectasias and 3/13 thin-walled cysts/atypical emphysema). In 2/15 patients a new diagnosis of Interstitial Lung Disease (ILD) was made with patients presenting a typical NSIP-pattern. Both the mean PI-US total score and the postero-inferior partial score resulted significantly higher in patients with abnormal CT/HRCT compared to those with normal CT findings (p =0.003 and p= 0.001 respectively). On the contrary, PI-US total and partial scores were not significantly different between ILD and non-ILD pSS patients (p = 0.103).

Conclusion: this study highlights the potential usefulness of PI-US as a sensitive, non invasive tool for the diagnosis of sub-clinical early lung alterations in pSS.

A COMPARATIVE STUDY ON CLINICAL AND SEROLOGICAL CHARACTERISTICS BETWEEN PATIENTS WITH RHUPUS AND PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Beatriz Frade Sosa1, J. Navarrete2, Tarek Carlos Salman Moreno2, Vera Ortiz Santamaria3, Vicenç Torrente Segarra3, Ivan Castellvi4, Beatriz Frade Sosa5, Raúl Castellanos-Moreira6, Delia Reina7, Sonia Minguez8, Maria Garcia Manrique de Lara9, Sergi Ordoñez10, Meritxell Sallés Lizarzaburu11, Elena Riera Alonso11, Jose A. Gómez-Puerta12, Roberta Ottaviani2, Micaela Fredi2.

Objective: To avoid misclassification, those patients with Rhupus but who had Jacobson’s arthritis or with overlap syndromes were excluded.

Methods: A total of 120 patients were included, 40 cases with Rhupus and 80 cases with SLE. Most of patients were female (95%) and Caucasian (75%). Mean age was 51 ± 14.7 years with a mean disease duration of 12.9 ± 9.2 years. Clinical characteristics were arthritic involvement (93.3%), cutaneous involvement (77.5%), haematological (72.5%), secondary Sjögren syndrome (38.7%) among others. Clinical and serological characteristics according different groups are shown in Table.

UTILITY OF RENAL REBIOPSY IN PATIENTS WITH LUPUS NEPHRITIS

Maria Jesús García Villanueva1, Sandra Garrone-Corral1, Walter Alberto Sifuentes-Giraldo1, Jose Renato Quiñones Torres1, Antía García Fernández2, Patricia Marín Álvarez2, Andrea Briones-Figueroa2, Lourdes Villalobos-Sánchez2, Adela Allá Jiménez2, Martha Díaz Domínguez3, Maite Rivera Gorín2, Milagros Fernández Lucas2, Nuria Rodríguez Mendiolea2.

1Hospital Ramón Y Cajal, Rheumatology, Madrid, Spain; 2Hospital Ramón Y Cajal, Rheumatology, Madrid, Spain; 3Hospital Ramón Y Cajal, Nephrology, Madrid, Spain.

Background: The pathological class of lupus nephritis (LN) may change to a different class during the course of the disease. Renal biopsy is repeated is repeated in many patients during a flare but there is there is no agreement about systematically recommending them because proliferative lesions on their original biopsy rarely switch to a pure non-proliferative nephritis during a flare. However, renal biopsy may be useful in some cases to make appropriate adjustments or changes of treatment.

Objectives: To analyze the impact of renal biopsy on the therapeutic approach in patients with previous histological diagnosis of LN who experience a worsening in the clinical parameters of renal involvement.

Methods: Retrospective study of patients with histological diagnosis of NL subjected to at least one renal biopsy. We studied the demographic, clinical, histopathological variables of the first and subsequent renal biopsies, received treatment and the therapeutic modifications in relation to the result of the rebiopsies.

Results: We analyzed 35 patients diagnosed with LN between 1978 and 2017. 9 of them had been rebiopsed at least on one occasion and made a total of 11 biopsies (7 patients with a rebiopsy and 2 patients with 2 rebiopsies). All patients were female and Caucasian, except for a Hispanic woman, with a mean age at the time of the biopsy of 31 ± 12 years (14–55). The mean serum creatinine at the time of the first biopsy was 0.8 ± 0.17 mg/dl (0.5–1.06) and in the second, 1.18 ± 0.05 mg/dl (1.15-1.23). The fundamental indication for the rebiopsy was the increase in proteinuria, up to non-nephrotic range in 64% of the patients (4.5% of patients had a proteinuria >100 mg.) 4 of the rebiopsies (36%) started from a proliferative class and within the nephrotic range in 36%. In comparison with the previous biopsy, 3 of the rebiopsies (27%) showed evolution from a non-proliferative to a proliferative form (from II to III, from II to IV and from V to V + IV), 4 of the rebiopsies (36%) started from a proliferative class and changed class but within these forms (3 from IV to III and 1 from III to IV). The remaining 4 rebiopsies (27%) showed no change in the histological type. Regarding the baseline biopsy, we observed a decrease in the index of activity of the rebiopsies (5.4 ± 2.2 vs 3.4 ± 2.5, p = 0.017) and an increase in the chronicity index (0.8 ± 0.7 vs 2.9 ± 3.2, p = 0.027). In all cases, therapeutic modifications were carried out. In 9 cases (82%) the immunosuppression was increased and in two of them (18%) it was decreased.

Conclusion: The repetition of renal biopsy in cases of LN with clinical data of renal deterioration is relevant. The change of histological class and the evolution of activity and chronicity indices support the decision to increase immunosuppression and are fundamental to diminish it.

PARATHORMONE BUT NOT VITAMIN D SERUM LEVELS ARE ASSOCIATED WITH SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Mayra Gianinetti1, Alkaterini Stamou2, Eleni Antypa3, Haralampos M. Moutsopoulos2, Clio Magragni1, 3Mesogion, Rheumatology, Athens, Greece; 2Mikras Asias, Pathophysiology, Athina, Greece; 3Mikras Asias, Physiology, Athina, Greece.

Background: Growing evidence supports a link between alterations in bone metabolism and cardiovascular (CV) disease in both general and autoimmune populations.

Objectives: In the current study we aimed to explore whether vitamin D deficiency and/or increased parathormone (PTH) levels, as well as impairment of bone mass density, influence CV risk in patients with systemic lupus erythematosus (SLE).

Methods: 138 consecutive SLE patients were enrolled in the study. Clinical features, hematological, serological and immunological profile, as well as therapeutic regimens was recorded in all patients. Classical CV and osteoporosis risk factors were assessed in all participants. Intima-media thickness (IMT) (and carotid and/or femoral) (CV-IMT) were evaluated by ultrasound. Assessment of bone mineral density (BMD) and asymptomatic osteoporotic fractures was also performed by dual X-ray absorptiometry and lateral thoracic and/or lumbar spine X-rays, respectively. Univariate and multivariate models were implemented for statistical analysis.

Results: PTH -but not 25(OH)vitamin D3- serum levels were found to be increased in lupus patients with subclinical atherosclerosis (plaque formation/or arterial wall thickening) compared to those without (51.1±27.4 vs 37.4±18.4 pg/ml, p= 0.003 and 54±32.7 vs 40±18.3 pg/ml, p= 0.02, respectively). Abnormal PTH serum concentrations (>65 pg/ml) in SLE patients was identified as a risk factor for both plaque formation and high IMT scores (>0.9mm) [OR 95% (CI): 8.2 (1.8-37.4) and OR 95% (CI): 4.4 (1.2-15.9), respectively]. Finally, an inverse correlation between femoral neck BMD values and total IMT scores was observed (r:-0.42, p=0.008).

Conclusion: Subclinical atherosclerosis in patients with lupus is associated with increased serum PTH levels and reduced bone mass density. These findings further support the presence of shared pathophysiogenetic mechanisms between arterogenesis and altered bone metabolism.

OBESITY AND WEIGHT LOSS IMPACT IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Maria Rita Giangreco1, Luca Petricca1, Clara Di Mario2, Anna Maria Paglionico1, Valentina Varriano2, Stefano Alivernini3, Barbara Aquilanti4, Maria Rosaria Magiurato2, Giacomo Tanti2, Barbara Toloso1, Gianfranco Ferraccio1, Elisa Gremese1, Fondazione PoliChir Universitario A. Gemelli – IRCCS, Division of Rheumatology, Rome, Italy; 2Università Cattolica del Sacro Cuore, Division of Rheumatology, Rome, Italy; 3Fondazione PoliChir Universitario A. Gemelli – IRCCS, Università Cattolica del Sacro Cuore, Division of Rheumatology, Rome, Italy; 4Policlinico Universitario A. Gemelli – IRCCS, Diabetes, Service, Rome, Italy; 5Fondazione PoliChir Universitario A. Gemelli – IRCCS, Psychology Service, Rome, Italy.

Background: Obesity is considered a chronic low-grade inflammatory status due to the release of bioactive substances, as pro-inflammatory cytokines, by the adipose tissue, and it is known negatively affecting some autoimmune inflammatory diseases, like Rheumatoid Arthritis. Few data are available on the role of obesity in Systemic Lupus Erythematosus (SLE) disease.

Objectives: To evaluate the distribution of Body Mass Index (BMI) categories in SLE patients and the association between SLE disease activity and BMI groups. Furthermore, to assess the impact of weight loss in a cohort of overweight/obese SLE patients, evaluated with a multidisciplinary approach.

Methods: Consecutive SLE patients, diagnosed according to the 2012 SLICC criteria, were enrolled. Clinical and demographic characteristics, disease duration, BMI category, laboratory indices and current therapies were collected at baseline and at follow-up visits. A subgroup of SLE patients with BMI>25 Kg/m2 underwent a scheduled diet under a Nutrition guide (1200 calories/day) and Psychologist support when necessary, maintaining the SLE therapy unchanged and were evaluated by a rheumatologist and a nutritionist every 3 months and clinical and laboratory data and the ACR/EULAR core data set were registered at each follow-up (FU) visit.

Results: Of the 277 patients (age 42±14.4 years, disease duration 8.4 ±8.0 years, SLEDAI-2K 6.6±7.6, SLICC 1.9±1.5), 47.6% had arterial, 32.3% renal, 23.6% neurological and 21.9% had serositis involvement, respectively. Considering the whole cohort, 66 (23.9%) patients had BMI between 25 and 30 Kg/m2 and 34 (12.3%) a BMI>30 Kg/m2 [of which 15 (5.4%) with BMI >35 Kg/m2]. Overweight/obese SLE patients were predominantly male (20.0%) with respect to patients with BMI<25 Kg/m2 (4.5%, p<0.001). Considering the therapeutic regimens, antimalarials treatment was ongoing in 39.4% of overweight SLE patients and in 61.8% of obese SLE patients compared to 28.7% in normal weight SLE patients (p< 0.001 for overweight and p<0.001 for obese patients), without any significant correlation between BMI and cumulative steroid dose during
the follow-up. Considering the whole SLE cohort, cardiovascular events were more frequent in obese patients (14.7%) than in overweight (7.6%) and normal weight (2.9%) SLE patients (ANOVA test: p<0.01). Twenty-nine SLE patients with BMI≥25 Kg/m² (BMI: 33.5 ± 5.1 Kg/m²; age: 47.7 ± 12.3 years, disease duration: 11.9 ± 9.0 years; SLEDAI: 10.5 ± 5.7; SLICC: 1.3 ± 1.1) underwent a scheduled low calories diet. A significant reduction in BMI was observed at 6 and 12 month follow-up [6.6 ± 5.7% at 6 months FU (p = 0.001) and 7.0 ± 7.2% at 12 months FU (p=0.002)] respectively as well as a reduction in disease activity [SLEDAI at 6 months FU: 4.5 ± 4.0 (p=0.001) and at 12 months FU (0.7 ± 0.9 (p <0.001)]. Finally, a significant decrease of systemic inflammatory markers as C-Reactive Protein (p<0.05) was observed in SLE patients who achieved >5% weight loss compared to SLE patients who did not.

Conclusion: Obesitas presents a modifiable factor for improving outcomes among obese SLE. A weight loss obtained with a controlled diet may reduce cardiovascular events and reduce the state of chronic inflammation subdued by the activity of adipose tissue.

AB0516 AUTOANTIBODY PROFILE ANALYSIS AND ITS ASSOCIATION WITH CLINICAL MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Elena Grau García1, Francisco Miguel Ortiz Sanjuan1, Cristobal Páez Perales1, Carmen Nájera Herranz1, Inés Cánovas Olmos1, José Ivorra Cortés1, 2

Department. HUP La Fe, Valencia, Spain

Biostatistical Unit. IIS La Fe, Valencia, Spain

Rheumatology Department. HUP La Fe, Valencia, Spain

Background: Systemic lupus erythematosus (SLE) is an autoimmune systemic disease characterized by autoantibody production. The presence of some of them is related to specific clinical manifestations. Previous studies have classified SLE patients according to an autoantibody profile, associating them to specific clinical groups.

Objectives: To define SLE patient groups according to an autoantibody profile and to analyze the correlation of these profiles to clinical manifestations, clinical activity and accumulated damage.

Methods: A cross-sectional observational study of SLE patients diagnosed according to SLICC 2012 criteria was conducted. A clinical and analytical evaluation was performed in all cases. Clinical manifestations were described according to RELESSEY study. We selected 8 autoantibodies to classify SLE patients in different subgroups according to autoimmune similar profiles: anti-dsDNA, anti-Sm, anti-RNP, anticardiolipin IgG o IgM (aCL IgG), anti-B2-microglobulin IgG or IgM (aB2M IgG/M), lupus anticoagulant (LA), anti-Ro and anti-La. Biostatistical analysis was performed using software R and immunological profiles were created according to previous study of Arlt-Esen B et al. 2014.

Results: 142 SLE patients were evaluated (94.4% female) with a mean age at diagnosis of 33.29 (13.53) and a mean time of disease evolution of 15.82 (10.56) years. Mean SLEDAI score was 5.91 (5.6) and mean SLICC value 1.1 (1.46). Frequency of the selected autoantibodies was: ANAs 87.3% (n=124), anti-dsDNA 36.62% (n=52), anti-Sm 9.2% (n=13), anti-RNP 3.5% (n=9), aCL IgG/M 20.15% (n=27), aB2M IgG/M 21.86% (n=28), LA anti-LA? 29.27% (n=31), anti-Ro 45.07% (n=64) and anti-La 16.2% (n=23).

Profile n°2 included SLE patients with anti-Sm/RNP positivity. Profile n°3 included patients with anti-Ro/La positivity and not included in profile n°2. Profile n°4 included patients with aCL IgG or aB2M IgG/M or LA (positivity and not included in previous profiles. Profile n°5 included patients who exclusively showed anti-DNA positivity. Profile n°7 included all patients excluded from the other profiles.

Depending on the results obtained, we analyzed autoantibody levels in order to assess their association with the presence of the described clinical affections. A significant association among hematological affection and high levels of anti-Ro (P<0.0001), anti-La (P<0.022) and anti-Sm (P=0.018) was observed. We also observed a tendency of presenting a higher rate of mucocutaneous affection, musculoskeletal and renal affection and Sjögren syndrome in patients classified in Profile 3.

Conclusion: Profile n°1 patients (absence of autoantibodies) were diagnosed earlier and had a longer disease evolution, whereas Profile n°5 patients (only anti-DNA positivity) were diagnosed at a mean age of 36 years and had a shorter disease evolution. We observed an association between the presence of anti-Ro/La and hematological affection, as well as a high incidence of Sjögren syndrome in this subgroup of patients.

