Annals of the Rheumatic Diseases

Annual European Congress of Rheumatology

EULAR 2019

Madrid, 12-15 June 2019

Abstracts

The EULAR Journal
Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome.

Editorial Board
Daniel Aletaha (Australia)
Johan Asling (Sweden)
Sang-Heol Bae (Korea)
Xenofon Baraliakos (Greece)
Anne Barton (UK)
Maarten Boers (The Netherlands)
Matthew Brown (Australia)
Maya Buch (UK)
Loreto Carmona (Spain)
Carlo Chizzolini (Switzerland)
Bernard Combe (France)
Philip Conaghan (UK)
Maurizio Cutolo (Italy)
José da Silva (Portugal)
Nicola Dalbeth (Australia)
Christian Dejaco (Austria)
Oliver Distler (Switzerland)
Thomas Dörner (Germany)
Dirk Elenewt (Belgium)
Axel Finckh (Austria)
Roy Fleischmann (USA)
Mary Goldring (USA)
Juan Gomez-Reino (Spain)
Laure Gossec (France)

New avenues of OA & osteoporosis management

Francis Berenbaum. Sorbonne Universite, France

All recommendations on the management of osteoarthritis (OA), including EULAR, consider that its treatment should include pharmaceutical and non-pharmacological treatments. In this lecture, the most recent advances in both fields will be addressed. Some of them can change our current practice like recommendations on physical activity or on the choice of analgesics. Moreover, this lecture will highlight some of the drugs and cell therapies in development that could be on the market in the very close years.

HOT: OSTEOPOROSIS @2019

Serge Ferrari. Geneva University Hospital, Medecine, Geneva, Switzerland

Background: The goal of osteoporosis therapy is to quickly prevent fragility fractures in subjects at risk and on the longer term to restore bone mass (Bone mineral density, BMD) to levels of appropriate bone strength. Currently approved drugs for treatment of osteoporosis in Europe, namely bisphosphonates, denosumab, and teriparatide all decrease vertebral fracture risk within one year, whereas the benefits on non-vertebral fractures may take nearly two years to appear.

Objectives: To provide an update of recent trials regarding osteoporosis treatment.

Methods: Literature review and expert insights into recent analyses of clinical trials.

Results: New H2B trials, notably with teriparatide compared to risudronate, have shown the superiority of the anabolic therapy in preventing fractures in high risk patients. In GIOP, denosumab increased BMD more than risudronate. More importantly, romosozumab, a monoclonal Ab against sclerostin, was superior to alendronate to reduce fractures in high risk subjects, whereas the sequence of romosozumab and denosumab was superior to placebo followed by denosumab and increased BMD over just two years equivalent to seven years of continuous denosumab. New analyses of long-term denosumab, up to ten years of continuous therapy, have shown continuous BMD gains and further reduction in fracture rates, with T-scores at hip near -1.5 achieving the lowest fracture risk. However several case reports as well as a post-hoc analysis of subjects discontinuing denosumab in the FREEDOM trial have reported an increased risk of multiple vertebral fractures, which may be prevented by a 1-2 yrs consolidation by a bisphosphonate following denosumab therapy (guidelines).

Conclusion: In summary, while new data and more potent drugs are emerging (romosozumab), fueling the concept that anabolics should be used earlier in the disease (romosozumab), bisphosphonates, denosumab, and teriparatide all decrease vertebral fracture risk within one year, whereas the benefits on non-vertebral fractures may take nearly two years to appear.

Managing patients with axSpA: What are the quality standards?

Uta Klitz. Rheumazentrum Ruhrgebiet at Ruhr-University Bochum, Rheumatology, Heme, Germany

Background: There is wide variation in the management of patients with axial spondyloarthritis (axSpA) worldwide with significant unmet needs such as delayed diagnosis and inequity in bMARD prescription. Assessing the quality of care provided to patients with axSpA is important not only to patients and physicians, but also to providers and purchasers of health care. There is no agreed methodology to quantify quality of care but several approaches have been proposed aiming to assess quality in a measurable construct, e.g. quality indicators, performance measures or quality standards. Definition of quality standards (QS) enable society to identify resources and processes which may need to be optimised in patients with axSpA.

Objectives: A major goal of the international organization Assessment of SpondyloArthritis International Society (ASAS) is to improve quality of care and health outcomes in patients with axSpA. Recognized gaps in current care prompted ASAS in 2016 to start developing a quality standard set (ASAS QS) to optimize access, treatment and patient outcomes in axSpA.

Methods: An ASAS task force developed a set of ASAS QS step-wise. First, key areas for quality improvement were proposed, discussed, rated and agreed on. Thereafter, key areas were prioritized and statements for the most important key areas were phrased on consensus. Appropriate tools were selected and measures developed to be able to assess and quantify the quality of care on the community level.

Results: The ASAS task force, consisting of 20 rheumatologists, 2 physiotherapists, and 2 patients, selected and proposed 34 potential key areas for quality improvement which were commented by 140 ASAS survey participants (86 physicians, 42 patients). Within that process 3 new key areas came up, which led to a reevaluation of all 37 key areas by 120 participants (86 physicians, 29 patients). Five key areas were identified as most important to determine quality of care: referral including rapid access, monitoring, treatment, education including patient information and comorbidities. On that background, 9 QS were agreed on and finally endorsed by ASAS.

Conclusion: ASAS successfully developed the first QS set for improvement of health care for adult patients with axSpA. All QS are measurable achievable in daily care in an optimized situation and intend to minimize variation in quality of care.

Disclosure of interests: Uta Klitz Grant/research support from: AbbVie, Chugai, Eli Lilly, Grünenthal, Janssen, MSD, Novartis, Pfizer, Roche, and UCB. Consultant for: AbbVie, Chugai, Eli Lilly, Grünenthal, Janssen, MSD, Novartis, Pfizer, Roche, and UCB.

Managing patients with axSpA: what are the quality standards?
ANCA-associated vasculitides (AAVs) are a group of diseases with frequent relapses that can sometimes be severe. Treatment comprises an induction-remission phase followed by a maintenance regimen. Induction-remission therapy is effective and now well-established, mainly based on the combination of corticosteroids (CS) and cyclophosphamide or rituximab. For decades, maintenance therapy was compulsory and consisted of azathioprine or methotrexate, combined or not with low-dose CS. That regimen was prescribed for at least 18 months but was sometimes taken for several years. Criteria for stopping treatment have never been codified. Since rituximab has been widely prescribed for induction, the indication for azathioprine maintenance has been challenged because its relapse rate at 18 months (29%) was comparable to that of placebo (32%) given in its stead. However, we considered those relapse rates unacceptably high and have tried to devise a different therapeutic approach to maintenance, with semestral evaluation of the indication of rituximab infusion over 18 months. MAINRITSAN1-trial results demonstrated the superiority of rituximab to maintain remission with a 5% relapse rate at 28 months vs 29% for azathioprine recipients. The 60-month follow-up of that trial confirmed the superiority of rituximab over azathioprine (37% vs 57%), even though rituximab did not abrogate relapses. Since the publication of those results, it is now clear that AAV remission-maintenance therapy should be rituximab—and not azathioprine or another equally effective immunosuppres sant like methotrexate.

Maintaining remission should now also be based on other factors predictive of relapse: vasculitis type, ANCA subtype and/or ANCA presence or absence at the end of the induction regimen. Granulomatosis with polyangiitis relapses more frequently than microscopic polyangiitis or eosinophilic granulomatosis with polyangilits. Relapse rates of the former two are probably linked mainly to ANCA type, anti-PR3 or anti-MPO, with the latter relapsing less frequently. The long-term MAINRITSAN1-trial results identified anti-PR3 presence 1 year after ending induction treatment and/or their persistence were predictor(s) of relapse. We also designed a study comparing fixed-schedule rituximab infusions to re-infusions(4) guided by ANCA titer and/or CD19+ circulating B lymphocytes. Results of that prospective study demonstrated that fewer rituximab infusions should be given but that ANCA titer and the circulating CD19+B cell level are not good predictors of relapse. ANCA presence—indeedently of their titer—is more frequently associated with relapse.

The optimal rituximab-administration duration has not yet been established. Our group is now awaiting the imminent results of a prospective trial comparing 4 vs 8 rituximab infusions at 6-month intervals after obtaining remission.

Conclusions: Major advances have been made in the therapeutic strategy for AAVs. After induction is obtained: 1) AAVs require maintenance therapy. 2) rituximab is superior to immunosuppressants, 3) the presence, persistence and/or reoccurrence of anti-PR3 ANCA predict relapses, 4) the 500-mg rituximab dose/infusion seems well-adapted. The optimal treatment duration remains to be elucidated.

Tailoring maintenance therapy is now the main therapeutic objective for AAV management. Future trials will attempt to evaluate very long-term maintenance treatment of AAVs with the goal of eradicating relapses.

SP0008  MANAGEMENT OF CPPD DISEASE
Abibhush Abhishek, The University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom

Background: Calcium pyrophosphate deposition disease (CPPD) is a common cause of arthritis. Its prevalence increases with ageing, and it manifests with asymptomatic chondrocalcinosis, acute crystal synovitis, and chronic arthritis.

Objectives: The objectives of this talk are to summarize the treatment options for the management of CPPD, and to review the evidence base supporting them.

Methods: A systematic literature search was performed to identify all studies published in the English language, and, reporting on the treatment of acute and chronic manifestations of CPPD. All published studies were included with the exception of case reports and conference abstracts. Similarly, a literature search was performed to identify the metabolic and hereditary risk-factors of CPPD. The findings of the systematic literature search are described in a narrative manner. Interventions for which there is no published data are recommended based on clinical experience and expert opinion.

Results: Based on clinical experience, oral or intra-articular corticosteroids are effective and recommended for the management of CPPD. Colchicine and interleukin-1 antagonists are effective and recommended for the management of acute CPP crystal arthritis. Interleukin-1 antagonists should be reserved for use in refractory cases. Oral NSAIDs should be avoided as people with CPPD are frequently elderly. Low-
Comorbidities in psoriatic arthritis

**SP0009**

**CARDIOVASCULAR RISK IN PSORIASIS AND PSORIATIC ARTHRITIS**

Iain McInnes, University of Glasgow, Institute of Infection, Immunity, and Inflammation, Glasgow, United Kingdom

**Background:** Psoriasis and psoriatic arthritis are associated with increased cardiovascular and cardio metabolic risk.

**Objectives:** To describe the prevalence and magnitude CV risk in psoriasis and psoriatic arthritis and to comment on the clinical therapeutic implications of this risk in our practice.

**Methods:** Review of literature concerning CV risk and interpretation of the same.

**Results:** MACE are elevated over time in people with psoriasis and PsA. The mechanisms driving this are currently unclear but likely include both the impact of traditional risk factors e.g. dyslipidaemia, hypertension, obesity and novel risk factors e.g. mediated via increased inflammatory burden. Increased vigilance is required to detect this risk and a low index of suspicion should be introduced in practice. Aggressive management of CV risk should improve outcomes.

**Conclusion:** Recognising and treating factors mediating CV risk in psoriasis and psoriatic arthritis should comprise part of our routine clinical practice.

**Disclosure of Interests:** Iain McInnes Grant/research support from: AstraZeneca and Oxford Immunotec, Consultant for: Abbvie, Celgene, Galvani, Lilly, Novartis, Pfizer, UCB Pharma

**DOI:** 10.1136/annrheumdis-2019-eular.8410

**SP0010**

**INFECTIOUS RISK AND MANAGEMENT OF VACCINATION**

Nico Wulffraat, Wilhelmina Children’s hospital/UMC Utrecht, Pediatric rheumatology and Immunology, Utrecht, Netherlands

**Background:** Over the years, awareness of vaccine-preventable infection in rheumatic diseases has increased. At the same time, the safety of vaccines is still a hot topic in the public arena. Large-scale registries with data on juvenile idiopathic arthritis or RA taking the combination of methotrexate and biologics have demonstrated an increased incidence of infections. EULAR recommendations for both vaccination in pediatric patients and adults with rheumatic diseases, provide evidence-based guidance based on data from published studies on safety and efficacy of vaccinations in adults and children with rheumatic conditions. Especially in children, few data exist on safety and efficacy of live-attenuated vaccines such as MMR. This is relevant given the decreasing vaccination coverage and occurrence of measles outbreaks.

**Objectives:** To provide an overview of vaccines used in patients groups with rheumatic conditions under medication such as MTX or and biologicals. Also we seek for evidence on adverse events, protection rates and persistence of protective antibody titers over time. From these studies general guidelines are proposed.

**Methods:** Literature review of vaccination studies performed in adults and children. In addition the clinical practice of boostering of MMR in JIA patients under immunosuppressive therapy was investigated in several large academic pediatric centers across Europe.

**Results:** EULAR recommendations are updated for children and adults. For most vaccines it is advised to follow the national vaccination guidelines. Non-live vaccines can be safely provided to AIIRD patients under immunomodulating treatment, whereas the administration of live attenuated vaccines should be avoided under immunomodulating treatment, with the possible exceptions of herpes zoster and MMR. In 234 children with JIA who received the MMR booster while using MTX and or a Biological only 7 of adverse events were reported. Adverse events reported were mild (skin reaction, mild fever, urinary tract infection). There was no relation between disease activity, disease type or duration, sex, age and outcome of vaccinations.

**Conclusion:** The EULAR recommendations of 2011 are currently updated and will provide an up-to-date guidance on the management of vaccinations in patients with inflammatory rheumatic conditions. There is still a scarcity of data on safety and efficacy of live attenuated vaccines under biologicals. The next challenge is the implementation into the clinical practice of health professionals across Europe.

**SP0011**

**HOW THE GUT INFLUENCES THE IMMUNE SYSTEM**

Mario Zaiss, Friedrich-Alexander University Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany

**Background:** A disturbed gut microbiota composition has been associated with autoimmune diseases. Recent findings support the hypothesis that the onset of RA might be linked with the gut microbiota. Moreover, we could recently show that high fiber diets change the microbiota, increase SCFA levels and attenuate inflammatory arthritis and bone destruction (1). However, direct mechanistic links between the gut microbiota and onset of autoimmune diseases remain largely unknown.

**Objectives:** Herein, we intended to identify if the intestinal barrier integrity could serve as a key checkpoint translating autoimmunity to inflammation.

**Results:** Restoration of the intestinal barrier in the pre-phase of arthritis using different approaches inhibited the development of arthritis.

**Conclusion:** In summary, our data identify a new preventive approach for the onset of autoimmunity disease by specifically targeting impaired intestinal barrier function.

**REFERENCE:**

Background and Aims: The frequency of autoimmune diseases has increased significantly in recent decades in developed countries. The hygiene hypothesis provides a possible explanation for this increase. The hypothesis is based on the observation of a concomitant decrease in the frequency of infectious diseases and an increase in the frequency of autoimmune diseases. It is also based on the geographical disparity in the frequency of autoimmune diseases, much more prevalent in the north than in the south of the northern hemisphere, a disparity that is not explained by genetics.

Method: The disease frequency which is very low in southern countries increases from the first generation among subjects migrating northward. The causal relationship between the decline in infections and the increase in autoimmune diseases remains to be proven. Most of the evidence is based on spontaneous experimental models of autoimmune diseases that show the higher frequency of these diseases in a clean sanitary environment and their prevention through the administration of various bacteria, viruses or parasites.

Results: The underlying mechanisms are beginning to be revealed. An important place is given to pathogens and more particularly to their TLR ligands. Some arguments suggest that commensal bacteria in the intestinal microbiota also play a role. At the cellular level, the stimulation of certain regulatory cells and more particularly those producing TGF beta is well documented.

Conclusion: These considerations are important for understanding the epidemiology and pathophysiology of autoimmune diseases but can also provide new guidance on their treatment and especially their prevention. The problem is, however, complicated by the fact that the theory applies to varying degrees depending on the disease, for instance more in systemic lupus erythematosus than rheumatoid arthritis.

Pharmaceutical pipeline in OA

GROWTH FACTORS AND CARTILAGE: FROM MECHANISMS TO DMARDS
Marc Hochberg, University of Maryland, School of Medicine, United States of America

Background: Growth factors are biologically active molecules that can stimulate cellular division, growth and differentiation and, in articular cartilage, can regulate development, homeostasis and regeneration of matrix. These anabolic factors can stimulate synthesis of proteoglycans, aggrecan and type II collagen, induce mesenchymal stem cell (MSC) proliferation and drive differentiation of MSCs into chondrocytes and decrease catabolic effects of cytokines and matrix metalloproteinases (MMPs). Growth factors would not, however, be expected to have a direct anabolic effect in patients with symptomatic knee osteoarthritis.

Objectives: To review the role of growth factors in articular cartilage, identify specific growth factors and review data from phase 1 and 2 studies of selected growth factors in subjects with knee osteoarthritis.

Methods: A PubMed search was performed using key words “cartilage or chondrocyte” and “growth factor”. The search included both original manuscripts and review articles as well as clinical trials but was limited to English language. From these searches, I selected review articles and clinical trials and excluded articles that solely examined molecular mechanisms of action of growth factors on chondrocytes.

Results: Growth factors for articular cartilage include molecules in the transforming growth factor-β (TGF-β) superfamily (including TGF-β1, bone morphogenetic protein [BMP]-2 and BMP-7), insulin-like growth factor-I, fibroblast growth factor (FGF) family (including FGF-2 and FGF-18), platelet-derived growth factor (PDGF) and Wnt ligands as well as platelet-rich plasma (PRP).

Conclusion: Data will be presented from phase 1 and 2 studies of rhFGF-18 and (PDGF) and Wnt ligands as well as platelet rich plasma (PRP).

What’s new: Latest news on biological treatment

GROWTH FACTORS AND CARTILAGE: FROM MECHANISMS TO DMARDS
Marc Hochberg, University of Maryland, School of Medicine, United States of America

Biologic medications have revolutionized the treatment of many rheumatologic diseases, but their high cost often limits patient access to these effective treatments. Biosimilars are legitimate copies of biopharmaceuticals, which no longer are protected by patent, that have undergone rigorous analytical and clinical assessment in comparison to their reference products and have been approved by a regulatory authority in a highly regulated area according to a specific pathway for biosimilar evaluation. In 2005, the European Medicines Agency (EMA) established a pathway for the review and approval of biosimilars and, one year later, approved the human growth hormone Omnitrope as the first biosimilar. As of March 2019, 56 of 60 biosimilars approved by the EMA were commercially available in the European Union, of which 6 were of rituximab and 15 were of TNF inhibitors to treat rheumatologic diseases.

Commercially available lots of a reference product are not identical to one another. All biologic medications are subject to normal batch-to-batch variability and are monitored to ensure that this variation is within “proven acceptable ranges” so that patients are not subjected to risks of lesser safety or efficacy. Since biosimilars have been compared extensively to their reference products and been shown to have highly similar structure, equivalent efficacy, and comparable safety, an approved biosimilar can be considered to be like another batch of its reference product. Thus, patients need not be apprehensive about using an approved biosimilar in place of its reference product.

The “nocebo effect” refers to the misattribution of bodily symptoms to a medication and may result in discontinuation of a treatment that is not actually causing the perceived symptoms. Studies have suggested that the nocebo effect may result in discontinuation of treatment with a biosimilar because of subjective perceptions. This may be addressed by providing encouragement and reassurance through education and open collaborative discussion between providers and patients. By taking this approach to counseling patients, the rate of biosimilar discontinuation may be reduced.

The NOR-SWITCH study demonstrated that patients with inflammatory diseases controlled on treatment with reference infliximab do not experience greater worsening of disease activity when switched to biosimilar infliximab CT-P13 than when continued on treatment with the reference product. Thus, when the cost of the biosimilar is significantly lower than that of its reference product, substituting the biosimilar for the reference product may provide an economic advantage with no loss of clinical benefit. In Norway, where there is an annual “winner takes all” competitive tender process for hospital administered medications, the price of bio- similar infliximab in 2015 was 69% lower than that of its reference product. Thus, in most countries, it is safe, effective, and cost-effective to switch to a biosimilar. However, competition from biosimilars has occasionally driven down the price of a reference product, as in Sweden where the price of reference adalimumab was reduced by 80% in 2018 and became lower than that of adalimumab biosimilars.

The availability of lower-priced biosimilars should decrease the cost of treating patients by introducing market competition. Biosimilars should be more readily available to patients for whom the reference product had been inaccessible because of cost. Greater global access to effective biologic medications should reduce disability, morbidity, and mortality associated with rheumatologic diseases.

How to perform low-budget high-quality research

**SP0016 YOUR VERY FIRST STEPS ON SYSTEMATIC REVIEW**
Loreto Carmona, Instituto de Salud Musculosqueletica, Research, Madrid, Spain

Systematic reviews (SR) are a type of clinical research, and thus they follow the hypothetical-deductive or scientific method. Their objective is to answer clinical questions and they do it based on a specific structure (protocol) and working through inferences. Interestingly, a SR is a type of study design that can answer all types of questions, from efficacy to incidence. They manage the information from previous studies in a newly established reproducible way, as unbiased as possible. They provide quick answers. However, they should be performed and interpreted with caution: a poor systematic review is much worse than a narrative review, as it gives the false impression of "science". This is even worse if the studies were combined in a meta-analysis.

In this lecture, we will review the protocol of a SR, the importance of rephrasing the question, the search strategy, selection criteria, and procedures of studies selection, primary endpoints, and quality and risk of bias. The last part of any SR is the analysis, which is always qualitative, supported by the evidence table, and following a synthetic discourse with the PICO order, and sometimes quantitative (meta-analysis). We will review some methods to evaluate publication bias, to combine results, and to explore heterogeneity. In this sense, it is essential to note that if we cannot find a valid explanation for heterogeneity, our results may not be valid.

**Disclosure of Interests:** Loreto Carmona Grant/research support from: Abbvie, Actelion, Astellas, BMS, Eisay, Gebro Pharma, Grünenthal, Leo Pharma, Lilly, MSD, Novartis, Pfizer, Roche, Sanofi-Aventis and UCB Pharma, Paid instructor for: Novartis

**SP0017 USING AVAILABLE DATASETS TO ANSWER NEW RESEARCH QUESTIONS**
Daniel Prieto-Alhambra, University of Oxford, NDORMS, Oxford, United Kingdom

**Background:** Clinical data are continuously recorded in clinical encounters in the form of electronic medical records, registries, audits and similar databases. Such large datasets are available to researchers, and provide unique opportunities. However, challenges arise from the use of routinely collected data, that need special attention and specific skills to minimize a waste in research.

**Objectives:** To discuss available data sources (data discovery), their advantages and limitations, their uses, and to cover examples of research conducted using routinely collected datasets.

**Methods:** We will discuss a list of data sources at high level (types of data), their main pros and cons, and then cover challenges and solutions through a number of previously published examples.

**Disclosure of Interests:** Daniel Prieto-Alhambra Grant/research support from: Grants from Amsen, UCB Biopharma and Servier outside the submitted work, Consultant for: UCB Biopharma, Speakers bureau: Amsen

Health Professional Welcome session

**SP0018 WHAT YOU SHOULDN'T MISS FROM THE HPR PROGRAMME AS A CLINICIAN**
Maria Bergström, Linköping University, Department of Social and Welfare Studies, Division of Occupational Therapy, Norrköping, Sweden

As a health professional, the EULAR congress is the place where I can get access to new and fresh rheumatology research of good quality. My presentation will take you through the possibilities the congress offers clinicians when it comes to different topics within the area of rheumatology. Further, my aim and hope is to give you a sense of what is in store for you during this year’s EULAR congress. People with rheumatic diseases today live their lives to a great extent having the diagnosis affecting their everyday life. The ability to work, interact with others or engaging in activities they want to, can be limited. So what do we need to know about them in order to provide the best possible treatment and rehabilitation? As a health professional clinician, I look forward to finding some of the answers to this during this congress.

During the EULAR congress, we as health professionals have the possibility to contribute to and acquire research of good quality in rheumatology, on our way to giving our patients the best possible treatment. Also, we have the possibility to contribute to the patients' health, and I look forward to sessions touching health topics such as exercise. The quality of research and the variety of topics during this EULAR congress can give us a bigger set of tools to work with when we get back to our patients and continue our path towards the best possible treatment and health for this big and important group of patients. I hope that this session can provide an overview of what this years’ congress can offer from a clinical perspective.

**Disclosure of Interests:** None declared

**SP0019 PRES HPR: DONT DELAY, COLLABORATE TODAY**
Jeanette Cappon1, PReS Committee for Health Professionals1, Department of pediatric rehabilitation, Reade Center for rehabilitation and rheumatology2, Dutch Health Professionals in Pediatric Rheumatology3, Reade Center for Rehabilitation and Rheumatology, Pediatric Rehabilitation, 1056AB Amsterdam, Netherlands

**Background:** The Pediatric Rheumatology European Society (PReS) is an international organization based in Europe which is dedicated to advance the care and improve the health and well-being of children and young people with rheumatic conditions, helping them to reach their full potential. Full PReS membership is extended to individuals from all European countries, whether they are within the EU or not, and includes countries in the middle east and from other parts of the world as associate members to enrich the collective experience and knowledge. PReS welcomes every practitioner/researcher in the field of pediatric rheumatology.

The PReS committee for Health Professionals in Pediatric Rheumatology aims to bring together nurses, physical therapists, occupational therapists, social workers, psychologists, pediatricians and other health professionals (HP) to foster dialogue, to set standards of clinical practice, education and research.

Collaboration between PReS and Eular Health Professionals starts today, here in Madrid. Collaboration in general starts with a shared goal to work on together. Our young patients of today might be your patients of tomorrow: what should you know about what they have been through? Your patients of today might have been our young patients of yesterday: what can we learn from their experiences of the past being a child with a rheumatic condition? Did they receive comprehensive care that sustained into their adulthood?

**Objectives:** To find shared goals between HP Eular and HP PReS to deliver comprehensive care for people with rheumatic diseases during their full life.

To find common interests to discuss between HP Eular and HP PReS.

**Methods:** Examples of common interests e.g. supporting self management of pain and health and illness education are presented.

Shared goals for collaboration are proposed and collected from the audience.

**Results:** Health Professionals from Eular and PReS experience common interests and shared goals. Positive relations are expected to develop upcoming years.

**Conclusion:** Collaboration between Eular and PReS can start today

**Disclosure of Interests:** None declared

EULAR Projects in paediatric rheumatology

**SP0020 THE GLOBAL CHALLENGE AND OPPORTUNITY FOR PAEDIATRIC RHEUMATOLOGY**
Christian Scott, University of Cape Town, Red Cross War Memorial Children’s Hospital, Paediatric Rheumatology, Cape Town, South Africa

**Background:** Poorly developed healthcare systems and the overwhelming burden of communicable diseases have limited the growth and development of Paediatric Rheumatology in non central and less resourced countries.1,2 Most children on earth reside in these less resourced environments and suffer from disproportionately poor access to adequate care for paediatric rheumatic diseases. Emerging evidence suggests that rates of rheumatic diseases are not likely to be different to European and North American children but that diseases severity and
outcomes may be worse and that children in these countries face the additional burdens of poverty, socio-political instability and communicable diseases. 3, 4

Objectives: To review the current situation and challenges faced by the children in less resourced countries with rheumatic diseases and those who provide medical care for them, and to explore opportunities that will drive the global development of paediatric rheumatology to the benefit of all children with rheumatic diseases.

Methods: A thorough review of published literature and gaps in knowledge on the epidemiology and outcomes of childhood rheumatic diseases from less resourced countries. A review of current and planned global initiatives to improve Paediatric Rheumatology care in less resourced countries.

Results: Despite increasing emerging data on paediatric rheumatic diseases from less resourced countries, data on paediatric rheumatic diseases from less resourced countries are sparse. Paediatric rheumatology services in most countries remain inadequate or non-existent to serve the needs of the population, despite encouraging growth in some areas. Improvements in healthcare systems in these countries offer opportunities for the growth of paediatric rheumatology care. Greater genetic diversity and different disease profiles offer opportunities for the advancement of genetic and environmental influences on rheumatic diseases.

Conclusion: An organised effort from the paediatric rheumatology global community can play an important role in the development of education, networks, services and research capabilities that could lead to increased scientific growth and clinical benefits for all children with rheumatic diseases, regardless of their geographical or socio economic position.

SP0021 DELIVERING FUTURE GLOBAL RESEARCH CHALLENGES IN PAEDIATIC RHEUMATOLOGY

Nicolino Ruperto, Istituto Gaslini, Clinica Pediatrica e Reumatologia-PRINTO, Genoa, Italy

The treatment of pediatric rheumatic diseases has improved tremendously in the last 20 years thanks to appropriate legislative initiatives, the existence of very large collaborative networks and the availability of new potent medications. In particular, JIA has transformed from a tremendous impairment of patients with juvenile idiopathic arthritis (JIA) with over 3500 children enrolled in trials with registriative purposes. For JIA now the tendency is to concentrate on oral therapies and on drugs targeting specific JIA categories. Also in juvenile systemic lupus erythematosus (SLE) the childhood counterpart of SLE there are several potential targets to be tested in children. In addition the field of paediatric rheumatology has provided an excellent example of large scale academic studies which, through the Paediatric Rheumatology International Trials Organisation (PRINTO) have enrolled over 38,000 children from over 60 countries.

Further improvement in future years will stem from a better definition of the paediatric disease entities, the discovery of laboratory and imaging biomarkers that could help the tuning of therapy, a smoother implementation of future clinical trials, a more standardized link between academia (clinical and basic science), regulatory authorities, learned societies such as the Pediatric Rheumatology European Society (PRES) and family organisations for the planning of future trials.

This lecture will present a general overview and a perspective for the future (mainly academic) work to align clinical data collection with basic researchers, PRES, and family associations in order to foster and facilitate drug evaluation in pediatric rheumatic diseases as well as academic research.

INTRODUCTORY TALK ON CRYSTAL ANALYSIS

RELIABILITY IN THE LAST 10 YEARS: OBJECTIVES:

1. Intra-observer reliability has been shown in several studies to be higher than inter-observer.
2. Assessment of ‘evaluability’ varies between observers and therefore also needs to be taken into account when assessing reliability.
3. Subject to evaluability, certain parameters demonstrate high intra- and inter-observer reliabilities. Reliability differs across different capillaroscopic parameters.

Conclusion: Recent studies examining reliability of capillaroscopy suggest that certain parameters, including image grade, capillary density and apex width have high intra-and inter-observer reliabilities (subject to nailfold image evaluability, which remains a major challenge). Standardisation training is likely to improve reliability.

Methods and tools for quantization of capillaroscopic morphological changes

Alberto Sulis, University of Genoa, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, Genova, Italy

Capillaroscopy is routinely used in clinical practice to assess nailfold microvascular structure. Unlike laser techniques that give functional information, capillaroscopy allows a morphological assessment of nailfold capillary bed. It is a recognized tool to early differentiate primary from secondary Raynaud’s phenomenon, as well as to follow scleroderma microangiopathy. As microangiopathy extent correlates with organ involvement degree, nailfold capillaroscopy abnormalities are also considered a possible biomarker in systemic sclerosis.1,2 Several tools may be used to quantitate morphological capillary changes, from devices with low magnification (20x), to instruments with high magnification (200x or more).3-5 The instruments with low magnification allow a global evaluation of the entire nailfold area (wide-field capillaroscopy), and they provide a panoramic vision of the whole nailfold microvascular network. Magnifying glass, ophthalmoscope and dermatoscope are example of optical instruments with low magnification. Obtaining a high-quality documentation may be difficult by these tools, as well as the identification of early capillary changes; furthermore, storing capillary images is not possible.

Stereomicroscope, usb-microscope or videocapillaroscope allow a sequential higher magnification up to 600x which enable detailed observation of small nailfold areas or single capillaries. However, by using a microscope, patient’s fingers must be placed under the lens, and this may make the exam sometimes difficult, for example in the presence of either finger contractures or arm disabilities.

The optical probe videocapillaroscope is currently considered the gold-standard for nailfold videocapillaroscopy, as it has the advantage to be moved to the finger of the patient at direct contact with the nailfold: this facilitates examination of patients with systemic sclerosis and finger flexion contractures, simply by moving the probe. The use of videocapillaroscope has a high sensitivity, a short time of execution after an easy operator training, allows early diagnosis of secondary Raynaud’s phenomenon by very early detection of microvascular changes, and also allows the counting and scoring of capillaroscopic parameters. Connection of the instrument with a software enable image recording, report writing and automated capillary number counting.

To quantitate capillaroscopic morphological changes (mainly capillary number, capillary dilations, giant capillaries, microhemorrhages, abnormal shape/ramified capillaries, capillary bed disorganization) a simple rating scale may be adopted to score each capillary abnormalities (score 0-3) (score 0 = no changes; score 1 = less than 33% of capillary alterations/reduction; score 2 = 33-66% of capillary alterations/reduction; score 3 = more than 67% of capillary alterations/reduction, per linear millimetre. Reduction = capillary number per linear millimetre ×0.5). The mean score value for each capillaroscopic parameter is calculated from the analysis of at least two millimetres in the centre of the nailfold, by evaluating the first row of capillaries in each finger from 2nd to 5th. The Microangiopathy Evolution Score (MES) (sum of scores of progression parameters: capillary number, abnormal shape/ramified capillaries, capillary bed disorganization - Score 0-9) may be calculated to follow the scleroderma microvascular damage.6,7 However, at least the simple capillary number per linear millimetre should be counted, as well as larger capillary diameters measured, to monitor microangiopathy in systemic sclerosis.1,2

**SP0029 RHEVITAL: CONTROLLING YOUR DISEASE ACTIVITY WITH AN APP**

Corrina Elling-Audersch, German Leage against Arthritis, NRW, Solingen, Germany

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease requiring long-term treatment with regular monitoring of the ongoing therapeutic process by a rheumatologist to achieve good health outcomes and prevent negative disease impacts.

**Objectives:** The RheVITAL App is the product of a new and multilayered concept of treatment. A combination of a team of rheumatologists, physiotherapists, IT specialists and research partners from the German League against Arthritis have all contributed to the development of this research project.

**Methods:** The presentation will show how this monitoring system improves the treatment of RA individually, monitors the patients on their way to self-empowerment and promotes participative collaboration between patients and rheumatologists.

**Results:** The patients play an active role in the whole system. The patients are trained about their diseases, their treatment and the medicine they are taking. Furthermore they are given much more information about the German patient organisation.

**Conclusion:** My talk will consider the function and management of the app, the difficulties as well as the efforts of data security and the role of the patient organisation as a research partner involved in this project.

**Disclosure of Interests:** None declared

**SP0030 DEVELOPING E-HEALTH SOLUTIONS FOR PATIENTS WITH PATIENTS**

Susanne Karlfeld, Karolinska Institutet, Academic Specialist Center, Center for Rheumatology, Stockholm, Sweden

**Background:** At the Center for Rheumatology the Patient’s voice and needs are always central in the planning and development of the organization and its services and structure. The Patient Council at the unit, with representatives from 14 different patient organizations, is a core facility that is always addressed when decisions are to be made that affects the patients. The need of a structure for digital re-visits at the clinic was raised in the Patient Council meeting.

**Objectives:** To develop a structure for a fully digital re-visit where all the preparations, the actual visit and the documentation and follow up could be conducted using different e-Health solutions and digital tools.

**Methods:** By first asking the involved patient representatives about desired interfaces and features of the end solution, we could decide on which available tools and structures we could build the digital re-visit around. A working group including patients, health care providers at the unit and technical staff, together formed the end product.

**Results:** A fully digitalized structure for re-visits to different health care providers (physicians, nurses, physiotherapists etc) is now up and running with an increasing number of visits every week.

**Conclusion:** By asking the patients about what is most important for them we focus on solutions and services that the patients really need and ask for. If we involve patients in the process from the very beginning, we know that we are doing the right thing and that we use our resources in the best way.

**SP0031 NEWS IN THE WORLD OF REHABILITATION**

Ann Bremerland, Ranb Spenshult, Sweden

The ageing population and the increasing prevalence of chronic diseases is a great challenge for future health care systems. There will be a growing demand for rehabilitation services and a need to strengthen rehabilitation in the health system. According to the World Health Organization (WHO), rehabilitation is “the key for health in the 21st century”. In the document Rehabilitation in health systems (2017), the WHO presents a number of overarching principles for rehabilitation services: the provision of person-centred care, the continuum of care across different levels of the health care system, and the importance of accessible, affordable care of high quality to everyone in need of rehabilitation. With reference to the WHO overarching principles, I will shortly address and discuss some achievements and challenges in the delivery of rehabilitation services supported by recent and ongoing studies. Rheumatic and musculoskeletal diseases (RMDs) include over 200 diagnoses why the talk will include examples from rehabilitation services given to people with inflammatory arthritis (IA). Over the last decades, pharmacological interventions has contributed to improved quality of life for a large number of people with inflammatory arthritis (IA). However, a relatively large group of people with IA lives with a persistent disease and experience pain, fatigue, physical disability, impaired work ability and decreased quality of life, emphasizing the need of rehabilitation services. I will discuss advancements and challenges in providing person centered care, in bridging the gap between health care sectors, the challenge to provide evidence of an effective rehabilitation service of high quality and if we provide accessible rehabilitation services according to the need of people with rheumatic diseases.

**SP0032 HOW TO MEASURE REHABILITATION**

Alison Hammond, University of Salford, Centre for Health Sciences Research, Salford, United Kingdom

**Background:** Measuring outcomes is fundamental to rehabilitation. A wide range of subjective and objective outcome are available to health professionals, with patient reported outcomes (PROs) being widely used. Fundamental to their use is understanding how to select appropriate measures and interpret results.

**Objectives:** This talk addresses: how to identify and select patient reported outcomes measures; the COSMIN taxonomy; understanding measurement properties; evaluating fitness for purpose; and understanding cross-cultural and linguistic validation of PROs, to enable PROs to be used across countries. This will be illustrated with an example of a Swedish – English-Dutch-German PRO, the Evaluation of Daily Activity Questionnaire.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.8491

---

**SP0033 RHEUMATOLOGICAL REHABILITATION, WHAT’S NEXT**

Thea Viert Vieland, Leiden University Medical Center, Orthopaedics, Rehabilitation and Physiotherapy, 2300 RC Leiden, Netherlands

Over the past years, there have been major changes in the delivery of rheumatology rehabilitation and advances in its evidence base. To make rheumatology rehabilitation future-proof, a number of developments in the medical treatment of people with rheumatic and musculoskeletal diseases (RMDs), health systems and society as a whole need to be taken into account with the planning of services and their evaluation and the training of health professionals in rheumatology (HPRs).

Regarding the health status and needs of people with RMDs, their profile has changed markedly over the past decades, to a large extent due to improvements in the medical treatment. But some patients may not respond well to treatment, and for those who do, there may still be challenges to keep up with the increasing demands of our society.

For reasons of transparency, quality and efficiency there is a need to demonstrate the added value of rehabilitation, by working along defined rehabilitation care pathways. But care also needs to be personalized, tailored to a person’s individual situation, abilities and needs. This includes, among others, that people with RMDs must be involved in any treatment decision, requiring a specific level of health literacy.

The actual delivery of rehabilitation services by means of extensive inpatient or outpatient trajectories is under pressure in many health care systems, for economic reasons but also because treatment in one’s own environment whenever possible, is preferred by many people with RMDs. For that purpose, adequate use of digital interventions, but also seamless care involving primary care clinicians with specific expertise is needed.

All of the abovementioned developments require specific competences of HPRs, not only including the optimal assessment and treatment of individual people with RMD, but also makes a strong appeal to e.g. their communication, advocacy and organizational skills and abilities to monitor the quality of their practices and redesign when needed.

This presentation addresses current and future challenges for HPRs in rheumatology rehabilitation and how they can anticipate to be prepared for the next phase.
RA-MAP. PATIENT STRATIFICATION IN RA

John Isaacs, Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom

Background: When we assess rheumatoid arthritis in the clinic we quantify inflammation. Apart from measuring auto-antibodies we do not assess the immune system.

Objectives: The MRC/ABPI RA-MAP study was an academia-industry consortium designed to characterise the immune dysregulation that presents clinically as RA. Key questions were:
- Are there baseline immune markers of prognosis/therapeutic response?
- What is the molecular signature of the disease state (is there an immune correlate of inflammation)?
- Can RA be defined in terms of immune dysregulation and are there distinct subtypes?

Methods: RA-MAP was a systems immunology analysis of 275 patients with seropositive, treatment-naive early RA (the TACERA cohort). Patients were assessed at baseline and every 3 months for up to 18 months. At each visit, clinical samples were collected for transcriptomic (blood), proteomic (blood and urine) analyses. Peripheral blood mononuclear cells were characterised by flow cytometry. Clinical and demographic information was collected at each visit. Primary analyses addressed the key questions by seeking associations between immune parameters and disease activity or disease state.

Results: Latent class analysis of clinical data revealed three main disease trajectories. Transcriptomic and systems approaches highlighted at least two subtypes of seropositive RA. Proteomic analyses also supported multiple RA subtypes. Metabolomic analyses revealed prognostic baseline signatures. Flow cytometry revealed a reduction in peripheral blood mononuclear cell complexity as disease became less active. Combinatorial analyses of different datasets is currently underway.

Conclusion: RA-MAP has provided important insights into the immunological and molecular heterogeneity of RA. Our findings require replication and validation, and some analyses are ongoing. RA is the consequence of dysregulated immunity characterized by distinct molecular ‘endotypes’.

REFERENCES:

SP0036 MASTERPLANS – TAILORING SLE FOR THERAPY

Ian N. Bruce, University of Manchester, United Kingdom

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease which is highly heterogeneous in its clinical manifestations and also in its response to specific therapies. Across a number of trials of novel agents, overall response rates are approximately 40-60% and in the past almost 60 years only one drug (belimumab) has been licensed for use in SLE. Current therapy is therefore based on a ‘trial and error’ approach frequently involving glucocorticoid co-therapy. Delayed and poor control of inflammation results in organ damage, cardiovascular disease and glucocorticoid toxicity. We established a consortium of academia and industry partners (Maximizing SLETherapeutic Potential, by Applicating Novel and Stratified approaches (MASTERPLANS)) with the aim of identifying key endotypes associated with response and low disease activity on particular therapies.

Objectives: Our consortium is addressing the hypothesis that strata exist within SLE populations that will enable more targeted use of existing and novel therapeutic agents and improve response rates. Specifically, B-cell related biomarkers including dynamics and function predict responses to mycophenolate mofetil (MMF) and B-cell targeted biologics and interferon signature/pathway dynamics identifies patients with poorer responses to these agents.

Methods: Our approach will firstly be to re-analyse data already available from large studies and trials to identify key predictive factors of response. Also, using data from a large UK cohort, the BILAG-Biologics Register, we will assess clinical factors and biomarkers that predict response and low disease activity. Combining results from these studies with that gained from previous studies will enhance our ability to identify endotypes of response.

Conclusion: Identifying biomarkers of response will allow better selection of therapeutic agents for individual patients. Using the right drug at the right time will improve control of inflammation for patients with SLE and contribute to improving long-term outcomes.

USING GENETICS IN PERSONALISED MEDICINE IN RHEUMATIC DISEASES

Anne Barton.
University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom

Background: For all treatments available for rheumatoid arthritis (RA), none are effective for all patients. For many drugs, patients are given 3-6 months of treatment before a decision is made regarding efficacy and, for those in whom the treatment does not work, that can be a period of on-going disease activity, exposure to the risk of side effects and possible accumulation of joint damage, all of which impact quality of life. Straited medicine approaches aim to better target treatments to those most likely to respond. However, currently, CRP/ESR are the only biological markers (biomarkers) routinely used to inform whether therapy is required and RF/ACPA status are often considered.

Objectives: To update in progress of using genomic approaches to inform treatment selection in rheumatoid arthritis

Methods: National and international precision/stratified medicine programmes are investigating whether genetic and epigenetic biomarkers could help in the selection of therapy and progress will be reviewed.

Results: Recent studies have developed new outcome measures to assess treatment efficacy for controlling synovitis, confirming previous findings from genetic studies of heritability. Issues around the best tissue to sample, the predictive ability of a test and confounding factors including adherence will be considered and emerging biomarkers reviewed.

Conclusion: Matching the right treatments to the right patients is the goal of personalised medicine and potential biomarkers are starting to emerge. However, caution is required as none have so far been proven to be clinically useful or cost-effective.

SP0038 FACTORS IMPORTANT FOR MEDICAL ADHERENCE

Bart van den Berst.
Sint Maartenskliniek, Netherlands

Factors important for medical adherence in rheumatic diseases

Disease-modifying antirheumatic drugs (DMARDs) are the cornerstone for the treatment of inflammatory arthritis and fundamental to prevent radiologic progression in patients with rheumatoid/pсорiatic arthritis. However, the full benefit of DMARDs can only be achieved if patients follow prescribed treatment regimes. Adherence, or the extent to which patients take medications as prescribed, is however low in chronic medical conditions: approximately 50% of all people with chronic medical conditions do not adhere to their prescribed medication regimens [1,2]. Previous research in patients with rheumatic diseases vary from 30% to 107%, depending on the used measurement method [7].

Thus, improving adherence to DMARDs could dramatically improve the efficacy of drug therapy in rheumatic diseases and reduce costs. However, so far, interventions designed to improve medication adherence are only partly effective in changing medication-taking behaviour [2-5].

To be able to improve adherence, factors should be known that are associated with medication adherence in RA. This will help us to target non-adherent patients and design interventions to improve adherence. Although several studies have examined factors associated with adherence to treatment with DMARDs, hardly any variable was found to be consistently and strongly related to adherence [6-7]. Despite this, there is evidence that especially patient’s need to take medication, prior DMARD use, patient’s self-efficacy and information delivered to the patient might be associated with medication adherence.

Overall, two types of non-adherent behaviour are commonly observed: unintentional (due to forgetfulness, regimen complexity or physical problems) and intentional (when the patient decides not to take the treatment as instructed). In case of intentional non-adherence, the decision to take medication is based on a cost-benefit analysis weighing the costs/risks of the treatment against the perceived benefits. This implicates that health care professionals should individually assess patient’s (un)intentional barriers to take medication and target medication adherence interventions on patient’s individual barriers. Thus, besides tackling (un)intentional) practical barriers, such as forgetfulness (with for example reminder services), clinicians should also be sensitive to patient’s personal beliefs that might impact medication adherence, and should discuss with their patient any concerns that they raise about prescribed medications. This lecture will give insight in the latest insights in the research of factors important for medication adherence and their practical consequences for adherence improving interventions in clinical practice.

Advances in understanding and treating of SLE

SP0039 WIN: DE-CONVOLUTING THE COMPLEXITIES OF SLE – RECENT INSIGHTS INTO THE PATHOPHYSIOGENESIS

Mary K. Crow.
Hospital for Special Surgery, Weill Cornell Medical College, Mary Kirkland Center for Lupus Research, United States of America

Background: SLE remains one of the most complex diseases in medicine, with protein alterations in immune system function contributing to autoimmunity, tissue inflammation and damage, and diverse clinical manifestations. While considerable advances in understanding the molecular pathways and mediators involved in SLE have led to identification of rational therapeutic targets, a full understanding of the upstream etiologic drivers of the disease and how genetic risk and environmental stimuli shape the evolution of the disease and its clinical heterogeneity requires continued investigation.

Objectives: To review recent literature relevant to the etiology, pathogenesis and heterogeneity of SLE.

Methods: Review and synthesis of recent literature.

Results: Recent advances in characterizing the mechanisms of regulation and degradation of endogenous nucleic acids, particularly invariants derived from disorders based on a variety of single gene mutations that result in production of type I interferon, suggest potential drivers of type I interferon production in SLE. The functional alterations in many aspects of T and B cell function in patients with SLE, some attributable to type I interferon, continue to be identified. Potential contributions of the microbiome expand our view of candidate disease-enhancing factors. Interest in defining patients at risk for evolving from pre-clinical to clinical disease...
that fulfills classification criteria for SLE may help to identify the essential elements of lupus pathogenesis and suggest approaches for disease prevention.

**Conclusion:** Endogenous nucleic acids have emerged as compelling candidates for drivers of lupus pathogenesis, along with their traditional role as antigenic targets of lupus autoantibodies. Although the clinical heterogeneity of SLE has contributed efforts to successfully test new therapies, advances in identifying sources of nucleic acids stimulating type I interferon and alterations in adaptive immune system function help us move toward a synthetic understanding of disease pathogenesis and suggest that therapeutic regimens targeting both innate and adaptive immune systems might be required to control or prevent disease.

**SP0040 HOT: NOVEL PARADIGMS IN THE MANAGEMENT OF SLE**

**Thomas Dörner,** Charité Berlin, Berlin, Germany

Heterogeneity of systemic lupus erythematosus (SLE) remains challenging and, thus, many unmet needs remain, including the development of safer and more efficacious therapies to better control SLE activity resulting in improved outcomes. To develop innovative therapies, we need a far better understanding of its pathogenesis including delineation of clinical phenotypes. Recently, the lupus community has developed new classification criteria, T2T principles as well as low lupus disease activity and remission definitions to overcome obstacles created by SLE heterogeneity and improve outcomes. New proposals for the histologic classification of lupus nephritis have also been put forward and undergo evaluation. Recent therapeutic advances and clinical developments hold promise for improved treatments in this challenging disease and will be discussed.

**From child to adult care – breaking down the barriers of transition**

**SP0041 TACKLING TRANSITION: THE CURRENT LANDSCAPE, AND WHERE WE ARE HEADING**

**Stephen Bait,** Manchester University Foundation Trust, Specialist Medicine, Manchester, United Kingdom

The transition from childhood to adulthood is a key life stage. While the time course of the bio-psycho-social development of young people is continuous, many of the health and social care services with which they may be involved have relatively fixed, rigid structures. This can be challenging for young adults: leading to a sense of marginalisation and alienation. Young people with long term health conditions who are not equivalent, a developmentally appropriate approach to transition has clear benefits: seeing the process as being outcome and skills-based, rather than time-based.

Adolescence and early adulthood are times when life-long health behaviours are set in place; good health for young people is a foundation for good health in later life. There is a need to invest in age appropriate health promotion and youth-friendly health services if we are truly committed to improving young people’s health outcomes and the health of the adult population they will go on to form. There is an opportunity to develop and sustain a generational shift in health literacy and health-related behaviours: a real legacy; and an investment in the future.

**SP0042 FROM PAEDIATRIC CARE TO ADULT CARE – THE NEEDS OF YOUNG PEOPLE, AND HOW HEALTHCARE PROFESSIONALS CAN FACILITATE OPTIMAL TRANSITION**

**Judy Ammerlaan,** University Medical Center Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands

In this presentation, the learning experiences and reflections of a healthcare team on redeveloping the transitional care for young adults with RMD’s are shared. In the process of redeveloping care, the healthcare team experienced that small steps, driven by patient stories and involvement of patients in all phases from development to evaluation, led to meaningful results. The eHealth interventions, developed to support the transition and to increase self-management were found to be feasible and evaluated positively by the young adult group. But the healthcare team also experienced that the focus on the patient alone, is not enough to implement self-management interventions and sustain patient centered care in daily practice. How healthcare professionals personally think and feel about patient centered care is essential and needs to be discussed in daily care. It determines the way of being present with attention and commitment in daily health care. It affects the hands, head and heart. A daily reflection on shared answers of the patient and the health care professional to the question ‘what is the most important to you?’ may help to implement patient centered care in health practice.

**SP0043 MY IDEAL TRANSITION**

**Indra Beer,** Rheuma – Liga Bundesverband e.V., Projekt “Mein Rheuma wird erwachsen!”, 53111 Bonn, Germany

In my lecture I will present the barriers of transition from the young patient’s point of view and show possible solutions. Every year 2,000 young people aged between 16 and 19 arrive at the transition phase in Germany. One third of these young rheumatic patients stop or interrupt their therapy when they have to change from the paediatric rheumatologist to the adult rheumatologist.

In my talk I will focus on significant changes in the lives of young people. This includes e.g. the changes due to education and training, the first partnership or just moving out of the parents’ house.

Especially in the difficult phase of transition young people should be strengthened and be made aware of the differences between the doctors treating them and the barriers they will be facing. They should learn to manage themselves and be made sensitive that long-term damage can be avoided.

So, based on my experience I will outline the various support services that are necessary to prepare and accompany young people in that transition phase. Only then, in addition to evidence-based medical care, young people with a rheumatic disease can achieve a successful long-term healthcare outcome that will enable full participation in life.

Disclosure of Interests: None declared
Spondyloarthritides and vasculitis – new perspectives on outcome.

Raashid Luqmani
University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: Cyclophosphamide and more recently rituximab have transformed the outcome for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), resulting in survival in most cases. However, patients are at risk of frequent relapses, low grade gumprone disease, drug toxicity and worsening co-morbidity. Historically, prolonged courses of cyclophosphamide (used for both induction and maintenance) increased the risk of malignancy (especially bladder cancer). More limited use of cyclophosphamide, or the use of other agents including rituximab or methotrexate (for milder forms) offer safer but still effective options. The high relapse risk in AAV (especially in GPA) means that maintenance therapy is necessary but there is uncertainty over the most effective, safe long term choice. Maintenance RTX (fixed dose at fixed intervals of 4-6 months) is superior to azathioprine, but it is not clear if combination maintenance is superior to RTX alone. Long term side effects of RTX include hypogammaglobulinemia and potential for reactivation of JC virus. Reducing the glucocorticoid burden in AAV remains a challenge. We still do not know how long to continue therapy in AAV. Two recent studies provide conflicting opinion on the duration of maintenance therapy using azathioprine on risk of future relapse. The use of low doses of rituximab has recently explored in AAV: in thyroid eye disease, 100mg rituximab is effective. Less frequent dose intervals, as used in rheumatoid arthritis, will not control AAV. Future studies could address optimal long term management of patients with AAV, in order to improve their quality of survival and well-being.

Objectives: To assess the risk of relapse of vasculitis and to review the evidence for the use, effectiveness and toxicity of different maintenance strategies in systemic vasculitis

Methods: A review of published studies of long term outcome in vasculitis and of maintenance therapy in systemic vasculitis

Results: Once remission has been achieved, relapse is increasingly common, perhaps over 70% in some forms of ANCA associated vasculitis such as GPA. A strategy of induction therapy for one year, without any maintenance results in relapse in most cases of limited GPA. A maintenance regimen is recommended in order to avoid recurrence of the disease, but the evidence base for use of maintenance therapies remains limited. Maintenance is different from treatment of a relapse, usually aiming to prevent recurrence of clinical evidence of disease. We will show the evidence for different types of maintenance regimens and the outcomes in terms of relapse and toxicity with a focus on recently completed clinical trials and observational cohorts in a variety of forms of systemic vasculitis

Conclusion: The management disease in systemic vasculitis requires induction therapy but increasingly recognised is the importance of a maintenance regimen. Current and future strategies should explore a mechanism based approach, to selectively modify the underlying immunopathogenic mechanisms.

Disclosure of Interests: Raashid Luqmani Grant/research support from: Roche, Vifor and GSK

The exact role for new imaging technologies in osteoarthritis (OA) depends in part on the setting (clinical trials or routine care) and also on the tissues we decide are important to be studied.

In clinical practice, modern imaging such as ultrasound provides a useful adjunct for patients where there is diagnostic uncertainty - the EULAR recommendations for the use of imaging in the clinical management of peripheral joint OA provide an evidence-based background to this use of imaging. The impact of imaging is minimal in guiding choice of therapy as our therapeutic options (outside of surgery) are very limited.

In clinical studies and trials, there are a number of imaging modalities that provide insights into a range of OA tissues, for both quantification and characterisation. Most techniques have been based on MRI because of its soft-tissue advantages. In OA trials, MRI-based quantification methods provide improved responsiveness advantages over semi-quantitative scores, which have served an important role in highlighting the multi-tissue nature of OA and frequency of pathology. Using appropriate sequences, manual segmentation of cartilage or contrast-enhancing synovium can be quantified, and dynamic-contrast enhanced images can also be used to provide volumetric and pharmacokinetic assessments of the synovium. Using such information, we now know how to power studies for cartilage thickness endpoints.

A number of MRI techniques have been developed to study cartilage composition, such as T2mapping and T1rho. They have provided insights into structural deterioration, but are limited by technical aspects which make them difficult to apply in multicentre clinical trials.

Artificial intelligence and supervised machine learning have promised much in medicine, but in MSK imaging there has been some useful applications. Early technology applied 2D statistical shape models (SSMs) to X-rays, usually of the hip, providing novel information on bone shape. However the advent of 3D MRI or CT-based SSM technology has provided the ability to do automated quantification of large OA datasets. One of the most interesting tissues studied to date has been 3D bone shape. Studies have shown changes in bone shape are more responsive than radiographic joint space narrowing or even MRI quantitative cartilage thickness, predict incident radiographic OA, and that bone shape is associated with subsequent joint replacement. Recent work has shown a relationship between bone shape and bone marrow lesions, though these likely represent different elements of subchondral bone pathology. Work is just beginning on other relevant tissues such as the meniscus, and on other OA joints.

Can drugs and surgery help people with joint pain increase activity?

Speaker Abstracts

CASE 1 PRESENTER: ALL THESE PAINKILLERS AND STILL NOT GOING ANYWHERE

Kristine Røren Nordén. Diakonhjemmet hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology and Norwegian National Unit for Rehabilitation for Rheumatic Patients with Special Needs, Oslo, Norway

Background: The session will present a case history of a 24 year-old male presenting with axial Spondyloarthritis and extensive pain problems. He had been treated with biological medication for a while, had a few inflammatory burden, but experienced persistent pain. Furthermore, he was on sick leave from his job as an electrician and had a very low physical activity level. The patient was admitted for a 3-week in-patient rehabilitation stay at the Norwegian National Unit for Rehabilitation for Rheumatic Patients with Special Needs. The unit offers person-centered, specialized interdisciplinary in-patient rehabilitation for patients with inflammatory rheumatic disease. Target group is patients with complex illness challenges and increasing function- or activity problems.

The rehabilitation was planned and organized through close cooperation between the patient and the specialized interdisciplinary team. Relationship between analgesics, pain and physical activity was a central issue in the rehabilitation process. The session will outline the patient response to comprehensive treatment modalities including changes in medication and participation in physical activity and exercise.

Objectives:
• To present the patient history
• To present results of the interdisciplinary examination
• To present the patient’s specific goals for the rehabilitation process
• To present experiences with pharmacological and non-pharmacological treatment modalities for this patient

Disclosure of Interests: None declared

CASE 2 PRESENTER: SITTING AROUND ON A NEW JOINT

Maaike Gademan. LUMC, Orthopaedics and Clinical Epidemiology, Leiden, Netherlands

The end-stage treatment for hip and knee osteoarthritis is arthroplasty. The main aims of this treatment are to improve pain and joint functioning. It is thereby conceivable that patients should become more physically active after surgery.

REFERENCES:
[3] Cook MJ, Bellou E, Bowes J, et al. The prevalence of co-morbidities such as cardiovascular diseases, diabetes and osteoporosis, and has beneficial effects on psychological health. The aim of this lesson will be to present a case history of a patient with extensive pain problems and discuss the treatment options based on relationship between analgesics, pain and physical activity.

Objectives:
• To discuss the effect of analgesics on activity
• To discuss the use of painkillers in connection with exercise
• To discuss pain tolerance during exercise
• To discuss the effect of physical activity on pain

Disclosure of Interests: None declared
Although the literature on the outcomes of total hip and knee arthroplasty (THA and TKA) is vast, relatively little is known about physical activity levels of OA patients undergoing surgery. This presentations summarizes the state-of-the-art literature on the physical (in) activity level of patients with an indication for THA or TKA and the changes of physical (in)activity levels after surgery. These results are presented taking into account the activity levels of the general population. The presentation will end with an informal quiz on physical (in)activity in THA and TKA patients.

REFERENCES:

Disclosure of Interests: None declared

Thea Vliet Vlieland.
Leiden University Medical Center, Orthopaedics, Rehabilitation and Physiotherapy, 2300 RC Leiden, Netherlands

The literature on the effect of total hip and knee arthroplasty (THA and TKA) on the amount of physical activity is scanty, with various studies suggesting that physical activity levels do not increase after surgery. These results raise several questions, such as: Are patients who will undergo or underwent THA or TKA more or less physically active than the general population? And, if not, should they become more physically active, what are barriers and facilitators for physical activity levels, what would be the potential benefits? Who are the stakeholders that should be involved in the promotion of physical activity in this patient group? These, and other questions will be highlighted in an interactive discussion with the attendees of the session.

My joints hurt and I’m overwhelmingly tired – fatigue in rheumatoid arthritis

José António P. da Silva. Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal

Background: Fatigue is a frequent and important symptom in rheumatoid arthritis (RA), and it is associated with significantly reduced health-related quality of life, thus contributing to the impact of disease upon patients’ lives.

Objectives: To collect, summarise and interpret available evidence on the nature of fatigue and the best ways to assess it in Rheumatoid Arthritis

Methods: A systematic literature research was performed in trying to (i) to synthesise the size of fatigue in the global impact of rheumatoid arthritis; (ii) describe validated instruments and their psychometric properties as measures of fatigue, among patients with RA; and finally (iii) propose a clinically meaningful, valid and feasible process to measure fatigue in clinical practice.

Results: Fatigue has a major relevance in the overall burden of disease in RA. Several instruments have been validated to measure it, but no consensus has yet been reached to recommend a “gold-standard”.

Conclusion: Although fatigue is recognized by the rheumatology community as an important consequence of RA and a major gap in its current management of the disease, it has not been easy to measure and grasp. The problem seems to reside in the multidimensional causality and subjective nature of this phenomenon, which may warrant dedicated measures and interventions.

Disclosure of Interests: None declared

HOW TO PREVENT AND MANAGE FATIGUE IN PATIENTS WITH RA

James Galloway. King’s College London, Inflammation Biology, London, United Kingdom

Background: Fatigue is, similar to pain, a subjective symptom that occurs in many different diseases, particularly in patients with RA. Indeed, RA patients consistently report fatigue as one of the most disabling features of the disease (second only to pain). Fatigue is multifactorial in origin and reflects a complex construct of psychological, biochemical and physiological processes.

Objectives: If we are to effectively support our patients with RA, we must address fatigue. This requires understanding of which of our interventions work. At the end of the talk you should be familiar with how you can help manage fatigue, know which non-pharmacological interventions have a robust evidence and be aware of the impact of our different mode of action targeted RA therapies upon fatigue. For most our patients, a multimodal approach is needed.

Methods: This talk will present a narrative review of the evidence base around fatigue interventions in RA.

Disclosure of Interests: James Galloway Consultant for: Pfizer Inc

DECONVOLUTION OF THE IMMUNE RESPONSE

Lars Rogge. Institut Pasteur, Immunoregulation Unit, Immunology Department, 75015 Paris, France

Background: Anti-TNF therapy has revolutionized treatment of many chronic inflammatory diseases, including rheumatoid arthritis, Crohn’s disease and spondyloarthritids (SpA). However, clinical efficacy of TNF-inhibitors (TNFI) is limited by a high rate of non-responsiveness (30-40%) both in SpA and other diseases, which exposes a substantial fraction of patients to important side-effects without clinical benefit. Despite TNFI having been used extensively for many years, it is still not possible to determine which patients will respond to TNFI before treatment initiation.

Objectives: In this study, we have tested the hypothesis that the functional analysis of immune responses of patients before and after anti-TNF therapy may not only improve our understanding of the molecular mechanisms of TNF-blocker activity, but also identify correlates of therapeutic responses in SpA patients.

Methods: To facilitate the potential translational of our findings into a clinical setting, we have used standardized whole-blood stimulation assays (“TruCulture” assays; Duffy et al., 2014), and have minimized sources of pre-analytical variability, implementing a highly sensitive and robust pipeline to assess immune functions in patients.

Results: We show that anti-TNF therapy induces profound changes in patients’ immune responses, affecting predominantly several innate immune pathways. Of note, all these effects could be measured in stimulated, but not in resting immune cells, and were already detectable early, after a single TNFI injection. Modular transcriptional repertoire analysis revealed that TNFI affect immune responses via multiple mechanisms, such as directing monocyte/macrophage polarization and the inhibition of a TNF- and IL-1-dependent feed-forward loop of NF-kB activation.

On the other hand, the action of anti-TNF treatment was surprisingly selective, in that it did not affect the IL-6/Th17 or Th1 arm of the patients’ immune response. These findings have important implications for therapy, given the recent approval of anti-IL-17 antibodies as an alternative agent for the treatment of several chronic inflammatory diseases.

To investigate the concept that the immune status of a patient will define their response to TNFI treatment, we have used machine-learning algorithms to identify, in whole-blood stimulation assays, immunological transcripts that correlate with clinical efficacy of TNFI. We found that high expression, before treatment initiation, of molecules associated with leukocyte invasion/migration and inflammatory processes predisposes to favorable outcome of anti-TNF therapy, while high-level expression of cytotoxic molecules was associated with poor therapeutic responses to TNF-blockers.

Conclusion: These findings suggest that SpA patients whose immune response is characterized by strong, NF-kB-mediated inflammation are more likely to benefit
It is becoming clear that the field of medicine needs to change to stay affordable. One way of doing that is by optimizing the patients’ journey with true personalized medicine approaches. In other words, how to give every patient the right drug, at the right moment for the optimal duration. Recent advances in molecular techniques have truly revolutionized research into molecular fingerprinting—classification of clinical phenomena on the basis of a molecular basis rather than a diagnosis based on organ, symptoms or clinical criteria. This makes personalized medicine reachable within the coming years.

In my presentation I will dive in to the various molecular technologies (multi-omics) to achieve molecular fingerprinting of patients. Next, I will explain the computational techniques necessary to process the big data originating from the molecular processes enabling researchers to visualize big data from clinicians and patients. Finally, I will provide several examples of how these exercises might improve care for patients covering the space of rheumatic and musculoskeletal diseases (RMDs).

At the end of my presentation I will show how big data can be used for drug discovery, immune monitoring in clinical trials and/or daily clinical practice as well as drug repurposing. Together, I will provide a glimpse of the future on personalized healthcare within the field of RMDs.

Disclosure of Interests: None declared
TOWARDS OPTIMAL INTENSITY

George Melkos. University of Glasgow, Institute of Infection, Immunity, and Inflammation, Glasgow, United Kingdom

Background: There is ample evidence now to suggest that exercise can help ameliorate RMD symptoms and comorbidities. Similar to the prescription of medication, the dosage of exercise should be optimized to achieve the best health benefits. However, a consensus on the dosage of exercise prescription for RMD patients is currently missing.

Objectives: This talk will explore the data required from RMD patients to develop the best exercise prescription, exercise principles and current state-of-the-art, as well as how we can use the current evidence to identify the optimum dosage for the exercise prescription in people with RMDs.

Methods: Suggestions have been synthesized using existing evidence-based resources, including recent systematic reviews and meta-analyses (EULAR, Cochrane Library and peer-reviewed journals publications) as well as randomized controlled trials. Data for the effectiveness of exercise dosage on various different outcomes has been extracted and will be explored.

Results: Different dosages of exercise have differing effects on symptoms of RMDs. The optimal dosage depends on various factors and on the outcome that the exercise prescription aims to improve.

Conclusion: Despite the increasing research on exercise in RMDs, a currently a consensus for the optimal exercise dosage is currently missing. More interdisciplinary research, with a heavy patient involvement, is required in the area.

Getting a grip on the co-morbidities in gout

Edward Roddy. Keele University, Research Institute for Primary Care and Health Sciences, Keele, United Kingdom

Patients with gout very commonly have multiple co-existent comorbidities. Associations between gout and hypertension, obesity, chronic kidney disease and cardiovascular disease have long been recognised whereas several new comorbidity disease associations, such as sleep apnoea and mental health problems, have been described more recently, including lower risk of neurodegenerative diseases. These associations are complex with some comorbidities such as obesity and sleep apnoea predisposing to the development of gout, whereas gout is a risk factor for incident cardiovascular disease and erectile dysfunction. The management of gout is often more complex in the presence of comorbidity and can present a significant therapeutic challenge. This talk will provide an update on the co-morbidities that are associated with gout and discuss their implications for the management of gout, in particular for long-term urate-lowering therapy.

Disclosure of Interests: None declared

COSTA RHEUMATOLOGY – AN LIFESTYLE INTERVENTION

Jorge M. Rodriguez. Hospital General Universitario de Alicante-ISAIBAL, Sección de Reumatología, Alicante, Spain

Background: Gout is an independent cardiovascular risk factor. Patients suffering from gout show a higher incidence of all forms of the atherosclerotic disease, as well as cardiovascular and all-cause mortality. This associates with both comorbidities and urate crystal-led inflammation. Thus, gout, along with being the most common form of inflammatory arthritis in rich countries, carries with significant morbidity and mortality. Proper management is essential. The purpose of this lecture is to analyse the potential strategies aimed to control the cardiovascular risk in patients with gout.

EULAR SCHOOL OF RHEUMATOLOGY 2019: A NEW ERA FOR EDUCATION

Annamaria Iagnocco, Academic Rheumatology Unit Università degli Studi di Torino, Academic Rheumatology Centre, Turin, Italy

The first strategic aim of EULAR for the period 218-2023 is to be the leading provider of education in Rheumatic and Musculoskeletal Diseases (RMDs). The benefits that the rheumatology community gets from high levels of education in the field of RMDs result in an increased knowledge of them as well as in the optimization of their management. This leads to a significant relief to the lives of people with RMDs.

EULAR has traditionally been a strong supplier of education in rheumatology and the launch of the EULAR School of Rheumatology has further increased the EULAR’s educational offering and its quality, by providing tailored learning materials, improving access to high quality education in the field of RMDs and developing innovative learning methods and recognised EULAR certifications.

The School of Rheumatology is as a fully integrated operational entity contained within EULAR which combines all educational offers, whether they are live activities and material addressed to rheumatologists, undergraduates, trainees, teachers, researchers, health professionals, and people with RMDs.

EULAR has traditionally been a strong supplier of education in rheumatology and the launch of the EULAR School of Rheumatology has further increased the EULAR’s educational offering and its quality, by providing tailored learning materials, improving access to high quality education in the field of RMDs and developing innovative learning methods and recognised EULAR certifications.

This presentation provides some theoretical and practical insights into “aktiv-hoch-r”.

13:30:00 – 15:00:00
Ultrasound basic I

Loreto Carmona, Instituto de Salud Musculoesquelética, Research, Madrid, Spain

This is not an easy task to do in 20 minutes, but we will try to engage the attendee and to pass the message through. The most important take home message of this lecture will be that “it is the learning, not the teaching, what we must master”.

Good teachers are, therefore, mere facilitators of the learning process, not the stars. This lecture will have two parts, one dedicated to teaching in general and a second one on assessment (because assessment style drives learning behaviour).

Four are the principles of teaching in medicine: 1) orientation not only to knowledge but to problem solving, 2) adaptation to needs, 3) evaluation of the efficacy of teaching, and 4) learning should be enjoyable. We will review each one of these principles and how to implement them in our daily teaching. Things like preparing a lesson plan, or tips to engage learners, will be part of this lecture.

In the second part we will outline how to improve assessment and generate good questions.

Disclosure of Interests: Loreto Carmona Grant/research support from: Abbvie, Actelion, Astellas, BMS, Eisai, Gebo Pharma, Grünenthal, Leo Pharma, Lilly, MSD, Novartis, Pfizer, Roche, Sanofi-Aventis and UCB Pharma, Paid instructor for: Novartis

THURSDAY, 13 JUNE 2019
13:30:00 – 15:00:00
HOW TO ASSESS US LESIONS FOR GOUT + DEMO

Sara Nyssom, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark

Gout is the most common inflammatory joint disease in Western developed countries. Diagnosis and monitoring have historically been based upon clinical assessment combined with biochemical results (primarily p-urate) but over the last decade ultrasonography (US) has received increasing attention for these purposes. US has been shown able to detect monosodium urate deposits in both joints and tendons. In 2015 the Outcome Measures in Rheumatology (OMERACT) US Working Group developed definitions of structural lesions in gout. These include double contour sign (deposits of crystals on the surface of cartilage), tophus (larger hyper-echoic aggregation of crystals), aggregates (small hyper-echoic deposits) and erosion (1). The double contour sign has been included in the ACR/EULAR 2015 gout classification criteria as a way to visualize urate deposits in joints (2). Furthermore, US can visualize potential concomitant inflammatory aspects of gout since it can visualize both joint inflammation and tenosynovitis.

In this talk the diagnostic properties of US will be described and the potential risk of false positive results due to artefacts or misinterpreted lesions will be discussed. Furthermore, the potential role of US in monitoring of treatment response will be explored.

Background: Greater trochanteric pain syndrome (GTPS) is a clinical diagnosis with the typical presentation of chronic intermittent lateral hip/thigh/buttock pain, aggravated with activity and when lying on the affected side. There is a lack of valid/speciﬁc diagnostic criteria for GTPS. GTPS can be attributed to a multitude of causes ranging from tendinopathy and/or rupture of the gluteal tendons and/or bursitis, to pathological alterations of the iliotibial band/fascia lata and other nearby anatomical structures located on the lateral part of the hip. To further complicate the diagnostic process, according to different studies, the prevalence of GTPS in adults with lower back pain has been found to be between 20-30%. Alterations of the lumbar biomechanics may interfere in the range of internal rotation of the hip and consequently produce a GTPS and vice versa. Changes in hip range of motion will trigger changes in the dynamics of lower extremities and the spine. Generalized myofascial pain can also be a source of confusion when evaluating patients with GTPS.

Objectives: Understand the clinical anatomy of the lateral hip. Interpret the US images of the lateral hip. Identify potential pain generators of the lateral hip.

Methods: The study of the static and dynamic sonoanatomy of the different components of the lateral region of the hip can contribute in a relevant way to clarify the diagnosis. In the eular guidelines of sonographic musculoskeletal (MSUS) exam published in 2017, the sonoanatomic exam of the lateral hip has been developed in detail and will be discussed during this lecture.

The anatomy against what is often thought is not stagnant knowledge but evolves over the years providing new and useful data applicable in daily clinical practice. The anatomy, both static and dynamic, of the trochanteric region, is complex. For example, the subgluteus maximus bursa, which is frequently incriminated in the GTPS, is located in the posterior facet of the greater trochanter and is related to the iliotibial tract, the fascial contributions of the gluteus maximus and the tensor of the fascia lata muscle to the iliotibial tract and the origin of the vastus lateralis. In order to understand the multifunction and relationships of the different structures of this region means one has to have seen images of them and for that purpose, the human cadaveric dissection is the best tool. Thanks to the fact that the speaker is involved as a professor in the anatomy department at the University of Barcelona, Belvitge campus, directed by prof M Miguel, the clinical anatomy part will be developed with real dissections made specifically for this lecture.

Results:

Conclusion: Knowledge of the clinical anatomy needed to understand the relationships between the different structures, the clinical history, and physical examination of GTPS patients and the therapeutic possibilities including ultrasound-guided injections are other steps that lead to an accurate diagnosis of GTPS.

Interstitial lung disease in rheumatic diseases and systemic sclerosis

Yannick Allare, France

Interstitial lung diseases (ILDs) are a group of heterogeneous disorders, either idiopathic (idiopathic pulmonary fibrosis-IPF) or associated with other diseases, particularly autoimmune diseases, from which systemic sclerosis is the leading disease at risk of developing ILD. It has been proposed that for clinical research and patient management various subsets of fibrosing ILD that have similar biological and clinical behaviours could be merged into a single entity although specificities within each disease remain, with various patterns of lung injury. Nevertheless, the shared part relates to progressive fibrosing ILD leading to progressive decline in lung function and early mortality. In SSC, a recent report from EUSTAR network showed that ILD was nowadays the first cause of death identified as contributing to 17% of deaths (1).

No drugs are licensed for the treatment of ILDs related to autoimmune diseases. Treatment guidelines issued by the European League Against Rheumatism (EULAR) recommend tailored therapy with cyclophosphamide (CYC) for SSC-ILD, in particular for patients with progressive ILD (2). Indeed, 3 randomized controlled trials showed some benefits of using CYC either orally or by infusion route although the effect size was small and the clinical translation of the findings was difficult to establish. The limitations of CYC trials in SSC-ILD led the experts to add that dose and duration of treatment need to be tailored individually dependent on the clinical condition and response. Furthermore, with regards to safety, potential risks of bone marrow suppression, teratogenicity, gonadal failure and haemorrhagic cystitis must be always considered. Beyond standard immunosuppression, the use of high dose CYC with or without irradiation, but using rescue with stem cells showed some effects on ILD measured through lung function and imaging. Nevertheless, considering the risk of potential treatment-related mortality and morbidity, the EULAR recommends that HSCT should be considered for the treatment of selected patients with rapidly progressive SSC at risk of organ failure, two domains which remain to be delineated. Altogether these results suggest that immunosuppressants might be beneficial in the context of SSC-ILD although the right drug, the right dosing and the right patients still need to be defined. In practice, because of SLSS trial, mycophenolate mofetil has emerged as the leading drug used when a physician aims at treating SSC-ILD. The understanding of SSC and SSC-ILD have improved in the recent years and subset at risk and candidate biomarkers have emerged. Indeed, interleukin 6 has been shown to predict some disease progression including lung involvement. Therefore, targeted therapy against IL6 is an appealing strategy to improve SSC outcomes. If the pivotal trials using tocilizumab had skin as a primary outcome and failed to meet the primary end-point, secondary analyses revealed stimulating lung results that will be showed during EULAR 2019 and discussed within the ILD session. B-cells role has also been scrutinized in SSC with promising data. Therefore, rituximab is used in some SSC patients with various indications according to physician views and experience. EUSTAR has assembled a large group of rituximab treated patients and performed a well-designed observational study that did not show clear evidence supporting some efficacy of rituximab on SSC-ILD although some clues emerged. The role of anti-fibrotic drugs (nintedanib, pirfenidone), that showed to slow disease progression in patients with IPF, in patients in other forms of fibrosing ILD remains to be determined. However, several trials are ongoing and the results of the SENSCIS trial evaluating nintedanib in SSC-ILD will be presented during EULAR 2019 and discussed during the ILD session. Altogether, the available results show some progresses made in the management of SSC-ILD, so far mainly through the use of treatment targeting immune disturbances. Considering the severity and the complexity of SSC pathogenesis and related lung complication, one might anticipate that if trials of biologic therapies are positive, the treatment of SSC-ILD, and maybe of all fibrosing autoimmune ILDs, might involve combination of immunosuppression and anti-fibrotic therapies.

Diagnostic challenges in vasculitis

Wolfgang Schmidt, Immanuel Krankenhaus Berlin, Medical Center for Rheumatology Berlin-Buch, 13125 Berlin, Germany

Background: Giant cell arteritis (GCA) and Takayasu arteritis (TAK) are large-vessel vasculitides (LVV). Recommendations demanded so far to confirm the diagnosis histologically, particularly in suspected GCA. Biopsy is however invasive, and results are not immediately available. Technology has rapidly improved; and many recent studies suggest that imaging may have comparable diagnostic accuracy.

Objectives: To provide an overview of new developments for ultrasound, magnetic resonance imaging (MRI), computed tomography (CT) and 18-fluorodeoxy-glucose positron emission tomography (PET) in diagnosis of LVV and to present new EULAR recommendations on imaging in LVV.

Methods: A systematic literature review and meta-analysis of diagnostic and prognostic studies enrolling >20 patients and investigating ultrasound, MRI, CT or PET in patients with suspected and/or established primary LVV was conducted (1). On this basis, a group of imaging experts, rheumatologists, patients and health care professionals developed EULAR recommendations on imaging in LVV (2). This review refers also to new data after the EULAR recommendations had been published.

Results: In suspected GCA, imaging should be done early, but without delaying treatment. No further diagnostic test (histology or other imaging) is necessary if results of imaging and clinical presentation correspond. Ultrasound of temporal and axillary artery arteries showing a non-compressible ‘halo-sign’ is the method of first choice in suspected cranial GCA. The meta-analysis showed positive and negative likelihood ratios of 19 and 0.2, respectively, for a final diagnosis of GCA. Good data is also available on MRI of cranial arteries. Ultrasound, MRI, CT or PET can be applied for confirming extracranial GCA. Ultrasound is of limited value for assessing particularly the thoracic aorta. MRI is first choice for suspected Takayasu arteritis, but ultrasound, CT or PET can be also applied. Conventional angiography is not recommended instead for interventions. Imaging might be used in suspected flare and to monitor damage. There is no convincing evidence to recommend routine monitoring in remission. Imaging should be done by a trained specialist using appropriate equipment. Particularly ultrasound of cranial arteries showed high diagnostic accuracy in a study for developing new classification criteria. Measuring intima thickness (cut-offs of around 0.4 mm for temporal and 1.0 mm for axillary arteries) may help to improve diagnostic accuracy and to use ultrasound for disease monitoring in trials (3). Reliabilities of sonographers both for evaluating videos and for examining patients directly were very high (4,5). Newer PET technology now allows to also show inflamed temporal, maxillary and vertebral arteries (6). The significance of positive imaging findings in follow-up studies still remains unclear. The incidence of vision loss decreased with the introduction of fast-track clinics. These clinics are increasingly established in centres. They include referral within one working day to a rheumatologist followed by immediate imaging for establishing the diagnosis. Imaging can be done by the rheumatologist (most commonly ultrasound) or by a collaborating department.

Conclusion: Ultrasound, MRI, CT and PET allow to confirm or exclude LVV provided that it is performed by a trained specialist using appropriate equipment. Fast-track clinics using ultrasound are increasingly established in rheumatology.
Ultrasound showed high diagnostic accuracy. Modern PET equipment may also delineate vasculitic temporal, maxillary and vertebral arteries. The significance of follow-up imaging studies in L UV still needs to be determined.

SP0073 DIAGNOSIS OF GASTROINTESTINAL VASCULITIS
Maria C Cid. Hospital Clinic. University of Barcelona. IDIBAPS, Autoimmune Diseases, Barcelona, Spain

The gastrointestinal vasculature can be involved by a variety of vasculitis affecting large, medium, small or variable vessel size according to the 2012 revised Chapel Hill consensus nomenclature. Gastrointestinal involvement (GI) is one of the most severe complications of vasculitis requiring intensive immunosuppressive therapy and sometimes revascularization techniques or emergency surgery and may affect a variety of organs including large or small intestines, liver, biliary tract, pancreas, and less frequently, stomach or oesophagus. It can complicate the course of patients with known or with overt suspicion of vasculitis or be the main or even the only manifestation of these diseases.

Clinical manifestations range from abdominal pain, sometimes colicky, that usually worsens after eating to overt signs of bowel ischaemia or perforation with diffuse and constant abdominal pain, reduced peristalsis, abdominal defence and distension, and signs of peritoneal irritation. GI bleeding, frequently in the form of occult blood loss or haematochezia and less frequently melena or rectalasia, is common. Non-specific symptoms such as nausea, vomiting or diarrhoea may be observed. Pancreatitis, cholecystitis or appendicitis may also occur.

In large-vessel vasculitis, including giant-cell arteritis (GCA) and Takayasu disease (TAK), inflammation usually affects the proximal portion of the celiac trunk, hepatic or mesenteric arteries. GI involvement is rare in GCA with only isolated cases or small series having been reported. About 30% of patients with GCA have elevated hepatic enzymes as part of the acute phase response and rarely reflect involvement of the hepatic vasculature. Imaging techniques disclose stenotic or occlusive lesions in 25% of patients with TAK but clinically manifest involvement occur in about 16% of patients. Abdominal pain suggestive of vascular insufficiency is present in about 16% of patients; abdominal bruits can be perceived in 14% but only 4% present with overt signs of mesenteric ischaemia. Due to the involvement of the proximal portion of the GI branches, the ischemic territories may be extensive but usually progression of vascular occlusion is not abrupt, and due to the size of vessels involved, patients may benefit from percutaneous revascularization procedures if immunosuppressive treatments are not sufficient. Interest-

PPS1208 A PHASE 3 RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL OF LA-015 IN PATIENTS WITH SYSTEMIC VASCULITIS WHO ARE NOT SUFFICIENTLY RECOVERING FROM AN ANEURYSMAL COMPLICATION

Among all forms of vasculitis, perhaps that affecting the CNS (CNS-V) poses the greatest challenge in diagnosis given the lack of any non invasive high specificity test, the complex and extensive list of mimicking conditions, its inaccessibility for biopsy and its genuine rarity. The diagnosis still requires the presence of an unexplained neurologic sign or symptom(s) following an exhaustive evaluation, evidence of vascular involvement (by direct or indirect angiography) or biopsy and most importantly the meticulous exclusion of all those conditions capable of producing mimicking clinical, radiographic or histologic findings that would confound accurate diagnosis. Despite these challenges CNS-V has been increasingly reported due to a combination of increased diagnostic awareness and advances in diagnostics. Two of these major advances will be discussed including the use of direct vascular wall imaging to differentiate vascular inflammation from atherosclerosis and the use of next generations sequencing to identify infectious etiologies and obviate the use of biopsy. Clinical examples will be presented.

How to manage and treat childhood onset lupus? A multidisciplinary point of view

CASE PRESENTER: CHILDHOOD ONSET OF NEUROLUPUS

Eve Smith, Alder Hey Children’s NHS Foundation Trust, Paediatric Rheumatology, Liverpool, United Kingdom

Background: In the series of talks ‘How to manage and treat childhood onset lupus?’ A multidisciplinary point of view’ the first talk focuses on achievement of the initial diagnosis of Lupus within the childhood period, including some potential pitfalls and how these can be avoided. Initial and ongoing treatment within the childhood period, alongside paediatric specific therapeutic considerations will be discussed. The role of the multidisciplinary team of doctors, nurses, physiotherapists, occupational therapists, psychologists and sub-specialists will be highlighted. The impact of the diagnosis on the child, family, education and social activities will also be described. This talk will be followed by a subsequent talks following the patient through transition and into adulthood.

Disclosure of Interests: None declared

CASE PRESENTER: TRANSITION OF NEUROLUPUS PHASE INTO ADULTHOOD

Lovro Lamot. The University of British Columbia and British Columbia Children’s Hospital Research Institute, Department of Pediatrics, Division of Rheumatology, Vancouver, Canada

Childhood-onset SLE (cSLE) accounts for approximately 20% of all SLE cases and is often regarded as one of the most complex rheumatic diseases. With the increase of five-year survival rate of cSLE patients to over 95%, there is a growing number of adolescents and young adults (AYA) transferring from pediatric to adult care. Even in the best-case scenario, there is often considerable challenges regarding this transition. Hence, it is not surprising that morbidity, mortality and disease activity in cSLE, as well as in many other chronic illnesses and conditions, worsen during or just after the transition. The reasons for these deteriorations are numerous, with most prominent arising from the nature of the disease and changes during the tumultuous period of adolescence, but also the differences between pediatric and adult clinical and healthcare settings. Besides, the AYA patients with chronic conditions often feel they are not well prepared for the transition to adult care, while the adult rheumatologists commonly report concerns about assuming the responsibility of patients with the pediatric-onset disease. Some of these concerns are probably motivated by increased vulnerability of AYA patients with cSLE, who are more likely than their adult counterparts to develop lupus nephritis and neuropsychiatric manifestations, as well as other organs involvement and atherosclerosis. Moreover, due to the severity of the disease, patients with cSLE are treated more aggressively, accumulating more drug-related toxicity than patients with adult-onset SLE, which results in significant SLE-related damage and complications such as osteoporosis during the childhood. On the other hand, there is decreased medication adherence in AYA, further complicated by the neurocognitive and memory impact of the disease, as well as high rates of comorbid depression and anxiety. Some additional problems in cSLE patients at transition age are sexuality, fertility, and pregnancy. All this makes patients with cSLE require specialized and multidisciplinary care at the transition, that is capable of addressing medical, psychosocial, educational and vocational needs.

This presentation will be part of the comprehensive session discussing distinct features of the SLE during the different phases of life. It will emphasize specific challenges of the transition from pediatric to adult care, with the use of a compelling clinical case as an example.

with a suspected diagnosis of neuropsychiatric pSLE. Underlying factors including infections, hypertension, metabolic abnormalities or adverse effects of medication should be excluded before considering a lupus-related neurological involvement. Finally, the diagnosis of pSLE should also be considered in case of severe complications such as macrophage activation syndrome or alveolar hemorrhage. Monogenic SLE should be suspected in early-onset SLE (<5-year-old) and mainly comprise complement deficiencies, genetic overproduction of interferon-α, B-cell apoptosis defects and rare inherited immunodeficiencies. Each of these conditions is associated with specific features: 1) Primary complement defects are associated with recurrent pyogenic or neisserial infections 2) type-1 interferonopathies are often associated with spasticity, cerebral calcifications, encephalopathy, skin ulcers and chills, and, in some cases, with a growth delay (spondyloenchondrodysplasia) 3) B-cell apoptosis defects (mutation in PRKCD gene) is associated with a lymphoproliferative disease. A proper diagnosis of SLE must therefore be based upon a complete family medical history as well as on clinical evaluation with details history of both present and past illnesses, analysis of growth chart as well as laboratory tests for SLE. The search for auto-antibodies towards nuclear antigens is a key step in the diagnosis strategy, keeping in mind that antinuclear antibodies are not specific for SLE. Screening for complement deficiencies via CH50, AP50, C3 and C4 is recommended in order to facilitate appropriate treatment of comorbidities including infections in pSLE patients.

Conclusion: The diagnosis of pSLE should be suspected in teenagers with acute unexplained symptoms, especially in case of abdominal pain or neuropsychiatric involvement. A monogenic predisposition to SLE should be considered in early-onset SLE, especially in patients with SLE family history, consanguinity, recurrent infections, and/or encephalopathy with spasticity.

CASE PRESENTER: LONGSTANDING NEURO LUPUS IN ADULT LIFE
Antonis Fanouriakis, "Atikou" University Hospital, Rheumatology and Clinical Immunology, Athens, Greece

Background: Juvenile-onset systemic lupus erythematosus (SLE) poses significant challenges for pediatric and adult rheumatologists. Longstanding disease in adult life carries the sequelae of the protracted course of the disease, as well as of the various treatments received.

Objectives: To present a didactic case of long-standing SLE of childhood onset, with the purpose to familiarise the audience with the multifaceted aspects of the disease, following transition from adolescence into adulthood.

Results: A 25-year old lady was diagnosed with SLE at the age of 9, due to generalised toxic-clonic seizures (status epilepticus), photosensitive rash and positive serology for SLE (ANA, anti-dsDNA, low complements). She was treated with high-dose glucocorticoids and cyclophosphamide with a good neuropsychiatric response. At the age of 15, she developed hematuria and nephrotic proteinuria; a kidney biopsy was compatible with class IV lupus nephritis (LN), with few crescents. She received mycophenolate mofetil (MMF), again with glucocorticoids, with complete response at 12 months. After entering adult life, 5 years later, at the age of 21, she had a severe renal flare with recurrence of nephrotic proteinuria and active urinary sediment. A second kidney biopsy was performed, which showed histologic transformation into mixed class IV + V LN, and increase in chronicity index. Readiministration of MMF failed to provide at least partial response; to this end, high-dose intravenous cyclophosphamide was administered, again with no response after 6 months. Finally, the patient was treated with rituximab, in combination with MMF, which managed to achieve partial remission, with proteinuria levels ~1.5 gr/day and normal renal function. Sixteen years following her initial diagnosis, apart from her ongoing renal inflammation, our patient has suffered significant side-effects from long-term glucocorticoid therapy and her quality of life is significantly affected.

Conclusion: This case illustrates the formidable challenges faced by both patients and treating physicians, for a patient diagnosed with SLE in childhood and had frequent flares during transition into adulthood and later in adult life.

Disclosure of Interests: Antonis Fanouriakis Paid instructor for: Amgen, GSK, Speakers bureau: Abbvie, Enorasis, Genesys Pharma
spine is the worst long-term outcome of this disease, although this occurs less frequently nowadays if compared to former decades. This fact might be related either to the natural course of the disease that becomes milder over time or to a consequent anti-inflammatory treatment initiated earlier in patients with axSpA.

Structural damage in the spine in axSpA is usually assessed on plain radiographs of the spine and, therefore, is frequently referred to as radiographic spinal progression. In the presentation, pathophysiology, assessment and ways of prevention and/or retardation of structural damage progression in the spine in patients with axSpA will be discussed.

Disclosure of Interests: Denis Podddubny Grant/research support from: Abbvie, Merck Sharp & Dohme, Novartis, Consultant for: AbbVie, Bristol-Myers Squibb, Janssen, Merck Sharp & Dohme, Novartis, Pfizer, Roche, UCBB Pharma, Speakers bureau: AbbVie, Bristol-Myers Squibb, Janssen, Merck Sharp & Dohme, Novartis, Pfizer, Roche, UCBB Pharma

SP0081 STRUCTURAL DAMAGE PROGRESSION IN PSA

Philip Hellwell. University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Psoriatic arthritis is a multifaceted disease in which the arthritis tends to be less frequent than in rheumatoid arthritis. This provides a challenge to measure radiographic progression using the simple and time-honoured fashion of assessing the hands and feet. Further, radiographic progression is slower in PSA and changes over a short time period, such as the placebo controlled phase of a trial, are minimal. Newer imaging, such as ultrasound and MRI may be more sensitive and responsive but data on these techniques are limited. These challenges, and how to overcome them, will be discussed.

Disclosure of Interests: Philip Hellwell Grant/research support from: Paid to charity: from AbbVie, Janssen and Novartis, Consultant for: Paid to charity: from AbbVie, Agen, Pfizer, and UCBB and Celpene. Paid to self: from Celpgene and Galapagos

Difficult to manage Sjögren’s syndrome and Myositis

SP0082 SCREENING FOR MALIGNANCIES IN SJÖGREN SYNDROME AND MYOSITIS

Albert Selva-O’Callaghan. Vall d’Hebron General Hospital. Universitat Autonoma de Barcelona, Internal Medicine Dept, Barcelona, Spain

Both myositis and Sjögren syndrome may be associated with cancer. However, there are differences between the cancer-associated myositis and cancer that appears in patients with Sjögren syndrome, and these differences make for a distinct tumor screening approach. The fact that any type of cancer – mainly of the adenocarcinoma type - can be associated with myositis -dermatomyositis, either classical or amyopathic, immune-mediated necrotizing myopathy, or polymyositis phenotypes- makes more difficult to know if an occult malignancy is present. Nevertheless, in recent years biological markers such as several autoantibodies, phenotypes- makes more difficult to know if an occult malignancy is present. Alternatively, the clinical situation and screening approaches in Sjögren syndrome are more focused in the detection of lymphoproliferative disorders, mostly in salivary glands (MALT type lymphoma) but also marginal zone or diffuse large B cell lymphomas. Several approaches for detecting MALT-type lymphoma or generalized lymphomas, beyond the well-known parameters such as low complement levels, cytopenias, cryoglobulins or persistent enlargement of salivary glands, are also discussed.

Anergy, exhaustion or post-activation in autoimmunity; Facts and future consequences

George Tsokos. Beth Israel Deaconess Medical Center/Harvard Medical School, Medicine, Boston, United States of America

The distribution and function of T cell subsets in patients with systemic lupus erythematosus (SLE) is aberrant. Distinct molecular and metabolic events dictate the numbers and function of T cells. Specifically, the transcriptional repressor cAMP response element modulator alpha (CREMα), which is increased in cells from patients with SLE, accounts for the decreased expression of the interferon (IFN)-γ receptor interferon (IL)-12 and the increased expression of IL-17 through distinct epigenetic processes. CREMα promotes Th17 cell expansion by promoting the expression of G1s1, the first enzyme in glutaminylation and by suppressing the expression of pyruvate dehydrogenase phosphatase catalytic subunit 2 that enables entry of pyruvate into the Krebs cycle. In parallel, calcium calmodulin kinase 4 which is responsible for the increased binding of CREMα to cAMP response elements of the IL-2and IL-17 loci, promotes the activity of pyruvate kinase M2 and promotes glycolysis and TH17 generation while suppressing the numbers of regulatory T cells. Understanding the exact molecular and metabolic processes that control T cell function in SLE enables therapeutic considerations.

Disclosure of Interests: George Tsokos Grant/research support from: Janssen Research & Development, LLC

SP0084 POST-ACTIVATED B CELLS IN AUTOIMMUNITY

Andrea Lin. Rheumatology and Clinical Immunology, Department of Medicine, Charité Universitätsmedizin Berlin and German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany

Background: B cells are key players in autoimmune diseases such as systemic lupus erythematosus (SLE), primary Sjögren’s syndrome (pSS) and rheumatoid arthritis (RA). In the past, it was believed that B cells from these patients were hyper-responsive to B cell receptor (BCR) and Toll-like receptor (TLR) signaling. New insights suggest that B cells from these patients present a post-activated functiotype.

Objectives: We aim at characterizing B cells and B cell responses of SLE, pSS and RA patients to understand which venues can be taken towards new therapies for these diseases.

Methods: B cells and B cell subsets from peripheral blood samples from SLE, pSS and RA patients and healthy donors (HD), as well as few autoimmune tissues, were analyzed for: phosphotyrosine kinase (PTK) phosphorylation kinetics, protein phosphatase activity, expression of phosphatases or of checkpoint molecules, such as e.g. PD-1, before and after BCR engagement, alone or together with TLR9 and CD40 stimulation, differentiation and proliferation. Expression of transcription factors, such as e.g. STAT1, and the effect of interferons in their expression in B cells from patients were also evaluated.

Results: B cell responses upon BCR engagement in SLE, pSS, RA patients were abnormal with diminished BCR downstream PTK phosphorylation. TLR9, but not CD40 responses were also abnormal. Part of the abnormality related to diffuse up-regulation of phosphatases that apparently counteracted PTK signaling. The abnormality was partially mimicked by repeated signaling through the BCR of HD B cells and could be overcome by CD40 engagement. Check-point molecules, such as e.g. PD-1, was differentially expressed in SLE naïve and memory B cells. SLE naïve and memory B cells expressed higher amounts of STAT1 compared to those of pSS, RA and HD.

Conclusion: Post-activated B cells are characterized by a phenotype of dysregulated expression of certain check-point molecules, such as PD-1, some transcription factors, like STAT1 and certain phosphatases (figure 1). Our data suggest that CD40 activation is involved in modulating BCR responses in post-activated B cells. This has implications for innovative therapies since blocking BCR signaling pathways and CD40 activation as well as targeting certain phosphatases may have synergistic value for treating systemic autoimmunity.
WHO TO IDENTIFY AND INVITE TO AN FLS? WHO IS THAT FRACTURE PATIENT?

Bo Abrahamsson, x, x, Denmark

Background: Though osteoporosis can be diagnosed through the presence of fragility fractures in the absence of other aetiology such as myeloma or metastases, patients with osteoporosis are also at increased risk of high impact traumatic fractures. Further, distinguishing between fracture mechanisms through chart review is often difficult and may lead to patients with osteoporosis being missed. On the other hand, focusing on identifying and treating patients at high imminent fracture risk rather than milder degrees of osteoporosis makes for better cost utility.

Objectives: To review the demographics of patients presenting with fragility fractures and the evidence for targeting osteoporosis assessment for each category of fracture in order to balance the need for maximum risk reduction with the requirement for an evidence based strategy.

Methods: Narrative review of recent epidemiology studies and national and international guidelines.

Results: Based on epidemiology data from Iceland[1] and Denmark[2,3], the risk of subsequent fractures following a sentinel fracture event is critically dependent on the recency and the site of the initial fracture, with the risk of new fractures being particularly high after major osteoporotic fractures[1] and pelvic fractures but less so after lower leg fractures[2].

In Danish women[2], 29.5% of patients suffering a pelvic fracture went on to sustain a hip fracture in the next ten years, compared with 25.9% after a vertebral fracture but only 12.5% after a lower leg fracture. Further, despite the high recurrent fracture risk in the FLS setting, it is important to appreciate that the majority of hip fracture patients have not consulted with a prior fracture in the last ten years prior to their hip fracture[3].

The following issues will be addressed in more detail
1) Demographics of fracture patients with particular emphasis on age, sex and BMD.
2) Which fracture types are indicators of elevated risk of subsequent major osteoporotic fractures?
3) Which fracture types will respond to osteoporosis treatment?
4) What is the role of DXA in FLS?
5) Identifying vertebral fractures

Conclusion: FLS patients are at elevated risk of sustaining additional fractures both in the long term and in the short term, with risks being particularly high in the first years after the sentinel fracture and especially if the initial fracture is a pelvic fracture or a major osteoporotic fracture.

Systemic lupus erythematosus (SLE) is also associated with smoking. A strong and specific connection of current smoking and >10 pack-years of smoking with dsDNA+ SLE has been observed. In patients with SLE, smoking exposure has deleterious effects on lupus morbidity and is related to cumulative chronic damage, and patients with SLE, smoking has a negative impact on the efficacy of belimumab and a 2-fold decrease in the proportion of patients achieving cutaneous improvement with antimalarials. Published data indicate that smoking has a dose-dependent impact on structural damage progression in Ankylosing Spondylitis.

In a large UK cohort, smoking was positively associated with the risk of psoriatic arthritis in the general population, but negatively associated among patients with psoriasis. In addition, smokers with psoriatic arthritis had a poorer response to TNFIs compared to non-smokers.

Regarding well-established risks of cardiovascular and respiratory diseases, this finding has eventually lead to incorporation of this risk factor into FRAX®. The impact of smoking on bone status is mainly associated with the number of smoking years. In a few reports, it has been observed an association between smoking and carpal tunnel syndrome and inflammatory bowel disease. Finally, current smoking in patients with fibromyalgia is associated with greater pain, possibly as a function of disease severity.

How to Support Yourself Quitting Smoking

Marios Kouloumpras, Cyprus League Against Rheumatism, Aglantzia, Patient Organization, Nicosia, Cyprus

Background: As a person living with Rheumatoid arthritis (RA) (a chronic inflammatory disease caused by both genetic and environmental factors) for the last 45 years (I have been diagnosed with RA at the age of 10 years old) I have been a smoker from the age of 14 years old. As I grew older, and was educated and involved concerning the management of my disease, I realized that smoking, besides its impact on my overall health, had a significant impact as one of the most important risk factors for RA that can increase the severity of the disease and to worsen symptoms. Smoking can also reduce the effect of treatments, including anti-TNF agents and disease-modifying anti-rheumatic drugs (DMARDs). Hence, quitting smoking will improve my overall health, reduce the severity of my disease and ensure that treatments work and reduce the risk for comorbidities e.g. cardiovascular disease and the progression of the disease (joint destrucions).

Objectives: To quit smoking after 40 years of being a smoker and to regain my health and quality of life as well as increase the efficacy of the RA treatments.

Methods: To succeed I plan to be very well informed and to understand the reasons of quitting smoking as well as the negative impact of smoking and to realize that quitting smoking will improve my health and social life. To inform all people close to me including family members as well as friends and coworkers about my decision to quit smoking. Mentally being prepared to cope with the desire to smoke as well as ridding the thought of “just smoke one”. It is also important to rid the mind and lose the connection of things associated with smoking, for example while drinking coffee. To ask for support if needed and to use tools to stop thoughts of smoking and to cope with the effects of nonsmoking and to try avoiding places that could increase my risk of starting to smoke again e.g. pubs.

Results: I have started to cut down on smoking and to minimize it and finally to fully quit smoking for the last 2 years.

Conclusion: Although, if you ask all smokers how difficult it is to stop smoking, the answer will unanimously be “very hard”, as a former smoker I can say that if you quit smoking, be aware of the reasons and the importance of quitting smoking and you will notice that after all it is not very difficult. Of course, when you set this goal it is important that in case of first time failure to not blame yourself and I can

Scientific data visualization: focus on (poster) presentation

Maarten Boers, Amsterdam University Medical Centers; Vrije Universiteit, Epidemiology and Biostatistics; Amsterdam Rheumatology and immunology Center, Amsterdam, Netherlands

This practical skills session introduces the principles of good graph and table design as pioneered by Cleveland1 and Tufte2 and updated by Few3, this year as freely downloadable.4,5

Its learning objectives include:

- choosing the data visualization that best fits the data
- identifying the basics of table and graph design
- choosing tables and graphs that tell the story in the data
- introduction to poster design

The session is linked to a special poster tour devoted to poster design on the next day.

EULAR POINTS TO CONSIDER ON BIG DATA

Disclosure of Interests: These EULAR points to consider provide a framework for the use of big data in RMDs. They refer to big data as a moving field in need of correct reporting of data collection, discussing privacy by design, use of specific data platforms, and data learning; they cover aspects of data sources and data disciplines including computer science and artificial intelligence. Levels of evidence and strengths of recommendations were allocated.

Methods: Based on a literature review of the current status of big data in RMDs and in other fields of medicine, on individual interviews of selected experts, and on the opinion of experts in a face-to-face meeting, points to consider were formulated, discussed, and finalised by an international group of 14 experts from a range of disciplines including computer science and artificial intelligence.

Results: The document comprises 5 overarching principles and 9 points to consider. The overarching principles address the definition of big data and artificial intelligence, types of big data, and ethical and general principles for dealing with big data in RMDs. The points to consider cover aspects of data sources and data collection, discussing privacy by design, use of specific data platforms, and data sharing; data analyses in particular through artificial intelligence and machine learning; they refer to big data as a moving field in need of correct reporting of methods used and of benchmarking; and data interpretation and implementation in clinical practice.

Conclusion: These EULAR points to consider provide a framework for the use of big data in RMDs.

MRI

MRI OF LARGE JOINTS IN ARTHRITIS: HOW TO DO AND HOW THEY ARE DIFFERENT FROM SMALL JOINTS?

Iris Eshed. Sheba Medical Center, Tel Aviv University, Department of Diagnostic Imaging, Ramat Gan, Israel

The appendicular skeleton is frequently involved in patients with rheumatic diseases. Involved joints are affected by inflammation of the synovium and joint’s enthese. Imaging depicts joint derangement and generally mirrors the pathophysiology of the disease. MRI is considered the imaging modality of choice for the detection of acute joint inflammation as well as its structural sequela. Thus, MRI plays an important role in identifying, monitoring disease activity and the patient follow-up.

The MRI features of inflammatory arthritis are well described, especially in the small appendicular joints of the hands and feet and include synovitis, erosions, osteitis, tenosynovitis and erosions. In the current presentation, the typical MRI properties of large joints arthritis in different rheumatic entities will be presented with special focus on the difference from inflammatory findings in smaller appendicular joints.

MRI OF ENTHESITIS: HOW TO DO AND WHAT TO LOOK FOR

Mikkel Østergaard. Copenhagen Center for Arthritis Research (COPECARE), Rigshospitalet, University of Copenhagen, Center for Rheumatology and Spine Diseases, Glostrup, Denmark

Enthesitis, inflammation at the insertion site of tendon, ligament or joint capsule into bone, is considered a key pathological feature in spondyloarthritis (SpA) and psoriatic arthritis (PsA)[1]. Compared to conventional assessment of enthesitis using clinical scores, MRI detects both soft tissue and intra-osseous abnormalities in active enthesitis, potentially aiding early diagnosis and outcome measurement in SpA and PsA[2]. With the advent of treat-to-target concept and novel therapies, objective and sensitive monitoring of response of enthesitis to therapy is desirable, and a validated MRI scoring system would be a useful adjunct to clinical practice as well as providing additional information as an outcome measure in clinical trials.

The Outcome Measures in Rheumatology (OMERACT) MRI in Arthritis Working Group recently undertook a systematic literature review (SLR) aiming to critically evaluate the published literature for available methods of evaluating enthesitis using MRI in SpA and PsA patients, describing the MRI variables, definitions and scoring systems used to diagnose and monitor enthesitis[3]. Considerable limitations were found regarding standardisation of MRI enthesitis definitions across studies and validity of available semi-quantitative scores as outcome measures. The findings suggested a need for reliable and validated MRI scoring system for enthesitis.

Subsequently, the OMERACT MRI group developed consensus definitions of key pathologies and three heel enthesitis multi-reader scoring exercises were done, separated by discussion, training and calibration[4]. In a final exercise, median pairwise single-measures intra-class correlation coefficients (ICCs; patient-level) for entheseal inflammation status/change scores were 0.83/0.82 for all readers. For radiologists and selected rheumatologists ICCs were 0.91/0.84 and quadratic-weighted kappas (lesion-level) 0.57-0.91/0.45-0.81. It was concluded that the proposed definitions and enthesis scoring system (OMERACT HEMIRIS) are reliable among trained readers and promising for clinical trials[4].

This talk will briefly review the evidence behind the use of MRI for diagnosis and monitoring enthesitis, describe the recently developed OMERACT consensus definitions of key pathologies, and provide examples of these pathologies, aiming for the attendees to learn to be able to recognize them. Finally, an interactive quiz using cases for audience review will be undertaken to test this ability.

CRYSTAL ARTHROPATHIES: IS THERE A ROLE FOR MRI?

Kay-Geert Hermann. Chante – Universitätsmedizin Berlin, Radiology, Germany

The plain radiographic features of gout are well known. However, the sensitivity of plain radiographs alone for the detection of signs of gout is poor in acute disease. Dual-energy computed tomography (DECT) and ultrasonography fill the gap for early stage and specific detection. However, there are instances in which MRI of the painful joints was already acquired. Therefore, it is crucial to know the imaging findings of gout in MRI. MRI per se is not suitable for imaging the calcified bone or soft tissue calcifications. However, there are special techniques such as gradient echo sequences or susceptibility-weighted imaging (SWI) to visualize calcifications. Furthermore, the inflamed joint with all its characteristics such as synovitis, tenosynovitis, and erosions is easily accessible by MRI. Specific findings in the...
MRI DIFFICULT CASES OF THE AXIAL SKELETON
Lennart Jans. Ghent University Hospital, Radiology, Gent, Belgium

MRI has revolutionized the assessment of axial spondyloarthritis (SpA) in clinical practice. MRI of the sacroiliac joint is a cornerstone for diagnosis and classification. MRI of the spine may help with difficult cases as spinal changes may antedate sacroiliac changes and indicate disease burden. In daily practice, the interpretation of axial MRI is challenging. Experience has tempered the initial enthusiasm as the limitations of the ASAS criteria in daily practice become evident.

Firstly, the ASAS criteria are intended to classify patients with 'back pain' of more than 3 months' duration and with onset before 45 years of age as having axial SpA. In other patient groups, however, sacroiliitis on MRI as defined by ASAS has a lower sensitivity and specificity.

Secondly, the definition of a 'positive' MRI for sacroiliitis is validated to limited extend only. MRI of the sacroiliac joint requires inflammatory changes to meet the criteria, without a clear quantitative requirement. Bone marrow oedema lacks sensitivity and specificity as MRI findings suggestive of sacroiliitis may be produced by non-inflammatory disorders, a point that remains poorly investigated.

Thirdly, structural changes in the sacroiliac joints are not taken into account in the ASAS criteria. The diagnostic performance of MRI of the sacroiliac joint could be improved by including structural lesions, but to date this is not the case.

Fourthly, spinal imaging is not included in the ASAS criteria. MRI of the spine is considered 'positive' when at least 3 inflammatory or several structural lesions are present, with a sensitivity and specificity similar to those of the sacroiliac joints. The difficulty here is the lack of data. It has not been reliably shown that inflammation proceeds synovial fluid formation and MRI seems incapable of accurately evaluating treatment response. Only about 4% of patients with negative sacroiliac MRI have sacroiliitis.

Clinicians should be aware of unreasonable expectations on MRI. If MRI findings are considered in isolation the findings are not reliable. The diagnosis of SpA can only be made by an expert if patient's history, clinical examination, laboratory findings, and imaging studies converge. When solving difficult cases, collaboration is key: clear communication between rheumatologist and radiologist is mandatory. Radiologists should withstand the pressure to call if a patient has SpA or not based on MRI alone.

Ultrasound advanced I

SP0101 US FOR ASSESSING LUNG INVOLVEMENT IN RHEUMATIC DISEASES – CLINICAL USE + DEMO
Andrea Delle Sedie. University of Pisa, Rheumatology Unit, Pisa, Italy

Background: Evaluation of interstitial lung disease (ILD) is always difficult (low sensitivity for X-ray and pulmonary function tests or high level of radiation for HRCT); ultrasound (US) has recently shown interesting results on truth, discrimination and feasibility. Due to the thickening of interlobular septa for edema or fibrosis, US beam can interact with those structure and produce artifacts on the screen: B-lines (BL) and pleural line irregularity (PLI). A positive correlation between BL and HRCT has been established both in systemic sclerosis patients and in other patients with ILD; more recently similar results have been published by using PLI as a finding for US assessment in patients.

BL has been recently defined by the EULAR as a vertical hyperchoic reverberation artifact that arise from the pleural line, extend to the bottom of the screen without fading, and move synchronously with lung sliding, while PLI has been defined as a loss of regularity that may be associated with an increase in thickness, focal, diffuse, or nodular.

A low number of BLs has been described in healthy subjects but they are generally confined to the posterior and lower part of the thorax. Up to now, many different scanning protocols have been used to assess BL or PLI in patients, providing similar results.

Conclusion: US lung evaluation is a useful and feasible imaging technique.

Disclosure of Interests: Andrea Delle Sedie Speakers bureau: Abbvie, UCB, Celgene, MSD

SP0102 US FOR SYNOVIAL BIOPSIES – CLINICAL RELEVANCE AND SAFETY + DEMO
Andrew Filer. University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom

Background: The introduction of ultrasound guidance to access synovial tissue samples has facilitated a rapid growth in tissue-related research. Ultrasound guidance enables operators to use less invasive approaches compared to a gold standard direct vision arthroscopy procedure while maintaining the quality of samples obtained. Patients find the procedures easy to tolerate and are willing to undergo repeat biopsy, facilitating the analysis of tissue samples in clinical trials and experimental medicine studies. Advanced analytic techniques including single cell analytics are now being used to exploit the tissue samples obtained in order to provide dramatic leaps in understanding of synovial pathology.

Objectives: In this session the key aspects of the dominant techniques in use will be presented, including safety, patient tolerability and quality of output. The research and clinical utility of synovial biopsy will be discussed. Sonographic approaches to the major techniques will then be illustrated through video demonstrations, and competencies required to undertake training will be discussed alongside current EULAR initiatives for training. Finally, examples of research outputs generated through synovial biopsy will be explored alongside the logistics required to deliver such clinical studies.

Fighting and fixing: from initiation to resolution of inflammation

SP0103 T LYMPHOCYTES AND INNATE IMMUNE CELLS BALANCE MUSCLE REGENERATION AND AUTOIMMUNITY
Patrizia Rovere-Querini. IRCCS Ospedale San Raffaele and Università Vita-Salute San Raffaele, Laboratory of Innate Immunity and Tissue Remodelling, Italy

Background: The skeletal muscle is the largest cellular compartment of the organism. It represents an immunologically unique or a “non classical” immunological privileged site, being normally protected from the noxious effects of inflammation. The molecular events that control the homeostatic response to acute muscle injury are however poorly understood. The available information indicates that it involves the cross-talk among various cell populations, which i) perceive the muscle damage and release alert signals, which attract and activate inflammatory cells and progenitor cells ii) organize and maintain regeneration and tissue repair. The scenario is possibly even more complex during inflammatory idiopathic myositis (IBM) in which the immune privilege fails to protect the environment and
muscle cells undergo continuous cycles of death and regeneration as a consequence of the pressure of the immune respose targeting antigens preferentially expressed within regenerating fibers (1, 2).

Objectives: I will review recent evidence on the relative role of unconventional cellular and molecular pathways activated in the tissues of subjects with IMM and in relevant experimental models of skeletal muscle regeneration and autoimmunity, focusing on the action of antigen-specific and regulatory T cells and immune cell populations of innate cells.

Methods: Review of available published data and of data recently generated on the topic.

Results: Muscle necrosis and the ensuing inflammation was consistently associated in mice with up-regulated expression of bona fide autoantigens targeted in particular with histidyl-transfer RNA synthetase (HisRS), Phagocytosis of HisRS-expressing apoptotic myoblasts and appropriate inflammatory costimuli are necessary to elicit the production of anti-HisRS autoantibodies and to jeopardize muscle regeneration. Soluble pattern recognition receptors, and in particular the prototypic long pentraxin PTX3 play a critical role in preventing the accumulation of cell debris in the inflamed skeletal muscle, restricting the immunogenic potential of dying and regenerating myofibers. Conversely the local expression of type I IFN is necessary for the prolonged autoantibody response and for the maintenance and spreading of the immune-mediated muscle damage, as demonstrated using IFNαR1-null mice (3-5). A specialized population of regulatory T (Treg) cells, has been recently characterized in the inflamed and regenerating muscle, which influence both the immune response, by promoting the M1-to-M2 switch, and the activation of precursor/stem muscle cells. Treg cells control the efficacy of muscle repair and might be involved in preventing the systemic effects of the autoimmune response generated as a consequence of the disruption of the immunologically protected environment of the skeletal muscle (6, 7).

Conclusion: Identification of the pathways that are physiologically involved in restricting the onset and accelerating the termination of autoimmune responses targeting the skeletal muscle might be valuable for the identification of novel targets for molecular intervention in patients with IMM.

THE JANUS-FACED GLADIATOR: NEUTROPHILS IN STERILE INFLAMMATION AND AUTOIMMUNITY

Markus Hofmann
University of Maryland, School of Medicine, United States of America

Background: Neutrophils, and particularly neutrophil extracellular traps (NETs), have been connected with inflammatory and autoimmune diseases, such as RA, SLE, gout and many others. However, the outcome of a deficiency of NET-formation can be observed in chronic granulomatous disease and Papillon-Lefèvre syndrome and is characterized by non-resolving inflammation and frequent autoimmunity.

Objectives: I will give an overview over pro- and anti-inflammatory effects of neutrophils and NETs, respectively, focusing on our results in gout and SLE.

Methods: We investigated the impact of NET-deficiency and/or neutrophil depletion on animal models of SLE (pristane-induced lupus) and gout (MSU crystal-induced arthritis). Mechanistic studies were performed with isolated neutrophils from mice and humans.

Results: In experimental lupus and gouty arthritis neutrophil depletion or neutropenia worsens disease. Also mice strains with normal neutrophil numbers but defects in NET formation (NOX2 or PAD4-deficient mice) have exacerbated and unresolved inflammation. Release of inflammatory mediators by stimulated neutrophils was highest at intermediate cell densities (20–40 × 10^6 cells/cm^3). Above such densities, mediator release by normal neutrophils was outweighed by proteolytic degradation via proteases expressed on aggregated NETs. Additionally, binding to aggregated NETs conferred protection of the serine protease neutrophil elastase (NE) against inactivation by α1-antitrypsin (α1AT).

Conclusion: Although neutrophils are often regarded as archetypical pro-inflammatory cells, evidence is increasing that they can also exert anti-inflammatory and immunoregulatory function. Formation and aggregation of NETs and degradation of inflammatory mediators by serine proteases are important neutrophil tools to resolve gouty arthritis and other forms of localized inflammatory conditions. On the downside, NETs come at the price of collateral tissue damage and may cause occlusion of ductal structures.

REGULATION OF AUTOANTIBODY ACTIVITY BY T CELL SUBSETS

Gerhard Kröbke
University Hospital Erlangen, Internal Medicine 3, Erlangen, Germany

Our recent data show that the IL-23–Th17 axis controls the intrinsic inflammatory activity of autoantibodies and thereby triggers the clinical onset of autoimmune arthritis in mice and humans suffering from rheumatoid arthritis. TH17 cells regulate expression of sialyltransferases in newly differentiating antibody-producing cells and determine the glycosylation profile and activity of immunoglobulin G (IgG) that is produced by the consecutively emerging plasma cells.

SEEING IS BELIEVING: NANOTECHNOLOGIES IN TISSUE IMAGING

Matthias Gunzer
University Hospital, University Duisburg-Essen, Institute for Experimental Immunology and Imaging, Essen, Germany

Background: Because bone marrow is the source of all immune cells, knowing the blood supply of bones is essential to understand diverse mechanisms such as arthritic bone inflammation, anti-infectious immune defense or sterile inflammation.

Objectives: We wanted to clarify, how immune cells are able to function inside of the bone and also leave bones for peripheral functions.

Methods: We used a variety of different imaging approaches and animal models as well as insights from clinical studies in humans we have made the bone open to ways of studying, that have not previously possible.

Results: Using these methods we have defined an entirely new concept of how a closed circulatory loop is established in long bones. Thereby we show the mechanistic role of osteoclasts and define, how T cells and neutrophils use the system to fight against viral infection or invade ischemic tissue. This allows an integrated

FRIDAY, 14 JUNE 2019 08:15:00 – 09:45:00
view how the blood circulation inside and outside of bones are interconnected to mediate functional or dysfunctional immunity.

SP0107 THE 4-D+ NANOSCOPE: THE RESOLUTION FOR BIOLOGICAL SAMPLES

L. Kling1,2, L. Milb3,4, A. Grüneboom5,6, M. Herrmann4, G. Schett4, A. Maier6, S.H. Christiansen2,3,4, Heilmüh-Zentrum Berlin für Materialien und Energie, Forscherguppe Christiansen, Berlin, Germany; 2Christiansen Research Group, Heilmüh-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin, Germany; 3Physics Department, Free University, Berlin, Anni11e14, 14115 Berlin, Germany; 4Max Planck Institute for the Science of Light, Günther-Scharowsky-Str. 1, 91058 Erlangen, Germany; 5Universitätsklinikum der Friedrich-Alexander-Universität Erlangen-Nürnberg, Med. 3, Ulmenweg 18, 91054 Erlangen, Germany; 6Friedrich-Alexander-Universität Erlangen-Nürnberg, Pattern Recognition Lab, Martensstr. 3, 91058 Erlangen, Germany

Background: In ageing societies all over the globe, the number of people suffering from bone disease, e.g. osteoporosis (OP) in the first place, has increased dramatically. OP considerably impairs patients’ life quality, and results in high societal costs. However, current understanding of OP is still insufficient due to the lack of appropriate high resolution tools that permit a thorough analysis of scale bridging bone architectures from macro to nano with statistical significance to support the development of better treatments by drugs or surgical intervention.

Objectives: To revolutionize our knowledge of bone diseases based on an increase in understanding of the underlying bone anatomy, cutting-edge correla-
tive high-resolution microscopy and spectroscopy together with advanced data analysis including machine learning approaches permit reaching the next, so far unprecedented level of understanding.

Methods: Correlative workflows starting from X-ray microscopy (XRM) volume analysis, with voxel sizes of <1μm, over light-sheet fluorescence microscopy and large scale scanning electron microscopy data acquisition, to dual beam micro-
scope analysis (focused electron- and ion beams) permit the scale bridging inves-
tigation of bone architectures and thus merging the “big picture” and the underly-

ing ultrastructure with statistical significance. In combination with addi-
tional analytical add-ons to these microscopes, physical properties such as optical, mechanical, compositional, structural etc. deliver a highly detailed correlated dataset of bone (cf. Figure 2).

The present paper demonstrates novel findings related to various partly age related bone diseases using advanced correlative data acquisition (cf. Figure 2).

Results: Figure 1 shows the different bone fine structures, composed of trabecu-
lar and vascular networks as well as a three-dimensional arrangement of osteo-
lacunae that host osteocytes, as obtained by volume analysis in a new generation of lab-based x-ray microscope (Zeiss XRM Versa 520). These fine structures can be assessed quantitatively with statistical significance and can be correlated with additional modalities as shown in Figure 2. Elucidating examples demonstrating the power of such an approach will be given [ref 1, ref 2, ref 3, ref 4].

Figure 2 shows the an example correlative workflow from sample collection over sample preparation and the acquisition of various image modalities utilizing corre-
lated data from electron-, ion-beam imaging and analytics, probes and focused laser light to study scale bridging bone architectures. We will demonstrate how these correlative workflows will permit to advance the current understanding of bone architectures and function substantially and will show some first systematic correlative microscopy and spectroscopy studies on mouse tibia and human bone [ref1, ref2, ref3, ref4].

Conclusion: Based on our correlative analytics and the data availability, the advanced data interpretation using machine learning approaches will be discus-
csed. Using this approach, all details of bone micro-nano-architecture can be used to provide a novel clinical tool-set for future for early detection of bone diseases.

SP0108 LSFM AND CATCHING UP IN JOINT IMAGING

Anika Grüneboom1

Background: Bone tissue differs from other organs by its hardness and high optical density. These physical characteristics are challenging in the context of fluo-

descence based imaging studies addressing bone anatomy and physiology. The development of novel imaging technologies, such as light-sheet fluorescence microscopy and X-ray microscopy, and tissue-specific preparation procedures like optical clearing allowed us to reveal a so far unseen network of blood ves-

s in the cortical bone. These trans-cortical vessels (TCVs) directly connect the bone marrow vasculization with the peristeum and make the major contribution to total blood flow in long bones. Furthermore, we could show that immune cells are recruited to the peripheral circulation via TCVs and that TCVs are highly remodelled and inflammatory conditions. In case of chronic arthritis we observed a massive increase in TCV numbers, especially at the metaphysis of long bones. This increase in bone vasculatization confirms observations of previous studies describing increasing numbers of microcanals in the bare area of metacarpal heads in the hands of rheumatoid arthritis patients. These alterations in bone anatomy might hint to an alternative mechanism by which immune cells are recruited into inflamed joint tissue. While current concepts describe the recruit-
ment of immune cells from the systemic circulation, immune cells can potentially infiltrate the articular joints directly from the underlying bone marrow.

Objectives: Clarifying the anatomical routes of cell recruitment as well as explor-
ing the regulatory mechanism guiding immune cells from the bone marrow to the site of inflammation might bear new therapeutic strategies to resolve inflamma-
tion and tissue injury in rheumatoid arthritis.

Methods: 3D optical imaging approaches like Light-sheet fluorescence micro-
scopy and 2-Photon laser-scanning microscopy enable the visualization of entire bones and joints. In combination with tissue-specific preparation procedures and labeling strategies inflammatory mediated changes in vasculatization and cell recruitment can be analyzed.

Results: The joint tissue architecture is massively affected by inflammatory arthritis processes leading to changes in vasculatization, permeability and cellular tissue composition. These processes are directly connected to the onset as well as the resolution of inflammatory arthritis.

Conclusion: Newly available imaging techniques as light-sheet fluorescence microscopy facilitate new insights into bone and joint tissue architecture, function and inflammatory processes. These findings might guide the identification of novel
proresolving mediators to develop therapeutic strategies for managing tissue-damage-induced inflammation.

Paradigm shifts in arthritides

SP0109 HOT: DIAGNOSIS AND TREATMENT OF INFECTION RELATED ARTHRITIDES

Robert Schoen. Yale School of Medicine, Rheumatology, Allergy, Clinical Immunology, New Haven, United States of America

Background: Management of infectious arthritis has evolved because of empiric knowledge, clinical studies, and emerging pathogens. For patients with bacterial arthritis, organism specific, effective anti-microbial therapy is essential, but assessment of co-morbidities, adequate joint drainage, and supportive care are also required. For patients with infectious arthritis an acute intervention is usually necessary, since delay in diagnosis often leads to unsatisfactory outcome. In some situations, the distinction between infection and a post-infectious inflammatory process may be challenging.

Objectives: The goal of this lecture is to review management of septic arthritis in native joints. In addition, I will discuss Lyme arthritis and chronic chikungunya arthritis as examples of the broadening spectrum of infectious arthritis.

Methods: This lecture will rely on my clinical experience and a PubMed literature search.

Results: In this HOT lecture, I will provide practical, up to date information about the diagnosis and management of septic (bacterial) arthritis of native joints. I will discuss longstanding treatment paradigms, as well as advances in management and areas of uncertainty. I will then consider two emerging infections, Lyme arthritis and chronic chikungunya arthritis, that illustrate the changing spectrum of infectious arthritis.

Conclusion: It is the intention of this lecture to assist rheumatologists in management of patients across the spectrum of infectious arthritis. Accurate diagnosis and treatment are often challenging, but critical to satisfactory patient outcome.

Safety First! Infectious complications and pregnancy issues in patients with rheumatic diseases

SP0110 WIN: PREGNANCY ISSUES IN PATIENTS WITH RHEUMATIC DISEASES: THE OB PERSPECTIVE FOR RHEUMATOLOGISTS

Catherine Nelson-Piercy. Guy’s and St. Thomas’ Foundation Trust and Queen Charlotte’s and Chelsea Hospital London, United Kingdom

Pregnancy issues in patients with rheumatic diseases: the OB perspective for rheumatologists

Learning Objectives:

- Understand the importance of pre pregnancy counselling for women with rheumatic disease in pregnancy
- Understand the risk factors for adverse pregnancy outcome in women with rheumatic disease
- Understand the medications which are compatible with use in pregnancy and lactation
- Understand the management of rheumatic disease in pregnancy

Abstract: Rheumatic disease predominantly affects women of child-bearing age and are commonly encountered in obstetric practice. Pregnancy poses an important challenge for doctors looking after these women. Knowledge about medication safety, the effect of pregnancy on the disease, and vice versa, together with pre-conception counselling and multidisciplinary team care, are important to provide the best obstetric and medical care to these women. Women with rheumatic have increased risks of miscarriage, preterm delivery, pre-eclampsia, fetal growth restriction, and disease flare in pregnancy. The main risk factor for adverse pregnancy outcomes in inflammatory arthritis is active disease flare. For women with SLE the risks are lupus nephritis, particularly with CKD class 3-5, anti Ro/La antibodies, active disease and antiphospholipid antibodies. The most important issues of delaying pregnancy until there is quiescent disease, ensuring continued remission by continuation of drugs that are safe in pregnancy and adequately and promptly treating any flare of disease will be discussed. Adequate surveillance of the mother and fetus is imperative, but stratification of women is important to ensure that those with low risk pregnancies are not over-medicalized. There is an understandable reluctance to prescribe drugs, particularly immunosuppressant drugs, in pregnancy and in breast feeding mothers. However much harm can result if drugs are withdrawn, omitted or the dose reduced inappropriately. Active disease has an adverse effect on female fertility and time to pregnancy as well as impacting adversely on pregnancy outcomes. Guidelines from the British Society of Rheumatology and EULAR have reviewed the safety data for antirheumatic drugs in pregnancy. These publications include recommendations for which drugs are compatible with pregnancy and during lactation. These guidelines should reduce errors of omission where important medication for disease control are discontinued prior to or in pregnancy and empower rheumatologists to help women to time their pregnancies during disease remission and with continuation of medications including biologics compatible with pregnancy.

Immunosuppression in SSc – a matter of timing!

SP0111 POTENTIAL CELLULAR AND MOLECULAR TARGETS

Jöra Distler. University of Erlangen-Nuremberg, Department of Internal Medicine 3, Erlangen, Germany

The pathophysiology of systemic sclerosis (SSc) is characterized by a cascade of microvascular injury with apoptosis of endothelial cells, Th2/M2 biased
immunosuppression or i.v. pulse cyclophosphamide? And if so, on the basis of what criteria should treatment intensity be stepped up? Second, how can patient selection be optimised so as to avoid transplanting dCSSc patients with little chance of responding? Third, is there a window of opportunity where the immune system can be robusted? Last but not least, how can the potentially eligible dCSSc patients access to HSCT? The latter may be the most (de)pressing one, as HSCT is only available in a small number of centres. Until efficacious disease-modifying drugs with a better risk-benefit ratio become available, HSCT will continue to be the only therapeutic option to reverse the disease course in dCSSc patients.

Disclosure of Interests: Jacob M. van Laar Grant/research support from: Genentech, Consultant for: F. Hoffmann-La Roche DOI: 10.1136/annrheumdis-2019-eular.8611

13:30:00 – 15:00:00

Predicting short-term fracture risk: can we foresee the (close) future?

SP0112 IMMUNOSUPPRESSION – ONE FITS ALL VS. INDIVIDUALIZED SELECTION?

Marco Matucci-Cerinic. University of Florence, Division of Rheumatology AUOC, Florence 50138, Italy

Systemic sclerosis (SSc) is an autoimmune disease characterised by skin, vascular and internal organ involvement leading eventually to tissue fibrosis and atrophy. The best control of the disease is usually achieved in the early phase which is characterised by a diffuse tissue inflammation and vasculopathy, of the tissues. In this phase an immunosuppressive strategy can in fact lead to disease remission even if some cases may escape control and progress inexorably to fibrosis.

Classically, the clinical profile of the patient needs to be achieved. The subset, the disease activity and the main clinical features should be defined in order to have the precise profile of the disease. The knowledge of the clinical conditions may therefore help in deciding the drug and shaping the therapeutic regimen and its intensity. Usually, the use of Cyclophosphamide (CYC) and Micophenolate (MMF) may fit the necessity of the largest part of the SSc population. In practice, CYC may be employed as an induction treatment, etile or intravenous, while MMF may be used as a maintenance therapy. Both drugs have been demonstrated to be useful in the treatment of SSc either on the cutaneous or on the lung involvement.

However, the most severe and refractory cases may be today considered for a hematopoietic stem cell transplantation (HSCT). In this case, an individualised selection is performed before a patient can be considered fit to receive this kind of therapeutic regimen. Therefore, the treatment is strictly individualised and only after having a thorough clinical evaluation the patient can be accepted for the systemic conditioning with high doses of CYC for bone marrow ablation. In conclusion, the treatment of SSc is today mainly centered on immunosuppression whose intensity must be decided and individualized according to the disease activity. New innovative targeted drugs are on the horizon in the effort to find the right immunosuppressive and antifibrotic therapeutic approach clinically tailored on the SSc patient.

SP0114 CASE 1 PRESENTER: IMMINENT FRACTURE RISK: ASSESSMENT AND DOES IT HELP CLINICAL MANAGEMENT

Nicholas Fuggle. University of Southampton, MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom

A 60 year old female was under long-term follow-up for rheumatoid arthritis, for which she took methotrexate. Ten years previously she had been found to have a single vertebral fracture and her fracture risk, assessed using The WHO Fracture Risk Assessment Tool (FRAX®), was calculated as a 13% risk of major osteoporotic fracture over the next 10 years. According to The National Osteoporosis Guideline Group (NOGG) recommendations, she underwent Dual X-ray Absorptiometry (DXA) which demonstrated a bone mineral density T-score of -1.7 at the femoral neck. Lifestyle, vitamin D and calcium intake were optimised and follow-up was arranged for 6 months. Prior to her next appointment she fell and sustained a fracture of the distal radius.

On fracture liaison review her FRAX® risk of fracture was 14% (rising due to an increased year of age) despite the recent change in clinical circumstances.

This case serves to emphasise the clinical conundra associated with imminent fracture risk (the 2 years after a fracture when the patient is at a significantly higher risk of fracture) and the difficulties with the decision to treat.

SP0115 CASE 1 DISCUSSANT: IMMINENT FRACTURE RISK: ASSESSMENT AND DOES IT HELP CLINICAL MANAGEMENT

Cyrus Cooper. University of Southampton, MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom

With an estimated 520,000 fragility fractures every year in the UK, delivering effective and efficient healthcare for this patient group has significant consequences for patients, families, the NHS, and society. A fragility fracture is a major risk factor for further fractures, and healthcare systems are now beginning to recognise the benefits of secondary fracture prevention. Despite this, less than 50% of patients receive effective secondary fracture prevention after a fragility fracture. This has led to national and international initiatives to improve clinical services by implementing fracture liaison services (FLSs). Successful funding of a new FLS is usually influenced by the number of fractures it is expected to prevent in the first few years after an index fracture. The expected number of fractures prevented is in turn determined by the baseline risk of subsequent fracture, the number of patients at high enough fracture risk to warrant anti-osteoporosis medication (AOM), and the degree of fracture risk reduction by AOMs. Underestimating fracture risk in the post-fracture period will lead to fewer expected fractures prevented and lower perceived benefit of the FLS by payers, and importantly also by patients, families, healthcare providers, and payers. Tools are available to determine the long-term risk of fracture based on patient factors, including previous fracture. Of these, FRAX® and QFracture have been incorporated within UK NICE clinical guidance, and the FRAX-derived intervention threshold is used to guide therapeutic options for AOM in the NHS.

CASE 2 PRESENTER: BREAKING BAD AND TRAGICALLY HIP. A CASE OF A MISSED OPPORTUNITY AFTER VERTEBRAL FRACTURE

Michael Skjødt. Norwegian University of Science and Technology (NTNU), Department of Public Health and Nursing, Trondheim, Norway

Mrs A is a 78-year old woman, admitted to the emergency room after a same level fall in her home earlier the same day. She has a history of Chronic Obstructive Pulmonary Disease with recurrent exacerbations, and hysterectomy at the age of 41. At admittance, she is complaining of agonising pain localised to her right hip, and she is unable to move the leg. Upon the physical examination, the right leg is shortened and outwardly rotated. Upon further questioning, Mrs A reveals that she has lost four or five cm of height during the past years. An X-ray of the hip demonstrates a neck of the femur fracture. Mrs A has surgery the following day and two screws are inserted. Due to a hospital-acquired pneumonia, Mrs A stays in the hospital for an additional 9 days after the operation, upon which she is discharged for a temporary placement at a nursing home for further rehabilitation.

Two months following discharge, Mrs A was called for a clinical evaluation by the hospital Fracture Liaison Service. Assessment with DXA confirms the osteoporosis diagnosis and VFA shows lower thoracic vertebral fractures. The FLS coordinator noted that Mrs A, related to a hospital admission for an acute exacerbation of her COPD 3 years before, had had a chest x-ray performed, on which vertebral fractures of the thoracic spine could be seen to be present. Mrs A has never previously been assessed nor treated for osteoporosis.

CASE 2 DISCUSSANT: AUTOMATED (IMPLEMENTED IN THE PRESENCE OF VERTEBRAL FRACTURES)

Bo Abrahamsen. x, x, x. Denmark

Identification of patients at high risk of osteoporotic fractures is commonly based on fracture history, bone mineral density or a combination of the two. However, vertebral fractures are very often either missed or not acted upon by our health systems and DXA scanning to measure BMD in itself requires a coherent case finding strategy. Current EPR systems may have built-in features to capture signs of sepsis or warnings to alert clinicians to cases with a diagnosis of atrial fibrillation with no apparent prescription for anti-coagulation. Building on the same principle, EPR systems or even national databases can be set up with appropriate decision rules to alert physicians to diagnoses such as RA, AS or COPD that we know strongly increases the risk of osteoporosis and to flag out medication patterns known to predict a high risk of osteoporotic fractures. This can then be checked against the presence of referrals for DXA and/or prescriptions for anti-osteoporosis medicines and a clinical decision aid triggered to alert healthcare professionals. The mechanism powering such a tool can be an existing clinical risk algorithm such as QFracture, FRACT, FREM, Garvan FRC or others, depending on the nature of routinely collected data, the setting and the timescale required, or a bespoke risk tool developed for the healthcare system in question. It is important to appreciate that risk tools need careful calibration to be appropriate across countries and clinics and that the trigger risk level is ultimately a trade-off between clinical judgment and health economics.

Vertebral fractures represent a particular challenge. It has been established in the past that vertebral fractures often are not mentioned in radiology reports even if clearly present, or reported using unclear terminology that does not make it sufficiently clear to clinicians that a vertebral fracture is present. Moreover, even when vertebral fractures are called out in the radiology report it is not uncommon for this to go unnoticed. Opportunistic identification of vertebral fractures by software tools is a possible new avenue for narrowing the treatment gap in osteoporosis. With increasing integration of DICOM images into EPR systems, DICOMs of CT scans and other modalities containing spine images could be used either for automated case finding with alert boxes in the EPR system itself or employed in radiology departments to automatically populate reports with additional information about the presence of vertebral fractures.

Primary and secondary fibromyalgia; are they different?

FIBROMYALGIA: AN ACCEPTABLE DIAGNOSIS?

Rinie Goege, Utrecht University, Department of Psychology, Utrecht, Netherlands

Background: Neither patients nor clinicians and researchers fully embrace the fibromyalgia diagnosis. A core objection relates to the huge overlap with other polysymptomatic distress disorders such as somatic symptom disorder and chronic fatigue syndrome. Another objection has to do with the classification of fibromyalgia as a rheumatic disease, which may hamper research and treatment of psychological factors.

Objectives: To get insight into the pros and cons of the fibromyalgia diagnosis. Methods: The scientific literature was reviewed with a focus on homogeneity and heterogeneity within the group diagnosed as fibromyalgia.

Results: That fibromyalgia is not a stable diagnosis of a homogeneous group is reflected in the ongoing development of new classification and diagnostic criteria; the newest including diagnostic criteria, common features, comorbidities, consequences, and putative mechanisms (Arnold et al., 2019). Moreover, treatment recommendations progressed from a focus on pharmacological treatment in 2008 to a focus on nonpharmacological therapies in 2017 (Macfarlane et al., 2017). Also, several studies showed that the group is quite heterogeneous with respect to type, number and severity of symptoms and comorbidities (e.g., Davis et al., 2018) as well as with respect adaptation profiles covering a spectrum of severely maladjusted to quite well adjusted in terms of objective and subjective management (Estevez-Lopez et al., 2018).

Conclusion: Although diagnostic classifications such as fibromyalgia help to examine underlying mechanisms and interventions and to define treatment recommendations, in clinical practice and research account should be taken of heterogeneity of patients in terms of symptoms and disorder-transcending biopsychosocial factors that influence the disorder. This suggests that fibromyalgia is an acceptable diagnosis to the extent that individually is accepted as part of the diagnosis.

SEARCHING FOR PATHOLOGY; HOW HARD SHOULD WE LOOK?

Ernest Choy. CREATE Centre, United Kingdom

Background: The 1990 American College of Rheumatology (ACR) classification criteria for Fibromyalgia (FM) was intended to facilitate research by defining a homogeneous patient population [1]. Two key features of the criteria are tender point examination and exclusion of other conditions that may cause widespread pain. This led to the view that FM is a diagnosis of exclusion. This is no longer the case in 2019.

Results: In 2010, the ACR published provisional criteria for the diagnosis of FM [2]. These allowed FM to be diagnosed by using questionnaire removing the need for tender point examination. One of the major advantages of the criteria is that the diagnosis of FM can be made by primary care physician and the first-line treatment be initiated without referral to secondary care. Such an approach was
recommended by the Canadian guidelines [3], which recommended “patients should undergo a physical examination which should be within normal limits except for tenderness on pressure of soft tissues however the specific tender point examination according to the 1990 ACR diagnostic criteria is not required to confirm a clinical diagnosis of fibromyalgia”. Furthermore, it stated that “Fibromyalgia should be diagnosed as a clinical construct, without any confirmatory laboratory test, and with testing limited to simple blood testing including a full blood count, erythrocyte sedimentation rate, C-reactive protein, creatine kinase, and thyroid stimulating hormone. Any additional laboratory or radiographic testing should depend on the clinical evaluation in an individual patient that may suggest some other medical condition.” However, many primary care physicians do not feel competent/confident to exclude other rheumatic conditions by physician examination.

Over the last decade, comorbid FM is increasingly recognized in many chronic musculoskeletal diseases including patients with inflammatory arthritis. A systematic review found that the prevalence of FM is 21%, 13% and 18% in RA, axSpA and PsA respectively [4]. Patients with comorbid FM have higher diseases activity score and more severe pain. In 2016, the ACR diagnostic criteria for FM were modified and stated that “A diagnosis of fibromyalgia is valid irrespective of other diagnoses. A diagnosis of fibromyalgia does not exclude the presence of other clinically important illnesses.” [5].

Conclusions: The motion that “FM is a diagnosis of exclusion” is no longer valid. FM should be a positive diagnosis and does not exclude other rheumatic diagnosis.

SP0120 PERSONALISED TREATMENT FOR FIBROMYALGIA; THE IMPACT OF COMORBIDITIES
Serge Perrot, France, France

Background: The heterogeneity of the clinical presentation, the co-morbidities and the pathophysiologic mechanisms associated with fibromyalgia (FM), and the modest results on average for any therapy, call for a more individualized management strategy.

How to develop personalized treatment?

Individualized treatment can be developed on the basis of subgrouping of patients according to associated conditions and co-morbidities (mental health problems, chronic overlapping pain conditions, other somatic diseases) or on disease severity. Personalizing treatment needs to classify FM in specific subgroups. It can be proposed on the basis of clinical assessment (e.g. degree of daily functioning), on co-morbidities or on dedicated questionnaires. Lastly, shared decision-making regarding treatment options can be directed according to patient preferences, co-morbidities, and availability in various health care settings.

What is currently recommended as a personalized approach?

The European League Against Rheumatism guidelines recommend a tailored approach directed by FM key symptoms (pain, sleep disorders, fatigue, depression, disability), whereas the German guidelines recommend management tailored to disease severity, with mild disease not requiring any specific treatment, and more severe disease requiring multicomponent therapy (combination of drug treatment with aerobic exercise and psychological treatments). When indicated, treatments should follow a stepwise approach beginning with easily available therapies such as aerobic exercise and amitriptyline. We will present how successful application of a tailored treatment approach that is informed by individual patient characteristics can improve outcome of FM.

Key points: This presentation will presents suggestions for an individualized treatment strategy for FM patients on the basis of symptoms, disease severity and co-morbidities.

Optimizing the access to new treatments for RMD patients

SP0122 OPTIMIZING HOLISTIC TREATMENTS: THE CHALLENGE OF IMPLEMENTATION
Krysta Dziiedzic, Keele University, School for Primary, Community and Social Care, Stoke on Trent, United Kingdom

International guidelines present recommendations for holistic care for RMDs, building upon best evidence. However, there is still a gap between what we know about best care and what we do to implement best care in our clinical services. Having EULAR guidelines alone (and multiple updates and revisions) is not enough to change complex systems. European funders are now investing in projects to accelerate the uptake of best care across multiple European partners.
Using one example of a completed EIT-Health funded implementation project, JIGSAW-E (Joint Implementation of Guidelines for oSteoArthritis in Western Europe), this presentation will highlight some of the challenges of implementation such as: understanding the context; competing priorities; lack of time and funding; stability of the workforce; and differing health care systems. It will describe the use of Knowledge Mobilization and Communities of Practice as methods for overcoming these challenges and optimizing holistic treatments.

The presentation will offer some of the key factors for implementation such as ‘leading from the middle’ and brokering across silos; working with patients and the public. ‘Patients are the most under-used resource in any health care system’: using theories, models and frameworks to plan, understand and evaluate implementation; using pilot sites to build momentum with dedicated Communities of Practice; and agreeing what success should look like.

SP0123 NEW TREATMENTS: WHY SHOULD WE WAIT?

Daniel Morales. University of Dundee, Population Health and Genomics, Dundee, United Kingdom

Background: Improving access to new and established medicines for rheumatological disease is of public health importance. However, drug development processes, medicines regulation and health technology requirements may significantly impact on when a new medicine become available to be used by health care professionals.

Objectives: The objectives of this session are to present some of the challenges and opportunities for accessing new and established medicines for rheumatological disease.

Methods: Drug development processes, medicines regulation and health technology requirements may significantly impact on when a new medicine become available to be used by health care professionals. Although these requirements may be perceived as barriers, many of these requirements are in place to ensure a medicines benefit risk profile is favorable and is cost effective in terms of quality of life. This session will briefly discuss issues around the process of making medicines newly available from drug development to gaining new market approvals with an emphasis on rheumatological disease, including the post-authorization safety requirements that are in place to safe guard public health.

New assessments in clinical practice

SP0124 WHICH MEASURES TO USE TO ASSESS REMISSION IN RHEUMATOID ARTHRITIS

Annamaria Iagnocco. Academic Rheumatology Unit Università degli Studi di Torino, Academic Rheumatology Centre, Turin, Italy

Remission is the ideal target of treatment in rheumatoid arthritis (RA) patients. However, the definition and characterization of remission is still a theme of discussion and its assessment can be a challenging issue in RA clinical practice. Indeed, nonetheless the new treatments and therapeutic strategies for RA make remission possible, sub-clinical inflammation can still be present both at the joint site and at the patient level, leading to damage progression and to occurrence of flares.

Clinically, remission entails persistent absence of any sign of joint and systemic inflammation. However, the presence of some residual joint inflammatory activity can be accepted by current clinical indexes such as DAS28, SDAI, CDAI and Boolean remission, although the latter is clearly based on more stringent parameters (1,2). Based on those criteria, and particularly with the use of SDAI and Boolean cut-off values, complete and persistent remission is then quite uncommon in late RA, while it seems to be more easily possible in early disease (3). Another interesting issue to consider in clinical practice is the presence of sustained remission which seems to occur less frequently than remission at different point times and with only a minority of cases reaching a complete disease recovery (4).

Depending on the modality that is used, the assessment of remission by imaging encompasses the evaluation of a wide spectrum of lesions. While ultrasound is able to show intra- and peri-articular signs of inflammation and to differentiate active from inactive synovitis with the use of Doppler modes, MR shows also bone marrow inflammatory-related abnormalities. Moreover, ultrasound detects inflammation at multi-site level and allows the measurement of stable remission over time on longitudinal evaluation. Interestingly, also tenosynovial Doppler inflammation has been demonstrated to be a frequent finding in patients in clinical remission and, compared to joint synovitis, it is more associated with self-perceived unstable remission (5). In addition, tenosynovial and joint Doppler positivity has been demonstrated to be an independent risk factor of flare in RA patients in remission (6). Residual joint inflammation in patients in remission can be demonstrated also by other imaging techniques, such as PET which shows enhanced tracer uptake at different joint sites (3). Basically, the capability of imaging to demonstrate sub-clinical disease activity even in patients in clinical remission, by allowing the detection of residual inflammation at different joint sites and at different disease stages gives it an added value compared to clinical assessment alone.

In conclusions, clinical evaluation of remission alone appears frequently inadequate to capture a real persistent lack of inflammation at different joint sites. Imaging can complement the assessment of patients in clinical remission, offering additional data that may still reveal a certain amount of sub-clinical disease activity. With new therapeutic strategies RA management has become increasingly complex over the last years (7). The relevance of this information is then substantial, being structural damage the result of both previous and current phases of disease activity.

SP0125 HOW TO ASSESS PATIENT WITH SUSPECTED VASCULITIS

Presshil Limpar. University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: Systemic vasculitides are multi-organ, multi-system conditions which can mimic many other diseases. They are rare but very significant because they can rapidly lead to end organ damage or death if left untreated. The difficulty faced by clinicians in diagnosing a patient with vasculitis is further compounded by the presentation of limited forms of vasculitis, which can be difficult to recognise as due to vasculitis, the effects of co-existing co-morbidity and the use of drugs either for medicinal or recreational purposes. Giant cell arteritis is one of the most common serious forms of vasculitis in adults, leading to blindness if untreated. In view of this risk, many clinicians will initiate treatment of any patients with suspected giant cell arteritis before definitive investigations have been performed. Unfortunately this can result in inadequate outcomes form diagnostic tests such as ultrasound or biopsy of the temporal artery. There are no diagnostic criteria for most forms of vasculitis apart from Behcet’s syndrome. Some tests can be very useful in ruling out other causes as well as helping to confirm a diagnosis of vasculitis. We will review some of the strategies for diagnosing vasculitis, complementing a thorough history and examination with selected investigations to improve diagnostic certainty.

Objectives: To consider the strategies used to assist the diagnosis of systemic vasculitis, to assess the frequency of multi-system involvement in systemic vasculitis; to critically evaluate the role of diagnostic testing in systemic vasculitis.

Methods: A review of current literature on the approach to diagnosis and classification of vasculitis.

Results: Table 1 summarises the clinical manifestations of some forms of primary systemic vasculitis, comparing the different frequencies of the common presenting features. Patients with large vessel vasculitis are usually more distinct as a clinical group from other forms of vasculitis but increasingly we see an overlap between GCA and older patients with Takayasu arteritis. There is considerable overlap of clinical features amongst the small vessel vasculitides, despite different immune-pathogenetic pathways. Amongst the anti-neutrophil cytoplasm antibody (ANCA) associated vasculitides (AAV), the presence of active nephritis characterises most patients with MPA; it is less common in GPA and least common in EGPA. Lung involvement is prevalent in all these forms of AAV, but has different characteristics: bronchial wall inflammation with ulceration plus nodules and infiltrates in GPA; transient infiltrates and bronchospasm in EGPA; lung haemorrhage at presentation in MPA, with subsequent risk of developing lung fibrosis. The different patterns of disease activity help in differentiating
individual forms of vasculitis, but it is important to remember that many features associated with medication and co-morbidity may make this patient group more homogeneous, especially if the original disease manifestations are now quiescent. We will explore the potential use of classification criteria as substitutes for diagnostic criteria in different forms of vasculitis and evaluate the role of specific tests to assist in the diagnosis, with a focus on ANCA testing in small vessel vasculitis and on imaging in large vessel vasculitis.