AB0517 CORRELATION BETWEEN PATIENT-REPORTED OUTCOMES OF HEALTH-RELATED QUALITY OF LIFE AND CLINICAL ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Elena Grau García1, Jorge Juan Fraga-Góñal1, Roxana Gonzalez Mazañor1, Carmen Nájera Herranz1, Inés Cánovas Olmos1, José Ivorra Cortés1, Cristina Alcañiz Escandell1, Inmaculada Chalmeta Verdejo1, Marta De la Rubia Navarro1, Luis González Puig1, Isabel Martínez Cordelías1, Rosa Neguerues Abusuech1, Jose Eloy Otero Rodriguez1, Francisco Miguel Ortiz Sanjuan1, Cristobal Páez Perales1, Elvira Vicens Bernabéu1, David Hervás Marín2, Jose Andrés Román Ivorra1, 2

Department. HUP La Fe, Valencia, Spain

Biostatistical Unit. IIS La Fe, Valencia, Spain

Rheumatology Department. HUP La Fe, Valencia, Spain

Background: Patient-Reported Outcomes (PROs) allow us to know the way the disease could affect patients, and maybe could not be detected in clinical measures. Among these, PROs of health-related quality of life (PRO-QL) represents patient evaluation of its health status and treatment, which affects the functional, psychological, social and emotional capabilities. In fact, patients with the same health status could show different PROs-QL. In the case of systemic lupus erythematosus (SLE), patients experience many inflammatory symptoms and all of them can affect the health-related quality of life in different ways.

Objectives: We aimed to measure the PRO-QL in SLE patients and correlate them with the clinical activity of the disease.

Methods: A cross-sectional observational study with SLE patients diagnosed according to SLICC 2012 criteria was performed. In all cases SLEDAI score was carried out, and patients full-filled questionnaires of fatigue (FACIT-FATIGUE), quality of life (EQ-5D-5L), disability (HAQ) and a Global Health Status Scale (GHS) (0-100). Biostatistical analysis with software R was performed, using the multivariate analysis of variance by software R.

Results: 54 SLE patients (91.84% female) participated in the study, with a mean age at diagnosis of 27.55±13.21 years and a mean time of disease evolution of 20.4±5.9 years. Mean SLEDAI score was 6.63±6.89, with a 37.04% of patients with SLEDAI>6. The 64.66% of patients were under glucocorticoid treatment, 38.77% under immunosuppressants (methotrexate, azathioprine or mycophenolate) and 51.02% under antimalarials. Patients showed a mean score of 34.02±13.38 in FACIT-FATIGUE, 0.72 ±0.26 in EQ-5D-5L, 0.62±0.71 in HAQ and 64.02±25.93 in GHS.

Statistical analysis showed correlation between SLEDAI score and the four questionnaires of PROs-QL (P<0.001). Particularly in those cases with high clinical activity we observed low scores of EQ-5D-5L, FACIT-FATIGUE and GHS, and an increment in HAQ. We performed the previous analysis considering as correcting factors the age, the years of disease evolution, glucocorticoid treatment, antimalarials and immunosuppressants. We also obtained a correlation between clinical activity and PROs-QL (P<0.0107).

Conclusion: We observed a correlation between PROs-QL full-filled by SLE patients with the clinical activity of the disease, independently of glucocorticoid treatment, antimalarials and immunosuppressants, the age and the disease evolution.

Disclosure of Interests: None declared

AB0518 | JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS RELATED PANCREATITIS: AN UNCOMMON MANIFESTATION OF A COMMON DISEASE
Anirjii Gummadi, Ankita Singh, Rakesh Kumar, Johnson Nameirakpam, Pandiarajan Vignesh, Deepthi Suri, Anju Gupta, Ankur Jindal, Amit Rawat, Sujit Singh. Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatrics, Advanced Pediatric centre, Chandigarh, India

Background: Pancreatitis is a rare but potentially life-threatening complication of juvenile systemic lupus erythematosus (jSLE).

Objectives: We report 3 children with SLE who presented with acute pancreatitis.

Methods: We have reviewed the clinical records of 140 children with SLE between period of 1993-2018. Three of them present with acute pancreatitis.

Results: Case 1-12-year-girl presented with fever of 1 month and alopecia. Examination revealed pedal oedema, periorbital puffiness, generalised lymphadenopathy, large joint arthritis and mild hematopoegetic.Investigations were consistent with lupus.Renal biopsy revealed Class 3 lupus nephritis and initiated on intravenous methylprednisolone. Two days after beginning her medication,she developed severe epigastric pain and vomiting which did not respond to antacids and analgesic. Serum amylase and lipase were elevated. Clinical possibilities included steroid induced pancreatitis and lupus pancreatitis. Intravenous methylprednisolone was continued following which she showed a dramatic improvement. Case 2- A 6-year-old prepubertal boy with pain abdomen and vomiting. Physical examination showed epigastric tenderness. Investigations showed elevated amylase levels. Computed tomography(CT) abdomen revealed acute necrotising pancreatitis. A ultrasound abdomen revealed a pancreatic pseudocyst. He had a second episode of acute pancreatitis along with anaesthesia after 3 months. In follow-up, he presented with anaesthesia. Investigation were consistent with lupus. Following the initiation of steroids, he improved and there has been no recurrence of pancreatitis over the next 4 years. Case 3- A 9-year-girl presented with generalised rash and alopecia for 5 months. She also had pain abdomen for last 2 months. Investigations showed elevated amylase and ultrasound abdomen revealed acute pancreatitis. She had undergone a laparotomy elsewhere. Examination showed generalised pigmented rash, periorbital edema, alopecia, periorbital puffiness, hard palate ulcer and surgical scar on the abdomen. Urinalysis showed nephrotic range proteinuria. Serum amylase levels were elevated. Ultrasound abdomen revealed a pancreatic pseudocyst. Further investigations were suggestive of lupus. Workup for APLA revealed positive lupus anticoagulant. She was initiated on oral prednisolone and was given pulses of intravenous cyclophosphamide. Workup for APLA revealed positive lupus anticoagulant. She was initiated on oral prednisolone and was given pulses of intravenous cyclophosphamide. She had undergone a laparotomy elsewhere. Examination showed generalised pigmented rash, periorbital edema, alopecia, periorbital puffiness, hard palate ulcer and surgical scar on the abdomen. Urinalysis showed nephrotic range proteinuria. Serum amylase levels were elevated. Ultrasound abdomen revealed a pancreatic pseudocyst. Further investigations were suggestive of lupus. Workup for APLA revealed positive lupus anticoagulant. She was initiated on oral prednisolone and was given pulses of intravenous cyclophosphamide. There has been no recurrence of pancreatitis over 12-years follow-up.

AB0519 | VITAMIN D CUT-OFF POINTS RELATED WITH CLINICAL FEATURES IN PATIENTS WITH SLE WITH ACTIVE LUPUS OR LUPUS NEPHRITIS
Renato Guzman1, Luis Gabriel Piñeros2, María Camila Mejía6, Anibal Teheran2, Luis Miguel Pombor3, Vanessa Cadavid3, COMPLEXUS: GIVFTA, 1Fundación Universitaria Juan N. Corpas, Research center, Bogota, Colombia, 2Fundación Universitaria Juan N. Corpas, Research center, Bogota, Colombia

Background: Vitamin D (25OHD) has immunomodulatory properties that can play a major role in patients with active lupus or lupus nephritis. His immunomodulatory function could be influenced by demographic factors, comorbidities (Charlson score), bone supplements, and other features.

Objectives: We explored the association between the best 25OHD cut-off points and specific clinical features that were present in patients with active lupus or lupus nephritis.

Methods: A retrospective descriptive research using clinical registers of patients diagnosed with systemic erythematosus lupus, attended in two rheumatology clinics was performed. A decision tree model was used to identify the best cut-off points of 25OHD (ng/ml) and clinical features associated with active lupus (SLEDAI-2k >6) or lupus nephritis.

Results: We identified 81 patients, median age 41 years, women 91.3%. Active lupus and lupus nephritis were present in 69.1% and 29.6%, respectively. Median 25OHD was 26.49, without a difference at comparing with active lupus patients 24.85, but lower in lupus nephritis patients 21.50 (p: 0.015). Lupus nephritis was absent in patients with 25OHD cut-off points >38.8 (alone) or <38.8 if they were older than >57 years. Active lupus was always present in patients ≤44 years with 1. High comorbidity or 2. Low comorbidity plus cut-off point 25OHD >35; in ≤44 years, both a euthyroid state and the absence of bone supplements were present in patients with active lupus.

Conclusion: Exist a strong relationship between vitamin D levels and LES activity.

AB0520 | A COMPARISON OF SHEAR WAVE ELASTOGRAPHIC FINDING OF SUBMANDIBULAR GLAND IN PATIENTS WITH EARLY-STAGE AND NON-SJÖGREN'S SYNDROME
Naoki Hashimoto1, Shozo Uchiyama2, Masayasu Kitano3, Takashi Nakazawa4, Tsuyoshi Iwasaki5, Takenori Hashimoto1. 1Department of Rheumatology, Osaka, Japan; 2Kansai Medical University, Temmabashi General Clinic, Osaka, Japan; 3Hyogo College of Medicine, Division of Rheumatology, Department of Internal Medicine, Nishinomya, Japan; 4Osaka Saiseikai Nakatsu Hospital, Department of Rheumatology, Osaka, Japan; 5Hyogo University of Health Sciences, Department of Pharmacy, Kobe, Japan

Background: Salivary gland (SG) ultrasonography proved valuable for assessing SG involvement in Sjögren’s syndrome (SS) and seemed to exhibit good diagnostic properties. We have reported that the submandibular gland ultrasonography (SGUS) is a useful noninvasive and inexpensive procedure for the evaluation of the structural changes of SG in SS (ISSS 2002, EULAR 2009, EULAR 2012, EULAR 2015). However, our previous study demonstrated that although SGUS findings were useful for the diagnosis of SS with low salivary flow they were not for early stage SS with normal salivary flow (EULAR 2016). Recently, we reported that the tissue elasticity was decreased due to structural changes in the SG at the advanced stage of the disease and that the shear wave
elastography (SWE) is useful to distinguish pathological changes of the SG between early stage with normal salivary flow and advanced stage (EULAR2018). The present study we demonstrated that the tissue elasticity was increased due to inflammation and high viscosity in the SG at the early stage of SS with normal salivary flow comparing that in non-SS patients, but was decreased due to structural changes in the SG at the advanced stage of the disease. The SWE may be a useful tool for elucidation of early stage pathological changes of the SG when salivary gland functions are not impaired in SS.

Objectives: The aim of this study was to elucidate the usefulness of SWE in early-stage SS patients.

Methods: Seventeen non-SS patients and eighty patients who fulfilled the American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria for SS were studied. SS patients were divided into three groups according to salivary flow using gum test (VL/SS: <5mL/10min, (n=33), LSS: 5-10mL/10min, (n=32) and N/SS: ≥10mL/10min, (n=15)). All patients were examined SGUS by a single investigator who was blinded to device (TUS-A300; Canon Medical Systems, Tokyo, Japan) with a linear transducer (7.5-10MHz). The examination consisted of conventional B-mode US (US staging score), pulsed wave Doppler US (PD grading score) and SWE with quantitative assessment of US staging scores were assessed. Technical University Munich, Otorhinolaryngology/Benedikt Hofauer, Andreas Knopf, Carmen Unterhofer, Naglaa Mansour, Laryngological Society protocol1, which includes five different items: perceptual assessment (roughness, breathiness, hoarseness), videotrinoscopy, acoustics (jitter, dysphonia severity index, DSI), aerodynamics and subjective rating by the patient (voice handicap index, VHI).

Results: The Vs and E values were correlated with US staging score placed over the stiffest areas of the lesion on SWE, the quantitative systems, Tokyo, Japan) with a linear transducer (7.5-10MHz). The examiners between patients with non-SS and early-stage SS with normal salivary flow comparing that in non-SS patients. The SWE may be a useful tool for the differential diagnosis of early stage pathological changes of the SG when salivary gland functions are not impaired in SS.

Conclusion: The evaluation of various laryngeal functions in patients with Sjögren’s Syndrome unfolded an impairment of different aspects. Questions on laryngeal involvement should be implemented in the anamnesis of these patients and the application of screening methods should be further investigated.

MENOPAUSE IN AN EGYPTIAN COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: EFFECT OF THE DISEASE

Sarah A. Elbakry, Salaa A. Hussein, Rasha M. Hamouda, Marina W. Naguib.
Internal Medicine Department, Division of Rheumatology, Ain Shams University, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease that mainly affects females in the reproductive age1. Although SLE generally emerges during reproductive ages, it was found that lupus patients experience menopause at younger age than the general population; however, whether the occurrence of menopause at a younger age in lupus patients results from the gonadotoxic effects of Cyclophosphamide treatment or from an autoimmune-mediated ovarian injury is debated2.

Objectives: To identify menopause characteristics in an Egyptian cohort of women with SLE with effect of the disease on menstrual symptoms and the characteristics of disease activity and disease damage in perimenopausal and post-menopausal patients.

Methods: In this cross-sectional observational study, data of 120 consecutive SLE female patients who fulfilled the 2012 ACR/SLiC criteria3 above the age of 35. Disease activity was assessed by using the SLE disease activity index (SLEDAI)4, and accumulated damage was assessed by Systemic Lupus International Collaborative Clinics/American College of Rheumatology Damage Index (SLICC/ACR Di)5. Laboratory assessment was done to all patients including follicle stimulating hormone (FSH) and luteinizing hormone (LH) blood levels.

Results: The mean age of the patients was 45.067 ± 8.211 years and mean disease duration was 5.074 ± 5.567 years (min 0.08 – max 21 years). It was found that the median of total SLEDAI score was 4.667 ± 3.357 and mean of total SLICC/ACR damage index was 0.633 ± 0.819. Of 120 patients 20% had premature menopause, 29.17% had natural menopause and 50.83% were still menstruating (table 1). It was found that the age at menopause (either natural or premature menopause) ranged from 26 to 54 years with the mean 45.170 ± 7.278 years. There was a statistically significant negative correlation between LH and total SLEDAI (r = - 0.178, P = 0.052). It was also found a statistically significant negative correlation between LH and total SLICC/ACR damage index (r = -0.214, P = 0.046*).

Conclusion: SLE has a reproductive and hormonal impact on female patients, either because of disease activity or due to pharmacological adverse effects. The mean age at menopause (either natural or premature menopause) is 45 years. High LH is associated with lower disease activity. High cumulative Cyclophosphamide dose is associated with high FSH and LH.

SELENA1, Suhan Can2, Bahar Arif-Esen3, Ahmet Gu5, Mahdume Lale Ocal3, Gunnur Deniz2, Murat Inan2, Istanbul University, Istanbul Faculty of Medicine, Internal Medicine, Istanbul, Turkey, Istanbul University, Aizir Sancar Institute of Experimental Medicine, Immunology, Istanbul, Turkey, Istanbul University, Istanbul Faculty of Medicine, Rheumatology, Istanbul, Turkey.

Background: BAFF and APRIL are cytokines involved in B cell development and they take place in the pathogenesis of SLE.

Objectives: The aim of this study was to investigate the relationship between serum BAFF/APRIL levels with clinical features and disease activity in SLE patients.

Methods: We included 79 patients with SLE (ACR criteria) and 27 healthy controls into the study. Serum BAFF and APRIL levels were assessed by ELISA. In 19 patients with active disease at the time of the assessment BAFF/APRIL levels were reassessed at least 6 months later (mean 7.8 months) and disease activity was evaluated by SLEDAI. New renal involvement was observed in 16 patients during the study and renal involvement was previously detected in 12 patients.

Results: Although both BAFF (median 0.7 vs 0.41 ng/ml) and APRIL (median 2.3 vs 1.05 ng/ml) levels were higher in patients with SLE compared to the control group (p <0.001), no correlation was found between BAFF/APRIL levels and SLEDAI scores. Only 9 patients (11.4%) had both BAFF and APRIL in normal range (95% confidence interval). When patients were grouped according to disease activity as no activity (SLE-DAI = 0), low disease activity and active disease, there was no difference in BAFF/APRIL levels between groups. Serum BAFF levels were higher in patients with renal disease activity (median 0.94 ng/ml vs 0.61 ng/ml, p=0.01), and there was a positive correlation between APRIL levels and proteinuria (r=0.42, p=0.02). There was no association between BAFF/APRIL levels and anti-dsDNA positivity but a weak inverse correlation was observed between BAFF and C3 levels (r=-0.25, P=0.02). No correlation was found between BAFF/APRIL levels and renal SLEDAI score, renal histopathology activity and chronicity index scores. In the active disease group after follow-up, there was no significant change in BAFF (from 1.63 ng/ml to 1.2 ng/ml) and APRIL levels (from 2.11 ng/ml to 2.31 ng/ml).

Conclusion: BAFF/APRIL levels were found to be significantly higher in patients with SLE compared to controls, but no association with disease activity was found. BAFF levels are correlated with decreased C3 levels. These results suggest that both cytokines are involved in the pathogenesis of SLE, and that serum BAFF and APRIL levels can be valuable as a biomarker in SLE especially in patients with renal activity. Long-term studies on the effect of treatment are needed.

Background: Anti-Smith (Sm) antibody is a highly specific antibody for systemic lupus erythematosus (SLE). Despite the remarkable specificity of anti-Sm antibodies for SLE, the association between anti-Sm antibody level and the clinical manifestation of SLE is still unclear.

Objectives: We aimed to evaluate the association between anti-Sm antibodies and disease activity in patients with new-onset SLE.

AB0526 PRIMARY SJÖGREN’S SYNDROME AND ORGAN SYSTEM INVOLVEMENT: A RETROSPECTIVE STUDY OF 153 PATIENTS FROM WESTERN INDIA

Girish Kakade, Piyush Joshi, Canchi Balakrishnan, Akash Khune. PD Hinduja National Hospital and Medical Research Centre, Rheumatology, Mumbai, India

Background: Primary Sjögren’s syndrome (pSS) is under diagnosed and improperly treated disease because of its variable modes of presentation.

Objective: To describe organ system involvement in patients with pSS and compare to other studies.

Methods: Retrospective proforma based analysis of patients with pSS (AECG 2002 criteria) from 2002-2012 at a tertiary rheumatology centre was done. Demographic data and systemic organ involvement of patients was noted.

Results: We had 153 consecutive patients of pSS (135 females, 18 males) in the 10 years which were included. Mean age at diagnosis was 47±11.62 years. Mean duration of sicca symptoms was 32 (±31) months prior to presentation. Organ system involvement was seen in 93 (65.7%) patients as follows: Musculoskeletal involvement in 90 (58.8%) patients, Skin involvement in 48 (31%) patients, Lung involvement in 27 (17.6%) patients, Renal involvement in 22 (14.3%) patients, Neurological involvement in 21 (13.7%) patients, GI involvement in 6 (3.9%) patients and Lymphoma in 2 (1.3%) patients. Comparison of organ system involvement with other major studies of pSS is shown in Table 1.

Table 1. Comparison with major studies of pSS from different populations.

Results: At baseline between patients with and without anti-Sm antibodies. The longitudinal association between disease activity and anti-Sm antibodies was also evaluated in total patients and in those with anti-Sm antibodies.

Conclusion: This study suggests that anti-Sm antibody level is associated with disease activity in patients with new-onset SLE, and that monitoring with the alterations in SLEDAI (P = 0.029).

AB0527 PREDICTIVE VALUE OF MiR200B-5P IN THE LYMPHOMAGENESIS IN SJÖGREN’S SYNDROME (SS): COMPARISON WITH THE PUBLISHED PREDICTION MODELS. PRELIMINARY RESULTS

Friasla Kapsoergou, Athanasia Protagouerou, Aristeia Papageorgiou, Michael Voulgaris, Athanasios Tzioucas. School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Background: MiR200B-5p expression levels are decreased in the minor salivary glands of SS patients who have or will develop non-Hodgkin’s lymphoma (NHL), discriminate them from those who will not (p<0.0001) and independently predicted NHL development (p<0.0001)1.

Objective: To compare the predictive performance of low miR200B-5p levels with the previously published multifactorial predictive models.

Methods: 27 SS patients who didn’t develop NHL during follow up (median follow up time upon biopsy performance, range: 5.9yrs, 1.33-14yrs) and 17 diagnosed with NHL during follow up (pre-lymphoma, median follow-up till lymphoma diagnosis, range: 3.67yrs, 0.42-8.5yrs) were studied. The multifactorial predictive models examined were: 1. Ioannidis et al2 who defined patients expressing at least one of low C4 levels, salivary gland enlargement (SGE) and purpura as high-risk, 2. Baillera et al3 who designed 3 models (1, 2 and 3) based on the expression of at least 1, 2 or 3, respectively, of neutropenia, cryoglobulinaemia, splenomegaly, lymphadenopathy and low C4 levels. 3. Guartucci et al4 who identified as high risk patients those having SGE and at least two of the following: low C4 levels, cryoglobulinaemia, anti-La antibodies and leukopenia, and 4. Fragkoudaki et al5 that defined as high-risk group those carrying ≥ 3 of the independent risk factors including SGE, lymphadenopathy, Raynaud phenomenon, anti-Ro/SSA and/or anti-La/SSB antibodies, rheumatoid factor positivity, monoclonal gammapathy and low C4 levels. Analyses were performed by estimating the area under the ROC curve (AUC), Kaplan-Meier (KM) lymphoma-free survival curves.
compared by the log-rank test, the positive and negative predictive values, sensitivity (Se) and specificity (Sp), as well as the PSEP index of the model intrinsic prognostic value.

Results: ROC analysis identified low mir200b-5p levels as the better prognostic tool from the other multifactorial models. Its predictive value was further supported by the other analyses (including PSEP index), where it ranked among the two best models, whereas it had the better combination of sensitivity and specificity (Table).

Table. Comparison of models predicting NHL development in SS

<table>

AB0528 ANALYSIS OF THE CASES OF 33 SLE PATIENTS THAT NECESSITATED CARDIOVASCULAR SURGERY

Toshio Kawamoto, Satoshi Matsuotu, Hirofumi Amano, Kentaro Minowa, Mai Yoshida, Masakazu Matsushita, Ken Yamaji, Atsushi Amano, Naoto Tamura.

Juntendo University, Bunkyo-ku, Japan

Background: In SLE, immune complexes are overproduced and deposited in tissues where they ultimately cause damage. The immunocomplexes, which are deposited in the myocardium, blood vessels and atrioventricular valves, have been suggested to cause damage to the relevant tissues, but it remains unclear in which cases tissue damage progresses to a point that surgical treatment is required.

Objectives: The purpose of our study was to classify heart diseases into valvular heart diseases (V), ischemic heart diseases (I) and aortic aneurysms (A), to compare each class in terms of the correlation between the activity of SLE and the progression and exacerbation of heart disease, and in the future, to use the features of the correlations to carry out the prevention and treatment of heart diseases complicating SLE.

Methods: Between the years 2012 and 2018, a total of 2852 patients diagnosed with SLE were admitted to our hospital, and 33 had heart surgery; however, 2 patients with infective endocarditis and one patient, who had not been diagnosed with SLE before surgery, were excluded from the study, therefore 30 cases were examined. Comparative studies were also carried out to examine the association between the levels of various autoantibodies and IgG and the onset of heart disease, the association between the total administered doses of steroids, the concomitant use of immunosuppressants as well as the association between DNA antibodies and complement.

Results: At the time of the surgical treatment of the heart diseases, the mean duration of illness was 25.4 years, and the age was V vs. I vs. A =56.7 (44-79, median value: 56.2) vs. 55.1 (34-72, median value: 57.0) vs. 63.2 (41-78, median value: 65.5), showing that the age tended to be higher in the A group. The integrated value of the duration of illness and the level of anti-DNA antibodies, which served an index of activity, was calculated, and the findings revealed that V vs. I vs. A was (14020 vs. 32666 vs. 29444), showing that the values tended to be slightly lower in valvular heart diseases. As for anti-phospholipid antibodies, the rate of positivity of either CL,β2GPI or anti-CL antibodies or LA was as follows: V vs. I vs. A (58% vs. 28% vs. 33%), showing that the rate tended to be higher in valvular heart diseases and that anti-CL antibody-positive patients were particularly higher in number among those with valvular heart diseases (V). The maximum preoperative levels of IgG as were as follows: V vs. I vs. A (2803 vs. 1889 vs. 1708), which showed that the levels were higher with valvular heart diseases (V); those of SS-A antibodies were as follows: (36% vs. 43% vs. 42%), which showed high positive rates in all classes; and RNP antibody-positivity rates were as follows: (9% vs. 29% vs. 25%), and were relatively lower in valvular heart diseases (V). Regarding the medical treatment, the total administered doses of steroids were (25g vs. 39g vs. 63g) and tended to be lower in valvular heart diseases (V); use of immunosuppressants was found in 5 of 30 patients (16%); and concomitant use of both was particularly low in valvular heart diseases (V) as it accounted for only one case.

Conclusion: Our study findings suggested that in SLE patients, prolonged duration of illness, positivity of SS-A antibodies and the absence of intake of immunosuppressants were highly likely to lead to cardiovascular diseases that need surgical treatment. Low integrated DNA antibody levels and the absence of concomitant use of immunosuppressants, despite high levels of IgG and the positivity of SS-A antibodies and anti-CL antibodies, might be risk factors for valvular heart diseases necessitating surgical treatment.

AB0529 SICCA SYNDROME DURING CHRONIC HEPATITIS C: PREVALENCE AND CHARACTERISTICS

KCHIR Ibra, 1Ons Gharbi2, Dhiel Issaou2, Dhouha Cherif2, Mejdia Essid2, Nadia Maamouri2, Medja Essid2, Nadia Maamouri2, La Rabba Hospital, Gastroenterology B, Tunis, Tunisia; La Rabha Hospital, Gastroenterology B, Tunis, Tunisia; Mongi Slim Hospital, Pathology, Tunis, Tunisia

Background: The prevalence of Sicca Syndrome (SS) in patients with Chronic Hepatitis C (CHC) ranges from 5% to 33%. A link between hepatitis C (HCV) and SS was evoked given the strong association of these two pathologies with mixed cryoglobulinemia (MC) on one hand and with the salivary tropism of HCV on the other hand.

Objectives: To study the prevalence and the characteristics of Sicca Syndrome during CHC.

Methods: All patients suffering from CHC followed over a period of 11 years (2002 – 2012) were retrospectively included. Only patients having clinical SS (xerostomia and/or xerophthalmia) were selected. We have analyzed all data concerning the patient, the hepatitis and the SS.

Results: Two hundred and four patients affected by CHC were included. All patients suffering from CHC followed over a period of 11 years (2002 – 2012) were retrospectively included. Only patients having clinical SS (xerostomia and/or xerophthalmia) were selected. We have analyzed all data concerning the patient, the hepatitis and the SS.

Disclosure of Interests: Efstathia Kapsogeorgou: None declared, Athanasie Protagoreou: None declared, Aristea Papageorgiou: None declared, Michael Voulgarelis: None declared, Athanasios Trioulas Grant/research support from: ABBEVIE, PFIZER, AMGEN, NOVARTIS, GSK
anti-SSB were absent in the 4 patients. Biopsy of accessory salivary glands revealed the presence of a grade 4 lymphocytic sialadenitis according to the Chisholm and Masson classification in 3 patients, while the remaining case had a lymphocyte grade 2 sialadenitis. The evaluation of hepatic fibrosis did not reveal cirrhosis in the 4 cases.

Conclusion: The prevalence of Sicca syndrome during hepatitis C is estimated at 8% in our study. It was mainly reported in women with perimenopausal age and seems to be associated with cryoglobulinemia, a high viral load and an advanced fibrosis.

AB0530 THE EFFECT OF MYCOPHENOLEATE MOFETIL ON NON-RENAL MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS FROM 2014 TO 2018: OBSERVATION STUDY FROM KOREAN LUPUS NETWORK (KORNET) REGISTRY

Seong-Kyu Kim1, Jung-Yoon Choe2, Li Hong-Jung3, 1Catholic University of Daegu School of Medicine, Daegu, Korea, Rep. of (South Korea); 2Catholic University of Daegu School of Medicine, Daegu, Korea, Rep. of (South Korea); 3Daegu Catholic University Medical Center, Daegu, Korea, Rep. of (South Korea)

Background: Mycophenolate mofetil (MMF) has been established to a potent therapeutic drug for regulate renal involvement in systemic lupus erythematous (SLE).

Objectives: The object of this study is to identify the effect of MMF on non-renal manifestations in SLE.

Methods: The study population was total 439 SLE patients enrolled from Korean Lupus Network (KORNET) registry. The KORNET registry was followed up annually and completed from baseline survey to the 2th visits from 2014 to 2018. In the subgroup analysis, the effect of MMF on clinical features was also evaluated in 110 patients with histologically confirmed lupus nephritis (LN). The changes of clinical features including mucocutaneous lesions, arthritis, serositis, neurologic disorder, and hemato logic abnormalities were assessed between MMF and non-MMF groups during follow-up period. Statistical analysis was used by multiple comparison analysis, considering time, group, and interaction of follow-up time and treatment group.

Results: There was significant difference of malar rash and renal disorder between MMF and non-MMF groups considering time and group in total SLE patients (p = 0.025 and p < 0.001, respectively). In hematologic abnormalities, proportion of leukopenia was significantly different between two groups during follow-up periods (p<0.001, p group < 0.001, and p time & group = 0.004). In 110 LN patients, there was not difference of non-renal clinical features between them. In contrast, proportion of leukopenia in patients with LN was significantly different between two groups during follow-up periods (p time < 0.001, p group < 0.003, and p time & group = 0.004).

Conclusion: This study showed that MMF might be beneficial to treatment for hematologic abnormalities in SLE.

AB0531 OBESITY INCREASES THE INCIDENCE OF NEW-ONSET LUPUS NEPHRITIS AND ORGAN DAMAGE DURING FOLLOW-UP IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Shin-Seok Lee, Ji-Hyoun Kang, Sung-Eun Choi, Haimuzi Xu, Dong-Jin Park, Cheonnam National University Hospital, Gwangju, Korea, Rep. of (South Korea)

Background: The object of this study is to identify the effect of MMF on patients with active non-renal SLE.

Methods: We obtained data on 393 SLE patients from the Korean Lupus Network registry. Demographic variables, clinical manifestations, laboratory findings, Physician Global Assessment (PGA), Systemic Lupus Erythema tosus Disease Activity Index (SLEDAI)-2000 and Systemic Lupus Interna tional Collaborating Clinics Group (SLICC) damage index scores were recorded at the time of enrollment. The tests were repeated annually for 3 consecutive years. We divided the patients into groups according to their body mass index (BMI) using the Asia-Pacific classification (normal, BMI < 23; overweight, 23 ≤ BMI <25; obese, BMI ≥ 25). Univariate and multivariate analyses were performed to assess the impact of obesity on clinical outcomes.

Results: Of the 393 patients, 59 (15.0%) were obese at the time of enrollment. Obese patients had more comorbidities, such as diabetes (P<0.002), hypertension (P<0.005), hyperlipidemia (P<0.005), and pulmonary hypertension (P=0.036) than non-obese patients. Nephritis at enrollment and newly developed nephritis during follow-up were more common in obese patients than in non-obese patients (P=0.002 and P=0.002, respectively). In addition, obese patients had higher daily and cumulative prednisolone doses (P=0.010 and P=0.010, respectively) and higher rates of intravenous cyclophosphamide (P=0.008), mycophenolate (P=0.030), tacrolimus (P=0.007), and cyclosporine (P=0.019) use than non-obese patients. Furthermore, the PGA and SLICC damage index scores were higher in obese patients than in non-obese patients (P=0.017 and P=0.039, respectively) for all 3 consecutive years. In the multivariate analysis, obesity was significantly associated with male gender (OR = 0.141, 95% CI: 0.047–0.419, P=0.001), newly developed nephritis (OR = 2.741, 95% CI: 1.280–6.957, P=0.034), and annual increase in SDI (OR = 2.185, 95% CI: 1.229–3.885, P=0.008).