**Conclusion:** A rational approach to diagnosis in vasculitis is required, based on a combination of clinical features together with relevant investigations. Diagnostic certainty can vary in the absence of definitive evidence from investigations, especially if patients have already been partly treated prior to completing all relevant investigations. Diagnostic testing is improving and with the development of new criteria for classification, this forms a stronger basis to develop a more sound approach to diagnosis. However, we should always be prepared to apply a provisional diagnosis and reconsider any emerging evidence to suggest an alternative condition.

The benefits of involving patients in health technology assessment

**SP0127**  
**PATIENT ENGAGEMENT WITHIN THE EUROPEAN MEDICINES AGENCY**

Nathalie Bere, European Medicines Agency (EMA), Public engagement Department, London, United Kingdom

The European Medicines Agency (EMA) is the European regulatory body whose role is to evaluate and supervise medicines across the European Union. EMA has been engaging with patients and consumers for many years and today, patient involvement is an integral part of the work at EMA, with a diverse range of opportunities in place to include the patient’s voice at various stages along the medicines regulatory life-cycle. Key to successful engagement has been the need for flexibility, a range of well-tested methodologies and a robust system of support and training.

Patients and caregivers’ real-life perspectives and unique insights complement the scientific data within EMA reviews; they provide input on proposed protocol designs and participate in expert meetings and written consultations on medicines evaluation. They are voting members of EMA committees and they review medical information written for the public. Evidence has shown their contributions make a difference and ultimately help ensure that the Agency’s outcomes are as meaningful and relevant as possible for all concerned.

Some of the key challenges and conclusions of our journey will be highlighted to serve as a guide to those considering a similar, rewarding path.

THE VARIOUS ROLES OF PATIENT PARTICIPATION IN HTA BY THE EXAMPLE OF IQWiG

Virginia Seiffart. Institute for Quality and Efficiency in Health Care (IQWiG), Drug Assessment, S0670 Köln, Germany

Background: The involvement of affected persons in preparing systematic reviews and HTA represents an established international standard of benefit assessment. The Institute of Quality and Efficiency in Health Care (IQWiG) is a professionally independent scientific institute founded within the framework of the German Health Care Reform of 2004 as an establishment of the Foundation for Quality and Efficiency in Health Care. IQWiG provides benefit assessments addressing issues concerning the statutory health insurance services. Its responsibilities include among others the preparation of scientific reports, expert opinions and recommendations for quality and efficiency issues taking age, gender, personal circumstances into account.

Objectives: The goal of this presentation is to provide an overview on different paths of involvement of patients and affected persons at IQWiG.

Methods: IQWiG’s legal basis and responsibilities are anchored in the Social Code Book Fifth Book – Statutory Health Insurance (SGB V) and have been adapted and extended several times in the course of further health care reforms. The Institute’s work is commissioned by the Federal Joint Committee or by the Federal Ministry of Health. The information for this presentation stems from IQWiG’s General Methods (currently in version 5.0), a publicly available paper provided on the Institute’s website, which explains the groundwork for its assessments.

Results: The involvement of affected persons at IQWiG primarily takes place during the initial work on a report within the framework of patient-relevant outcomes and relevant subgroups. Moreover, involvement can also include partaking in hearings. Affected persons include in particular patients (represented by parents or relatives, when appropriate) as well as potential participants in prevention measures. Affected persons are found via the patient representation of the Federal Joint Committee, as well as national or local self-help organizations or groups, hospitals or medical practices, external experts or other routes. The involvement can consist of a personal consultation or providing information in writing (through questionnaires or reports on personal experience), in both cases with documents indicating potential conflicts of interest.

Conclusion: As representatives of patients or self-help groups are sometimes not always present and cannot directly account for symptoms or their impact on the quality of life, focus is placed on involving persons directly affected. Different assessments require distinct types of involvement depending on the available time and the confidentiality of the topic.

A PATIENT’S VIEW ON PATIENT INVOLVEMENT

Souzi Makri. CYPLAR, Limassol, Cyprus

Background: HTA as defined by the EUPATI:
Health technology assessment aims to inform decision making by health care policy makers. It is a systematic process that considers health technologies (such as medicines) and can involve a review of: Clinical evidence compared to existing models of care, Cost effectiveness, Social and ethical impacts on the health care system and the lives of patients EUPATI Overarching principle: We recommend close cooperation and partnership between the various stakeholders including healthcare professionals’ organisations, contract research organisations, patient’s and consumers’ organisations, academia, scientific and academic societies, regulatory authorities and HTA bodies and the pharmaceutical industry. Experience to date demonstrates that the involvement of patients has resulted in increased transparency, trust and mutual respect between them and other stakeholders. It is acknowledged that the patients’ contribution to the discovery, development and evaluation of medicines enriches the quality of the evidence and opinion available.

Objectives: Inform decision making by health care policy makers. It is a systematic process that considers health technologies (such as medicines) and can involve a review of:
1. Clinical evidence compared to existing models of care,
2. Cost effectiveness,
3. Social and ethical impacts on the health care system and the lives of patients

EUPATI Overarching principle:
“We recommend close cooperation and partnership between the various stakeholders including healthcare professionals’ organisations, contract research organisations, patients’ and consumers’ organisations, academia, scientific and academic societies, regulatory authorities and HTA bodies and the pharmaceutical industry. Experience to date demonstrates that the involvement of patients has resulted in increased transparency, trust and mutual respect between them and other stakeholders. STANDARDISATION OF NORMAL VERSUS ABNORMAL AND PATHOLOGICAL CAPILLAROSCOPIC IMAGES

V. Smith1,2,3, on behalf of the EULAR Study Group on Microcirculation in Rheumatic Diseases. 1Department of Rheumatology, Ghent University Hospital, 2Department of Internal Medicine, Ghent University, "Unit for Molecular Immunology and Inflammation, VIB Flemish Institute for Biotechnology (VIB), Ghent, Belgium

Medical doctors frequently get patients with Raynaud’s phenomenon (RP), a frequent symptom in the general population, referred. The importance of
distinguishing normal capillaroscopic findings from (pathognomonic) abnormal (pathological) findings (scleroderma pattern), lies in the fact that this distinction allows the differentiation between a primary RP (not connected to any connective tissue disease [CTD]) from a secondary RP due to systemic sclerosis (SSc) and diseases of the scleroderma spectrum.

What is normal in primary RP?

A normal capillaroscopic pattern, by qualitative assessment, is characterized by a homogeneous distribution of hairpin shaped capillaries as a “comb-like structure”, with a density of >7 capillaries per mm, with a normal dimension and absence of large hemorrhages. Yet, there exists a wide intra- and inter-individual variety in a normal population which will be discussed in this session.

What is pathognomonic abnormal in patients with RP due to SSc?

Patients with the RP who have an underlying clinically recognizable (= with skin involvement) SSC show a very characteristic combination of capillary abnormalities in the nailfold, which can easily be assessed through qualitative assessment (= pattern recognition). Maricq et al. described last century, with the widefield technique (magnification X12–14) the scleroderma pattern. This pathognomonic combination contains the following: a striking widening of all three segments of the capillary loop (arterial, venous and intermediate), loss of capillaries and disorganization of the nailfold capillary bed. Many branched “bushy” capillaries may also be observed.

In 2000, Cutolo et al. qualitatively assessed the nailfolds of an SSc cohort with patients fulfilling the American College of Rheumatology (ACR) criteria for SSc with the nailfold videocapillaroscopy (NVC) technique (magnification X200). According to the different proportions of the hallmark parameters of the scleroderma pattern (giants, capillary loss, hemorrhages and abnormal shapes: (neo)angiogenesis), Cutolo et al. defined three patterns: “early”, “active” and “late”.

The central role of capillaroscopy in distinction between a primary and secondary RP due to SSc is reflected by the fact that capillaroscopy is one of the new ACR/EULAR criteria for classifying a patient as having SSc. In this lecture the standard “FAST TRACK” recognition system of the EULAR Study Group on Microcirculation in Rheumatic Diseases to discern scleroderma patterns from non-scleroderma patterns will be taught to the attendees.

SP0132

METHODS AND TOOLS FOR QUANTIZATION OF CAPILLAROSCOPICT MORPHOLOGICAL CHANGES

Francesca Ingegni, Academic Rheumatology Unit University degli Studi di Torino, Academic Rheumatology Centre, Turin, Italy

Nailfold capillaroscopy is the one most used technique in both clinical and research settings by adult physicians and paediatric rheumatologists to assess patients with Raynaud’s phenomenon as shown by an international survey on non-invasive techniques to assess the microcirculation performed under the aegis of members of the EULAR Study Group on Microcirculation in Rheumatic diseases [1].

Nailfold capillaroscopy is a simple non-invasive imaging technique mainly used to observe capillaries on the skin surface. After application of a drop of immersion oil, capillaries can be observed with a magnification lens because they run parallel to the epidermis at the nailbed area [2]. A number of different instruments can be used to perform the exam. They have different characteristics in terms of their cost, quality of images, magnifications, training period, portability, software for image analysis and storage.

Some of these instruments can be used both in clinical and research settings such as the stereomicroscope and the videocapillaroscopy. The stereomicroscope allows the widefield visualization of the nailfold with low magnifications, the training is relatively short, but the examination is difficult to perform in patients with digital flexion contractures.

There appears to be consensus regarding the use of videocapillaroscopy that allows a detailed visualization of capillary morphology using higher magnifications (100-300x). Contact probe with polarized light microscopy permits easier observation of the skin surface, and the training period is briefer. Specific software are available for images analysis, storage, and complete medical reports (text + images) can be produced. By contrast, in a clinical setting, nailfold capillaries can generally be visualized using more simple, but also efficient tools such as a dermatoscope, USB microscope, ophthalmoscope or smartphone device. The quality of images can be quite good, although the lower magnification means that some details are unlikely to be seen, and they often lack the possibility of image storage and measurement. In particular, the dermatoscope with magnification of the order of x10 is a small, inexpensive and easily portable piece of equipment that has been suggested to be comparable to videocapillaroscopy within routine clinical practice. As the study of capillary morphology provides clinically relevant information in the management of patients with scleroderma-spectrum diseases, the development of specific software to standardize and automate the analysis is ongoing [3-4].

REFERENCES:
Gout is the most common inflammatory joint disease in Western developed countries. Diagnosis and monitoring have historically been based upon clinical assessment combined with biochemical results (primarily p-urate) but over the last decade ultrasonography (US) has received increasing attention for these purposes. US has been shown able to detect monosodium urate deposits in both joints and tendons. In 2015 the Outcome Measures in Rheumatology (OMERACT) US Working Group developed definitions of structural lesions in gout. These include double contour sign (deposits of crystals on the surface of cartilage), tophus (larger hyper-echoic aggregation of crystals), aggregates (small hyper-echoic deposits) and erosion (1). The double contour sign has been included in the ACR/EULAR 2015 gout classification criteria as a way to visualize urate deposits in joints (2). Furthermore, US can visualize potential concomitant inflammatory aspects of gout since it can visualize both joint inflammation and tenosynovitis.

In this talk the diagnostic properties of US will be described and the potential risk of false positive results due to artefacts or misinterpreted lesions will be discussed. Furthermore, the potential role of US in monitoring of treatment response will be explored.

Conclusion: Knowledge of the clinical anatomy needed to understand the relationships between the different structures, the clinical history, and physical examination of GTPS patients and the therapeutic possibilities including ultrasound-guided injections are other steps that lead to an accurate diagnosis of GTPS.

Defining the concept of US-detected ‘minimal disease’ is crucial to enable investigators to identify a threshold (or cut-off) to differentiate normal physiological from minimal pathological changes at the joint level. This threshold, subsequently, will be used to evaluate the best sensitivity to detect changes in therapeutic response and assess remission, as well as facilitate diagnosis of early disease. In order to address this important research question, the OMERACT US SIG has formed the US Minimal Disease Taskforce at the OMERACT 2016 meeting. This collaboration between 24 OMERACT ultrasound centres in 11 countries has successfully recruited more than 600 subjects into the Minimal Disease Study. US data of healthy individuals encompassing synovial hypertrophy, synovial effusion, and Doppler enhancement will be presented.

HOW TO PERFORM US-GUIDED INTERVENTIONS + DEMO

Juhanni Keski, Mikkel Central Hospital, Internal Medicine, Mikkel, Finland

Background: Aspiration and injection of joints and soft tissues is an indispensable skill used in everyday practice by the clinical rheumatologist. These tasks are usually conducted by palpation-guided techniques. These procedures are not always successful [1] and thus US-guided interventions have been developed. Objectives: to explain the effect of needle and sound beam angle on needle visualization, describe different techniques of needle insertion under US guidance, to identify different approaches to the target under US guidance and finally to discuss about the accuracy and efficacy of the ultrasound guided technique.

Methods: There are two common methods for US puncturing: semi-guided or indirect method (skin surface marking) and needle guidance under direct sonomic vision (2,3). The scanning plane is optimized for visualization of the target and penetration of the needle should be at least 0.5cm from the transducer. The movement of the needle in the soft tissue should be followed on the screen during the procedure. The needle appears as a bright echogenic line if the transducer is oriented longitudinally on the needle, and the needle tip may be followed as it reaches the target. If the ultrasound beam is transverse to the needle, the needle is seen as a bright echogenic dot. In case of no visualization of the needle several means are available: steering of the ultrasound beam against the needle (in new machines), curved or virtual convex probe, toeing-in of the probe, shaken the needle slightly and moving the probe a bit from side to side.

Results: According to the clinical and cadaveric studies the ultrasound guided technique is more accurate than the landmark guided technique in the glenohumeral, acromioclavicular, wrist, hand, hip, knee and foot joints and in the tendons of the biceps, wrist, hand hip, knee and ankle (4). Synovial biopsies are more accurate using an ultrasound guided method (5).

Conclusion: Ultrasound is the most applicable and feasible imaging modality for routine clinical use in guiding musculoskeletal procedures. Though many studies have examined the role of imaging guidance for injection there needs to be more examination of how the use of ultrasound prior to injection can alter the pathological and anatomical diagnosis. There is a trend towards an expanded number of advanced applications of interventional musculoskeletal ultrasound which can also be performed by a rheumatologist like nerve blocks or needling of calcifications. Which ultrasound guided technique (direct or semi-guided) is the most appropriate in different anatomical areas and clinical settings remains to be studied. More studies are needed to show the accuracy and efficacy of ultrasound guided injections in different anatomical areas (4).

**CORE COMPETENCIES**

Theda Vliet Vlieland, Leiden University Medical Center, Orthopaedics, Rehabilitation and Physiotherapy, 2300 RC Leiden, Netherlands

Background: To maintain and optimize the quality of care provided by health professionals in rheumatology (HPRs), adequate educational offerings are needed. Ideally, these are based on defined core competences.

Objectives: A task force (TF) aimed to develop evidence-based recommendations for the generic core competences of nurses, physical therapists (PTs) and occupational therapists (OTs) to serve as a basis for their postgraduate education.

Methods: The EULAR standardised operating procedures for the development of recommendations were followed. A TF including rheumatologists, nurses, PTs, OTs, patient-representatives, an educationalist, methodologists and researchers from 12 countries met twice. In the first TF meeting, 13 research questions were defined to support a systematic literature review (SLR). In the second meeting, the SLR evidence was discussed and recommendations formulated. Subsequently, level of evidence and strength of recommendation were assigned and level of agreement (LoA) determined (0-10 rating scale).

Results: Three overarching principles and 10 recommendations for the generic core competences of HPRs were developed supported by the SLR and expert opinion. The SLR included 79 full-text papers, 20 of which addressed the competences, knowledge, skills, attitudes or educational needs of HPRs from multiple professions. The average LoA for each recommendation ranged from 9.42 to 9.79. Consensus was reached on education and research agendas.

Conclusion: Evidence and expert opinion informed a set of recommendations providing guidance on the generic core competences of nurses, PTs and OTs in rheumatology. Implementation of these recommendations in the postgraduate education of HPRs at the national and international level is advised, considering variation in health care systems and professional roles.

WHAT WE ARE BRILLIANT AT: OT PERSPECTIVE

Ingrid Kleven, Norwegian Advisory Unit on Rehabilitation in Rheumatology, Department of Rheumatology, Díakonhjemmet Hospital, 0370 Oslo, Norway

The unique contribution of occupational therapy is its focus on occupation, which may be defined as “groups of activities and tasks of everyday life, named, organized and given value and meaning by individuals and a culture. Occupation is everything people do to occupy themselves, including looking after themselves (self-care), enjoying life (leisure), and contributing to the social and economic fabric of their communities (productivity).” Occupation is further being influenced by the environment, one’s social roles and one’s developmental level; being client-defined; and consisting of both a performance (objective) dimension and a satisfaction (subjective) dimension (1). Knowledge of the International Classification of Functioning (ICF), occupational performance covers the domain of Activity and Participation in the ICF model.

In clinical practice, occupational therapists use assessment and interventions to determine, recover, or maintain meaningful occupations of individuals, groups, or communities. Lately, occupational therapists have also been increasingly concerned with occupational injustice, which relates to conditions wherein people are deprived, excluded or denied of occupations that are meaningful to them. Within rheumatology, the most frequently applied occupational therapy interventions are patient education concerning ergonomic principles and activity pacing, therapeutic exercise and activity programs, provision of orthoses and assistive technology, and environmental and task modifications.
In the presentation, patient cases will be used to illustrate how occupational therapists may work to enhance occupation in individual clients with a rheumatic condition, and evidence for some of the core interventions will be discussed.

SP0139 WHAT WE ARE BRILLIANT AT; NURSING PERSPECTIVE
Ricardo Ferreira, Centro Hospitalar e Universitário de Coimbra, EPE, Rheumatology, Coimbra, Portugal

The challenges confronting health care delivery systems worldwide are rapidly changing, and this calls for practice-defined competencies for nurses and other health care workers (Zhang, Luk, Arthur, & Wong, 2001). The definition of competency or competence in nursing has been a subject of debate (Axley, 2008; Fukada, 2018; Zhang et al., 2001). Its clarification is important and still needed to establish a foundation for realistic working behaviours, for nursing education and management.

Although there has been an extensive and valuable work in the definition of core competencies of nursing profession, which includes both autonomous and inter-dependent activities within the multidisciplinary team, little scientific research has been done to clarify the way in which nursing profession is unique.

This presentation will address the following questions:

- What are nurses (collectively) really brilliant at?
- What leads them to develop unique characteristics?
- How do they bring into care, that matches or complements other health professions to result in better quality care?

The presentation is informed by a scoping review, a survey of international nurse leaders and researchers.

Overdiagnosis and overtreatment in inflammatory arthritis

SP0141 DOES IMAGING LEAD TO OVERDIAGNOSIS AND OVERTREATMENT?
Duncan Porter, Garthavell General Hospital, Rheumatology, Glasgow, United Kingdom

Background: The use of musculoskeletal ultrasound (MSUS) and magnetic resonance (MR) imaging is widespread in the diagnosis and management of patients with rheumatoid disease. Interpreting the images, and their implication for clinical management is challenging, particularly in the community, in mild/early disease, when there is discordance between clinical and imaging findings, and in the presence of co-morbid joint disease.

Objectives: – to review the evidence about whether the use of imaging results in over-diagnosis and over-treatment
Specifically, the following issues will be addressed, using rheumatoid arthritis as the exemplar:

- To review the prevalence of ‘abnormal’ MSUS and MR findings in the general population
- To understand the prevalence and significance of sub-clinical joint inflammation
- To summarise the evidence from clinical trials about the risks/benefits of treating to a target of imaging (rather than clinical) remission

Methods: If clinicians are to interpret the available imaging correctly, several issues are pertinent. Firstly, it is important to understand the prevalence of erosions, synovitis and bone marrow oedema in the general population, in different joints, at different ages and in the presence of co-morbid conditions such as osteoarthritis. Secondly, in RA what are the implications of sub-clinical inflammatory changes for disease progression? Thirdly, do clinical trials support the hypothesis that ‘treat to target’ strategies should aim at a target of ‘imaging remission’ rather than clinical remission? The results of the TaSER, ARCTIC and RA-IMAGINE trials will be reviewed to identify if the systematic, routine use of imaging results in over-treatment or clinical harm. Lastly, the possibility that imaging could have a role in reducing over-treatment will be discussed.

Conclusion: It is impossible to interpret the results of imaging correctly, without knowing the clinical context. Clinicians need to understand the value and the limitations of imaging, and should not pursue a simplistic or binary approach when interpreting the results - otherwise over-diagnosis and over-treatment will be the result. To date, the evidence from RCTs in the management of RA suggest that a ‘treat-to-target’ approach should aim for clinical and not imaging remission.

The multiple rheumatological faces of PsA (or PsA is more than just poly-arthritis? – Consequences for management in daily practice)

SP0142
CASE 1 PRESENTER: A PATIENT WITH PERSISTING MONO/OLIGO-ARTHRITIS (ETHER AT START OR REMAINING AFTER TREATMENT OF POLY-ARTICULAR DISEASE)
William Tillett. Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom

Background: The varied clinical phenotypes of psoriatic arthritis present treat-ment challenges in clinical practice. The dominant phenotype represented in clini-cal trials is polyarthritis with little representation of oligoarticular or monoarticular disease.

Objectives: To review the phenotypes of psoriatic disease and treatment of resistant oligo/monoarthritis in the context of a clinical case.

Methods: Clinical case history

Conclusion: The clinical phenotype of articular disease in psoriatic arthritis can evolve over time. There is limited data to inform the treatment of resistant oligo/ monoarthritis

SP0143
CASE 1 DISCUSSANT: HOW IS TACKLING OLIGO-ARTICULAR DISEASE DIFFERENT FROM POLYARTHRITIS? CAN WE USE TRIAL RESULTS FROM POLY-ARTICULAR PSA IN A PATIENT WITH MONO/ OLIGO-ARTHRITIS?
Laura C Coates. University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: Oligoarthritis is a well recognised phenotype in psoriatic arthritis (PsA) where less than 5 joints are involved with active arthritis. In cohort studies, the proportion of patients presenting with mono/oligoarthritis varies from 20-70% depending on the timeframe studied and duration of disease. However most studies of therapeutic agents in PsA have focused on polyarthritis disease. Although the majority of studies accept a minimum of 3 active joints for inclusion, the average tender and swollen joint counts are usually over 10 at baseline.

Objectives: To review data supporting treatment of psoriatic mono/oligoarthritis including comparisons of response rates in therapeutic trials in PsA and the differential performance of outcome measures in this subtypes of disease.

Results: When considering the applicability of RCT data to mono/oligoarthritis in PsA it is important to address the populations included in these studies. Nearly all large therapeutic studies exclude monoarthritis, and while some oligoarthritis patients are eligible for inclusion in most RCTs, the demographics of the population included suggest that this is a minority. Unfortunately most clinical trials have not reported the efficacy results separately for oligoarthritis and polyarthritis patients. The other key consideration is that the outcome measures used in the majority of trials are developed and validated on patients with polyarticular PsA. Thus assessing effectiveness of therapies may be limited in the oligoarthritis population as the response measures are less sensitive to change.

Conclusion: Although data from polyarticular RCT populations is often used to choose therapies in oligoarticular PsA, there is a real paucity of data to ensure that we are treating these patients optimally. Future research is needed to address the variable prognosis seen in mono/oligoarticular PsA, to ensure that appropriate outcome measures are used to test different therapies and to provide clear evidence on the efficacy of drugs in this important subtype of disease.

CASE 2: SOLITARY ENTHESIS AS A THERAPEUTIC CHALLENGE
Philipe Carron. Ghent University Hospital, Rheumatology, Gent, Belgium

The enthesis is a site crucial for mobility of the musculoskeletal system yet it is also commonly a target of inflammation, especially in spondyloarthritis. Because the enthesis is prone to high biomechanical forces, it has been hypothesized that biomechanical forces may be implicated in the onset of the enthesis and spondyloarthritis in general. However, treatment recommendations involve exercise ther-apy which at first glance appears to pose a paradox. Using a case, we will discuss the current knowledge on enthesitis, the link with mechanical stress and the impli-cations thereof in diagnosis and management of spondyloarthritis.

Disclosure of Interests: None declared

Cannabis for arthritis: hype or hope?

SP0146
BENEFITS OF CANNABIS TO YOUR JOINTS: HYPE OR HOPE?
Serge Perrot. France, France

Cannabis-based medicines have been approved for pain management in a num-ber of countries. However, there are uncertainties and controversies about their role and the appropriate use of these medicines for the management of chronic pain, particularly in musculoskeletal conditions. These ancient drugs are now being rediscovered and considered as modern analgesic approaches in the con-text of cannabis legalization in more and more countries. The fight for cannabis legalization is frequently confused with the search for new analgesics in a medical context. Furthermore, there is a confusion between herbal cannabis, medical can-nabis and cannabinoids. Therefore, it is important to differentiate products and
situations and look beyond prejudice and misconceptions, to discover whether there are pharmacological and clinical data to support the use of medical cannabis and cannabinoids in musculoskeletal conditions and arthritis. Aside from media and social discussions, we will try to answer to the current hot question for a clinician is ‘Is it possible to recommend medical cannabis as a new anagolic option in musculoskeletal conditions?’

Disclosure of Interests: None declared

SP0147

ETHICAL ISSUES IN MEDICAL CANNABIS USE
Steve Alexander. University of Nottingham, School of Life Sciences, Nottingham, United Kingdom

Background: The human history of Cannabis is chequered. We have evidence from the Ebers papyrus of ancient Egypt (1450 BCE) that ‘sh-hm-t’ was used as a medication for what appears to have been topical inflammatory issues. In the Atharva Veda (~1500 BCE), ‘bhang’ was considered one of the five sacred plants of India. The Old Testament refers to ‘kanah-bosm’ as a component of a ceremonial anointing oil. In the UK’s Elizabethan era, Cannabis, as hemp, was grown widely for fibre to make rope and sail for the Royal Navy. In Victorian times, WB O’Shaughnessy brought back from India to the UK the medicinal use of Cannabis preparations for its reputed analgesic, anti-emic, anti-inflammatory and anti-consulant properties. In the modern era, Cannabis is a Schedule 1 drug in many countries - a legal status defined as having high abuse potential with no currently accepted medical value.

Objectives: To consider the ethical issues associated with the use of Cannabis-derived preparations for medicinal purposes.

Conclusion: Cannabis is unique among the Schedule 1 list, because extracts from the plant are licensed medicines in different parts of the world. The two most widely-researched metabolites from the plant are Δ⁹-tetrahydrocannabinol and cannabidiol (THC and CBD). The clinical uses of nabiximols (THC:CBD 1:1, combined with other minor cannabinoids) and nabiximol (a synthetic THC analogue) for multiple sclerosis and aneurism, respectively, as well as cannabinol and dronabinol ((-)-trans-THC) for childhood intractable epilepsy and cachexia, respectively, identify that Cannabis-derived medicinal products have therapeutical value.

Cannabis or THC in acute administration has a remarkably low association with mortality, however, there are a number of potential issues in the use of Cannabis itself rather than the above-mentioned extracts/compounds. Long-term heavy use of Cannabis is associated with the risk of addiction in about 10% of individuals. Severe anxiety attacks and psychotic episodes have been linked to higher doses of THC, although this has not been systematically identified. Both THC and CBD have identified metabolic profiles which might influence the turnover of other drugs.

A major feature of the use of Cannabis itself is the variability observed. In part, this derives from the natural product nature of the plant and the associated variation in the metabolites between different parts of the plant, different plants, different methods of harvesting, storage as well as method, dose and frequency of administration, the subject’s prior exposure to Cannabis and the immediate environment context. Even with the well-controlled clinical trials, there has been identified a variability in plasma levels of the administered agents. In those countries where medicinal Cannabis is more freely available, there are also concerns about patient use of black market sources.

Reproductive issues in rheumatology

SP0148

DOES PREGNANCY REALLY AMELIORATE DISEASE ACTIVITY OF WOMEN WITH CHRONIC ARTHRITIS? OLD BELIEFS VS NEW PARADIGMS
Laura Andreoli. University of Brescia, Spedali Civili of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy

Rheumatoid arthritis (RA) and Spondyloarthritis (SpA) are chronic inflammatory diseases whose onset can occur during childhood or adolescence. Juvenile Idiopathic Arthritis (JIA) can be active still during adulthood. Therefore, the disease course during pregnancy has been a topic of interest over the decades [1]. The approach towards the management of pregnancy in the rheumatic diseases has greatly changed in the last 30 years, as it became evident that active maternal disease is associated with adverse pregnancy outcomes, such as miscarriage, pre-term birth, small-for-gestational age babies. A well-controlled maternal disease during pregnancy is associated with a better pregnancy outcome: the key-point is the treatment of maternal disease with drugs which are not harmful for the fetus. To achieve this "ideal setting" is of fundamental importance to perform a preconception counselling and to maintain a tailor the management of the patient according to the patient risk stratification [2].

Historically, pregnancy has been considered to have a beneficial effect upon RA, with around 90% of women improving and up to 75% going into remission, following drug flares in puerperium in about 80% [3]. Modern prospective and serial and objective evaluations of disease activity, revealed that the validated measures of disease activity reveal less impressive ameliorative effects of pregnancy on RA [4]. A recent systematic review of prospective studies, using serial and objective evaluations of inflammatory disease, reported that RA improves in 60% of patients through pregnancy and flares in 46.7% of cases after delivery [5].

What are the possible explanations for this shift in the course of RA during pregnancy over decades? 1) methodological issues are obviously present (different study design; different patient population in terms of disease subset, duration, and severity); 2) disease activity as a "self-reported outcome" vs of validated indices [6]; 3) change in treatment strategies over time: in the '80s women with RA were likely to be treated with steroids only and probably those women with active disease despite treatment were not able to carry out a pregnancy, therefore it is possible that only patients with mild disease forms of RA were observed during pregnancy. Conversely, the current wide therapeutic armamentarium to reach disease remission also in patients with aggressive forms of RA, therefore it is likely to observe disease flares (rather than amelioration) during pregnancy if the drug is stopped at conception. Interestingly, among 75 prospectively-followed RA pregnancies, in patients treated with tumor necrosis factors inhibitors before conception, the discontinuation of the TNFI early in pregnancy resulted in increased risk for disease flares during pregnancy [7]. On the other hand, if disease is well controlled with drugs which are maintained during pregnancy, then there is little room to detect any improvement during pregnancy. Spondyloarthropathies (SpA) is a heterogeneous group of diseases and limited data are available about the disease course of different subsets (axial SpA –axSpA and Psoriatic Arthritis –PsA-) during pregnancy. Recently, prospective data from the RInFLus registry showed that the majority of women with axSpA who had stable or low disease activity from preconception period to 1 year after delivery with a small increase in the second trimester [8]. Previous studies reported that axSpA tend to be stable or to get worse [9]. Only one small retrospective work showed that the majority of women with AS displayed a decrease in disease activity during pregnancy [10]. In a recent report of 61 pregnant women with axSpA prospectively followed the discontinuation of TNFI early in pregnancy was a risk factor for flare [7]. Regarding Pa, data are scarce. The only two prospective studies demonstrated improvement during pregnancy and deterioration in the postpartum period [11, 12]. Similarly to axSpA, discontinuation of TNF1 at conception is associated with an increased number of flares during pregnancy [13].

In general, it seems that the changes in management of chronic arthritis has determined a shift in paradigm in the disease course during pregnancy. The major determinant of this change has been the growing confidence in using immunosuppressive drugs during pregnancy and breastfeeding. The increasing evidence about the safety of the majority of anti-rheumatic drugs has been recognized by many national and international working groups under the umbrella of scientific societies which endorsed guidelines and points to consider about this topic [14, 15]. Regarding biologic agents (bDMARDs), they can differ in molecular structure; however, they are all big size proteins which cannot passively diffuse and reach the fetus during the first trimester of gestation. Based on this assumption, unintended pregnancies exposed to these drugs are not a problem. As the active transport of IgG immunoglobulins across the placenta becomes significant after week 16 of gestation, it is understood that these bDMARDs which are IgG monoclonal antibodies will be transferred to the fetus. It was demonstrated that the drug concentration of monoclonal antibodies was higher in the newborn as compared to the mother, as expected for any IgG. Therefore, it is recommended to stop bDMARDs (with different timing according to their structure) in the second trimester- early third trimester in order to minimize the exposure to the drug and avoid that the new born will be immunosuppressed because of the drug received from the mother [14, 15]. Among TNFI, certolizumab pegol (CTZ) does not have the Fc portion needed for transplacental passage and so no minimal drug was detectable in the blood of neonates whose mothers received the drug until delivery [16]. Regarding breastfeeding, it is possible to consider bDMARDs as a homogenous class. They are all large proteins, which are unlikely excreted into breastmilk due to their high molecular weight. But even if they were present in breastmilk, bDMARDs will be degraded in the newborn’s digestive tract with no chance for absorption (consider that bDMARDs are administered intravenously or subcutaneously, not orally). CTZ was shown to be absent in the breastmilk and breastfed babies did not show any particular adverse event [17]. The exposure to immunosuppressive drugs, especially to bDMARDs, during late pregnancy poses the question about the immune competence of the neonate and the approach towards vaccinations. Data from large administrative US databases showed that children exposed during the third trimester to TNFI did not have an
Assisted medical procreation includes all the techniques based on the manipulation of reproductive cells that will allow infertile couples to conceive a child. Main techniques are ovulation induction with or without intrauterine insemination, controlled ovarian stimulation and in vitro fertilization (IVF). Intrauterine insemination: sperm (from partner or donor) is inserted directly into woman’s cervix, or uterus at the time of ovulation. Controlled ovarian stimulation is aimed at stimulate ovarian to allow egg retrieval few hours later. Protocols usually include gonadotropin-releasing hormone agonists or antagonists associated with recombinant follicle-stimulating hormone (with few hours later). Protocols usually include gonadotropin-releasing hormone agonists or antagonists associated with recombinant follicle-stimulating hormone (with concomitant close ovarian monitoring). Controlled ovarian stimulation is generally followed by egg retrieval and then by IVF which is performed in the laboratory by putting into contact collected oocytes with sperm (partner or donor). Intracytoplasmic sperm injection (ICSI) is performed in case of inadequate quality of the partner’s sperm (oligospermia notably). One or 2 embryos are transferred in uterus 2/3 or 5 days later (or during the next cycle), while other good quality embryos are cryopreserved for later use. There is no difference in the rates of ongoing pregnancy between transfers of frozen or fresh embryos [1].

By definition, an IVF procedure is defined by the transvaginal egg retrieval: even if the X obtained embryos are implanted Y times, this is still counted as the same procedure. A retrospective study of 14,469 women undergoing IVF, found that the cumulative live birth rates by procedure steadily increased with the number of collected oocytes, reaching 70% when ≥25 oocytes had been retrieved [2]. Women with auto-immune diseases or inflammatory chronic rheumatisms may have infertility as in the general population or because of previous gonadotoxic treatment as cyclophosphamide. While artificial inseminations and oocyte or embryo donations can be considered equivalent to a natural conception in terms of risk, particular attention is needed during IVF in women with systemic lupus erythematosus (SLE), antiphospholipid syndrome (APS) and/or biology (APS) because of the increased level of estradiol after ovarian stimulation (risk of lupus flare and of thrombosis) [3].

Ovulation induction treatments with in vitro fertilization can be safely used in patients with SLE with stable/inactive disease [4]. Similarly, women with rheuma
toid arthritis or spondyloarthritides can underwent IVF safely. In case of APS or APL, an adaptation of the treatment is usually required, especially around the egg retrieval. Management of pregnancy (both treatment and monitoring) must be planned before IVF [4].

As for a normal pregnancy, pre-counselling is important to adapt the treatment (interruption of contraindicated drugs in pregnancy as mycophenolate mofetil or methotrexate before conception due to their potential teratogenicity or at the end of the second trimester for anti TNF agents) [4]. Some treatments, especially hydroxychloroquine in SLE, have to be maintained during all this period and during pregnancy. In women with APS or APL, prophylactic dose of low weight molecular heparin (LMWH) is recommended during the period of stimulation. In case of treatment with coumadine, switch for curative LMWH is needed. In both cases, short interruption is required for the oocyte puncture. Low dose of aspirin is added after the embryo implantation. Folic supplement is recommended, especially in cases of treatment with methotrexate of current treatment with sulfasalazine. Immunizations are also important. Given its potential to reduce the miscarriage rate, LT4 supplementation is recommended for infertile women with subclinical hypothyroidism or thyroid autoimmunity who are undergoing IVF [5].

Finally, a key role of inflammatory immune response has been shown in reproductive failures but a recent meta-analysis did not find any positive effect of immunotherapy (especially anti-TNF) in improving the live birth rate in women undergoing IVF treatment [6].

SP0150 THE IMPACT OF RHEUMATIC DISEASES AND ANTI-RHEUMATIC DRUGS ON MALE FERTILITY IN ADULT AND YOUNG PEOPLE
Monika Østensen, Sorlandet Hospital Kristiansand, Rheumatology, Kristiansand, Norway

Background: The chronic, systemic inflammation in rheumatic diseases can impair male fertility by direct effects on the gonads or by affecting the hypothala-
mic-pituitary-gonadal (HPG) axis resulting in hypogonadism. Impaired gonadal function is reflected by reduced sperm quality and sometimes lowered testoster-
one levels. Drugs may impair fertility by impairing spermatogenesis or interfere with the HPG axis.

Objectives: To summarize the knowledge on the impact of rheumatic disease and its therapy on fertility in adult and pediatric patients

Methods: Search of the literature

Results: No impairment of spermatogenesis has been shown for azathioprine, cyclosporine, and mycophenolate mofetil. Risk of permanent infertility is associ-
ated with cytotoxic drugs, particularly the alkylating agent cyclophosphamide. Effects of methotrexate (MTX) on male fertility are related to dose. There is no indi-
cation that low-dose MTX 5 – 25 mg/week impairs male fertility. Case reports of men with psoriasis treated with low-dose MTX have either found completely nor-
mal sperm quality or detected oligo- and azoospermia.

Cyclophosphamide (CYC) is administered to adult and pediatric patients with sys-
temic lupus erythematosus, other connective tissue disease and vasculitides. Gonadal damage by CYC is dose-dependent revealed by oligo- and azoospermia
as well as low testosterone, low inhibin B and elevated FSH levels. Cumulative doses of > 7.5 g/m² carry a high risk of permanent infertility in adults. In survivors of childhood cancer treated with CYC recovery of spermatogenesis was sometimes seen after many years. Sulfasalazine (SZ) can induce transient infertility with oligospermia, abnormal morphology of sperm cells and reduced sperm motility in about 40-86% of treated men. Plasma levels of steroids and gonadotropins remain normal during SZ therapy. Recovery of normal sperm quality is observed one to three months after discontinuation of SZ.

Studies comparing men treated with TNF inhibitors (TNFi) with disease-matched and/or healthy controls did not find impairment of sperm quality neither after short term or long-term treatment. Several studies found significantly better sperm quality in patients receiving long-term TNFi therapy than untreated disease matched controls.

Conclusion: Rheumatic disease has an impact on male fertility both by the disease process and by therapy. Most antirheumatic drugs have no negative effect on reproduction, however, treatment with cyclophosphamide increases the risk of infertility both in adults and pediatric patients. Increasing awareness about reproduction issues and infertility risk is needed among adult and pediatric rheumatologists. Clinicians should actively involve themselves in counseling their patients.

The future of therapeutic strategies

SP0151 MICROFABRICATION TECHNOLOGIES FOR CARTILAGE REPAIR
Marcel Karperien. Technical Medical Centre University of Twente, Developmental BioEngineering, 7522 NB, Netherlands

Background: Cartilage trauma is a major risk factor for the development of post-traumatic osteoarthritis. Treatment options are limited, are ineffective in the long run or come with disadvantages. Hence unconventional new strategies need to be explored to address this problem.

Objectives: In this lecture, I will present three strategies that are currently explored in my lab and that rely on the integration of biology with micro- and nano-technologies to solve this problem.

Results and Methods: In a first strategy, we invested in the development of injectable and in situ gelating hydrogels that can be used as fillers of a cartilage defect stimulating its regeneration. We developed a panel of natural polymer (e.g. hyaluronic acid, dextran, heparin, gelatin, collagen) – tyramine conjugates which crosslink in a macromolecular network in an enzymatic reaction. The reaction is fast, can be tuned and using this method a wide variety of extracellular matrix mimics can be engineered. Moreover, the crosslinking reaction fixes the gel in the surrounding tissue through covalent bonding between tyramine residues in the hydrogel with lysine residues in extracellular matrix proteins, effectively acting as a glue. The hydrogel can be applied during an arthroscopic procedure. We tested the potential of the hydrogel to facilitate the repair of an acute focal cartilage defect in an equine chondral defect model and evaluated the repair process after 2 weeks, 3 months and 7 months. We compared the repair of a hydrogel-filled defect with the microfabrication procedure, a frequently used but largely ineffective procedure due to the formation of fibrous cartilage instead of hyaline cartilage. After two weeks massive cell ingrowth in the hydrogel was observed. This continued and after 3 months hydrogel treated defects resulted in near complete defect filling with predominantly hyaline cartilage and without noticeable reactions in the subchondral bone. This was in marked contrast to the defects treated with microfabrication, which showed a massive response in subchondral bone and the formation of fibrous tissue. The repair was consolidated after 7 months. Defect filling might be a viable solution for treatment of focal cartilage defects to prevent early onset, post-traumatic osteoarthritis.

In a second strategy, we use the same material platform for cell delivery in the joint. Co-injection of cells with the in situ gelating hydrogels might be beneficial in the repair of particularly large (osteochondral) defects. We have developed microfluidic-based systems for the encapsulation of 10-15 cells in microgels of approximately 100 µm or even at the single cell level in microgels with a diameter of 30 µm slightly larger than the cell itself. We postulated that encapsulation of Mesenchymal Stromal Cells (MSCs) could prolong the retention time in the joint after an intra-articular injection over “naked” MSCs and may, therefore, improve the therapeutic benefit of these cells. We tested this hypothesis in a rat model and indeed showed that, while “naked” near infrared labeled MSC rapidly disappeared from the injected joint, encapsulated cells remained present up to 4 months. We are currently exploring its potential to improve the therapeutic efficacy of the MSCs.

In a third strategy, we use the material platform in combination with cytokine neutralizing antibodies to generate easily injectable microgels that can sequester pro-inflammatory cytokines from the synovial fluid. Rather than using conventional antibodies, we rely on the variable domain of single chain, heavy chain-only antibodies, which can effectively neutralize cytokines in cell assays in vitro and are currently explored for its potential to neutralize cytokines in synovial fluid and after intra-articular injection.

Conclusion: In conclusion, the integration of biology with microfabrication technologies has the potential to generate the next generation of therapies for the treatment of cartilage defects and osteoarthritis.

Disclosure of Interests: None declared

SP0152 3D PRINTED DRUGS
Matthew Peake, Alder Hey Children’s Foundation NHS Trust, Paediatric Medicines Research Unit, Liverpool, United Kingdom

Background: With the advent of personalised medicine, the need for flexible dosing is increasingly important. Conventional pharmaceutical manufacturing processes can be constrained in their ability to offer flexible dosing options to meet patient need. This is particularly important in specific populations, for example children, where available formulations are frequently not age-appropriate and need to be modified to achieve an intended dose. 3D-printing of solid dosage forms offers a disruptive technology which enables solid dosage forms to be manufactured at flexible, precise doses meeting the needs of individual patients. This technology has relevance for manufacture of existing active pharmaceutical ingredients for a range of conditions including inflammatory diseases.

Objectives: To develop 3D-printed oral solid dosage forms of medicines which are age-appropriate for children and young people. To determine the acceptability of 3D-printed medicines to children and young people by conducting intervention studies of tablet administration.

Methods: Tablets containing a range of active pharmaceutical ingredients (API) were produced using two stages: (i) hot melt extrusion of a filament containing API and excipients; (ii) 3D printing of the filament using fused deposition modelling (FDM) to produce the desired shape in a layer-by-layer pattern. Acceptability of 3D-printed tablets to children and young people (CYP) aged 4-12 years was assessed by the swallowability and mouthfeel following administration of different size 3D-printed placebo tablets.

Results: Using hydrocortisone as an exemplar API, Tablets were successfully produced by the FDM 3D printing process. Thermal analysis indicated that HC remained stable below 160°C and the tablets had very high mechanical strength with friability of 0%. This illustrates the ability of the printer to produce a ready-to-use tablet without the need for a drying or finishing step. The disintegration took 9.2–14 min confirming immediate release properties. We administered for the first time globally an ingestible 3D-printed tablet to a child. CYP were able to swallow and ingest 3D-printed bi-convex tablets of either 6mm, 8mm or 10mm diameter. The 3D tablets were reported by CYP to have a slightly more discernible mouthfeel than placebo tablets of the same size manufactured in a GMP facility.

Conclusion: FDM 3D printing offers a disruptive technology for the manufacture of solid dosage forms of medicines of flexible doses with excellent dose precision and pharmaceutical properties. In circumstances where modification of existing dosage forms is hydrogel based, this offers an alternative reliable means of achieving the intended dose. This technology is also suited to the manufacture of solid dosage forms of small molecules which may be particularly important in the treatment of inflammatory diseases.

Disclosure of Interests: None declared
Calming the cytokine storm in children and adults

Jan van Laar, Erasmus MC, University Medical Center Rotterdam, Internal Medicine, Division of Clinical Immunology, Netherlands

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare and often overlooked clinical manifestation of an aberrant hyperinflammatory immune response leading to a fatal cytokine storm(1). Diagnostic criteria according to The HLH Study Group of the Histiocyte Society include fever, splenomegaly, bicytopenia, hypertriglyceridemia and/or hypofibrinogenemia, hyperferritinemia, low/absent NK activity, increased soluble CD-25 levels and hemophagocytosis(2). Prompt recognition and differentiation from severe sepsis is essential to improve the outcome. HLH reflects a disbalanced immune system in response to infectious, malignancy, or autoinflammatory/autoimmune mediated triggers(1). The latter group of patients are regarded as having Macrophage Activation Syndrome (MAS-HLH)(4). In adults MAS-HLH comprises 12.5% of all HLH causing triggers(4).

The most frequent immunological disorders associated with adult HLH-MAS are systemic lupus erythematosus and adult onset Still’s disease, but every other immunological disorder can be involved(4,5).

Treatment: Treatment of adults HLH patients requires swift recognition and an experienced team of specialists that are acquainted with the critical factors influencing the balance between co-morbidity, cytokine storm induced septic-like symptoms and toxicity of chemo-immunotherapy(6). In general, adult patients do not tolerate doses of etoposide that are given in HLH-94 based chemo-immuno-therapy schedules that have been shown effective in children(7,8). Dose and frequency modifications of etoposide may avoid prolonged neutropenia, infectious complications or hepatic toxicity. The same precautions account for adults patients with MAS-HLH in which treatment differs from the HLH schedules. A step-down approach depending on clinical features and severity is warranted(9, 10). High doses of corticosteroids are recognized as first-line treatment(9, 10). In patients with MAS-HLH and SLE steroids, cyclophosphamide or etoposide are given(10). Cyclosporine can be added in patients with insufficient immediate response(9).

The cytokine blocking agent anakinra (anti-IL-1B) given in high doses is emerging as an alternative or additional treatment of adult MAS-HLH(11, 12, 13). Another promising cytokine blocker is anti-IL-6 (tocilizumab). Etoposide at a reduced dose can be initiated in patients with severe non-responsive and active disease or CNS-involvement(10).

Conclusion: Awareness of the clinical emergency MAS-HLH in patients with autoinflammatory/autoimmune mediated disorders is essential for timely recognition and potential life-saving treatment. The management of MASH-HLH in adults requires a team of dedicated specialists with experience in the treatment of critically ill patients with immunological disorders and anticipation on its rapidly changing and deteriorating nature.

Know your methods! Interactive discussion

Romualdo Ramos, University Medical Center Utrecht, Netherlands

Qualitative research plays a pivotal role in clinical practice by providing insights from the patient’s perspective. This becomes all the more relevant, as we move into the era of patient-centered care. In this presentation, we shed light on the different approaches to quantitative data collection and analysis, as well as systematic literature reviews of qualitative research. We will also elaborate on how qualitative research methods are used to better understand which outcomes are relevant to patients, self-management of symptoms, non-adherence to medication and non-pharmacological methods, the doctor-patient relationship, and to evaluate policy and interventions within the realm of RMDs. Finally, in an open panel, we will discuss how qualitative and quantitative methods triangulate, contributing to mixed methods approaches.

MISSING DATA: IS IT ALL THE SAME?

Sven Lydersen, Norwegian University of Science and Technology, Department of mental health, Trondheim, Norway

Introduction: In most studies, there are “holes” in the data set, such that data are missing partly or completely for some of the subjects. This results in reduced statistical power. More seriously, missing data may cause biased results, since data are usually not missing completely at random.

Missing data mechanisms: In which way, and to what extent, does the probability that data are missing, depend on observed and/or unobserved data values? This is called the missing data mechanism, and is important for an appropriate choice of analysis method. Three types of missing data mechanisms have been defined, see for example (Sterne et al. 2009).

MCAR: Missing completely at random. There are no systematic differences between the missing values and the observed values. The probability that values are missing does not depend on any of the data, observed or unobserved.

MAR: Missing at random. The probability that values are missing may depend on observed data values, but not on unobserved data values. For example, some variables are missing more frequently for patients with higher age. Data are missing at random conditionally on observed data.

MNAR: Missing not at random.

Even after the observed data are taken into account, systematic differences remain between the missing values and the observed values: The probability that values are missing depends on unobserved data values as well.

It is possible to distinguish between MCAR and MAR by inspecting the data at hand. But it is never possible to determine whether data are MNAR from your data.

Methods for handling missing data

Some commonly used methods, from the less to the more complex ones, are listed below, with an indication of when they give unbiased estimates:

- Complete case analysis (disregarding cases with partially missing data) (MCAR)
- Single imputation methods (sometimes under MAR but underestimates uncertainty)
- Multiple imputation (MAR)
- Full information maximum likelihood (MAR)
- Linear mixed models in longitudinal studies (MAR)

In longitudinal studies, Last observation carried forward (LOCF) is a simple method for imputing missing values. But it is not unbiased under any sensible assumptions, and should not be used (Lydersen 2019).

Reporting: In general, report the amount of missing data in the different variables, and how this was handled in the analysis. This is recommended in the Consort Guidelines (Moher et al. 2010) as well as the STROBE Statement (STROBE 2014), see also (Lydersen 2015)

Disclosure of Interests: None declared

DOUGADOS Maxime.

The recently proposed sophisticated statistical methods to impute missing data are very attractive. For the clinical researchers in charge of data collection, it might be tempting to “neglect” the quality of data collection in favor of the time spent by one database manager/statistician to impute missing data. This presentation will be a plea in favor to make all the possible efforts to collect appropriately the data in clinical research studies/trials. In particular, emphasis will be placed on the importance of writing a specific section in any research protocol describing the technics used to avoid these missing data and also the a priori decided technic that will be used to manage the missing data. One point of importance in this section: to specify in advance the maximum percentage of missing data over which no imputation can be made.

Two different situations:
- Cross-sectional studies. Any item (for example HLA B27, MRI SIJ inflammation positivity) should be considered as mandatory or not before running the study.
- Longitudinal studies: any longitudinal protocol should include a section detailing the technic to appropriately follow the patients in order to avoid the “lost of follow-up patients”. This is particularly important in longitudinal follow-up of patients suffering from a recent onset disease (e.g. early synovitis cohorts, early inflammatory back pain cohorts) since it is well known that the “lost of follow-up” have specific baseline characteristics suggesting a less severe disease. It is also important to decrease at a minimum level the “lost of follow-up” patients participating at a therapeutical trial/registry since the reason of “lost of follow-up” might be related to a specific drug-effect.

Don’t panic – round table discussion on risk perception

SP0159 WHAT DO WE KNOW – WHAT SHALL WE DO – WHAT DO WE TELL

Timothy R. Radstake, University Medical Center Utrecht, Netherlands

There is an increasing need for patients to be involved in research as well as matters that can influence their own clinical journey. One aspect of science that links optimal clinical care is the increased use of biomarkers for so-called personalized medicine approaches.
In my presentation I will showcase the State of the Art technologies of biomarker research and how the information that comes from this can be implemented for improving clinical care. I will discuss the revolution of molecular profiling and how the large amount of data coming from these approaches is used to molecularly classify patients into molecular fingerprints. How this technology leads to a disruptive change in medicine for the coming 5-10 years. I will close of with the role of biomarkers in the treatment of diseases, trial design and drug development for the coming 5 years.

DISEASE REMISSION: DO WE AIM FOR THE SAME THING?

Ricardo Ferreira. Centro Hospitalar e Universitário de Coimbra, EPE, Rheumatology, Coimbra, Portugal

It is consensually accepted that the most important therapeutic goals for treating rheumatoid arthritis (as well as other inflammatory arthritis) are eliminating signs and symptoms (such as joint pain, swelling, and stiffness); preventing joint damage or its progression; and maximizing physical function and quality of life (Aletha & Smolen, 2019). According to current medical knowledge, these aims are believed to be best accomplished by achieving disease remission, a state in which no or only minimal residual inflammation is discernible (Aletha & Smolen, 2019). However, different studies have been providing evidence that achieving inflammatory remission is not enough as a considerable proportion of patients with no or minimal inflammation remain with high levels of pain, fatigue, functional impairment, mental health problems, among other symptoms (Boone et al., 2019; Ferreira et al., 2019; Ferreira et al., 2017). The perfect path to achieve good results is still to be defined, namely, regarding the T2T strategy (van Vollenhoven, 2019). Recent studies still show that despite a high level of patient agreement with RA T2T, patient engagement in this process needs to be improved in order to individualize therapy adjustments, make shared decisions and decide on targets that accurately reflect disease control according to patients (Benham et al., 2019).

In this session I would address the following questions:

- Is aiming for one target enough nowadays?
- Do health professionals and patients aim for the same thing when defining treatment strategies?
- Do the current treatment targets pose a risk of overtreatment with immunosuppressive therapy?

This presentation is informed by current research in this area including research from our own group (Ferreira et al., 2018; Santos et al., 2018).

LOOKING FOR A NEEDLE IN A HAYSTACK: HELPING YOUNG PEOPLE TO MAKE SENSE OF EVIDENCE BASED HEALTH CARE

Simon Stones. University of Leeds, School of Healthcare, Leeds, United Kingdom

While it has been suggested that there are no differences in the occurrence of risk-taking behaviours in young people with chronic conditions compared with healthy peers, young people with chronic conditions often face the dilemma of balancing twice the amount of risk to that of other young people, owing to their condition and treatment. For example, young people with juvenile idiopathic arthritis taking methotrexate face the risks of alcohol consumption plus the increased risk of toxicity from consuming alcohol while taking methotrexate. However, such issues are often ignored or overlooked (1). Research has suggested that a lack of experience with, and not worrying about serious health consequences may desensitise young people with chronic conditions to potential health risks (2). It is also recognised that young people’s perceived focus of health and wellbeing can often be on short-term goals; which is often paradoxical to the focus of families and healthcare professionals thinking about longer-term outcomes and prognosis.

It has been demonstrated that young people with chronic conditions value interventions that enable them to live a “normal” life – extending beyond the clinical management of their condition (3). The emotional, social, and vocational consequences of condition management can be profound (4). When this is coupled with the challenges of accessing accurate, trusted and individualised information and support, it can often leave young people and their families feeling as though they are looking for a “needle in a haystack”. Finding the best evidence requires knowledge of the best quality and most appropriate sources, as well as the ability to use and navigate such resources appropriately (5). In an era where health information is easier and faster to find than ever before, it is often a challenge for young people to be able to filter the ‘good’ from the ‘not so good’. There are significant amounts of unreliable and irrelevant content on the internet, which ultimately places the responsibility for interpretation of information and advice onto young people and their families.

Therefore, age- and developmentally- appropriate opportunities to discuss health, wellbeing and the effects of treatment need to be provided early and regularly, across the lifespan, in multiple formats to suit individual needs and circumstances. Attempts have already been made to make health information more accessible, for example, with the introduction of the Accessible Information Standard within the National Health Service (6). However, this is not necessarily enough to engage and support young people with chronic conditions in making sense of evidence-based healthcare. Information needs to be taken, in the right formats, to where young people are interacting, such as on certain social media platforms. This needs to be multifaceted, using peer- and community-driven approaches to enhance engagement. Furthermore, periodic consideration of the long-term risks and benefits of health and wellbeing interventions needs to happen across the life-course, both as a prompt for young people to air their concerns, but to also check their understanding. Only through understanding young people’s values, preferences, and concerns can a sustainable balance between condition control, treatment burden and quality of life be achieved.

Remission – the holy grail? Looking across diseases

**SP0162 REMISSION IN RA: DOES THE DEFINITION MATTER?**
Daniel Aletaha, Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Austria

Remission is the ultimate target for chronic inflammatory rheumatic disease, and so also for rheumatoid arthritis (RA). In this presentation, we will review the challenges in defining and assessing remission. Further, we will discuss if remission should be a clinical target, or whether imaging results, e.g. from ultrasound or MRI examinations, should be included in the concept of remission. Many symptoms in patients with RA may mimic RA disease activity, while they are not directly a consequence of the disease process, with secondary pain syndromes being a typical example. Finally, patients are the most important stakeholders on the question of whether or not a musculoskeletal disease is in remission. Patient reported outcomes have been criticized for their subjectivity and their role in remission indices has been questioned. We will also explore the influence and Pro’s and Con’s of these measures on remission assessment.

**Disclosure of Interests:** Daniel Aletaha Grant/research support from: AbbVie, Bristol-Myers Squibb, and MSD, Consultant for: AbbVie, Bristol-Myers Squibb, Eli Lilly, Janssen, Medac, Merck, MSD, Pfizer Inc, Roche, and UCB, Speakers bureau: AbbVie, Bristol-Myers Squibb, Eli Lilly, Janssen, Medac, Merck, MSD, Pfizer Inc, Roche, and UCB

**SP0163 REMISSION IN SLE: WHAT TO AIM FOR?**
Marta Mosca, Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

It is generally acknowledged that, in SLE, disease activity is associated with poor prognosis, high glucocorticoid use, damage development and increased mortality; therefore reaching low level of disease activity or remission are main treatment targets for SLE.

Definitions for disease remission and low disease activity are being proposed and validated as meaningful targets to be pursued in SLE management. In detail an international task force has recently developed a definition of remission in SLE (DORIS) taking in consideration four different domains: clinical activity, serological activity, treatment and duration. This approach led to the development of different levels of remission i.e. clinical remission off/on treatment and complete remission off/on treatment. Recently data from different cohorts have been published, showing that remission is an achievable target in SLE. Achieving remission appears associated with reduced damage accrual, however persistence in remission is rare being maintained in an average of 7% of patients over 5 years. In addition, the more stringent is the definition, the more difficult is to achieve remission and a longer time to remission is observed in patients with high activity, high therapy, hematological activity, African-American ethnicity.

Low disease activity may represent another target in SLE treatment and a definition of (lupus low disease activity state (LLDAS) has been developed by Franklyn et al. LLDAS is defined based on three domains which are SLEDAI-2k, 4. physician global assessment (PGA) 1. absence of new manifestations and stable and well tolerated treatment with a prednisolone (or equivalent) dose of 7.5 mg/day.

Interestingly, LLDAS is achieved by a high percentage of patients over follow up, ranging between 33 and 86% in different cohorts and it is maintained over follow up in up to 50% of patients for 50% of follow up time. Predictive factors for LLDAS attainment are shorter disease duration, lower disease activity score, lower mean PGA, lower mean SLEDAI, older age; while persistent LLDAS is less frequent in patients with vasculitis, neurological, renal, cardiopulmonary and mucocutaneous manifestations.

Achievement and persistence of LLDAS are associated with lower prednisone dose during follow up, reduction of disease flares, lower damage accrual, better quality of life.

In conclusion, definitions of remission and low disease activity in SLE have been proposed and validated against outcomes such as glucocorticoids usage, damage accrual, quality of life. Both targets are associated with improved outcomes, however at present persistence in remission is not common. The achievement of LLDAS is not rare, persistence in LLDAS is achievable.

Ultrasound advanced II

SP0166  ULTRASOUND OF THE HAMSTRING MUSCLE COMPLEX-CLINICAL APPLICATION + DEMO

David Andrew Bong, Instituto Poal de Reumatologia, Universitat de Barcelona, Rheumatology, Anatomy, Barcelona, Spain

The hamstring muscle complex (HMC) are the "brakes" of human bipedal ambulation and are susceptible to injury during concentric contraction. Although common in sports medicine practice, a recent systematic review of severe hamstring injuries (grade II-III) suggests that greater than 10% of these severe injuries are non-injuries related and disproportionately affect older women. Musculoskeletal ultrasound (MSKUS) is one of the basic imaging techniques utilized to detect and define these injuries and eliminate other potential causes of posterior thigh pain. This presentation will discuss the clinical application of MSKUS of the HMC in rheumatology/musculoskeletal medicine and offer a systematic anatomically-based method of examining this important non-articular region.

US FOR ASSESSING LUNG INVOLVEMENT IN RHEUMATIC DISEASES – CLINICAL USE + DEMO

SP0167  US FOR ASSESSING LUNG INVOLVEMENT IN RHEUMATIC DISEASES – CLINICAL USE + DEMO

Andrea Delle Sedie, University of Pisa, Rheumatology Unit, Pisa, Italy

Background: Evaluation of interstitial lung disease (ILD) is always difficult due to poor correlation of X-ray and pulmonary function tests. HRCT: ultrasound (US) has recently shown interesting results on truth, discrimination and feasibility. Due to the thickening of interlobular septa for edema or fibrosis, US beam can interact with those structure and produce artifacts on the screen.

B-lines (BL) and pleural line irregularity (PLI). A positive correlation between BL and HRCT has been established both in systemic sclerosis patients and in other patients with ILD; more recently similar results have been published by using PLI as a finding for US assessment in patients.

Conclusion: US lung evaluation is a useful and feasible imaging technique.

Complement and autoimmunity – emerging therapeutic opportunities

SP0169  COMPLEMENT AND LUPUS IN THE YOUNG AND THE OLD

Marina Botto, Imperial College London, Centre for Inflammatory Disease/Immunology and Inflammation, London, United Kingdom

Complement component C1q is known to play an important recognition role in adaptive and innate immunity. More recently evidence has emerged that C1q may have roles outside the complement system and the relevance of these functions may change with ageing. Homozygous deficiency of the first component of the complement system, C1q, is one of the most powerful susceptibility genetic factors for the development of systemic lupus erythematosus (SLE). The vast majority of patients with C1q deficiency develop a syndrome closely related to SLE. The disease is typically of early onset and is often very severe. Although the phenotype of disease varies between patients, the fact that C1q deficiency is sufficient to cause SLE in almost all humans identifies a pivotal role for this molecule. The challenge is to identify the relevant physiological activity that can explain this strong association.

On the other hand, C1q seems to play a different role in old people. The concentration of C1q rises with ageing and can be modulated by exercises. Of note, increased levels of C1q have been reported in the central nervous system of old people, with the highest levels being seen in close proximity to synapses and central regions of the brains suggesting that C1q may play a role in the development of problems associated with aging. Consistent with this hypothesis aged C1q-deficient mice showed less cognitive and memory decline in hippocampus-dependent behaviour tests compared to their wild-type litter mates.

In summary, the traditional view of the role of C1q as just initiator of the classical complement pathway needs revision. Evidence is emerging that C1q has roles outside the complement system and these will be discussed.

Disclosure of Interests: None declared

IS COMPLEMENT A CRITICAL INGREDIENT IN THE DEVELOPMENT OF RA?

SP0170  IS COMPLEMENT A CRITICAL INGREDIENT IN THE DEVELOPMENT OF RA?

V. Michael Holers, University of Colorado Denver, Rheumatology, Aurora, CO, United States of America

Background: Prior studies of patients with classified rheumatoid arthritis (RA) have demonstrated in synovial fluid, on cartilage surfaces and in the synovium the presence of pro-inflammatory complement activation fragments C3a and C5a, the membrane attack complex (MAC), and C3 fragment-bound immune complexes.

Ex vivo studies of RA-related autoantibodies have shown the capacity to activate complement pathways, and also demonstrated the presence of disease-
associated changes in antibody glycosylation that promote engagement of the complement system. In contrast, clinical trials in patients with classified RA utilizing inhibitors of complement C5 have demonstrated minimal improvement. Nevertheless, recent translational research studies of patients during the natural history of RA have opened up new avenues for therapeutic intervention. Specifically, there exists in seropositive RA a prolonged asymptomatic preclinical stage wherein mucosal autoantibody production in the lung is associated with NETosis, elevated cytokines and evidence of activated innate immunity, with the capacity of each to interact and promote localized inflammation. Beyond this, murine studies have strongly suggested that complement C3d generation promotes autimmune and therapeutic pathway inhibitory strategies should encompass all of the effector mechanisms and not just those at C5 and beyond.

Objectives: The presentation objective is to explore the evidence for involvement of the complement system in the preclinical development of RA, and what mechanisms may be involved to promote autoimmunity and ultimate joint damage.

Methods: The presentation will review studies of the natural history of human RA, with an emphasis on the potential roles for complement in multiple stages of disease. In addition, the presentation will review informative murine studies which have explored the mechanisms by which the complement system can modulate the development of experimental autoimmune arthritis will be summarized.

Results: Studies of preclinical RA in subjects have suggested the potential for complement and NETs to interact and promote seromucosal inflammation in the lung. In addition, murine studies of the roles of complement have supported that all components of the pathway, including C3d linked to antigens, the anaphylatoxins C5a and C3a, as well as the MAC, are centrally involved in promoting arthritis.

Conclusion: Complement likely plays a role in multiple phases of RA development, including: 1) mucosal inflammation and the break in systemic tolerance to citrullinated antigens, 2) initial inflammation following targeting of ACPA to the synovium and 3) activation of RA-related autoantibody production. In addition, it is likely that inhibition of C3 and C5 convertases in tandem will be necessary to see major clinical effects in patients with active synovitis. Finally, the use of a complement inhibitor or modulator in the pre-clinical, transitioning and/or early RA populations are all intriguing approaches.

REFERENCE:

SP0171 THE NEW COMPLEMENT THERAPEUTICS
Claire Harris, Newcastle University, School of Medicine, Newcastle-upon-Tyne, United Kingdom

Despite a wealth of knowledge in the complexities of the complement cascade, and many decades of endeavour, very few drugs have progressed to the clinic. Recently, strong genetic associations of complement with common diseases have emerged and fuelled the fire of complement drug discovery leading to an explosion in complement therapies in development; while many of these agents and others before them have failed to progress, their legacy is key to future success. Obstacles to successful drug development include target concentration and turnover rates, and ability to target to the appropriate site. The drug development landscape is littered with agents that have failed at the preclinical or early clinical stage; their modes of action and modalities are wide-ranging. It is becoming clear that engagement of complement C3 and C5 convertases in tandem will be necessary to see major clinical effects in patients with active synovitis. Finally, the use of a complement inhibitor or modulator in the pre-clinical, transitioning and/or early RA populations are all intriguing approaches.

SP0172 CASE 2 PRESENTER: ALWAYS AT THE EDGE: SEVERE GI COMPLICATIONS
Kristina Clark, University College London, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom

Gastrointestinal tract involvement is almost universal in systemic sclerosis but in most patients is relatively mild with symptoms of gastro-oesophageal dysmotility and reflux or lower bowel symptoms of constipation. A minority of cases have severe involvement, and this can be life-threatening. The key issues related to severe disease are attacks of pseudo-obstruction with complications such as pneumonia, or perforation of infection. Additional issues include malnutrition and intestinal failure that may require long-term home parenteral supplementation. Finally, the most severe lower tract involvement can result in intractable diarrhoea, persistent anorectal incompetence and complications of severe chronic constipation such as sigmoid volvulus. Management is challenging and requires interaction with gastroenterology and nutrition expert colleagues. Some newer approaches that have been beneficial include long term intravenous immunoglobulin therapy although in general response to immunosuppression are relatively modest. This discussion will focus on treatment with immunomodulation and use of antibiotic therapy to treat small intestinal bacterial overgrowth and also to manage other infectious problems and the potential impact on intestinal dysbiosis.

Disclosure of Interests: Christopher Denton Grant/research support from: GlaxoSmithKline, Inventiva, CSF Behring, Consultant for: Roche Genetech, Actelion, GlaxoSmithKline, Sanofi Aventis, Inventiva, CSL Behring, Boehringer Ingelheim, Bayer DOI: 10.1136/annrheumdis-2019-eular.8459

SP0173 CASE 2 DISCUSSANT: IMMUNOSUPPRESSION OR ANTIBIOTICS – WHEN TO CHOOSE WHAT?
Christopher Denton, Royal Free Campus, x, x, United Kingdom

The clinical impact of lower gastrointestinal tract involvement in systemic sclerosis will be illustrated through a case presentation. This will describe the challenges of managing patients with systemic sclerosis presenting with pseudo-obstruction, severe malnutrition, and electrolyte imbalance and how these were managed to optimise patient care.

SP0174 ADVANCES IN THE DETECTION OF PATHOGENIC AUTOANTIBODIES IN SLE
Luis Munoz, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Internal Medicine 3, Erlangen, Germany

Background: The accumulation of late apoptotic or so-called Secondary Necrotic Cells (SNEC) in germinal centers challenges B and T cell tolerance and leads to the development of autoimmunity and the production of autoantibodies.

Objectives: Determine the test performance of immobilized SNEC autoantigens for the diagnosis of Systemic Lupus Erythematosus.

Methods: SNEC ELISA of sera from patients with SLE and test performance statistics were deployed to evaluate the diagnostic potential SNEC-derived autoantibodies. Functional assays confirmed its pathophysiological relevance.

Results: SNEC contains nuclear autoantigens bearing apoptosis-associated modifications such as histone H3 and histone H4AcK8,12,16, and histone H2B-AcK12. The SNEC ELISA clearly discriminated patients with SLE from patients with Rheumatoid Arthritis (RA), Primary Anti-Phospholipid Syndrome (PAPS), Spondyloarthropathy (SpA), Psoriatic Arthritis (PsA), and Systemic Sclerosis (SSc). A positive test result in SNEC ELISA significantly correlated with...
serological variables and reflected the uptake of opsonized SNEC by neutrophils in the blood.

**Conclusion:** SNEC ELISA allows for the sensitive detection of pathologically relevant autoantibodies in the serum of patients with SLE. The clearance of nuclear remnants by neutrophils enhances inflammatory responses supporting the role of clearance deficiency in the etiopathogenesis of SLE.

**SP0175 POST-TRANSLATIONAL MODIFICATIONS OF ANTIBODIES: WHERE THERE’S SMOKE THERE’S FIRE**

Rene Toes, Leiden University Medical Center, Rheumatology, Leiden, Netherlands

Rheumatoid arthritis (RA) is a prototype autoimmune disease, with the hallmark signs of synovial inflammation and the presence of autoantibodies. One of the most prominent examples of such autoantibodies are anti-citrullinated protein antibodies (ACPA), which are directed against a wide-array of citrullinated proteins. The immune response to citrullinated antigens is a dynamic response that expands before the onset of disease and generates antibodies that are extensively glycosylated in the variable domain. This feature of ACPAs is remarkable and might be involved in the breach of tolerance to citrullinated proteins as well as function as an additional biomarker to predict disease onset in subjects at risk.

Next to ACPA, it has become clear that the autoantibody response in RA extends to other proteins. For example, antibodies against citrullinated beta2-glycoprotein I (anti-DI-beta2GPI) are also frequently present in triple aPL positive patients. Nevertheless, it is far too soon to recommend replacement of anti-DI-beta2GPI testing with an anti-DI-beta2GPI antibody assay because it was shown that about 30% of patients with anti-DI-beta2GPI antibodies are negative for anti-DI-beta2GPI antibodies (8). The clinical significance of autoantibodies reacting with epitopes other than DI was also investigated in multicenter study (9).

**SP0176 PATHOGENIC ANTIBODIES IN PHOSPHOLIPID SYNDROM**

Sasa Curnik, University Medical Center Ljubljana, Department of Rheumatology, Immunology Laboratory, Ljubljana, Slovenia

Antiphospholipid syndrome (APS) is a thrombotic systemic autoimmune disorder characterized with multisystem manifestation, most commonly venous and arterial thromboembolism and/or recurrent pregnancy loss. The varying clinical phenotype is associated with heterogeneity in the pathogenic antiphospholipid antibodies (aPL). These antibodies may be useful as risk stratification for clinical events. aPS/PT antibodies also represent strong risk factor for thrombosis. Results of multicenter study demonstrated that IgG aPS/PT detection might contribute to a better and more reliable identification of APS patients (10).

Due to the heterogeneity of aPL (criteria and non-criteria) the interpretation of aPL results is a challenge in daily routine practice and should always be related to clinical symptoms and therefore, interaction between the laboratory and clinician is essential.

**Lessons learned from checkpoint inhibitors**

**SP0177 IMPACT OF CHECKPOINT INHIBITORS ON B CELLS**

**David Peatley,** Duke University Medical Center, Medicine/Immunology, Durham, North Carolina, United States of America

Immune checkpoint inhibitors (ICI) are a new class of biological agents that has revolutionized the treatment of cancer. Unlike conventional cytotoxic agents that
are designed to kill cells, ICI block interactions that regulate the T cell response to cancer. At present, two classes of ICI are available to treat a wide variety of malignancies: antibodies to cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) and antibodies directed to the programmed death-1 (PD-1) and PD-1 ligand (PD-L1) axis, either to PD-1 or PD-L1. While both anti-CTLA-4 and antibodies to PD-1/PD-L1 are effective, these systems differ in the T cell populations affected, the location of these cells and the downstream signaling pathways involved. ICI can be used alone or in combination. Despite differences in mechanism of action, treatment with both types of ICI is associated with severe side effects that have been termed immune-related adverse reactions (irAE). irAE include, among other manifestations, dermatitis, colitis, pneumonitis, endocrinopathy (hypothyroidism, hypophysitis, adrenal insufficiency) and arthritis and related conditions. Because of the goal of ICI therapy is the induction or stimulation of cytotoxic T cells, the effect of these agents on B cells has received much less attention. In general, effects of ICI on tumors are considered the action of T cells. irAE, however, may result from B cell effects and the induction of autoantibodies. Thus, autoantibodies to thyroid antigens may lead to thyroiditis and subsequent hypothyroidism. Similarly, ICI can lead to the production of antibodies to islet antigens as well as glutamic acid decarboxylase 65 and induction of diabetes. On the other hand, while arthritis can be an irAE, affected patients usually do not show antibodies to citrullinated proteins (ACPA). Importantly, functional and phenotypic properties of B cells following ICI can help predict the emergence of urticaria. Moreover, changes of these cells and from a detailed analysis of patients with melanoma treated with anti-CTLA-4, anti-PD-1 or the combination. With this combination, B cells of treated patients showed characteristic changes that include a decrease in the number of circulating B cells in conjunction with an increase in plasmablasts and a population of B cells characterized by low expression of CD21. Furthermore, in treated patients, the CD21lo B cell population showed greater clonality as well as a higher frequency of clones in comparison to the CD21hi population. These changes, which can resemble those seen in patients who have unresponsive for CTLA-4, may predict the development of irAE. The CD21lo B cell population may have a particular role in the development of irAE since these cells appear to be recent emigrants from germinal centers and may undergo rapid activation. The effects of ICI on B cell populations is also relevant for ICI use in the setting of pre-existent inflammatory or autoimmune disease marked by autoantibody production. While ICI, either alone or in combination, can lead to the exacerbation of these conditions, the effect on autoantibody production has not yet been well studied. These exacerbations, however, can respond to agents such as glucocorticoids or TNF blockers whose B cell effects are not clear. Since B cells can express PD-1 as well as PD-L1, the effects of ICI may direct actions or the indirect effects on other cell populations. Future studies are needed to delineate more precisely the contribution of B cells to the response of cancer to ICI as well as the development of irAE.

Orthotic treatment: is it in or out?

SP0179 ORTHOSES AND ASSISTIVE DEVICES FOR THE HAND
Nina Osteras, Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway

This presentation will summarize the scientific evidence for the effects of orthoses and assistive devices for the hand. The main focus will be on hand osteoarthritis. The presentation will shed light on how orthoses and assistive devices may facilitate participation.

Disclosure of Interests: None declared

SP0180 FOOT ORTHOSES IN RA
Jim Woodburn, Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom

In this presentation I will: (1) Provide a general overview of the indications and use of foot orthoses in rheumatoid arthritis (RA) 1, (2) Explore mechanisms of action with respect to preserving, maintaining and restoring foot biomechanics 2, (3) Summarise current evidence on the use of foot orthoses for managing foot pain, disability, deformity and quality of life by drawing on recently published systematic reviews and meta-analyses3. Further I will direct delegates to national, European and International evidence-based clinical guidelines where they exist1,4, and (4) Introduce new technology advances with regards to materials and digital design and manufacturing concepts2. I will conclude the presentation by setting out future directions and priorities for both clinical practice and research and innovation.

TREATMENT OF GCA

The treatment of giant cell arteritis (GCA) has taken a dramatic leap forward over the past 18 months, with the start of the era of interleukin-6 inhibition for the treatment of this disease. For the first time in 70 years, rheumatologists now have a highly-effective alternative to continuous therapy with doses of glucocorticoids that are often unacceptably high, leading inevitably to steroid-related toxicity. Clinicians now have many questions about the optimal approach to treatment in this new era: When should IL-6 inhibition begin? How quickly should glucocorticoids be tapered? Should prednisone be stopped completely? Can tocilizumab ever be discontinued? How does one monitor for the possibility of disease flare? This session will address all of these questions using a data-driven approach, with reference to new data from the GIACTA trial.

Disclosure of Interests: None declared

SP0181 TREATMENT OF GCA
John H. Stone, USA

TREATMENT OF AAV

Background: ANCA associated vasculitis is an autoimmune disease classified by clinical phenotype and serology. A genetic predisposition has been determined which differs between PR3-ANCA and MPO-ANCA patients. Experimental models have confirmed the pathogenicity of ANCA for certain aspects of pathology and have defined a role for alternative complement pathway activation but have failed to explain granuloma formation or gain insights into the origin of breakdown of tolerance. Therapy has emerged empirically to include the combination of high dose glucocorticoids and immunosuppression with B cell depletion, Rituximab, emerging as an alternative immunomodulator over the last 20 years. Studies have evaluated the role of Rituximab in induction, in refractory and relapsing disease and in the prevention of relapse and have explored the role of B biomarkers in monitoring therapy. AAV patients continue to suffer poor outcomes especially if renal, cardiac or gastrointestinal features are present at diagnosis. Adverse event rates remain high and the majority of patients pursue a relapsing course. Inhibition of the alternative complement component C5a is emerging as a new therapeutic opportunity.

Objectives: To define the outcomes and predictors for adverse outcomes in AAV. To review recent clinical trial data in the context of established guideline statements and to discuss the treatment of more complex clinical scenarios.

Methods: A description of current approaches to classification and subgrouping by severity. Review of recent clinical trial data and guidelines and application of learned knowledge to clinical scenarios.

Conclusion: AAV remains a disease with poor outcomes. There is a need for further understanding of the barriers to early diagnosis and access to specialist care. Treatment decisions are now well supported by evidence from clinical trials. Rituximab has had a major influence on current management strategies and is leading to improved outcomes and reduced glucocorticoid exposure. Complement inhibition is a potential new therapy for AAV.

DIAGNOSIS AND TREATMENT OF HCV RELATED VASCULITIS

Peter Langer, University of Lubeck, Department of Rheumatology and Clinical Immunology, Lubeck, Germany

Chronic hepatitis C virus (HCV) infection is the most common cause of cryoglobulinarminic vasculitis. In contrast, non-cryoglobulinemic vasculitis is rare in chronic HCV infection. Cryoglobulinemic vasculitis is a systemic immune complex-mediated vasculitis predominantly affecting small vessels and associated with the presence of serum cryoglobulins, i.e. cold-precipitable immunoglobulins. HCV is a hepato- and lymphotropic virus. Notably, secondary transition from benign lymphoproliferative disease to malignant non-Hodgkin lymphoma (NHL) as well as primary co-manifestation of cryoglobulinemic vasculitis and NHL has been reported in chronic hepatitis C. While cryoglobulinemia is detected in 50%-60% of the patients with chronic hepatitis C, less than 5% develop related vasculitis. In this disorder, HCV induces clonal proliferation of memory phenotype marginal zone-like B-lymphocytes with restricted Ig heavy chain variable (VH) 1-69 gene expression encoding for the IgM rheumatoid factor (RF) WA idiotype. Monoclonal IgM RF binding to the Fc region of polyclonal IgG with anti-HCV reactivity facilitates the formation of cryoprecipitable multi-molecular immune-complexes. Cryoglobulins are preferentially deposited in tissues with high blood flow per unit mass of tissues; e.g. skin, synovium, choroid plexus and glomerulus, where they bind to endothelial cells via the C4q receptor.

Endothelial cryoglobulin deposition induces the activation and recruitment of circulating neutrophil granulocytes and other immune cells to the endothelial lesion eventually resulting in complement-consuming vasculitis. The histopathologic changes in HCV-related vasculitis range from cutaneous leukocytoclastic vasculitis to severe necrotizing arteritis. Type I membraneproteolytic granulonephritis is frequently found in patients with renal involvement. Clinical features of HCV-associated vasculitis comprise purpura, Meltzer’s triad (purpura, arthralgia, asthenia), polyneuropathy, renal involvement and Raynaud’s

Disclosure of Interests: Peter Langer has received support from the following companies: Lilly, Roche, MSD, Pfizer, MSD, AstraZeneca, Novartis, Genzyme, Boehringer-Ingelhein, Biocon, Mylan, Gilead, GSK and FMS.

SP0183 DIAGNOSIS AND TREATMENT OF HCV RELATED VASCULITIS
phenomenon. Hemorrhagic alveolitis, interstitial lung disease, gastrointestinal vasculitis, cardiac involvement, osteosclerosis and hyperviscosity syndrome are less common manifestations. Diagnostic criteria have been developed for HCV-associated cryoglobulinemic vasculitis.

International therapeutic guidelines recommend treatment of HCV-related vasculitis to be guided according to the severity of disease. In patients with mild to moderate disease, interferon-free therapy regimens with direct acting antivirals (DAA) are considered as first-line treatment. In patients with severe manifestations, rituximab is given for the control of vasculitic manifestations, followed by HCV eradication using DAA. High rates of clinical responses and sustained virologic responses (SVR) have been reported for DAA treatment in HCV-associated cryoglobulinemic vasculitis. However, relapse of cryoglobulinemic vasculitis may occur in patients despite earlier treatment-induced clinical response and SVR. Persistence of clonal B-lymphocyte proliferation and perseverance of perturbations of the immune homeostasis have been shown in HCV-cured patients with relapse of cryoglobulinemic vasculitis.

Workshop: #ConnectToday and tomorrow: the campaigning continues

SP0184 DON’T DELAY, CONNECT TODAY IN FINLAND: A VIDEO TO PROMOTE EARLY DIAGNOSIS

Maria Ekroth, Institute of Anatomy, Paracelsus Medical University, Imaging and Functional Musculoskeletal Research, Salzburg, Austria

Positive Encounter - Don’t Delay Connect Today

Background: Too often people suffer the symptoms of rheumatoid arthritis for too long before they visit a doctor. The positive encounter between physician and patient can lead to a good relationship, follow-up care and positive health outcomes. We conducted a survey about the need for a treatment plan and found that less than 30% of patients know their treatment plan and patients who do know their plan are better committed and more satisfied with their physicians. 72% of survey respondents who know their treatment plan are happy with their treatment as whole. Of the remainder, only 33% are satisfied.

Objectives:
1. The aim of this campaign is to illustrate and inform people of the symptoms of rheumatoid arthritis and encourage them to visit a doctor, enabling the doctor to assist the patient.
2. To give advice to patients on how to prepare for a doctor’s appointment.
3. The campaign also includes a section directed at rheumatologists and rheumatology nurses, that advises on the importance of the encounter and the creation of the treatment plan.
4. To increase awareness about our association, and to recruit new members

Methods: Video for patients and the wider public. Video for rheumatologists and rheumatism professionals. Mailing of brochures on the importance of the treatment plan to all Finnish rheumatologists and arthritis treatment units. We also thanked doctors and attached a fruit gift card. We sent flyers and posters to our member associations. Members have handed out materials directed at patients locally. They have distributed them to libraries, municipalities, sports centres . . . and given away fliers at the events.

Results: Patients have reported being better prepared for the visits and having written down important questions in advance. We achieved attention value amongst professionals and were invited to design a national treatment path with rheumatism professionals for children with JIA. All the main hospitals are involved and will start to use it. Free TV air time was offered for the patient video on the national main TV channel. The Finnish Society for Rheumatology offered us the possibility of promoting our campaign at the Scandinavian Congress of Rheumatology.

Conclusion: The campaign was successful.

DON’T DELAY, CONNECT TODAY IN TWELVE VIDEO’S: HOW TO GET EARLY DIAGNOSIS OF RMD’S ON THE TABLE IN POLAND

Jolanta Grygielska, Polish Rheuma Federation ‘REF’, National Board, Warsaw, Poland

Background: Early diagnosis and appropriate treatment is a mile stone in future progress of rheumatic and musculoskeletal disease (RMD), especially inflammatory. We know from our experiences that delays of diagnosis are connected with knowledge and attitude of patient, of primary care physician (fast referral to rheumatologist) and with access to rheumatologist. New EUULAR campaign ‘Don’t delay, connect today’ gives an opportunity to pay attention to the problem of RMDs, increase public awareness and remind persons about responsibility for their health. Lack of knowledge about RMDs and faith in myths are a first step to loose a time from first symptoms of diseases to appropriate diagnosis. The first step was translation of EUULAR campaign slogan into Polish and preparing of Polish version of logo. It was done very fast after launching EUULAR campaign.

Objectives: Aim of our project was to increase public awareness about RMDs and self-awareness of patients, to present how important is a role of everybody being face to face with progressing disease. It was most important to reach to younger people believing that rheumatic diseases are typical only for older people. Lack of knowledge about RMDs and faith in myths are a first step to loose a time from first symptoms of diseases to appropriate diagnosis. The first step was translation of EUULAR campaign slogan into Polish and preparing of Polish version of logo. It was done very fast after launching EUULAR campaign.

Methods: We have many ideas which subject are more important for people around diagnosis. We decided to start with choice of subjects and connecting them with the first letter of Polish names of months. We tried to order them in logical process: from self-awareness to the sin of neglect though to greater knowledge and attitude of patients, of primary care physician (fast referral to rheumatologist), of rheumatologist, of society. Every invited speaker received only one subject and main message to present in his/her film. Form, place and comments were suggested by speaker and discussed with a team preparing videos. Part of films were supported by our regional member associations. Forms of videos prepared in regions were decided by associations. In two films members of associations present their opinions and experiences to give a strength for new rheumatic persons to live with RMD and avoid unnecessary health situations. One video was enriched by physical exercises presented by students of physiotherapy under supervise of rheumatologist. All videos were filmed and prepared by our member, translation was done by another our member - both are professionals on their fields and with experiences of living with RMD. It gives added value to our campaign. After that videos were posted on our channel on YouTube and information about them was shared by our websites, facebook and Twitter. We sent information by e-mail to our colleagues and supporters. We invite every viewer to subscribe our channel to have easy access to our newest films.

Results: “Video for every month” is a series but every video can be used separately. Order of videos watching can be optional according to the viewer’s choice. At the same time when videos were posted one by one, project on early diagnosis of rheumatoid arthritis supported by European founds and with our partnership start in Poland. Thanks to this our message “Don’t delay, connect today” is stronger. Parallel our new project ‘RA - don’t resign’ starts from World Arthritis Day 2018. All actions give an occasion to focus on early diagnosis and appropriate treatment of RMDs.

Conclusion: Every aim can be achieve in co-operation and engagement of main players. We involve in our project members of regional associations, rheumatologists, students. During realization of other projects we used every occasion to share information about our videos. All subjects of videos are overtime. Every patient with RMD can receive new knowledge about her/his disease from reliable source everywhere and at every time in two languages versions Polish (voice) and English (subtitles). We are planning to use this form of information in next project.

PATHOPHYSIOLOGY AND THERAPEUTIC CONSEQUENCES AUTO-INFLAMMATORY BONE DISORDERS

SP0187

Christian Hedrich, Institute of Translational Medicine, University of Liverpool, Department of Women’s and Children’s Health, Liverpool, United Kingdom

Chronic nonbacterial osteomyelitis (CNO) is an autoimmune bone disorder, covering a clinical spectrum with asymptomatic inflammation of single bones at the one end, and chronic recurrent multifocal osteomyelitis (CRMO) at the other end. Bone inflammation, however, can also be a symptom of other autoimmune/inflammatory conditions. Rare monogenic autoinflammatory diseases with bone involvement have informed research and provide models for the more common and pathophysiologically complex disorder CNO/CRMO.

Despite recent efforts, the exact molecular pathophysiology of CNO remains incompletely understood. Profound dysregulation of cytokine responses was demonstrated in CNO/CRMO. Failure to produce antiinflammatory cytokines interleukin (IL)-10 and IL-19 contributes to activation of inflammmasomes and subsequent IL-1β release. In IL-10-deficient and in CNO-prone chronic multifocal osteomyelitis mice, IL-1β was linked to bone inflammation. Recently, increased inflammmasome component expression and inflammmasome assembly have been linked with CNO/CRMO in humans. Furthermore, alterations to the gut microbiome were suggested in contributing to IL-1β release from innate immune cells in mice, offering an interesting target in the search for molecular mechanisms in CNO.

This presentation will review molecular alterations in autoinflammatory bone disease, focussing on CNO and discuss therapeutic consequences.

SP0188 SAPHO – AN ADULT PERSPECTIVE

Gunter Assmann; University Medical School of Saarland, Medicine I, Oncology and Rheumatology, Homburg, Germany

Background: The acronym SAPHO has been introduced to describe a syndrome in adolescents and adults suffering from synovitis, acne, pustulosis, hyperostosis, and non-bacterial osteitis preferentially in the sternum region. Currently, this also includes the entity CNO with non-bacterial chronic recurrent multifocal osteomyelitis (CRMO) in cases which primarily occur in adult age.

Objectives: The diagnostic certainty of SAPHO syndrome in case of incomplete presentation of the clinical features has been unclear so far. Furthermore, the treatment approach of SAPHO syndrome is difficult because the etiology remains unknown, although a reactive infectious osteitis in genetic predisposed subjects seems appealing.

Methods: Here we present relevant case series of SAPHO patients which should elucidate the relevance of different diagnostic procedures and treatment options. It has been noted, however, that particularly in respect of the use of antirheumatic drugs case series with predominantly small numbers of SAPHO patients suggest different treatment approaches.

Results: The diagnosis of SAPHO syndrome is made not only in the full picture of the disease according to the acronym, but also in non-bacterial and non-malignant osteitis with hyperostosis with simultaneous or delayed onset of acne, psoriasis and/or PPP. In addition, the primary manifestation of CNO in adulthood is nowadays classified as SAPHO syndrome. Recent studies have previously confirmed the usefulness of skeletal scintigraphy in 2 phases as a diagnostic. Imaging with MRI is frequently used preferentially for the assessment of osteitis activity, CT for the assessment of destruction and hyperostosis. The CT-guided biopsy of the lesion should be performed in solitary manifestation of osteitis. Basically, SAPHO syndrome has a high impact on patients’ general health resulting in high burden of disease. There are many approaches to drug therapy, but only a few have been investigated in larger case series - none of them as controlled studies. Smaller case series of less than 10 patients reported limited efficacy of DMARD with MTX, azathioprine, or ciclosporin. Studies with larger case numbers show a moderate efficacy of bisphosphonates as well as TNF-alpha blockers. A short-term but not sustained effect has been demonstrated for the antibiotic azithromycin, as well as for steroids per os or as infiltration into osteitis. Referring to the treatment approach in SpA newly approved biologicals with IL-17 or IL-12/23 blocking effects demonstrated promising results in individual case reports of SAPHO patients.

Conclusion: Modern diagnostic imaging methods are increasingly being used for SAPHO syndrome. The selection of potentially effective drugs for SAPHO syndrome has increased. However, prospective studies to develop guidelines for the diagnosis and therapy of SAPHO syndrome are still lacking. Until further notice, the therapy is based on the recommendations for psoriatic arthritis or spondyloarthritis.

09:00:00 – 10:50:00

EULAR Projects in clinical affairs

SP0189 UPDATE ON EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF SLE

Antonis Fanouriakis, "Attikon" University Hospital, Rheumatology and Clinical Immunology, Athens, Greece

Background: Recent advances in treatment strategies and goals of treatment in systemic lupus erythematosus (SLE) called for an update of the EULAR recommendations for the disease, capitalizing on the strengths of and experience from similar previous projects.

Objectives: To update the EULAR recommendations for the management of SLE

Methods: Systematic literature review (01/2007-12/2017) followed by modified Delphi method to form questions, elicit expert opinions and reach consensus.

Results: Treatment in SLE aims at remission or low disease activity and prevention of flares. Hydroxychloroquine is recommended in all lupus patients, at a dose not exceeding 5mg/kg real body weight. During chronic maintenance treatment, glucocorticoids should be minimized to less than 7.5 mg/day (prednisone equivalent) and, when possible, withdrawn. Appropriate initiation of immunomodulatory agents (methotrexate, azathioprine, mycophenolate) can expedite the tapering/discontinuation of glucocorticoids. In persistently active or flaring extracranial disease, add-on belimumab should be considered; rituximab may be considered in organ-threatening, refractory disease. Updated specific recommendations are also provided for cutaneous, neuropsychiatric, haematological and renal disease. SLE patients should be assessed for their antiphospholipid antibody status, infectious and cardiovascular diseases risk profile, and preventative strategies be tailored accordingly.

Conclusion: The recommendations provide physicians and patients with updated consensus guidance on the management of SLE, combining evidence-base and expert-opinion.

Disclosure of Interests: Antonis Fanouriakis Paid instructor for: Amgen, GSK, Speakers bureau: Abbvie, Enorasis, Genesis Pharma

2019 EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF SJÖGREN’S SYNDROME WITH TOPICAL AND SYSTEMIC THERAPIES

Manuel Ramos-Casals1, Hospital Clinic, Autimmune Diseases, Barcelona, Spain; Manuel Ramos-Casals1,2, Pilar Brito-Zerón2, Stefano Bombardieri5, Hendrika Boodaghian7, Salvatore De Vita8, Thomas Dörner9, Benjamin A. Fisher8, Jacques-Eric Cottereng8, Gabriela Hernández-Molina10, Agnes Kocher12, Belchin Kostov15, Ake A. Krüe11, Thomas Mandl13, Wan-Fai Ng11, Soledad Palermo10, Raphaële Serres14, Yehuda Sofferf15, Antoni Sicó-Amiras11,13,14, Athanasios G. Tzoufas15, Claudia Viola13, Simon Bowman10, Xavier Mariette18, on behalf of the EULAR-Sjögren Syndrome Task Force Group. The Task Force endorsed the presentation of general principles for the management of patients with SjS with symptoms as the most important goal. In view of this scenario, the European League Against Rheumatism (EULAR) supported and promoted an international collaborative study (EULAR SJ Task Force) aimed to develop the first EULAR evidence-based recommendations for the management of patients with SjS with topical and systemic medications. The aim was to develop a rational therapeutic approach to SjS patients useful for healthcare professionals, doctors in specialist training, medical students, pharmaceutical industries and drug regulatory organizations following the 2014 EULAR standardized operating procedures.

Methods: The Task Force included rheumatologists, specialists in internal medicine, dermatology, ophthalmologists, gynaecologists, specialists in otorhinolaryngology, and diabetes care. One national study group was formed including 21 physicians, 1 healthcare professional, and 2 patients, from 10 countries. Research questions were developed using the Delphi method. A systematic literature review of published articles up to January 2018 was performed. 11 countries. Research questions were developed using the Delphi method. A systematic literature review of published articles up to January 2018 was performed. The level of evidence and experts opinion, a set of 3 overarching principles and recommendations. We hope that the current recommendations will be widely applied in clinical practice and serve as a template for national societies to develop local recommendations.

Disclosure of Interests: None declared

Aims: The therapeutic management of Sjögren’s syndrome (SjS) has not changed substantially over the past decades: treatment decisions remain challenging in clinical practice, without a specific therapeutic target beyond the relief of symptoms as the most important goal. In view of this scenario, the European League Against Rheumatism (EULAR) supported and promoted an international collaborative study (EULAR SJ Task Force) aimed to develop the first EULAR evidence-based recommendations for the management of patients with SjS with topical and systemic medications. The aim was to develop a rational therapeutic approach to SjS patients useful for healthcare professionals, doctors in specialist training, medical students, pharmaceutical industries and drug regulatory organizations following the 2014 EULAR standardized operating procedures.

Methods: The Task Force included rheumatologists, specialists in internal medicine, dermatology, ophthalmologists, gynaecologists, specialists in otorhinolaryngology, and diabetes care. MANAGEMENT OF ADULT APS: RECOMMENDATIONS FROM AN EULAR TASK FORCE

Maria Tektonidou, National and Kapodistrian University of Athens, Joint Rheumatology Program, Greece

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterized by arterial and venous thrombotic events or pregnancy morbidity in the presence of persistently positive antiphospholipid antibodies. There is a great heterogeneity in clinical and laboratory classification of the syndrome and treatment approaches over the past four decades.

Objectives: To develop evidence-based recommendations for the prevention and management of adult APS that will help guide clinical practice.

Methods: EULAR standardised operating procedures were followed. A task force was formed including 21 physicians, 1 healthcare professional, and 2 patients, from 11 countries. Research questions were developed using the Delphi method. A systematic literature review of published articles up to January 2018 was performed.

Results: Based on the evidence and experts opinion, a set of 3 overarching principles and 12 recommendations including their level of evidence and grade of recommendation was developed and voted. The level of agreement for each recommendation was high. The overarching principles include the risk stratification, general measures, and education/counselling of patients with APS. Recommendations for primary prevention address the primary thromboprophylaxis (low dose aspirin in no treatment) in antiphospholipid antibody individuals
including asymptomatic carriers, patients with systemic lupus erythematosus without history of thrombotic or obstetric APS, and non-pregnant women with a history of obstetric APS only. Recommendations for the management of thrombotic manifestations address different types of anticoagulation in patients with definite APS and first provoked or unprovoked venous thrombosis and the management of recurrent venous thrombosis, as well as the type and intensity of anticoagulation in patients with first or recurrent arterial thrombosis. Recommendations for the management of obstetric APS describe the management of various types of pregnancy complications in APS and of refractory to treat- ment cases. Recommendations for catastrophic APS refer to precipitating factors, first-line treatment of catastrophic APS, and management of refractory cases.

Conclusion: These recommendations based on evidence and expert opinion aim to guide practice and improve quality of care in patients with APS.

SP0192 UPDATE OF THE EULAR RECOMMENDATIONS LAGE VESSEL VASCULITIS MANAGEMENT
Bernhard Helbich, Medius Kliniken, Klinik für Innere Medizin, Rheumatologie und Immunologie, Kirchheim-Teck, Germany

Background: Since the publication of the European League Against Rheuma- tism (EULAR) recommendations for the management of large vessel vasculitis (LVV) in 2009, several relevant randomized clinical trials and cohort analyses have been published, which have the potential to change clinical care and there- fore supporting the need to update the original recommendations.

Objectives: To update the 2009 EULAR recommendations for the management of LVV.

Methods: Using EULAR standardized operating procedures for EULAR- endorsed recommendations, the EULAR task force undertook a systematic litera- ture review and sought opinion from 20 experts from 13 countries. We modified existing recommendations and created new recommendations.

Results: Three overarching principles and 10 recommendations were formulated. We recommend that a suspected diagnosis of LVV should be confirmed by imaging or histology. High dose glucocorticoid therapy (40-60 mg/day prednisone-equiva- lent) should be initiated immediately for induction of remission in active giant cell arteritis (GCA) or Takayasu arteritis (TAK). We recommend adjunctive therapy in selected patients with GCA (refractory or relapsing disease, presence of an increased risk for glucocorticoid-related adverse events or complications) using tocilizumab. Methotrexate may be used as an alternative. Non-biologic glucocorti- cold-sparing agents should be given in combination with glucocorticoids in all patients with TAK and biologic agents may be used in refractory or relapsing patients. We no longer recommend the routine use of antplatelet or anticoagulant therapy for treatment of LVV unless it is indicated for other reasons.

Conclusion: We have updated the recommendations for the management of LVV to facilitate the translation of current scientific evidence and expert opinion into better management and improved outcome of patients in clinical practice.

Skin and eye manifestations in rheumatic diseases...

SP0193 WIN: SKIN AND RHEUMATIC DISEASES
Annegret Kuhn, University Hospital Muenster, Executive Department of the University Hospital, Muenster, Germany

Background: The main underlying mechanisms of skin manifestations in rheu- matic diseases include autoimmune responses, auto-inflammatory processes, and tissue-specific alterations. In psoriasis, therapies targeting T cell activation, T cell migration, or neutralization of disease-related cytokines are highly effective. However, targeted therapies still need to be developed in less frequent autoimmune diseases, such as systemic lupus erythematosus (SLE), systemic sclerosis (SSc), or dermatomyositis (DM).

Objectives: To provide an update for rheumatologists on the management of skin manifestations in autoimmune diseases based on recent insights into the pathogenesis.

Methods: Several agents are approved for the treatment of SLE, including the monoclonal antibody belimumab, a B lymphocyte stimulator-specific inhibitor, but no drugs have been licensed specifically for the treatment of skin manifestations in this disease. The aim of the European guideline was to achieve a broad consen- sus on treatment strategies for patients with cutaneous lupus erythematosus (CLE) by a European subcommittee. In total, 16 European participants were included in this project and agreed on all recommendations.

Results: First-line treatment options in CLE include topical corticosteroids or cal- cineurin inhibitors; in patients with disfiguring and widespread disease, systemic agents need to be applied. The first-line systemic treatment is antimarialarials, but some patients are therapy-resistant and immunosuppressive agents, such as methotrexate, are used as alternative therapeutic option. In 2011, the monoclonal antibody belimumab was introduced for SLE as an adjunct therapy for patients with autoantibody-positive disease who despite standard therapy show high dis- ease activity, intolerance of other treatments, or an unacceptably high need for corticosteroids. So far, a validated skin score has not been used to confirm the effi- cacy of belimumab on mucocutaneous manifestations. In SSC, the therapeutic modalities are even more limited. Treatment with endothelin-receptor antagonists has been proven to reduce the occurrence of new digital ulcers in SSC patients but has no or limited effect on healing of digital ulcers. DM is a further idiopathic autoimmune disease characterized by inflammation of the muscles and skin, which is treated with immunosuppressives. Corticosteroids are still the first-line treatment for muscle involvement in DM, but skin lesions often flare by reduction or discontinuation.

Conclusion: In summary, there is a high unmet need for new therapeutic strat- egies focusing on skin involvement in systemic autoimmune diseases. Therefore, innovative designs of randomized controlled trials based on the pathogenesis are warranted to develop new therapies for patients with skin manifestations in rheu- matic diseases.

To image or not to image in spondyloarthritis?

SP0194 WHEN AND HOW TO USE AND NOT USE IMAGING FOR DIAGNOSIS?
Frans A. van Gaalen. Leiden University Medical Center, Rheumatology, Leiden, Netherlands

Since axial spondyloarthritis (axSpA) has no single shared distinguishing feature that distinguishes the disease from other causes of back pain, diagnosis of axSpA requires recognition by the clinician of a pattern of features that taken together are characteristic of axSpA. Information from patient history and physical examina- tion, laboratory, and imaging findings may all aid in recognition of axSpA and the diagnosis of axSpA requires exclusion of other potential causes for these abnor- malities/differences.

Traditionally, plain radiography is used to assess sacroiliac and spinal involve- ment of disease. A weakness of radiography in assessing sacroiliac involvement - apart from its inability to detect early disease - is reader variability. Additionally, involvement of the spine (i.e. detection of syndesmophytes) is very uncommon in early disease.

The use of MRI in diagnosing axSpA has increased over the past ten years and MRI greatly facilitates earlier diagnosis of axSpA. However, it has also become increasingly clear that MRI detectable lesions associated with SpA including bone marrow edema and fatty lesions - may also occur in patients without axSpA.
The aim of this presentation is to provide insight into the pitfalls of imaging in diagnosing SpA, with a particular focus on false positives in imaging as well as the importance of interpretation of the clinical context.

SP0195  IMAGING IN DISEASE AND TREATMENT MONITORING – DOES IT MATTER?

Xenofon Baraliakos. Rheumazentrum Ruhrgebiet, Ruhr University Bochum, Rheumatology, 44649 Herne, Germany

Background: Imaging of the axial skeleton is a crucial step in classification and diagnosis of axial Spondyloarthritides. After diagnosis, patients with axSpA are being treated with non-steroidal anti-inflammatory drugs (NSAIDs) or with disease-modifying anti-rheumatic drug (DMARD). Despite the fact that the latter treatment is referred to as disease-modifying and modification of the disease is supposed to be relating to the objective course of the disease, as assessed by imaging, recommendations for monitoring of the course of axSpA by imaging are still lacking mostly due to the lack of data. Nevertheless, this aspect is mentioned in the treat-to-target principle for axSpA over all, earlier data have shown that the course of lesions documented by magnetic resonance imaging (MRI) is correlating well with other objective measures of changes of systemic inflammation such as C-reactive protein (CRP), than with patient-reported measures of disease activity. Similarly, conventional radiographs (CR) are being used for documenting of the development of structural changes over many years.

Objectives: The objective of this presentation is to show the current evidence of the possibilities of different imaging techniques used in axSpA for assessment of the course of the disease (both for the inflammatory and chronic changes) and give practical tips about when imaging would be advised for monitoring the disease course or where this can be avoided.

Disclosure of Interests: Xenofon Baraliakos Grant/research support from: AbbVie, Boehringer Ingelheim, Bristol-Myers Squibb, Celgene, Centocor, Chugai, Janssen, MSD, Novartis, Pfizer Inc, Roche and UCB, Consultant for: AbbVie, Pfizer, Merck Sharp & Dohme, UCB Pharma, Novartis, Consultant for: AbbVie, Bristol-Myers Squibb, Boehringer Ingelheim, Celgene, Chugai, Janssen Biologics, Novartis, Pfizer, UCB Pharma, Galapagos, Speakers bureau: Abbvie, Chugai, Janssen, Novartis, Pfizer, UCB Pharma

SP0196  IS THERE ROOM FOR OTHER IMAGING MODALITIES BEYOND CONVENTIONAL X-RAYS AND MRI?

C.-J. van der Laken. Amsterdam UMC location VUMc, Rheumatology, Amsterdam, Netherlands

Early diagnosis of spondyloarthritides is still tempting since objective measures to assess disease activity are often missing. MRI provides highly sensitive visualization of inflammation, but detection levels in early spondyloarthritides are varying. Another clinical temptation is early treatment evaluation of spondyloarthritides. An important outcome measure is therapeutic efficacy on bone formation in vertebral column and sacro-ilial joints. Conventional X-rays only allow for assessment of bone formation over a time span of at least 2 years. In this presentation, opportunities with new upcoming imaging techniques to address above mentioned clinical issues will be discussed in relation to longer existing imaging techniques.

The lung in rheumatoid arthritis

SP0197  CASE 1 PRESENTER: EARLY RA WITH LUNG PROBLEMS IN THE CONTEXT OF BIOLOGICAL TREATMENT

Ana Miona Illán Arciniegas. Santa Creu i Sant Pau Hospital, Rheumatology, Barcelona, Spain

We present a 77-year-old male patient with a history of former smoker, arterial hypertension and dyslipidemia, whose diagnosis of Rheumatoid Arthritis was made in July 2017 by arthritis of metacarpophalangeal joints, wrists and knees and positivity for anticryctic citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF). Treatment with Methotrexate and prednisone was started but the patient did not achieve adequate control of joint symptoms, so we decided to add Etanercept to the treatment. A good joint response was obtained but in a follow-up control he explained breathlessness with cough and low grade fever. The chest X-Ray was not conclusive and we decided to perform a high resolution computerized tomography (HRCT) scan. An interstitial involvement was detected and an accurate differential diagnosis was made.

Disclosure of Interests: None declared

SP0198  CASE 1 DISCUSSANT: HOW TO TREAT DIFFICULT ILD FROM OTHER CAUSES OF LUNG INVOLVEMENT IN RA

Ivan Castellví. Hospital Universitari de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain

The lung in Rheumatoid Arthritis (RA) can be affected by different manifestations and Interalstitial Lung Disease (ILD) related to RA is one of the most devastating complications that we can find in the disease. The lung parenchyma involvement can be present with different patterns. As opposite with other forms of connective tissue diseases the usual interstitial pneumonia pattern (UIP) is more frequent than non-specific interstitial pneumonia pattern (NSIP) in RA. Currently high-resolution computed tomography (HRCT) and pulmonary function test are the best tools to detect and to follow ILD in RA. Nevertheless, other lung involvements, infections and drug toxicity of nonbiological and biological disease-modifying anti-rheumatic drugs (DMARDs) can affect patients with rheumatoid arthritis and simulate ILD. To know which affection are present in our patients with interstitial lung compromise is crucial to proceed against the problem. Patient characteristics, clinical presentation, radiological distribution or bronchoalveolar lavage would be helpful to discriminate ILD from other causes of lung involvement. An individual and multidisciplinary approach is very important to do the best management in these patients.

Disclosure of Interests: None declared

SP0199  CASE 2 DISCUSSANT: HOW TO TREAT DIFFICULT ILD

Toby Maher. Imperial College London and Royal Brompton Hospital, National Heart and Lung Institute, London, United Kingdom

Background: ILD frequently results in progressive and irreversible destruction of the lung through scarring. Prompt therapy can help rescue lung function and prevent subsequent respiratory decline. This case will demonstrate the challenges inherent in diagnosing and managing interstitial lung disease in the context of connective tissue disease.

Objectives: To discuss typical presentation of CTD-ILD; Review challenge of making diagnosis and choosing best treatment; Assess treatment options, duration of therapy and measurement of treatment response.

Conclusion: A range of therapeutic options exist for CTD-ILD albeit with a paucity of trial data to support best practice. Accurate diagnosis of systemic disease, paired with careful assessment and monitoring of the respiratory system are vital in ensuring optimal management. Intraavenous therapy is often necessary in advanced disease or for disease which proves refractory to oral immunosuppression.

DISCLOSURES
Novel treatments and old challenges: where do we stand in the management of antiphospholipid syndrome

SP0200 TARGETED TREATMENTS: WHAT’S ON THE HORIZON FOR OBSTETRIC ANTIPHOSPHOLIPID SYNDROME?

Jane E. Salmon. Hospital for Special Surgery – Weill Cornell Medicine, Rheumatology, New York, United States of America

Pregnancy in women with APS and/or lupus is dangerous both for mother and offspring, and, in the past, patients were advised not to have children. Among complications frequently seen in women with lupus are preeclampsia (also known as toxemia of pregnancy), preterm birth, markedly underweight newborns, and fetal death. Identifying women destined for complications remains challenging and limits our ability to counsel and care for pregnant lupus patients.

There is currently no effective treatment for women with these high-risk pregnancies; treatments to prevent poor pregnancy outcomes require an understanding of mechanisms of injury. Our research in an animal model that mimics the human condition shows that blockade of well-established mediators of inflammation, speciﬁcally complement and TNF-alpha, prevents adverse outcomes. To translate these discoveries to lupus patients, we launched the PROMISSE Study (Predictors of Pregnancy Outcome: biomarkers in antiphospholipid antibody syndrome and Systemic lupus erythematosus) to determine which pregnancies were at highest risk for adverse outcomes. Over 20% of pregnancies in patients with SLE resulted in an adverse pregnancy outcome. We discovered that the presence of a lupus anticoagulant which can be detected in the blood before pregnancy or in the first trimester, confers a 10-fold increase in risk of complications. Furthermore, we found that early in pregnancy, measurable alterations in the balance of angiogenic factors (proteins that circulate in blood, promote proper placenta development, and are required to maintain the health of the mother’s vascular system) are highly predictive of preeclampsia and other pregnancy complications.

The results of the PROMISSE Study provide models for early risk stratiﬁcation to allow physicians to identify patients early in pregnancy who are at low risk and reassure them that their pregnancies were likely to be uncomplicated and their babies healthy. Conversely and importantly, we can reliably predict which patients are destined to have poor pregnancy outcomes, and we conducting a trial with a TNF-alpha inhibitor that does not cross the placenta in patients at highest risk an experimental therapy to prevent placental dysfunction. Treatments to prevent poor pregnancy outcomes require an understanding of mechanisms of injury. Experiments in mouse models have enabled us to embark upon a trial of a potential treatment.

Consultant for: L Gossec has received honoraria from Celgene as investigator for this study.

SP0201 CATASTROPHIC APS TREATMENT GUIDELINES

Ricard Cervera. Hospital Clinic, Barcelona, Department of Autoimmune Diseases, Barcelona, Spain

The current recommendation for speciﬁc therapy of catastrophic antiphospholipid syndrome (CAPS) is the triple therapy with anticoagulation, glucocorticoids, plasma exchange and/or intravenous immunoglobulins. Of note, only anticoagulation had a signiﬁcant effect improving the vital prognosis of these patients. From the experimental point of view, there is only indirect evidence to advocate the use of these immunomodulatory therapies in CAPS.

Recently, two monoclonal antibodies, rituximab and eculizumab, have been successfully used in some cases of severe or refractory CAPS. The ﬁrst decreases the generation of pathogenic autoantibodies such as antiphospholipid. The second prevents the generation of C5b-C9 complex.

The current presentation will describe the conventional and recent modalities of CAPS treatment, discussing the rationale for each one.

How low should you go? What is the relevant target in T2T in rheumatoid arthritis?

SP0202 WHAT DOES REMISSION MEAN FOR PHYSICIANS?

Laure Gossec. Sorbonne Universite and Pitié-Salpetriere Hospital, Rheumatology, Paris, France

Remission is the announced objective is rheumatoid arthritis. However, there are several deﬁnitions of remission. In this talk, we will review different health professional based deﬁnitions of remission, the components of these deﬁnitions, and their advantages and drawbacks.

Disclosure of Interests: Laure Gossec Grant/research support from: AbbVie, BMS, Celgene, Janssen, Lilly, MSD, Novartis-Sandoz, Pfizer, Sanofi, and UCB. Consultant for: AbbVie, Biogen, BMS, Celgene, Janssen, Lilly, MSD, Nordic Pharma, Novartis-Sandoz, Pfizer, Roche, Sanofi, and UCB. Consultant for: L Gossec has received honoraria from Celgene as investigator for this study.

SP0203 WHAT DOES REMISSION MEAN FOR PATIENTS?

Ruth Williams. Kings College London, Department of Inflammation Biology, London, United Kingdom

What does remission in Rheumatoid arthritis mean to patient? This session discusses what remission means to patients. Remission holds different meaning for researchers, clinicians and patients. In addition it holds different meaning for individual patients and for individual patients at different points of time in their lives. I shall reﬂect on over ﬁfty years living with Rheumatoid arthritis, as both a patient and a doctor. To consider the changes in my care, my therapy and in my own and my clinicians objectives and treatment aims, at different points in time. Looking at how things have progressed from pain relief, splinting, physical therapy, rehabilitation and surgery. To progressively more effective DMARD’s, anti-TNF’s & Biologics and an aim of complete ‘clinical remission’. However commonly ‘clinical remission’ can conﬂict with a patients concept of remission, as patients are individuals and the tools used to deﬁne remission are research based and consider populations not people. ‘Disease activity scoring’ and ‘Treat to Target’ has had signiﬁcant impact on patients, clinicians and their rheumatology consultations. The absence of inﬂammation does not equal remission for many patients and it is important to consider the differing needs of patients who were diagnosed pre and post biologic therapies and those with refractory disease. Currently maximal energy appears to be concentrated on the newly diag nosed and even pre-diagnosis, but has this been at the detriment of those with long established disease?

I will share my own and different patients viewpoints of what ‘remission’ means and consider the beneﬁts of progress in effective therapies but also to reﬂect upon some of the important things that may have been lost from clinical ‘care’ along the way. To list simple things that can help patients achieve remission that can easily be forgotten. I will explain the phenomenon of ‘DAS blindness’ and the potential failings it can lead to. Discuss how improved shared decision making of treatment aims might improve outcomes for patients whilst reducing risk and possi bly costs; aiming to increase patient autonomy and improve the doctor patient dynamic.

In order to achieve ‘remission’ for patients we need to have a clear shared understanding of what ‘remission’ means to each individual and only then can we aim to achieve it.

Case presentation: facilitating behaviour links between sleep quality and immunity in physical activity, chronic musculoskeletal pain

Yeliz Prior. University of Salford, Centre for Health Sciences Research, Manchester, United Kingdom

Background: Fibromyalgia is a chronic pain condition which is, commonly accompanied by the symptoms of fatigue, sleep disturbance, low mood and cognitive dyscognition. EULAR Revised Recommendations for the management of Fibromyalgia suggests initial management should involve patient education and focus on non-pharmacological therapies [1]. Occupational Therapists at the Rheumatology Outpatients Department, Leighton Hospital, Mid Cheshire NHS Trusts Foundation Trust developed the Fibromyalgia Self-Management Education (FAMe) Group Programme, based on the current evidence-base and patient partner involvement. The primary aim of this programme is to support self-management of Fibromyalgia using behaviour change interventions as outlined in the NICE recommendations. FA Me comprises 2.5 hrs weekly sessions over six weeks (6-Wks) and core components include education about Fibromyalgia, pain, fatigue, sleep and mood management, dealing with dyscognition, physical exercise and practicing mindfulness, based on Cognitive Behavioural Therapy (CBT) and Motivational Interview (MI) approaches.

Objectives: Service evaluation aims to assess how well a service is achieving its objectives. This service evaluation was undertaken with a view to benefit patients using the FA Me Group Programme and is designed and conducted with the sole purpose of defining and examining the current occupational therapy service provision for people with Fibromyalgia at the Mid Cheshire NHS Trust Hospitals. This Case Study will report on the findings of this service evaluation with reference to patient outcomes and discuss the barriers and facilitators of implementing this programme at an NHS Hospital setting.

Methods: Patients with a primary diagnosis of FM were screened and recruited from the rheumatology department of the Mid-Cheshire NHS Hospitals. Patients self-completed postal questionnaires at home (including socio-demographic characteristics; General Health Questionnaire SF-12; Revised Fibromyalgia Impact Questionnaire; Arthritis Self Efficacy Scale; Multidimensional Assessment of Fatigue Scale) at baseline, and again at 6 and 12-week follow-up. Focus groups were held at the hospital following the completion of the FAME Group Programme, to obtain patients’ views on the programme content, delivery and the impact on their self-management. Quantitative data from the baseline, 6 and 12-week follow-up questionnaires were analysed using paired t-tests and effect sizes calculated using eta-squared. Focus groups were transcribed and analysed by three independent researchers, not involved in the initial design or the delivery of this programme, using Thematic Analysis [2].

Results: As the service evaluation is in progress at the time of submitting this abstract, the results will be presented and discussed at the annual meeting.

Conclusion: To be discussed at the meeting.

Restless lives: managing fatigue, sleep and pain

Tanja Lange. University of Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany

Summary: Sleep and the immune system are bi-directionally linked. An immune activation induces fatigue, sleepiness and changes in sleep architecture. These range from a deepening of sleep to severe sleep disturbances with shallow and fragmented sleep. Patients with rheumatic and musculoskeletal diseases (RMDs) often complain about feelings of debilitating fatigue, of problems initiating and maintaining sleep and of unrefreshing sleep. Chronic low-grade inflammation due to the RMD, disease symptoms such as pain, concurrent diseases such as depression and medication such as glucocorticoids are potential triggers of poor sleep. Often it is demanding to delineate the exact cause(s) of sleep impairments in patients with RMDs and attempts to improve sleep quality therefore often fail. However, as fatigue and sleep problems can substantially impair quality of life and as poor sleep may further aggravate RMDs and their symptoms it is key to unravel the pathophysiology of fatigue and poor sleep in these patients. A deeper understanding of sleep-immune interactions in RMDs will advance targeted interventions that presumably will encompass a combination of immunomodulatory drugs, chronopharmacology and cognitive behavioral therapy.

How to build a clinical scientist

Annet van Royen. Background: Clinician scientists are at the heart of the translational medicine process. Over the last decades many reports and studies have showed that they risk becoming extinct, and that efficient career pathways are lacking. Recently more reports show that alarming numbers of clinicians and clinician scientists suffer from burn out and depression. To address this issue, next to thorough study of the root factors leading to mental problems it is important to develop career pathways for clinician scientists and educational programs to improve resilience. New educational programs such as those offered by the Eureka Institute help to build networks of translational scientists and help to strengthen resilience, needs to overcome the challenges they face while pursuing translational research.

Physical activity, chronic musculoskeletal pain and insomnia

Eivind Skarpnes. Norwegian University of Science and Technology (NTNU), Department of Public Health and Nursing, Trondheim, Norway

The interplay between physical activity, chronic musculoskeletal pain and insomnia

The unfavourable consequences of insomnia and musculoskeletal pain for both individuals and society underscore the importance of identifying modifiable factors for prevention and treatment. Prospective studies have shown that there exists a bidirectional relation between insomnia and musculoskeletal pain, i.e., insomnia is associated with risk of chronic musculoskeletal pain and vice versa. This suggests that management of insomnia symptoms may be an efficient treatment objective for people with musculoskeletal pain and that management of musculoskeletal pain has the potential to improve sleep quality. Furthermore, some evidence shows that physical activity may represent an efficient initiative that can improve both sleep quality and chronic pain, potentially leading to effects as beneficial as pharmacological treatment. However, many unresolved questions need to be resolved before physical activity can be prescribed as an optimal treatment.
Pain is well known to be a common dominant symptom in people with rheumatic musculoskeletal diseases (RMDs). Perhaps less well acknowledged by healthcare professionals are fatigue and sleep disturbances in these patients. Individually these symptoms are problematic but when combined their effect and impact on patients’ lives is greatly amplified; often leaving people in a vicious cycle whereby being in pain results in poor sleep leading to fatigue the next day, which lowers patients’ pain tolerance resulting in a poorer night’s sleep, more fatigue and increased pain.

Pain, fatigue and sleep disturbance greatly reduce quality of life for people with RMDs. Patients have to adapt their daily and leisure activities, or give them up altogether with negative psychological consequences such as anxiety and depression. Patients can end up feeling helpless and sometimes suicidal. Relationships with partners and friends are often altered affecting their sexual and social lives. Major life decisions, such as having a baby, can be put on hold or shelved.

People with RMDs may also have to reduce their working hours or stop working, which has financial repercussions for them and their families. This can exacerbate stress, anxiety and depression leading to poorer health outcomes. It is therefore of great importance that healthcare professionals understand the extent to which pain, fatigue and sleep difficulties impact on patients’ lives so that priority can be given to addressing these distressing symptoms as part of any management strategy.

Ingrid Möller. University of Barcelona, Instituto Pau de Reumatologia, Barcelona 08022, Spain

**Background:** Ultrasound-guided needle biopsy of synovium is a minimally invasive tool to complete the study and in the investigation of the therapeutic response in some patients with arthritis. As a consequence, there is a need to have a didactic material and a form of training. This EULAR project: Development of a standardized training model for ultrasound-guided synovial biopsy’s in small and large joints, covers these objectives

**Objectives:**
1. To develop educational material on the procedures for ultrasound-guided minimally-invasive synovial biopsy in small and large joints.
2. To test the consistency, reliability and feasibility of these procedures on cadaveric specimens (Barcelona University, Barcelona, Spain).
3. To validate these procedures by assessing the synovial tissue quality (i.e., number of graded tissue samples per biopsy procedure, amount of RNA extraction) obtained by this biopsy modality in patients (5 patients) from the participating centres. Tissue will be analyzed in a central laboratory (Joint and Bone Laboratory, Fundación Jiménez Díaz, Madrid, Spain).

**Methods:** Meeting in Barcelona was in January 2019 from the 21 to the 25. During the meeting, part of the educational material was produced and the exercise to test the consistency, reliability, and feasibility of these procedures on cadaveric specimens (Barcelona University, Barcelona, Spain) was done. Then the material was circulated among the experts. The validation of these procedures by assessing the synovial tissue quality (i.e., number of graded tissue samples per biopsy procedure, amount of RNA extraction) obtained by this biopsy modality in patients (5 patients) from the participating centres and Tissue analysis in a central laboratory (Joint and Bone Laboratory, Fundación Jiménez Díaz, Madrid, Spain) is ongoing.

**Results:** Here is presented the teaching material produced by the members of this EULAR task force in animal model and cadaver as a basis for learning the ultrasound-guided synovial biopsy technique.

**Conclusion:** The animal model and the cadaver, having the appropriate anatomical and musculoskeletal ultrasound knowledge, are useful for learning ultrasound-guided biopsy. As a complement, you can include the stay with an expert to face the problems of the technique with the real patient. The visualization of the produced video is a useful tool for this learning.

SP0213 **HIGHLIGHTS FROM THE SCIENTIFIC PROGRAMME**

Alexandre Sepriano. Leiden University Medical Center, Rheumatology, Leiden, Netherlands

This talk will cover highlights from the Congress Scientific Programme, encompassing a wide range of topics in the field of rheumatology.

**Disclosure of Interests:** None declared

Background: TNF-α-inhibitor therapy is effective in controlling several rheumatic diseases and has been shown to reduce pain. Non-steroidal anti-inflammatory drugs (NSAIDs) are commonly used for treatment of pain and stiffness in inflammatory arthridities and are the first treatment line in axial spondyloarthritis.

Objectives: To study the prescriptions of NSAIDs in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and anklyosing spondylitis (AS) registered in ICEBIO and matched controls, and explore their relationship with disease activity measures. In addition, to explore the impact of initial TNF-α-inhibitor therapy on NSAID prescription rates.

Methods: All patients receiving biologic DMARD therapy in Iceland for rheumatic diseases are registered in a nationwide database; ICEBIO. The Icelandic Directorate of Health operates a prescription database that includes over 90% of all drug prescriptions in Iceland. On February 1st 2016 we extracted data for all patients with RA, PsA and AS from ICEBIO along with all filled prescriptions for NSAIDs made two years before and after the initiation of TNF-α-inhibitor therapy. We then extracted NSAID prescriptions for five randomly selected individuals matched on age, sex, and calendar time of TNF-α inhibition for each patient.

Results: Data from 366 patients with RA, 218 with AS, 251 with PsA and 4760 controls was included. Control group was prescribed a mean of 23 defined daily doses (DDD) of NSAIDs per year. In total the ICEBIO patients were prescribed 6.7 times more DDDs of NSAIDs than the controls, a mean of 149 per year. After initiation of TNF-α-inhibitor therapy the use of NSAIDs was reduced to a mean of 85 DDD per year, or 3.9 times that of the controls.

Among the patients with RA, consumption was reduced by 43% (mean 148 to 85 DDD/year), 47% in the AS group (154 to 83 DDD/year) and 43% in the PsA group (157 to 90 DDD/year). The 20% of patients who used the largest amounts of NSAIDs over the 4 year period reported worse visual analogue scale (VAS) pain scores (mean ±SD 65 ±20 vs 60±23), VAS global health scores (70±19 to 65±23), and HAQ scores (1.19±0.64 to 1.03±0.67) when TNF-α-inhibitor therapy was initiated compared to the rest of the ICEBIO group (p<0.05 by students t-test), though there was no statistically significant difference in the number of swollen (4.5±4.7 vs 4.2±4.4) or tender (5.4±4.8 vs 5.5±5.4) joints or in the physician global VAS assessment (56±17 vs 57±18).

Conclusion: Patients with inflammatory arthridities requiring TNF-α-inhibitor therapy use more NSAIDs than general population controls, but consumption is significantly reduced following the initiation of the first-line biologic drug. The patients with the highest NSAID use have worse patient reported outcome measures but physician outcome measures are similar, which may suggest a non-inflammatory etiology of the pain.

WE M WEDNESDAY, 12 JUNE 2019

OP0003 CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION IN A COHORT OF 52 PATIENTS WITH GITELMAN SYNDROME

Emilie Choutard1, Anne Blanchard2, Gilles Gaill1, Rosal Vargas Poussou3, Agnès Ostertag1, Hang Komp EA-a,1,4,1 APHP – Lariboisière Hospital, Rheumatology department, Viguier Hospital Centre, Paris, France, 2APHP – Georges Pompidou European Hospital, Nephrology department, Paris, France, 3APHP – Georges Pompidou European Hospital, Department of Genetics, Paris, France, 4University Paris Diderot, INSERM UMR1132 – Bioscal, Paris, France

Background: Gitelman syndrome (GS) is a rare recessively inherited hypomagnesemia and hypocalciuric. Calcium pyrophosphate (CPP) crystal deposition is frequently described in GS case-reports but its prevalence and clinical phenotype are unknown.

Objectives: The aim is to describe clinical, biological and radiological features of CPP in a cohort of patients with genetically proven GS.

Methods: All patients (pts) with genetically proven GS in the French national reference center of rare diseases were proposed to have a consultation with a senior rheumatologist. Demographic data, history of joint pain and flare and biological disorders were recorded. Other causes of CPP disease were systematically ruled out. CPP crystal deposition was assessed by X-rays (all peripheral joints and cervical spine) and ultrasonography (US) (wrist, knee, ankle joints and symtomatic joints). Patients with history of cervical pain underwent computed tomography (CT) of the full cervical spine from occipital bone to C1-T1 disk, including temporomandibular joints.

Results: Fifty-two GS pts (21 men, mean age 46.5±12.2 years) have been examined by a rheumatologist. Almost all pts had an heterozygous mutation on SLC12A3 gene. Forty-four pts experienced joint pain (84.6%), 23 joint flares (44.2%) and 25 cervical pain (48.1%). X-rays were performed in 42 pts, US in 38 and CT in 23. CPP depositions were observed in 36 (85.7%), 27 (71.1%) and 15 pts (65.2%) by X-rays, US and CT, respectively. All techniques combined, chondrocalcinosis was discovered in 42 patients. Deposits occurred in knees (n=32), wrists (n=29), cervical spine (n=23), ankles and feet (n=22) and shoulders (n=16). CPP depositions were widespread involving at least 3 joints in 27 (51.5%) pts. In knees, CPP depositions involved menisci (n=24), hyaline cartilages (n=16) and ligament or joint capsule (n=15). Cervical spine CT demonstrated CPP deposition in vertebral discs (n=17), transverse lagment (n=13), other ligament (n=13), vertebral facets (n=3) and temporomandibular joints (n=5).

Patients with CPP crystal deposition in more than 3 joints were significantly older (52.8±10.5 years) than patients with 2 or 3 affected joints (46.6±11.6 years; p=0.02) or patients without any affected joint (36.6±8.1 years; p=0.001). They were also more symptomatic with significantly more joint flares (p<0.0001). Magnesemia was inversely correlated with the number of affected joints: patients with >3 or 2-3 affected joints had a significantly lower magnesemia (0.57±0.1 and 0.59±0.1 mM, respectively) than patients with only 1 affected joint (0.63±0.1 mM). CPP crystal deposition was not associated with potassium level.

Conclusion: CPP crystal deposition occurred in more than 80% of patients with GS, was widespread and often symptomatic. The most affected sites were wrists, knees and the cervical spine. CPP crystal deposition was associated with longstanding GS, older age and lower serum magnesium level.

WE M WEDNESDAY, 12 JUNE 2019

OP0005 INCIDENCE OF OVERALL AND SITE-SPECIFIC Cancers in TNF INHIBITOR TREATED PATIENTS WITH PSORIATIC ARTHRITIS: A POPULATION-BASED COHORT STUDY FROM 4 NORDIC COUNTRIES

Christine Ballegaard1,2, Karin Høffgensen3, Rand Carlsen1,2, Bénédicte Delcoigne4, Björn Gudbjörnsson5,6, Thordvarud Jon Love7, Kalle Aaltonen8, Dan Nordström9, Selma Ararestad Provan5, Johan Askling10, Lars Erik Kristensen11,12, Laura Eriksen11,12, Lars Erik Kristensen11,12, Lars Eriksen11,12, Lene Dreyer11,12, 1Bispebjerg and Frederiksberg Hospital, The Parker Institute, Frederiksberg, Copenhagen, Denmark, 2Rigshospitalet – Gentofte, Centre for Rheumatology and Spine Diseases, Copenhagen, Denmark, 3Karolinska Institute, Clinical Epidemiology Division and Department of Medicine Solna, Stockholm, Sweden, 4National University Hospital of Iceland, Centre for Rheumatology Research, Reykjavik, Iceland, 5University of Iceland, Faculty of Medicine, Reykjavik, Iceland, 6Ministry of Social Affairs and Health, Helsinki, Finland, 7RCB-FIN, Helsinki University Hospital and Helsinki University, Department of Medicine, Helsinki, Finland, 8Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway, 9Aalborg University and Aalborg University Hospital, Aalborg, Denmark, 10DANBIO, Nationwide, Denmark

Background: Turnover necrosis factor inhibitors (TNFi) effectively reduce inflammation in Psoriatic arthritis (PsA). However, a possible association between treatment with TNFi and an increased cancer risk has previously been suggested.

Disclosure of Interests: None declared

Objectives: To investigate the risk of cancer in TNFi-treated PsA patients compared with standardized rates from the general population in Denmark, Finland, Iceland and Sweden.

Methods: TNFi-treated PsA patients were followed from first registration with TNFi-treatment in ARTIS (Sweden), DANBIO (Denmark), ICEBIO (Iceland) or ROB-FIN (Finland) and linked to the national Cancer Registry in each country. Patients with a cancer history prior to start of follow-up were excluded. We investigated the risk of primary cancer among TNFi-treated PsA patients compared with general population cancer rates standardized to age, sex and calendar period within each country. Standardized incidence ratios (SIRs) were estimated for each country and pooled SIRs were subsequently calculated for both any cancer and site-specific cancers of interest.

Results: A total of 5218, 2039, 270 and 526 patients were registered as ever treated with TNF inhibitors from ARTIS, DANBIO, ICEBIO and ROB-FIN, respectively, contributing a total of 44,041 patient years of follow-up across all 4 countries. For all cancers, the SIRs of TNFi-treated patients from ARTIS, DANBIO, ICEBIO and ROB-FIN were 0.94 (0.80 to 1.10), 0.99 (0.77 to 1.26), 1.71 (0.88 to 2.99) and 1.28 (0.92 to 1.90), respectively. The number of observed and expected cancers and the SIRs of any and selected site-specific cancers are listed in table 1.

</tbody>
</table>

Conclusion: Our results suggest that the overall cancer risk for TNFi-treated PsA patients is not increased compared to the general population. Further analysis of the risk of malignant lymphomas will inform on whether the increased risk we observed is attributed to the PsA disease or treatment with TNFi.

Objectives: To investigate the impact of Olmesartan and Rosuvastatin on endothelial dysfunction and inflammation in PsA.

Methods: 54 PsA patients randomized to receive 24 weeks of treatment with Olmesartan (OLME) (10mg/day, n=18), Rosuvastatin (Rvs) (10mg/day, n=18), and placebo (PL) (n=18) as an adjunct to existing stable anti-rheumatic drugs. FMD assessed by AngioDefender. EPCs estimated by flow cytometry. Serum nitrite, TBARS, ICAM-1, VCAM-1 and lipid levels estimated at baseline and after treatment. Inflammatory measures included DAS28, DAPSA, ESR and CRP, pro-inflammatory cytokines. Quality of life and CV 10-year risk (SCORE high risk charts) were estimated using standard tools.

Results: Baseline levels of FMD and EPC population were impaired indicating endothelial dysfunction. Basal concentrations of inflammatory markers, pro-inflammatory cytokines and markers of endothelial dysfunction were elevated among three groups. After 24 weeks treatment, FMD improved significantly in rosuvastatin and olmesartan group as compared to placebo. [OLME vs. PL (p<0.01), Rvs vs. PL (p<0.01), Rvs vs. OLME (p=0.10)] (Fig.1A). EPCs and nitrite (Fig.1B) levels improved significantly in both rosuvastatin and olmesartan groups. Significant reduction found in ICAM-1 after rosuvastatin treatment (p<0.01) where as olmesartan significantly decreased VCAM-1 (p=0.04) and ICAM-1 levels (p=0.05). Both rosuvastatin and olmesartan resulted in significant reductions of DAS28, DAPSA, ESR, CRP, IL-6 (Fig.1C) and TNF-α (Fig.1D) as compared to placebo. There was a significant reduction in SCORE, HAQ-DI and SF-36 (PH) score after treatment with rosuvastatin and olmesartan.

Conclusion: Olmesartan and rosuvastatin improve endothelial dysfunction, inflammation, CV risk and quality of life in PsA patients. Olmesartan and Rosuvastatin lower the proinflammatory cytokines, especially TNF-α, that down regulates production of CRP, adhesion molecules and nitric oxide which in turn improves endothelial dysfunction. Both drugs also decrease nitrite concentration and improve the EPC population in PsA patients. The augmentation of EPCs by olmesartan and rosuvastatin represents a fascinating new approach for the management of PsA. However, Rosuvastatin in addition also favourably impacted ICAM-1 and lipid abnormalities. In contrast, olmesartan has beneficial effect on blood pressure. Thus, both rosuvastatin and olmesartan demonstrate immunomodulatory, vasculoprotective and cardioprotective potential in PsA mediated through anti-proinflammatory cytokine action.

High Body Mass Index (BMI) in Psoriatic Arthritis (PsA) is Associated with Higher Disease Activity in Joints and Skin, Impaired Quality of Life and More Disability: Results from the PsA Bio Study

Stefan Siebert1, Paul Bergmans2, Kurt de Vlam3, Elise Gremese4, Beatrix Joven Ibáñez5, Tatiana Korotaeva6, Wim Noël7, M.T. Nurmohamed8,9, Petros Sfikakis10, Ana Laiz11, Pavel Smirnov12, Elke Theander13, Josef S. Smolen14

Background: The link between obesity and disease activity in PsA is unclear. Obesity has been associated with a poorer therapeutic response and higher treatment discontinuation rates in patients with PsA being treated with tumour necrosis factor inhibitors (TNFi). Recent data confirm the favourable effect of weight reduction on these factors. There are no data available for other biologics.

Objectives: To investigate the relationship between baseline overweight/obesity and disease activity, patient-reported outcomes and disability, in a large real-world cohort of patients with PsA starting biologic treatment with either ustekinumab (UST) or TNFi.

Methods: The PsABio study (ClinicalTrials.gov: NCT02627768) is an ongoing observational study evaluating efficacy, tolerability and persistence of 1st, 2nd- and 3rd-line UST or TNFi in PsA in 8 European countries1 when introduced as part of standard clinic. Baseline data of the study population were collected and analysed for BMI, disease activity (cDAPSA, psoriasis BSA), patient-perceived impact (PsAID-12), disability (HAQ-DI) and presence or history of CVD/MET. Descriptive statistics are used for the analysis. The patients were assessed with 66/68 joints count, Leeds enthesitis index, skin involvement, patient-reported outcomes and disability.

Results: The PsABio study enrolled 467 patients with PsA (Caspar criteria) and obesity (body mass index BMI ≥ 25 kg/m²) with or without treatment. The mean (SD) age 49.7 (12.5) years, 55.5% female. The mean (SD) baseline BMI (N=467) was 28.1 (5.8) kg/m², with 40.0% and 30.4% in BMI categories overweight (≥25–30) and obese (>30), respectively. In univariate analyses, obesity was associated with more severe disease (Table 1). More severe disease was associated with higher BMI (Table 2). In a regression model, obesity was independently associated with higher BMI (β = 0.09, p = 0.028) with higher patient-perceived disease activity impact measured by PsAID-12 (BMI: β = 0.16, p < 0.0001) and decreased HAQ-DI (BMI: β = 0.21, p < 0.0001).

Conclusion: This multi-country routine-care PsA cohort of patients in need of biologic treatment confirms the high prevalence of overweight/obesity and indicates an independent association between high BMI and disease activity as well as patient-reported impact of disease and disability. These results emphasize the need for lifestyle-directed approaches in PsA, such as overweight management in parallel with joint- and skin-focused treatment.

Environmental influences on disease development_  

OP0009 RESISTANT STARCH INTAKE ALLEVIATES COLLAGEN-INDUCED ARTHRITIS IN MICE BY MODULATING GUT MICROBIOTA AND PROMOTING SCFAs PRODUCTION

Yunqiang Bai, Yanli Tong, Yi Liu, Yubin Luga, Department of Rheumatology and Immunology, West China Hospital, Sichuan University, chengdu, China

Background: Dietary intervention has been an auxiliary therapy in many diseases treatment. Increasing evidences indicate that dietary compositions vary in their impacts on gut microbial constitution and function capable of affecting the systemic immune status of the host. Recently, a high fiber diet (HFD) receives close attention due to its effective improvement in symptoms in metabolic diseases and inflammatory diseases. It is also reported that intake of fruits and vegetables can improve the clinical symptoms of rheumatoid arthritis (RA) to a moderate extent. However, it remains unclear how a high fiber diet cross-talks with gut flora and RA initiation or remission.

Objectives: To systematically evaluate the effect of a high fiber diet mainly composed of resistant starch, a new resource of soluble fiber, on collagen-induced arthritis (CIA) mice and gut microbial composition. Meanwhile, the relative mechanisms was explored in this study.

Methods: CIA was established by immunization mice with collagen on day 0 and 21. Arthritis severity was evaluated by clinical score, histological staining and micro CT. Fresh stool was collected and gut microbiota analyses were performed via 16s RNA sequencing. Gut barrier dysfuction was evaluated by detecting the Na+K+ channel and Claudin-1 gene expression in the intestine. ScFAs level was examined via GC-TOFMS and real-time PCR, respectively.

Results: High fiber feeding accelerated the arthritis remission in CIA mice, evidenced by the inflammatory cell infiltration reduction in the joints and bone erosion improvement. TH1, 2 and 17 cell population were not affected by HFD. While, regulatory T cell (Treg) percentages in the intestinal lamina propria and spleen were significantly increased with the gut flora alteration. Meanwhile, HFD-treated CIA mice had much higher levels of SCFAs in the blood and GPR43 gene expression in the intestine. Blocking SCFAs production by adding hogs extract β-acids into drinking water completely eliminated the beneficial effect of HFD on joint swelling, bone erosion and Treg cell expansion in CIA mice.

OP0010 CARTILAGE THICKNESS MODIFICATION WITH SPRIFERMIN IN KNEE OSTEOARTHRITIS PATIENTS TRANSLATES INTO SYMPTOMATIC IMPROVEMENT OVER PLACEBO IN PATIENTS AT RISK OF FURTHER STRUCTURAL AND SYMPTOMATIC PROGRESSION: POST-HOC ANALYSIS OF THE PHASE II FORWARD TRIAL

Hans Gühling1, Jeffrey Kranier2, Flavie Moreau2, Benjamin Daaeten1, Christoph Ladef1, Wolfgang Wirth3,4, Philip G. Conaghan3,4, Felix Eckstein3,4; 1Merck KGaA, Darmstadt, Germany; 2Paracelsus Medical University, Salzburg, Austria; 3Chondrometrics GmbH, Alling, Germany; 4University of Leeds, Leeds, United Kingdom; 5University of Maryland, Baltimore, United States of America

Background: Results from the 5-year Phase II FORWARD study showed significant dose-dependent modification of total femorotibial joint (TFTJ) cartilage thickness change with sprifermin at 2 and 3 years, by quantitative MRI. Total Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores improved by >50% in all treatment groups, excluding placebo (PBO). Selection of a patient (pt) subgroup with higher pain scores and lower joint space width (JSW) at baseline (BL), to identify pts who are at risk of further structural and symptomatic progression, may facilitate better WOMAC discrimination.

Objectives: Post-hoc analysis to evaluate cartilage thickness changes and symptomatic outcomes in an “at risk” subgroup of pts (BL medial or lateral minimum [m]JSW 1.5–3.5 mm and BL WOMAC pain score of 40–90).

Methods: Pts in FORWARD were randomized 1:1:1:1:1 to: sprifermin 100 μg every 6 months (q6mo); 100 μg q12mo; 30 μg q6mo; 30 μg q12mo; and PBO. The treatment period was 2 years, with an extended follow up at 3 years. Post-hoc analysis was conducted in the “at risk” subgroup. Treatment effects were estimated using a repeated measures model, controlling for BL, treatment, time, country and treatment by time interaction. Linear dose-effect trend tests were performed exploratively at each timepoint. Confidence intervals (CIs) were adjusted for multiplicity of treatments using Dunnett adjustment.

Results: 161/549 (29%) pts met criteria for the “at risk” subgroup. In this subgroup, BL characteristics were balanced between treatment arms. Pts in the PBO arm had more cartilage loss and greater JSW changes at BL compared to other groups. Treatment effects were estimated using a repeated measures model, controlling for BL, treatment, time, country and treatment by time interaction. Linear dose-effect trend tests were performed exploratively at each timepoint. Confidence intervals (CIs) were adjusted for multiplicity of treatments using Dunnett adjustment.

PAIN IN THE TREATMENT OF OVERWEIGHT AND
KNEE OSTEOARTHRITIS: A RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

Henrik Gudbergsen1, Anders Overgaard1, Marius Henriksen1,2, Eva Eijersen Wahlrens1,2, Henning Biddal1, Robin Christensen1,2, Sabrina Mai Nielsen1, Mikael Boesen1,5, Filip Krag Knoop1,2, Anne Astup1, Marianne Uggen Rasmussen1, Cecile Radgaard Bartholdy1, Cecile Daugaard1, Elise Marie Bartels1, Karen Etegaard1, Berit Lilenthal Heltmann1, Lars Erik Kristensen1,2, Bisselberg-Frederiksberg Hospital, University of Copenhagen, The Parker Institute, Frederiksberg, Denmark; Bisselberg-Frederiksberg Hospital, University of Copenhagen, Department of Physio- and Occupational Therapy, Frederiksberg, Denmark; Research Unit for General Practice, Institute of Public Health, University of Southern Denmark, Research Initiative for Activity Studies and Occupational Therapy, Odense, Denmark; Odense University Hospital, Department of Rheumatology, Odense, Denmark; Bisselberg-Frederiksberg Hospital, University of Copenhagen, Department of Radiology, Frederiksberg, Denmark; Steno Diabetes Center Copenhagen, Gentofte Hospital, Clinical Metabolic Physiology, Hellerup, Denmark; Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; Faculty of Science, University of Copenhagen, Department of Nutrition, Exercise and Sports, Copenhagen, Denmark; Section for General Medicine, University of Copenhagen, Department of Public Health, Copenhagen, Denmark

Background: Weight loss is recommended as treatment of concomitant knee osteoarthritis (OA) and overweight. The GLP-1 receptor agonist liraglutide has been shown effective in maintaining or even further reducing weight loss, but the compound has not been tested in a population of patients with overweight and knee OA.

Objectives: The objective of this trial was to investigate if liraglutide in a 3 mg/day dosage was effective in maintaining weight loss and symptomatic effects 52 weeks after an initial 8-week dietary-based weight loss intervention dosing in patients with overweight and knee OA.

Methods: Patients with overweight or obesity and knee OA participated in a randomised, double blind, placebo-controlled, parallel group, single-centre trial. Patients were provided an initial 8-week run-in diet intervention (week -8 to 0) including a low-calorie diet from Cambridge Weight Plan and dietetic counselling. At week 0 patients who had lost at least 5% of their initial body weight were randomised to liraglutide 3 mg/day or placebo for 52 weeks. The co-primary outcomes were changes in body weight and the KOOS pain subscale from week 0 to 52.

Results: 168 patients (Kellgren-Lawrence grade 1-3) were enrolled in the initial 8-week diet intervention and 156 patients were randomised (Figure 1). Before randomisation the 156 patients had lost 12.46 kg (SD:3.82) (∼12%) and improved in KOOS pain corresponding to 11.86 points (SD.15.13) (∼19%). Baseline characteristics were similar in the intervention and control groups. From baseline to 52 weeks there was a statistically and clinically significant difference in the weight loss between the liraglutide and the placebo groups (mean -2.76 and 1.17 kg, respectively; group difference, 3.93 kg; 95%CI -6.85 to -1.02; p=0.008), there was no difference between groups in change in KOOS pain (mean changes: 0.35 and -0.14 kg respectively; group difference, 0.50 kg; 95%CI -0.90 to 1.90; p=0.51).

Additional analyses of the weight loss effect showed no differences between baseline and end of intervention in the subgroups at 2 and 3 years. There was a statistically and clinically significant difference in the WOMAC pain subscale improvements vs PBO increased over time and were significant at Year 3. This supports further investigation of liraglutine as a potential disease-modifying osteoarthritis drug in a targeted population where structural improvement may translate into symptomatic benefit vs PBO within a reasonable timeframe.
-0.55 points, respectively; group difference, 0.89 points; 95%CI -3.89 to 5.68; p=0.713). Week 52 least squares means for body weight and knee pain intervention significantly reduced body weight and knee pain. Liraglutide treatment added after the initial diet-induced weight loss provided further weight loss over 1 year but did not reduce knee pain any further compared to placebo.

**EFFECTIVENESS OF TNFI AFTER A FIRST SWITCH IS LOWER IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS: A LATERALISATION ANALYSIS OF THE DESIR COHORT**

Marion Pons1, Sylvie Chevret2, Karine Briot1, Marie-Antoinette D’Agostino3, Christian Roux1, Maxime Dougados1,2, Anna Molto1,2, Laurence Carton1, Claire Cardon1, Francoise Alliot Launois1, Gerard Chales1, Christian Roux1,2, Maxime Dougados1,2, Anna Moltó1,2, Laurence Carton1, Claire Cardon1, Francoise Alliot Launois1, Gerard Chales1.

#### Background:

Some contradictory data has been reported on the effectiveness of a second and third line of TNFi in early axial spondyloarthritis (axSpA). **Objectives:** To evaluate the effectiveness after a first and second TNFi switch, in real life conditions, over 5 years of follow-up in an early axSpA population.

#### Methods:

Observational prospective French cohort (DESIR) with 5 years of follow-up, including 708 TNFi-naïve early axSpA patients. Study visits were scheduled every 6 months in the first two years of follow up then yearly up to 5 years. Treatment (TNFi or other) was at the discretion of the treating rheumatologist(s). The characteristics of patients who received a second and a third TNFi were compared to those who never switched. Effectiveness was defined by the drug survival of the first, second and third TNFi were estimated by the Kaplan-Meier method, and compared using the log-rank test.

#### Results:

Of the 708 patients included in the analysis, 258 (36.4%) patients initiated a first TNFi during the 5 years of follow up. Of these, 127/258 (49.2%) patients switched to a second TNFi, and among them 59/127(46.5%) switched to a third TNFi. Patients who switched to a second or a third TNFi were more frequently older, predominantly females, HLA-B27 negative with MRI and radiographic sacroiliitis negative, without history of peripheral arthritis, and with higher BASFI and BASDAI scores at baseline of the DESIR cohort (see table). Estimated median drug survival for the first, second and third TNFi was 21.7 months [95%CI 17.6-33.8], 16 months [95%CI 15.1-24.4] and 25 months [95%CI 11.8-NA] respectively. Drug survival was significantly extended for the first TNFi compared to the second one (p<0.04), but no differences were observed between the 2nd and the 3rd TNFi.

#### Conclusion:

Our study suggests a poorer TNFi effectiveness after a first switch in real-life conditions in early axial spondyloarthritides.