Conclusion: Obese SLE patients had a higher incidence of newly developed nephritis and cumulative organ damage than non-obese patients. Therefore, lifestyle modifications, including those aimed at weight loss, should be recommended for these patients to improve their clinical outcomes.

AB0532 SOLUBLE SIGLEC-5 IS A NOVEL SALIVARY BIOMARKER FOR PRIMARY SJOGREN’S SYNDROME

Jennifer Lee, Moon Young Kim, Sung-Hwan Park, Seoul St Mary’s Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Despite advances in the understanding of the pathogenesis, disease-specific biomarkers have not been included in the classification criteria for Primary Sjogren’s syndrome (pSS).

Objectives: Based on the microarray of peripheral blood mononuclear cell (PBMC) of pSS patients, we aimed to investigate whether sialic acid-binding immunoglobulin-like lectin (siglec)-5 might serve as a biomarker for pSS.

Methods: Microarray of PBMCs obtained from 26 pSS patients and 10 healthy control (HCs) were performed to screen potential biomarkers for pSS. The concentration of siglec-5 in saliva and sera was determined by ELISA. Clinical parameters related with pSS were obtained from pSS registry and correlation with salivary siglec-5 level was evaluated.

Results: The level of salivary siglec-5/14 was significantly higher in pSS patients (n=170) compared with HCs (n=25) or non SS sicca patients (n=78) (1346.8 [202.8-4280.0] pg/mL, 6.08 [0-134.0] pg/mL, and 195 [0-947.5] pg/mL, median [interquartile range], P<0.001), meanwhile the serum level was not different between the groups. Clinical parameters were analyzed in 170 patients in pSS registry. Salivary siglec-5 level negatively correlated with salivary flow rate ( spearman’s rho: -0.420, P<0.001), and positively correlated with ocular surface score (rho: 0.331, P<0.001) and serum immunoglobulin G level (rho = 0.202, P=0.008). However, the level
of salivary siglec-5 was not correlated with ESSDAI or focus score. On ROC analysis, area under the curve was 0.7740(724.0-0.826). With cut off value 400pg/mL, sensitivity and specificity was 0.69 and 0.70 respectively. In validation cohort (45 psS patients and 45 non SS sicca patients) where patients without sicca symptom but have 1 or more positive items in ESSDAI were included, sensitivity and specificity of siglec-5 was 64.4% and 77.8%, respectively.

**Conclusion:** The level of soluble siglec-5 is significantly increased in the saliva of psS patients and reflects the severity of hyposalivation and ocul- lar surface damage. Although the mechanism of the contribution to gland dysfunction is unclear yet, this easily obtainable salivary biomarker may add benefits on the diagnosis of psS.

**AB0534 DEVELOPMENT OF A MULTI-MODALITY IMAGING APPROACH TO EVALUATE LUPUS NEPHRITIS AND INITIAL RESULTS**

**AB0534 DEVELOPMENT OF A MULTI-MODALITY IMAGING APPROACH TO EVALUATE LUPUS NEPHRITIS AND INITIAL RESULTS**

Fatigue is a common symptom in patients with Systemic Lupus Erythematosus (SLE). The aim of this study was to characterize the relationship between fatigue and other factors, including disease activity, vitamin D level, pain, depression, anxiety, sleep quality, exercise, and exercise in SLE. More specifically, we aimed to identify a number of factors that are significantly related to fatigue; of these it is most strongly dependent on depression and pain. This suggests that the etiology of fatigue in SLE is multifactorial and that in SLE patients reporting fatigue, the underlying cause needs to be identified and treated.

Conclusion:

Fatigue is highly prevalent in SLE patients. This study identified a number of factors that are significantly related to fatigue; of these it is most strongly dependent on depression and pain. This suggests that the etiology of fatigue in SLE is multifactorial and that in SLE patients reporting fatigue, the underlying cause needs to be identified and treated.

AB0535 PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND LYMHOPLA in a TERTIARY HOSPITAL: DESCRIPTIVE ANALYSIS OF NINE PATIENTS

Maria Martín López, Aimara Garcia, Minerva Montalvo, María Galindo-Izquierdo.

Hospital 12 de Octubre, MADRID, Spain

Background: Evidence of an increased risk to develop haematological malignancy, and especially non-Hodgkin’s lymphoma (NHL) in autoimmune diseases, has been gathered since the 1970s. In the last decade studies from SLE cohorts have consistently shown a markedly increased risk of NHL.

Objectives: To analyze clinical and disease characteristics in SLE patients who developed a lymphoma during follow-up, as well as to define characteristics of the lymphoma and its evolution.

Methods: Retrospective observational, longitudinal study conducted in a tertiary hospital. Medical records of 362 patients with >4 SLICC classification criteria of SLE were reviewed, including those with lymphoma diagnosis. Demographic and clinical data, comorbidities, SLE manifestations and therapy, data related to lymphoma and outcome were collected.

Descriptive statistic analysis with measures of central tendency and measures of variability was performed.

Results: Of the 362 SLE patients, 9 (2.5%) were diagnosed of lymphoma, of which 100% female. Mean age at SLE diagnosis was 34 y.o (SD 11) and average duration from SLE diagnosis to lymphoma diagnosis was 17 years (SD 14). 7 patients were caucasian and 2 hispanic. Observed comorbidities were hypertension (6 pt, 67%), diabetes (2 pt, 22%), dyslipidemia (3 pt, 33%), HBV infection (1 pt, 11%) and active smoking (6 pt).

No malignancy history was detected. Most frequent SLE features were haematological (9 pt, 100%), joint (5 pt, 56%) and skin (5 pt) involvement. The serious ones were: 3 patients with haemolytic anaemia (1 of them, platelets <20000), 2 epilepsy (1 of them with CNS vasculitis), 1 glomerulonephritis, 1 pulmonary hypertension and 1 hemophagocytic syndrome.

Only 1 patient had overlap with Sjogren’s syndrome. At the time of lymphoma diagnosis, 7 patients were on steroids, 4 on immunosuppressants, 2 on mycophenolate, 1 azathioprine and 1 rituximab and 3 on antimalarials (Table 1). Mean age at lymphoma diagnosis was 51 y.o (SD 10), 5 patients (56%) had diffuse large B-cell lymphoma (DLBCL), 1 had NHL, 1 had Hodgkin’s lymphoma, 1 had mantle B-cell lymphoma and 1 had MALT lymphoma. Only 1 patient, of 4 with available data, had EBV positive in the tissue. 7 patients (78%) received chemotherapy and 2 patients completed treatment with autologous peripheral stem-cell transplantation. Three patients died, 2 due to lymphoma and one due to other causes (severe flaccid paralysis, Miller Fisher syndrome). Overall survival after lymphoma diagnosis was 8 years (SD 6).

Conclusion: In our patients, unlike that reported in the literature, lymphoma diagnosis was in SLE with longer duration of the disease, and all cases were female. Most frequent subtype was NHL, and all patients had previous haematological manifestations. Regarding previous SLE treatment, 5 patients had been exposed to immunosuppressants.

AB0537 CHRONIC DAMAGE CONTRIBUTION TO COGNITIVE IMPAIRMENT IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

Gabriela Medina1, Judith Rodríguez Torres2, Antonio Montiel Rivera2, Erk Cimé Aké3, Miguel A. Saavedra2, Maria Pilar Cruz Domínguez4, Olga Lídia Vera Llastra5, Luis Javier Jara5, “Instituto Mexicano del Seguro Social, Clinical Research Unit, Mexico City, Mexico; 2Instituto Mexicano del Seguro Social, Internal Medicine, Mexico City, Mexico; 3La Salle University Nezahualcóyotl, Psychology, Nezahualcóyotl, Mexico; 4Instituto Mexicano del Seguro Social, Internal Medicine, Mexico City, Mexico; 5Instituto Mexicano del Seguro Social, Rheumatology Department, Mexico City, Mexico; 6Instituto Mexicano del Seguro Social, Research Division, Mexico City, Mexico; 7Instituto Mexicano del Seguro Social, Direction of Education and Research, Mexico City, Mexico

Background: There is a gamut of affections at neurological level in patients with primary APS (PAPS) including cognitive impairment (CI). It presents in middle age population carrying a high risk of dementia.

Objectives: To analyze the impact of chronic damage in CI and its associated factors in patients with PAPS.

Methods: Cross-sectional study in patients with PAPS (Sidney criteria). Demographic data, clinical and laboratory data were retrieved. The diagnosis of CI, MoCA version 8.1 questionnaire was employed and HAD questionnaire for depression screening. Patients were divided into two groups with and without CI. Chronic damage was measured with DIAPS, considering chronic damage as the damage established for over 6 months and with a score ≥1.

Results: Sixty PAPS patients were included, 76.7% were females. Clinical characteristics, associated risk factors and cognitive assessment by domain in both groups are shown in table 1. Only 1 patient presented depression and 3 had anxiety/depression by HAD test. Mild CI was present in 61.7%, moderate CI in 6.7% and no CI in 31.7%. Median depression and 3 had anxiety/depression by HAD test. Mild CI was present in 61.7%, moderate CI in 6.7% and no CI in 31.7%. Median depression and 3 had anxiety/depression by HAD test. Mild CI was present in 61.7%, moderate CI in 6.7% and no CI in 31.7%. Median depression and 3 had anxiety/depression by HAD test. Mild CI was present in 61.7%, moderate CI in 6.7% and no CI in 31.7%. Median depression and 3 had anxiety/depression by HAD test. Mild CI was present in 61.7%, moderate CI in 6.7% and no CI in 31.7%

Conclusion: The high score of DIAPS and persistence of aCL were associated with CI in PAPS. Chronic stress generated by accumulated chronic damage coupled with APS vasculopathy may contribute to cognitive deterioration. Prevention of chronic damage as well as a cognitive intervention are necessary in order to decrease CI.

AB0538 INFLUENCE OF IMMUNOLOGICAL FEATURES, DISEASE ACTIVITY AND FATIGUE ON THE HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH PRIMARY SJOGREN’S SYNDROME

Rada Miklova1,2, Aleksandra Plavsic1, Maja Stojanovic1, Zikica Jovicic1,2, Aleksandra Velcic Popadic1,2, Vesna Tomic Spirtic1,2, Sanvila Raskovic1,2,1 Clinical Center of Serbia, Clinic of Allergy and Immunology, Belgrade, Serbia; 2Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: Studies show that the health-related quality of life (HRQoL) is significantly reduced in patients with primary Sjögren’s syndrome (pSS). However, potential predictors of HRQoL in these patients are not well known.

Objectives: To investigate potential influence of main immunological features, fatigue and disease activity on the HRQoL in patients with pSS.

Methods: We studied 41 consecutive in- and outpatients with pSS diagnosed according to the AECG criteria in the Clinic of Allergy and Immunology. The SF-36 questionnaire has been used to assess HRQoL. The SF-36 values have been compared with the population based reference values. Fatigue was assessed using Fatigue Severity Scale (FSS). ESSDAI was used for the evaluation of systemic involvement and disease activity and ESSPRI for the evaluation of the patient-reported outcomes.

Results: There were 38/41 female patients. The mean age was 56.2 ±13.5 years and the mean disease duration was 3.9 ±5.8 years. HRQoL was reduced in almost all SF-36 domains in the comparison to healthy population: physical functioning (PF) (p=0.0161); role physical (RP) (p<0.0005); social functioning (SF) (p<0.0023); role emotional (RE) (p=0.0421). The mean value of FSS score was 4.6±2.2, with 53.6% of patients having FSS score more than 4.8 (which is considered to be pathological). There were no significant differences in HRQoL depending on the presence of ANA (p=0.44), anti-SSA Abs (p=0.0756), anti-SSB Abs (p=0.218), cryoglobulins (p=0.8), complement consumption (p=0.122).

Patients with elevated values of RF had significantly higher HRQoL (rho=0.486, p=0.00139), and especially with the domains of SF (rho=0.502, p=0.0005) and RF (rho=0.491, p=0.00129). We found a significant negative correlation between HRQoL and FSS score (rho=–0.794, p=0.001). The mean ESSDAI score was 3.8 (0–23), and 75.6% of patients had some level of disease activity according to ESSDAI. Patients with low disease activity had higher HRQoL compared to those with moderate disease activity in following SF-36 domains: physical composite score (PCS) (p=0.0148), PF (p=0.0328), RP (p=0.00697) and vitality (VT) (p=0.05). The mean ESSPRI score value was 5.1±2.7 (dryness scale – 6.1, fatigue scale – 5.4, limb pain scale – 3.8). ESSPRI score negatively correlated with HRQoL (rho=–0.763, p<0.001) in all SF-36 domains.

Conclusion: Our study identified ESSDAI, ESSPRI and FSS scores, serum RF and IgG concentrations as potential predictors of HRQoL in patients with pSS.
TEN YEARS OF THE MONASH LUPUS CLINIC: INSIGHT INTO THE CHARACTERISTICS AND OUTCOMES OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN AUSTRALIA

Rachel Koelmeyer1, Sumanpreet Toor2, Stellamay Gwini3, Vera Golder1,2, Erin F. Morand4,5

1Institute of Medical and Veterinary Science, Biobank (ALRB). Since its inception in 2007, the clinic has been co-run by rheumatologists and nephrologists. A carefully curated clinical dataset has been collected since clinic inception.

Objective: We provide an overview of the characteristics and longitudinal outcomes of adult lupus patients treated at the Monash Lupus Clinic over the last ten years.

Methods: A ten-year-long dataset from the original Monash Lupus Clinic cohort, of patients subsequently enrolled in the Australian Lupus Registry and Biobank, was used for the analysis. The dataset included information on patient demographics, lupus diagnosis, serological profile, treatments, disease activity, damage accrual and other medical outcomes such as renal failure, adverse pregnancy outcomes and hospitalisations. Descriptive statistics were used to summarise the characteristics of the study population. Bivariate tests and regression analyses were used for comparisons between inception cohort patients, enrolled in the registry within 15 months of their Systemic Lupus Erythematosus (SLE) diagnosis, and existing SLE patients enrolled later in their disease course.

Results: Of the 329 enrolled patients, the median age at enrolment was 38.0 years and 87.8% of were female. Most patients were either of Caucasian (48.6%) or Asian (36.5%) ethnicity. Patients were enrolled a median of 4.0 years after their SLE diagnosis; 31.0% of patients were inception cohort patients. Most patients (95.4%) had an abnormal titre of anti-nuclear antibodies; 65.0% of the cohort were positive for anti-dsDNA, antinucleosomal, anti-P protein only in 8.8% in men. The cognitive dysfunction with moderate to severe disability was found in 43 (61.4%) patients. There was found the statistically significant difference between two groups (with and without CD) in serum levels of vitamin D, 54.01 nmol/l (±22.6) and 68.48 nmol/l (±27.1), resp. (p<0.01). The average value of the activity index (SLEDAI) score over the observation period was 4.0; 49.1% of the cohort spent ≥50% of the observation period in the Lupus Low Disease Activity State and 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients. The average value of the activity index (SLEDAI) score over the observation period was 4.0; 49.1% of the cohort spent ≥50% of the observation period in the Lupus Low Disease Activity State and 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients. The average value of the activity index (SLEDAI) score over the observation period was 4.0; 49.1% of the cohort spent ≥50% of the observation period in the Lupus Low Disease Activity State and 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients.

Conclusion: Running a multi-disciplinary clinic alongside research activity is both feasible and worthwhile. Systematic collection of longitudinal data on SLE patients has shown that adverse outcomes such as end-stage renal disease and mortality at death are rare; however, with more than half of the cohort having damage present at the end of the observation period, there is still work to be done to improve outcomes for SLE patients in Australia. Expansion of the Australian Lupus Registry and Biobank beyond the Monash Lupus Clinic will provide further insight into the characteristics and outcomes of SLE patients in Australia and provide a beneficial framework for future studies.