### OP0013-PARE

**AFLAR’s – FRENCH LEAGUE AGAINST RHEUMATISM – POSITION AND PATIENT INFORMATION ACTION ABOUT BIOSIMILAR MEDICINES IN FRANCE**

Laurence Carton1, Claire Cardon1, Françoise Alliot Launois1, Gerhard Chales1, Brigitte Lisée2, Laurent Grange2,3, PATIENTS’ of AFLAR, 1Association Française de Lutte AntiRhumatismale A.F.L.A.R, Paris, France; 2Association Française de Lutte AntiRhumatismale A.F.L.A.R, Paris, France; 3University hospital of Grenoble Alps-Stud hospital, Rheumatology, Écholeurs, France

#### Background:

20 years after biotherapies were introduced in rheumatic diseases treatment in France, biosimilars are a new medical and economic issue in terms of therapeutic opportunities, and innovative treatment spreading and development. Patients’ rights - quality of life, information on treatment and safety - as well as public health cost management, medical and other caregivers’ practices are involved.

#### Objectives:

AFLAR wants to play an active role in these fields, as about one million of patients with inflammatory rheumatic diseases, and next other diseases, are concerned.

#### Methods:

AFLAR’s patient led board (1), medical and scientific experts and especially expert patients have been working together to:

1. state AFLAR’s position about biosimilars
2. define the most adapted association’s actions in the field of biosimilars
3. create the most proper tool to inform and empower patients to their rights, especially in the field of treatment efficacy and safety.

#### Results:

A position paper leading to a press release dated Dec. 7th, 2018 prior to national rheumatology medical congress opening has been achieved. An informative tool to be used for shared medical decision when biosimilars are involved, is currently in progress. AFLAR’s position on biosimilars includes 2 statements and 6 advises addressed to patients, caregivers and other stakeholders:

#### Statements:

1. Biosimilars are a medical and healthcare cost reduction effective solution in rheumatic diseases treatment
2. Biosimilars have scientifically proved their efficacy and safety in past and ongoing studies; drug safety monitoring is ensured by national and European drug safety agencies.

#### Advices:

1. Further continuous clinical post-marketing studies should be achieved, and their results easily available to patients
2. Patient should be properly informed each time a biosimilar is proposed if their results easily available to patients.
3. Biosimilar drug can be prescribed for cost reduction reason as initial biotherapies treatment, when not contraindicated
4. Blind random switch from originator to biosimilar and among biosimilar products should not be done, based on precautionary principle
5. Patient should be precisely informed of product with biosimilar name (not only international non–proprietary name), and batch number, as this allows
mandatory pharmacovigilance by professionals and patients. As per law (2) and professional ethics, patient preference and right to informed consent must prevail.

6. Self-assessment surveys, and patient reported outcomes using studies, should be encouraged. These are facilitated by new information technologies and practices and devices.

Conclusion: The information tool will be proposed in the form of an information letter to be remitted by professionals to patient when biosimilar prescription or initiation is planned. The process includes:

1. creation of document by expert patients
2. user testing of tool (assessment about understandability and usefulness), in hospital departments, patient groups and on-line
3. knowledge assessment and opinion gathering among patients about biosimilars.

REFERENCES:
[1] According to its current by-laws, AFLAR board consists of at least 2/3 of persons affected with/considered by rheumatic diseases, and/or presidents of affiliated patient associations.

How to perform low-budget high-quality research

NO ASSOCIATION BETWEEN THE PROPORTION OF ELDERLY PEOPLE AND TRIAL RETENTION IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS TRIALS: A SYSTEMATIC REVIEW WITH META-REGRESSION ANALYSES

Andriko Palmowski1, Sabrina Mai Nielsen2, Thomas Buttgerite1,2, Yannick Palmowski1,2,3, Maarten Boers3, Robin Christensen2, Frank Buttgerite1,3
1Charité – University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Musculoskeletal Statistics Unit, The Parker Institute, Bispertjerg and Frederiksberg Hospital and The Rheumatology Research Unit, Department of Rheumatology, Odense University Hospital and University of Southern Denmark, Kopenhagen and Odense, Denmark; 3Charité – University Medicine Berlin, Department of Dermatology, Venerology, and Allergology, Berlin, Germany; 4Charité – University Medicine Berlin, Center for Musculoskeletal Surgery, Berlin, Germany; 5Department of Epidemiology and Biostatistics, and Amsterdam Rheumatology and Immunology Center, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Background: The elderly (defined by an age of ≥65 years) are underrepresented in current rheumatoid arthritis (RA) and osteoarthritis (OA) trials. This is partly due to age-related exclusion criteria. Investigators might be reluctant to include more elderly people because they fear reduced trial retention.

Objectives: To evaluate whether the proportion of included elderly individuals (PE) is associated with trial retention in current RA and OA trials.

Methods: This study is registered with protocols.io (dx.doi.org/10.17504/protocols.io.uan62e). In our previous study,1 two systematic searches in MEDLINE and Cochrane had yielded randomized controlled trials (RCTs) in rheumatoid arthritis (RA) and osteoarthritis (OA) on any intervention published in 2016 and 2017. Here we included all trials reporting data on retention. We either extracted the PE from the research manuscript or estimated it from an assumed (truncated) normal distribution. We coded retention into proportional effect sizes (logit-transformed for analysis and back-transformed for reporting). Subsequently, multiple mixed effects meta-regression models with several covariates assessed whether there is an association between the PE and trial retention. Sensitivity analyses evaluated whether associations were connected to attrition due to lack of efficacy (LoE) or adverse events (AE).

Results: 243 RCTs comprising 48,288 participants were deemed eligible, and 227 RCTs provided complete data on overall retention and all covariates. Pooled trial retention (random effects) was 88% (95%-CI 87% to 90%; p² = 90%). The PE was not associated with trial retention in the unadjusted (slope β = 0.0 [-0.0 to 0.0]; p = 0.97; Figure 1), or any protocolized adjusted model (p-values depending on the adjustment: 0.14 to 0.90). Of all included covariates, only study duration (longer study duration being associated with inferior retention; p < 0.001) and the type of intervention (surgical interventions averaging the highest retention; psychological interventions averaging the lowest retention; p < 0.001) were associated with trial retention. Post hoc analyses allowing for interaction revealed a small statistically significant association between the PE and trial retention in pharmacological (retention increasing with the PE) and physical/physiotherapeutic (retention decreasing with the PE) interventions. Further sensitivity analyses showed no significant associations between attrition due to LoE or AE and the PE in any model.

Conclusion: Trial retention in RA and OA trials is very high, and unaffected by the proportion of elderly.

Kitas1, Dimitrios Vasilopoulos1,4,5; Joint Rheumatology Program, University of Athens School of Medicine, Athens, Greece; 2Rheumatology Clinic, University of Ioannina, Ioannina, Greece; 3Clinical Immunology and Allergy Department, University of Crete, Heraklion, Greece; 4Rheumatology Unit, KAT Hospital, Athens, Greece; 5Rheumatology Unit, Sismanoglio Hospital, Athens, Greece; 6Department of Rheumatology, University of Thessaly, Larissa, Greece; 7Rheumatology Unit, WIMTS Hospital, Athens, Greece; 84th Department of Medicine, University of Ioannina, Thessaloniki, Greece; 9Rheumatology Unit, Agios Andreas Hospital, Patras, Greece; 10Private Practice, Levidia, Greece; 11Private Practice, Athens, Greece; 12Private Practice, Thessaloniki, Greece.

Background: Identification of the risk factors for the development of serious infections in patients with rheumatoid arthritis (RA) is critical for designing preventive measures and early treatment.

Objectives: To identify risk factors for serious infections and to validate the RABBIT risk score in RA patients in daily clinical practice.

Methods: Multicenter prospective study of RA patients in Greece. Demographics, disease characteristics, treatments and co-morbidities were prospectively collected via a web-based platform at baseline and one year later. The observed incidence of serious infections was compared to the one estimated by the RABBIT score.

Results: 1,549 RA patients were included (women: 78%, mean age: 63 years, mean disease duration: 10.4 years, RF and/or anti-CCP positive: 54%, mean DAS28: 3.4, mean HAQ: 0.5, bDMARD use: 46%, corticosteroid use: 36%). During follow-up, 38 serious infections were recorded (incidence: 2.3/100 patient-years). Patients who developed a serious infection had longer disease duration (14.2 vs. 10.3 years, p=0.02), higher HAQ at baseline (0.85 vs. 0.5, p=0.006), a history of previous serious infection (26% vs. 10%, p=0.002) and were more likely to have chronic lung disease (23% vs. 9%, p=0.008) or cardiovascular disease (23% vs. 11%, p=0.04). Disease duration (OR: 1.04, CI: 1.01-1.08, p=0.025), history of previous infection (OR: 3.3, CI: 1.3-8.1, p=0.01) and chronic lung disease (OR: 3.03, CI: 1.77-5.85, p=0.005) remained statistically significant in multivariate logistic regression analysis. NDUMARD use was not associated with increased risk in uni- or multi-variate analysis. Data for RABBIT score calculation were available in 1,349 patients. Estimated incidence per 100 patient-years was divided in Q1-Q4 quartiles (25-75th percentiles: 0.94-1.35-2.15). Estimated and observed incidence rates were in Q1: 0.8 and 0.54, Q2: 1.14 and 0.97, Q3: 1.76 and 1.84 and Q4: 3.7 and 5.6, respectively (Hosmer-Lemeshow test, p=0.9).

Conclusion: In this large, real-life, prospective study of RA patients, the incidence of serious infections was 2.3/100 patient-years. Longer disease duration, history of previous serious infections and chronic lung disease were independently associated with the development of serious infections. RABBIT score predicted rather accurately the risk for serious infections in our cohort.

Scientific Abstracts

WHAT TO CHOOSE: A SECOND TNFI OR AN ALTERNATIVE CLASS OF BIOLOGIC FOR PATIENTS WITH JIA WHO HAVE FAILED THEIR FIRST TNFI

Lianne Kearsey-Fiek1; Rebecca Davies1, Jennifer Page2, Eileen Baldam2, Michael Beresford3, Helen Foster1, Taunton Southwood3, Wendy Thomson1, Kimme Hyrich1, 4; 1The University of Manchester, Manchester, United Kingdom; 2Aber Hey Children’s NHS Foundation Trust, Clinical Academic Department of Paediatric Rheumatology, Liverpool, United Kingdom; 3University of Liverpool, Institute of Translational Medicine (Child Health), Liverpool, United Kingdom; 4Great North Children’s Hospital and Newcastle University, Paediatric Rheumatology, Newcastle upon Tyne, United Kingdom; 5University of Birmingham and Birmingham Children’s Hospital, Institute of Child Health, Birmingham, United Kingdom; 6Manchester University NHS Foundation Trust, NIHR Manchester BRC, Manchester, United Kingdom

Background: Biologic therapies, second-line treatment after failure of methotrexate, have revolutionised treatment pathways and outcomes for patients with juvenile idiopathic arthritis (JIA). The expanding choice allows patients to switch biologic if current treatment is not working. Current NHS England guidelines recommend most patients with JIA to start a tumour necrosis factor inhibitor (TNFI), and if that fails switch to a second TNFI rather than change class. The evidence base for this in JIA is limited.

Objectives: The aim of this study was to compare the effectiveness of a second TNFI versus an alternative class of biologic therapy in patients with polyarticular JIA following initial TNFI therapy in routine clinical practice.

Methods: Analysis included patients with JIA starting a second biologic following initial TNFI therapy in two UK cohort studies; B Spar-ETN and BCRD. Within the studies, data percent per 12 months, 6 months, 1 year, 2 years, 3 years and 5 years of data per patient were collected of efficacy and anti-rheumatic therapy. Patients with extended oligoarticular and polyarticular (rheumatoid factor positive and negative) JIA were included. Patients with a history of uveitis at start of second biologic were excluded. Patient characteristics and anti-rheumatic therapy were compared between patients starting a second TNFI versus an alternative class. Kaplan-Meier drug survival was used to assess drug survival on second biologic. Stop reasons of second biologic were described. Change in core outcome variables, JADAS-71, American College of Rheumatology Paediatric 50% response (ACR Pedi 50), and Minimal Clinically Important Difference (MCID; ≥0.13 reduction in CHAQ) from baseline to one year was compared between the two cohorts. Multiple imputation and propensity scores were used to account for missing baseline co-variate data and adjust for confounding by indication.

Results: 151 patients with polyarticular JIA starting a second biologic up to 13-Nov-2018 were included; 115 (76%) a second TNFI, 36 (24%) an alternative class. Patient characteristics at the start of second biologic were mostly similar except patients starting a non-TNFI had lower CRP levels (p=0.001). There was no difference in second biologic drug survival between the two cohorts (p=0.8), with approximately 60% remaining on drug by one year. The majority reported inefficacy as stop reason (51%). There was no difference between one year improvement in core outcome variables or JADAS-71 after start of second biologic, and no difference in the odds of achieving ACR Pedi 50 response (odds ratio 0.8; 95% confidence interval [CI] 0.3, 2.5; p=0.7) and ACR Pedi 70 (OR 1.0; CI 0.3, 3.1; p=0.9) between patients starting a second TNFI versus a non-TNFI.

Conclusion: In this real-world cohort of children and young people with JIA starting a second biologic following initial TNFI therapy failure, there appears to be no difference between drug survival and effectiveness outcomes in those patients switching to a second TNFI compared with a non-TNFI biologic. Further research on larger sample sizes is required to know whether there is any initial advantage to switching class of drug following failure of a first TNFI.

Background: In the SENSICS trial, nintedanib reduced the progression of interstitial lung disease associated with systemic sclerosis (SSc-ILD) compared with placebo, as demonstrated by a significantly lower rate of decline in forced vital capacity (FVC) over 52 weeks (primary endpoint).

Objectives: To assess the effect of nintedanib on the rate of decline in FVC in the SENSICS trial across pre-specified subgroups defined by baseline characteristics.

Methods: Patients with SSc-ILD with onset of first non-Raynaud symptom <7 years before screening and >10% fibrosis of the lungs on a high-resolution computed tomography scan were randomised to receive nintedanib 150 mg bid or placebo double-blind. The annual rate of decline in FVC (ml/year) assessed over 52 weeks (primary endpoint) was analysed in the overall population using a random coefficient regression model (with random slopes and intercepts) including anti-topoisomerase I antibody (ATA) status, age, height, gender and baseline FVC as covariates. Analyses in subgroups by baseline characteristics included additional terms for treatment-by-subgroup and treatment-by-subgroup-by-time interaction.

Results: A total of 576 patients were treated (288 in each group). Most (75.2%) of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline. Mean ± SD age was 54.0 ± 12.2 years and 21.4% of patients were female, 51.9% had diffuse cutaneous SSc, and 48.4% were taking mycophenolate at baseline.

Conclusion: Nintedanib is effective at reducing ILD progression in a broad range of patients with SSc-ILD.
(KO) mice were bred to generate homozygous KOs and mouse articular cartilage was isolated to culture chondrocytes. Results: miR-34a expression was significantly elevated in the plasma as well as cartilage and synovium of TKA patients (KL IV) compared to healthy controls and early OA patients (KL I), respectively. Similarly, miR-34a was significantly downregulated in mouse knee joints (cartilage and synovium) at 10 weeks post OA surgery compared to sham. To identify the biological effects of miR-34a on chondrocyte and synovial fibroblast (SF), functional studies were conducted in vitro. Chondrocytes treated with miR-34a mimic had a significant reduction of SIRT1 (a direct target of miR-34a), anabolic (type II collagen and aggrecan) and autophagy markers, as well as, elevated catabolic markers (MMP13), suggesting that miR-34a contributes to cartilage degeneration. Chondrocytes treated with miR-34a inhibitor reversed these destructive effects. SFs treated with miR-34a mimic expressed elevated inflammatory (TNF-α, IL-6), fibrotic (TGF-β), Type 1 Collagen), and autophagy markers, suggesting that miR-34a is involved in mediating synovial inflammation and fibrosis. SFs treated with miR-34a inhibitor reversed these effects.

In vivo, intra-articular injection of miR-34a mimic induced cartilage damage, loss of proteoglycan content, and elevated cell death markers (PARP p85 and Caspase 3) in the articular cartilage. To confirm the destructive effects of miR-34a in the articular cartilage, we used miR-34a KO mice. miR-34a KO mice further confirmed that general inhibition of miR-34a resulted in marked elevation in the expression of anabolic markers (type II collagen and aggrecan) and decreased expression of catabolic ADAMTS-5 in the articular cartilage. To test the therapeutic potential of blocking miR-34a, we intra-articularly injected miR-34a inhibitor in mice subjected to OA surgery. Results showed marked reduction in the severity of cartilage degeneration in mice treated with miR-34a inhibitor.

Conclusion: This study, for the first time, demonstrates miR-34a as a crucial mediator involved in OA pathogenesis and as a potential therapeutic target for lim- iting cartilage destruction during OA.

LESS IS MORE: ANA-LYING THE IMPACT OF REPEATED ANTIMICROBIAL ANTIBODY TESTING

Ai Li Yeo1,2,3, Jason Ong3, Kathryn Connelly1, Suong Le2, Ronnie Ptasznik2, Jane Ross3, Eric F. Morand1,3, Michelle Leech1,3, Monash Health, Department of Rheumatology, Melbourne, Australia; 2Monash Health, Department of Rheumatology, Melbourne, Australia; 3Monash Health, Department of Informatics, Melbourne, Australia; 4Monash University, Melbourne, Australia

Background: Minimising unnecessary tests is a global health economic priority with multiple initiatives in place to avoid inappropriate healthcare utilisation(1) and harm. Anti-nuclear antibody (ANA) testing is frequently performed as a diagnostic test for autoimmune conditions, such as systemic lupus erythematosus (SLE) or as a screening test in patients with inflammatory or musculoskeletal symptoms. The value of serial testing in the monitoring of such conditions is unclear and false positive tests can lead to unnecessary further investigation and increased patient harm.

Objectives: To evaluate the frequency of repeated ANA testing as a prelude to Electronic Medical Record (EMR) test alert design in an Australian healthcare network. The primary endpoint was calculation of the total cost associated with repeated testing and whether a longitudinal change in ANA resulted in any new ANA associated rheumatological diagnoses. Our secondary endpoint was the examination of baseline ANA testing behaviours.

Methods: We retrospectively analysed data from a multi-centre tertiary health network in Melbourne, Australia across a 7-year period (19 March 2011 to 23 July 2018). ANA and other autoimmune test results were obtained from the hospital pathology system with a positive ANA cut off set at 1:160. Clinical information was sourced from clinical information systems on patients who had a change in ANA from negative to positive on repeat testing. The associated cost of repeated ANA testing was calculated based on the baseline cost to the public system.

Results: A total of 36,715 ANA tests (excluding 980 cancelled same-day requests) were performed in 28,840 patients. Of these, 14,058 (38.3%) were positive with females accounting for 9,265 (65.9%, p<0.001). The most frequent ANA patterns were homogenous (47.4%) and nucleolar (23.3%). ANA titres were as follows; 1:160 (41.4%), 1:320 (15.3%), 1:640 (13.1%) and 1:1280 (29.2%). 7,875 (21.4%) of tests were repeat tests. Of these 511 (6.5%) results changed from negative to positive. The median time between a negative ANA result to the first positive result was 1.71 years (IQR 0.50-3.55). Clinical information was captured for a median duration of 1.24 years (IQR 0.50-2.07) following a positive ANA result. A change to positive ANA was associated with a new ANA-associated rheumatological diagnosis in only 5 cases (2 SLE, 1 scleroderma and 2 undifferentiated connective tissue disease) with a positive predictive value calculated at 0.01. When comparing patients who with a new diagnosis to those with no new diagnosis, there was no difference between ANA titre, pattern, duration to first positive ANA, ordering location or clinician, or age of first positive ANA test. The direct total cost for the government of all ANA testing was AUD$903,189, of which repeat testing contributed AUD$193,725.

Conclusion: Repeat ANA testing after a negative result had limited utility in the diagnosis of ANA associated rheumatological conditions with a positive predictive value of only 0.01, and resulted in high cost. New technology and clinical alert systems may help reduce unnecessary testing with potential significant direct cost savings when extrapolated across the Australian healthcare system.

PREDICTING SEVERE INFECTION IN REPEAT CYCLES OF RITUXIMAB AND EFFECTS OF HYPOGAMMAGLOBULINAEMIA IN THE TREATMENT OF RHEUMATIC AND MUSCULOSKELETAL DISEASES

Md Yuzaiful Md Yusof1,2, Edward Vital1,2, Damien M McEvoy1,2, Elizabeth Hensor1,2, Sudipto Das1, Shouvik Dass1. Andy C. Rawstron1,2, Maya Buch1,2, Paul Emery1,2, Sinisa Savic1,2, Annette van der Helm - van Mil1,2, Ellis Niemantsverdriet1,2, Leiden University Medical Centre, Rheumatology, Leiden, Netherlands, 3Erasmus University Medical Centre, Rheumatology, Rotterdam, Netherlands.

Background: Rituximab (RTX) is effective in treating various rheumatic and musculoskeletal diseases (RMDs). Repeat cycles are often required for disease control but may lead to hypogammaglobulinaemia. Low IgG at baseline has been associated with an increased risk of severe infection event (SIE) post-RTX. However, there are limited data on predictors of SIEs in repeat cycles including immunoglobulin levels and B-cell numbers as well as outcomes of hypogammaglobulinaemia.

Objectives: To assess predictors of SIEs in repeat RTX cycles and effects of hypogammaglobulinaemia in terms of SIEs rates, humoral response and its persistence post-cessation of RTX.

Methods: A retrospective study was conducted in the first 700 consecutive ARD patients treated with at least a cycle of RTX in Leeds. IgM, IgA and IgG levels were measured at baseline and 4-6 months after each cycle. For cycles 2-4 (C2-4), predictors for SIEs were analysed using mixed-effects logistic regression analysis.

Results: 550 patients were female, mean(SD) age 56(16) years and median (IQR) disease duration 7.9(3.4-15.0) years. 507/8 (72%) had RA, 94(13%) SLE, 49(7%) AAV, 14(2%) idiopathic inflammatory myopathies, 9(1%) pSS, 5(1%) APS, 6(1%) SSc and 16(3%) other CTDs. 364(52%) were biologic-naïve and 514(73%) were on therapy as outcome (median follow-up 17 months). Analyses were corrected for age, gender, patient's country of origin, smoking status, education level, BMI, EGFR mutation status, tobramycin exposure, comorbidities and RTX specific for RA.

Conclusion: IgG (9.7 PY), 5/8(64%) had impaired humoral response to pneumococcal and influenza vaccinations. For cycles 2-4, in multivariable analysis, lower IgG as this is a consistent predictor of SIE and may affect infection outcomes when patients are switched to a different bDMARD. For those at risk of SIEs, reduction of corticosteroid dose could reduce risk. Low B-cell numbers were not predictive of SIEs.

OP0201

DO MRI-DETECTED EROSIONS IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA PREDICT PROGRESSION TO RHEUMATOID ARTHRITIS? A LONGITUDINAL STUDY

Fenne Wouters1, Xanthe Mathijssen1, Debbie Boeters1, Robin Ten Brinck1, Annette van der Helm - van Mil1,2, Ellis Niemantsverdriet1,2, Leiden University Medical Centre, Rheumatology, Leiden, Netherlands.

Background: Radiographic joint erosions are a hallmark of Rheumatoid Arthritis (RA), MRI is more sensitive than radiographs in detecting erosions. It is unknown if MRI-detected erosions are predictive for RA-development in patients with Clinically Suspect Arthritis (CSA).

Objectives: We investigated the prognostic value of MRI-detected erosions (any MRI-erosion, or MRI-erosion characteristics that were recently identified as specific for RA) in CSA.

Methods: Patients presenting with CSA (n=491) underwent contrast-enhanced 1.5T MRI of the wrist, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints at baseline. MRIs were scored according to RAMRIS. Presence of any MRI-erosion (erosion score ≥1) and RA-specific erosion characteristics as identified previously (grade ≥2 erosions, erosions in MTP5, erosions in MTP1 if aged <40) were studied with clinically apparent inflammatory arthritis development as outcome (median follow-up 17 months). Analyses were corrected for sex, age, CRP, ACPA and MRI-detected inflammation.

Results: Erosions were present in 20.6% of patients. Presence of erosions was not associated with arthritis development (HR multivariable analysis 0.85 (95% CI 0.52-1.40)). Also the different erosion characteristics were not predictive in CSA-patients (grade ≥2 HR 1.99 (95% CI 0.40-4.14), erosions in MTP5 HR 0.89 (95% CI 0.38-2.09) and MTP1 if aged <40 HR 0.98 (95% CI 0.23-4.21)). MRI-erosions were more prevalent in ACA-positive patients (32.3% versus 18.8%, p=0.02). However, no association with arthritis development was observed in both subgroups.

Conclusion: MRI-detected erosions in hands and feet of patients with CSA were not predictive for arthritis development. These data warn against overinterpretation of MRI-detected erosions in CSA.

LB0002

Conclusions: The selective JAK1 inhibitor FIL, at doses of 200mg and 100mg led to significant improvement in signs and symptoms of RA, prevented radiographic progression, and improved physical function compared to PBO, was well tolerated among patients with RA with prior inadequate response to MTX. Efficacy of FIL200mg was non-inferior to ADA based on DAS28-CRP ≤3.2 and ≤2.6, had lower radiographic progression, and reported improvements in HAQ-DI, SF-36 PCS, and FACIT-Fatigue scores (Table 1). Non-inferiority of FIL 200mg to ADA was met based on DAS28-CRP ≤3.2. The FIL safety profile was consistent with prior studies through week 24 (Table 2).

Methods: This phase 3, double-blind, active- and placebo-controlled (PBO)-controlled study randomized patients with active RA (3:3:2:3) to FIL 200mg, FIL 100mg, active comparator (adalimumab [ADA] 40mg every 2 weeks), or PBO daily for up to 52 weeks; results through week 24 are presented. Patients were also receiving MTX for ≥12 weeks with a stable dose of MTX for ≥24 weeks before initiation of study drug. Primary efficacy endpoint was proportion of patients achieving ACR20 response at week 12; additional clinical assessments were ACR50 and ACR70 responses, DAS28-CRP score ≤3.2 and ≤2.6, van der Heijde modified total Sharp score (mTSS), and patient-reported outcomes were HAO-DI, SF-36 PCS, and FACIT-Fatigue. Safety endpoints included types and rates of adverse events. Logistic regression adjusting for stratification factors with nonresponder imputation was used for superiority test of FIL vs PBO for ACR response and other binary endpoints. Mixed-effect model adjusting for baseline value, stratification factors, treatment, and visit by visit interaction as fixed effects with observed cases was used for continuous endpoints. Non-inferiority test of FIL to ADA (preserving >50% of ADA response) was performed for DAS28-CRP ≤3.2 and <2.6.

Results: Of 1,759 patients randomized, 1,755 received study drug and were ana- lyzed, with 475 FIL 200mg; 480 FIL 100mg; 325 ADA; and 475 PBO, of which 89.5%, 90.4%, 89.8%, and 81.3%, respectively, completed week 24 study drug. Most patients (81.8%) were female, mean (standard deviation [SD]) duration of RA was 7.8 (7.6) years, and mean (SD) DAS28-CRP was 5.7 (0.9). At week 12, significantly more patients in the FIL 200mg and 100mg arms achieved an ACR20 response compared to PBO (Table 1). Similarly, compared to PBO, more patients receiving FIL achieved ACR50 and ACR70 responses, DAS28-CRP scores ≤3.2 and ≤2.6, had lower radiographic progression, and reported improvements in HAQ-DI, SF-36 PCS, and FACIT-Fatigue scores (Table 1). Non-inferiority of FIL 200mg to ADA was based on DAS28-CRP ≤3.2. The FIL safety profile was consistent with prior studies through week 24 (Table 2).

Background: Tildrakizumab (TIL), a high-affinity anti-interleukin-23p19 mono- clonal antibody, is approved for moderate-to-severe plaque psoriasis treatment and is under investigation for psoriatic arthritis (PsA).

Objectives: To evaluate the 24-week efficacy and safety results from the randomised, double-blind, placebo-controlled, multiple-dose, phase 2b TIL study in patients with active PsA (NCT02980692).

Methods: Patients with active PsA were randomised 1:1:1:1:1 to receive TIL (200 mg once every 4 weeks [Q4W] [n = 78], 200 mg every 12 weeks [Q12W] [n = 79], 100 mg Q12W [n = 77], 20 mg Q12W to week 24 [n = 78], or placebo) Q4W to week 24 (n = 79). Stable concomitant methotrexate or leflunomide use was permitted but not mandated. The primary efficacy endpoint was the proportion of patients who achieved a 20% reduction from baseline in American College of Rheumatology response criteria (ACR20) at week 24. Other outcome measures included proportion of patients achieving ACR50/70 response and Psoriasis Area and Severity Index (PASI) 75, PASI 90, and changes in swollen and...
Results: Of 500 patients screened, 391 patients met inclusion criteria (including =18 years old, PsA diagnosis with symptoms for 6 months, and =3 tender and =3 swollen joints). Demographics and baseline disease characteristics are shown in Table 1. There were significantly greater proportions of ACR20/50/70 and PASI 75/90 responders with TIL vs PBO at week 24, and in some cases differences in parameters were noted as early as week 8 (Figure 1 and Table 2).

The most frequent TEAEs through week 24 included nasopharyngitis (pooled TIL arms: 5.4% [173/32]; PBO: 6.3% [5/79]; and diarrhea (TIL: 1.3% [4/312]; PBO: 0). There were no reports of candidiasis, inflammatory bowel disease, major adverse cardiac events, or malignancy. No patients discontinued treatment due to TEAEs and no deaths were reported. Serious TEAEs occurred in 2.2% (7/312) of TIL-treated patients vs 2.5% (7/289) in PBO-treated patients.

Conclusion: By week 24, TIL was significantly more efficacious than PBO in treatment of joint and skin manifestations of PsA. Furthermore, there was a clear separation between TIL and PBO as early as 8 weeks for ACR20 (TIL 200 mg Q4W and 100 mg) and 12 weeks for ACR50 (all TIL arms). Shortening the dosing interval from Q12W to Q4W for the 200-mg dose did not result in a measurable increase in skin or joint response scores. There was a low rate of TEAEs in the TIL-treated group.

Xanthe Matthijsen, Ellis Niemantsverdriet, Thomas Huizinga, Annette van der Helm - van Mil. Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Over the last 25 years, treatment of rheumatoid arthritis (RA) has changed considerably, and clinically relevant joint damage and deformations have become infrequent. It is unclear to what extent the long-term outcomes mortality, sustained drug-free remission (DFR) and physical functioning have improved, and whether ACPA+ and ACPA- patients have benefited equally from treatment-improvements.

Objectives: To investigate the influence of treatment strategies that have been improved for 25-years on mortality, DFR and functionality, and whether these effects differed for ACPA+ and ACPA- RA-patients.

Methods: In the Leiden early arthritis cohort, 1291 patients with RA (1987 criteria) were included between 1993-2016. Patients were treated in routine care; initial and subsequent treatment changed over time; divided in 5 inclusion periods. Patients included between 1993-1996 (n=168) received initial NSAIDs and started DMARDs with delay, patients included 1997-2000 (n=148) were treated early with mild DMARDs (e.g. hydroxychloroquine, penicillamine), in 2001-2005 (n=210) patients started early with methotrexate, in 2006-2010 (n=338) early methotrexate was followed by treat to target treatment adjustments. In 2011-2016 (n=390) this was similar and additional efforts were undertaken for very early referral. Patients were followed yearly including assessments of swollen joints, DAS28-ESR and health assessment questionnaires (HAQ). Mortality data were obtained from the civic registry. DFR was defined as the persistent absence of synovitis after cessation of DMARD-therapy during all available follow-up (> 1 year). DAS28-ESR and HAQ data were analysed with linear mixed models; mortality and time to DFR with multivariable and univariable Cox regression. Inclusion period 1993-1996 was used as reference. Analyses were stratified for ACPA-status (anti-CCP2).

Results: Baseline age, sex and antibody status did not differ between inclusion periods. With 1993-1996 as reference, the DAS28-ESR decreased in the first year and thereafter remained lower in all inclusion periods (all p<0.05).

Compared to 1993-1996, mortality was decreased in all inclusion periods (1997-2000 HR 0.67 [0.46;0.99]; 2001-2005 HR 0.66 [0.45;0.97]; 2006-2010 HR 0.64 [0.42;0.98]; 2011-2016 HR 0.31 [0.14;0.68]). DFR achievement was faster in 1997-2000 (HR 0.40 [0.17;0.94]); 2001-2005 HR 0.35 [0.14;0.86]; 2006-2010 HR 0.26 [0.10;0.69]; and 2011-2016 (0.11 [0.04;0.29]), compared to 1993-1996. Additionally, HAQ over time was lower in 2006-2010 (<0.25 [0.36-0.14]) and 2011-2016 (<0.21 [0.32-0.10]).

Stratification for ACPA revealed that ACPA+ patients in the first two inclusion periods remained to have a higher DAS28-ESR over time (1993-1996 beta 0.76 [0.42;1.10]; 1997-2000 beta 0.40 [0.07;0.74]); thereafter there was no difference in DAS28-ESR between ACPA+ and ACPA- patients. The decrease in mortality was similar for ACPA+ and ACPA- patients. The increased rate of DFR was more prominent in ACPA+ patients than ACPA- patients in the two most recent inclusion periods (2006-2010 HR ACPA+: 3.85 [1.25;11.9]; ACPA-: 2.27 [1.34;3.83]; 2011-2016 HR ACPA+: 6.48 [1.89;22.2]; ACPA-: 3.04 [1.65;5.55]). Within ACPA+ RA, the HAQ over time had improved in 2001-2005 (-0.19 [-0.34;-0.04]), 2006-2010 (-0.35 [-0.49;0.22]) and 2011-2016 (-0.26 [-0.40;0.13]), compared to 1993-1996.

This effect was absent ACPA- RA.

ACKNOWLEDGEMENTS

**ACR20/50/70 response rates: TIL placebo; QW, every 4 weeks; QW/4, every 12 weeks; TIL, stratified/stratum.**
Conclusion: Improvements in treatment strategies during the last 25 years have resulted in lower disease activity, less mortality, more DFR and better physical functioning of RA-patients. ACPA+ patients, traditionally the most severe subset, benefited most from these improvements and have become more similar to ACPA- patients.

Disclosure of Interests: Xanthe Matthijssen: None declared, Ellis Niemanveldriet: None declared, Thomas Huizinga Consultant for: Merck, UCB, Bristol Myers Squibb, Pfizer, GSK, Novartis, Roche, Sanofi-Aventis, Abbott, Crecedo Bioscience Inc., Nycomed, Boeringher, Takeda, Zydus, Epirus, Eli Lilly, Annette van der Helm - van Mil Grant/research support from: The research leading to these results has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (Starting grant, agreement No 714312) and from the Dutch Arthritis Foundation. The funding source had no role in the design and conduct of the study.

**PATIENT DISCUSSIONS OF GLUCOCORTICOID-RELATED SIDE EFFECTS WITHIN AN ONLINE HEALTH COMMUNITY FORUM**

Arani Vivekanantham, Maksim Belousov, Lamiece Hassan, Goran Neradic, Will Dixon. University of Manchester, Manchester, United Kingdom

**Background:** Social media websites are an important, largely untapped source of data about patients’ experience of living with disease and its treatment. This includes information on drugs such as the occurrence, nature and impact of side effects. However, there are few published studies reporting drug safety profiles using such data.

Health Unlocked (HU), Europe’s largest social media network for health that supports patients and health care providers, hosts over 200 communities including the UK’s National Rheumatoid Arthritis Society (NRAS). Using the example of glucocorticoid (GC) therapy, this study aims to explore the potential of HU posts in providing information about the occurrence and nature of drug side effects.

**Objectives:**
1. Evaluate the accuracy of a computerised system for automated suspected adverse drug reaction (sADR) detection from posts from HU compared to human annotation.
2. Explore themes of discussion about GC-related ADRs within posts from HU.

**Methods:** HU provided a dataset of de-identified posts from the NRAS community from December 2015 to December 2016. Posts mentioning GCs were processed by automated Natural Language Processing software, which identified the drug and health issues, mapped them to the Medical Dictionary for Regulatory Activities (MedDRA®) dictionary and categorised as a sADR or not. A sample (n=50) of sADR posts were randomly selected and manually reviewed to determine whether they were true ADRs. Additionally, a sample (n=50) of the posts that included GC and were labelled as having a health issue but not thought to have an ADR, were also assessed for true ADRs.

Posts identified as containing GC ADRs from manual analysis were reviewed to identify themes.

**Results:** Of the 35,904 posts from 1,998 users, 2,409 posts mentioned GCs, of which 324 posts were identified as containing information representing a sADR.

After manual review of the 50 sampled sADRs, only 36% (18/50) of these posts contained a true ADR. Of the 50 sampled posts that included a mention of GCs and a health issue but were not a sADR, 28% (14/50) were found to contain true ADRs. Thematic analysis of the 32 posts containing true GC ADRs found the most frequently mentioned ADRs were fractures (n=6), infection (n=5), headaches (n=3) and weight gain (n=3). Posts included rich descriptions about the nature of side effects (“my weight tripled in size with steroids”). This included experiences of how side effects changed with time (“huge mood swings settles after a while”). Users also described how ADRs impacted on their quality of life (“with steroid induced diabetes, I lost a stone in three days, it was grim”), and their value judgements about the importance of side effects (“my taste buds are making everything taste strange, either salty, metallic, or plain awful ... but I cope with it, as hardly any pain with steroids.”) Posts also described frustrations about how well informed they were about side effects (“I had two eye ops for cataracts, no one told me steroids caused cataracts”). Within posts where ADRs were discussed, patients also commented on the benefits of treatment (“my pain subsided with steroids”) and the difficult balance between benefits and harms (“wonderful to not feel like I had RA in the first month of having [pred], but now I have more acne then when I was a teenager”).

**Conclusion:** Current machine learning models for ADR detection in social media still need further improvements to identify sADRs in health forum data. Nonetheless, manual review shows there are important themes relating to patients’ experiences and perceptions of using GC that may not be obtained using traditional methods such as analysis of health records or spontaneous pharmacovigilance. With improved automated ADR detection, this rich data source may be useful to identify ADRs most important to patients and the impact on quality of life.

**Disclosure of Interests:** None declared

A PHASE 3 STUDY OF THE EFFICACY AND SAFETY OF PEFICITINIB (ASP015K) IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAD AN INADEQUATE RESPONSE TO METHOTREXATE

Background: Peficitinib (ASP015K), a novel oral JAK inhibitor, demonstrated efficacy as once-daily monotherapy in patients with moderate-to-severe rheumatoid arthritis (RA) in a phase 2b study (NCT01649999). Objectives: To evaluate the efficacy and safety of peficitinib–methotrexate (MTX) combination in patients with RA who had an inadequate response to MTX. Methods: This multicentre, randomised, double-blind, parallel-group, placebo (PBO)-controlled, phase 3 study (NCT02305849) was conducted in Japan. Patients had RA diagnosed within the past 10 years (1987 ACR or 2010 ACR/EULAR criteria), active disease (≥6 tender and painful joints and ≥6 swollen joints, using 88 and 66-joint assessment respectively; CRP >1.0 mg/dl; bone erosion; and ACPR or RF positivity) and inadequate response to MTX (administered for ≥90 days; ≥8 mg/week for ≥28 days prior to baseline). Patients were randomised 1:1:1 to S2-week MTX plus PBO, peficitinib 100 mg/day or peficitinib 150 mg/day. At week 12, inadequate responders in the PBO group (<20% improvement from baseline in tender and swollen joint counts) were switched (under blinded conditions) to peficitinib 100/150 mg until end of treatment. Remaining patients in the PBO group were switched (under blinded conditions) to peficitinib at week 28. Concomitant stable MTX dose (≥16 mg/week) was mandatory.

Primary efficacy variables were ACR20 response rate at week 12/early termination (ET) and change from baseline in modified Total Sharp score (mTSS) at week 28/ET.

**EFFECT OF SHORT-TERM METHOTREXATE DISCONTINUATION ON THE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: POSTHOC-ANALYSIS OF TWO RANDOMIZED CLINICAL TRIALS**

Min Jung Kim, Yeong Woong Song, Eun Bong Lee, Jin Kyun Park. Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

**Background:** Patients with rheumatoid arthritis (RA) require a continuous, potentially lifelong immune suppression with disease modifying antirheumatic drugs (DMARDs) including methotrexate (MTX). However, in specific circumstances such as life-threatening infections, vaccinations or major surgeries, use of MTX should be minimized to restore the treatment-associated immune suppression. While a long-term or permanent discontinuation of MTX is associated with a disease flare or relapse, the effect of short-term discontinuation on disease activity has not been fully elucidated.

**Objectives:** To investigate the effect of short-term discontinuation of MTX on the disease activity in patients with RA on stable dose of MTX.

**Methods:** This is a post hoc analysis of 2 randomized controlled studies investigating effect of MTX discontinuation for 2 weeks or 4 weeks on vaccine response to seasonal influenza vaccination in patients with RA. In the 4-week discontinuation study, 54 patients continued MTX and 44 patients discontinued it for 4 weeks before vaccination with trivalent seasonal influenza vaccine. In the 2-week discontinuation study, 159 patients continued MTX and 161 patients held it for 2 weeks after a seasonal quadrivalent influenza vaccine. Disease activity (DAS28 change, DAS28 flare rate and flare-free survival) was compared between the patients who continued MTX and those held it. A RA flare was defined as an increase in DAS28 of >1.2 or >0.6 if the baseline DAS28 was >3.2.

**Results:** In the 4-week MTX-hold group, the mean DAS28 increased at the 4 weeks after MTX discontinuation by 0.38 ± 0.94 and then improved back to baseline after reintroduction of MTX, whereas the mean DAS28 in the MTX-continue group remained stable over time (Figure 1A). The overall flare-free survival during 20 weeks did not differ between the groups (log rank p=0.142) (Figure 1B). However, numerically more patients in the MTX-hold group experienced a flare than those in the MTX-continue group during the 4-week MTX discontinuation (20.5% vs. 7.4%, p=0.058). After resuming MTX, the flare rate did not differ between the groups up to 20 weeks of observations (Figure 1C). A temporary MTX discontinuation for 2 weeks was not associated with any clinically meaningful change in disease activity.

**Conclusion:** A short-term MTX discontinuation for 2 weeks is safe without any change in disease activity. A 4-week MTX discontinuation is associated with transient increase in disease activity without affecting long-term outcomes.

long-term safety. To our knowledge, this is the first long-term comparative RWD analysis of tofacitinib.

**Objectives:** To compare 5-year adverse event (AE) incidence rates (IRs) in patients (pts) starting tofacitinib vs biological (b)DMARDs using cohorts from the US Corrona RA registry.

**Methods:** This prospective, observational 5-year study embedded in the ongoing US Corrona RA registry routinely collected 9 categories of predefined AEs from participating physicians. Real-world safety event rates of major adverse cardiovascular events (MACE), serious infectious events (SIEs) and herpes zoster (HZ; serious and non-serious) were compared in pts with RA who started tofacitinib or a bDMARD regardless of dose/schedule between 6 Nov 2012 (US FDA approval) and 30 Jun 2017 (follow-up through 31 Dec 2017). Endpoints were selected as having sufficient power to detect a 2-fold difference between cohorts at this datacut; there was insufficient power to assess malignancy. Baseline variables with a standardised difference > 0.10 between tofacitinib and bDMARD initiators, and a priori selected covariates (gender, age, line of therapy, history of AE of interest) were used to construct propensity scores (PS) to derive a PS-trimmed (primary) population and a PS–matched population for sensitivity analysis (ratio: max. 4 bDMARD:1 tofacitinib; calliper=0.05). Pts were followed from initiation until an AE of interest; discontinuation and/or start of a new therapy >90 days, death or end of follow-up, whichever came first. Crude IRs (events/100 pt-years [PY]) were estimated; multivariable-adjusted Cox regression was used to estimate hazard ratios (HRs) comparing rates of first events between cohorts.

**Results:** In total, 1544 tofacitinib (2138.2 PY) and 7083 bDMARD (9904.9 PY) initiators were included. PS-trimmed resulted in 1117 tofacitinib and 5542 bDMARD initiators. Rates of MACE and SIEs were similar in both cohorts (Fig 1A); adjusted HRs (95% confidence intervals [Cls]) were: MACE 0.60 (0.30, 1.18); SIEs 0.99 (0.72, 1.36; Fig 1B). HZ IR was higher for tofacitinib vs bDMARDs (Fig 1A); HRs for HZ were significantly increased with tofacitinib vs bDMARDs (adjusted HR 2.12 [1.22, 3.66]; Fig 1B); all HZ events were non-serious with tofacitinib. Similar results were observed in PS-matched populations.

**Conclusion:** This was the first comparative analysis of RWD data for tofacitinib and bDMARDs to use PS-trimmed and PS-matched analyses to adjust for channeling/prescribing patterns for newly approved therapies. Pts starting tofacitinib or bDMARDs for RA had similar rates of MACE and SIEs. Tofacitinib initiators had higher HZ IRs vs bDMARD initiators. These results are consistent with long-term clinical trial findings.

**Acknowledgement:** Sponsors: Corrona, LLC. Corrona is supported by contracted subscriptions with multiple companies. This was a Corrona/Pfizer collaboration with Pfizer financial support. Medical writing support provided by Anthony G McCluskey of CMC Connect and funded by Pfizer Inc.
**Results:** Of the 651 and 327 pts randomized to receive UPA and ADA, 126 (19%) and 77 (24%), were considered NR and switched to ADA and UPA respectively. NR demographics were consistent with the overall randomized population. Of the switched pts, ~90% remained in the study through 6 mos ps. Patients switched to ADA (UPA-NR) achieved 59% (26%/12%) improvements in ACR20/50/70 responses, and 35% achieved DAS28 (CRP) ≤3.2 at 6 mos ps (Table). Patients switched to UPA (ADA-NR) achieved 75%/49%/24% improvements in ACR20/50/70, and 54% achieved DAS28 (CRP) ≤3.2 at 6 mo consistent with data observed in a phase 3 study of UPA in BDMARD-RD RA pts. The proportion (95% CI) of pts with infection and serious infection through 6 mos appeared consistent with those observed for ADA and UPA during comparable periods (ADA, switched from UPA: infection: 34.1 [26.43, 42.77], serious infection: 1.6 [1.44, 5.60]; UPA, switched from ADA: infection: 40.3 [30.02, 51.42], serious infection: 3.9 [1.33, 10.94].

**Conclusion:** Data from this blinded, controlled study indicate that pts with initial non-response to either UPA or ADA can benefit from switching to the other therapy. No additional safety concerns were observed. These are the first data to demonstrate effectiveness of a TNF inhibitor following failure of a JAK inhibitor.

PATIENTS WITH RADIOPHARMIC SACROILIAC: COMPARISON IN A COHORTS?

Anne Boel1, Anna Moltó2, Désirée van der Heijde1, Adrian Ciurea2, Maxime Dougados2, Lianne S. Gensler4, Maria Jose Santos5, Eugenio de Miguel5, Denis Poddubnyy6, Martin Rudwaleit7, Astrid van Tubergen11, Floris A. van Gaalen7, Sofia Ramiro13,11, 2UMC, Leiden, Netherlands; 3Cochin Hospital, Paris, France; 4University Hospital Zurich, Zurich, Switzerland; 5University of California, San Francisco, United States of America; 6Hospital Garcia de Orta, Almada, Portugal; 7Hospital Universitario La Paz, Madrid, Spain; 8Chanté Universitätsmedizin Berlin, Berlin, Germany; 9German Rheumatism Research Centre, Berlin, Germany; 10Klinikum Bielefeld Rosenhöhe, Bielefeld; Germany; 11UMC, Maastricht, Netherlands; 12Zuyderland MC, Heerlen, Netherlands

Background: Axial spondyloarthritis (axSpA) patients with radiographic sacroiliitis may be classified using the modified New York (mNY) criteria and the more recent ASAS criteria. In the mNY criteria these patients are referred to as ankylosing spondylitis (AS) patients and in the ASAS criteria as radiographic axSpA (r-axSpA) patients. In both the mNY and the ASAS r-axSpA classification sets the radiographic criterion is the same but the additionally required features differ (figure), for example patients with age at onset of back pain ≥45 cannot fulfil the ASAS criteria. This raises the question whether the two sets can be used interchangeably in the classification of axSpA patients with radiographic sacroiliitis.

Objectives: To investigate to what degree patients with axSpA and radiographic sacroiliitis who fulfil the mNY criteria also fulfil the ASAS criteria for r-axSpA and vice-versa.

Methods: Patients diagnosed with axSpA who had back pain longer than 3 months and definite radiographic sacroiliitis (i.e. common and mandatory features for both classification criteria sets (figure)) were selected from several cohorts (ASAS, Esperanza, GESPIC, OASIS, Reuma.pt, SCQM, SPACE, and UCSF). Subsequently we calculated how many patients fulfil the mNY criteria and/or the ASAS r-axSpA criteria. Inversely, of the 3434 patients fulfilling the ASAS r-axSpA criteria for the classification of patients with axSpA and radiographic sacroiliitis.

Results: Of the 3892 patients fulfilling the mNY criteria, 93% also fulfilled the ASAS r-axSpA criteria. Inversely, of the 3434 patients fulfilling the ASAS r-axSpA criteria, 96% also fulfilled the mNY criteria (table). In total, 89% (3607/4041) of patients with axSpA and radiographic sacroiliitis fulfilled both criteria sets; 7% only the mNY criteria; 3% only the ASAS criteria and 1% neither set.

Conclusions: AxSpA patients classified as AS according to mNY criteria and those classified as r-axSpA according to ASAS criteria are mostly the same: 93% of mNY positive patients also fulfil the ASAS r-axSpA criteria while 96% of ASAS r-axSpA positive patients also fulfil the mNY criteria. These findings support the interchangeable use of the terms r-axSpA and AS, which was also approved by a vote of ASAS members at the 2019 annual workshop in Amsterdam.

LOCALIZATION AND MORPHOLOGY OF MAGNETIC RESONANCE IMAGING FEATURES OF PATHOLOGIC CHANGES IN THE SACRILIAC JOINTS SUGGESTIVE OF AXIAL SPONDYLOARTHRITIS – A SYSTEMATIC COMPARISON OF PATIENTS AND CONTROLS WITH CHRONIC BACK PAIN

Xenophon Baraliakos1, Jonas Thomaschoff2, Martin Fruth1, Juergen Braun1, 1Rheumazentrum Rheinland, Ruhr-University Bochum, Herne, Germany; 2Radiologie Herne, Herne, Germany

Background: Bone marrow edema (BME), fat metaplasia (FM) and erosions have been identified as relevant for magnetic resonance imaging (MRI) changes in the sacroiliac joints (SIJ) of patients with axial spondyloarthritis (axSpA). However, a high prevalence of MRI changes has recently also been reported in subjects with no evidence of axSpA (1,2).

Objectives: To map the MRI lesions suspicious of axSpA in patients diagnosed with axSpA and compare them to those in patients with chronic back pain (cBP, non-SpA).

Methods: Consecutive patients with cBP < 45 years were included if they had at least one pathologic lesion of any type in the SIJ-MRI performed on time. BME was found positive by both readers for the respective lesions.

Results: A total of 200 consecutive patients (100 axSpA, 100 non-SpA), mean age 36±11.3 and 40±11.0 years, respectively, were analyzed. BME was found in 85% vs. 80% of patients with axSpA and non-SpA respectively had sclerosis and erosions, respectively. The largest surface area covered by BME was found in 85% vs. 80% of patients, while 80% vs. 69% had FL, 54% vs. 40% had sclerosis and 64% vs. 12% had erosions, respectively. The largest surface area covered by BME, FL, sclerosis and erosions. In addition, length and width were digitally measured for BME, FL and sclerosis, and signal intensity was measured digitally in each individual patient in comparison to the cerebrospinal fluid signal for BME and the subcutaneous fat for FL (no units).

Comparisons were calculated by Mann-Whitney-U-test for patients classified as positive by both readers for the respective lesions.

Results: A total of 200 consecutive patients (100 axSpA, 100 non-SpA), mean age 36±11.3 and 40±11.0 years, respectively, were analyzed. BME was found in 85% vs. 80% of patients with axSpA, while 80% vs. 69% had FL, 54% vs. 40% had sclerosis and 64% vs. 12% had erosions, respectively. The largest surface area covered by BME in axSpA vs. non-SpA was found in the lower and dorsal SIJ: 60±10.1 mm² in the iliac and 47±19.4 mm² in the sacral part vs. the upper and ventral SIJ: 18.7±3.4 mm² in the sacral and 5±20.1 mm² in the iliac part.

Patients with axSpA showed a larger surface area covered by FL than found in the upper and anterior sacral SIJ (30±5.5±6.3 mm²), whereas patients with non-SpA showed larger FL areas in the lower and posterior sacral SIJ (197.9±1.2 mm²). Regarding sclerosis, the upper and anterior iliac part had more surface involvement in both SpA (139±3±11.6 mm²) and non-SpA (81±8.2 mm²) patients.
86

Wednesday, 12 June 2019

The mean signal intensity of all lesions and MRI planes differed between axSpA
(102.385 units?) and non-SpA (48.995) patients for BME (p<0.001) but not for FL.
Overall, axSpA patients also had significantly more SIJ quadrants with pathologic
changes, except for BME and sclerosis in the ventral and fat located in the retroauricular part of the SIJ. The occurrence of erosions in the mid (61 vs. 7) and the
ventral (51 vs. 8) part of the SIJ could discriminate best between axSpA and nonSpA (both p<0.001).
Conclusion: These data show that although all types of lesions may be found in
both patient groups, the anatomic pattern of SIJ involvement can still distinguish
axSpA from non-SpA. The localization and morphological appearance of SIJ-MRI
features suggestive of axSpA may serve as an additional feature in the definition
of a ‘positive’ MRI both for diagnosis and classification.

Scientific Abstracts
meaningful) classes with best data fit. Each class was labelled by us and named
according to most prominent features. The latent axSpA classes were then used
as ‘gold-standard’ against which the ASAS axSpA, pSpA (ignoring IBP) and both
(SpA criteria) were tested. Finally, 5-year follow-up data from DESIR were used to
perform a latent transition analysis (LTA) in order to examine if patients change
classes over 5-year time.

OP0033

WHAT IS AXIAL SPONDYLOARTHRITIS? A LATENT
CLASS AND TRANSITION ANALYSIS IN THE SPACE
AND DESIR COHORTS

Alexandre Sepriano1, Sofia Ramiro1, Désirée van der Heijde1, Pierre Hoonhout2,
Anna Moltó3, Alain Saraux4, Maxime Dougados3, Robert B.M. Landewé5. 1Leiden
University Medical Center (LUMC), Leiden, Netherlands; 2ISEG – Lisbon School of
Economics and Management, Lisboa, Portugal; 3Hospital Cochin, Paris, France;
4
Hospital La Cavale Blanche, Brest, France; 5Amsterdam Rheumatology and
Immunology Center, Amsterdam, Netherlands
Background: Axial spondyloarthritis (axSpA) is a disease with a rather heterogeneous presentation that may be difficult to diagnose. Classification criteria, such
as the ASAS criteria, which have been developed and validated against the goldstandard ‘expert diagnosis’, exist, but may suffer from inappropriate circularity
because features deemed important by experts (e.g. sacroiliitis on MRI) may have
easily got a too prominent, and therefore biased, role. If classification criteria are
used inappropriately to confirm a diagnosis, overdiagnosis (‘too much SpA’) may
be an unwarranted consequence.
Objectives: To gain an unbiased insight into the concept of axSpA, by circumventing expert opinion and investigating its ‘latent constructs’: We examined the
SpA-features’ mutual statistical coherence, established the unbiased ‘Gestalt’ of
SpA, and evaluated how well the ASAS axSpA classification criteria capture these
‘latent constructs’.
Methods: Two independent cohorts of patients (pts) with early onset chronic
back pain (SPACE cohort) and inflammatory back pain (IBP) (DESIR cohort) were
included. Latent class analysis (LCA) (different than a cluster analysis) was used
to estimate the latent (i.e. unobserved) ‘Gestalt’ of axSpA by modelling the covariance of the observed SpA features (without ‘a priori’ assumptions on their
‘weights’). The selected best LCA model splits axSpA into a number of (clinically

Results: In total, data of 465 (SPACE) and 576 (DESIR) pts were analyzed.
SPACE yielded 4 latent classes (Table 1). The ‘Axial’ class characterized by highest likelihood on abnormal imaging and HLA-B27-positivity; the ‘IBP+Peripheral’
class had 100% likelihood of IBP in association with peripheral signs. The ‘At risk’
class is anchored on a positive family history and HLA-B27 positivity in association with IBP; and the ‘No SpA’ class had very low likelihoods for all SpA-features
which were correlated. The independent analysis in DESIR (without ‘no-SpA’
patients) yielded identical latent classes (‘Axial’:19%; ‘IBP+Peripheral’:27% and
‘At risk’:55%) (Table 2). The ASAS axSpA criteria, tested in SPACE (‘No SpA’
absent in DESIR), captured 67% of the patients in the ‘Axial’ and ‘IBP+Peripheral’
classes (‘latent gold-standard’), but sensitivity was better (87%) if axSpA and
pSpA criteria were combined. Of note, the axSpA criteria captured only 4% of the
patients from the ‘No SpA’ class. Importantly, the LTA suggests that transition
between classes over time was highly unlikely. ‘Axial’ and ‘IBP+Peripheral’
patients did not switch and only 11% of ‘At risk’ pts had switched to ‘IBP+Periphheral’ after 5 years.
Conclusion: The ‘Gestalt’ of axial spondyloarthritis comprises three distinguishable clinical entities (‘pure axial SpA’, ‘axial SpA with peripheral signs, and ‘axial
SpA at risk’). Patients keep their clinical entity over 5 years and transition is very
rare. The ‘Axial’ and ‘IBP+Peripheral’ entities are best captured by combining the
ASAS axSpA and pSpA criteria.

DO SMOKING AND SOCIO-ECONOMIC FACTORS INDEPENDENTLY INFLUENCE IMAGING OUTCOMES IN AXIAL SPONDYLOARTHRITIS? FIVE-YEAR DATA FROM THE DESIR COHORT

Elena Nikhzhonovich1, 2, Sofia Ramoni1, Alexandre Sepulveda1, Adeline Ryusseyn Witrand3, Robert B.M. Landewé3, Robert B.M. Landewé3, Désirée van der Heijde1. 1Leiden University Medical Center, Leiden, Netherlands; 2Kings College London, London, United Kingdom; 3Hôpital Pierre-Paul-Riquet, Toulouse, France; 4ARC, Amsterdam, Netherlands

Background: Smoking and systemic inflammation have been shown to independently associate with radiographic spinal progression in patients with axSpA. Furthermore, evidence suggests that certain socioeconomic (SE) factors (e.g. physically demanding jobs) may modify these associations, but clarity on the intricate relationships between smoking, axial damage and SE factors is yet to be achieved. Moreover, the impact of smoking and SE factors and their interplay on axial inflammation have not been thoroughly investigated to date.

Objectives: To investigate the relationship between smoking and imaging outcomes (SI joints, spine, MRI and radiographs) over time in axSpA and to assess if SE factors first modify and if not, confound, such a relationship.

Methods: Patients with axSpA from the DESIR cohort who fulfil the ASAS axSpA classification criteria were included. Four imaging continuous outcomes (X-ray spine [mSASSS, range 0-72]; X-ray SIJs modified New York grading [mNY, 0-8]; MRI-Spine [SPARCC, range 0-414] and MRI-SJ [SPARC, range 0-72]) have been scored by 3 central readers independently (average score used) in one session, blinded to the order (baseline, 2 and 5 years). Smoking, the main variable of interest, was tested as a binary variable to indicate smoking status since last visit. SE variables tested were: age, gender, ethnicity (Caucasian vs other), job type based on ‘collar’ (blue [manual labour work] vs white [office-based work]); educational status (low vs high [university]); parental (number of children) status. Potential interactions between smoking and SE factors were first investigated and, if statistically (p<0.15) and clinically relevant, models were stratified. The effect of smoking on imaging outcomes was assessed in multivariable time-varying models using generalized estimating equations making use of all available observations and adjusted for other known possible confounders (see table).

Results: In total, 425 axSpA patients were included: 225 [53%] male, 167 [40%] smokers and 287 [68%] blue collar. The mean baseline (SD) MRI-SIJ SPARCC was 4.67 (7.40), MRI spine SPARCC 2.73 (7.92); mSASSS 0.38 (1.66); mNY: 1.70 (1.84). A significant interaction was found between smoking and job type with MRI-SJ inflammation as the outcome (p=0.031) as well as with mNY grading (p=0.096). Similarly, educational status also proved to modify the association between smoking and MRI-SJ inflammation (p=0.026). In the multivariable models, smoking was significantly associated with more MRI-SJ inflammation over 5 years of follow-up but only in patients with a blue-collar job [β [95% CI]: 3.35 [0.54, 6.17]) (table). Results were similar in the low education stratum ([β [95% CI]: 2.69 [0.48, 4.91]). Smoking was not significantly associated with any of the other imaging outcomes over time. Male gender was positively associated with MRI-SJ inflammation regardless of job type, and also with MRI-Spinel inflammation and structural damage although only for blue-collar patients in the case of SJ damage.

Conclusion: There is a strong association between smoking and MRI-SJ inflammation over time in axSpA patients with blue collar job type or with low education, irrespective of other socio-economic factors, systemic inflammation and treatment. These findings suggest a possible role for mechanical stress (seen with manual jobs) amplifying the effect of smoking on axial inflammation in axSpA. No significant relationship was found between smoking and spinal inflammation or axial damage, possibly also due to the limited imaging changes in this cohort.

Disclosure of Interests: Elena Nikhzhonovich: None declared, Sofia Ramoni Grant/ research support from: MSD, Consultant for: AbbVie, Lilly, MSD, Novartis, Pfizer, Sanofi, Speakers bureau: AbbVie, Lilly, MSD, Novartis, Pfizer, Sanofi, Alexandre Sepulveda: None declared. Adeline Ryusseyn Witrand: None declared, Robert B.M. Landewé: None declared. Désirée van der Heijde Consultant for: AbbVie, Amgen, Astellas, AstraZeneca, Bristol-Myers Squibb, Boehringer Ingelheim, Celgene, Daiichi, Eli-Lilly, Galapagos, Gilead, GlaxoSmithKline, Janssen, Merck, Novartis, Pfizer, Regeneron, Roche, Sanofi, Takeda, Union Chimique Belge

DEPRESSION IN ANKYLOSING SPONDYLITIS AND THE ROLE OF DISEASE-RELATED AND CONTEXTUAL FACTORS: A STRUCTURAL EQUATION MODELLING APPROACH

Casper Weber1, 2, Laura Vanhoof1, Cansten Leus2, Annelies Booren1, 2, Sebastian Köhler1, 3, 4, 5, 6, 7, 8, MUMC, Rheumatology, Maastricht, Netherlands; 6Maastricht University, Care and Public Health Research Institute (CAPPHRI), Maastricht, Netherlands; 2Kings College London, London, United Kingdom; 3Hôpital Pierre-Paul-Riquet, Toulouse, France; 4ARC, Amsterdam, Netherlands

Background: Patients with ankylosing spondylitis (AS) are at increased risk of depression compared to the general population. Comorbid depression in AS likely has a multifactorial origin. While several disease-related and contextual factors have been associated with depressive symptoms in AS, a comprehensive model of their interrelations is currently lacking. Such a model could help understand the mechanisms leading to, or maintaining, depression in AS.

Objectives: To determine which factors contribute to depressive symptoms in AS, and to understand the relationships between relevant factors.

Methods: Data from patients with AS participating in the Dutch cross-sectional multicentre survey-based Social Participation in Ankylosing Spondylitis Study (SPASS) were used. Potential determinants included both contextual and disease-related factors. Depression symptoms were assessed by the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D). A latent ‘depression’ variable was constructed by regressing the 7 manifest items of the HADS-D questionnaire on the outcome ‘depression’, to represent it more accurately. Candidate variables for the model were selected using univariable negative binomial regression. Direct and indirect associations between risk factors and the dimensional latent depression outcome were explored using structural equation modelling. Both theory-driven and data-driven approaches were explored. A final model was selected based on model fit criteria, clinical plausibility and explained variance in the outcome.

Results: Among 245 patients, median (interquartile range) HADS-D was 3 (1-6) and 44 patients (16%) had a HADS-D >8, indicating possible depression. The theory-driven model had poor fit and was rejected. The data-driven approach led to a model with good fit. In this final model (see Figure), contextual factors associated with depressive symptoms were male gender, a history of depression, being employed, lower income, lower mastery and worse satisfaction with social role participation. Regarding disease-related factors, Bath AS Disease Activity Index (BASDAI) was the only determinant in the final explanatory model, acted only indirectly, and had less effect on depressive symptoms than several of the contextual factors. Mastery had a central role in the path diagram and was a mediator for the effects of BASDAI, income and satisfaction with social role participation on depressive symptoms. The final model explained 64% of the variance in the latent depressive symptoms outcome.

Conclusion: Both contextual and disease-related factors contribute to depressive symptoms in AS, but contextual factors have a larger contribution. Mastery, the extent to which one feels in control over life and disease, has a key role in this process. These results support a relevance of self-efficacy in disease management and patient education. In order to improve patients’ mental health, research is warranted whether mastery and its relation with depression can be modified.

Disclosure of Interests: None declared

OP0036 EROSIONS ARE THE MOST OFTEN REPORTED STRUCTURAL LESION ON MRI OF THE SACROILIAC JOINTS IN AXSpA PATIENTS WITH IBP

Manouk de Hooge1,2, Ann-Sophie De Craemer1,2, Thomas Renson1,2, Philippe Carron1,2, Liseлотte Deroo1,2, Dirk Elewaut4,5, Filip van den Bosch1,2, 1Ghent University Hospital, Gent, Belgium; 2VIB Inflammation Research Center, Gent, Belgium

Background: HLA-B27 and sacroilitis on MRI form the basis of the Assessment of SpondyloArthritis International Society (ASAS) axial spondyloarthritis (axSpA) classification criteria. In addition, while not an entry criterion of the classification criteria, inflammatory back pain (IBP) is fundamental in the axSpA diagnostic process and it is endorsed as referral parameter in primary care. Besides inflammation on MRI, which is the hallmark of axSpA, there is still debate on the value of structural MRI lesions in these patients.

Objectives: To report on MRI of the sacroiliac joints (MRI-SIJ) findings in newly diagnosed axSpA patients stratified for the presence of IBP and HLA-B27 positivity.

Methods: Newly diagnosed and anti-TNF naïve axSpA patients of an ongoing Belgian (Be-Giant) cohort were included in this study. MRI-SIJ assessment was performed independently by 3 calibrated readers according to an adapted method of the SpondyloArthritis Research Consortium of Canada score, evaluating erosions, fatty lesions, sclerosis and ankylosis (T1-weighted and STIR images viewed simultaneously). Also, the ASAS definition of a positive MRI-SIJ was evaluated. MRI sum scores were calculated as 2 out of 3 (median) reader scores.

Results: In 138 axSpA patients MRI-SIJ data was available; 68 (49.3%) patients were male, 104 (75.4%) HLA-B27 positive and 131 (94.9%) patients fulfilled the IBP criteria according to ASAS. In the IBP+ patient groups, a large amount of structural MRI lesions were seen. In these groups, erosions are most frequently reported, with an average extent of 5 erosions. IBP- patients were rarely seen in this cohort and erosions and fatty lesions were the only structural lesions observed in these patients, with a much lower extent compared to the IBP+ patients (see table 1). There were no axSpA patients with negative MRI-SIJ, negative HLA-B27 and without IBP.

Conclusion: In this cohort of newly diagnosed anti-TNF naïve axSpA patients, structural lesions are frequently and with a high extent seen in IBP+ patients. Only in the IBP+ axSpA patients the previously reported threshold for axSpA patients of ≥3 erosions and ≥3 fatty lesions is maintained, as IBP+ axSpA patients have far fewer lesions. IBP seems to be an indicator for the presence of structural MRI-SIJ lesions in newly diagnosed axSpA patients.

OP0037 ASSOCIATION BETWEEN BONE MARROW EDEMA AND STRUCTURAL PROGRESSION IN THE SAME QUADRANT IN AXIAL SYPNDIOLARTHRITIS – 5-YEAR DATA FROM THE DESIR COHORT

Santiago Rodrigues-Manica1,2, Alexandre Sepriano1,2, Sofia Ramiro3,4, Robert B. M. Landewé5, Pascal Claudepierre6, Anna Moltò1,7, Maxime Dougados1,2, 1Hospital Egas Moniz, Lisbon, Portugal; 2Cedoc, Lisbon, Portugal; 3Leiden University Medical Center (LUMC), Leiden, Netherlands; 4Zuyderland Medisch Centrum, Heerlen, Netherlands; 5Academic Medical Center, Amsterdam, Netherlands; 6Hôpital Henri-Mondor Ap-Hp, Créteil, France; 7University Paris Descartes, Paris, France

Background: The overall presence of inflammation in the MRI-SIJ is associated with overall 5-year radiographic damage in patients with axSpA1. But we do not know if a bone marrow edema (BME) lesion leads to a structural lesion at the same place (i.e. in the same quadrant).

Objectives: To investigate the association between BME and structural progression in the same quadrant of the SIJ, over time.

Methods: Patients from the DESIR cohort (early axSpA according to the rheumatologist) with ≥2 consecutive MRI-SIJ (out of baseline, 2 and 5 years), were included. Each image was independently scored by 3 trained central readers blinded to chronological order. BME was considered present in a time point if detected in ≥1 slices in each of the 8 quadrants. The prevalence of BME (yes/no) and structural lesions (sclerosis, erosions, fatty lesions and ankylosis; all yes/no) defined, per quadrant, by the agreement of ≥2 out of 3 readers, was described at BL and at 5 years. The longitudinal association between BME and each of the structural lesions in the same quadrant was tested in time-lagged multilevel Generalized Estimating Equation (GEE) models with autoregression, taking individual reader data into account, and adjusting for clinical variables selected a priori on clinical grounds (age, gender, disease activity and treatment).

Results: In total, 197 patients were included (age 34 (SD 9) years, 48% male and 61% HLA-B27 positive). While BME and fatty lesions were evenly distributed across quadrants, erosions and sclerosis occurred preferably in the iliac side (i.e. C1 and C4) (Table 1). The prevalence of BME decreased over time (baseline range: 11%–16%; 5-year range: 7%–14%), while erosions (baseline range: 2%–23%; 5-year range: 3%–28%) and especially fatty lesions (baseline range: 4%–14%; 5-year range: 9%–21%) increased. Ankylosis and sclerosis were rare in this early axSpA cohort. In the multivariable models, BME was longitudinally associated with sclerosis (OR 1.7 (95% CI 1.0; 2.8)) and fatty lesions (1.7 (1.1;2.5)). The possible association with ankylosis could not be tested due to too low number of lesions (Table 2).

Table 2. Longitudinal association between BME and structural outcomes in the same quadrant

Conclusion: We here demonstrate that in early axSpA-patients inflammation in one SIJ quadrant leads to structural damage in the same quadrant. This finding reinforces the pathophysiological implications of inflammation in axSpA.

### High Prevalence of Sacroiliac Bone Marrow Edema on MRI in Postpartum Women: A Temporary Phenomenon

**Objectives:** To explore the association between pregnancy and giving birth on the one hand, and the occurrence of MRI lesions compatible with SpA on the other hand; and (B) if these lesions are transient.

**Methods:** Twenty-five women underwent an MRI of the sacroiliac joints (SIJ) in the first 10 days after vaginal delivery. The scan was repeated after 6 months. Both time points were scored in pairs by 3 trained readers, blinded for time sequence and subject characteristics. MRI assessment was done on 6 consecutive slices for inflammatory and structural SpA-like lesions; bone marrow edema (BME), capsulitis, enthesitis, high signal intensity in joint space, erosions, fatty lesions, sclerosis and (partial) ankylosis. In addition, the Assessment of SpondyloArthritis international Society (ASAS) definition was applied. MRI reader scores were reported as 2 out of 3 (median) scores.

**Results:** Twenty out of 25 (80.0%) subjects displayed BME; the median SPARCC score was 5 (IQR 1-11) (see table). One subject was lost to follow-up. After 6 months, 11 out of 24 (45.8%) subjects still showed BME; however, 75.5% of the baseline lesions were located in the anterior part of the SIJ; 57.3% situated on the iliac side. Structural lesions were rarely detected in this study population (see table).

Table: Number of MRI-SIJ lesions in 25 postpartum women.

**Conclusion:** A very high prevalence of sacroiliac BME on MRI was seen in women immediately postpartum with 64.0% even having a positive MRI for sacroiliitis according to the ASAS definition. A significant decrease in BME was seen over 6 months time, yet a substantial fraction continued to display BME after follow up. History of back pain and childbirth are crucial to take into account when interpreting an MRI-SIJ. In case of a recent pregnancy and clinical suspicion of SpA, it may be wise to postpone MRI-SIJ imaging until at least 6 months after the delivery.

46% and 25% of ABA- and PBO-treated pts, respectively, but this was not enriched for any specific event and there were no new ABA safety signals.

Conclusion: Despite favourably impacting biomarkers of disease activity, abatacept therapy was no better than PBO for improving the clinical measures of disease. These results do not indicate a clinical benefit of abatacept in PsS.

groups (groups 2-4) with decreased glomerular and tubular damage scores (Figure 1G). Most importantly, frequencies of CD8+CD25+FoxP3+ regulatory T cells and CD19+CD5+CD1dhigh regulatory B cells were significantly higher in MIC-treated (groups 2-4) compared to control animals of group 1, whereas double negative T cells were markedly reduced (Figure 1H).

Conclusion: MIC therapy inhibits progression of active lupus nephritis. Interestingly, preemptive MIC therapy was even able to prevent onset of disease with no significant disease activity at completion of the study. In accordance with our previous pre-clinical EAE experiments (1) and a first-in-human clinical trial in living-donor kidney transplantation (TOL-1 study), MIC therapy was able to induce an in vivo induction of regulatory cell subsets. This clinically applicable cell therapeutic approach may control lupus nephritis by specifically silencing deleterious autoimmune responses.

OP0041 MAINTENANCE OF EFFICACY AND SAFETY AND REDUCTION OF BILAG FLARES WITH USTEKINUMAB, AN INTERLEUKIN-12/23 INHIBITOR, IN PATIENTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): 1-YEAR RESULTS OF A PHASE 2, Randomized Placebo-Controlled, CROSSOVER STUDY
Ronald van Vollenhoven1, George Tsokos2, Robert Gordon3, Kim Hung Lo3, Y Irene Gregan4, Kayin Fei5, Shaha Rosenz5, Brian H. Hahn6, Amsterdam Rheumatism and Immune Cell Research, Amsterdam, Netherlands; 2Beth Israel Hospital, Boston, United States of America; 3Janssen Research and Development, LLC, Spring House, United States of America; 4University of California LA, Los Angeles, United States of America

Background: Both IL-12 and IL-23 have been implicated in the pathogenesis of SLE. We have previously reported that treatment with an anti-IL-12/23 p40 monoclonal antibody ustekinumab (UST) resulted in greater improvement in several SLE disease measures through week 24 compared with placebo (PBO).1

Objectives: Results of global and organ-specific disease measures and flares through 1 year are reported here.

Methods: We conducted a PBO-controlled phase 2 study in 102 patients with seropositive active SLE (defined by SLICC criteria, SLEDAI score ≥6, and ≥1 BILAG A and/or ≥2 BILAG B scores). Patients were randomized (3:2) to UST (6 mg/kg single IV infusion, then 90 mg SC q8w beginning at week 8, n=60) or PBO (n=42), both added to standard background therapy. Patients receiving PBO crossed over to UST (90 mg SC q8w) at week 24. The primary endpoint was the proportion of patients achieving SLE Responder Index (SRI)-4 response at week 24. Modified intention-to-treat (mITT) analyses across SLE disease measures were performed to evaluate maintenance of response with UST between week 24 and week 48 and severe BILAG flares (≥1 new BILAG A score). Safety was assessed through week 56.

Results: As previously reported, SRI-4 response rate at week 24 was significantly greater (p=0.0007) in patients receiving UST (62%) vs PBO (32%).1 In the UST group, SRI-4 (week 24: 62% vs week 48: 63%), SRI-6 (week 24: 43% vs week 48: 48%), and SRI-6 (week 24: 43% vs week 48: 47%) response rates were sustained at 1 year. Proportions of patients with ≥4-point improvement from baseline in SLEDAI-2K score (week 24: 65% vs week 48: 67%) and with ≥30% improvement from baseline in Physician’s Global Assessment score (week 24: 66% vs week 48: 75%) were also maintained in the UST group. UST response rates were also sustained through 1 year in organ-specific disease measures (≥50% improvement in active joint counts: week 24: 87% vs week 48: 87%; ≥50% improvement in CLASI activity score: week 24: 53% vs week 48: 69%). In PBO patients who crossed over to UST at week 24 (n=33), response rates across outcomes studied were 10-20% higher at week 48 vs week 24. flare rates for patients with severe BILAG flares were 2.1/10,000 patient-years in week 0-24 and 1.1/10,000 patient-days in week 24-48 in the UST group. In the PBO group, severe BILAG flare rates were 8.4/10,000 patient-days in week 0-24 and, following UST crossover, were 4.6/10,000 patient-days in week 24-48. The occurrence of severe BILAG flares seemed to diminish after approximately 8 weeks (week 8 in UST arm, week 32 in PBO arm) of treatment with UST (Figure). No deaths, malignancies, opportunistic infections, tuberculosis cases, or unexpected serious AEs (SAEs) were observed. Incidences of ≥1 SAE were UST (week 0-24) 8.3%, PBO (week 0-24) 9.5%, UST (week 24-48) 8.9%, and PBO-UST (week 24-48) 12.1%. Safety events were consistent with the known UST safety profile.

Conclusion: UST provided sustained clinical benefit in global and organ-specific SLE-activity measures and reduced flares through 1 year, with a safety profile consistent with other indications. Thus, UST may have durable therapeutic benefit in SLE.

OP0042 LONG-TERM EFFECTS OF SYNERGISTIC B CELL IMMUNOMODULATION WITH RITUXIMAB AND BELIMUMAB COMBINATION TREATMENT IN SEVERE, REFRACTORY SLE: TWO YEAR RESULTS
Tineke Kraaij1, E.J. Arends1, Laura van Dam1, Sylvia Kamerling1, Paul J.A. van Dale2, Obbo Winne Breadoweld1, Argo Ray1, Jaap Bakker1, Ingeborg Bajema1, Hans Ulrich Scher1, Thomas Huizinga1, Tom Rabe1, Cees van Rooij1, Y.K. Chio Teng1, Leiden University Medical Center (LUMC), Nephrology, Leiden, Netherlands; 2Erasmus MC, Division of Clinical Immunology, Rotterdam, Netherlands; 3Leiden University Medical Center (LUMC), Clinical Chemistry and Laboratory Medicine, Leiden, Netherlands; 4Leiden University Medical Center (LUMC), Pathology, Leiden, Netherlands; 5Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

Background: We conducted a phase 2, proof-of-concept study (SynBioSe study) in which we combined rituximab and belimumab (RTX+BLM) for treatment of SLE patients with severe, refractory disease. We have previously reported that RTX+BLM effectively reduced relevant anti-nuclear autoantibodies (ANAs) and showed a clinical response at 24 weeks.1

Objectives: The aim of the present study is to investigate the long-term immunological and clinical effects of RTX+BLM in severe, refractory SLE patients.

Scientific Abstracts
Wednesday, 12 June 2019 91
Methods: Fifteen severe, refractory SLE patients were included and followed for 2 years. Patients received RTX at week 0 and 2 and BLM at week 4.6, 8 and then 4-weekly until week 104. Clinical response was assessed by achievement of low level of disease activity (LLDAS). By using specific antibody assays and high sensitivity flowcytometry (HS-FACS), we longitudinally followed, respectively, levels of SLE-specific ANAs and B-cell subsets.

Results: Ten patients (67%) showed a good clinical response after 24 weeks, referred to as ‘responders’. Two of these patients (13%) switched treatment after 24 weeks due to a pregnancy wish and 6 patients (33%) continued study treatment throughout the complete 2 years of follow-up. Five patients (33%) discontinuation treatment due to persistent LN (n=2), major flare (n=2) or relapsing minor flare (n=1), together referred to as ‘non-responders’. Responders achieved LLDAS at a median of 24 weeks [range 12-36] and remained in LLDAS for 76 weeks [56-92] out of 104 weeks of follow-up. In 7 patients with active LN, 6 attained a complete renal response. In responders, ANAs showed significant and specific reduction throughout 2 years with achievement of seronegative anti-dsDNA immunofluorescence in 6 out of 6 anti-dsDNA positive patients at baseline while total IgG, anti-tetanus and anti-rubella antibodies remained stable. By using HS-FACS, a median decrease of 97% [99.3±35] CD19- B-cell depletion was achieved at 24 weeks. Long-term follow-up showed that B-cell repopulation was inhibited throughout 2 years with a persistent median decrease of 84% [-92±22] compared to baseline. Further analysis of B-cell subsets revealed that in the responders, double negative (DN) B-cells (CD27-IgD-) reached maximum depletion at 4 weeks (median 1.09±10^6 cells/liter [range 0.23±10^6-4.31±10^7]), which lasted up to week 72 with a median of 1.26±10^6 cells/liter [0.79±10^6-4.11±10^7] at week 72, similar to values at nadir. This was in contrast to non-responders, where maximum depletion of DN B-cells was reached at 12 weeks (0.48±10^5 [0.17±10^5-0.86±10^5] after which these cells increased to 2.29±10^5 [0.49±10^5-3.49±10^6] at 24 weeks.

Conclusion: Over 2 years follow-up, RTX+BLM for severe, refractory SLE patients prevented complete B-cell repopulation with persistent and specific reduction of ANAs. Clinical response was observed in 67% of patients and treatment discontinuation due to high disease activity was associated with early repopulation of DN B-cells. These data warrant further studies on clinical and immunological benefits of combination treatment RTX+BLM.

that reported the incidence of sustained amenorrhoea (defined as at least 12 months of amenorrhoea) during i.v.CYC treatment in patients with ARD; and those that assessed sustained amenorrhoea in patients receiving GnRHα and i.v.CYC, compared to controls receiving i.v.CYC alone.

Results: 1099 articles were identified and their titles and abstracts screened, following which 81 papers were selected for full text review. 31 studies were then identified that addressed the risk of sustained amenorrhoea with i.v.CYC in n=1382 patients with ARD. The majority of these patients had systemic lupus erythematosus (1326 out of 1382 patients, 96.0%). The mean age was 24.9 (range 13-36.1) years. Sustained amenorrhoea occurred in 269 (19.5%) patients (mean age range 23.9-25.6 years) receiving GnRHα and i.v.CYC, and 37 controls (mean age range 25-29.4 years) given i.v.CYC only. Sustained amenorrhoea occurred in 29/6 (3.6%) patients treated with GnRHα, compared to 15/37 (40.5%) of controls. The pooled odds ratio of sustained amenorrhoea with GnRHα and i.v.CYC compared to i.v.CYC alone was 0.0543 (95%CI 0.0115-0.2576, p=0.0002). The number needed to treat was 2.7 (95%CI 2.0-4.4) and the absolute risk reduction was 92.0% (95%CI 35.6-38.4%).

Conclusion: Although the risk of POI with i.v.CYC was associated with increasing age, it was observed across all age groups and from cumulative doses of 1g or more. GnRHα markedly reduced this risk in ARD, and therefore should be considered for concomitant use with i.v.CYC in all women of child-bearing age with ARD.

* Average of left and right eye.

* Average of left and right eye.

Objectives: To compare efficacy and safety of cyclosporine (CYA) with mycophenolate mofetil (MMF) and with azathioprine (AZA) in the long-term maintenance therapy of LN.

Methods: Ninety-six patients (pts) (93 females, mean age 31.9±12.7 years) with SLE and biopsy proven LN (16 pts/class III; 64 pts/class IV, 16 pts/class V ISN/RPS). Fifty-six pts entered this study at diagnosis of LN and 40 during a course of a LN flare. Twenty-five pts (30%) had Glomerular Filtration Rate (eGFR) <60ml/min (MDRD) and proteinuria was 3.88±2.89 g/day. Induction therapy: 3 methylprednisolone pulses followed by oral prednisone in 92 pts and oral prednisone in 4 pts; cyclophosphamide in 74% of pts, MMF in 9.4%, AZA in 5.2%, and other immunosuppressors in 11.4%. After six months, 30 pts started maintenance therapy with CYA, 32 with MMF and 34 with AZA. At induction therapy there were not significant differences between the three groups in histological classes at renal biopsy, mean serum creatinine, eGFR and proteinuria, and type of induction therapy. The mean follow-up after the beginning of the study was 15.9 years for CYA, 10.5 for MMF, 14.1 AZA. Primary endpoint was renal response at 1, 5 and 10 years defined as complete renal response: eGFR>60ml/min and proteinuria <0.5g/die, partial response: eGFR>60ml/min and proteinuria 0.5-5g/die, no response: eGFR<60ml/min. Secondary endpoint: incidence of flare and safety.

Results: At the beginning of maintenance therapy, the mean serum creatinine and eGFR were similar in the 3 groups (0.92±0.26mg/dl, eGFR 109.9±49.5ml/min in CYA, 0.86±0.4mg/dl, eGFR 119.1±44.8 in MMF, 0.85±0.3mg/dl, eGFR 108.6±43.9ml/min in AZA). Proteinuria was higher in CYA group (CYA: 2.03±1.7g/day; MMF: 0.77±0.8g/day; AZA: 1.2±1.1g/day). At the beginning of maintenance therapy, complete, partial and no response were 26.6%, 60%, and 13.4% in CYA, 53.1%, 43.8% and 3.1% in MMF and 38.2%, 58.8% and 3% in AZA group (Fig 1). At 1 year, after 6 months of maintenance therapy, in CYA group the percentage of pts in complete remission increased to 73% (vs 65.6% in MMF and 40% in AZA), at 5 years it was 80% (vs 83% in AZA and in MMF) and 88% at 10 years vs 70% in MMF and 68% in AZA (Fig 2,3,4). The percentage of non-responding pts was stable from 1 to 10 years in the CYA group (around 13%), it slightly increased in MMF group (from 3.1 to 13.5%) and in AZA group (from 15 to 24%). During the study, SLE flares occurred in 30% of CYA group, 41% in MMF and 32% of the AZA. The average time from the beginning of the study and the first flare was 3.95±2.76years in CYA, 3.62±1.60 in MMF and 5.9±2.37 in AZA. No side effects were reported in 90% of pts treated with CYA, in 81.3% with MMF and in 85.3% with AZA group.

Conclusion: This is the first study comparing these 3 drugs as maintenance therapy in the long term. After 10 years of observation, CYA, AZA and MMF have proven to be effective in consolidating and maintaining the remission of LN. Of interest are the results achieved in the CYA group. Despite worse clinical conditions at the beginning of maintenance therapy, CYA allowed a rapid achievement of LN remission in the great majority of pts compared to AZA and MMF. Remission persisted over 10 years of observation. The number and type of flares and of side effects were not different between groups.

WEDNESDAY, 12 JUNE 2019

Crystals
Objectives: The first ever GWAS of clinically defined gout cases and asymptomatic hyperuricemia (AHUA) controls was performed to identify novel gout loci that aggravate AHUA into gout, as distinct from loci causing SUA elevation.

Methods: We carried out a GWAS of 945 clinically-defined gout cases and 1,003 AHUA controls followed by two replication studies. In total, 2,860 gout cases and 3,279 AHUA controls (all Japanese males) were analyzed. And also, we compared the odds ratios (ORs) for each locus in the present GWAS (gout vs. AHUA) with those in the previous GWAS (gout vs. normouricemia). Furthermore, we investigated the effect of each locus on SUA using the results from our recent GWAS meta-analysis of SUA with a total of 121,745 Japanese subjects.

Results: This new approach enabled us to identify two novel gout loci (rs7927466 of CNTN5 and rs9952962 of MR302F) and one suggestive locus (rs12980365 of ZNF724) at the genome-wide significance level (P<5.0×10^-8). One of them, rs671 of ALDH2, was identified as a gout locus by GWAS for the first time. Comparing ORs for each locus in the present vs. the previous GWAS revealed three “gout vs. AHUA GWAS” specific loci (CNTN5, MR302F and ZNF724) to be clearly associated with mechanisms of gout development which distinctly differ from the known gout risk loci that basically elevate serum uric acid (SUA) level. The effect of each locus on SUA using the results from our recent GWAS meta-analysis of SUA are consistent with those of the present study.

Conclusion: This first discovery of “AHUA to Gout” loci using a new GWAS strategy will lead to elucidation of the molecular mechanism of the last step of gout development and to the prevention of gout attacks in high-risk AHUA individuals.
OP0049 FACTORS ASSOCIATED WITH EARLY FLARES WHEN INITIATING URATE LOWERING THERAPIES. POST-HOC ANALYSIS OF CLEAR 1.2 AND CRYSTAL TRIALS

Pascal Richellet1, Fernando Perez-Ruiz2, Ravi Karna3, Augustin Latourte1, Imane Wild1, Prashanthan Kandaswamy4, Heiko Hagedorn5, Thomas Bardin1, 6
1Hospital Lanboisire, Paris, France; 2Servicio de Reumatología, Hospital Universitario Cruces, Cruces, Spain; 3Grunenthal, Aachen, Germany

Background: Initiation of urate lowering therapies (ULT) in patients with gout can trigger flares which could contribute to poor treatment adherence. The EULAR guidelines recommend a prophylactic treatment with colchicine or low dose NSAIDs for up to 6 months. However, long term treatment with either NSAIDs or colchicine can be poorly tolerated or contra-indicated. Thus, identification of risk factors for flares to identify patients who would benefit more from a prophylactic treatment could improve patients care.

Objectives: To investigate the influence of patient and treatment related factors on the occurrence of flares 1 month after the initiation of ULT.

Methods: Data are from n=1018 patients (mean age 52.0 (SD 11.1) years; 95.2% male) not responding to allopurinol or febuxostat monotherapy and who received lesinurad (200 mg or 400 mg) in the CLEAR and CRYSTAL trials. Patients were prescribed colchicine (84%) or NSAIDs (12.9%) as prophylactic treatment. Data from 3 trials were pooled and the following covariates were considered in the main analysis using a Generalized Estimation Equation (GEE) model: age, gender, serum uric acid (SUA) levels, baseline body mass index, renal function, and presence of tophus, type of gout flare prophylaxis, triglycerides, comorbidities (smoking, tobacco, diabetes, hypertension, hyperlipidemia) antihypertensive and lipid lowering medications at baseline and newly started and change in SUA levels. A multivariate analysis was conducted using the occurrence of flares as response measured from baseline until month 1.

Results: In the multivariate analysis, tophus at baseline and gender (female) were both associated with an increased risk of early flares: OR=2.7 (95% CI: 1.7-4.2) and OR=1.8 (95% CI: 1.0-3.4), respectively, whereas hyperlipidemia and hypertension were associated with a decreased risk of flares: OR=0.64 (95% CI: 0.45-0.91) and OR= 0.82 (95% CI: 0.39-0.90). There was a trend toward a reduced risk of flares with colchicine versus NSAIDs: OR=0.71 (95% CI: 0.47-1.05). Neither the duration of gout nor the change in SUA levels modified the risk of flares.

Conclusion: This analysis shows that gender (female) and tophus are independent risk factors of early flares when initiating ULT, and suggests that colchicine can be poorly tolerated or contra-indicated. Thus, identification of risk factors for flares to identify patients who would benefit more from a prophylactic treatment could improve patients care.

OP0050 ADDITIVE VALUE AND DIAGNOSTIC ACCURACY OF DUAL-ENERGY CT FOR THE DIAGNOSIS OF GOUT: A PROSPECTIVE STUDY IN SUBJECTS WITH UNCLASSIFIED MONO OR OLIGOARTHRITIS

Mihaela Gamala1,2, Johannes W. G. Jacobs3, Suzanne Linn-Rasker2, Maarten Niv4, Ben Heggelman5, Pieterem Pasker6, Jacob M. van Laar7, Ruth Klaasen1
1University Medical Center Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands; 2Northwest Clinics, Rheumatology, Alkmaar, Netherlands; 3University Medical Center Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands; 4Meander Medical Center, Rheumatology and Clinical Immunology, Utrecht, Netherlands; 5Meander Medical Center, Rheumatology, Amersfoort, Netherlands; 6Meander Medical Center, Radiology, Amersfoort, Netherlands; 7Meander Medical Center, Meander Academy, Amersfoort, Netherlands

Background: The latest diagnostic technique to visualize monosodium uric acid (MSU) deposits is Dual Energy CT scan (DECT).1

Objectives: To assess the additive value and accuracy of DECT in diagnosing gout in a prospective study in subjects with unclassified arthritis.

Methods: We included 100 consecutive patients with acute unclassified mono or oligo arthritis who presented to the outpatient clinic of the Department of Rheumatology of Meander Medical Centre, Amersfoort, the Netherlands, ClinicalTrials.gov NCT03038386. Eleven patients dropped out, see Figure. Patients underwent aspiration of the arthritic joint (see Table) and a DECT scan of hands and wrists, knees, ankles and feet bilaterally. The 2015 EULAR/ACR gout classification criteria were used to score the subjects, with and without DECT result, to determine the additive value of DECT. Sensitivity and specificity of DECT for diagnosing gout were calculated separately for at the joint and at individual persons’ level, using as reference standards microscopy of synovial fluid (SF) and the gout classification criteria.

Results: For demographic and clinical characteristics of the patients see Table 1, and for study data and outcomes see Figure and Table 2. Sixty-eight of 89 patients (76.4%) fulfilled the 2015 EULAR/ACR criteria for gout. Of the 98 patients with SF aspiration, 55 (56%) were positive for MSU; of these, 89 subjects underwent DECT, of whom 38 had a negative microscopy result. Of these 38 subjects, 14 (37%) met the gout classification criteria only after a positive DECT result.

Conclusion: Our findings suggested that DECT could have an additive value to clinical algorithms in subjects with undifferentiated arthritis when microscopy of SF fails to demonstrate the presence of MSU crystals.

COP0051 DEVELOPMENT OF A MULTIVARIABLE IMPROVEMENT MEASURE FOR GOUT
Naomi Schlesinger1, N. Lawrence Edwards2, Anthony Yeo3, Peter Lipsky1
1 Rutgers Robert Wood Johnson Medical School, New Brunswick, United States of America; 2 University of Florida, Gainesville, United States of America; 3 Horizon Pharma, Lake Forest, United States of America; 4 AMPPEL Biosolutions, LLC, Charlotteville, United States of America

Background: Inflammatory rheumatic diseases are generally multifaceted disorders and the complex pathology underlying these conditions makes it difficult to assess patient status and the efficacy of therapy with a single outcome measure. This has prompted the development of composite measures for many rheumatic diseases. Gout is also a multifactorial inflammatory disease in which patients experience a wide range of signs and symptoms, including intermittent and persistent pain and inflammatory arthritis, tophi and disability. Most assessments of gout and response to urate-lowering therapy (ULT) have focused primarily on the ability to lower serum urate and decrease the frequency of flares. Recognition that assessment of ULT and other treatments for gout could be facilitated by endpoints that more closely reflect the multidimensional impact of the disease has prompted an interest in developing composite measures, although there is no consensus on the most appropriate composite measure to employ.

Objectives: To develop an evidence-based gout multivariable improvement measure (GMIM) that captures the spectrum of gout manifestations and is sensitive to change.

Methods: Databases from patients with chronic refractory gout who participated in two randomized 6 month clinical trials (RCTs) of pegloticase were reviewed

Sub-sets who had persistent urate lowering (responders) to bi-weekly pegloticase (n=36) and those who had only transient urate lowering (non-responders, n=49) were identified and compared to those who received placebo (n=43). Initially individual patients were assessed for achievement of previously reported criteria for remission: serum urate <6 mg/dL, absence of tophi and flares, patient global assessment, and pain (each <2 on a 10-point visual analog scale). A repeated measures mixed effects model controlling for repeated observations with backward elimination using data from these patients was employed to determine the model components that best correlated with time to maximum benefit. This analysis resulted in the addition of swollen and tender joints to the outcome measure. In order to assess the degree of improvement, each subject was scored based upon a serum urate >6 mg/dL and 20, 50 or 70% improvement in 4 of the 6 clinical evaluations and termed GMIM0, 20, 50, 70.

Results: GMIM was able to capture gradation of change in the treated populations and also distinguish responses in those with persistent versus those with transient urate lowering and subjects treated with placebo (Figure 1). At 3 and 6 months, achievement of GMIM20, 50 and 70 in persistent responders occurred significantly more often vs placebo and versus non-responders without persistent urate lowering. Sensitivity analysis indicated that flares contributed minimally to the model.

Conclusion: GMIM effectively captures changes in disease severity in response to treatment in patients with advanced gout treated with pegloticase. GMIM0, 20, 50, 70 may serve as an evidence-based tool for assessment of the quality of response to therapies in subjects with gout in medical practice or in clinical trials.

COP0052 FAILURE TO REACH SERUM URATE TARGET IS ASSOCIATED WITH ELEVATED MORTALITY IN GOUT
Fernando Perez-Ruiz1, Pascal Richette2, Austin Stack3, Ravi Karna4, Maria Jesus Garcia de Yebenes5, Loreto Carmona5, Cruzes University Hospital, Rheumatology Division, Baracaldo, Spain; 2 Labiosiere Hospital, Rheumatology Division, Paris, France; 3 University Hospital Limerick, Nephrology Division, Limerick, Ireland; 4 Grunenthal, Aachen, Germany; 5 Innusus, Madrid, Spain

Background: Gout is associated with an increased risk of cardiovascular events and death. It has been shown that both overall and risk of death are associated with increasing gout severity, as reflected by the number of tophi. It remains to be proven whether better control of gout through lowering of serum uric acid (sUA) confers a survival advantage.

Objectives: To determine the impact of achieving sUA less than 6 mg/dL (vs greater) on mortality risk among gout patients.

Methods: Analysis of data from a prospective follow-up cohort (1992 to 2017) of patients attending a gout clinic (85% of patients with microsopce or ultrasound diagnosis) and with at least one follow-up visit. Mortality was confirmed from medical records, patients’ families, or local death registries if needed. sUA levels were monitored during follow-up and the average sUA until sUA was stable was used as the primary exposure dichotomized as < 6 mg/dL (versus > 6 mg/dL). Descriptive variables and potential confounders included: age, gender, body mass index, previous treatment with urate-lowering drugs (ULDs), number of joints affected at entry, presence of subcutaneous tophi, radiographic evidence of articular damage, number of gout flares in the year preceding evaluation, previous diagnosis of cardiovascular (CV) disease, loop diuretic use, alcohol intake, diabetes, hypertension, hyperlipidemia, and renal function impairment. In addition, the Kaiser Permanente documentation of comorbidities was further used to risk stratify patients from low to high risk of death. Univariate and multivariate Cox proportional hazards models were used to determine mortality risks expressed a hazard ratios (HR) and 95% Confidence Intervals (CI).

Results: The study cohort included 1,193 patients (92% men, mean age 60.6, 6.8 years disease duration, with an average of 3-4 flares in the previous year). Mean follow-up was 48 (median 30, IQR 12-66), with 4,830 patient-year observation. Mean sUA at baseline was 9.1 mg/dL and 16.3% of the patients maintained sUA levels <6 mg/dL despite treatment. A total of 158 deaths occurred (13% overall mortality), with loss to follow-up in 286 cases (24%). Overall crude mortality rate was 32.7% per 1,000 patient-years (95% CI: 28.0-38.2) and was significantly higher for patients with sUA >6 mg/dL, 80.9 per 1,000 person years (95% CI: 59.4-110.3) compared to patients with sUA <6 mg/dL, 25.7 per 1,000 person-years (95% CI: 21.3-30.9). With adjustment for age, sex, previous CV events, and baseline sUA concentration, a sUA > 6 mg/dL was associated with a HR of 2.39 (1.64 - 3.50).

Conclusion: Failure to reach a target sUA level of 6 mg/dL is an independent predictor of mortality in gout patients. Control of gout with achievement of sUA target <6 mg/dL should be considered in order to improve patient survival.

COP0053 CERAMIDES AND DIHYDROCERAMIDES LEVELS ARE ASSOCIATED WITH THE INFLAMMATORY RESPONSE IN A MURINE MODEL OF GOUT
Alexander Sjö1, Florence Meh1, Nicola Harris2, Veronique Chobaz1, Hector Gallart-Avala3, ChEV, Rheumatology, University of Lausanne, Lausanne, Switzerland; 2 Monash University, Melbourne, Australia

Background: The metabolic syndrome is strongly associated with gout and hyperuricemia in man. Patients with gout commonly report acute flares after eating particular foods and it is suspected that metabolic changes, apart from serum urate levels, influence the triggering of the inflammatory response to MSU crystals.

Disclosure of Interests: Alexander Sjö, Nicola Harris, Veronique Chobaz, Hector Gallart-Avala Employee of: ChEV, Rheumatology, University of Lausanne, Lausanne, Switzerland; 2 Monash University, Melbourne, Australia

REFERENCES:

Objectives: By studying the metabolic changes that impact on the response to MSU crystals in a murine model of gout, we hope to identify the dietary effect on metabolites that are associated with the inflammatory response to MSU crystals.

Methods: Male mice (C57Bl/6) were fed either a normal diet (ND) or high fat diet (HFD, D12492O) for 6 weeks. During the last 4 weeks of feeding, half the mice in each group were treated with antibiotics (Enrofloxacin 0.25% + ceo-amoxicillin) to induce a germ-free state. At day 0, mice were injected i.p with 1mg of MSU crystals. Mice were sacrificed 6h after i.p injection. Serum, plasma and peritoneal exudate samples were collected at sacrifice and plasma obtained 3 weeks before sacrifice. Untargeted and targeted liquid chromatography – mass spectrometry based-metabolomics approach was performed on serum and plasma samples. IL1 and IL6 were measured in serum and peritoneal exudates by ELISA. Animal experimental authorization was obtained for these experiments.

Results: Mice fed a HFD had a greater serum and peritoneal IL6 response to MSU. In an untargeted analysis, multiple metabolic alterations were observed related to diet. Targeted analyses of sphingolipids were performed. Both diet and inflammation (MSU injection) altered plasma sphingolipid levels. No effect of antibiotics was observed. MSU injection induced marked changes in the sphingolipid profile (38.2% of explained variance), while diet had a lesser effect (12.6% of explained variance). Mice fed an HFD had significantly higher serum IL6 before and peritoneal IL6 levels after MSU injection than mice fed a ND. DhCer C16:0 and Cer C16:0 showed significantly negative correlations with IL6 levels. DhCer C16:0 and Cer C16:0 levels decreased significantly after MSU injection. Pre-MSU levels of DhCer C16:0 and Cer C16:0 showed significantly negative correlations with IL6p levels after i-p injection in HFD animals.

Conclusion: The sphingolipid profile was significantly changed by diet and inflammation. In mice given a HFD, the levels of particular ceramides were significantly correlated with subsequent inflammatory response as assessed by IL6 secretion, suggesting that they may play a role in modulating the inflammatory response to MSU. These same ceramides and their derivatives have been linked to susceptibility to diabetes and cardiovascular diseases. Further investigation of these sphingolipids in gout in man is warranted.

OP0054 OCCUPATIONAL EXPOSURE TO INORGANIC DUST – A NOVEL RISK FACTOR FOR INCIDENT GOUT?

Valgerdur Sigurdardottir1,2, Anna Sváð1, Lennart T.H. Jacobsson3, Linus Schöler4, Kjell Tönn5, Mats Dehlin6, Uppsala University, Center for Clinical Research Dalarna, Falun, Sweden; 2Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 3Sahlgrenska Academy, University of Gothenburg, Section of Occupational and Environmental Medicine, Gothenburg, Sweden

Background: Hyperuricemia and factors contributing to it are strong risk factors for gout but it is still unexplained why only some individuals with hyperuricemia develop gout. Additional risk factors for gout could be genetic or related to comorbidity, lifestyle or occupation. Occupational exposure to inorganic dust has previously been linked to an increased occurrence of inflammatory rheumatic diseases such as rheumatoid arthritis and could possibly increase the risk of gout.

Objectives: To evaluate if occupational exposure to inorganic dust increases the risk of incident gout.

Methods: Gout was defined as having at least one ICD-10 code for gout (M10 or M14.0) in the population based health care database of the Western Swedish Health Care Region (VEGA), during the years 2006-2012, without any gout diagnosis during at least 6 years previously. Individuals with gout that were employed in the 5-year period prior to first diagnosis were included for analysis. Population controls without gout were identified in the census register by Statistics Sweden, in the 5-year period prior to first diagnosis were included for analysis. Population controls, n=19339; Men: Gout cases, n=4751; Women: Gout cases, n=1369. Population controls, n=25074; Men: Gout cases, n=7074; Women: Gout cases, n=32 (2) 182 (13)

Results: The exposure to inorganic dust increased the risk of incident gout. Exposure to inorganic dust was described with odds ratios, calculated using conditional logistic regression, for the whole population and stratified by sex.

Conclusion: As expected, previous known risk factors for gout such as obesity and alcoholism were strongly associated with incident gout. In univariate analyses, exposure to inorganic dust was also associated with gout. After adjusting for alcohol abuse and obesity, the relationship was attenuated in men but remained in women, providing evidence that occupational exposure to inorganic dust might be a previously unknown risk factor for gout.

Jacobsson Consultant for: LJ has received lecture and consulting fees from Pfizer, Abbvie, Novartis, Eli-Lilly and Janssen, Linus Schöler: None declared, Kjell Tönn: None declared, Mats Dehlin: None declared

Methods: This Phase 3b/4 study had 2 parts. Of 182 enrolled pts, 166 pts with inactive disease (ID) (cohort 1; 68pts) and CAN-naive pts (cohort 2; 98pts) were administered subcutaneous CAN 4mg/kg q4w in Part I. Per protocol titration off CS and/or methotrexate (MTX) was attempted during Part I. Eligible pts (ID for 24 weeks[wks]) and being CS- and MTX-free for at least 4 wks) advanced to Part II wherein, pts were randomised to either a 3-step CAN dose reduction (2mg/kg/q4w, followed by tapering to 1 mg/kg/q4w and then discontinuation) or dose interval prolongation (4mg/kg/q4w, followed by tapering to 4mg/kg/q12w and then discontinuation); pts advanced to the next tapering step if ID was maintained for 24 wks. Adapted American College of Rheumatology (ACR) paediatric criteria, its individual components and Juvenile Arthritis Disease Activity Score (JADAS) were assessed.

Results: In total, 75 pts were randomised to a dose reduction (n=38) or dose interval prolongation (n=37) CAN tapering regimen in part II. The pts who maintained ID for 24 wks exceeded the predefined threshold of 40% for the reduced CAN dose arm (71%) and prolonged dose interval (84%) treatment arm of Step 1 (primary endpoint). A total of 68.4% (26/38) and 61.1% (30/37) pts in the dose reduction and interval prolongation arms, respectively were successful in Step 2; 33% (25/75) of pts successfully discontinued CAN and maintained ID for 24 wks. ID, ACR 90/100 and JADAS 27 C-reactive protein (CRP) scores are summarised in the table. Adverse events (AEs) and serious AEs observed within the 2 cohorts and across Parts I and II were similar. The most frequent AEs were common infections (nasopharyngitis, upper respiratory tract infection, pharyngitis) followed by SJIA-related events (rash, pyrexia and arthralgia).

N, total number of patients; n, number of patients

Conclusion: SJIA pts with ID for 24 wks on CAN monotherapy can successfully taper CAN by either reducing the dose or prolonging the dosing interval. However, only a minority of pts overall successfully discontinued CAN treatment and maintained ID for 24 wks. The safety profile was similar and consistent with other CAN SJIA studies. No new safety signals were identified.

Early Treatment with Anakinra in Systemic Juvenile Idiopathic Arthritis

Manuela Pardo, Claudia Braccaglia, Anna Tulone, Antonella Insalaco, Giulia Marucci, Rebecca Nicolai, Virginia Messia, Emanuela Sacco, Fabrizio De Benedetti, JPCZ-16 Pediatric Rheumatology, Rome, Italy

Background: Systemic juvenile idiopathic arthritis (sJIA) accounts for 10-20% of all patients with JIA. The prominent systemic clinical features, the marked elevation of inflammatory markers and the absence of autoantibodies make this disease different from other JIA forms. sJIA should be considered as a polygenic autoimmune disease. Interleukin 1 (IL-1) has been shown to be a major mediator of the inflammatory cascade that underlies sJIA. Treatment with anakinra has been reported to be effective in a sizable portion of patients with sJIA.

Objectives: To assess clinical response rate and disease course in sJIA patients treated with anakinra. To evaluate whether the response to anakinra was related to baseline variables.

Methods: We reviewed 56 (28 F) consecutive patients with sJIA treated with anakinra for at least 6 months in our institution. The diagnosis of sJIA was established according to the International League of Associations for Rheumatology (ILAR) classification criteria. We analyzed the effect of anakinra on fever, rash, number of active joints, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), white blood cells count, platelets count and ferritin levels. Clinically inactive disease (CID) was defined according to Wallace criteria. Clinical and laboratory data were obtained using a standard data collection form.

Results: The median age at the disease onset was 5.7 (IQR 2.9-10.2) years. The median time from onset to received anakinra was 1.9 (IQR 0.7-9.7) months. At baseline 52/56 (93%) of patients had fever and median number of active joints was 2 (IQR 1-4). After 6 months of treatment 39 patients (69.6%) met criteria for inactive disease. Among 56 patients 17 (30.3%) received anakinra in monotherapy and 39 (69.6%) received anakinra with glucocorticoids. There were no statistically significant differences between the two groups for demographic, clinical and laboratory features. 13/17 (76.4%) patients treated with anakinra alone and 26/39 (66.6%) patients treated with anakinra and glucocorticoids met criteria for CID off glucocorticoids at 6 months (p=0.54). Among the 56 patients, 29 (51.7%) received anakinra within 2 months from disease onset. There were no statistically significant differences for demographic, clinical and laboratory features among patients who started anakinra in the first 2 months from disease onset compared to those that started anakinra after 2 months. At 6 months after beginning of anakinra treatment, 27/29 patients (93.1%) who started anakinra within 2 months from disease onset and 12/27 (44.4%) who started anakinra after 2 months from disease onset reached clinical inactive disease off glucocorticoids (p=0.0011). Patients who started anakinra after the first 2 months from disease onset have a significantly higher risk of non-response (OR=8.06, 95% CI 2.03-32.0).

Conclusion: According with several observations, anakinra is effective in a significant proportion of patients with sJIA. A possible approach to introduce IL-1 inhibitor, with or without concomitant glucocorticoids, early in the disease course taking advantage of a "window of opportunity" has been suggested. Our observation confirms that earlier treatment with anakinra is associated with a better short-term outcome. Moreover, our results show that beginning of treatment after two months of disease is correlated with a high risk of non-response.

REFERENCE:
Results: A total of 8,309 patients were included in this study. 290 gastrointestinal disorders were reported in 260 patients. 50 cases in 47 patients were classified as IBD or suspected IBD. Age at JIA onset was significantly higher in patients who developed IBD (9.1 vs 7.1 years p=0.002), and female predominance was lower (48.9% versus 67.6% p=0.011). Enthesitis related arthritis (ERA) was the JIA subtype in 40.4% of the patients who developed IBD. In 14 out of 47 patients more detailed information about IBD disease onset was available, such as date of disease onset and medication used at that time. 71.4% of all 14 patients used enotenap and 50.0% used MTX 3 months prior or at IBD onset. Enotenap exposure prior to IBD onset varied from no exposure to 6.39 years with a median of 1.3 years. Methotrexate exposure prior to disease onset varied from no exposure to 8.10 years with a median of 2.9 years. Information regarding quality of life was available for 2,752 patients of which 17 IBD patients. Quality of life, both physical and psychosocial, was significantly lower in patients who developed IBD patients (p=0.019 and p=0.046 respectively). Conclusion: In this study ERA patients were more at risk of developing IBD and 71.4% used enotenap while developing IBD. We did not find a protective role of MTX since 50% of patients with available data developed IBD while using MTX. Lastly, IBD has an important physical and psychosocial impact on quality of life.

Gaslini Hospital; therefore, my role does not allow me to render private consultancies resulting in personal income. I perform consultancy activities on behalf of the Gaslini Institute for the companies listed below: AbBeie, Biogen, Boehringer Ingelheim, Bristol-Myers Squibb, EMD Serono, Janssen, Novartis, Pfizer, Pfizer, B-Pharm.
The money received for these activities are directly transferred to the Gaslini Institute’s bank account. Before March 2016, I was the head of the Pediatric Rheumatology Department at the G. Gaslini Hospital, where NR works as full-time public employee, has received contributions (> 10,000 EUR) from the following industries in the last 3 years: BMS, Eli-Lilly, GlaxoSmithKline, Hoffmann-La Roche, Janssen, Merck, Novartis, Pfizer, R-Pharma, SanofiServier, Sinergie, Sobi and Takeda. The money received has been invested for the research activities of the hospital in a fully independent manner, without any commitment with third parties. Consequently: For received honoraria for consultancies or speaker bureaus (< 10,000 USD each) from the following pharmaceutical companies in the past 3 years: AbbVie, Biogen, AstraZeneca-Medimmune, Biogen, Boehringer, Bristol-Myers Squibb, Eli-Lilly, EMD Serono, GlaxoSmithKline, Hoffmann-La Roche, Janssen, Merck, Novartis, Pfizer, R-Pharma, SanofiServier, Sobi, and Takeda.

Andrea Uva1, Lucilla Rava2, Hanan Jadoon3, Angela Aquilani2, Fabio Basta2, Rebecca Nicolai2, Fabrizio De Benedetti4, Silvia Magni-Manzoni1, ‘La Sapienza, Università of Rome, Department of Pediatrics, Rome, Italy; 1IRCCS Ospedale Pediatrico Bambino Gesù, Clinical Epidemiology unit, Rome, Italy; 2IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy

Background: Glucocorticoid injections in periarticular sites (PAGI) such as ten- dons and bursae often complete the local treatment of active disease in juvenile idiopathic arthritis (JIA). However, the use of PAGI and their role in the achieve- ment of disease remission has seldom been studied.

Objectives: To identify the clinical features of JIA patients treated with PAGI at the study center in a 6 years period, the sites most frequently injected, the fre- quency of and the time for achieving local remission.

Methods: Records of JIA patients treated with PAGI at the study center from 2012 were retrospectively reviewed. Demographic and clinical features, including ongoing systemic treatment, sites of injection, procedure setting, type and dosage of glucocorticoid injected, time to achieve local remission (complete or partial when one/or some of the injected sites were in remission and one/some showed per- sistent synovitis), frequency of remission of the injected sites at the last follow-up and side-effects were recorded.

Results: In a total of 293 procedures 647 tendons and 26 bursae were injected in 191 patients. Most of the patients were females (74%), with ILAR oligoarticular JIA subtype (50% persistent, 23% extended), followed by RF-negative polyarthritis (23.2%), RF-positive polyarthritis (0.7%) and systemic JIA (1.3%), with a median age of 8.2 years (IQ 4.7-11.3) at the PAGI. All procedures were ultra- sound-guided, 281 (96%) under general sedation. Acetate methylprednisolone in 96% of the procedures (average dosage 0.45 mg/kg/tendon, 0.89 mg/kg/bursa), whereas trimcinolone exacetonide in 4%. In 255 procedures (87%) patients experienced remission in the injected sites after a median of 2.6 months (IQ 1.9-3.5). Forty-seven patients (24.6%) underwent to repeated injections in the same sites after at least 3 months from the 1st procedure. A total of 96 tendons and 9 bursae were re-injected during 69 procedures (23.5%). At the last follow up, after a median period of 29.4 months (IQ 15.45-48.4) from PAGI, patients experi- enced complete local remission in 259 (88.4%) injected procedures and partial local remission in 23 (7.8%). In 53 procedures with repeated injection(s) in the same site(s) (77%), patients were in local remission at the last follow up. In 77 pro- cedures (26.3%) patients presented flare of disease in periarticular sites. Con- cerning concomitant therapy, at the time of each PAGI 115 patients (39.2%) were not on treatment, 137 (46.7%) were on methotrexate, 29 (9.9%) on methotrexate and biologics, 8 (2.7%) on biologics and 4 (1.5%) received others. Patients were started with a new treatment in around three months following 139 (47.4) proce- dures due to poor control of disease. In 156 (53.2%) procedures, patients experi- enced complete/local remission and maintained the same treatment before or after the injection at the last follow up in a median period of 20.8 months (IQ 12.67- 39.35). Of notice, 81.4% of patients who experienced complete remission follow- ing the injection were not on concomitant treatment; 85.9% of patients who experi- enced complete remission at the last follow up did not receive concomitant treatment. In 24 injection procedures (8.2%) patients showed only mild side local effects (atrophy and hypogammaglutimation).

Conclusion: PAGI are a safe option in the management of JIA. In our cohort, patients treated with PAGI had more frequently persistent oligoarticular JIA sub- type: acetate methylprednisolone was by far the most frequently used glucocor- ticonid. In 88.4% procedures patients experienced remission at last follow up. However, further investigations are mandatory to assess the role of concomitant therapy in achieving and maintaining remission.

SAFETY PROFILE OF ETANERCEPT IN LONG-TERM USE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA)

Jens Klotsche1, Ariane Klein1, Martina Newerth1, Gerd Ganser4, Peer Aries2, Marisa Walther4, Peter Haas4, Gerrit Keyßer1, Gerd Horneff1, Kirsten Minden1,2.

1German Rheumatism Research Center, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Berlin, Germany; 3Asiplitz Kinderklinik St. Augustin GmbH, St. Augustin, Germany; 4St-Josef-Stift Sendenhorst, Sendenhorst, Germany; 5Internistisch-Rheumatologische Praxis, Hamburg, Germany; 6Das Endokrinologium, Berlin, Germany; 7Zentrum für Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany; 8Universitätsklinikum Halle, Rheumatologie, Halle, Germany

Background: Etanercept is the most frequently used biologic drug in patients with JIA. Children and adolescents with JIA are treated with etanercept often over long periods of time, sometimes even into adulthood. The knowledge about its long-term safety, especially with regard to the occurrence of new-onset immune-mediated diseases and malignancies, is limited.

Objectives: To investigate the exposure-adjusted rates of adverse events (AE) and serious AE (SAE) in patients with JIA with long-term use of etanercept.

Methods: Patients with JIA who were enrolled in the German biologic register BiKeR and were born before 30.05.2000 (at least 18 years of age at this date) were considered for this analysis. The follow-up register JuMBO ensures the long-term follow-up into adulthood. An AE or SAE was attributed to etanercept when the treatment was either ongoing or terminated in less than 3 month prior to the event. The incidence of malignancies was estimated in patients who were ever exposed to etanercept with at least one dose.

Results: Of 4546 patients who were currently enrolled in BiKeR a total of 2584 JIA patients were eligible for the JuMBO register (18 years). Among those, 1765 (68%) were ever exposed to etanercept and observed for a mean of 6.8±4.9 years (including 1101 into adulthood). The majority of them had polyarthritis (35%), followed by enthesitis-related arthritis (20%) and extended oligoarthritis (17%). The patients were exposed to etanercept for a total of 4.2 years (mean, 6.726 exposure years, EY); 518 patients were continuously treated with etanercept for at least 5 years (4,534 EY). In total, 124 autoimmune events (1.84/100EY) and 7 other immune disorders (0.10/100EY) were reported in 102 (5.6%) and 7 (0.4%) patients with onset on average 10.2 years after JIA onset, and 6.8 years after start with etanercept, respectively. The number of selected immune-mediated events and the exposure-adjusted rates are given in the table. In addition, 11 malignancies (0.10 events/100 person-years) were reported in patients ever exposed to etanercept. Among those (mean age at onset 20.3 years), 4 malignancies were reported in childhood and 7 in young adulthood. Three patients were also exposed to etanercept before the incidence of malignancy. The malignancies occurred on average 12.1 years after JIA onset, 10.4 years after start with a first DMARD and 7.5 years after first exposure to etanercept.

Conclusion: This is the first long-term large safety study in prospectively followed JIA patients with an emphasis on new-onset immune-mediated diseases and malignancies in etanercept. The study also highlights that it is important to prospectively collect data on adverse events under treatment with biologics in JIA, in particular with respect to the risk of malignancies in young adulthood.

Table 1. Adverse and serious adverse events under treatment with etanercept

CONSUMER PERSPECTIVE ON PAEDIATRIC RHEUMATOLOGY CARE AND SERVICE DELIVERY: RESULTS FROM AN EARLY JUVENILE IDIOPATHIC ARTHRITIS (JIA) COHORT STUDY

Michaela Heinrich1, Jens Klotsche2, Claudia Sengler3, Martina Newerth1, Frank Welter-Heinemann1, Peter Haas4, Gerd Horneff1, Toni Hospach1, Kirsten Moenkemoeller1, Angelika Thon1, Ivan Foeldvari9, Kirsten Minden1.

1Charité Universitätsmedizin Berlin, Berlin, Germany; 2German Rheumatism Research Centre, Berlin, Germany; 3ICON study group, Bremen, Germany; 4ICON study group, Garmisch-Partenkirchen, Germany; 5ICON study group, Sankt Augustin, Germany; 6ICON study group, Stuttgart, Germany; 7ICON study group, Köln, Germany; 8ICON study group, Hannover, Germany; 9ICON study group, Hamburg, Germany

Background: Timely access to specialized and multidisciplinary care is a core principle in the management of JIA patients and crucial to achieve the best possible outcome for children and adolescents with JIA.

Objectives: To assess satisfaction with access to specialized care and used health care services of families with children with JIA and to identify factors associated with unmet needs.

Methods: Parents of JIA patients enrolled in the early JIA cohort study ICON completed the Child Healthcare Questionnaire on Satisfaction, Utilisation and Needs (CHC-SUN)1 and the Family Burden Questionnaire (FaBel) 3 months after enrolment. The socioeconomic status, disease activity, patients’ functional ability and quality of life were also assessed. Factors associated with unmet needs were identified by logistic regression analysis.

Results: Data were available from 835 families with children diagnosed with JIA 3 months (median, IQR 1.6) after symptom onset and cared for by paediatric rheumatologists (68% females). At assessment (4.6 months after diagnosis, median), 67% of patients received non-steroidal anti-inflammatory drugs, 50% received conventional synthetic DMARDs and 8% biologic DMARDs. In addition, the following health care services were utilized: 84% physiotherapy, 23% occupational therapy, 21% supply with physical aids, 17% telephone counselling, 15% health education, 13% social worker services, and 11% psychological counselling. Unmet needs were most frequently reported for health education (19%), rehabilitation services (11%), psychological counselling (11%), self-help groups (10%), and lowest for physiotherapy (2%). Unmet needs varied depending on the type of service and JIA category (Table). They were more frequently observed in families with higher burden as indicated by FaBel, but were not associated with migration background and socioeconomic status. Most parents were generally satisfied with their child’s health care (satisfied 30%, very satisfied 42%, extremely satisfied 23%). Satisfaction was highest with the behaviour of doctors and lowest with school-related services (e.g. 36% not or partly satisfied with teachers’ knowledge about the child’s illness) and diagnosis/information (e.g. 29% not or partly satisfied with the time required for the diagnosis).

Conclusion: There are, although infrequently, unmet needs and dissatisfaction with health services among families with children who have JIA and receive specialized care. Whether these deficits are relevant for long-term JIA outcomes will be further investigated in the ICON study.

IDENTIFICATION OF SIX DERMATOMYOSITIS SAFETY OF MYCOPHENOLATE MOFETIL TREATMENT

Huiyi Zhu, Chanyuan Wu, Nan Jiang, YanHong Wang, Jiulian Zhao, Dong Xu, Xiaoleng Zeng, Li Mengtao. Department of Rheumatology, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing, China; 2Department of Epidemiology and Biostatistics, Institute of Basic Medical Sciences Chinese Academy of Medical Sciences, School of Basic Medicine Peking Union Medical College, Beijing, China

Background: Dermatomyositis (DM) is a heterogeneous disease with a wide range of clinical manifestations. Bohan and Peter suggested four subtypes of DM: idiopathic DM, juvenile DM, DM associated with cancer, and DM associated with other connective tissue diseases. Different DM subtypes have distinct clinical manifestations, responses to therapy and prognoses.

Objectives: The aim of the present study was to identify the clinical subtypes of DM by applying cluster analysis.

Methods: We retrospectively reviewed the medical records of 720 DM patients and selected 21 variables for analysis, including clinical characteristics, laboratory findings, and comorbidities. Principal component analysis (PCA) was first conducted to transform the 21 variables into independent principal components. Patient classification was then performed using cluster analysis based on the PCA-transformed data. The relationships among the clinical variables were also assessed.

Results: We transformed the 21 clinical variables into 9 independent principal components by PCA and identified 6 distinct subgroups. Cluster A was composed of two sub-clusters of patients with classical or moderate DM. Cluster-B patients were older and had malignancies. Cluster C was characterized by interstitial lung disease (ILD), skin ulcer, and minimal muscle involvement. Cluster D included patients with prominent lung, muscle, and skin involvement. Cluster E contained DM patients with other connective tissue diseases. Cluster F included all patients with prominent lung, muscle, and skin involvement. Cluster E contained DM patients with other connective tissue diseases. Cluster F included all patients with prominent lung, muscle, and skin involvement.

Conclusion: We applied cluster analysis to a large group of DM patients and identified six clinical subgroups, underscoring the need for better phenotypic characterization to help develop individualized treatments and improve prognosis.

SAFETY OF MYCOPHENOLATE MOFETIL TREATMENT IN SYSTEMIC SCLEROSIS IN REAL LIFE: REPORT FROM A SINGLE CENTER LARGE COHORT OBSERVATIONAL STUDY

Rosseña Chieffo, Maria Sofia Ciliento, Veronica Giacco, Giuseppe Scalise, Serena Vettori. University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Rheumatology Section, Naples, Italy

Background: Mycophenolate mofetil (MMF) has been increasingly used in the treatment of early diffuse cutaneous Systemic Sclerosis (dcSSc) and SSC-associat ed interstitial lung disease (SSC-ILD), and a recent Randomized Controlled Trial confirmed its efficacy and safety in SSC-ILD. However, the safety of this drug in the long term use has not been assessed in a real life setting.

Objectives: We aimed to analyze the period prevalence and the type of adverse events (AEs) associated to MMF treatment in a single center large cohort.

Methods: Charts of all SSC patients meeting the 2013 ACR/EULAR classification criteria consecutively visited at our outpatient clinic from January 1st 2017 to December 31st 2017 were retrospectively analyzed. Demographics, clinical, serological, functional, imaging data, treatments, and AEs were recorded. Patients were subgrouped according to the immunosuppressant (IS) taken during the observation period (e.g. MMF, azathioprine- AZA, or cyclophosphamide- CYC, no IS). The period prevalence of AEs was calculated and correlations of between AEs and patient features were investigated by univariate and multivariate analyses.

Results: Two-hundred and thirty-seven patients were included (92.4% were females, aged 56.4±11.3 years, with a median disease duration of 17 years, range 1-60). Among them, 85 (35.9%) were taking MMF, 34 (14.3%) AZA or CYC, 118 (41.5%) no IS; p=0.03). No AE required hospitalization and resolved after treatment suspension. The period prevalence of total infectious AEs was 27.6% in the no IS group; p<0.05), predominantly airway infections (41.2% of all infectious AEs). Given so, we investigated the correlations of the infectious AEs in the MMF group with ILD, smoking history, and concurrent GC. However, we didn’t find any significant association with these variables. When we looked for correlations of infectious AEs in the MMF group with other disease features, we found that they were correlated with the duration of the disease (median= 4 years; r=0.25; p=0.02) and with the presence of digital ulcers and/or pitting scars (r=0.22; p=0.03). No AE required hospitalization and resolved after treatment suspension.

Disclosure of Interests: None declared

Background: Intestinal lung disease in systemic sclerosis (SSc-ILD) occurs frequently and carries a high burden of morbidity and mortality. To date, there are no existing guidelines for screening, diagnosis and management of SSc-ILD that would aid early recognition and treatment and improve the care of these patients.

Objectives: To develop expert consensus recommendations for the identification and management of SSc-ILD.

Methods: Based on the results of a comprehensive systematic literature analysis conducted in line with NICE/CRD and IQWiG guidelines and PRISMA methodology, evidence-based statements on SSc-ILD risk, screening, diagnosis, treatment and follow-up were developed. A modified Delphi process was then used to establish consensus statements for the identification and management of SSc-ILD. Briefly, an expert panel of 27 European-based pulmonologists, rheumatologists and internists with experience in treating SSc-ILD was established. Between July and November 2018, the panel took part in 3 rounds of online surveys, a face-to-face discussion and a WebEx meeting to establish consensus-based recommendations for the management of SSc-ILD. Statements were categorised by topic: risk factors (including biomarkers); screening; diagnosis; assessment of severity; treatment initiation; treatment options; disease progression; treatment escalation; other management options. Panellists indicated their level of agreement with proposed statements on a scale of 1 (strong disagreement) to 7 (strong agreement), and consensus was considered achieved when >80% either disagreed (score of 1–3) or agreed (score of 5–7) with a statement. Based on panel feedback, statements that did not reach consensus were modified and re-voted in later rounds.

Results: At the close of the Delphi process, the panel agreed on the following:

1. Risk factors: The presence of anti–topoisomerase I antibodies, male gender and diffuse cutaneous SSc all increase risk for ILD.
2. Screening: All SSc patients should undergo screening for ILD, using HRCT and lung function testing. Frequency of screening using HRCT should be guided by risk of developing ILD, in combination with clinical symptoms and lung function.
3. Diagnosis and assessment of severity: Use of HRCT to diagnose SSc–ILD and assess severity, with supporting findings from lung function testing and other management options.
4. Treatment initiation and options: All patients with severe or progressive SSc–ILD should be considered for pharmacotherapy, with mycophenolate mofetil and cyclophosphamide recommended as treatments. Patients not receiving treatment should be followed closely for signs of disease progression.
5. Disease progression: Indicators of progression include sustained decline in lung function, worsening of clinical symptoms, and change in extent and/or pattern of fibrosis on HRCT.
6. Treatment escalation: Patients with inadequate treatment responses should be considered for treatment escalation. Suitability for lung transplant should be evaluated early, especially for patients diagnosed with advanced disease. Autologous haematopoietic stem cell transplantation may be considered in carefully selected patients.

Conclusion: These evidence-based expert consensus recommendations, developed using a modified Delphi process, provide important guidance for the identification and management of SSc-ILD.

Background: Systemic sclerosis (SSc) is characterized by stiffness and contraction of tissues, which leads to a limitation in the execution of day-to-day activities. The aim of our study was to investigate the impact of specialized physical-occupational therapy (POT) focused on the hands/face and QoL of SSc patients.

The aim of our study was to investigate the impact of specialized physical-occupational therapy (POT) focused on the hands/face and QoL of SSc patients. The 2015 ESC/ERS guidelines and 2018 WSPH consensus recommended the use of risk assessment (classified as low, intermediate, and high risk) based on the variables to predict prognosis, but the clinical utility of risk stratification in patients with CTD- or SSc-PAH has not been established.
Objectives: To evaluate utility of risk stratification strategy in predicting outcomes in CTD-PAH patients by post-hoc analysis of prospectively collected AMBITION data. 

Methods: This study examined 216 patients with CTD (COMB: n=117; MONO n=99) enrolled in the AMBITION study mTTF population. The most commonly underlying CTD etiology was SSc (n=137). Abbreviated average risk score was determined at baseline and at 16 weeks based on 6-minute walking distance, NT-proBNP, and WHO-FCC. Time to clinical failure (TTF) was compared between groups stratified by the risk stratification and/or treatment assignment using the log-rank test.

Results: At baseline, CTD patients were divided into low (n=27, 12.5%), intermediate (n=179, 82.9%), and high risk (n=10, 4.6%) and at Week 16, subjects were classified as low (n=55, 27.9%), intermediate (n=133, 68.5%), and high risk (n=7, 3.6%). Clinical failure was lowest for subjects in the baseline low risk group and highest in the baseline high risk group. When TCF was compared between COMB and MONO arms of CTD-PAH patients in individual risk groups at baseline, risk of clinical failure event was lower in COMB than in MONO in the low and the intermediate risk groups (P<0.05, hazard ratio [HR] NA due to no event in COMB, and P=0.02, HR 0.519, 95%CI 0.297-0.955, respectively), however, no difference in the high risk group was observed. The same analysis was conducted using risk stratification at week 16, resulting in a 30% risk reduction in TCF after Week 16 in COMB, compared with MONO in the low risk group (P=0.001, HR 0.069, 95%CI 0.040-0.120), but no difference between treatments in the intermediate risk group (P=0.3). Risk of clinical failure event was comparable between patients with low and intermediate risk after 16 weeks of treatment with MONO.

Conclusion: A simplified risk stratification at baseline and week 16 may be useful in predicting PAH-related outcomes in patients with CTD-PAH. Among those achieving a low risk status at week 16, which could be considered a treatment goal, COMBO was associated with an improved outcome, when compared to MONO.

OP0068 ABATACEPT IN EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS – RESULTS OF A PHASE 2 INVESTIGATOR-INITIATED, MULTICENTER, DOUBLE-BLIND RANDOMIZED PLACEBO-CONTROLLED TRIAL

Dinesh Khanna1, Cathie Spino1, Erica Bush1, Sanjiv Soni2, Sindhu Johnson3, Manisha Bhattacharya1, Christopher Denton4, Jeri Mollot5, Virginia Steen6, Robert Lafayys2, Robert Simms2, Suzanne Kajita2, Tracy Frew1, Vivian Hsu1, Robin Domsic1, Janet Pope2, Jessica Gordon1, Maureen Mayes1, Elena Schiopu1, Amber Young1, Sara Sandorfi5, Jane Park6, Fayehanh7, Elana Bernstein8, Soumya Chatterjee9, Flavia Castelino10, Ali Ajami11, Yannick Allanore12, Daniel Furst9.

Objectives: To evaluate the safety and efficacy of ABA 125 mg subcutaneous (SC) versus placebo SC given every week on skin fibrosis using the modified Rodnan skin score (mRSS) in diffuse cutaneous SSc (dcSSc; clinicaltrials.gov NCT02161406).

Methods: A 12-month, investigator-initiated, multicenter double-blind, randomized placebo-controlled trial was conducted between September 2014 and February 2018 at 27 US, Canadian and UK sites. Eligible subjects were randomized in a 1:1 ratio to either ABA or matching placebo, stratified by duration of dcSSc (<18 vs >18 to ≤36 months). Key inclusion criteria included dcSSc with disease duration of ≤36 months (defined as first non-Raynaud phenomenon) and mRSS ≤10 and ≤35 units for disease duration ≤18 months and mRSS ≤15 and ≤45 units with evidence of active disease for disease duration of >18-36 months. Escape therapy was allowed at 6 months for worsening SSC. Primary outcomes include safety and change in mRSS over 12 months (mRfSS). Secondary endpoints include ΔFVC%, ΔHAQ-DI, sp to physician global assessment, and ACR CRiSS1 (composite measure in dcSSc). The primary endpoint of mRfSS was assessed using a linear mixed model (see Table) with primary end point data censored after initiation of escape therapy.

Results: 88 subjects were randomized (44/group) and formed the mTT group: 34 (77%) and 35 (80%) completed the 12-month double-blind treatment period in ABA and placebo groups, respectively. At baseline, the mean age was 49 years, 75% were female, mean disease duration was 1.59 years, 60% had disease duration ≤18 months, mRSS was 22.4, mean FVC% was 84.3%, and mean HAQ-DI was 1.0. Compliance with both drugs was >98%. ABA was well tolerated with comparable adverse events (AEs), serious AEs, and AEs of special interest (e.g., infections and malignancies) between treatments. There were 3 deaths during the treatment period (2 in ABA (both scleroderma renal crisis days 11 and 17) and 1 in placebo (sudden cardiac arrest- day 310). The primary endpoint showed an adjusted mean improvement of mRSS of -6.24 in ABA vs. -4.49 in placebo, p<0.08 (Table).

The secondary outcome measures were statistically significant and clinically meaningful (HAQ-DI and physician global assessment) or showed numerical results favoring ABA (Table). A larger proportion of placebo subjects required escape immunosuppressive therapy vs ABA (36% vs 16%, p<0.03).

Estimates are from a linear mixed model with treatment group, month (3, 6, and 12), treatment x month interaction, duration of dcSSc (<18 vs >18 to ≤36 months), and baseline outcome measure as fixed effects and participant as a random effect (except for ACR CRiSS). For ACR CRiSS, treatment differences were assessed by the non-parametric Van Elteren test. Multiple imputation was used for ACR CRiSS analysis.

Conclusion: In patients with early dcSSc, ABA was well tolerated, but ΔmRSS was not statistically significant. Secondary outcome measures showed evidence in favor of ABA, including greater requirement of escape therapy in the placebo group, mRSS showed large variability, despite recruiting an early dcSSC population.

**PERFORMANCE OF AMERICAN COLLEGE OF RHEUMATOLOGY (ACR) COMBINED RESPONSE INDEX IN DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (CRSS) SCORE IN PHASE 2 TRIAL OF LENABASUM IN DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (DCSS)**

Robert Spiera1, Dinesh Khanna2, Nancy Dgetluck3, Brian Conley3, Barbara White3.

1Hospital for Special Surgery, New York City, United States of America; 2Corbus Pharmaceuticals, Inc., Norwood, United States of America

**Background:** Change in modified Rodnan skin score (mRSS) has been used as primary efficacy outcome in at least 13 failed controlled studies in dcSSc. In 2016, the ACR proposed the ACR as a primary efficacy outcome for clinical trials in dcSSc. Its performance as a primary efficacy outcome has not been tested in a clinical trial.

**Objectives:** To evaluate performance of ACR CRSS outcome measure in the lenabasum Phase 2 study in dcSSc, the first study in which it was used prospectively as the primary efficacy outcome.

**Methods:** The Phase 2 study JBT101-SSc-001 (NCT02465437) included a 16-week, double-blinded, randomized, placebo-controlled Part A followed by an open-label extension (OLE). ACR CRSS score is calculated from a weighted exponential formula that includes change in mRSS, Patient Global Assessment (PtGA), HAQ-DI, Physician Global Assessment (MDGA), and FVC% predicted. Spearman correlations were determined for: pairs of core items at baseline; change in pairs of core items; and change in a given core item and calculated ACR CRSS score. Median ACR CRSS score was determined in subjects with different levels of improvement in patient-reported outcomes (PROs).

**Results:** Correlations among pairs of CRSS core items at baseline and change in core items were all < 0.80 at 4 and 12 months. The strongest correlations (r $>$ 0.60, P $<$ 0.001) for changes in pairs of core items were between PtGA and HAQ-DI, HAQ-DI and MDGA, and MDGA and FVC% predicted. The strongest correlations (r $>$ 0.50, P $<$ 0.001) for changes in pairs of core items were between PtGA and HAQ-DI, HAQ-DI and MDGA, and MDGA and FVC% predicted, all others were < 0.30 (Table 1). Correlations between change in each core item and ACR CRSS score were all statistically significant, p $<$ 0.05 at both 4 and 12 months and very strong for change in mRSS and ACR CRSS (Table 1).

**Conclusion:** In the context of the lenabasum Phase 2 clinical trial, ACR CRSS core items at baseline and change in ACR core items were not redundant (r < 0.80). Change in each core item correlated with ACR CRSS score, indicating each contributed to the score at both 4 and 12 months. The 12-month median ACR CRSS score was higher in subjects with greater levels of improvement in PROs, even PRO that were not core items, showing that ACR CRSS score reflects long-term clinical benefit in how the patient feels and functions. These data provide preliminary evaluation of the ACR CRSS score as a clinical trial endpoint in dcSSc.

**OP0070-PARE**

**GEOCACHING AS AN ENCOURAGEMENT FOR BEING ACTIVE**

Tinja Saarela. The Finnish Rheumatism Association, Helsinki, Finland

**Background:** The Finnish Rheumatism Association and Novartis started a project in 2017 to energise our local associations, members and their families by adapting an active lifestyle. Geocaching is a fun, family-friendly way to exercise body and mind. It is for everybody to enjoy.

Geocaching is an outdoor recreational activity, in which participants use a Global Positioning System (GPS) receiver or mobile device and other navigational techniques to hide and seek containers, called “geocaches” or “caches”, at specific locations marked by coordinates all over the world.

There are about three million geocaches hidden around the world. A typical cache is a small waterproof container containing a logbook and sometimes a pen or pencil. The geocacher signs the log with their established code name and dates it to prove that they found the cache. After signing the log, the cache must be placed back exactly where it was found.

**Objectives:** The main goal of the project was to hide 70 new caches all over Finland to create an enjoyable experience for other geocachers. Those caches were named “Reumaged” at the beginning of the cachename. For all the associations that were involved in this project received money allocated to sport and physical activity out of the 15,000 euro project budget. The project ended on 12 October 2018, and all logged caches were included in the game.

**Methods:** We started our project by training association representatives. The training included the basics of geocaching: how to find caches, how to hide your cache and create your cache page, different geocachetypes and everything you should know geocaching. The trained representatives told about geocaching in their own associations, and they were responsible for creating at least 2-3 new caches and handling the new caches. The main idea was that when you have found about 15-20 caches you would start to hide your own caches. Together with local associations our aim was to create 70 caches all over Finland to celebrate the 70-year-old Finnish Rheumatism Association.

Outdoor geocaching adventure starts indoors with preparation and online geocaching. You need a Global Positioning System (GPS) receiver or a mobile device, your own account at the site geocaching.com. The site offers a completely free access to the caching data and all the site features. The site offers also a “premium” member status to access certain features. You can also download the Geoaching intro app onto your smartphone, like Geocaching.
Results: There were 43 members from 30 local associations in Oulu, Mikkeli, Helen-sinki and Turku in these geocaching trainings. All members are suffering from rheumatic and other musculoskeletal diseases (RMDs) and work as volunteers for sport and physical activity, and now for geocaching. By 12 October 2018 there were 49 geocaches made by 13 local associations. The caches were logged 6593 times. So local associations earned 173-4303 euros each to be used for promoting sport and physical activity programmes and active lifestyles.

Conclusion: Promoting an active lifestyle is part of the health and wellbeing policy in the Finnish Rheumatism Association. The goal is to encourage people of all ages to stay healthy by getting enough exercise.

The geocaching project shows that it is easy to some of local associations to start projects like this. Some associations thought that it is too difficult to learn new methods especially when their members are elderly people. Geocaching is increasingly popular, inclusive, a fun and healthy pastime for individuals of all ages. It is also great for groups like local associations, families, friends, and youth groups working as teams. Those local associations that were involved in this project received a great budget for their local sport and physical activity programmes. It is great to see something evolving from the beginning and come into being.

Cartilage, synovium and bone

OP0071 REVEALING THE LINK BETWEEN OSTEOARTHRITIS DEVELOPMENT AND MESENCHYMAL STEM CELL SENESCENCE

Oliver Malaise1,2, Yassin Tachikara2, Michael Constantindes2, Marcus Mumme3,3, Danièle Noël2, Jing Wang, Christian Jorgensen2,3, Jean-Marc Brandel2,3,2. 1GIGA-Research and Chu De Liége, Liége, Belgium; 2IRM Inserm U1183, Université de Montpellier, Montpellier, France; 3Hospital of Bazel, Bazel, Switzerland; 4INM Inserm U1051, Université de Montpellier, Montpellier, France; TCHU La Peyronie, Montpellier, France

Background: Tissue accumulation of p16INK4A-positive senescent cells is associated with age-related disorders such as osteoarthritis (OA). These senescent cells induce a tissue loss of function through a particular secretory phenotype called SASP (senescence-associated secretory phenotype).

Objectives: Links between OA onset and cellular senescence remain poorly detailed. We wanted to determine the localization of articular senescent cells in in vivo OA mouse models and study the involvement of mesenchymal stem cells (MSC) senescence in OA pathogenesis.

Methods: Wild-type mice C57BL/6, SAMP8/R1 (senescence accelerated mouse-prone and resistant), transgenic p16INK4A+Luc and p16INK4A−Luc/Luc were used. Experimental OA was induced by intraarticular injections of collagenase (CIA). Cartilage, synovial tissue and subchondral bone were analyzed by histology, RT-qPCR and micro-tomography. MSCs come from healthy human donors (CIOA). Cartilage, synovial tissue and subchondral bone were analyzed by histology, RT-qPCR and micro-tomography.

Results: (1) CIA was induced in senescence-driven luciferase transgenic mice. Under CCD camera, a peak in luminescence was detected at day 24 post-injection revealing the presence of senescent cells. The senescence marker p16INK4A is not only a marker of the pathology but contributes to OA onset: mice deficient in p16INK4A, a main senescence-driving known cell cycle inhibitor, were partially protected against CIA. These results were confirmed in C57Bl/6 mice after CIA by showing an increase in gene expression for senescence, catabolic and inflammatory markers in the synovial tissue preceding cartilage degradation.

(2) MSCs found in synovial, cartilage, fat pad and bone marrow participate in joint homeostasis. Because MSC are proposed to be at the root of OA development, we hypothesized that cellular senescence onset in these progenitor cells would be a possible etiological factor for OA. We have established an in vitro p16INK4A-induced senescence model on human primary MSC. Their intrinsic properties such as self-renewing are altered during senescence onset. Furthermore, in co-culture conditions with chondrocytes from OA patients, senescent MSC lost their extrinsic chondroprotective properties.

(3) To in vivo challenge these findings, we rely on the mouse model of accelerated senescence SAMP8, which develop spontaneous OA at the age of 6 months with cartilage degradation, synovial hypertrophy, osteophytosis and subchondral bone remodeling associated to meniscal calcification. Isolated MSC from these mice express senescence but non-inflammatory markers (p16INK4A+, p21wa1a1, MMP13, TGF-β1). Remarkably, intra-articular injection of these isolated SAMP8-derived MSC compared to SAMR1-derived control MSC, in young wild-type C57Bl/6 mice, was sufficient by itself, to induce significant articular cartilage degradation (OA score of 12.2 ± 1.5 vs 6.1 ± 3.5 for SAMP8 and SAMR1 MSC respectively, p < 0.05).

Conclusion: p16INK4A-induced cellular senescence in MSC played a causative role in cartilage loss of function and OA pathogenesis. In vitro, senescent MSC show altered intrinsic and extrinsic supportive tissue functions. In vivo, intra-articular injection of senescent MSC was sufficient to induce cartilage degradation. Specific targeting of such deleterious senescent cells could be an innovating and promising treatment in OA.

OP0072 INHIBITION OF CLK2 AND DYRK1A BY SM04690 AS A NOVEL MOLECULAR REGULATOR OF WNT SIGNALING, CHONDROGENESIS, AND INFLAMMATION, A POTENTIAL DISEASE-MODIFYING TREATMENT FOR KNEE OSTEOARTHRITIS

Background: In the synovial joint, Wnt pathway upregulation contributes to osteoarthritis (OA) by increasing osteocyte differentiation, cartilage thinning and inflammation. SM04690, a novel small molecule, has previously demonstrated potential OA disease-modifying effects through Wnt pathway inhibition in vitro and in vivo.

Objectives: To elucidate the novel mechanism of action for SM04690 on Wnt pathway inhibition, chondrocyte differentiation, and anti-inflammation.

Methods: Wnt pathway activity was measured using a cell-based TCF/LEF luciferase reporter in SW480 colon cancer cells. A kinome screen (318 kinases) was performed. The effects of SM04690 on protein phosphorylation of serine and arginine rich splicing factors (SRSF proteins), Sir1, and FoxO1 in hMSCs, chondrocytes, and synovial fibroblasts were measured by Western blot. The effects of SM04690 and siRNA knockdown (KD) on chondrogenic and Wnt pathway gene expression were measured by NanoString gene expression panels and effects on LPS-induced inflammatory cytokines (IL-6, IL-8, TNF-α) in BEAS-2B cells were measured by qPCR and ELISA. In vivo, the pharmacodynamic effects of SM04690 were evaluated in monosodium iodoacetate injection-induced and anterior cruciate ligament transection with partial medial meniscectomy rat knee OA models in which a single intra-articular SM04690 (0.1 μg, 0.3 μg, 1.0 μg) or vehicle injection was administered. Cartilage was isolated at Day 10 and 35, phosphorylation and expression of SRSF proteins, Sir1, FoxO1, STAT3, and NF-κB were measured by Western blot.

Results: SM04690 was a potent (EC50=11nM) inhibitor of Wnt signaling. Cdc-like kinases (CLKs) and dual-specificity tyrosine kinase (DYRK1A) were identified as molecular targets of SM04690. In hMSCs and chondrocytes, compared to DMSO, SM04690 potently inhibited CLK-mediated phosphorylation of SRSF proteins. SM04690 also inhibited DYRK1A-mediated Sir1 and FoxO1 phosphorylation, thus increasing total and nuclear FoxO1 levels. Compared to siRNA control, DYRK1A/CLK2 KD increased expression of chondrogenic genes (COL3A1, ACAN, COMP, CD44 [all P<0.05]). CLK2 and DYRK1A KDs each inhibited Wnt pathway genes (AXIN2, TCF7, TCF4, LRP5, FZD6, FZD7, PITX2 [all P<0.05]) with no effects on β-catenin levels, compared to siRNA control. In synovial fibroblasts, compared to DMSO, SM04690 decreased phosphorylation of NF-κB and STAT3. In BEAS-2B cells, compared to siRNA control, DYRK1A KD inhibited inflammatory cytokine production (IL-6, IL-8, TNF-α [all P<0.05]), while DYRK1A/CLK2 dual KD enhanced anti-inflammatory effects of DYRK1A KD. In cartilage from rat OA models, compared to vehicle, SM04690 inhibited phosphorylation of SRSF proteins, Sir1, FoxO1, and STAT3, as well as expression of NF-κB.

Figure 1. Schematic representation of SM04690's proposed mechanism of action via CLK2 and DYRK1A inhibition in OA.
Establishment of Human Induced Pluripotent Stem Cell-lines (iPSc) for In Vitro Modelling Hand Osteoarthritis

Rocio Castro-Viñuelas1,2, Clara Sanjurjo-Rodríguez1,2, María Piñeiro-Ramí1,2, Tamara Hermida Gómez1,2, Isaac Fuentes-Boquete1,2, Javier de Toro-Santos1,2, Francisco J. Blanco1,2, Silvia María Díaz-Prado1,2, University of A Coruña, Physiotherapy, Medicine and Biomedical Sciences, A Coruña, Spain; Institute of Biomedical Research of La Coruña, A Coruña, Spain; Leeds Institute of Rheumatic and Musculoskeletal Disease, University of Leeds, Leeds, United Kingdom

Background: Research results in the field of hand OA are currently limited due to the unavailability of tissue samples and lack of animal models replicating the features of the disease in humans. Cellular in vitro models are important tools to elucidate molecular mechanisms and pathways that are involved in hand OA. Specifically, induced pluripotent stem cells (iPSc) are considered ideal tools for this purpose since they allow the use of unlimited cells with chondrogenic differentiation potential. However, there are not studies published generating iPSc from patients with hand OA.

Objectives: To generate and characterize iPSc-lines from patients with radiographic hand OA and healthy donors, which can be used as cellular models of the disease, for studying the pathogenesis of the disease in vitro and for testing new drugs.