AB0540 CAN LOW SERUM VITAMIN D LEVELS AFFECT THE COGNITIVE FUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS?

Radka Moravcova1, Marie Posmurova2, Marta Olejárova1, 1Institute of Rheumatology, Prague 2, Czech Republic; 2Hospital of Charles University, Psychiatry Faculty, Prague 2, Czech Republic

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease involving various organs and systems including the nervous system. Neuropsychiatric SLE (NPSLE) occurs in 30 - 40% of SLE patients. One of the most common manifestations of NPSLE is cognitive dysfunction (CD), which is found in 20 - 80% of SLE patients. Epidemiological studies have reported vitamin D to be a potential risk factor of cognitive impairment within the general population. There have also been found associations between vitamin D deficiency and multiple disease states such as Alzheimer’s disease, multiple sclerosis and SLE. It is hypothesised that vitamin D contributes to neuroprotection by modulating the production of proinflammatory cytokines. Vitamin D deficiency is highly prevalent in SLE patients due to photoprotection, renal insufficiency and the use of different medication.

Objective: To establish a possible association between serum vitamin D levels and cognitive function in SLE patients. To determine the presence of certain auto-antibodies (anti-dsDNA, antinucleosomal, anti-P protein, and antiphospholipid) in the serum, and the disease activity.

Methods: We included a total number of 70 patients diagnosed with SLE according to the American College of Rheumatology (ACR) classification criteria. We assessed disease activity according to SLE Disease Activity Index (SLEDAI). CD was evaluated on the basis of psychological analysis of cognitive functions with testing of attention, memory, psychomotor speed, visual spatial skills and speed of cognitive information processing. Serum vitamin D levels were measured by standardized immunochemical assay from blood samples.

Results: We analyzed 70 patients, 64 (91.4%) women and 6 (8.6%) men. The cognitive dysfunction with moderate to severe disability was found in 43 (61.4%) patients. There was found the statistically significant difference between two groups (with and without CD) in serum levels of vitamin D, 54.01 nmol/l (±22.6) and 68.48 nmol/l (±27.1), resp. (p<0.01). The average value of the activity index (SLEDAI) score over the observation period was 4.0; 49.1% of the cohort spent ≥50% of the observation period in the Lupus Low Disease Activity State and 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients. The average value of the activity index (SLEDAI) score over the observation period was 4.0; 49.1% of the cohort spent ≥50% of the observation period in the Lupus Low Disease Activity State and 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients. The average value of the activity index (SLEDAI) score over the observation period was 4.0; 49.1% of the cohort spent ≥50% of the observation period in the Lupus Low Disease Activity State and 43.5% had ever had a SLEDAI score ≥10. Just over half (57.4%) had accrued damage at the end of the observation period; however, pleasingly only a very small minority had an abnormal frequency of vitamin D deficiency among SLE patients.

Conclusion: On the basis of obtained results it can be stated that cognitive dysfunction was present in a high number of SLE patients. We demonstrated a high frequency of vitamin D deficiency among SLE patients with CD and statistically significant lower levels of vitamin D than in patients without CD. These results suggest that low vitamin D level could be associated with impaired cognitive function.

AB0542  PREGNANCY OUTCOMES IN ANTIPHOSPHOLIPID SYNDROME: 8 YEAR-EXPERIENCE FROM A MULTIDISCIPLINARY UNIT

Agna Neto1,2, Patricia Martins3,4, Susana Capela4, Áglida Araujo2, Monicça Cerelito2, Manuelo Costa2, Luisa Pinto5, Reumatologia, Hospital de Egas Moniz, CHLLO, Lisboa, Portugal; 2Rheumatologia, Hospital Central do Funchal, Madeira, Portugal; 3Reumatologia e Doenças Ossés Metabólicas, Centro Académico de Medicina de Lisboa, Lisboa, Portugal; 4Instituto de Medicina Molecular, FUMIL, Centro Académico de Medicina de Lisboa, Lisboa, Portugal, 5Departamento de Ginecologia, Obstetrícia e Medicina da Reprodução, Hospital de Santa Maria, CHLN, Lisboa, Portugal

Background: Women with antiphospholipid syndrome (APS) are at increased risk of recurrent miscarriage, fetal death, placental insufficiency, preeclampsia and fetal growth restriction. Although treatment improves fetal-maternal outcomes, there are still some unsuccessful pregnancies. A multidisciplinary approach with strict monitoring is essential in order to attain obstetrical success.

Objectives: To assess pregnancy outcomes in Portuguese women with APS who were surveilled at a multidisciplinary unit.

Methods: Pregnant women fulfilling the Sydney classification criteria for definite APS, who attended our specialized Rheumatology and Obstetrics outpatient clinic between 2010 and 2018, were included in this retrospective observational study. Cases of suspected APS not meeting the classification criteria were excluded. All pregnancies were followed by a multidisciplinary team (rheumatologists, obstetricians and nurses). Data was collected from medical records. Adverse Pregnancy Outcomes (APO) were defined as: spontaneous abortion (<10w), fetal death (≥10w), neonatal death, fetal growth restriction (FGR) and delivery prior to 36 weeks of gestation with or without preterm premature rupture of membranes (PPROM).

Results: A total of 35 pregnancies were identified in 25 women with APS. Twelve (48%) patients had thrombotic APS, 9 (36%) had obstetric APS and 4 (16%) had mixed APS. Primary APS was seen in 56% of patients, while systemic lupus erythematosus was found in 44%. The average maternal age at conception was 32.8 ± 5.2 years. Mean duration of disease prior to pregnancy was 6.4 ± 5.5 years. In regard to antiphospholipid antibody (APL) profile, 28.6%, 25.7% and 28.6% of patients were triple, double and single positive, respectively. Although they had fulfilled laboratory criteria in the past, 17% of patients were negative for all APL. All patients were instructed to receive prophylactic or therapeutic low-molecular-weight heparin combined with low dose aspirin for the duration of pregnancy. Regarding fetal outcomes, there were 2 (5.7%) cases of first-trimester miscarriage, 1 (2.9%) medical abortion due to exposure to teratogenic drugs at the time of conception and 4 (11.4%) fetal deaths. Among the cases of fetal death, one concerned a patient who suspended heparin on her own initiative and another one who became pregnant under warfarin and whose fetus had trisomy 18. The other cases occurred at 11 and 18 weeks of gestation, under regular therapy. There were no cases of neonatal death or other fetal malformations. The rate of live births was 80%, with a mean gestational age of 37.3 ± 1.5 weeks and mean birth weight of 2796.4 ± 462.2 g. Most women delivered by cesarean section (54.3%) of cases. There were 6 (17.1%) cases of preterm birth, three (8.6%) corresponding to fetus with FGR. Concerning maternal outcomes, there was one single case (2.9%) of PE. There were no cases of eclampsia or HELLP syndrome.

AB0541  LUPUS MANIFESTATIONS IN A PATIENT WITH SPONDYLOARTHRITIS TREATED WITH TUMOUR NECROSIS FACTOR-ALPHA ANTAGONIST: SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) OR DRUG-INDUCED LUPUS ERYTHEMATOSUS (DILE)?

Mariam Hamid Mustapha1,2, Syang Pyng Gan1, Haslna Baharudin2, Norliza Zainudin1, Shereen Suzin Ch3,4, Hospital Selangor, Malaysia; 1Universiti Teknologi MARA (UiTM), Faculty of Medicine, Selangor, Malaysia

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune inflammatory disease. Drug-induced lupus erythematosus (DILE) is defined as the development of lupus-like symptoms that is temporarily related to continuous drug exposure which resolves with cessation of the offending drug. It is usually accompanied by serologic findings of a positive antinuclear antibody (ANA) and anti-histone antibodies. Tumour necrosis factor-α (TNFα) antagonist-induced lupus-like syndrome (TAILS) is a well-known side effect of this class of substances. A retrospective study reported twenty two cases whose lupus manifestations abated within a few weeks (median eight weeks) in all patients except one with longer-lasting evolution of six months.

Objectives: We reported a case which posed a diagnostic challenge to us, a patient with spondyloarthritids (SpA) who presented with lupus-like features during treatment with Golimumab.

Methods: Case report

Results: A 35-year-old lady was diagnosed as spondyloarthritis when she presented with peripheral arthritis, plantar fasciitis, right eye anterior uveitis and bilateral chronic sacroiliitis confirmed via sacroiliac magnetic resonance imaging. Investigations revealed raised erythrocyte sedimentation rate (ESR) and negative HLA-B27. She developed allergic reaction to sulfasalazine and non-steroidal anti-inflammatory drugs (NSAIDs), thus intravenous Golimumab was initiated. Although she responded to this therapy and ESR had reduced during assessment at 24 weeks, Golimumab was stopped due to funding issue. It was restarted after six months but had to be discontinued again after four months because she developed recurrent fever and malar rash. During this presentation, investigations revealed leucopenia of 2.46 × 109/L, ESR of 93 mm/hr, low complements and positive direct coombs’ test. ANA, anti-double stranded DNA, anti-histone antibody and anti-smith antibody were all negative. Inflammatory screen- ing was negative. TAILS secondary to Golimumab was diagnosed. Apart from discontinuation of Golimumab, 0.5mg/kg/day of prednisolone was started which resulted in improvement of the malar rash and leucopenia. However, four months after the last dose of Golimumab, recurrent fever and leucopenia recurred when the prednisolone dose was reduced to 5mg on alternate-days. At this time, we considered diagnosis of SLE rather than TAILS because of persistent SLE manifestation despite cessation of Golimumab and improvement with oral corticosteroid. Furthermore, although not pathognomonic, the anti-histone antibody was negative.

Conclusion: This case posed a diagnostic challenge as both SLE and DILE can present similarly. The approach to managing this patient with coexisting SpA and SLE is also a challenge since there is a dilemma as to what can be offered after failure of NSAIDs and conventional disease-modifying antirheumatic drugs since anti-TNFαIs is contraindicated in SLE.

REFERENCES
found between poor obstetric outcomes and history of thrombosis, presence of SLE or low complement levels (table 1).

Conclusion: In our study, most pregnancies were uneventful. Despite the small sample size, we reinforce the importance of a multidisciplinary evaluation and surveillance before, during and after pregnancy in women with APS in order to implement early treatment and to optimize fetal-maternal outcomes.

AB0543 FEATURES ASSOCIATED WITH RENAL DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS DECEASED OVER A 10-YEAR PERIOD

Ivan Padjen1, Marijan Ercog2, Mislav Cerovec2, Miroslav Mayer3, Ranko Stevanovic4, Branimir Anic5. 1University Hospital Centre Zagreb, University of Zagreb School of Medicine, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, Zagreb, Croatia, 2Croatian Institute of Public Health, Zagreb, Croatia

Background: Renal damage (RD) is one of the most important contributors to morbidity and mortality in patients with systemic lupus erythematosus (SLE).

Objectives: We aimed to assess features associated with RD in a group of 90 deceased SLE patients routinely followed-up at our institution, which serves as a national referral center for SLE.

Methods: We retrospectively analyzed 90 SLE patients (68 females) deceased from 2002 to 2011. All patients were ≥18 years of age at death, fulfilling ≥4/11 classification criteria of the American College of Rheumatology (ACR). We identified patients with RD, as defined by the Systemic Lupus International Collaborating Clinics (SLICC)/ACR index. An extensive set of variables was compared between patients with and without RD (RD and RD-N, respectively): demographics, ACR criteria at diagnosis and cumulatively at death, total damage and its components one year following diagnosis and non-renal damage and its components cumulatively at death, as well as components of the metabolic syndrome, smoking, sicca and Hughes syndrome. Frequencies were compared using the chi-square and Fisher’s exact test, and continuous variables using the t-test and Mann-Whitney U test. Variables associated with RD were analyzed using multivariate logistic regression.

Results: We identified 25/90 patients who accrued RD over the course of their disease. In the univariate analysis, we found no difference between RD and RD-N patients in any of the following parameters: demographics, total count of ACR criteria at diagnosis and death, as well as damage at one year after diagnosis and cumulative non-renal damage at death. Compared to RD-N patients, RD patients had a higher proportion of malar rash at diagnosis (11/25 vs. 13/65, p = 0.021) and a higher cumulative proportion of renal disorder (19/25 vs. 30/65, p = 0.011), including proteinuria and urinary casts (17/25 vs. 23/65, p = 0.005, for both). RD was associated with a higher proportion of renal disorder (19/25 vs. 30/65, p = 0.011), including proliferative lesions, and with more frequent occurrence of malar rash at diagnosis (11/25 vs. 15/65, p = 0.049). Conversely, hematological disorder and leukopenia at diagnosis were less frequent in RD compared to RD-N patients (4/25 vs. 30/65, p = 0.008 and 1/25 vs. 21/65, respectively). In the final multivariate model (adjusted for gender, age at diagnosis and disease duration), malar rash at diagnosis and the cumulative presence of renal disorder (classification criteria of the ACR) were positively associated with RD. Conversely, leukopenia at diagnosis was inversely associated with RD (Figure 1).

Conclusion: More than a quarter of deceased patients accrued RD. While malar rash at diagnosis may be associated with a higher likelihood of developing RD, early leukopenia may be associated with its lower likelihood in deceased patients.

AB0544 ECHOCARDIOGRAPHIC CHANGES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS BEFORE TO INITIATION OF IMMUNOSUPPRESSIVE THERAPY

Tatiana Panafidina1, Tatiana Popkova2, Alexander Volkov3. V.A.Nasonova Research Institute of Rheumatology; Systemic rheumatic diseases, Moscow, Russian Federation; V.A.Nasonova Research Institute of Rheumatology, Systemic rheumatic diseases, Moscow, Russian Federation; V.A.Nasonova Research Institute of Rheumatology, Diagnostic department, Moscow, Russian Federation

Background: Cardiovascular diseases are becoming the leading cause of death among SLE patients due to increasing life-spans. Transthoracic echocardiography (TTE) is a reliable and widely available modality in everyday clinical practice useful to identify specific pathological cardiac changes and predictors of heart failure (HF).

Objectives: Obtaining of specific TTE findings in SLE patients prior to initiation of pathogenic immunosuppressive therapy was the objective in this study.

Methods: Thirty four pts (91% females, aged 30[26-34]years [median [interquartile range 25%-75%]) with “non-treated” SLE (ACR 1997 and SLICC 2012 criteria) were included. None of pts was treated either with prednisone or cytotoxic drugs at the moment of inclusion.

Results: Median SLE duration was 18[6-60]months, SLEDAI-2K - 13[1-19], SLICC/DI - 0[0-6]scores. Leading SLE clinical manifestations included: hematological changes (74%), kidney involvement (59%), joints (50%) and skin involvement (50%). Immunological abnormalities were detected in all patients and were as follows: ANA positivity – in 100%, anti-dsDNA antibodies – in 76% of SLE patients. Concurrent antiphospholipid syndrome was found in 2(6%) patients. Valve insufficiency with varying degree of regurgitation was the commonest pathology found in “non-treated” SLE patients based on TTE data: mitral valve insufficiency – in 31(91%), tricuspid valve – in 31(91%), pulmonary valve insufficiency – in 21(62%), aortic valve insufficiency – in 4(12%) patients. Endocarditis was a rare pathology found in 5(15%) patients, while mitral and tricuspid valves prolapse was seen more often – in 16(47%), while not a single case of valve stenosis was found. Pericardial pathology was detected in 16(47%) patients: exudative – in 9(26%), and adhesive (thickening, hardening and separation of leaflets) in 7(21%). There were no cases of CAD or MI, although there were 2(6%) documented cases of chest pain in history, and 1(3%) case of confirmed CHF. Most common TRF were dyslipidemia and hypertension - in 15(44%) and 11(32%) SLE patients respectively. Median LVEF was 64[59-67], LV end-systolic dimension – 30[27-32]mm, LV end-diastolic dimension – 48[45-51]mm, pulmonary artery systolic pressure – 2[22-32]mmHg. LV diastolic dysfunction (LVDD) was found in 10 (29%), systolic dysfunction (LVSD) – in 4(12%), LV myocardial hypertrophy (LVH) – in 5(15%); left atrium dilatation (LAD) was found in 4(12%), and increased dimensions of right atrium was detected in 3(9%) SLE patients.