Methods: Patients with hand OA (non erosive hand OA with right thumb OA) and one healthy donor. Three weeks after reprogramming, embryonic stem cell-like colonies emerged in culture. These cells were positive for alkaline phosphatase activity (fig. 1A) and the pluripotency markers Tra1-81 and Nanog (fig. 1B). Molecular analyses showed high relative expression levels of the pluripotency-related genes OCT4, SOX2, NANOG and CRIPTO in the iPSc. These cells were also able to give rise to cells from the three germ layers (fig. 1C). Indeed, during mesodermal differentiation, spontaneously beating cardiomyocytes were seen in culture. Regarding SNP studies, cells from the patient with hand OA were homozygous for the at-risk allele in both genes studied, both before and after reprogramming (fig. 1D). The “i” iPSc-line (MOAIPS 15/64657) showed worse chondrogenic differentiation than the “healthy” iPSc-line (NIPS 15/63747), as shown by the micromasses collagen and proteoglycan content (fig. 1E).

Conclusion: The generation of one iPSc-line form patients with hand OA is reported for the first time. The presence of the at-risk alleles within the ALDH1A2 and SMAD3 genes were maintained after fibroblast reprogramming. The iPSc lines obtained showed differences in their chondrogenic differentiation capacity, to which their usefulness to test the role of these genetic variants in the pathogenesis of hand OA.

Tofacitinib Promotes Fundamental Processes of Bone Healing

Timo Gaber1,2, Antonia Brinkman1, Alexandra Damerau1,2, Moritz Pfeifferberger1,2, Lisa Ehlers1,2, Frank Buttergem1,2, Paula Hoff2,3, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2, German Rheumatism Research Centre (DRFZ), Berlin, a Leibniz Institute, Berlin, Germany; 3, Endokrinologikum Berlin, Berlin, Germany

Background: Inflammatory diseases like rheumatoid arthritis (RA) and anti-inflammatory treatment of RA with glucocorticoids (GC) or NSAIDS negatively influence bone metabolism and fracture healing. Janus kinase (Jak) inhibition with tofacitinib has been demonstrated as a potent anti-inflammatory therapeutic agent in the treatment of RA but its impact on the fundamental processes of bone regeneration such as recruitment of human mesenchymal stromal cells (hMSCs) and chondrogenesis, osteogenesis and osteoclastogenesis is still controversial and in part elusive.

Objectives: Therefore, in this study, we aim to examine the effects of Tofacitinib on processes of bone healing under reduced oxygen availability mimicking the in vivo situation of the fracture gap.

Methods: To this end, we analyzed the influence of Tofacitinib on the (i) invasion of hMSCs towards TNFα using a trans-well assay, (ii) chondrogenic differentiation of hMSCs in a 3D-micro-mass culture under hypoxic conditions, (iii) osteogenic differentiation of hMSCs, (iv) M-CSF/RANKL-mediated differentiation of isolated monocytes towards osteoclasts and (v) hypoxia-mediated target gene expression in non-differentiated, osteogenic and chondrogenic differentiated hMSCs.

Results: We demonstrate that Tofacitinib dose-dependently promotes the recruitment of hMSCs under hypoxia but inhibits recruitment of hMSCs under normoxia. With regard to the chondrogenic differentiation of hMSCs, we observed that Tofacitinib did not inhibit survival and at therapeutic relevant doses of 10-100 μM. Tofacitinib dose-dependently enhances osteogenic differentiation of hMSCs and reduces osteoclast survival and differentiation under hypoxic conditions. We show that Tofacitinib does not affect chondrogenic HIF target gene expression but increases HIF target gene expression in human osteogenic differentiated hMSCs.

Conclusion: We conclude from our data, that Tofacitinib may influence bone healing by promotion MSC recruitment into the hypoxic microenvironment of the fracture gap, does not interfere with the cartilaginous phase of the soft callus phase of fracture healing process. We assume that Tofacitinib may promote bone healing by promoting MSC recruitment into the hypoxic microenvironment of the fracture gap.
PAR2 ACCELERATES OSTEOARTHRITIS-LIKE JOINT CHANGES IN A MURINE MODEL OF POST-TRAUMATIC OSTEOARTHRITIS

Kendal McCulloch1, Carmen Huesta2, Lynette Dunning1, Rob Van’t Hof3, John Lockhart1, Carl Goodyear4, 1University of West of Scotland, Institute of Biomedical and Environmental Health Research, Paisley, United Kingdom, 2University of Edinburgh, The Queen’s Medical Research Institute, Edinburgh, United Kingdom, 3University of Liverpool, Institute of Ageing and Chronic Disease, Liverpool, United Kingdom, 4University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom

Background: Post-traumatic osteoarthritis (PTOA) is associated with articular cartilage damage and represents a major clinical challenge due to the poor regenerative capability of cartilage. We have recently developed a novel and robust dual injury murine model of PTOA, which combines destabilization of the medial meniscus (DMM) and cartilage scratch (DCS). Twenty-eight days post-surgery, osteophytogenesis and bone changes were monitored using microcomputed tomography. Dynamic weight bearing was assessed as an indirect measurement of pain at day 14.

Results: Evaluation of the presence and number of osteophyte revealed no significant differences between WT and PAR2-/- mice at day 28. However, quantification of osteophytes revealed that PAR2-/- mice had significantly smaller osteophytes (p<0.006) with less mineralised bone (p=0.003). Moreover, analysis of metaphyseal trabecular bone on the operated leg showed a significant decrease in % bone volume/tissue volume (BV/TV) (p=0.025). Assessment of pain-related behaviour, using dynamic weight bearing at day 14, demonstrated that PAR2-/- mice exerted less load on their front paws.

Conclusion: The findings in this study show that PAR2 plays a role in accelerated OA-like symptoms (i.e., osteophyte formation) in a dual injury model of OA, where both destabilisation of the medial meniscus and cartilage damage drive disease pathology. Furthermore, the loss of PAR2 decreases pain behaviour suggesting that PAR2 is involved in pain sensing. Taken together, these results support the future exploration of PAR2 as a therapeutic target for PTOA.

OP007 JAK-INHIBITORS TOFACITINIB AND BARICITINIB IMPROVE PATHOLOGICAL BONE LOSS IN VIVO

Susanne Adam1, Nils Simon2, Ulrike Steffen (née Hare)3, Fabian Andes4, Dorothea Müller5, Stephan Culemann1, Darja Andreev4, Madelaine Hahn1, Carina Scholtsyke1, Georg Schett5, Gerhard Körnke6, Silke Frey7, Axel Hueber5,8

1Friedrich-Alexander-University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 2Sozialstiftung Bamberg, Rheumatology, Bamberg, Germany

Background: Targeting cytokines relevant to rheumatoid arthritis (RA) has proven efficient in clinical practice, but there is still demand for therapies that rebuild joint tissues which have been subjected to deterioration. Since many cytokines involved in RA rely on the intracellular janus kinase – signal transducer and activator of transcription (JAK-STAT) signalling pathway, targeting them presents itself as option. For this approach, JAK-inhibitors such as Tofacitinib and Baricitinib, targeting JAK1/JAK3 and JAK1/JAK2 respectively, seem favorable, as they have been approved for the treatment of RA. Moreover, preliminary data indicates an impact of JAK inhibition on local bone formation.

Objectives: To investigate the influence of JAK-inhibition on structural bone damage in vivo and its impact on osteoclast/osteoblast-mediated bone homeostasis in vitro.

Methods: In vivo analysis comprised unchallenged steady-state, the ovariectomy-induced mouse model of postmenopausal osteoporosis (OVX) and the serum-induced arthritis (SIA) mouse model. For steady-state analysis C57BL/6 WT (WT) mice obtained tofacitinib CB by oral gavage for 6 weeks. For OVX, WT mice received tofacitinib CB by oral gavage for 6 weeks. WT mice of the SIA model were fed tofacitinib or baricitinib CB for 14 days. Experimental readout included clinical parameters, ELISA (RANKL/OPG levels in serum), qPCR (mRNA expression in bone) and μCT. For in vitro analysis, murine osteoclasts (OC) were analyzed with TRAP staining (osteoclastogenesis) and von Kossa staining (Resorptive capacity). Murine osteoblasts (OB), derived from mesenchymal stem cells (MSC) and calvariae were assessed with qPCR (differentiation) and Alizarin red staining (mineralization capacity).

Results: In steady-state conditions, JAK-inhibition by tofacitinib enhanced trabecular bone density and decreased RANKL/OPG fraction in blood serum. These findings, and increased trabecular bones, were also applicable to spinal bone of tofacitinib-treated OVX mice. In SIA, both baricitinib and tofacitinib improved clinical symptoms and halted trabecular and cortical bone loss. In vitro OC-differentiation and function were not affected by JAK inhibition. However, tofacitinib and baricitinib amplified OCN expression in MSC-derived OBs at day 1 after osteogenic induction, together with reduced LIFγ1 and elevated Dkk1 levels at day 7. Moreover, as a result of JAK-inhibition RANKL expression was decreased in calvaria-derived OBs. Accordingly, both MSC- and calvaria-derived OBs showed increased mineralization when treated with JAK-inhibitors.

Conclusion: Our results suggest that JAK-inhibition by tofacitinib and baricitinib causes increased mineralization by osteoblasts, resulting in enhanced bone density in vivo, in both unchallenged and pathological mouse models.

OP0077 INNOVATIVE TRANSLATIONAL MODELS TO STUDY HUMAN SYNOVIAL PATHOLOGY: TARGET VALIDATION AND PRECLINICAL IMAGING

Irene Di Ceccoli, Mathijs Broeren, Claire Waterborg, Daphne Dorst, R.M. Thurlings, Peter Laverman, Fons van de Loo, Peter van der Kraan, Peter van Lent, Marie Koenders, Radboud University Medical Center, Nijmegen, Netherlands

Background: Many experiments to study inflammation, hyperplasia, and fibrosis in the synovium have been performed in animal models of RA and OA. However, the predictive value of these models for the screening of potential drugs in RA is variable and for OA, none were sufficiently effective in clinical trials. Translational
OBJECTIVES: To define the specific lipid profile and distribution in human control and OA synovial membranes.

METHODS: Human synovial membrane samples of OA patients (n=13) and controls (n=10) were compared by matrix-assisted laser desorption ionization mass spectrometry imaging (MALDI-MSI). Tissue sections at 10 μm thickness were mounted on conductive slides and coated with norharmane matrix (7mg/ml, 2:1 chloroform/methanol) for lipid extraction. MALDI images were acquired using a MALDI TOF-TOF instrument (Rapiflex MALDI Tissuetyper, Bruker, Germany) in reflectron positive and negative ionization mode at a pixel size of 50 μm. Multivariate statistical analysis was used to search for the lipids with the highest differences between OA and control synovial membranes. Then, lipid spatial distribution was investigated with FlexImaging 4.1 software. Identifications were based on tandem mass spectrometry analyses in comparison to LIPID MAPS Structure Database.

RESULTS: MALDI-MSI in combination with principal component analysis (PCA) and discriminant analysis (DA) revealed differential lipid profile between OA and control samples. Data acquired in positive ion mode showed a good separation of OA patients and controls (Figure 1A). OA tissues showed higher lipid content in the mass/charge (m/z) range 600-800, compared to controls (Figure 1B). Among identified lipid species, we found 35 phospholipids significant differentially expressed between OA and controls, mainly classified in phosphatidylethanolamines (30%), phosphatidylethanolamines specifically in OA samples, whereas lysophosphatidylcholines were more abundant in control samples compared to OA. Most of these molecules, mainly PIs, were also spatially distributed in the lining layer of the OA synovium.

CONCLUSION: OA synovial tissues were characterized by a higher content of phospholipids, mainly PCs and PIs, compared to control synovial biopsies. Specific phospholipids related to morphological features of the synovial membrane have been described for the first time by MALDI-MSI. These molecules could have an important role in the synovitis associated with the pathogenesis of OA and constitute relevant molecular disease classifiers for the OA diagnosis.

Blanco: None declared, INIBIC – Railway University of A Coruña, Spain, Proteomics Group-ProteoRed/ISCIII, Grupo de Investigación de Reumatología (GIR), A Coruña, Spain; 4Maastricht Multimodal Molecular Imaging Institute (4M4), Division of Imaging Mass Spectrometry, Maastricht University, The Netherlands; 5Maastricht, Netherlands; INIBIC – Hospital Universitario de A Coruña, A Coruña, Spain, CIBER-ESM Instituto de Salud Carlos III, A Coruña, Spain; INIBIC – Hospital Universitario de A Coruña, A Coruña, Spain, RIER-RED de Inmunología y Enfermedades Reumáticas, A Coruña, Spain

Background: Synovial inflammation or synovitis causes severe histological changes in the tissue affecting its normal functioning. These morphological changes are one of the most characteristic events in the OA pathology. Additionally, lipid species are recognized as important key factors in the development and regulation of inflammatory processes. Therefore, the lipid signature of the synovial membrane can provide new markers involved in the synovitis process undergoing the OA disease.

Figure 1. A) PCA-DA analysis separates control and OA samples according to lipid profile. B) Loading plot of PCA-DA analysis representing the lipid classes characteristic to OA (negative side) and control (positive side) samples given by MALDI-MSI. C) MALDI-MSI images showing the differences in the spatial distribution of two phosphatidylethanolamines in OA synovium.

**Background:** Although health professional (HP) treatments are considered to be a corner stone in the management of systemic sclerosis (SSc), little is known about the referral process to and the content of non-pharmacological care in SSc.

**Objectives:** To describe non-pharmacological care in SSc from the perspective of Dutch HPs, including referral reasons, diagnostic focus, interventions used and alignment in the communication between HPs and rheumatologists.

**Methods:** Dutch HPs were invited through their SSc patients to complete an anonymous online survey provided by the Dutch ARCH (Arthritis Research and Collaboration Hub) working group. The survey comprised multiple response and open questions covering six topics: sociodemographic questions, referral reasons, diagnostic focus, treatment targets, interventions and the assessment of quality of communication between HPs and rheumatologists based on the Consumer Quality Index (CQI) (rheumatoid arthritis, version 2.0). Referral reasons and treatment targets were examined by means of open questions, and then linked to the ICF (International Classification of Functioning, Disability and Health) following the refined ICF Linking Rules (Cieza, 2016).

**Results:** A total of 79 HPs, 65.8% women (N=52), with a mean age of 41.2 years, were included. The majority of Dutch HPs, including referral reasons, diagnostic focus, interventions and the assessment of quality of communication between HPs and rheumatologists as perceived by the HPs is shown in Table 2.

**Conclusion:** The results of this study show clear discrepancies between referral reasons and reported interventions, visible in the clear focus on body functions and structures on one hand and the broad spectrum of applied interventions on the other hand. It is possible that HPs make a translation of the reasons given for referral to the needs of the individual patient. Viewed from this perspective, it is questionable whether the referrals by the rheumatologists are sufficiently targeted. Further, the results describe a suboptimal communication between rheumatologists and HPs that should be targeted in practice and further research.

Conclusion: Compared with RIS, DMAb was associated with sustained improvements in cortical bone structure, assessed by HR-pQCT of the radius and tibia. It remains to be confirmed whether increased cortical thickness with DMAb is associated with improved bone strength in GIOP. These results further support DMAb as a treatment for GC-treated patients at increased fracture risk.

OP0081

RELATIONSHIP BETWEEN DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS AND FRAILTY VERTEBRAL FRACURE – A PROSPECTIVE STUDY IN OLDER MEN

Anais Guéli1, Pawel Szuk2, Roland Chapurlat1.1Hospital Edouard Herriot, Pavillon F, Lyon, France; 2Hospital Edouard Herriot – INSERM, Pavillon F, Lyon, France

Background: Diffuse idiopathic skeletal hyperostosis (DISH) is a common disorder of unknown cause characterized by ossifications of entheses with spinal and extraspinal manifestations(1). The prevalence ranges from 4% to 35%, depending on the diagnostic criteria (2). An increased risk of vertebral fracture in DISH has been suggested, due to the loss of flexibility of the fused spine, reminiscent of what is observed in ankylosing spondylitis(3–6).

Objectives: The aim of this study was to prospectively analyze the risk of vertebral fracture in men with DISH, compared with men without DISH.

Methods: Men older than 50 (n = 782) had coronal and lateral spine radiographs along with DXA and were monitored prospectively. We analyzed the risk of incident vertebral fractures (over 7.5 years) in men with DISH defined by flowing ossification alongside the anterolateral aspect of at least four contiguous vertebral bodies, relative intervertebral disc preservation and the absence of apophyseal ankylosis and inflammatory changes of the SI joints, according to Resnick criteria (7). Incident vertebral fracture was defined by a decrease of at least 20% or 4 mm in any vertebral height (anterolateral or posterolateral) between the follow-up and the baseline radiographs.

Results: DISH was present in 21.7% (170/782) of men (mean age = 68). Among the 782 examined at baseline, 761 had at least one spine X-ray after baseline and 164/170 men with DISH had enough available data to be analyzed. Vertebral fracture incidence was higher in men with DISH compared with those without DISH (mean 10/164 (6.1%) vs. 16/597 (2.7%); p<0.05). DISH was also associated with the risk of vertebral fracture after adjustment for age, BMI, lumbar spine bone mineral density (BMD), prevalent vertebral fractures (Grade 2&3), disc space narrowing and endplate irregularity (OR = 2.89, [95%CI]: 1.15 – 7.28; p<0.05). 6.3% (10/ 149) of men with DISH had both normal BMD (=0.912 g/cm²) and increased risk of vertebral fracture (OR=6.54 [95%CI: 2.13 – 20.26]; p<0.05).

Conclusion: DISH is associated with higher risk of vertebral fracture, independently of BMD. The risk of vertebral fracture of men with DISH but normal BMD may be underestimated.

OP0082

TEMPORAL TRENDS OF BISPHOSPHONATE DISCONTINUATION AND FACTORS ASSOCIATED WITH ALENDRONATE DISCONTINUATION AND RESTART AT POPULATION LEVEL

Giovanni Adams1,2, Ayesha Jaleel1, Jeffrey Curtis1, Rui Chen1, Huleyng Yun1, Sharenet Daigle1, Tarun Arora1, Maria Danila1, Nicole Wright1, Suzanne Cadarette1, Amy Mudano1, Jeff Foster1, Kenneth Saag1, 1University of Alabama at Birmingham, Birmingham, United States of America; 2University of Verona, Rheumatology Unit, Verona, Italy; 3Baptist Brookwood Hospital, Birmingham, United States of America; 4University of Toronto, Toronto, Canada

Background: Bisphosphonates are the most commonly used class of osteoporosis medication worldwide. Rare adverse events related to long-term use of bisphosphonates have raised interest in planned temporary drug discontinuation. Due to chronicity of osteoporosis, restarting osteoporosis medication is likely to be needed after such a discontinuation. Trends in the discontinuation and the restart of bisphosphonates and their reasons are not fully understood.

Objectives: We investigated the temporal trends of bisphosphonate discontinuation from 2010 to 2015 and evaluated the factors associated with alendronate only discontinuation and restart of any osteoporosis medication at a population level.

Methods: To determine the temporal trends of discontinuation (at least 12 months without prescription claims) from 2010 to 2015, we identified a cohort of women with long-term bisphosphonate therapy (medication possession ratio (MPR) ≥ 80% for at least 3 continuous years) derived from the enhanced 5% Medicare sample and a cohort of beneficiaries with evidence of osteoporosis (defined using diagnosis and fracture codes, and medication claims). We used a case-crossover design, nested within the cohort study, to identify factors associated with discontinuation of long-term alendronate therapy and restart of any osteoporosis medication. We used conditional logistic regression adjusted for potential confounders to compare factors associated with alendronate discontinuation and osteoporosis therapy restart in the hazard period (120 days) referent to the preceding control periods (120 days).

Results: We identified a total of 73,800 women with exclusive long-term alendronate (59,251), risedronate (6,806), or zoledronic acid (7,743) use, respectively, of which 26,281 (35.6%) women discontinued therapy. The proportion of long-term bisphosphonate users who discontinued therapy increased from 1.7% in 2010 to 1.4% in 2012, and remained relatively stable thereafter (Figure 1). After adjustment, factors most strongly associated with the discontinuation of alendronate included: a new prescription of benzodiazepines (adjusted Odds Ratio [aOR] = 2.5, 95% CI [2.1, 3.0]), prior dual-energy X-ray absorptiometry (DXA) scan (aOR = 1.95, 95% CI [1.7, 2.0]), skilled nursing facility care utilization (aOR = 1.8, 95% CI [1.6, 2.1]). Factors most strongly associated with the restart of any osteoporosis discontinuation were: women older than 75 years (aOR = 3.0, 95% CI [2.5, 3.5]), osteoporosis diagnosis after 2005 (aOR = 2.0, 95% CI [1.8, 2.3]), and osteoporosis diagnosis after 2005 (aOR = 2.0, 95% CI [1.8, 2.3]).
Prevalence of vertebral fractures in postmenopausal women with rheumatoid arthritis

Carmen Gómez Vaquero1, Dacia Cerda2, Cristina Hidalgo3, Martínez López4, Luis Marcelino Arboleya Rodríguez5, Javier Aguilera del Rey6, Silvia Martínez Pardo7, Dacia Cerda2, Cristina Hidalgo3, Jr Martínez López4, Salamanca, Salamanca, Spain

Objectives: To determine the prevalence of vertebral fractures in postmenopausal women with RA and to analyse their characteristics and associated risk factors.

Methods: We included 346 postmenopausal women diagnosed with RA according to the ACR/EULAR 2010 criteria in 18 Spanish Rheumatology Departments, randomly selected from the registry of RA patients in each center, recruited during 2014. Lateral radiographs of the dorsal and lumbar spine were obtained from all patients, to evaluate morphometric vertebral fractures. Expert rheumatologists diagnosed vertebral fractures according to the Genant grading scale. The spinal deformity index (SDI) was calculated by assigning numbers 1, 2 and 3 to each fractured vertebra and adding the total score of each patient. The study variables were: a) age, body mass index (BMI), b) factors related to RA: time of evolution, FR, ACPA, and c) fracture risk factors: prior fragility fracture, parental hip fracture, glucocorticoids, smoking, alcohol intake > 3 units daily, secondary osteoporosis and time since menopause.

Results: The mean age was 66.8 (SD: 10.1) years and the median evolution of the disease, 8.00 (IQR: 3.00-15.5) years. 77.2% (n: 267) and 75.7% (n: 252) had FR and ACPA, respectively. The mean duration of the postmenopausal period was 15.0 (SD: 9.6) years. 23.4% (n: 79) of patients had at least one vertebral fracture: 10.7% (n: 36) had a single fracture and 12.7% (n: 43), multiple fractures. The most fractured vertebrae were D12, L1 and L2 (fractured in > 5% of patients). The median SDI was 3 (IQR: 2-5). The vertebral with the highest mean IDE was D8.

Conclusion: One out of every 4 postmenopausal women with RA has at least one vertebral fracture. Vertebral of the dorso-lumbar hinge are the most frequently involved and the magnitude of the spinal deformity is relevant. Vertebral fractures are related to the time of evolution of RA and to the risk factors for fracture.

Laura López-Vives: Waves declared, Á Martinez-Ferrer: None declared, Helena Borrell: None declared, Pilar Aguado: None declared, Raul Castellanos-Moreira: Speakers bureau: MSD, Lilly, Núria Guaschabens: Consultant for: Advisory Boards from Amgen, Alexion and UC, Speakers bureau: Fees and lectures from Eli Lilly

Background: Denosumab discontinuation (DD) induces bone turnover markers (BTMs) increase, bone mineral density (BMD) decrease, and increased risk of spontaneous vertebral fractures. Prescribing a bisphosphonate after DD could avoid this rebound effect. 

Objectives: This exploratory analysis of the SEMIRA (Steroid EliMination In RA) study compared changes in markers of bone and cartilage metabolism in RA patients with low disease activity (LDA) or remission on tocilizumab (TCZ + GC) with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) who received either slow GC tapering (GCtaper) or continuation (5 mg; GC5mg).

Methods: Patients had at least stable LDA (DAS28-ESR ≤2.6) received either slow GC tapering (GCtaper) or continuation (5 mg; GC5mg). This exploratory analysis of the SEMIRA (Steroid EliMination In RA) study compared changes in markers of bone and cartilage metabolism in RA patients with LDA or remission on tocilizumab (TCZ + GC) with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) who received either slow GC tapering (GCtaper) or continuation (5 mg; GC5mg).

Results: Figure 1 shows changes from baseline to week 24 in markers of bone and cartilage metabolism in RA patients with LDA or remission on tocilizumab (TCZ + GC) with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) who received either slow GC tapering (GCtaper) or continuation (5 mg; GC5mg).

Conclusion: Previous studies showed lower survival in patients discharged for conventional home care (1,2). In our cohort, despite more than half the sample was discharged home, no difference was found in mortality or re-fracture. Further studies will assist to clarify this matter.

TRENDS IN HIP FRACTURE INCIDENCE IN WOMEN

Shreyasee Amin.

Disclosure of Interests:
Burmester GR, et al. Arthritis Rheumatol 2018;70(suppl 10).

Conclusion: The findings of this biochemical marker analysis suggest that withdrawal from GC after achievement of LDA or remission with TCZ results in a decrease in hip fracture risk after cessation of GC therapy, our results offer further insight on the reversible risk of systemic harm to noninfamed joints in the context of LDA or remission.

OP0088 COMORBIDITIES AS RISK FACTORS FOR RHEUMATOID ARTHRITIS (RA) AND ACCRUAL AFTER RA DIAGNOSIS

Vanessa Khonze1, Cynthia S. Crawford1, Jeffrey Sparks1, Elena Myasoedova1, John Davis1, Mayo Clinic, Rochester, United States of America; Brigham and Women’s Hospital, Boston, United States of America

Background: Understanding the timeline of comorbidity development in patients with RA may inform disease pathogenesis and help identify targets for improving outcomes (1).

Objectives: We first aimed to compare the prevalence of a comprehensive list of comorbidities in RA cases versus controls. Second, we aimed to investigate the time association of comorbidity development relative to RA onset to identify which comorbidities might predispose to developing RA and comorbidities that might result from RA.

Methods: We performed a case-control study using a biobank at a single center, identifying 821 cases of RA (143 incident) using a rules-based algorithm combining two diagnosis codes with use of a DMARD (PPV = 95%). We matched each case to three controls based on age, sex, and location of residence at the time of the biobank survey. Participants self-reported the presence or absence and age of onset for 77 comorbidities on the survey.

Results: Among the 3,276 RA cases and controls, mean age was 62 years, and 73% were female. Cases with RA had the same number of comorbidities as controls before RA diagnosis (median 1.0 vs 1.0, P = 0.49) but had more comorbidities by the time of the survey (median 5.0 vs 4.0, p < 0.001). At the time of the survey, several comorbidities were more common in participants with RA than controls (Table1). Cancer was not more common in RA cases than controls (31% vs 32%, p = 0.80), even among all cancer subtypes. The only comorbidities that tended to develop in the time period before RA diagnosis more often than controls were inflammatory bowel disease (1.9% vs 0.5%, p = 0.001) and type 1 diabetes (1.3% vs 0.4%, p = 0.01). In contrast, in the time period after RA diagnosis, myocardial infarctions were more common in cases with RA (3.8% vs 1.2%, p < 0.001) and hyperlipidemia was less common (11.4% vs 16.4%, p = 0.004) compared to controls.

Conclusion: There appears to be different trends in hip fracture rates for women and men and by age groups. The factors contributing to the observed recent increases in hip fracture rates among women and men ages 40-59 yrs warrant further attention. As suggested by others, there may be a recent plateau vs. slight increase in hip fracture rates in older women, which we noted in women age > 80 yrs since 2010. The decrease in hip fractures in older men, particularly in those age > 80 yrs, may reflect improved awareness in recent years of osteoporosis in men with initiation of treatment or better mitigation of risk factors, but warrants further review.

When rheumatoid arthritis (RA) does not walk alone: new data on comorbidities in RA

OP0087 TRENDS IN HIP FRACTURE INCIDENCE IN WOMEN AND MEN OVER 1980-2015 IN OLMSTED COUNTY, MINNESOTA, USA

Delano Beleite, Ann Keams, Elizabeth Atkinson, Shreyasee Amin, Mayo Clinic, Rochester, United States of America

Background: Hip fracture incidence, which has been generally declining in North America, may have recently plateaued in women (Lewiecki, et al 2018).

Objectives: We examined the trends in hip fracture incidence over 1980-2015, in both women and men, from Olmsted County, Minnesota, USA.

Methods: Using the Rochester Epidemiology Project, a unique medical records linkage system that allows access to all (inpatient and outpatient) community medical records for Olmsted County residents, we identified all incident hip fractures among residents age ≥18 years between 1980-2015. Available medical records were reviewed by trained nurse abstractors to validate hip fractures identified and to determine their antecedent cause (pathological process [e.g., malignancy], severe trauma [e.g., motor vehicle accidents] and those due to no more than moderate trauma [by convention, equivalent to a fall from standing height or less]). Overall incidence rates were summarized separately for women and men, as well as by 5 year strata for different age groups (ages 18-39, 40-49, 50-69 and ≥ 80 yrs). Rates for women and men were each directly age-adjusted to the population distribution of US whites in 2010.

Results: Between 1980-2015, we identified 2488 hip fractures in women (73%, median age 84 yrs and 918 hip fractures in men (27%, median age 80 yrs), 97.4% of which were in whites. The majority of hip fractures were due to no more than moderate trauma (88% in women; 81% in men). The overall age-adjusted annual incidence of first hip fracture over 1980-2015 was 154 per 100,000 person-years (p-y) for women and 98 per 100,000 p-y for men. Hip fracture rates have decreased overall in women since 1980 (Table), however since 2005, there has been a trend for increasing hip fractures among women age 40-59 yrs and since 2010, a possible plateau vs. slight increase in hip fracture rate for women age ≥ 80 yrs. In men, there has been a general decrease in rates among those age 60-79 yrs and, at least since 2005, in men age ≥ 80 yrs, but there may be a trend for increasing hip fractures since 2010 in men age 40-59 (Table).

Conclusion: There appears to be different trends in hip fracture rates for women and men and by age groups. The factors contributing to the observed recent increases in hip fracture rates among women and men ages 40-59 yrs warrant further attention. As suggested by others, there may be a recent plateau vs. slight increase in hip fracture rates in older women, which we noted in women age ≥ 80 yrs since 2010. The decrease in hip fractures in older men, particularly in those age ≥ 80 yrs, may reflect improved awareness in recent years of osteoporosis in men with initiation of treatment or better mitigation of risk factors, but warrants further review.
METABOLIC SYNDROME IS COMMON AROUND THE CROSS-SECTIONAL DATA WERE ANALYZED FROM PATIENTS MEETING 1987 OR LATER CRITERIA FOR THE METABOLIC SYNDROME. PATIENTS TREATED IN ROUTINE PRACTICE SETTINGS. VARIATIONS BY SEX, AND BY MENOPAUSAL STATUS WERE ALSO EXAMINED.

**Background:** Prevalence studies of metabolic syndrome (MetS) in early rheumatoid arthritis (ERA) are sparse and estimates are variable. Differences by sex and menopausal status have not been formally assessed.

**Methods:** Cross-sectional data were analyzed from patients meeting 1987 or 2010 ACR/EULAR criteria enrolled in the Canadian Early Arthritis Cohort (CATCH) from January 2007-March 2017. CATCH is a prospective multicenter observational study of patients diagnosed and treated for early inflammatory arthritis (symptoms <1 year) by a rheumatologist. Participants completed standardized clinical assessments and patient-reported outcome measures. Laboratory testing of metabolic parameters was encouraged, but left to the discretion of the rheumatologist. MetS was defined according to modified WHO criteria1 as > 2 of the following: body mass index (BMI) >30, hypertension, low high-density lipoprotein (HDL) cholesterol, dyslipidemia, or impaired glucose intolerance (IGT)2. Univariate and multivariable logistic regression was used to estimate crude and adjusted associations between baseline demographic, clinical and lifestyle variables with prevalent MetS in men and in women, respectively.

**Results:** The sample included 1543 participants; 71% were female and mean (SD) age was 54 (15) years. 476 (31%) of the total sample met criteria for MetS. Participants with MetS were older, more frequently past smokers and reported more comorbid conditions, including cardiovascular disease (CVD) (p<0.0001).

MetS prevalence was higher in men (42%) than women (26%, p<0.0001) and higher in post-menopausal (33%) vs. pre-menopausal women (15%, p<0.0001). Post-menopausal women had a higher frequency of hypertension (65%), IGT (32%) and dyslipidemia (21%) compared to pre-menopausal women (p<0.001). In multivariable logistic regression MetS was negatively associated with seropositivity and pulmonary disease in men; with corticosteroid use in menopausal women; and with psychiatric comorbidity in pre-menopausal women.

**Conclusion:** Approximately 1 in 3 ERA patients met criteria for MetS. Though men had a higher prevalence of MetS and individual MetS components, post-menopausal women had a similar MetS profile as men, and should equally be considered high risk for CVD development. Characteristics and associations with MetS differed in men and women suggesting sex-specific variations are important considerations for comorbidity screening and surveillance of CVD outcomes in ERA.

**REFERENCE:**

**Disclosure of Interests:** None declared.
Conclusion: The maintenance of remission was strongly associated with a reduced risk of clinical and subclinical atherosclerosis and regression analyses exploited the ORs for the occurrence of these end points. In the 3-year prospective follow-up, 797 patients (82.7% female, median age of 60 years, range 21-89) were assessed. We also observed a median RA duration of 8.35 years (range 0.1-35), 70.9% of patients showed rheumatoid factor and 55.7% ACPA. Among “traditional” CV risk factors, we observed that BMI was 27.21 ± 4.05, 33% of patients reported smoking habit, 49.3% were affected by high blood pressure (HBP) and 12.3% by type 2 diabetes (T2D). Corticosteroids were administered in 75.5% of patients (low dosage 66.8%), methotrexate in 86.8%, hydroxychloroquine in 28.1% and biologic DMARDs in 60.7%. The remission was reached and maintained in 42.6% of patients, during the follow-up. We recorded an increased rate of subclinical atherosclerosis (70 vs 130 patients p<0.0001) and clinical atherosclerosis (30 vs 46 patients, p=0.001), at the end of follow-up. The multivariate regression analysis showed that T2D (OR: 4.50, 95%CI:1.74-11.82, p=0.002), HBP (OR: 2.03, 95%CI:1.04-4.14, p=0.042), ACPA (OR: 2.36, 95%CI:1.19-4.69, p=0.002) and mean values of CRP during the follow-up (OR: 1.07, 95%CI:1.03-1.14, p=0.040) were associated with subclinical atherosclerosis. Differently, the maintenance of remission was associated with a reduced risk of subclinical atherosclerosis (OR: 0.25, 95%CI:0.11-0.56, p=0.001). The multivariate regression analysis showed that T2D was associated with clinical atherosclerosis (OR:2.1, 95%CI:1.91-7.17, p=0.001). Conversely, the maintenance of remission was associated with a reduced risk of clinical atherosclerosis (OR:0.20, 95%CI:0.09-0.95, p=0.041).

Conclusion: The maintenance of remission was strongly associated with a reduced risk of clinical and subclinical atherosclerosis in 3-year prospective follow-up. Among “traditional” CV risk factors, T2D was significantly associated with both clinical and subclinical atherosclerosis.

OP0091
RISK OF MEDICAL COMPLICATIONS FOLLOWING TOTAL HIP OR KNEE ARTHROPLASTY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE REGISTER-BASED COHORT STUDY
René Cordtz1,2, Lars Erik Kristensen3, Anders Odgaard3, Søren Overgaard3, Lene Dreyer1,6, Righospitalet – Gentofte, Center for Rheumatology and Spine Diseases, Høllern, Denmark; 2Bispebjerg and Frederiksberg Hospital, The Parker Institute, Frederiksberg, Denmark; 3Herlev and Gentofte University Hospital, Department of Orthopaedic Surgery, Høllern, Denmark; 4Odense University Hospital, Department of Orthopaedic Surgery and Traumatology, Odense, Denmark; 5Aalborg University and Aalborg University Hospital, Dept. of rheumatology, Aalborg, Denmark; 6DANBIO, Nationwide, Denmark

Background: Total hip and total knee arthroplasty (THA/TKA) are major sur-
geries carrying a risk of complications. Patients with rheumatoid arthritis (RA) are at increased risk of venous thromboembolism (VTE), arterial thromboembolic events (ATE), and infections in a non-surgical setting.

Objectives: To investigate the risk of VTE, ATE, and non-surgical infection fol-
lowing THA/TKA in patients with RA compared with osteoarthritis (OA); and to explore the impact of biologics treatment.

Methods: In a nationwide register-based study, patients with RA and OA who had elective THA/TKA in 2000-2014 were identified in the Danish Hip Arthroplasty Register/Danish Knee Arthroplasty Register and followed up to 90 days after sur-
gery for the occurrence of VTE, ATE, and infections. Cox models stratified on sex and type of surgery (THA vs TKA) and adjusted for age, calendar period, history of chronic obstructive pulmonary disease (COPD), diabetes mellitus (DM), cancer, VTE and CVD were carried out. Outcome information was obtained through link-
age with the Danish National Patient Registry.

In DANBIO, we identified RA patients treated with biologics within 90 days preced-
ing surgery and estimated their risk of each outcome compared with non-biologics treated RA patients in a Cox model adjusted for the propensity score (PS) of receiving biologics as a restricted cubic spline covariate. The PS was conditional on age, sex, calendar period, use of methotrexate, other csDMARDs, and/or glu-
corticoids, pre-surgical DAS28, HAQ-DI, VAS physician, and COPD, DM, can-
cer and/or VTE.

Results: In total, 2899 and 112,571 patients with RA and OA were followed-up (Table).

Conclusion: In this nationwide cohort study, RA patients were at increased risk of infection after THA/TKA compared to OA patients, but treatment with biologics did not further increase the risk.

As seen in other studies RA patients had a lower risk of VTE following TKA when compared with OA patients, but our finding of an increased incidence of VTE in biologics-treated patients warrants further studies.

Disclosure of Interests: René Cordtz: None declared, Lars Erik Kristensen Grant/research support from: UCB, Biogen, Janssen Pharmaceuticals, and Novartis, Consultant for: Consultant for AbbVie, Amgen, Biogen, MSN, Celgene,

Table. Patient characteristics and risk of venous thromboembolism (VTE), arterial thromboembolism (ATE), and non-surgical infection following total hip or total knee arthroplasty (THA/TKA) among patients with rheumatoid arthritis (RA) compared with osteoarthritis (OA), and biologics treated compared with non-biologics treated RA patients.

RA was associated with an increased risk of infection, but a lower risk of VTE (HR=3.0, 3.0 vs 1.0,p<0.04); Compared with non-biologics treated, biologics-treated patients were not at increased risk of infection but had a 5-fold increased risk of VTE.

ASSOCIATIONS BETWEEN CLINICAL VARIABLES AND PSYCHOLOGICAL SYMPTOMS IN RHEUMATOID ARTHRITIS: A NETWORK SCIENCE PERSPECTIVE

Hsiu Yen Tung1, Sam Norton2, Faith Matcham1, James Galloway1, Matthew Hotopf2. 1King’s College London, London, United Kingdom

Background: Rheumatoid arthritis (RA) is associated with an increased prevalence of common mental disorders, including anxiety and depression (Matcham et al. 2013). Borsoom’s (2017) network theory of mental illness is gaining traction as a model for depression which incorporates biological, social and psychological aspects of depression by looking at interactions between individual symptoms and other variables within a wider network. Currently applications have been restricted to psychiatric samples, however, this model may potentially help gain a clearer understanding of the causal links clinical variables and mental health symptoms in RA.

Objectives: To study the prescriptions of NSAIDs in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) registered in ICEBIO and matched controls, and explore their relationship with disease activity measures. In addition, to explore the impact of initial TNF inhibitor therapy on NSAID prescription rates.

Methods: The data used are from patients attending rheumatology clinics at King’s College Hospital who completed patient reported outcomes (PROs) electronically via the Integrating Mental and Physical Healthcare (IMPARTS) system. Over 1,000 patients completed PROs via IMPARTS, with a subsample of 211 extracted for this analysis where psychological screening and inflammatory markers were recorded concurrently (<14days). The screening tools used were the two-item Patient Health Questionnaire (PHQ2) and the two-item Generalised Anxiety Disorder (GAD2), which assess the core symptoms of depression and anxiety: low pleasure/interest, low mood, high anxiety, uncontrollability of worry. Additional data recorded were joint counts and visual analogue scales for pain, fatigue and global disease activity. Missing data were imputed using multiple imputation. Network analysis was conducted using the ggraph package in R based on the regularised correlations between variables. With a graphical network model of variables created to calculate centrality values.

Results: Figure 1 below illustrates that the symptoms with the most connections were PHQ1 (low pleasure/interest), GAD2 (uncontrollable worry), pain and global disease activity. As expected the strongest connections were between PHQ1 (low pleasure/interest) with PHQ2 (low mood), GAD1 (high anxiety) with GAD2 (uncontrollable worry), pain with patient global, tendon joints with swollen joints, and ESR with CRP.

The results highlight pain and PHQ2 (low mood) as having both the highest degree (3.9 & 3.8, respectively) and betweenness centrality (22 & 10, respectively). This indicates that these are the variables with both the highest number of connections and providing the shortest pathway between other symptoms and so may act as key variables linking inflammation and mental health. Pain and global disease activity had the highest closeness centrality (0.033 & 0.032, respectively), illustrating that they have the shortest path with all other symptoms and capture the influence of both inflammation and mental health. Tender and swollen joints have weak connections to the mental health variables, suggesting that that extrarticular aspects of pain may be important.

Conclusion: Inflammation in RA does not appear to have a strong influence on mental health, with pain providing the main connection between these areas of the network. Concerning the symptoms of mental health considered, all were strongly connected but low mood provided the main connection between clinical and psychological variables. This indicates mood as potentially a key variable in RA, which is easy to monitor in routine care.

THE INCIDENCE AND RISK FACTOR OF NEW CAROTID PLAQUES AND THE PROGRESSION RATE OF CAROTID PLAQUES IN PATIENTS WITH RHEUMATOID ARTHRITIS IN 6 YEARS PROSPECTIVE CASE CONTROL STUDY. -TOMORROW STUDY-

Shohei Ariga1,2, Kentaro Inui2, Tasadhi Okano2, Kenji Mamoto2, Yuko Sugikawa2, Masahiro Tada1, Tatsuya Kojie3, Hiroki Nakamura3, Osaka social medical center, Orthopaedic Surgery, Osaka, Japan; 2Osaka City University Graduate School of Medicine, Orthopaedic Surgery, Osaka, Japan; 3Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 4Osaka, Japan; 5Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; 6Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan

Background: Cardiovascular disease is one of the complications of rheumatoid arthritis (RA). Patients with RA show higher rates of cardiovascular disease mortality and overall mortality compared with individuals without RA. The presence of an abnormally increased intima–media thickness (IMT) in the carotid artery and carotid plaques are on ultrasound are useful for assessing the presence of subclinical atherosclerosis. A greater presence of carotid artery IMT and carotid plaques is a predictor of cardiovascular disease events.

Objectives: The objective of this study was to evaluate progression of carotid plaques in 6 years by comparing 2011 and 2017, and to assess the risk factors of progression.

Methods: This study included 208 patients with RA and 204 age- and sex-matched controls (Co) in the T0tal Management Of Risk factors in Rheumatoid arthritis patients to iMprove morbidity and mortality (TOMORROW) study. This was a 10-year cohort study that started in 2010. Carotid ultrasound was performed in 2011 and 2017. Ultrasound examination of bilateral carotid arteries was performed using high-resolution B-mode ultrasound (Hi VISION Avius; Hitachi Aloka Medical, Tokyo, Japan) with a 6- to 18-MHz linear array transducer. IMT was evaluated as the distance between the luminal–intimal interface and the medial–adventitial interface. IMT was measured using two calipers on the freeze frame of a suitable longitudinal image. The upper limit of normal for IMT was defined as 1.0 mm. Lesions with any focal structure that protruded into the vessel lumen for at least an IMT > 1.1 mm were defined as atherosclerotic plaques. Subsequently, the plaque score was assessed as the sum of the maximal thicknesses of all plaques in bilateral carotid arteries in the scanning area. Plaque scores were categorized as follows: none, no plaques; mild, score of 1.1–5.0; moderate, score of 5.1–10.0, and severe, score of >10.0.

Results: A total of 175 patients with RA (mean age: 58.9 ± 12.7 years, female ratio: 85.7%; mean disease duration: 15.0 ± 11.7 years) and 185 Co (mean age: 58.5 ± 12.5 years, female ratio: 84.3%) were finally analyzed. Carotid plaques were observed more frequently in the RA group than in the Co group in 2011 (n = 82 vs n = 66, p = 0.04). However, the incidence of new plaques was not significantly different between the RA and Co groups (n = 33 vs n = 44, p = 0.94). Age (p = 0.015) and the presence of diabetes (p = 0.009) were higher in patients with RA and new plaques than in those without new plaques. Multivariate logistic regression analysis did not show that RA was a risk factor for the incidence of new plaques (OR: 0.90, 95% CI: 0.47–1.73, p = 0.750). However, the presence of hypertension (OR: 3.11, 95% CI: 1.43–6.74, p = 0.004), the presence of diabetes (OR: 6.13, 95% CI: 1.13–32.4, p = 0.038) were risk factors for the incidence of new plaques. The plaque score became advanced in the RA and Co groups (both p < 0.001) in 6 years.

Conclusion: There were no significant differences in the incidence of new plaques and the progression rate of the plaque score between patients with RA and Co. This finding might due to the recent advances in RA treatment, such as methotrexate or biologic DMARDs. In patients with RA, the presence of hypertension and diabetes represents a risk factor for the incidence of new plaques.

Tackling chronic pain; fibromyalgia and back pain...

OP0296 DYSREGULATED BONE MARROW Stromal CELLS in MODIC TYPE 1 CHANGES

Stefan Dudli1, Dominik Haenni1, Astrid Juengel1, Michael Betz2, Jose Spiring3, Florian Brunner1, Mazda Farshad1, Oliver Distler1, 1Baigrist University Hospital and University Hospital Zurich, Centre of Experimental Rheumatology, University Clinic of Rheumatology, Zurich, Switzerland, 2University of Zurich, Center for Microscopy and Image Analysis, Zurich, Switzerland, 3Balgrist University Hospital, Department of Orthopaedic Surgery, Zurich, Switzerland

Background: Modic type 1 changes (MC1) are fibro-inflammatory vertebral bone marrow lesions adjacent to degenerating discs. Patient with MC1 often develop low back pain [1]. In MC1, extra-cellular collagen is deposited, myelopoiesis is dysregulated, and bone is rapidly remodeled. These are signs of a chronic inflammation. The cellular mechanisms are unknown, yet bone marrow stromal cells (BMSC) are key regulators of myelopoiesis, can differentiate into collagen-secreting cells, and modulate inflammation [2].

Methods: From patients undergoing lumbar spondylodesis, bone marrow aspirates (n=5) were processed and cell surface markers were analyzed by flow cytometry (CD1, CD16, CD19, CD34, CD45, CD73, CD90, CD105, CD284) (t-test).

Results: Biopsies: Collagen was qualitatively more abundant in MC1 than in Ctrl bone marrow, particularly in areas of adipocyte clusters and around adipocytes (Figure 1, arrows). FLIM was able to distinguish adipocytes (T =2.1-2.7ns), leukocytes (T =0.4-0.8ns), erythrocytes (T =0.2-0.4ns), and collagen (T <0.15ns) based on their different auto-fluorescent life-times (Figure 1, right). BMSCs: By RNA sequencing 154 genes were differentially expressed between MC1 and Ctrl BMSCs (p<0.01; log2 ratio >0.5). Pathway analysis revealed significant alterations in processes important for ‘cell adhesion’ (p<9.3e-13) and ‘extracellular matrix organization’ (p<1.8e-7). Aggrecan (fold change=+0.25, p<1e-7) and osteopontin (fold change=+5.26, p<1e-5) were the first and third top-most differentially regulated genes, indicating a shift away from chondrogenic polarization towards osteogenic polarization. A shift in BMSC polarization was corroborated with differentiation assays: MC1 vs. Ctrl BMSCs had a reduced adipogenic (mean ±sd: -33±13%, p=0.03) and chondrogenic (-31±25%, p=0.18) differentiation capacity (Figure 2). In addition, an increased duplication rate of MC1 vs. Ctrl BMSCs (29.3±1.7 vs. 26.2±1.0 hours, p<0.07) was observed, also indicate a change in phenotype. There were no changes in the expression of surface markers.

Conclusion: These data suggest that MPE-FLIM is a prime technology to investigate fibrotic pathologies and it allows to morphologically study the importance of BMSCs in MC1. The BMSC/adipocyte axis seem to play a pivotal role in the fibrotic pathomechanism. Adipocytes have not been regarded as pathomechanically relevant yet and hence open novel targets for therapeutic approaches.

**OP0097** CHRONIC PAIN AND SICK LEAVE IN A 21-YEAR FOLLOW UP
Beata Drab1, Katarina Aili2,3,4, Emma Haglund5, Stefan Bergman1,3.

**Background:** Chronic musculoskeletal pain (CMP) is a common cause of disability and impaired quality of life. In Sweden, chronic pain and mental illness are major causes of sick leave. But sick leave itself is also proposed as a risk factor for prolonged sick leave and disability pension.

**Objectives:** To study CMP and sick leave as potential risk factors for long term sick leave or disability pension in a 21 year follow up of a general population cohort.

**Methods:** In a cohort study, with a baseline survey in 1995, 1466 individuals aged 20-67 years were followed for 3 years and 691 for 21 years, or up to the age of 67. CMP (>3 months duration) was reported on a pain mannequin. Sick leave and disability pension were self-reported. Mental health was measured by the mental health (MH) score of the SF-36 health status, and categorized into tertiles (best, medium and worst). CMP, sick leave, and mental health at baseline, were studied as potential predictors for long term sick leave (disability pension or sick leave >3 months) at a 3 and 21 year follow up. Other potential predictors (socioeconomic group, education, and immigrant status) were introduced in multiple regression analyzes but did not add to the results and were removed from the final models, which were controlled for age and sex.

**Results:** CMP and mental health predicted long term sick leave at the 3 year follow up (OR 2.11, p=0.010 and OR 2.11, p=0.001). Mental health (OR 1.92, p=0.046), but not CMP (OR 0.77, p=0.409), was also a predictor at the 21 year follow up. Sick leave >3 months, irrespectively if due to pain or not, predicted long term sick leave both at the 3 and the 21 year follow up (Table). Sick leave for ≤3 months also predicted long term sick leave at both follow ups when due to pain (OR 2.70, p=0.008 and OR 2.78, p=0.012), but not when due to other causes (OR 1.52, p=0.212 and OR 1.17, p=0.060).

**Conclusion:** Sick leave and especially sick leave due to pain predicted long term sick leave up to 21 years later, independently of pain status or mental health at baseline. It is thus important to early identify individuals at risk and minimize sick leave by providing proper rehabilitation.

EFFECTIVENESS OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION IN PATIENTS WITH FAILED BACK SURGERY SYNDROME

Canan Bursali, Fezya Uru  Okzan, Meryem Yilmaz Kaysin, Nimet Dörtcan.

Background: Failed back surgery syndrome (FBSS) is the term of persistent back and/or leg pain after lumbar surgery (1). Repetitive transcranial magnetic stimulation (rTMS) is a technique that allows non-invasive and relatively painless stimulation of cerebral cortex. It can reduce the experience of chronic pain by using magnetic field to produce small electrical currents in the cortex (2).

Objectives: The aim of this study is to determine the effectiveness of r-TMS treatment on patients with FBSS.

Methods: In this double-blinded, randomized, placebo-controlled trial, 20 patients (aged 34-65 years) clinically diagnosed as FBSS, who had a history of surgery for lumbar disk herniation with persistent back and leg pain. Only patients with no root compression in postoperative magnetic resonance imaging of lumbar spine were included. Patients were randomly assigned to 3 groups: rTMS (n = 10) and sham (n = 10) groups. Participation in each group was balanced with regard to age, sex, history of surgery, and duration of symptoms. The control group received sham rTMS with the same protocol. Patients were assessed before and after the 3rd and 6th sessions, at the end of the treatment and at 2 weeks, 1 month and 3 months after treatment. Visual Analogue Scale (VAS), DN-IV, Oswestry Disability Index (ODI), Beck Depression Inventory (BDI), Pittsburgh Sleep Quality Index (PSQI) were used for evaluation.

Results: There were no statistically significant differences between the groups for age, sex, number of surgery, pain duration, working status and drug usage. Significant improvements were achieved in VAS, ODI, BDI and PSQI scores in rTMS group in comparison to sham group. Both groups displayed improvements in VAS scores while improvement in the sham group was limited to first month. Achieved improvements in r TMS group in terms of VAS, VAS, ODI, BDI and PSQI scores were sustained at third month.

Conclusion: Repetitive transcranial magnetic stimulation might be an effective treatment alternative in patients with FBSS, further studies with larger groups are needed.

OP0101
COMPARATIVE EFFECTIVENESS OF LAND AND WATER-BASED EXERCISE ON QUALITY OF LIFE OF PATIENTS WITH FIBROMYALGIA: PRELIMINARY FINDINGS FROM THE AL-ÁNDAUS RANDOMISED CONTROLLED TRIAL

Blanca Gávilián Carreras1, Víctor Segura-Jiménez2, Pedro Acosta-Manzano3, Fernando Estevez-Lopez1,4, Mikara Boris Cosic1, Virginia A Apaíroz2, Ana Carbonell-Baeza3, Manuel Delgado-Fernández1,2,3, Faculty of Sport Sciences, University of Granada, Department of Physical Education and Sports, Granada, Spain; 2Faculty of Education Sciences, University of Cádiz, Department of Physical Education, Granada, Spain; 3Faculty of Sport Sciences, University of Granada, Department of Physical Education and Sports, Granada, Spain; 4Ulster University, Belfast, United Kingdom; 5Faculty of Pharmacy, Faculty of Sport and Institute of Nutrition and Food Technology Sciences, Department of Physiology, Granada, Spain; 6Faculty of Education Sciences, University of Cádiz, Department of Physical Education, Cádiz, Spain

Background: Compelling evidence supports the efficacy of physical exercise in the management of fibromyalgia (FM) (1). Although exercise interventions have typically focused on either land or water-based programs, research comparing the efficacy of both protocols is limited.

Objectives: The aim of this study was to compare the effect of two exercise interventions (land-based and water-based training) on quality of life (QOL) of patients with FM.

Methods: Among the 272 participants initially randomized, a total of 151 (age:50.6 ±7.6 years, 98%women) completed all the assessments with an attendance >70% (land-based n =48, water-based n =42, control n =61). The intervention groups trained 3 non-consecutive days/week (60 minutes per session) during 24 weeks. Each session involved exercises to improve cardiovascular fitness, muscular strength, and flexibility. Physical and mental domains of QOL were assessed...
through the 36-item Short Form Health Survey (SF-36). Participants were evaluated at baseline (pre-test), at the end of the intervention (post-test) and following a detraining period of 12 weeks after the end of the intervention (re-test). Land-based, water-based, and control groups were comparable in sex, sociodemographic characteristics, disease duration, drugs intake, and BMI. Age, tenderness, and baseline outcomes values were used as covariates in the comparisons of the changes from baseline (post-test vs. pre-test and re-test vs. pre-test) between groups.

Results: Post-intervention changes from baseline in QOL dimensions in the land-based exercise group were better for physical role (compared to the control and water-based groups; all, p<0.01), bodily pain, general health, social function, emotional role, mental health, and mental component (compared to the control group; all, p<0.05). Post-intervention changes from baseline in the water-based exercise group were not statistically significant compared to land-based or control groups (p>0.05). After a detraining period of 12 weeks, changes in QOL from baseline in the land-based exercise group were better for physical role, bodily pain (compared to the control and water-based exercise groups; all, p<0.01), physical function and physical component (compared to the water-based exercise group; all, p<0.05). No significant changes were observed in the control group.

Conclusion: A land-based exercise intervention improved FM patients’ QOL, whereas a water-based exercise intervention showed no significant effect. Improvements in the physical role and bodily pain domain of QOL were sustained in a 12-week detraining period. Land-based exercise might be an easily accessible treatment option that improves QOL to a greater extent than water-based exercise for FM patients.

OP1003 EFFECTS ON A FRENCH MASS MEDIA CAMPAIGN ON BACK PAIN BELIEFS AND BEHAVIORS

Martin Badiali1, Marie Hélène Certain2, François Rannou3, Patricia Ribik4, Xavier Dufou5, Florian Bailly5, Bruno Fautrel5; Violaine Foltz5. French national public health insurance (CNAMTS), BVA, Rachis section, Therapeutic education section of French Society of Rheumatology, CEDR (Pain Center Study of Rheumatology). 1AP-HP, Paris, France; 2College of GPs, Paris, France; 3University Paris Diderot, Paris, France; 4Hospital Center of Genesee, Genesee, France; 5College of Physiotherapists, Paris, France; 6SU AP-HP, Paris, France

Background: Low back pain (LBP) in general and chronic LBP specifically is frequent with high impact on both individuals and Society. In 2017, the French national public health insurance (CNAMTS, Caisse Nationale d’Assurance Maladie des Travailleurs Salariés) has decided to launch a countrywide mass media campaign to improve general population (POP) and general practitioners (GPs) beliefs and behaviors about LBP and tend to reduce its impact on health resource use and including sick leaves.

Objectives: To evaluate the impact on population and physician beliefs and behaviors of the nationwide population-based campaign on LBP.

Methods: A campaign was conducted by the CNAMTS with the help of health experts (rheumatologists, rehabilitation specialists, allogists, GP and physiotherapists). It ran between November 2017 and November 2018, using multi media: booklets for POP and GPs available on CNAMTS website, TV and radio spots, large size wall posters hanged in public areas, videos on social networks, publicity articles and a smartphone application. The campaign main messages were: “LBP is not a severe disease” and “rest doesn’t help to heal” with a tagline: “Low back pain? The right treatment is the movement”. The impact of the campaign was assessed by internet surveys conducted by a private polling company (BVA, Brulé, Ville et Associés), in random samples of the two populations (POP and GP). The respondents were selected according to the quota method, which enabled adequate representativeness based on sex, age, region of living and socio-economic status. The pre-test survey was performed on June 2017 and the post-test in May 2018, 6 months after beginning of the campaign. The questions explored different domains: 1) memorization, understanding and perception of the campaign, 2) knowledge and beliefs about LBP, and 3) repercussions on behaviors. Statistical significance at 5% was assessed with student test for means and sd, and chi2 test for categorical variables.

Results: Among the 2000 POP, 92% have already experienced LBP with mean pain intensity of 5.7/10 onVAS. Among the 400 GPs, 74% reported to be consulted for LBP almost every day. 35% of the POP and 74% of GPs saw, read or listened the campaign. Overall, it was well perceived with an average rating of 7.0 and 7.3/10, respectively. POP and GP beliefs and behaviors about LBP are summarized in the table 1. There were statistically significant improvements in beliefs and behaviors related to activity in both populations. GPs are more confidence in preventing chronicization of back pain and declare to prescribe less sick leave superior to 5 days.

Table 1. Evolution in beliefs and behaviors concerning LBP in GPs and POP before and after campaign

**Conclusion:** Those with higher levels of SF MCP-1 and IL-6 at the time of injury had a significantly worse outcome at 2 years. The presence of haemarthrosis, clinical effusion and impairment/pain at the time of injury were also independent predictors of outcome. In contrast, no baseline plasma/serum markers were associated with outcome. Stratifying individuals at high risk of persistent symp- toms after knee injury may enable clinical trials of interventions to prevent or treat PTOA.

**Background:** Knee injury increases the risk of knee osteoarthritis at least 7 fold. We have shown an immediate inflammatory response to acute knee injury which is measurable both in mouse joint tissues and also in human synovial fluid (SF). **Objectives:** We set out to test whether the measured inflammatory protein response in SF or plasma/serum was associated with knee symptoms at 2 years after knee injury. **Methods:** 150 individuals were recruited within 8 weeks of a significant acute knee injury to the Knee Injury Cohort at the Kennedy (KIOC; REC 10/10H080/39; NCT02667756) from 2011-2014. The primary outcome was the Knee Injury and Osteoarthritis Outcome Score (KOOS)-4 at 2 years (a composite measure of 4 KOOS domains, where 100 is normal knee health). Baseline covariates were sex, age, body mass index (BMI), clinical effusion, SF blood staining, radiographic Kellgren/Lawrence (KL) Grade. 14 SF and 4 plasma/serum biomarkers were defined based on our prior translational studies. Regression models assessed association of biomarkers with 2 year KOOS4, adjusting for significant covariates. Regressions were weighted using multinomial proportions. **Results:** 123/150 (82%) were male, mean age (SD) 27(8) years and BMI 26(4) kg/m2. Mean KOOS4 increased from 38(18) at baseline to 70(18) at 2 years. 64 (43%) had KL 0/1, 24 (16%) KL 2 and 11 (7%) KL 3, 75 (50%) medium/large effusion (43%) had KL 0/1, 24 (16%) KL 2 and 11 (7%) KL 3, 75 (50%) medium/large effusion and 50 (39%) moderate/severe SF blood staining. Medium/large knee effusion (7.2;-13.5,0.9)(P=0.025) and moderate/severe SF blood staining (-10.1;-18.6,1.6)(P=0.02) were significant. Significant biomarkers adjusted for these covariates are shown in Table. MCP-1 and IL-6 were each significantly associated with 2 year KOOS4 independently in the fully adjusted model and in the multivariable model.

Background: Cryopyrin associated periodic syndromes (CAPS) are a group of autoinflammatory diseases linked to gain-of-function mutations in the NLRP3 gene that cause uncontrolled IL-1β secretion. CINCA syndrome is the most severe CAPS disease characterized by central nervous system disabilities with a long-term risk of secondary amyloidosis. Proton pump inhibitors (PPIs), commonly used as inhibitors of gastric acid production, also display anti-inflammatory properties, making them promising drugs in sepsis and in inflammatory disorders.

Objectives: To develop a novel NLRP3 knock-in (KI) mouse model of CAPS to evaluate amyloid deposition and to test alternative therapeutic approaches.

Methods: We generated KI mice by engineering N475K mutation associated with CAPS phenotype into mouse Nlrp3 gene. KI and Wild Type (WT) mice received PPIs or PBS intraperitoneally and were analyzed for survival, inflammation, cytokine secretion, and amyloidosis development. Cytokines secretion from bone marrow derived dendritic cells (BMDCs) and peritoneal macrophages (PMs) was evaluated by ELISA. Hystological analysis of all organs was evaluated by hematoxylin and eosin staining. Amyloid deposition was quantified through Congo Red stain.

Results: Mutant NLRP3 KI mice displayed features that recapitulates the immunological and clinical phenotype of CAPS. These mice had systemic inflammation, with high levels of serum pro-inflammatory cytokines compared to WT controls. Hystological analysis revealed the presence of active and chronic inflammatory cell infiltrates and amyloid deposits in spleen, liver and kidneys. As in CAPS monocytes, BMDCs and PM from KI mice showed a strong increase in IL-1β, IL-8, and IL-1α secretion and decreased levels in interleukin-1 receptor antagonist (IL-1Rα), the naturally occurring IL-1β inhibitor. PPIs treatment of KI mice showed a clear clinical impact with improvement of inflammatory conditions and regression of amyloid deposits. Remarkably, BMDCs and PMs from PPI-treated mice presented reduced secretion of pro-inflammatory cytokines and re-established the levels of IL-1Rα.

Conclusion: NLRP3 KI mice display a CAPS phenotype with many characteristics of autoinflammation, including amyloidosis. The therapeutic effectiveness associated with lack of toxicity indicates that PPIs could represent relevant adjuvants to the anti-IL-1 drugs in IL-1 driven diseases.
HETEROZYGOUS MUTATIONS IN COPA ARE ASSOCIATED WITH ENHANCED TYPE I INTERFERON SIGNALLING

Marie-Louise Frémont1, Alice Legépely1, Carolina Uggens2, Maria José Martín-Nicolás1, Marine Deppi1, Vincent Bonder1, Darsagh Duffy2, Gillian I Rice2, Mary Brennan1, Caroline Thomson1, Shiam Boulisla4, Marie Legendre2, Serge Amselem2, Thierry Molina3, Nadia Nathan3, Yanick Crow1,2, Imagine Institute, Laboratory of Neurogenetics and Neuroinflammation, Paris, France; 1Institute of Genetics and Molecular Medicine, Centre for Genomic and Experimental Medicine, Edinburgh, United Kingdom; 2Institut Pasteur, Immunology of Dendritic Cells, Paris, France; 3Manchester Academic Health Science Centre, Division of Evolution and Genomic Sciences, Manchester, United Kingdom; 4Royal Hospital for Sick Children, Department of Paediatric Rheumatology, Edinburgh, United Kingdom; 5CHU de Lille, Pediatrics Department, Lille, France; 6Trudeau Hospital-APHP and Sorbonne Université, Genetic Department and Inserm UMR S933, Paris, France; 7Necker Hospital- APHP, Pathology Department, Paris, France; 8Rebiere, Trudeau Hospital-APHP and Sorbonne Université, Inserm UMR S933 and Pediatric Pulmonology department and Reference Centre for Rare Lung Diseases, Paris, France

Background: Heterozygous mutations in COPA, encoding coatomer protein subunit alpha, cause an autosomal dominant syndrome associating lung, joint and renal disease, showing some overlap with STING-associated vasculopathy with onset in infancy (SAVI). Mutations were originally described to cause endoplasmic reticulum (ER) stress and priming of a T helper 17 response. More recently, increased transcription of interferon (IFN)-stimulated genes (ISGs) was reported in blood circulating cells of affected individuals. However, the precise pathophysiology of this disease remains unclear.

Objectives: To better decipher the mechanism of COPA syndrome.

Methods: We studied 8 patients from 3 unrelated families, each segregating a heterozygous mutation in COPA. We assessed type I IFN status by IFNα ultra-sensitive digital quantification in plasma, STAT1 phosphorylation and RNA expression of ISGs in whole blood from patients. In vitro assays also were performed in HEK293T and THP-1 cells to study IFN signalling in the context of COPA mutations.

Results: We observed commonalities in the lung pathology between COPA and SAVI, as well as an IFN signature, raised levels of IFNα protein in the serum and phosphorylation of STAT1 in patient T cells. In a cellular model of HEK293T, phosphorylation of IRF3 and increased ISG expression were observed in cells co-transfected with wild type STING and mutant COPA plasmids. In THP-1 cells, short hairpin RNA knockdown of COPA induced IFN signalling that was abrogated in the absence of STING.

Conclusion: Our data suggest that mutations in COPA lead to constitutive activation of type I IFN signalling through STING. Based on these results, one patient has been treated with the JAK/1 inhibitor ruxolitinib for the last 12 months. How COPA interacts with ER-resident STING remains to be investigated.

Psoriatic arthritis: old and new drugs and how to deal with them?

Christopher T. Ritchlin1, Arthur Kavanaugh2, Joseph F. Merola3, Georg Schett4

1University of Rochester Medical Centre, Rochester, United States of America; 2UC San Diego School of Medicine, La Jolla, United States of America; 3Harvard Medical School, Brigham and Women’s Hospital, Boston, United States of America; 4Friedrich Alexander University Erlangen-Nürnberg, Erlangen, Germany

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease that affects psoriasis and joints and, as such, is a common comorbidity of psoriasis. PsA can present with an acute or chronic type and can occur at any time during the course of psoriasis.

Objectives: To review the current knowledge on the treatment of PsA and to discuss the role of new drugs in the management of PsA.

Methods: The literature was reviewed using Medline, Embase, and Web of Science databases.

Results: The treatment of PsA is challenging due to its heterogeneity and the presence of comorbidities. conventional synthetic DMARDs (cDMARDs) and biologics are commonly used to treat PsA, and their combination can be effective in some patients. New biological drugs, such as JAK inhibitors and small molecule inhibitors, have shown promise in treating PsA.

Conclusion: The management of PsA is complex and requires a multidisciplinary approach. New drugs, such as JAK inhibitors and small molecule inhibitors, offer new therapeutic options for the treatment of PsA.

Results from a 48-week phase 2b randomised bimekizumab in patients with active psA: OVERALL AND TNF-INHIBITOR-NAÏVE POPULATION RESULTS FROM A 48-WEEK PHASE 2B RANDOMISED

Christopher T. Ritchlin1, Arthur Kavanaugh2, Joseph F. Merola3, Georg Schett4

1University of Rochester Medical Centre, Rochester, United States of America; 2UC San Diego School of Medicine, La Jolla, United States of America; 3Harvard Medical School, Brigham and Women’s Hospital, Boston, United States of America; 4Friedrich Alexander University Erlangen-Nürnberg, Erlangen, Germany

Background: Bimekizumab (BKZ) is a humanised monoclonal antibody that potently and selectively neutralises IL-17A and IL-17F, over 48 weeks in patients (pts) with active PsA.

Objectives: The objective of this Phase 2b study (NCT02969525) was to assess the dose response, long-term efficacy and safety of bimekizumab (BKZ), a mAb that selectively and partially neutralises IL-17A and IL-17F, over 48 weeks in patients (pts) with active PsA.

Methods: 206 pts with active PsA, ≥376 swollen joint count, ≥378 tender joint count and CASPAR score ≥3, were randomised (1:1:1:1:1) to receive subcutaneous BKZ 16mg, 160mg, 160mg with 320mg loading dose (160mg [LD]), 320mg or placebo (PBO) Q4W, for 12 weeks (double-blind period). After Week 12, pts receiving PBO or BKZ 16mg were re-randomised (1:1) to BKZ 160mg or 320mg; all other pts continued on their initial dose (dose-blind period). The primary end- point was ACR50 response at Week 12.

Results: 203/206 and 189/206 pts completed the double- and dose-blind periods, respectively. Overall, demographics and baseline disease characteristics were balanced across groups. 19% of pts had prior exposure to TNF inhibitors (TNFi). There was a statistically significant (p<0.05) dose-response at Week 12 for ACR50 response rates. At Week 12, significantly more pts receiving BKZ versus PBO achieved ACR50 (primary endpoint: 16–160mg [LD] doses), ACR20 and PASI90 (in those pts with baseline body surface area ≥3%; 160–320mg doses) (table). ACR20/50/70, PASI75/90/100, MDA and resolution of enthesitis response rates increased between Week 12 and Week 24 in those continuing on their initial BKZ dose; Week 24 responses were maintained through the study; responses were similar across the three highest dose groups at Week 48 (PASI90 analyses were post hoc). Rapid improvements were observed across all response criteria in pts re-allocated to BKZ 160 or 320mg (table). BKZ-treated pts naïve to TNFi achieved ACR20/50 and PASI90/100 at comparable rates to the overall population at Week 12 and 48. There was no apparent relationship between dose and TEAEs. Serious AEs were reported by 9/206 (4.4%) pts up to Week 48 (8/206 [3.9%] patients were receiving BKZ). The most common TEAE up to Week 48 was nasopharyngitis 25/206 (12.1%). Oral candidiasis was reported at Week 48 by 10/206 (4.9%) pts (all cases during BKZ treatment). No deaths, or cases of CIB or MACE were reported.

Conclusion: Dual neutralisation of IL-17A and IL-17F with BKZ provided substantial improvements in both musculoskeletal and skin outcomes; response rates increased after Week 12 (primary analysis) and were sustained from Week 24 to 48, with a safety profile consistent with previous BKZ studies. These data provide further support that neutralising IL-17F in addition to IL-17A with BKZ is a promising therapeutic approach in pts with active PsA.

Efficacy of Filgotinib vs Placebo in Active Psoriatic Arthritis: Patient-Level Data from Equator, a Randomized, Phase 2 Study

Philip J. Mease1, Dafna D Gladman2, Filip van den Bosch3, Mykola Stanislavchuk4, Anna Ryckiewska-Hanczewska5, Chantal Tasset6, Luc Meuleners6, Robin Besuyeu7, Jingjing Gao8, Laura C Coates9, Filip Hellwell10, Anna Rychlewska-Hanczewska5, Chantal Tasset6, Luc Meuleners6, Robin Besuyeu7, Jingjing Gao8, Laura C Coates9, Filip Hellwell10.

Background: Filgotinib (FIL) is an oral, selective Janus kinase 1 inhibitor in development for the treatment of several inflammatory diseases. In the phase 2 EQUIATOR trial (NCT03101670), FIL was efficacious vs placebo (PBO) in patients with active psoriatic arthritis (PsA), and was well tolerated [1].

Objectives: To evaluate the onset and maintenance of response to FIL vs PBO in EQUIATOR by evaluating patient-level response over time.

Methods: EQUIATOR was a 16-week, multicenter, double-blind study in which patients with active PsA were randomized 1:1 to FIL 200 mg or PBO once daily [1]. Disease activity was assessed at screening, day 1 and weeks 1, 2, 4, 8, 12 and 16, and the primary efficacy endpoint was the proportion of patients achieving 20% American College of Rheumatology (ACR20) response. The onset of response was assessed by calculating the median time to ACR20 response using the Kaplan-Meier method and compared between FIL and PBO using the log-rank test. Maintenance of response was assessed by analysing ACR20 response patterns over time in the FIL and PBO groups.

Results: Of 131 patients randomized (FIL: n=65; PBO: n=66), 124 (95%) completed the study. Demographics and baseline disease characteristics were similar between groups. The onset of response to FIL was early, with a median (95% confidence interval) time to first ACR20 response of 4.07 weeks (2.29, 4.14) in the FIL group compared with 12.29 weeks (12, not reached) in the PBO group (p<0.0001; Figure 1). ACR20 responses were achieved at week 16 in 80.0% (52/65) and 33.3% (22/66) of patients in the FIL and PBO groups, respectively, using the non-responder imputation method, and 86.7% (52/60) and 34.4% (22/64), respectively, using observed cases. The number of patients who presented with a stable ACR20 response (i.e. the response was maintained once initially achieved regardless of the time point at which the patient first became a responder) among those who were responders at week 16 (i.e. the primary endpoint) was higher in the FIL group than in the PBO group (80.8% [42/52] vs 68.2% [15/22]) (Figure 2).

Similar trends were observed for other efficacy endpoints representing various manifestations of PsA.

Conclusion: In general, patients treated with FIL achieved an ACR20 response earlier than those on PBO and these responses appeared to be more stable. In the PBO group, there were more occurrences of the response being lost over time and fewer cases of regaining a lost response.

A RANDOMIZED, PHASE 3, DOUBLE-BLIND TRIAL EXAMINING METHOTREXATE AND ETANERCEPT AS MONOTHERAPY OR IN COMBINATION FOR TREATING PSORIATIC ARTHRITIS: A COMPARISON OF THE COMPOSITE MEASURES USED TO EVALUATE DISEASE ACTIVITY

Philip J Mease1, Dañsa D Gladman2, David Collier3, Christopher T. Ritchlin4, Philip Helliwell5, Laura C Coates6, Vibeke Strand7, Lyric Liu8, Greg Kircorian9, James Chung10,11, Swedish Medical Center and University of Washington, Seattle, United States of America; 1University of Toronto, Toronto, Canada; 2Amgen Inc., Thousand Oaks, United States of America; 3University of Rochester Medical Center, Rochester, United States of America; 4University of Leeds, Leeds, United Kingdom; 5University of Oxford, Oxford, United Kingdom; 6Stanford University, Palo Alto, United States of America

Background: Optimal treatment regimens and measuring outcomes in psoriatic arthritis (PsA) remain key areas of research.

Objectives: To examine methotrexate (MTX) and etanercept (ETN) as monotherapy or in combination in a randomized trial and assess the relative performance of PsA-specific composite measures using trial efficacy data.

Methods: Patients with active PsA naïve to biologic drugs (no prior MTX for PsA) were randomized to 3 groups for 48 weeks: ETN 50mg+MTX 20mg weekly (Combo; N=283); ETN 50mg-placebo weekly (ETN-mono; N=284); or MTX 20mg+placebo weekly (MTX-mono; N=284). At week 24, the American College of Rheumatology (ACR20) and Minimal Disease Activity (MDA) responses were the primary and key secondary endpoints, respectively. Other PsA-specific composite measures used for disease activity included the Psoriatic Arthritis Disease Activity Score (PASDAS) and Disease Activity Index for Psoriatic Arthritis (DAPSA).