Conclusion: Most common cardiac abnormalities in “non-treated” SLE patients with high activity (SLDAI-2K > 13 scores) were valve dysfunction (insufficiency with regurgitation), mitral and tricuspid valve prolapse and pericarditis. Of importance is the presence of early subclinical features of HF almost in 1/3 of naïve to treatment SLE patients: LVDD (29%), LVH (15%), and LAD (12%). SLE patients should be thoroughly monitored both for adequate control of SLE activity, and cardiac pathology with correction of TRF, regular assessments by a cardiologist, TTE, and early administration of cardio-protection therapy in view of increased HF risk in SLE patients, predetermining unfavorable prognosis.

Disclosure of Interests: None declared

DYNAMICS OF N-TERMINAL FRAGMENT OF BRAIN NATRIURETIC PEPTIDE PROGENITOR LEVEL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS, WITHOUT HEART FAILURE SIGNS BEFORE AND AFTER IMMUNOSUPPRESSIVE THERAPY

Tatiana Parašordiala, Tatiana Popkova, Maria Cherkasova a, V.A. Nasonova Research Institute of Rheumatology, Systemic rheumatic diseases, Moscow, Russian Federation; b, V.A. Nasonova Research Institute of Rheumatology, Laboratory department, Moscow, Russian Federation

Background: Cardiovascular mortality is increased in systemic lupus erythematosus (SLE). Elevated plasma concentration of N-terminal fragment of brain natriuretic peptide progenitor (NT-proBNP) is a laboratory marker of heart failure (HF), associated with cardiovascular morbidity and mortality in the general population.

Objectives: To measure NT-proBNP serum levels in SLE patients without HF signs before initiation of the therapy. To monitor NT-proBNP levels during therapy up to achieving SLE remission.

Methods: The study included 15 patients (87% females, aged 31[29-33] years (median [interquartile range 25-75%]) with untreated SLE (ACR 1997 and SLICC 2012 criteria) without HF. These patients were a new-onset and long-standing disease, who discontinued administered therapy. The control included 39 healthy donors (27[24-44] years, 87% females). A comprehensive SLE patients’ evaluation was made twice: at baseline and at the end of follow-up (FUP), median FUP was 7[2-7] years. Serum levels of NT-proBNP (pg/ml) were measured using electrochemiluminescence method Elecsys proBNP II (Roche Diagnostics, Switzerland). Normal NT-proBNP levels should vary within <125pg/ml.

Results: At enrollment median SLE duration was 1[1-7] years, SLEDAI-2K - 10[8-20], SLICC-DI - 0[0-1] scores, SLE patients had elevated (vs controls) values of NT-proBNP: 150[77.7-650.5] vs 44.6[29.7-66.9]pg/ml, p<0.001, NT-proBNP concentrations >125pg/ml were found in 8(53%) SLE patients without HF. Glucocorticoids and hydroxychloroquine were initiated in all patients, and additionally cyclophosphamide was administered in 7(47%) patients, mycophenolate mofetil – in 5(33%), rituximab – in 3(20%). By the end of FUP patients’ median age was 36 [34-39] years p>0.001, SLE duration - 8[7.5-11] years, stable remission was achieved in 14(93%) patients, a relapse of exacerbation was documented in 1(7%) patient, SLEDAI-2K - 2[0-4] p<0.01, SLICC-DI - 0[0-2] scores p<0.05. NT-proBNP levels were comparable to values in the control group: 26.6[19.3-64.9] vs 44.6[29.7-66.9]pg/ml, p>0.05, with only one case (7%) with NT-proBNP level >125pg/ml.

Conclusion: NT-proBNP concentrations in "untreated" SLE patients with high disease activity and without CV pathology and HF were significantly higher than in the control group (p<0.001), and more than 50% of these patients had elevated NT-proBNP (>125pg/ml) baseline concentration. Elevated NT-proBNP concentrations were associated with markers renal function (creatinine, urea, GFR). Adequate immunosuppressive therapy resulted in achievement of SLE remission and normalization of NT-proBNP concentrations.

Disclosure of Interests: None declared

IS IMMUNOLOGICAL PROFILE THE PRIMARY DRIVING FORCE BEHIND CLINICAL PICTURE OF SJÖGREN SYNDROME?

Katja Perdan-irkmajer, Aljosa Hecevar, Ziga Rotar, Matija Tomsic, Nalasa Gaspersic, Sonja Porcarin, V.A. Nasonova Research Institute of Rheumatology, Ljubljana, Slovenia; a, University Medical Centre Ljubljana, Rheumatology, Ljubljana, Slovenia; b, University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: Primary SS (pSS) is a unique autoimmune disorder with a diverse spectrum of clinical and serological manifestations. Multiple clinical and laboratory determinants have been suggested to affect disease progression. Among these, early-onset (up to 35 years) has been proposed to indicate more severe disease.

Objectives: To determine possible clinical and laboratory differences between pSS patients diagnosed at 35 years or younger and those diagnosed after the age of 35.

Methods: We analyzed a single-centre cohort of 228 adult patients with pSS. For 189 consecutive patients diagnosed between the years 2002 and 2008, the data were collected retrospectively from medical charts, while 39 consecutive patients diagnosed from 2016 to 2018 were followed prospectively. Clinical and laboratory data at diagnosis were collected as defined by ESSDAI. The patients were monitored for new organ involvement during the follow-up period. Categorical variables were compared between those diagnosed ≤ 35 years and after 35 years using the χ2-test or Fisher’s exact test. Continuous variables were compared using the Mann-Whitney U test. A multivariate logistic regression model was used to test the association between early- and over 35 years-onset pSS, anti-SSA positivity, baseline ESSDAI, the duration of follow-up period and the progression of pSS defined as new organ involvement during the follow-up period.

Results: All patients in our cohort fulfilled the 2002 classification criteria. There were 24 (87.5% female, median age 32.5 (IQR 29-34)) early-onset patients and 204 (92.9% female, median age 59 (IQR 51-67)) patients diagnosed after the age of 35. The patients were monitored for new organ involvement during the follow-up period (6.5 (IQR 3-13) years in the early-onset group and 5 (IQR 2-10) years in the > 35 years group). The early-onset group presented with a significantly higher frequency of salivary gland enlargement (25.0% vs 7.8%, p = 0.017), cutaneous involvement (25.0% vs 5.9%, p = 0.006) cryptoglobulinemia (27.5% vs 12.3%, p<0.004), RF positivity (50% vs 25.5%, p = 0.028), anti-SSA positivity (87.5% vs 51.5% (p<0.001) and anti-SSb positivity (50% vs 22.8% (p<0.004). The presence of anti-SSA (odds ratio (OR) 3.93, 95% CI 1.69-9.12, p<0.001), and longer period of follow-up (OR 1.16, 95% CI 1.09-1.25, p<0.001), but not early onset of pSS (OR 0.68, 95% CI 0.32-1.43), associated with higher rate of active disease.

Conclusion: Early-onset pSS is a more severe disease with increased cardiovascular, cutaneous and immune-related manifestations compared with late-onset pSS, with increased risk of new organ involvement during the follow-up period.

AB0547 LUPUS ENTERITIS SERIES OF CASES IN DEVELOPING COUNTRY: FROM CLINICAL FINDINGS TO THERAPEUTIC MANAGEMENT

Guillermo Razo, Diego Felipe Garcia Rodriguez, David Alejandro Herrera Van Oostdam, Carlos Abdul Mendoza, Enrique Cuervas Orta, Alejandra Perez, Luis Gonzalo Hernandez. Hospital Central Ignacio Morones Prieto, Rheumatology, San Luis Potosi, Mexico

Background: The prevalence of lupus enteritis (LE) is 2% one of gastrointestinal manifestation of the involvement of the LES. The rapid onset of these symptoms requires determining the life-threatening conditions, but their detection becomes a challenge. We present a series of 6 cases of LE, the most clinical findings and limitations in our environment.

Objectives: Our objective was to describe six cases of lupus enteritis, its diagnostic challenge in our country with limited resources, frequent clinical presentations and its management.

Methods: We retrospectively reviewed the medical records of 6 patients in our hospital with a diagnosis of SLE according to SLICC ACR 2010 criteria between 2017-2018 for suspicion of lupus enteritis. We discard infectious etiology.

</table>

Results: We describe 6 cases, all the patients were woman with a mean age of 23.1 years and an average of 3.6 years until the presentation of enteritis. The clinical symptoms included mainly abdominal pain (100%), vomiting (50%), diarrhea (83%), nausea (50%) and fever (16%). The laboratory characteristics mainly reflect the high lupus activity: SLEDAI 23 pts. Low levels of complement (83%), anemia (50%). The homogeneous pattern predominated in 83%, antiDNA was quantified only in one patient due to a lack of resources, with high titer. The median level of CRP was 3.3 mg/dL. Only two patients (33%) presented class III lupus nephritis by biopsy. In CT, the sign of target shot was present in all cases. Only 1 patient could be biopsied with non-specific chronic colitis. All patients received corticosteroids as first-line treatment, with additional immunosuppressants with significant improvement. One patient died due to pulmonary complications.

Conclusion: We should consider lupus enteritis as a possible initial digestive manifestation in patients with SLE. Its diagnosis requires a high index of suspicion, being the CT one of the fundamental pillars for the diagnosis. There is no consensus in the management, however, it was initiated with pulses of methylprednisolone, with limitations to request immunological studies and biological therapy due to economic implications. Finally, we emphasize the need for a prospective evaluation of this rare disease by encouraging the establishment of an international registry.

AB0549  NEUROPSYCHIATRIC DISEASE IN SYSTEMIC LUPUS ERYTHEMATOUS AND PRIMARY SJÖGNENS SYNDROME: THE ADAPTATION OF A QUESTIONNAIRE

Inês Rego de Figueiredo, Maria Moraes-Fontes. Unidade de Doenças Auto-imunes/Medicina 7.2, Hospital de Curry Cabral, Centro Hospitalar Universitário Lisboa Central (CHULC), Lisboa, Portugal

Background: Systemic Lupus Erythematosus (SLE) and Primary Sjögren Syndrome (pSS) are systemic autoimmune diseases, both associated with neurological and psychiatric manifestations. In SLE there are several questionnaires used for neuropsychiatric screening and evaluation, however for pSS there are no specific tools available. Their development is required in order to standardize symptom assessment and allow for accurate disease prevalence estimation.

Objectives: The main objective of this project is to assess the prevalence of neurological and psychiatric manifestations in our cohort of SLE and pSS patients through the adaptation to Portuguese of a screening questionnaire developed by Mosca et al 2010 (1) and its relationship to quality of life.

Methods: A cross sectional study was performed by applying a screening questionnaire, adapted from Mosca et al (1), to patients with SLE and pSS. The outcomes were evaluated both as binary (neurologic (ND)>9 pts) and psychiatric (PD)>10 pts) disease versus no disease) and continuous variables (score average) and in relationship to demographic data, disease scores (SLEDAI and SLICC, and ESSDAI and ESSPRI) and a quality of life instrument (VAS score).

Results: A total of 70 participants (15 SLE and 54 pSS patients) participated in the study. Neurological disease was present in 63% and 48% and psychiatric disease in 25% and 15% of SLE and pSS patients, respectively. There was a statistically significant association between the presence of neurological and psychiatric disease and quality of life (pSLE PD 20 vs 75, p-value 0.004; SLE ND 60 vs 80, p-value 0.001 and PD 50 vs 76.5, p-value 0.008). There was a trend for higher ESSPRI scores, with higher psychiatric scores (0.54 Spearman correlation coefficient; p-value=0.03). SLE higher neurological scores correlated with older age (0.34 Spearman correlation coefficient, p-value=0.01).

Conclusion: The questionnaire yielded a frequency of neurological and psychiatric disease similar to literature, as well as correlation to quality of life. This study represents the first step in the validation process for the Portuguese language but results should be regarded with caution considering this questionnaire was designed for screening and not for diagnosis.

We would like also to thank Professor Brian Cleggatt for help in statistical issues, as well as the Harvard Medical School Portuguese Clinical Research Training Center.

Disclosure of Interests: None declared
Results: FLS+/Ro- patients were predominantly White (82% vs 77%), had a higher frequency of oral (97% vs 92%) and ocular (95% vs 91%) dryness, a lower frequency of ANA (60% vs 87%), hypocomplementemia (13% vs 23%), rheumatoid factor (26% vs 56%), cryoglobulins (5% vs 9%), a lower mean ESSDAI score (4.6 vs 6.6), and a lower systemic activity in the constitutional, lymphadenopatic, glandular, cutaneous, renal, hematological and biological domains (p<0.001 for all comparisons). Abnormal salivary flows and ANA remained significant independent variables after adjustment by age and gender.

Conclusion: Biopsy-proven primary SjS with negative anti-Ro antibodies is characterized by high frequency of sicca symptoms, mild immunological profile and low systemic activity.

AB0552  25 HYDROXY-VITAMIN D LEVEL IN SYSTEMIC LUPUS ERYTHEMATOSUS: IS IT RELATED TO DISEASE ACTIVITY AND LUPUS NEPHRITIS?

Ahlimam A, Rezk L, Rezk A, Alnaggar A, Ahmed Fayed, Ahmed Soliman. Cairo University, Faculty Of Medicine, Kasr Al Ainy, Internal Medicine, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease. SLE is attributed to different autoimmune mechanisms leading to the production of several autoantibodies and formation of immune complexes with subsequent organ damage. 25 hydroxy-vitamin D3 (25(OH)D3) plays a significant role in immune system regulation and is an important immunomodulatory hormone involved in various biochemical reactions.

Objectives: Are to assess the levels of 25(OH)D3 in patients with SLE and to investigate the relationship between 25(OH)D3 levels and disease activity in patients with and without lupus nephritis.

Methods: 300 subjects were included in the study and were divided into 3 groups: group 1 consisted of 100 patients with SLE and lupus nephritis (LN), group 2 consisted of 100 patients free from LN and group 3 consisted of 100 healthy volunteers as a control group. All patients fulfilled the American College of Rheumatology criteria for diagnosis of SLE and were recruited from Internal Medicine department and out-patient clinics, Cairo University Hospital. Exclusion criteria included diseases and drugs which affect the endothelial function such as: smoking, diabetes mellitus, essential hypertension, and coronary artery disease and drugs such as nitrates, hypolipidaemic drugs and aspirin. Disease activity was evaluated by systemic lupus erythematosus disease activity index (SLEDAI), 25(OH)D3 was measured using ELISA. 25(OH)D3 level (≥30 ng/ml) was considered as recommended, <30 ng/ml was considered vitamin D deficiency.

Results: The mean value of 25(OH)D3 was significantly lower in patients with lupus nephritis (17.1±5.5 ng/ml) and those without lupus nephritis (16.6±5.9 ng/ml) than in controls (36.7±3.3 ng/ml) (p-value 0.001). Serum 25(OH)D3 level was inversely correlated with the duration of SLE disease (r = -0.676, p-value <0.001) and with the duration of lupus nephritis (r = -0.363, p-value<0.001). There was also highly significant negative correlation between 25(OH)D3 level and prednisolone dose, hydroxychloroquine, cyclophosphamide and mycophenolate mofetil but not with NSAIDs.

Conclusions: 25(OH)D3 levels are markedly lower in patients with SLE. Low 25(OH)D3 levels are significantly correlated with disease activity parameters, disease duration and disease treatment.

AB0553  STUDY OF ANXIETY AND DEPRESSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Maria Rosas-Giménez1, Stack John2, James Galloway2, Natalia Mená-Vázquez1, Clara Fuego-Varela1, Antonio Fernandez-Nebro1, 1Rheumatology Service of the Regional University Hospital of Malaga (HRUM), Biomedical Research Institute of Malaga (IBIMA), University of Malaga, Malaga, Spain. 2KING’S COLLEGE HOSPITAL NHS FOUNDATION TRUST, London, United Kingdom

Objectives: To study the prevalence of anxiety and depression in a cohort of patients with SLE at King’s College Hospital in London, as well as its relationship with characteristics of disease and treatments

Methods: Cross-sectional study of a cohort of patients with SLE. All patients with SLE who had been included in the IMPARTs project (Integrating Mental and Physical healthcare: Research, Training and Services) were recruited between 2012-2016. All patients filled out the following questionnaires on a tablet device: PHQ9 (Patient Health Questionnaire) (Scores of 10 or more have an sensitivity and specificity close to 90% for major depression) and GAD-7 (7-item Generalized Anxiety Disorder) (Scores of 10 or more have an sensitivity and specificity close to 89% and 82% for GAD). Variables demographic, duration of the disease (months) and the profile of autoantibodies, Previous history of depression or anxiety, SLE-DAI, treatments, ESR, CPR, C3 and C4. Statistical analysis: descriptive, bivariable using T-Student and χ2.

Vit. D level in studied groups:

Conclusion: The prevalence of anxiety and depression in our group of patients was high, both related, as well as with the perception of pain and fatigue. A correct assessment of these manifestations and early treatment could help improve the quality of life of patients.

AB0554 RISK OF CORONARY ARTERY DISEASE AND STROKE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING JAPANESE HEALTH INSURANCE DATABASE

Ryoko Sakai, Suguru Honda, Shoz Suzuki, Masako Majima, Naoko Konda, Hideo Takada, Masayoshi Harigai, Hisashi Yamamaka. Tokyo Women’s Medical University. 1. Department of Rheumatology, Tokyo, Japan

Background: Patients with systemic lupus erythematosus (SLE) have higher risk of coronary artery disease (CAD) and stroke than the general population.1,2 Because these comorbidities influence on patients' vital prognosis and quality of life, it is essential for rheumatologists to manage them appropriately. Considering differences in lifestyle and ethnicity, it is of great interest and needed to investigate risk of these comorbidities in Asia. However, to date, such evidence is scarce.

Objectives: To estimate incidence rate (IR) and identify risk factors of CAD and stroke in patients with SLE using a Japanese health insurance database.

Methods: This retrospective longitudinal population-based study was conducted using claims data provided by Medical Data Vision Co., Ltd (Tokyo, Japan). We defined individuals as SLE cases if they met all of the following: 1) had at least one ICD10 code (M321 or M329); 2) had at least one prescription of oral corticosteroids (CS), methylprednisolone (mPSL) pulse therapy, immunosuppressive drugs (IS) (azathioprine, mizoribine, tacrolimus, mycophenolate mofetil, cyclophosphamide, methotrexate), biologics (belimumab, rituximab) or hydroxychloroquine between April 2008 and July 2017; 3) were 16 years old or over. The start of observation was defined by the first month in which cases met all of the above criteria. Patients were followed until the earliest of date of first CAD event or stroke, date of loss of follow-up, or the end of follow-up (June 2018). CAD and stroke were defined as follows: for CAD, at least one ICD10 code (I20.x or I21.x or I23-24.x) and either percutaneous coronary intervention, coronary artery bypass procedure, or thrombolytic agents during hospitalization: for stroke, at least one ICD10 code (I60-62.x or I63-64.x) and either cerebrovascular procedures, thrombolytic agents, or antiplatelet drugs during hospitalization. Patients were excluded if they had a previous diagnosis of CAD or stroke and were prescribed antiplatelet drugs or anticoagulants during the first 3 months. We defined baseline characteristics using the data from the first 3 months, and calculated IR and adjusted hazard ratio (HR) of risk factors for CAD or stroke after adjusting for baseline characteristics using a Cox proportional hazard model.

Results: In this study, 19,138 cases were included. The median age was 53 years and 81.3% were female. Median observation period was 3.1 years. IR (95% CI), 1,000 patient-years (PY) of CAD or stroke was 1.41 [1.11-1.77] and 4.10 [3.56-4.70], respectively. IR of any CAD or stroke was increased age-dependently (2.06 [1.47-2.80] for 16-39 years-old, 5.07 [4.36-5.86] for 40-69, 13.0 [10.9-15.5] for 70-). Adjusted HR [95% CI] was 1.37 [95% CI, 1.27-1.47] for age by decade, 3.34 [1.76-6.28] for CS use, 1.48 [1.16-1.84] for presence of hypertension (HT), 1.38 [1.04-1.85] for diabetes mellitus (DM), 1.73 [1.25-2.38] for chronic kidney disease (CKD), and 1.95 [1.15-3.32] for atrial fibrillation (AF).

Conclusion: This is the first study investigating the risk of CAD or stroke in Japanese patients with SLE using a large health insurance database. Older age, use of CS, and presence of HT, DM, CKD, and AF were identified as significant risk factors of these comorbidities.

AB0555 POTENTIAL ROLE OF PAROTID ELASTOGRAPHY IN DIAGNOSIS AND CLASSIFICATION OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Hasan Sato1, Belül Nur Demir1, Reyhan Bilici Salman1, Esra Temeli2, Hakan Babaoglu1, Nuh Atas1, Ásli Sayhi1, Betül Nur Demir1, Reyhan Bilici Salman1, Esra Temeli2, Seminur Haznedaroğlu1, Bema Göker1, Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 2Gazi University Faculty of Medicine, Radiology, Ankara, Turkey

Background: Despite the improvements in classifying patients with primary Sjögren’s syndrome with usage of the new 2016 ACR/EULAR classification criteria, there remains to be a need for improvement and investigating the value of new modalities in diagnosing as well as classifying these patients.

Objectives: to investigate potential role of parotid elastography in diagnosing and classification of patients with primary Sjögren’s syndrome (pSS)

Methods: This is a cross-sectional analysis of patients with primary Sjögren’s syndrome followed up in our out-patient Rheumatology clinic. We performed chart reviews and retrospectively investigated the available data on files to search whether or not our clinically diagnosed patients satisfied the 2002 AECG and/or 2016 ACR/EULAR criteria sets. Ultrasonographic and elastographic evaluation of parotid and submandibular glands bilaterally were performed on consecutive patients with clinical diagnosis of pSSs and contributions of these findings to classification criteria sets were interpreted.

Results: There were 95 pSS patients and 30 healthy gender and age matched controls. Strain ratio, shearwave velocity and Pascals values of the glands were examined. Parotid strain ratio, submandibular velocity and submandibular pascal values were statistically significantly different compared to healthy controls (Table).%66 of patients considered clinically as Sjögren syndrome satisfied 2016 ACR/EULAR criteria patients and% 84 satisfied 2002 AEC criteria classification criteria. We grouped patients with respect to parotid strain ratio taking 1.057 as the cut-off value. Those patients who did not satisfy 2016 ACR/EULAR criteria, but clinically diagnosed as pSSs (non criteria pSSs patients), also had significantly higher parotid strain ratio and submandibular velocity compared to healthy controls (p=0.016 and p<0.001 respectively). Interestingly, both criteria and non-criteria pSSs patients had similar parotid strain ratio and submandibular velocity (p=0.892 and p=0.260, respectively).

Conclusion: Parotid shear elastography is an easy and non-invasive method and can be a useful tool for the diagnosis and classification of patients with pSSs (1).

AB0556 PARTICULARITIES OF PULMONARY HYPERTENSION IN SYSTEMIC LUPUS ERYTHEMATOSUS

sameh sayhi, Nouha Ghris, Najej Boussetta, Bilel Aftaoui, Faida Aji, Nadia Ben Abdelflahid, Bassem Louzir. Military Hospital of Tunis, Autoimmune Diseases Unit Research: UR17DN02, Tunis, Tunisia

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that primarily affects young women. It is characterized by the production of autoantibodies and immune complexes. Vascular pulmonary involvement has long been considered rare, a consequence of thromboembolic events. It is in fact a proper entity, often of multifactorial mechanism, with spontaneous evolution to pulmonary arterial hypertension (PAH), which makes its gravity.

Objectives: The objective of our study is to determine the particularities of PAH during SLE.

Methods: We conducted a mono-centric, retrospective and descriptive study of the follow up of patients in the internal medicine department of the Military Hospital of Tunis for LES (diagnosis according to the ARA criteria) between January 2010 and December 2015.

Results: All patients underwent external echocardiography or during their stay in the department.

Results: We collected 87 patients diagnosed with SLE. PAH was recorded in 16 patients (38%) including 6 men and 10 women with a F/M sex ratio of 1.66. The average age was 37.23 years with extremes ranging from 16 to 70 years old. Clinically, we observed dyspnea in 10 patients (62%), chest pain in 7 cases (43%), dry cough in 2 cases (12%), palpatations in 1 case (6%), and right heart failure in 1 case (6%). At cardiac auscultation, 5 patients were tachycardic (31%), 5 had a tricuspid systolic murmur and 1 had an irregular rhythm. A burst of 82 in the pulmonary focus was noted in 3 patients (18%). Nine of the 16 patients with PAH had electrical signs: five had sinus tachycardia (31%), two had signs of right ventricular hypertrophy. A complete arrhythmia with atrial fibrillation was noted in one patient. The chest X-ray showed cardiomegaly in 6 patients (37%). Among the 16 patients, there was a tricuspid valve insufficiency associated with PAH in 7 patients (43%), 2 had mitral valve insufficiency (12%), 6 patients had pericarditis, one patient had endocarditis (6%) and myocarditis was found in another one (6%). PAH was isolated in 12 cases. In Immunological tests, NAs were positive in all patients. Three quarters of the patients (12) had native anti-DNA positive (75%) and ¼ of the patients (4) had anti-Sm positive and anti-RNP positive antibodies (25%). The complement was consumed in 5 cases (31.2%). Anti-phospholipid antibodies were noted in 4 cases (25%). Added to non-specific measures (smoking cessation, elimination of intense physical effort ...) adopted for all patients, oxygen therapy was indicated in four patients. Diltiazem 180 mg/day vasodilator therapy was prescribed in 3 patients. Effective anti-vitamin K anticoagulation was prescribed in a patient with severe PAH at 80 mg/ day.

Conclusion: Pulmonary arterial hypertension (PAH) is a rare complication of systemic lupus erythematosus, its prevalence varies from 0.5 to 17.5% depending on the series. SLE is the second leading cause of PAH in connective tissue disease after systemic sclerosis. This vascular involvement is essential for the prognosis and is an important evolutionary step in the management.

AB0557 NON-CORONARY CARDIAC MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN ADULTS

Nouha Ghris, sameh sayhi, Najeh Boussetta, Nour El Houla Gueddich, Faida Aji, Nadia Ben Abdelflahid, Bassem Louzir. military hospital, autoimmune diseases unit research: UR17DN02, tunis, Tunisia

Background: Systemic lupus erythematosus (SLE) is a common chronic multi-system autoimmune disorder of unknown etiology causing injury to many organ Systems. It predominantly affects young women. Cardiac manifestations develop in the majority of patients with SLE at some time during the course of their disease.

Objectives: The aim of our study is to assess cardiac abnormalities in patients with systemic lupus erythematosus (SLE) by echocardiography and to compare the 2 groups of patients with and without cardiac manifestations.

Methods: We have performed a transversal, descriptive study of SLE patients hospitalized in the Internal Medicine department at the Military Hospital of Tunis between January 2016 and June 2018. Diagnosis of SLE was made according to the criteria of ACR. All patients underwent a cardiac ultrasound externally or during their stay in our department.
Results: The patients were 61 females and 19 males (sex-ratio=3) with a mean age of 38 years. Forty two patients had cardiac involvement. They were 33 female and 9 male with a mean age of the disease of 31,8 years (16-80 years) at the beginning of the disease and 41 years at the time of the study. 83% of patients were symptomatic. The symptoms were dominated by objective chest pain (43%). In Doppler echocardiography, pericarditis was found in 23 patients (55%) with a single case of cardiac tamponade. Libman Sachs endocarditis and lupus myocarditis were found in one case each. Pulmonary hypertension (HTP) was observed in 16 patients (38%) and valvular disease in 22 patients (52%). Cardiomegaly was observed in 9 patients (21%). Electrical abnormalities were dominated by microvoltage in 8 patients. The general symptoms (83%), skin lesions (76%) and musculoskeletal involvement (64%) were the most frequent events associated with the cardiac manifestations in group 1. ANA were positive in 97% of cases and antiphospholipid antibodies in 24%. Prednisone: 1mg/kg/day and immunosuppressive therapy were indicated respectively in 71% and 38% of patients.

Conclusion: Cardiac abnormalities are very common in lupus patients even when clinically asymptomatic. SLE is among systemic diseases most providers of heart disease. Echocardiography is an excellent non-invasive tool for cardiac evaluation. Their research is systematic with echocardiography in order to reduce subsequent cardiac morbidity and mortality among the lupus patients.

AB0559 TIME OF DIAGNOSTICS OF SJOGREN’S SYNDROME DEPENDING ON ITS FIRST MANIFESTATION

Olexandr Kuryata1, Tetiana Lysunets2, Iliana Karavanska1, Anastasia Rytska1, Iryna Molokova1, Viktor Semenov1, 1 State Establishment “Mechinov Dnipropetrovsk Medical Academy of Health Ministry of Ukraine”, 2 Internal Medicine, Dnipro, Ukraine; 3 Municipal Institution “Mechinov Dnipropetrovsk Regional Hospital”, Rheumatology Department, Dnipro, Ukraine

Background: Sjogren’s syndrome (SS) is a rare autoimmune disease with multisystem manifestations. Diagnostics of SS is intricate due to its low prevalence and deed of invasive tests for diagnosis confirmation.

Objectives: To investigate influence of the first symptom of SS on the time of diagnosis establishment.

Methods: The study was conducted at Dnipropetrovsk Mechinov Regional Hospital, Dnipro, Ukraine. 23 patients (1 male and 22 females, mean age 54 [47;61] years) with SS that received medical care at Rheumatology Department from 2007th to 2017th were enrolled to the study. Diagnosis of SS was provided according to American-European Consensus Group criteria (2002). We analyzed time from the first symptom appearance to diagnosis of SS establishment. Symptoms of the disease onset were classified into 4 groups: fever (body temperature>37°C), arthritis (swelling and/or tenderness of >1 joints), signs of salivary glands injury (swelling of salivary glands, dry mouth syndrome) and other signs of autoimmune diseases (Raynaud’s phenomenon, rash, myalgia).

Results: Median time between the first symptoms and SS diagnostics was 8 [2;17] years. Time to SS diagnostics depending on the first manifestation is in the table below.

Table 1. Time of SS diagnostics depending on the first symptom.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Present</th>
<th>Absent</th>
<th>Log rank test [p]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fever</td>
<td>3 [1;8]</td>
<td>9.5 [2.2;17]</td>
<td>0.06</td>
</tr>
<tr>
<td>Arthritis</td>
<td>17 [6;22.5]</td>
<td>6.5 [2;11.5]</td>
<td>0.06</td>
</tr>
<tr>
<td>Salivary glands injury</td>
<td>11 [6;19.5]</td>
<td>4.5 [2;10]</td>

</tr>
<tr>
<td>Symptoms of autoimmune diseases</td>
<td>4 [2;8]</td>
<td>10.5 [2;18]</td>
<td>0.09</td>
</tr>
</tbody>
</table>

Presence of fever or symptoms of autoimmune diseases led to faster diagnostics of SS. Presence of salivary glands injury didn’t influence time of SS diagnostics, while arthritis enlarged it (Figure 1).

Conclusion: Fever and signs of autoimmune diseases may be useful in diagnostics of SS. Greater alertness of symptoms of salivary glands injury is needed.

A 10-YEAR REVIEW OF DAMAGE ACCRUAL AND PROGRESSION IN A MULTI-ETHNIC COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN MALAYSIA

Syahruil Saziyyah Shahrir1, Wong Michelle Heng Ting2, Asrul Abdul Wahab2, Sakthiswary Rajalingham1, Abdul Halim Abdul Gafor1, Mohd Shahrir Mohamed Said1, Ruslinda Mustafar3.

1Universiti Kebangsaan Malaysia, Rheumatology unit, Department of Internal Medicine, Kuala Lumpur, Malaysia; 2Universiti Kebangsaan Malaysia Medical Centre, Immunoimmunology and Microbiology Department, Kuala Lumpur, Malaysia; 3Universiti Kebangsaan Malaysia, Nephrology Unit, Department of Internal Medicine, Kuala Lumpur, Malaysia.

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease with an unpredictable course of disease. The severity and outcomes of SLE vary across different ethnicities.

Objectives: This study is aimed to determine the pattern of development and progression of organ damage in a cohort of multi-ethnic SLE patients followed for at least 10 years, and to identify the factors associated with the damage accrual.

Methods: We reviewed the medical records of an inception cohort of patients who attended regular monitoring since 2007 at the Rheumatology and Nephrology/SLE Clinic, National University of Malaysia Medical Centre (UKMMC). Their medical records were retrospectively reviewed to obtain SLE disease characteristics, frequency of disease flares, cumulative corticosteroid dose and the use of other immunosuppressive treatment from 2007 until their last visit in 2017. The Systemic Lupus International Collaborating Clinics/american College of Rheumatology damage index (SDI) was used to determine the organ damage at baseline and after 10 years of being followed up. For patients who have succumbed or lost to follow up during the 10-year observation period, the SDI scores just before death or time of follow up loss were recorded.

Results: A total of 258 patients were included with majority of them were Malays (n=145, 56.2%), followed by Chinese (n=100, 38.8%) and Indians (n=13, 5.0%). The mean SDI score increased from 0.39±0.79 at baseline to 1.13±1.47 after 10 years, p<0.001. At 10 years, Indian patients were found to have a significant increase in their SDI scores from baseline compared to Malay and Chinese (p<0.05). New damage accrual was recorded in 38.8% patients with the most common new organ damage significantly occurred in renal (p<0.001), ocular (p<0.05) and cardiovascular (p<0.07). Higher age at baseline, higher ACR criteria at diagnosis, persistent active disease ≥ 6 months, and prednisolone use of ≥ 1mg/kg were independently associated with higher risk of damage accrual. In contrast, hydroxychloroquine treatment was associated with lower risk of damage accrual.

Conclusion: The SDI scores of our SLE cohort increased significantly over 10 years which predominantly affecting the renal. Indian patients accumulated higher SDI scores while persistent active disease, higher ACR criteria at diagnosis, and the use of high dose steroid were associated with new organ damage.

AB0651 RISK FACTORS FOR ADVERSE PREGNANCY OUTCOMES AND LOW RISK FACTORS FOR ADVERSE PREGNANCY OUTCOMES AND LOW APGAR SCORES OF NEWBORNS IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Hironi Shisada, Risa Wakiya, Mai Mahmoud Fahmy Mansour, Shusaku Nakashima, Mikiya Kato, Taichi Miyagi, Tomohiro Kameda, Hiroaki Dobashi, Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that occurs in women of childbearing age, and has high risk for adverse pregnancy outcomes (APOs) (1,2). Moreover, it is unclear whether maternal SLE influences the growth and development of children born from SLE mothers. Apgar score at five minutes is a predictive factor of neurological development of newborns. However, there is no report about the association between maternal SLE and Apgar score of newborns.

Objectives: The aim of this study was to identify risk factors for APOs and for low Apgar scores of newborns from SLE mothers.

Methods: We investigated 50 SLE patients who were delivered from May 2006 to December 2018 in our institution. We examined retrospectively regarding APOs including spontaneous abortions, preterm births, premature rupture of membranes (PROM), light-for-date (LFD) newborns, and low Apgar scores of newborns. We analyzed the association between disease activity, laboratory findings, treatment agents, and APOs or Apgar scores.

Results: As for APOs of SLE mothers, cases with preterm births showed higher SLE disease activity index (SLEDAI) during the first trimester (P = 0.01) and higher titers of anti-double-stranded DNA (anti-dsDNA) antibodies at the time of conception (P < 0.01) compared to full-term births. In these cases, mean glucocorticoid doses during pregnancy (P = 0.02) and the rate of treatment intensification (P < 0.01) was higher than full-term birth. In the mothers who delivered LFD newborns, serum complement levels at conception were lower than in those with non-LFD newborns (C3: P = 0.02; CH50: P = 0.05). Cases with spontaneous abortions and PROMs did not differ significantly from the cases without spontaneous abortions and PROMs. Apgar scores at one minute were correlated with SLEDAI during the third trimester (P < 0.01) and with the titer of anti-dsDNA antibodies at conception (P < 0.01). Additionally, Apgar scores at five minutes were correlated with the titer of anti-dsDNA.
antibodies (P < 0.01). In multivariate analysis, there were significant associations between Apgar scores at five minutes and the titre of anti-dsDNA antibodies (P < 0.01, Table 1).

</tbody>
</table>

Conclusion: In SLE, immunological abnormalities at conception, high SLE-DAI and glucocorticoid doses were risk factors for preterm birth and having a LFD newborn. Apgar scores at five minutes were significantly associated with the titre of anti-dsDNA antibodies. Minimizing disease activity before pregnancy may decrease risks for mothers and their newborns. In preconception counseling, it is important for rheumatologists to explain these risk factors to patients with SLE who hope to conceive. There is a need for long-term follow-up studies focusing on the neurological development of children born from SLE mothers.

AB0562 CARDIOVASCULAR RISK FACTORS AND FRAMINGHAM RISK SCORE IN PRIMARY SJÖGREN SYNDROME PATIENTS: A COMPARATIVE STUDY WITH MATCHED CONTROLS

Joana Silva1, Daniela Faria1, Joana Neves2, Marcos Cerqueira2, Joana Rodrigues1, Soraia Azevedo1, José Tavares-Costa1, Filipa Teixeira1

Background: The association between cardiovascular (CV) risk and chronic systemic inflammatory diseases has been an issue of debate. There is compelling evidence of increased CV morbidity in conditions such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) (1). Primary Sjögren’s syndrome (pSS) is a chronic immune-mediated disease characterized by glandular and systemic manifestations, sharing clinical and immunological similarities with RA and SLE. However, in pSS patients the weight of cardiovascular disease attributed to traditional CV risk factors remains unclear.

Objectives: To determine the prevalence of traditional CV risk factors and long-term CV events based on the risk prediction tool of the Framingham risk score (FRS) in pSS patients.

Methods: The study included patients diagnosed with pSS, fulfilling both the 2016 ACR/EULAR and 2002 AECG criteria for the disease, followed-up at our Rheumatology department and aged 49 and age-sex-matched controls. Inclusion criteria were aged 30 to 74 and no history of CV events in order to calculate the FRS. In total, 46 out of 54 patients were eligible for the study. Data on the prevalence of traditional CV risk factors (diabetes, arterial hypertension and smoking), systolic blood pressure (SBP) values, total and high-density lipoprotein (HDL) cholesterol levels were collected and compared between groups. The 10-year risk for CV events according to FRS was calculated and means of patients and controls were compared. Parametric and nonparametric tests were used and the level of significance was defined as p<0.05.

Results: The mean age of pSS patients and healthy individuals was 58.0 ±11.6 and 54.1±13.6 years, respectively. The prevalence of arterial hypertension was higher in pSS patients than controls (52.2% versus 24.5%, p=0.005). The prevalence of diabetes and smoking did not differ significantly between the two groups (p=0.674 and p=0.949, respectively). The SBP values, total and HDL cholesterol levels were also similar between pSS patients and healthy subjects (p=0.063, p=0.413 and p=0.217, respectively).

Mean 10-years risk for CV events assessed by FRS was 11.8±8.3 for pSS patients and 7.8±4.3 for matched controls, with statistically significant difference (p=0.013).

Conclusion: In our study, pSS patients had a higher prevalence of arterial hypertension, which is in agreement with the M. Juarez et al (1) study. Although there were no significant differences in the other traditional CV risk factors, the results showed an increased 10-year risk for major CV events based on FRS assessment in pSS patients in comparison to age and sex-matched controls.

AB0563 TRAUMA AND SLE-CONSiderations regarding a Group of patients from Romania

Ana Alwina Stan, Monica Copotoiu. Tرغu-Mureş Emergency Clinical County Hospital, Rheumatology, Tرغu-Mureş, Romania

Background: Systemic lupus erythematosus (SLE) represents a complex disease, which hasn’t got a clear etiology established yet. Many genetic-susceptibility factors, environmental triggers, antigen-antibody (Ab) responses, B-cell and T-cell interactions, and immune clearance processes interact to generate and perpetuate autoimmunity. One of the triggers could be trauma-surgeries, serious infections or accidents.

Objectives: To assess the presence of history of trauma in patients diagnosed with SLE admitted in our Department, as well as the association with different co-morbidities.

Methods: We included 62 patients, admitted in the Rheumatology Department of the Tرغu-Mureş Emergency Clinical County Hospital between 01.01.2018-29.01.2019, previously diagnosed with SLE. We performed a retrospective analysis of their medical documents, looking for evidence of traumatic risk factors.

Results: The majority of the patients were female (17±8.70%) and had some kind of trauma before being diagnosed with SLE (17±27.41%). Among the operations the most frequent were hysterectomy with bilateral oophorectomy and classical appendectomy, respectively (6±9.67% each), followed by cholecystectomy and tonsillec tomy (2±3.22%). There were also one case of cerebral injury following a car accident and a complicated peri tonitis-related to IUD extraction. The majority of co-morbidities was represented by neurologic involvement (16±25.80%), followed by thyroid (13±20.96%) and renal involvement (12±19.35%).

Conclusion: Patients with SLE from our department have a significant history of traumatic triggers, mainly open surgeries, which might explain the development of autoimmunity. They also have various organ involvement that sometimes warrants aggressive measures. Further studies have to be conducted in order to better examine the possible link between traumatic events and development of this multifaceted disease.

Background: Rowell syndrome is a rather rare and highly debated entity, initially defined by Rowell et al as discoid lupus associated with...
EXPERIENCE IN THE USUAL PRACTICE OF PATIENTS WITH POLYAUTOIMMUNITY AND MAJOR ORGAN INVOLVEMENT: A PROSPECTIVE STUDY AT THE DONOSTIA UNIVERSITY HOSPITAL

Jesús Alejandro Valero Jaimes, Andrea De Diego Sola, Cesar Antonio Egües Díaz
Donostia, Rheumatology, San Sebastian, Spain

Background: Inflammatory myopathies (IM) are a heterogeneous group of acquired diseases, characterized by the presence of muscle weakness and inflammation. This group includes idiopathic polymyositis (PM), idiopathic dermatomyositis (DM), PM/DM associated with neoplasia, associated with rheumatic autoimmune diseases, juvenile PM/DM, inclusion body myositis (IBM) and immunomodulated necrotizing myopathies (IMM). Methods: A cross-sectional study included 179 patients [160 (89%) females and 19 (11%) males] diagnosed with primary SJögren’s syndrome (SjS) and fulfilling the ACR classification criteria (1) that had been admitted to our outpatient clinic between December 2008 and December 2018. Demographic and disease-specific characteristics were recorded in all patients. Results: In our cohort the median age at diagnosis was 57 years (range: 20-85). Thyroid AID was found in 55/179 (30%) patients, with the following distribution: Hashimoto thyroiditis (n=46), Graves’s disease (n=22), Graves’s disease without (n=4) and with thyroidectomy (n=5). Liver AID was detected in 8/179 patients (4%), 3 patients with autoimmune hepatitis and 5 patients with primary biliary cirrhosis. Regarding major organ involvement, 20/179 (11%) patients had renal manifestations: renal insufficiency (n=12), glomerulonephritis (n=3), interstitial nephritis (n=2) and IgA nephritis (n=3). Eight/179 (4%) patients had lung manifestations: interstitial fibrosis (n=6), emphysema (n=1) and chronic obstructive pulmonary disease (n=1).

Next, provide the content of the scientific abstracts. The abstracts are listed as AB5055, AB5056, etc., indicating their unique identifiers.
Conclusion: Our results add evidence for the presence of polyautoimmunity and major organ involvement in SJL. We found a slightly lower prevalence of polyautoimmunity and major organ involvement compared to recently reported data (2). Nonetheless, extra-glandular organ involvement should be assessed in order to elucidate cumulative damage and how it might impact outcome, prognosis and therapeutic approaches in SJL.

AB0567 DISEASE PATTERN IN EARLY AND NON-EARLY SYSTEMIC LUPUS ERYTHEMATOSUS

Sadović-Robecija Victoria1, Maria Garabajiu2, Lucia Mazur-Nicorici2, Mariana Cebanu2, Virginia Salzara, Minodora Mazza3, 1 State University of Medicine and Pharmacy “Nicolae Testemitanu”, Rheumatology, Chişinău, Moldova, Republic of, 2 State University of Medicine and Pharmacy “Nicolae Testemitanu”, Chişinău, Moldova, Republic of

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a high degree of variability at onset, creating challenges in the accurate estimation of its pattern in early stages1.

Objectives: To evaluate the pattern of the disease in patients with early and non-early systemic lupus erythematosus from physician’s perspective.

Methods: Performed case-control study included SLE patients that fulfilled SLICC 2012 criteria for SLE. Consecutive patients who fulfilled SLICC 2012 criteria for SLE were recruited. Depressive and anxiety symptoms were assessed by the Hospital Anxiety and Depression Scale (HADS).

Results: A total of 101 SLE patients was analyzed. First group (early SLE) included 34 patients while the second group (non-early SLE) included 67 patients. The disease duration ± SD (range) was 12,42±8,70 (0.1-24) and 146.41±81.64 (31-432) months, respectively. The disease duration ± SD (range) was 12,42±8,70 (0.1-24) and 146.41±81.64 (31-432) months, respectively. The disease duration was assessed by SLEDAI-2K, SLAM, PGA and PhGA for SLE activity, SLICC/ACR DI for disease irreversible changes and SF-8 for the quality of life (QoL). We correlated disease activity scores within groups and activity indices with the QoL using intra- and inter-class correlation coefficients.

Conclusion: The clinical picture of SLE was characterized by high disease activity and low QoL in both, early and non-early lupus, while occurrence of irreversible organ changes was more characteristic for the longer disease duration and development of irreversible changes during the course of lupus.

AB0568 THE EFFECT OF DEPRESSIVE AND ANXIETY ON QUALITY OF LIFE IN PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN RENAISSANCE COHORT

Lvubov Vorobyova, Elena Aseeva, Sergey Sololoyev, V.A.Nasonova Research Institute of Rheumatology, Intensive care department, Moscow, Russian Federation

Background: Systemic lupus erythematosus (SLE) patients are at high risk of depression and anxiety. These two states cause severe loss of health related quality of life (HRQoL) for patient with SLE.

Objectives: To assess the effect of depressive and anxiety on HRQoL in a cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE).

Methods: Consecutive patients who fulfilled SLICC 2012 criteria for SLE were recruited. Depressive and anxiety symptoms were assessed by the Hospital Anxiety and Depression Scale (HAD) scale (0-21 points). Health-related quality of life (HRQoL) was assessed by the validated specific questionnaire LupusQoL-Russian. Disease activity was evaluated by the SLEDAI-2K, and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI).