Results: Baseline characteristics were well balanced in the 3 arms. Mean (SD) age was 48.4 (13.1) years and mean/median PsA duration 3.2/0.6 years. ACR20 and MDA responses at week 24 were significantly greater with ETN-mono vs MTX-mono and Combo vs MTX-mono; ETN-mono and Combo had similar results (Table). PASDAS also showed differences between each ETN-containing arm vs MTX-mono and no difference for ETN-mono vs Combo, whereas study arm differences were not seen with DAPSA. PASDAS had a greater effect size and standardized response vs DAPSA.

Conclusion: In this large randomized, controlled PsA trial, ETN-mono or Combo had greater efficacy than MTX-mono. Combining ETN and MTX did not improve ETN efficacy. Compared with the joint-focused PASDAS, PASDAS captured a wider range of PsA manifestations and performed better in this trial.

management of pain due to inflammation, less is reported on pain despite inflammation control, with most such reports addressing rheumatoid arthritis (RA).

Objectives: To investigate the prevalence of pain despite inflammation control after start of a first anti-TNF therapy in psoriatic arthritis (PsA) patients and its relation to EULAR treatment response.

To test the feasibility of a network analysis approach to examine associations between clinical variables and mental health symptoms in RA.

Methods: PsA patients starting a first anti-TNF therapy 2004-2010 were identified in the prospective, observational South Swedish Arthritis Group register (n=352, 48% women), with mean age 47 years and mean disease duration 10 years. At anti-TNF start, 63% of patients had ongoing methotrexate and 68% were on any conventional DMARD(s). Based on the patient acceptable symptom state (PASS) 1, unacceptable pain was defined as >40 mm on a Visual Analogue Scale (VAS) of pain (scale 0-100 mm), and concomitant inflammation control (as in earlier RA studies) was captured through CRP<10 mg/L in combination with <1 swollen joint (of 28) 3. Assessments were performed at baseline, 1.5, 3, 6 and 12 months after anti-TNF start. Furthermore, analyses were conducted in relation to EULAR treatment response after 3 months (good, moderate, no response). Differences in pain measures between treatment response groups were estimated by logistic regression.

Results: At start of a first anti-TNF therapy, 84.5% of PsA patients reported unacceptable pain, which declined to 42.9% after 3 months and then remained stable during the rest of the study period, being 39.5% at 12 months (Figure 1A). In contrast, the fraction showing unacceptable pain despite inflammation control was largely unchanged over the study period (24.0% at treatment start, 26.7% at 3 months and 26.2% at 12 months). Unacceptable pain at 3 months was strongly related to EULAR 3-month response (23.7% of good responders vs. 70.8% of non-responders; p<0.001), whereas for unacceptable pain despite inflammation control the relation was less pronounced (19.3% of EULAR good responders vs 37.5% of non-responders, p=0.016). Among EULAR good responders, unacceptable pain despite inflammation control constituted 81% of all unacceptable pain at 3 months (Figure 1B).

Conclusion: A considerable proportion of PsA patients starting their first biological treatment reported unacceptable pain throughout the first treatment year. Among EULAR good responders non-inflammatory pain made up more than 4/5 of this pain load at 3 months, indicating insufficient effects of biologics on a subset of patients with inflammation-independent pain, and strongly warrants alternative treatment strategies in affected patients.

HISTOLOGICAL AND MOLECULAR PORTRAIT OF THE SYNOVIAL TISSUE IN EARLY TREATMENT-NAIVE PSORIATIC ARTHRITIS IN COMPARISON WITH RHEUMATOID ARTHRITIS

Alessandra Nerviani1, Gloria Lisso Ribena1, Marie Astrid Boutel1, Katriona Goldmann1, Stephen Kelly1, Michele Bombardieri1, Myles Lewis1, Frances Humber1, Costantino Pitzalis1, 1William Harvey Research Institute, Queen Mary University of London, UK, Centre for Experimental Medicine and Rheumatology, London, United Kingdom; 2Barts Health NHS Trust, Rheumatology, London, United Kingdom

Background: Psoriatic Arthritis (PsA) and Rheumatoid Arthritis (RA) are autoimmune joint diseases characterised by chronic inflammation of the synovial tissue (ST). It has been previously suggested that PsA-ST has less marked hyperplasia of the synovial lining and fewer infiltrating T/B cells in comparison with RA. However, several confounders such as treatment, disease duration, sampling techniques and predominance of large joints samples may have influenced these findings.

Objectives: To compare the synovial features of PsA/RA at the beginning of the disease process and prior to any treatment for defining their histological/molecular individual characteristics, and to correlate the histological pattern with clinical parameters.

Methods: 183 consecutive treatment-naïve patients with <12 months symptoms and active synovitis of at least one joint were enrolled into the Pathobiology of Early Arthritis Cohort (PEAC) at the Barts Health NHS Trust, and underwent a baseline US-guided synovial biopsy of an inflamed joint. ST inflammatory infiltrate was evaluated by semi-quantitative score (0-4) of the immunostaining for CD68 (macrophages), CD3 (T cells), CD20 (B cells) and CD138 (plasma cells). Patients were classified as: pauci-immune if CD68sublining (SL)<2 and/or CD3/CD20-CD138<1; diffuse-myeloid if CD68SL>2, CD20<2 or CD138>2; lymphoid/myeloid if CD20<2 or CD138>2. RNA sequencing of the ST was performed on 93RA/15PsA patients.

Results: 39/183 patients were diagnosed with PsA (32 polyarticular, 7 oligoarticular) and 144/183 with RA (2010 ACR/EULAR criteria). Age was significantly lower in PsA patients. The comparison of the age-adjusted baseline variables showed: significantly higher number of tender and swollen joints in RA, but no significant differences between ESR, CRP and DAS28; higher US synovial thickening score of the biopsied joint in PsA, but comparable power-doppler. ST was evaluated by semi-quantitative score (0-4) of the immunostaining for CD68 (macrophages), CD3 (T cells), CD20 (B cells) and CD138 (plasma cells). Patients were classified as: pauci-immune if CD68sublining (SL)<2 and/or CD3/CD20-CD138<1; diffuse-myeloid if CD68SL>2, CD20<2 or CD138>2; lymphoid/myeloid if CD20<2 or CD138>2. RNA sequencing of the ST was performed on 93RA/15PsA patients.

Conclusion: The identification of specific histological and molecular signatures characterising early-untreated PsA will help to better understand the disease pathogenesis and explore novel therapeutic targets.

MACHINE LEARNING TOOLS IDENTIFY PATIENT CLUSTERS AND SWOLLEN AND TENDER JOINT CORRELATION PATTERNS IN A LARGE DATABASE FROM THE SECUKINUMAB PSORIATIC ARTHRITIS CLINICAL DEVELOPMENT PROGRAM

Matthias Kormaksson1, Effie Pournara2, Gregory Ligozio3, Luminita Pricop3, Ken Abrams1, Bruce Kirkham4, Kristian Rech5, Iain McInnes6,7, Novartis Pharmaceutical Corporation, New Jersey, United States of America; 2Novartis Pharma AG, Basel, Switzerland; 3Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; 4University Medical Center Hamburg-Eppendorf, Skin Inflammation Center, Hamburg, and Dermatologikum, Berlin, Germany; 5University of Glasgow, Glasgow, United Kingdom

Background: Identifying patient phenotypes using machine-learning (ML) techniques amidst the variability and heterogeneity of the clinical manifestations of psoriatic arthritis (PsA) could be the first critical step towards better understanding of the disease eventually leading to individualized medicine.1

Objectives: To identify distinct clusters of patients with PsA based on patients’ tender joint (TJ) and swollen joint (SJ) counts and correlation patterns among TJ and SJ counts at baseline as captured in the secukinumab FUTURE trials program.

Methods: Pairwise correlations were explored among 76 SJ and 78 TJ measurements of >2,700 patients with PsA across 5 phase III studies with ~425,000 data entries at baseline and were visualized using heatmaps. Due to high correlations between SJs and corresponding TJs, a composite variable “swollen/tender joint count” was constructed for each joint. Hierarchical clustering was then performed on the composite using “1-correlation” as the dissimilarity metric and Ward’s agglomeration method for pairwise grouping of joints. A dendrogram was used to visualize and assess the resulting joint groupings.

Results: The hierarchical clustering algorithm grouped the 78 individual joints into distinct and natural clusters (Figure 1A). At higher level of the dendrogram, the algorithm grouped separately all foot, larger joints (jaws, clavicles, hips, wrists, knees, shoulders, elbows), and hand joints. Cutting the dendrogram at 15 clusters separated all the joints into distinct groups; hand joints (distal and proximal phalanges, metacarpals and thumbs), and foot joints (distal and proximal phalanges, metatarsals and toes). Similar clustering algorithms were explored to identify patient clusters at baseline with distinct swelling and tenderness patterns across the identified joint groups. High correlation between swelling/tenderness of the left and swelling/tenderness of the corresponding right joint was observed across all individual joints (Figure 1B); a high correlation was also observed between swelling and tenderness at all individual joints. More localized patterns showed that there is a gradual decrease in correlation (from highest to lowest) among TJs and SJs in adjacent vs non-adjacent fingers, which is evident from grey-scale patterns (Figure 1C). Specifically, a gradual decrease in correlation between the swelling of 2nd–5th distal interphalangeal joint and the tenderness of the 2nd–5th distal phalanges was noted.

Conclusion: Machine learning methodology confirmed a natural grouping of joints in patients with psoriatic arthritis based on baseline swelling and tenderness and revealed complex correlation patterns. Additional cluster analyses have demonstrated distinct patient clusters across the identified joint groups. Further investigating potential associations of other disease manifestations such as skin and nail involvement to define additional phenotypes may explain differences in disease pathogenesis and treatment outcomes.

Objectives: We sought to determine the value of ultrasound (US) to predict arthritis development among ACPA positive patients with musculoskeletal (MSK) pain.

Methods: We prospectively followed 82 ACPA-positive patients with MSK pain but without arthritis upon baseline clinical examination (mean follow-up 68 months, range 23-91). US at baseline assessed joint erosions, synovial hypertrophy in grey scale (GS), and inflammatory activity judged by power Doppler (PD) in 36 small joints in hands and feet. We used a ProFocus system (BK Medical) with pulse repetition frequency 0.8 kHz for PD grading. The US and PD results were blinded to patients and treating rheumatologists during the initial 3 years. US findings among patients were compared to 100 age-matched healthy blood donors.

Results: Significantly more patient joints had synovial hypertrophy (GS score >0) compared to control joints in metacarpophalangeal (MCP) (5.2% vs. 2.5%; p<0.001) and proximal interphalangeal (PIP) joints 2-5 (6.6 vs. 1.5%; p=0.001). In contrast, metatarsophalangeal (MTP) joints 1-5 of the controls were more often scored GS=0 compared to patient joints (49% vs. 24%, p=0.001). Positive PD (>0) occurred significantly more often in patient joints compared to the controls in all joint areas (p<0.05). At patient level, the mean sum score of all investigated joints was higher among patients than controls, regarding GS as well as PD (p<0.001). In Cox regression adjusting for potential confounders (Hazard ratio ≥4.2, 95% CI 1.7-10.4, p=0.002). Out of the 13 erosions detected on US, 4 could be identified on conventional radiographs. Neither GS nor PD findings were significantly associated with arthritis development.

Conclusion: Arthritis-related US findings are more common among patients at increased risk of RA compared to healthy controls, but with site-specific differences. Erosions detected on US predicted arthritis development. Thus, US assessment of erosions among patients is an important tool in early disease identification, prior to the appearance of radiographic changes.
Microstructural changes associated with anti-citrullinated vimentin autoimmunity in RA-at-risk individuals precipitate the onset of rheumatoid arthritis

Andr Kleyer, David Simon, Cong Duy Bui, Axel Huerbe, Holger Bang, Andreas Ramming, Jürgen Reich, Gerhard Kröcke, Georg Schett, Friedrich Alexander University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, 91054 Erlangen, Germany; Orgetec Diagnostika, 55129 Mainz, Germany

Background: Development of rheumatoid arthritis (RA) is characterized by a several years lasting phase of autoimmunity, characterized by the presence of anti-citrullinated vimentin antibodies (AcpA), recognizing citrullinated, carbamylated or acetylated proteins, as well as rheumatoid factor (RF) which precedes the onset of clinical disease (1,2). High resolution peripheral quantitative (HR-pQCT) technique enables the depiction of small cortical changes in peripheral joints (3).

Objectives: To describe microstructural bone lesions in rheumatoid arthritis (RA) at-risk individuals using HR-pQCT technique, their relation to rheumatoid arthritis specific autoimmunity, particularly osteoclast-inducing citrullinated vimentin (cVIM) antibodies and their impact on the later development of RA.

Methods: Cortical micro-channels (CoMics) as well as volumetric cortical and trabecular bone densities were analyzed by high-resolution computed tomography in the hand joints of RA at-risk individuals. Anti-modified protein antibody (AMP) response was profited including reactivities against citrullinated proteins (vimentin, enolase, fibrinogen) as well as carbamylated and acetylated vimentin. All subjects were followed for the development of RA.

Results: RA at-risk subjects (all n=75) with high-level (>1000U) cVIM antibodies showed a broader AMPA response and significantly more severe microstructural changes (higher CoMics, lower cortical and trabecular bone volume) compared to subjects with low cVIM reactivity. High cVIM antibodies and microstructural changes (>15 radial CoMics/joint) were associated with the presence of arthralgia. Furthermore, progression to RA was high in subjects with high cVIM (53%) vs. those with low (22%) or no (5%) antibodies and those with microstructural changes (46%) vs. those without such changes (16%).

Conclusion: cVIM antibodies are associated to microstructural changes in RA at-risk individuals and predict the onset of RA. These data support the concept of structural priming of joints by autoimmunity before the onset of RA.

Discrete patterns of citrullinated peptide autoantibody reactivities emerge during progression from pre-disease state to diagnosis of rheumatoid arthritis

Matthew J Lopez1, Suril Nagpal, Renee Laird, Suzanne Cole2, Frederic Barbuda1, Ian Anderson1, Mark Riddell1, Chad Portier2, Janssen Research and Development, LLC, Spring House, PA, United States of America; 1Navy Medical Research Center, Enteric Diseases Department, Silver Springs, MD, United States of America; 2Edward Hebert School of Medicine, Uniformed Services University, Bethesda, MD, United States of America

Background: Rheumatoid Arthritis (RA) patients with established disease can have autoantibodies reactive to a broad array of citrullinated antigens. Autoantibodies reactive against several citrullinated proteins can develop 10-15 years before the clinical onset of disease.

Objectives: We aimed to identify common patterns of citrullinated peptide reactivities that emerge among subjects during progression from a pre-disease state through diagnosis of RA.

Methods: 500 subjects with RA (based on the ACR/EULAR 2010 criteria) were identified from the Defense Medical Surveillance System. For each subject, up to four serum samples were obtained from the Department of Defense (DoD) serum repository: 1) earliest time point before diagnosis (9.2 ± 2.0 years before, mean ± SD); 1) proximal to (immediately prior to or after) disease diagnosis (127 ± 125 days before diagnosis); plus 2) intermediate time points. A discovery subset of serum samples from 88 RA subjects confirmed to be positive for anti-citrullinated protein antibodies (AcpA) at the diagnosis-proximal time point (>5 U/mL) for cyclical citrullinated peptide (cCP)-II test was assessed for IgG antibodies to 36 antigens (24 citrullinated-peptide antigens among 14 proteins and 12 non-citrullinated antigens among 9 proteins) using a custom LumineX-based assay. Subjects testing above the upper limit of detection for the cCP-II test (300 U/mL) were considered ACPA-high (n=28), with the remainder considered moderate (n=60).

Results: For the group of ACPA-high subjects at the diagnosis-proximal time point, average IgG autoantibody binding to 9 citrullinated peptide antigens (from 7 proteins: clusterin, enolase, fibrinogen A, fibrinogen B, filagrin, fibronectin, vimentin) showed significant increases from the earliest through diagnosis-proximal time points at the population level (FDR<0.05). In ACPA-moderate subjects, IgG levels to only one antigen (citrullinated-fibrinogen) had a nominally significant but small increase (mean ±8%) during this time frame. Significant reactivity to the not-obstructed antigens was not observed. In ACPA-high but not moderate subjects, group averages for a composite score of the 9 citrullinated-peptide antigens increased relative to the earliest time points, with increased average levels observable 6-years before diagnosis that steadily increased as approaching diagnosis age. Patterns of increases in IgG to citrullinated peptides differed among subjects, for both ACPA-high and -moderate groups. In the ACPA-high group, 46% of subjects had >50% increase in a majority (>5) of the 9 citrullinated-peptide antigen set and the remaining had >50% increase for at least 1 of the antigens. In contrast, in the ACPA-moderate group, 56% of subject did not achieve >50% increase for any of the 9 antigens and only 8% of subjects had >50% increase in a majority of the 9-antigen set. The most commonly increased IgG reactivities were for citrullinated -filagrin and -fibrinogen A, with >50% increase in 64% of ACPA-high and 20% of ACPA-moderate subjects.

Conclusion: Novel patterns of citrullinated peptide autoantibody reactivities that begin to emerge on average about 6 years before diagnosis of RA have been identified in samples from the US DoD serum repository. Evaluation of specific anti-citrullinated peptide autoantibodies could potentially provide sensitive, patient-tailored biomarkers to monitor disease trajectories as at-risk individuals progress to clinically-defined RA.

The pre-treatment gut microbiome predicts early response to rheumatoid arthritis therapy

Sandrine Isaac1, Alejandro Artacho1, Renuka Nayak2, Alejandra Flor1, Steven Abramson1, Pamela Rosenthal1, Leonor Puchades4, Andrew Patterson5, Antonio Pineda-Lucena2, Peter Turnbaugh2, Carlos Llobet3, Jose Scher1
1FISABIO, Valencia, Spain; 2University of California, San Francisco, United States of America; 3New York University, New York, United States of America; 4Centro de Investigación Príncipe Felipe, Valencia, Spain; 5Penn State University, Pennsylvania, United States of America; 2Instituto de Investigación Sanitaria La Fe, Valencia, Spain

Background: Early treatment initiation in rheumatoid arthritis (RA) is fundamental to avoid chronic joint destruction and disability. Despite remarkable advances in RA therapeutics, oral methotrexate (MTX) remains the anchor drug and mainstay of treatment worldwide (1,2). However, MTX bioavailability has a wide inter-individual variability and >50% of patients with moderate or severe RA show no or subtherapeutic improvement in their symptoms in response to MTX (1,3). The reasons for these disparities in treatment response remain unclear. Prior studies have shown that the biotransformation of MTX is altered in germ-free and microbiome-
depleted mice (4), prompting us to hypothesize that inter-individual differences in the human gut microbiome could impact drug bioavailability and thus clinical efficacy.

**Objectives:** To determine differences in the microbiome of drug-naïve, new onset RA (NORA) patients that could predict response to MTX therapy.

**Methods:** We performed 16S rRNA gene and shotgun metagenomic sequencing on the baseline gut microbiomes of 27 drug-naïve, NORA patients.

**Results:** Our analysis revealed significant associations between the abundance of gut bacterial taxa and genes including gene families related with purine and methotrexate metabolism. Machine learning techniques were applied to this metagenomic data, resulting in a robust predictive model based on bacterial gene abundance that accurately predicted response to MTX therapy in an independent group of patients. Finally, MTX available levels remaining after ex vivo incubation with distal gut samples from pre-treatment RA patients significantly correlated with the magnitude of future clinical response, suggesting a direct effect of the gut microbiome on MTX bioavailability and response to therapy.

**Conclusion:** Together, these results provide the first step towards predicting response to oral MTX in NORA patients and support the utility of the gut microbiome as a prognostic tool and perhaps even as a target for manipulation in the treatment of rheumatic and autoimmune disease.

**Cohort Study (PEAC)**

**Baseline Cellular and Molecular Characteristics of Synovial Tissue and Relation with TNFi Response. Results from the Pathobiology of the Early Arthritis Cohort (PEAC)**

Gloria Lliso Ribera1, Frances Humber1, Alessandra Nerviani1, Myles Lewis1, Stephen Kelly2, Michele Bombardieri1, Katriona Goldmann1, Rebecca Hands1, Chris Buckley2, Peter C. Taylor3, Iain B McNees3, Costantino Pitlizitis3, William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom; 2Barts Health. Mie End Hospital, Rheumatology, London, United Kingdom; 3Division of Immunity and Infection, The University of Birmingham, Birmingham, United Kingdom; 4Kennedy Institute of Rheumatology, University of Oxford Bothar Research Centre, Oxford, United Kingdom; 5Glasgow Biomedical Research Centre, University of Glasgow, Glasgow, United Kingdom

**Background:** Despite early intervention with disease modifying therapy a high percentage of patients (~30%) fail to respond and require escalation to advanced therapies such as TNFi, with no available biomarkers to predict response. Whether synovial signatures predicting subsequent response to TNFi therapy can be identified at disease onset remains an unanswered question although critical for long term prevention of disease progression and overall health economic impact.

**Objectives:** The aim of this study was to evaluate in a cohort of treatment naïve early RA patients, whether baseline synovial cellular and molecular signatures predict subsequent response or not to anti-TNF therapy.

**Methods:** A total of 186 consecutive DMARD naïve inflammatory arthritis patients (disease duration <1 year) recruited as part of the multicentre PEAC study at Barts Health NHS Trust were evaluated. After 12 months 35 patients commenced therapy with a TNFi (DAS28<5.1), failed 2 x DMARDs as per UK NICE guidelines, EULAR response (DAS28 and DAS improvement from baseline) was calculated 12 months after TNFi was initiated. All patients underwent an US guided baseline synovial biopsy of a clinically active joint along with collection of clinical characteristics. Following H&E staining, sections underwent immunohistochemical staining and semi-quantitative scoring (0-4) to determine the degree of CD20+ B-cells, CD4+ T cells, CD68+ infiltration (I) and sublining (s) macrophage and CD138+ plasma cell infiltration. Sections were categorised into three pathotypes: (i) Fibroid: (CD68≥2 and CD3, CD20, CD138+); (ii) Myeloid: (CD68≥2, CD20<1 and CD3<1) and (iii) Lymphoid: (grade 2-3 CD20+ aggregates, CD20≥2). Synovial gene expression was evaluated with Nanostring and RNA sequencing.

**Results:** 12 months after TNFi was initiated 17/35 (48%) patients responded to therapy (TNFi good EULAR response) and 18/35 (52%) had a moderate or non-response to TNFi. Baseline demographic or US characteristics did not differentiate between the 2 groups. Although we saw no significant differences between groups there was a trend for higher levels of B (CD20+) and T (CD3+) cells, sublining macrophages (CD68+) and plasma cells (CD138+) in the TNFi response group. The cohort was segregated by pathotype and each clinical parameter was compared from baseline to 12months. Interestingly, we observed a significant reduction of levels of CRP, VAS and DAS28 and number of tender and swollen joints in those patients with Lymphoid and Myeloid pathotype (p<0.05), but not in those with Fibroid pathotype (Figure 1). We also evaluated gene expression (using Nanostring and RNA-sequencing) and observed increased expression of genes related to macrophages, plasma cells and B/T regulatory cells expression/activation and/or stimulation at baseline in patients who responded to TNFi.

**Conclusion:** This study demonstrates first evidence of potential novel signatures/biomarkers of TNFi response in treatment naïve early RA. Clinical or US assessment cannot discriminate between responders to TNFi. Lymphoid and Myeloid pathotypes associated with significant falls in clinical outcome. Finally, molecular signatures including differential upregulation of T cells, B cells and macrophage associated genes are associated with good response to TNFi therapy.

PATIENT CHARACTERISTICS AND INCIDENCE OF SIGNS OF INFLAMMATION IN PATIENTS WITH NEW ONSET OF NON-SPECIFIC MUSCULOSKELETAL SYMPTOMS AND POSITIVE ANTI-CITRULLINATED PEPTIDE POINT-OF-CARE TEST IN GERMANY – THE PANORA TRIAL

Michaela Koehm1,2, Ulf Henkemeier1, Tanja Rossmanith1, Karola Mengenthal2, Juliana J. Petersen1, Harald Burkhardt1,2, Frank Behrens1,2, PANORA Working Group. 1Fraunhofer IME-TMP. Clinical Research, Frankfurt, Germany; 2Goethe-University Frankfurt, Rheumatology, Frankfurt, Germany. *Goethe-University Frankfurt, Institute for General Practice, Frankfurt, Germany

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory joint disease affecting approx. 1% of the adult population of Northern Europe. Strategies for its early detection and diagnosis are of high importance as prompt treatment improves clinical and structural outcome. Formation of autoantibodies against cyclic citrullinated proteins (anti-CCP) are identified to be associated to RA development. Often, patients with initial symptoms are referred to General Practitioners (GP) without access to a sensitive rheumatologic assessment.

Objectives: To evaluate incidence of patients with positivity in anti-CCP rapid-test and signs and symptoms of subclinical and clinical inflammation in a on risk population for RA.

Methods: In this prospective study (PANORA), 980 patients with new onset of nonMSK pain at GP were included in 77 GP sites in Germany. In case of positivity formation of anti-CCP rapid-test at GP. At RD, validation of anti-CCP testing (using ELISA) and a rheumatological examination including ultrasound was performed. Subclinical signs of inflammation defined as increase of microvascularisation were monitored by Fluorescence-optical imaging (FOI). In case of ELISA positivity but missing clinical evidence of RA, patients were monitored every 6 months for a total follow-up of 36 months or until RA-diagnosis.

Results: Data from 980 patients with completion of visits at GP and/or RD was monitored every 6 months for a total follow-up of 36 months or until RA-diagnosis. In the screened population, already 10 patients were diagnosed with RA (1 in the RA-/ELISA- group), thereof one case of a newly detected RA at month 6 of the follow-up period. In the three groups at baseline (figure 1), age was well balanced, the proportion of female patients was highest in the RA-diagnosis cohort (80%) as well as the proportion of patient with current or past smoking-status (40% vs. 22.2% in the RA/ELISA- group).

Conclusion: Here, for the first time data from patients suspect for RA development was monitored using anti-CCP point-of-care test at GP and reported. Within the group re-evaluated at RD due to positive point-of-care test, only 21% were confirmed positive using ELISA testing. In the screened population, already 10 patients were diagnosed as RA at RD including 1 patient in the follow-up period until now. The continuation of the PANORA patients in the follow-up period will give more insights in specific characteristics of the RA-risk population at early stages of the disease when combining serological and imaging markers using ultrasound and FOI.

Figure 1. Study Flow Chart

Disclosure of Interests: Michaela Koehm Grant/research support from: BMS, Pfizer, Janssen, Consultant for: Pfizer, Celgene, Janssen, Speakers bureau: Pfizer, Celgene, Janssen, Ulf Henkemeier Grant/research support from: BMS, Tanja Rossmanith Grant/research support from: BMS, Pfizer, Janssen, Karola Mengenthal: None declared, Juliana J. Petersen: None declared, Harald Burkhardt Grant/research support from: BMS, Pfizer, Janssen, Consultant for: Abb-Vie, BM, Pfizer, Janssen, Roche, Chugai, Speakers bureau: Abb-Vie, BMS, Pfizer, Janssen, Roche, Chugai, Frank Behrens Grant/research support from: Abb-Vie, Pfizer, Roche, Chugai, Propylle, Bioline, Novartis, Consultant for: Abb-Vie, Pfizer, Roche, Chugai, UCB, Bristol-Myers Squibb, Celgene, MSD, Novartis, Biotest, Janssen, Genzyme, Eli Lilly, Speakers bureau: Ad board: Abb-Vie, Pfizer, Chugai, UCB, Bristol-Myers Squibb, Celgene, Novartis, Biotest, Janssen, Genzyme, Eli Lilly.

Conclusion: Data-driven cluster analysis of RA patient characteristics at entry into the BRASS registry identified five distinct patient phenotypes, providing a convenient method to potentially derive novel insights into the multifactorial drivers, commonly co-occurring health conditions, and manifestations of RA. Investigation of longitudinal outcomes in these different clusters in the BRASS registry and validation in an independent dataset is ongoing.

SPARRA questionnaire. This questionnaire asks about a variety of joint symptoms, other symptoms and severity of joint pain in specific parts of the body, allowing identification of symptomatic, small and large joint pain. We identified subjects with moderate/severe symptoms and rheumatoid distribution (symmetrical, small and large joints). We also stratified these groups by 1) seropositivity (RF or anti-CCP positive) and 2) elevated CRP.

Results: By July 2018, 1866 participants had completed the study questionnaire and provided a blood sample. Of those 870 (47%) returned the SPARRA questionnaire and in this subgroup, 43 (5%) were seropositive and 124 (14%) had elevated CRP. The most frequently reported symptoms were sleep problems (34%), joint pain (18%) and fatigue (17%). The proportion with joint stiffness, symptomatic joint pain or small joint pain was higher in the seropositive and elevated CRP groups. This difference was statistically significant in those with elevated CRP, respresentative differences in proportions (95% CI) of small and symptomatic joint pain were 10.7 (1.9 to 19.5) and 11.5 (3.2 to 19.8) (Table 1).

Conclusion: This is the first time the SPARRA questionnaire has been applied in FDHS of patients with RA. Some of the most prevalent symptoms e.g. sleep problems or fatigue, did not identify patterns suggestive of progression to RA. However, the distribution of joint involvement (symmetrical, small joint pain), was in keeping with RA features. This part of the questionnaire may be useful in identifying individuals most likely to develop RA.
Objectives: To investigate the association between the different aPL and SLE manifestations as well as to elucidate the influence of the load of antibodies.

Methods: Patients from the RELESSER-T registry were included. RELESSER-T is a multicenter, hospital-based registry, with retrospective cross-sectional collection of data adult non-selected patients with SLE attending Spanish rheumatology services from the public national health system.

Results: Out of a total of 3651 SLE patients, 1368 were positive for aPL (44.9% of patients were positive for anticardiolipin (aCL) antibodies, 27.3% for anti-biologic-coprotein I (aB2GPI) and 24% for lupus anticoagulant (LA)). Regarding the load of antibodies, 20.6%, 12.1% and 4.8% were positive for one, two and three antibodies, respectively. The association between the different aPL, the number of positive antibodies and antiphospholipid syndrome related manifestations is showed in Table 1. Overall, all types of aPL were associated with classic APS manifestations, although LA, IgG isotypes, and patients with more than one aPL display a higher risk to develop clinical APS.

Regarding specific lupus manifestations, aPL types showed a significant negative association with cutaneous manifestations. LA and aCL were associated with an increased risk of cardiac, respiratory and neuropsychiatric manifestations (p<0.001). Furthermore, LA was also associated with an increased risk of renal disease (p=0.001), aCL IgG was associated with a higher risk of specific lupus manifestations compared with aCL IgM. Interestingly, aB2GPI IgG were only associated with cardiac, respiratory and neuropsychiatric manifestations (p<0.001). aCL IgG was associated with a higher risk of specific lupus manifestations (p=0.001), as well as the cardiac (p=0.003), and pulmonary manifestations (p=0.001), significantly increased with a higher number of positive antibodies. Inversely, the risk of cutaneous symptoms decreased while the number of positive antibodies increased (OR 0.89, 95% CI 0.82-0.96, p=0.003).

Conclusion: There is a hierarchy for aPL and the risk of APS and lupus manifestations. aCL, and especially LA, confer a higher risk for major organ involvement in SLE patients. IgG isotypes and the load of aPL antibodies increase the risk for clinical APS and major lupus manifestations.

Methods: ESSDAI and ESSPRI scores were collected from patients with a confirmed diagnosis of pSS attending a pSS clinic at a single UK centre over a ten-year time period. Anonymised data from 2009 to 2019 were analysed for patterns of change in the (overall and domain-specific) ESSDAI and ESSPRI scores over time. Time between clinic visits was also plotted against each patient’s ESSDAI and ESSPRI score at each clinic visit to give an idea of real-world fluctuations in these assessment outcomes over a period time in this large group of patients. Baseline characteristics were also analysed to determine predictors in ESSPRI and ESSDAI changes.

Results: 634 patients used the clinic with 467 of them had more than one visit and 297 of them having three or more clinic visits. 32% had an ESSPRI at least 1 point higher at the last compared to the first visit (ESSPRI-worse group). 16% had an ESSPRI at least 1 point lower (ESSPRI-improved group) and 48% had a change of less than 1 in ESSPRI between the first and last visits (ESSPRI-unchanged group). The ESSPRI-worse group had a lower mean initial ESSPRI (4.59), compared to the ESSPRI-unchanged and ESSPRI-improved group (6.27 and 6.29 respectively). There were no significant differences in age, sex and anti-Ro positivity between the three groups; age, percentage female and percentage anti-Ro were 60 years, 89%, 66% (ESSPRI-worse); 60 years; 86%, 60% (ESSPRI-improved); 62 years, 91%, 73% (ESSPRI-unchanged). 16% had an ESSDAI at least 3 points higher at the last visit (ESSDAI-worse group); 19% patients had an ESSDAI at least 3 points lower (ESSDAI-improved); and 62% of patients had a difference of less than 3 in ESSDAI between the first and last visits (ESSDAI-unchanged). The mean ESSDAI at first visit was significantly higher in the ESSDAI-improved group (9.2) compared to the ESSDAI-unchanged and ESSDAI-worse groups (3.1 and 2.4 respectively). There was no difference in age between the 3 ESSDAI groups. The ESSDAI-worse group had more female subjects and less anti-Ro positivity (93% & 54% respectively) compared to the ESSDAI-unchanged group.

Conclusion: ESSPRI and ESSDAI scores did not change significantly over time when looking at an overall cohort level. However, there were significant changes in these outcomes on an individual level. Worsening ESSPRI was associated with lower baseline score whereas improvement in ESSDAI was associated with higher baseline score. Given the lack of proven treatment available for pSS, our data may reflect natural history of the disease course rather than treatment effects.

OP0125

REAL WORLD LONGITUDINAL DATA USING EULAR OUTCOME ASSESSMENT TOOLS FOR PRIMARY SJÖGREN’S SYNDROME (PSS) PATIENTS IN A UK CLINIC

Nadia Howard Tiplag1,2, Ben Hargreaves3, Jessica Tam2, Dennis Lundgren2, Wan Fai Ng2,3, Newcastle University, Newcastle upon Tyne, United Kingdom; 2Newcastle Upon-Tyne NHS Foundation Trust, Newcastle-upon-Tyne, United Kingdom; 3Newcastle University, Newcastle-upon-Tyne, United Kingdom

Background: The EULAR Sjogren’s Syndrome Study Group has developed standardised outcome assessment tools for PSS, which are used in clinical trials and routine clinical assessment. While there has been a growing body of data on the use of these outcome assessment tools, data on their application in routine clinical practice, particularly over time, remains scarce.

Objectives: This paper aims to investigate how EULAR Sjogren’s Syndrome Disease Activity Index (ESSDAI) and EULAR Sjogren’s Syndrome Patient Reported Index (ESSPRI) scores change at multiple timepoints in a large cohort of PSS patients.

Methods: ESSDAI and ESSPRI scores were collected from patients with a confirmed diagnosis of pSS attending a pSS clinic at a single UK centre over a ten-year time period. Anonymised data from 2009 to 2019 were analysed for patterns of change in the overall and domain-specific ESSDAI and ESSPRI scores over time. Time between clinic visits was also plotted against each patient’s ESSDAI and ESSPRI score at each clinic visit to give an idea of real-world fluctuations in these assessment outcomes over a period time in this large group of patients. Baseline characteristics were also analysed to determine predictors in ESSPRI and ESSDAI changes.

Results: 634 patients used the clinic with 467 of them had more than one visit and 297 of them having three or more clinic visits. 32% had an ESSPRI at least 1 point higher at the last compared to the first visit (ESSPRI-worse group). 16% had an ESSPRI at least 1 point lower (ESSPRI-improved group) and 48% had a change of less than 1 in ESSPRI between the first and last visits (ESSPRI-unchanged group). The ESSPRI-worse group had a lower mean initial ESSPRI (4.59), compared to the ESSPRI-unchanged and ESSPRI-improved group (6.27 and 6.29 respectively). There were no significant differences in age, sex and anti-Ro positivity between the three groups; age, percentage female and percentage anti-Ro were 60 years, 89%, 66% (ESSPRI-worse); 60 years; 86%, 60% (ESSPRI-improved); 62 years, 91%, 73% (ESSPRI-unchanged). 16% had an ESSDAI at least 3 points higher at the last visit (ESSDAI-worse group); 19% patients had an ESSDAI at least 3 points lower (ESSDAI-improved); and 62% of patients had a difference of less than 3 in ESSDAI between the first and last visits (ESSDAI-unchanged). The mean ESSDAI at first visit was significantly higher in the ESSDAI-improved group (9.2) compared to the ESSDAI-unchanged and ESSDAI-worse groups (3.1 and 2.4 respectively). There was no difference in age between the 3 ESSDAI groups. The ESSDAI-worse group had more female subjects and less anti-Ro positivity (93% & 54% respectively) compared to the ESSDAI-unchanged group.

Conclusion: ESSPRI and ESSDAI scores did not change significantly over time when looking at an overall cohort level. However, there were significant changes in these outcomes on an individual level. Worsening ESSPRI was associated with lower baseline score whereas improvement in ESSDAI was associated with higher baseline score. Given the lack of proven treatment available for PSS, our data may reflect natural history of the disease course rather than treatment effects.

Objectives: To analyse the phenotype of patients with primary Sjogren syndrome
(SjS) in whom a lymphoproliferative disease is diagnosed concomitantly.
Methods: By January 2019, The Big Data Sjögren Project included 11,420 consecutive patients with primary SjS recruited from 24 countries of the five
continents.
Results: 117 (1%) patients were diagnosed with lymphoma and primary SjS synchronously. Age-gender adjusted multivariate analysis identified the following features associated with lymphoma (OR; CI95%): male gender (4.61; 2.88-7.18),
White ethnicity (3.51; 1.78-7.91), abnormal oral tests (3.4; 1.38-10.88), positive
biopsy (3.2; 1.3-10.17), positive RF (2.27; 1.48-3.53), hypocomplementemia (3.39;
2.06-5.54), and cryoglobulins (4.74; 2.57-8.38). Activity (score > 1) in the constitutional (2.97; 1.86-4.62), glandular (3.11; 2.1-4.57), cutaneous (2.17; 1.28-3.52),
peripheral nerve (2.56; 1.4-4.41) and hematological (2.49; 1.64-3.75) ESSDAI
domains was associated with lymphoma (frequencies summarized in the Figure).

Conclusion: Patients diagnosed concomitantly with primary SjS and lymphoma
have a very specific, highly-active phenotype (men, White, severe oral

Scientific Abstracts
involvement, cryoglobulinemic-related immunological markers, and high systemic
activity).

Background: To our knowledge the influence of ethnic background in childhoodonset SLE (cSLE) presentation was not evaluated in a large population of Latin
American country.
Objectives: To assess demographic data, clinical manifestations, laboratory
abnormalities and disease activity score in cSLE patients according to ethnic
groups at diagnosis
Methods: This multicenter study included cSLE patients(ACR criteria) followed in
27 Pediatric Rheumatology services of Brazil. Ethnicities were classified in four
groups according to the parents´ and all four grandparents´ self-reported ethnicity.
The statistical analysis was performed using the Bonferroni’s correction
(p<0.0027).
Results: According to ethnic groups, 1,537 cSLE patients were classified in: Caucasian (n=786), African-Latin American(n=526), Asian(n=8) and others/unknown
(n=217). Comparisons between 1,312 African-Latin American and Caucasian


Systemic Lupus Erythematosus Disease Characteristics Associated with the Type I Interferon Gene Signature: Baseline Data of the SLE Prospective Observational Cohort Study (SPOCS)

Edward R. Hammond, Martin Aringer, Laurent Arnaud, Christine Peschken, Jacob Knagenhjelm, Vokhan Banul, Xia Wang, Bamabas Desta, Raj Tummala, David Ginkel, Richard Furie, Eric F. Morand, Gustav Carus, TU Dresden, Dresden, Germany; Service de Rhumatologie, Centre National de Référence Maladie Auto-immune et Systémique Rares (RESO), Université de Strasbourg, Inserm-Urc 5109, Strasbourg, France; Department of Medicine and Community Health Sciences, University of Manitoba, Winnipeg, Manitoba, Canada; AstaZarzeca, Gothenburg, Sweden; AstraZeneca, Cambridge, United Kingdom; Hofstra Northwell School of Medicine, New York, NY, United States of America; Centre for Inflammatory Disease, Monash University, Clayton, VIC, Australia

Background: Despite accumulating data on the role of type I interferons (IFN) in the pathogenesis of SLE, real-world, longitudinal clinical data on the type I IFN gene signature (IFNGS) collected from patients with SLE are limited.

Objectives: This initial analysis of the SLE Prospective Observational Cohort Study (SPOCS; NCT03198875) examined the prevalence of the type I IFN gene signature (high vs low) and its association with baseline SLE disease characteristics in patients with moderately to severely active SLE receiving standard-of-care treatment.

Methods: SPOCS is an international, multicenter, prospective observational cohort study of patients enrolled with moderately to severely active SLE receiving standard-of-care treatment. The profile of patients with a baseline high type I IFN signature was compared with those with a low type I IFN signature.

Results: As of November 15, 2018, a total of 307 patients were enrolled in SPOCS (North America, n=184; Europe, n=123), of whom 96.1% (n=295) were female, with a median age of 46 years (range: 18–88). At study entry, the prevalence of high type I IFN was significantly higher in African-Latin American, whereas malar rash (45% vs. 58%, p<0.0001) was more frequent in Caucasian. The presence of antiphospholipid antibody (23% vs. 12%, p<0.001), low complement levels (58% vs. 41%, p<0.001) and isolated Coombs test (10% vs. 5%, p=0.001) were also significantly higher in the former group.

Conclusion: Our study demonstrated that disease presentation severity of African-Latin American SLE patients is comparable to Caucasian. Mucocutaneous manifestations and autoantibodies profile were the only distinctive features of the former group. The unique mixed background of Brazilian patients probably minimized race diversity spectrum of these patients.

Thermal Regulator's Stabilization and Dynamics of Antiphospholipid Syndrome in Patients Admitted to the Intensive Care Unit with a New Thrombotic Manifestation

Marc Pinetof de Chambournay, Alexis Mathian, Alain Combes, Charles-Edouard Lucy, Zahr Amoura, Registre SAPHIR, Hôpital La Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Service de médecine interne 2, centre de référence national malade rare lupus systémique et syndrome des anticorps antiphospholipide, institut E3M, Sorbonne Université, Paris, France; Hôpital La Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Service de médecine intensive-réanimation, institut de cardio-métabolisme et nutrition (ICM), Sorbonne Université, Paris, France

Background: Catastrophic antiphospholipid syndrome (CAPS) is the most severe manifestation of antiphospholipid syndrome (APS), characterized by the simultaneous occurrence of thrombosis in multiple organs.

Objectives: The objectives of this study were to evaluate the distribution and the characteristics of CAPS criteria in APS patients admitted to the intensive care unit (ICU) with acute thrombotic manifestation.

Methods: We conducted a multicentre retrospective study, from January 2000 to September 2016, including all APS patient admitted to 24 French ICUs with any new thrombotic (arterial, venous or microvascular) manifestation.

Results: 134 patients were admitted to the ICU for 152 episodes. The number of patients with definite CAPS, probable CAPS and no CAPS was: 11 (7.2%), 60 (39.5%) and 81 (53.5%) respectively. We compared patients with definite/probable CAPS (group 1, n=11) and no CAPS (group 2, n=81).

Conclusion: Differences were found in the proportion of APS-involved organs between the two groups. The number of patients with definite CAPS was 11 (7.2%), 60 (39.5%) and 81 (53.5%) respectively. We compared patients with definite/probable CAPS (group 1, n=11) and no CAPS (group 2, n=81).

Morand Grant/research support from: AstraZeneca, Bristol Myers Squibb, Janssen, Merck Serono, and UCB., Consultant for: AstraZeneca, Eli Lilly, Janssen, and Merck Serono, Speakers bureau: AstraZeneca

and Charlson comorbidity score were not different between group 1 and 2. The median [IQR25-75] number of organs involved (4 [3-4] vs 2 [1-3], p=0.0001) and the frequency of proven microvascular thrombosis (23 (37.7%) vs 8 (11%), p=0.0001) were higher in group 1. Treatment and outcomes are reported in Table 2. Aside plasmapheresis there was no difference in terms of APS treatments between both groups. The in-hospital mortality was not different between patient with definite/probable CAPS and no CAPS (23% vs 28.8% respectively, p=0.4). The Kaplan-Meier curve of cumulative probability of survival retrieve no difference of survival between both groups (log-rank test p=0.5, Figure 1).

Figure 1

Conclusion: In this study, CAPS criteria were not associated with mortality in APS patients admitted to the ICU with new thrombotic manifestations. Further studies are needed to evaluate the accuracy of CAPS criteria in this population. Disclosure: None declared DOI: 10.1136/annrheumdis-2019-eular.5130

PREMATURE OVARIAN FAILURE IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOSUS: A CROSS-SECTIONAL CASE CONTROL STUDY

Valeria Orefice1, Fulvia Ceccarelli1, Giuseppina Pirrone2, Carmelo Prione1, Carlo Pericorne1, Simona Truglia1, Francesca Miranda1, Viviana Antonella Pacucci1, Francesca Spinelli1, Paola Galoppi2, Cristiano Alessandri1, Guido Valesini3, Fabrizio Conti3, Pollicofino Umberto I, Rheumatology, Department of Internal Medicine and Medical Specialties, Roma, Italy; 2Pollicofino Umberto I, Gynecological Sciences, Roma, Italy

Background: Women suffering from autoimmune diseases, such as Systemic Lupus Erythematosus (SLE), could develop menopause at a younger age in comparison with healthy population. In particular, a higher frequency of abnormal ovarian function has been described in SLE cohorts1-4. The presence of a cause-effect link between the disease and such modifications remains poorly understood. The role of disease activity and chronic damage, combined with the intake of some drugs, such as cyclophosphamide (CYC), has been suggested5.

Objectives: We evaluated the age at natural menopause and the prevalence of premature ovarian failure (POF) in a monocentric Caucasian SLE cohort. Additionally, we analyzed the possible association with the disease features.

Methods: We performed a cross-sectional case-control study, enrolling consecutive SLE women and reporting their clinical and laboratory data. As control group (healthy controls - HC), women without autoimmune diseases were enrolled. By using an interview, gynecological characteristics were investigated in patients and controls: in particular, we registered age at menarche, occurrence and age of menopause, history of hysterectomy. Natural menopause was defined as the absence of menses for at least 12 months in women aged >40 years and POF as amenorrhea of at least 12 months in women <40 years.

Results: We enrolled 196 Caucasian women with SLE (median age 47.0 years, IQR: 16.7; median disease duration 132 months, IQR: 180) and 90 HC (median age 49.9 years, IQR: 15.0). Ninety-four SLE patients (48.0%) and 26 HC (23.4%) referred a condition of menopause: the median age at occurrence was significantly lower in SLE than HC (47 years, IQR: 8.0 versus 50.5 years, IQR: 4; P=0.0001). Among the SLE patients, a natural menopause was observed in 70 subjects (74.4%), surgical in 7 (7.4%), iatrogenic in 17 (18.1%). In particular, 13 (13.8%) SLE patients referred the occurrence of menopause after CYC exposure. Excluding SLE patients with surgical menopause, we registered POF in 16 patients (17%); this prevalence was significantly higher in comparison with HC group, in which none of subjects experienced POF (P=0.0001). The comparison between SLE patients developing POF and those with natural menopause history demonstrated a significant higher prevalence of anti-Sm (31.2% versus 10.2%; P=0.0004), anti-RNP (25.0% versus 12.8%; P=0.02), anti-cardiolipin (aCL) IgG/ IgM (50.0% versus 26.9%; P=0.0008) and lupus anticoagulant (37.5% versus 17.9%; P=0.002). As expected, a significant more frequent CYC treatment was identified in patients developing POF (56.0% versus 11.0%; P=0.0001). Moreover, POF subjects showed a significant more frequent history of treatment with azathioprine (62.5% versus 30.7%; P=0.0001), mycophenolate mofetil (50% versus 20.5%; P=0.0001) and cyclosporine A (37.5% versus 19.2%; P=0.007). No significant differences were found in terms of clinical manifestations and mean SLICC/ACR damage index (SDI).

Conclusion: In the present study, we observed a significantly lower age at menopause in SLE patients in comparison with HC; in addition, a significantly higher frequency of POF was observed. POF was associated with a more active disease, in terms of autoantibodies prevalence and use of immunosuppressant drugs. Finally, for the first time, it was found an association between POF and antiphospholipid positivity, suggesting a possible role of these antibodies, in particular aCL, in POF development.

Diagnostics and imaging procedures

HOW ACCURATE IS PHYSICAL JOINT EXAMINATION OF THE MTP-JOINTS, AND WHAT CAN WE LEARN FROM ADDITIONAL MAGNETIC RESONANCE IMAGING ON FOREFOOT INVOLVEMENT IN EARLY ARTHRITIS?

Yousra Dakkak, Aleid Boer, Monique Reijnierse, Annette van der Helm-van Mil.

Leiden, Netherlands; Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: Magnetic resonance imaging (MRI) is known to be more sensitive than physical examination in detecting inflammation, and has predominantly been studied in metacarpophalangeal (MCP) and wrist-joints. Data on the concordance and discordance of physical examination and MRI-detected inflammation of metatarsophalangeal (MTP) joints is scarce, which is surprising as physical examination of these joints is generally considered more challenging than MCP-joints.

Objectives: We aimed to study the concordance and discordance of arthritis upon physical examination with MRI-detected inflammation of MTP-joints. Analyses on MCP-joints were included for comparison.

Methods: 1764 MTP (2-5) joints and 1764 MCP (2-5) joints of 441 consecutive patients presenting with early inflammatory arthritis (36% RA, 64% other inflammatory arthritides) underwent physical examination (PE) of joint swelling and 1.5T contrast-enhanced MRI of unilateral MCP- and MTP-joints. MRI-detected synovitis and bone marrow oedema were scored according to the RA MRI score (RAMRIS), and tenosynovitis according to Haavardsholm by two experienced readers (scores ranged 0-3). Analyses were done on joint level and joints were grouped as PE+MRI, PE–MRI+, PE–MRI and PE–MRI+. MRI positivity required the presence of the same MRI-inflammatory feature on joint level that was scored by both readers; ≥1. In addition, to be classified as PE+MRI, the joints required to have clinical swelling as objectified by two independent observers. After categorisation, the MRIs of the joints that were PE+MRI– were further studied by two other, independent observers among whom an experienced musculoskeletal radiologist, to investigate the presence of contrast-enhancement that was not scored according to RAMRIS guidelines.

Results: Physical examination of joints and MRI were concordant in 79% of MTP-joints (6% PE+MRI+, 74% PE–MRI–). For the MCP-joints this was 71% (15% and 56% respectively). Next discordance was studied. Subclinical joint inflammation (PE–MRI+) was present in 14% (n=248) of MTP-joints. This was less frequent than in MCP-joints, where subclinical inflammation was present in 27% (n=465, p<0.001). Discordance in the opposite direction (PE+MRI–) was present in 5% of MTP-joints (n=78). This was observed more frequent than in other inflammatory arthritides (58% vs 26%, p<0.005). At the MCPs no extra-articular inflammation was found.

Conclusion: Joint examination and MRI were mostly concordant in MTP- and MCP-joints. In MTP-joints MRI-detected subclinical joint inflammation was infrequent (14%), especially when compared to MCP-joints (27%). Clinical joint swelling without MRI-detected joint inflammation according to RAMRIS was also infrequent (5% of MTP-joints) and in part caused by extra-articular inflammation that can be detected by further detailed imaging studies. Further detailed imaging studies are needed to determine if extra-articular inflammation at the level of MTP-joints, with or without concomitant intra-articular inflammation, is a novel finding that is characteristic for early RA.

ONE-YEAR PROGRESSION OF EROSI VE DISEASE EVALUATED WITH HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY IN PATIENTS WITH ANTI-CITRULLINATED PEPTIDE ANTIBODIES AND ARTHRALGIA

Kresten Kragan Keller, Jesper Skovhus Thomsen, Kristian Stengaard-Pedersen, Josefine Therkildsen, Andreas Wiggers Nielsen, Berit Schiøttz-Christensen, Lone Svendsen, Merete Graaakjaer, Peter Molsgaard Petersen, Barbara Unge, Garen Gel Kjekshavn, Bente Langhild, Ellen Margrethe Haage.

Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; Silkeborg Regional Hospital, Diagnostic Centre, Silkeborg, Denmark; Aarhus University, Department of Biomedicine, Aarhus, Denmark; Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; Spine Center of Southern Denmark, Midoe, Denmark; Private Rheumatology Practice, Skanderborg, Denmark; Clinic of Rheumatology, Aarhus, Denmark; Randers Regional Hospital, Department of Internal Medicine, Randers, Denmark; Horsens Regional Hospital, Horsens, Denmark; Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark.

Background: Bone erosions are common at diagnosis of rheumatoid arthritis (RA). However, bone erosions in predilacal RA (pre-RA) are not well described, and have not been studied prospectively.

High resolution peripheral quantitative computed tomography (HR-pQCT) has a spatial resolution of 82 μm and may therefore be ideal to detect bone erosions.

Objectives: To evaluate erosive progression with HR-pQCT in anti-citrullinated peptide antibody (ACPA) positive patients with arthralgia compared with healthy subjects.

Disclosure of Interests: None declared

Methods: Patients were recruited by specialists in rheumatology at hospital clinics and in private practice, and healthy controls were recruited from a website for research subjects. Patients with arthritis, ACPA and no rheumatic disease, and controls without arthritis, ACPA, or rheumatic disease were included. Medical history, ACPA, clinical examination and ultrasound of symptomatic joints were performed in all patients and controls. A 2.7-mm-long volume of interest in the 2nd and 3rd MCP joint of the right hand was HR-pQCT scanned at a spatial resolution of 92 μm at baseline and after one year. Cortical and trabecular bone structure were evaluated in a 12.9-mm-long volume of interest proximal to the MCP head using the provided scanner software. Erosions were defined as cortical breaks in two consecutive slices, in two planes, non-linear in shape, and with loss of underlying trabecular structure. Number, depth, width, and volume of erosions were measured using the Osiris DicomViewintra. Intra observer agreement for erosion was evaluated with Cohens Kappa and coefficient of variance (CV). Values are median (interquartile range).

Results: Twenty-two patients (aged 53(36-63) years) and 23 controls (aged 48 (42-57) years) were evaluated. Ten patients were diagnosed with RA after 86 (24-200) days. There was a significant increase in the number of patients with erosions during follow-up in the patient group (4 vs. 10, p=0.031), but not in the control group (1 vs. 4, p=0.083). In addition, at follow-up more erosions per individual were demonstrated in patients compared to controls (p=0.031).

The increase in average and total volume of erosions from baseline to follow-up was larger in patients compared with controls (Fig. 1) (p=0.031 and p=0.027). At follow-up average and total volume of erosions in patients were larger in patients compared with controls (p<0.001 and p=0.045). Percent change in bone density, cortical, as well as trabecular parameters did not differ between patients and controls. Agreement was 95% equivalent to a kappa of 0.89 for erosions. CV for width, depth, and volume of erosions were 8%, 23%, and 39%.

Conclusion: Progression of erosive disease in ACPA positive patients with arthritis using HR-pQCT is reported for the first time. The results highlight that an even earlier diagnosis of RA is crucial to prevent erosive disease.

ULTRASOUND IN THE MANAGEMENT OF EARLY RHEUMATOID ARTHRITIS: MRI OUTCOME DATA FROM THE ARCTIC RANDOMIZED CONTROLLED STRATEGY TRIAL

Ulf Sundin1,2, Anna-Birgitte Aga1, Øivind Skare1, Lena B Norberg1,2, Till Uhlig1,2, Hilde Berner Hammer1, Desirée van der Heijde3, Tore K. Kvien1,2, Siri Lillegraven1, Espen Haavardsholm1,2, Diakonhjemmet Hospital, Oslo, Norway, 1University of Oslo, Oslo, Norway, 2Leiden University Medical Center, Leiden, Netherlands

Background: It has been debated whether treatment outcomes in early RA would be improved by targeting imaging remission, assessed by ultrasound or MRI, in addition to clinical remission. The primary analyses of the ARCTIC and TaSER trials (1, 2) did not show a beneficial effect of adding structured ultrasound assessment to a treat-to-target tight control strategy. However, both studies reported a trend toward less radiographic progression in the ultrasound arm.

Objectives: We aimed to investigate whether management of early RA by a tight control strategy incorporating ultrasound information in treatment decision-making would lead to improvement in MRI remission or less structural damage, compared to a conventional tight control strategy.

Methods: The ARCTIC trial was a 24-month RCT with inclusion criteria age 18-75 years, fulfillment of ACR/EULAR criteria for RA, DAS28-CRP < 2 years from first patient reported swollen joint, and indication for DMARD treatment. Patients were randomized to an ultrasound tight control strategy targeting DAS < 1.6, no swollen joints and no power-Doppler signal in any joint, or a conventional strategy targeting DAS < 1.6 and no swollen joints. Patients in both arms were treated by the same treat-to-target drug escalation algorithm starting with MTX, then triple combination therapy MTX/SSZ/HCQ, then biologic DMARD. In the ultrasound arm, treatment was started up if indicated by the ultrasound score, overruling the DAS and swollen joint count. MRI of dominant wrist and hand was performed at 6 times and scored in chronological order by a reader blinded to study arm and clinical data. MRI acquisitions and scoring were done according to the RAMRIS (3) recommendations. Of the 230 patients in ARCTIC, 218 (ultrasound n=116, conventional n=102) had MRI at baseline and ≥1 follow-up visit, and were included in the analyses. RAMRIS synovitis, tenosynovitis and bone marrow edema scores were summarized to a combined inflammation score, erosions and joint space narrowing to a combined damage score. Mean change from baseline to each follow-up was estimated by a linear mixed model adjusted for baseline score, age, gender, center and anti-CCP status. The mean combined MRI inflammation score decreased during the first year (1-year change in ultrasound arm –10.8 (95% CI: –12.0 to –9.6), conventional arm –10.3 (95% CI: –11.5 to –9.0), p=0.56), and maintained at the same level throughout the 2nd year. There were no significant differences in changes from baseline to the study arms at any time (figure 1a). The mean combined MRI damage score showed a small increase over time, without any significant differences between study arms (figure 1b).

Conclusion: A light control strategy incorporating ultrasound information in treatment decisions did not lead to improved MRI remission or less structural damage, compared to a conventional tight control strategy. The findings support the conclusion of the ARCTIC trial that systematic use of ultrasound does not provide added value in the follow-up of patients with early RA treated according to current recommendations.

Background: Whole body MRI (WBMRI) is a new promising tool for assessing joint inflammation in rheumatoid arthritis (RA) patients on joint and patient level.

Objectives: To evaluate the agreement between US, WBMRI and clinical assessment of joint inflammation in rheumatoid arthritis (RA) patients on joint and patient level.

Methods: US, WBMRI and clinical assessment for tender joints (TJ) and swollen joints (SwJ) were performed in 19 RA patients (90% Women, median age 55 (26-73), diseases duration 5.5 years (1-42), SwJ(28) 5 (1-13), TJ(28) 7 (2-24) and SJC(28) 15 (0-52). Whole body MRI (WBMRI) was performed mono-parametrically (slice thickness 3 mm) and separately on the right and left side. For the wrist and hand, an additional slice thickness of 1.5 mm was used. In total 382 joints were evaluated on WBMRI. Based on the knee evaluation of WBMRI, the whole body was divided into 26 regions: 10 upper limbs, 6 lower limbs, and 2 trunk regions. Joints with osteitis (WBMRI excluding osteitis) were considered as osteitis only. Agreement was assessed between the different methods.

Results: When considering joint inflammation by WBMRI as synovitis and/or osteitis, US28 for synovitis and WBMRI26 for WBMRI - same 28 joints except elbows (due to poor image quality). The max score of a joint in US and WBMRI including osteitis was 2, while WBMRI excluding osteitis was 1. The agreement between the clinical joint assessment, US and WBMRI for joint inflammation was calculated with Cohen’s kappa (κ). The correlations between US28, WBMRI26 and DAS28-CRP were calculated by Spearman correlation coefficient (ρ).

Conclusion: US and WBMRI sum scores of joint inflammation showed good correlation. Agreement at joint level was variable.

Disclosure of Interests: none declared.

OPTIMIZING SUBJECT SELECTION IN KNEE OSTEOARTHRITIS CLINICAL TRIALS BY RADIOGRAPHIC JOINT SPACE WIDTH: POST-HOC CLINICAL RESPONSE ANALYSIS FROM A PHASE 2B TRIAL OF WNT PATHWAY INHIBITOR, SM04690

Sarah Kennedy1, Christopher Swearingen1, Jeynesh Tambiah1, Philip G. Conaghan1,2, Samumed, LLC, San Diego, United States of America; 2University of Leeds, Leeds, United Kingdom

Background: Knee osteoarthritis (OA) trial radiographic inclusion criteria usually comprises Kellgren-Lawrence (KL) grading, which mixes features such as osteophytes and joint space narrowing and leads to study population heterogeneity. Selecting subjects with baseline medial joint space width (mJSW) 2-4 mm has been shown to reduce heterogeneity and improve responsiveness to radiographic change in comparison to broader knee OA populations.1,2 However, effects of baseline mJSW on symptom responsiveness are unknown.

Objectives: To evaluate the impact of baseline mJSW 2-4 mm on patient-reported outcomes (PROs) as measured by effect size in a 24-week phase 2b trial of SM04690, a Wnt pathway inhibitor in development as a potential disease-modifying OA drug (DMOAD).

Methods: Knee OA subjects with KL grades 2-3 and Pain Numerical Rating Scale (NRS, 0-10) ≥4 and ≤8 in the target knee and <4 in the contralateral knee received a single IA 2 mL SM04690 injection (0.03, 0.07, 0.15, 0.23 mg), vehicle (NRS, 0-10)/C21

Knee OA subjects with KL grades 2-3 and Pain Numerical Rating Scale (NRS, 0-10) ≥4 and ≤8 in the target knee and <4 in the contralateral knee received a single IA 2 mL SM04690 injection (0.03, 0.07, 0.15, 0.23 mg), vehicle placebo (PBO), or sham (dry needle) in the target knee at baseline. PRO 24-week endpoints included change from baseline in weekly average of daily OA target knee pain by NRS, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain [0-100], WOMAC Physical Function [0-100], and Patient Global Assessment (PigA) [0-100]. Primary results are presented elsewhere3. A post-hoc completer analysis of subject results with baseline mJSW 2-4 mm is reported.

Results: 635 subjects (91.4%) completed the study (mean age 59.0 [±8.5] years, 63.5% female). In both full analysis set (FAS, all dosed subjects) and mJSW 2-4 mm subjects, significant improvements compared to PBO (P<0.05) were seen in pain NRS, WOMAC Pain, WOMAC Function, and PigA for 0.07 mg and 0.23 mg SM04690 dose groups at Week 12 (Figure 1). The effect sizes were improved in the mJSW 2-4 mm group in comparison to FAS for most doses at weeks 12 and 24.

Conclusions: In this post-hoc analysis of SM04690-treated knee OA subjects, those with baseline mJSW 2-4 mm showed increased PRO effect sizes compared to those in the FAS. Previous data also demonstrated SM04690-treated subjects with mJSW 2-4 mm had improved radiographic sensitivity to change. Data from SM04690 studies suggest mJSW 2-4 mm should be considered as an inclusion criterion for trials of potential knee DMOADs.

THE ROLE OF ULTRASONOGRAPHY IN THE DIAGNOSIS OF PRIMARY SJÖGREN SYNDROME AND ITS CONCORDANCE WITH SALIVARY GLAND BIOPSY

Laura Barrio Nogal1, Cristina Bohónquez1, Adrián Abbasi2, Lucía Ruiz2, Ana Peru Gómez1, Adela Castelló1, Melchor Álvarez de Molín1, Hospital Universitario Príncipe de Asturias, Madrid, Spain; CIBER Epidemiología y Salud Pública, Madrid, Spain

Background: Minor salivary gland biopsy (MSGB) is the gold-standard technique for primary Sjögren Syndrome (SSp) but nowadays the use of major salivary gland ultrasonography (MSGUS) is increasing because it is a fast and non-invasive technique and with no adverse events for the patient.

Objectives: To assess the utility of MSGUS as a diagnostic tool for SSp and to study the concordance with MSGB.

Methods: 72 patients were recruited consecutively with clinical and/or analytical suspicion of SSp, from the Rheumatology outpatient consultations at the Príncipe de Asturias Hospital (2015-2018). Demographics, clinical and serological data and validated activity indexes, ESSPRI and ESSDAI, were recorded. All patients underwent a MSGB and blindly, both for clinical and histological results, a MSGUS. The histological results were classified according to Cheholin and Mason scores (pathological grades 3/4), and the US results according to the system by Cornejo et al. (pathological grade ≥2). The final SSp diagnosis was made using both the 2002 and the 2016 ACR/EULAR classification criteria. The data was analyzed using the software STATA. The validity of the US and the MSGB to diagnose SSp according to the 2002 and 2016 ACR/EULAR classification criteria was evaluated by calculating the percentage of agreement between the tests, along with the specificity (Sp), sensitivity (S), positive and negative predictive values (PPV and NPV) and area under the curve (AUC).

Results: Descriptive analysis of the main variables is shown in Table 1. Using the MSGUS as a gold-standard, the total% of agreement was 78% with a good AUC (0.75) (IC95%:0.65-0.84). Using the 2002 classification criteria as a gold-standard, the total% of agreement was 82% for US and 79% for MSGB with an AUC of 0.78 (IC95%:0.67-0.88) and 0.80 (IC95%:0.70-0.89) respectively. In this case, US had a S of 53% (IC95%:0.82-0.99) and a Sp of 62% (IC95%:0.41-0.80) whereas MSGB had a S of 78% (IC95%:0.64-0.89) and a Sp of 81% (IC95%:0.61-0.93). Similar results were obtained using ACR/EULAR criteria: US% of agreement 83%, AUC 0.78 (IC95%:0.67-0.90), S 90% (IC95%:0.79-0.97) and Sp 67% (IC95%:0.43-0.85); while MSGB% agreement 81%, AUC 0.83 (IC95%:0.75-0.92), S 76% (IC95%:0.63-0.87) and Sp 90% (IC95%:0.70-0.99). In addition, 9 patients who fulfilled the 2002 classification criteria with a negative histological result had a pathological US.

Conclusion: MSGUS has a similar diagnostic value compared to MSGB in patients with SSp, which could be part of the classification criteria used to date. In this series of patients and compared to MSGB, it has a higher sensitivity and a lower specificity, so it could be used as an initial diagnostic method in patients with high suspicion of disease. The MSGUS for those cases in which US and other clinical and serological data are inconclusive. With this approach, the disadvantages derived from an invasive technique such as MSGB would be avoided.

REFERENCES:
Results: Light weighted kappa for grading and diagnostic evaluation for intra- and inter-reader reliability was moderate to excellent (see Table for details).

Conclusion: The developed US definitions and the scoring system for salivary gland lesions in pSS showed a good to excellent reliability in patients with SS. Next step is to apply the scoring system in clinical trials.

ASSESSMENT OF ULTRASOUND DEFINITIONS AND A SCORING SYSTEM FOR SALIVARY GLAND DISEASE IN PRIMARY SJÖGREN’S SYNDROME: AN OMERAC US PATIENT RELIABILITY EXERCISE

Stephanie Finzel1, Sandrine Jousse-Joulin1, Annamaria Iagnocco2, Esperanza Naredo, A, Nizojija Hocevar, Sarah Ohmdorf, Petra Hanova, Maria-Antonietta D’agostino, Felicie Costantino, Lene Terslev, Helen Keen10, George Bruyn11, University of Clinic of Freiburg, Department of Rheumatology and Clinical Immunology, University Medical Centre, Freiburg, Germany, 2Cavale Blanche Hospital and Brest Occidentale University, EA 2216, ERI 29, Rheumatology Department, Brest, France; 3University degli Studi di Torino, 3Academic Rheumatology Centre, Turin, Italy; 4Hospital Universitario Fundación Jiménez Diaz, Universidad Autónoma, Rheumatology Department, Joint and Bone Research Unit, Madrid, Spain; 5University Medical Centre Ljubljana, Rheumatology Department, Joint and Bone Research Unit, Ljubljana, Slovenia, 6Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 7Charing Cross University, Department of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Prague, Czech Republic; 8Hôpital Ambroise Pare, Boulogne-Billancourt, France; 9Righospitalet, Centre for Rheumatology and Spinal Diseases, Copenhagen, Denmark; 10Porth University, Department of Rheumatology, Perth, Australia; 11MC Groep Hospitals Lelystad, Department of Rheumatology, Lelystad, Netherlands

Background: Salivary gland ultrasound (SGUS) may have the potential of facilitating diagnosis and therapy monitoring of salivary gland disease in patients with primary Sjögren’s syndrome (pSS). The aim of the Outcome Measures in Rheumatology Clinical Trials (OMERACT) US subgroup on SG is to validate US as an outcome measurement instrument in pSS. Following the OMERACT US stepwise validation approach, preliminary consensus definitions for elementary lesions based on a systematic literature review were developed and subsequently a scoring system has been agreed upon and tested through a web-based Delphi exercise.

Objectives: To assess the reliability of consensus based SGUS scoring system in patients with SS.

Methods: Nine sonographers conducted an US reliability exercise of the parotid and submandibular glands (PG, SMG) of 9 patients with primary and secondary SS in 3 rounds. A 4-grade semi-quantitative scoring was applied in B-mode for structural lesions as follows: Grade 0: normal, grade 1: mild inhomogeneity without anechoic or hypoechoic areas, grade 2: moderate inhomogeneity with focal anechoic or hypoechoic areas, grade 3: severe; diffuse inhomogeneity with an-/hypoechoic areas occupying all the surface of the gland. Next, presence or absence of typical pSS-lesions was scored in binary fashion. Intrareader and interreader reliability were computed by Cohen and Light kappa. Weighted k coefficients with absolute weighting were calculated for B-mode abnormalities.

Results: Among 250 pts treated in the double-blind period, 215 entered part 2 and 197 (92%) completed 3 years in the trial. Among the 81 TCZ QW and 36 TCZ Q2W pts in CR at wk 52, 38 (47%) and 13 (36%) pts, respectively, maintained CR during part 2. Of these 51 original TCZ pts, 33 (65%) were treatment-free (no TCZ and no GC treatment), which was higher than the treatment-free proportion of original PBO pts who maintained CR in part 2 (17/38; 45%). Median time to first flare while not receiving TCZ was longer for pts in the original TCZ groups (TCZ QW, 575 days; TCZ Q2W, 428 days) than for pts in the original PBO groups (PBO+26, 182 days; PBO+52, 295 days); TCZ QW pts remained flare-free the longest (Fig. 1). Retreatment with TCZ (with or without GC) for flare was effective for restoring CR in part 2. Cumulative GC dose over the 3-year study was lowest in the TCZ group (median dose [mg/day]: TCZ QW, 2372.8; TCZ Q2W, 2686.0; PBO +26, 5006.0; PBO+52, 5322.5). Rates of serious adverse events per 100 pt-years over 3 years (double-blind period + part 2) were comparable for pts who never received TCZ (23.2) and who did receive ≥1 dose of TCZ (25.4), and rates of...
serious infections were 4.6 and 3.5 per 100 pt-years, respectively. Additional results will be presented for original PBO pts.

Conclusion: Nearly half the pts treated with TCZ QW maintained CR for the entirety of part 2, though flares still occurred in the remaining pts once they discontinued TCZ treatment. Among pts who maintained CR in part 2, higher proportions of those originally assigned to TCZ were treatment-free compared with those originally assigned to PBO. Retreatment with TCZ restored CR in pts who experienced flare. Cumulative GC doses over 3 years were lower in pts originally assigned to TCZ than in those originally assigned to PBO. No new safety signals were observed with TCZ exposure in GCA pts during the 3-year study.

CD28 AS A POTENTIAL THERAPEUTIC TARGET FOR GIANT CELL ARTERITIS

Ryu Watanabe1, Hui Zhang1, Gerald Berry2, Steven Nadler3, Jörg Goronzy4, Cornelia Weyand5, Stanford University School of Medicine, Department of Medicine, Division of Immunology and Rheumatology, Stanford, United States of America; 2Stanford University School of Medicine, Department of Pathology, Stanford, United States of America; 3Bristol-Myers Squibb, Princeton, United States of America

Background: Giant cell arteritis (GCA) is a granulomatous vasculitis of medium and large arteries. In GCA-affected arteries, vascular wall is destroyed by tissue-infiltrating CD4 T cells and macrophages, which leads to intramural neoangiogenesis and differentiation of IFN-γ- and IL-21-producing effector T-cells. Blocking CD28 signaling and differentiation of IFN-γ- and IL-21-producing effector T-cells. Blocking CD28 signaling disrupted T-cell metabolic fitness; particularly, glucose utilization. Expression of the glucose transporter Glut1 and of glycolytic enzymes as well as mitochondrial oxygen consumption all rely on CD28 signaling. CD28 blockade effectively suppressed vessel wall remodeling processes such as advanced microvessel formation and intimal hyperplasia as well as induction and maintenance of CD4+CD103+ tissue-resident memory T cells.

Methods: CD28 stimulation provides a metabolic signal required for pathogenic effector functions in GCA, implicating CD28 signaling as a promising therapeutic target.

Conclusion: CD28 stimulation provides a metabolic signal required for pathogenic effector functions in GCA, implicating CD28 signaling as a promising therapeutic target.

THE IMPACT OF DISEASE EXTENT AND SEVERITY DETECTED BY QUANTITATIVE ULTRASOUND ANALYSIS IN THE DIAGNOSIS AND OUTCOME OF GIANT CELL ARTERITIS: RESULTS FROM THE TEMPORAL ARTERY BIOPSY VERSUS ULTRASOUND (TABUL) STUDY AND VALIDATION IN AN INDEPENDENT COHORT

Sara Mori1, Cristina Ponte1, Claudio Pereira2, Federica Rum3, Greta Carras3, Catherine Klersy4, Andrew Hutchings5, Wolfgang A. Schmidtt6, Bhashak Dasgupta1, Roberto Caporal1, Carmaurozio Montecucco1, Raashid Luhman1, 2University of Pavia, IRCSS Policlinico S. Matteo Foundation, Department of rheumatology, Pavia, Italy; 3University of Pavia in Experimental Medicine, Pavia, Italy; 4Hospital of Santa Maria, Lisbon; and Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon Academic Medical Centre, Department of Rheumatology, Lisbon, Portugal; 5University of Oxford, NDORMS, Rheumatology Department, Nuffield Orthopaedic Centre, Oxford, United Kingdom; 6Italian Society of Rheumatology, Epidemiology Unit, Milan, Italy; 7IRCSS Policlinico S. Matteo Foundation, University of Pavia, Biometry and Clinical Epidemiology, Pavia, Italy; 8London School of Hygiene and Tropical Medicine, Department of Health Services Research and Policy, London, United Kingdom; 9Medical Centre for Rheumatology Berlin-Buch, Immanuel Krankenhae Berlin, Berlin, Germany; 10Southend University Hospital, NHS Foundation Trust, Westcliff-on-Sea, United Kingdom

Background: Colour duplex sonography (CDS) is used in patients with giant cell arteritis (GCA) to detect inflammatory oedema of the vascular wall, known as “halo”. A quantitative analysis of halo characteristics to grade the severity and extension of vascular involvement detected by CDS could improve GCA assessment.

Objectives: To develop a quantitative CDS score to improve the diagnosis of GCA, and to correlate the score with histologic findings and clinical outcome. To determine the additional role of clinical signs/symptoms to the CDS score.

Methods: We selected patients with a positive CDS and a diagnosis of GCA recruited into the Temporal Artery (TA) Biopsy (TAB) vs Ultrasound in Diagnosis of GCA (TABUL) study. Due to collinearity we fitted 4 different CDS models including combinations of the following items: number of sites and distribution of halos, average and maximum intima-media thickness (IMT) at the level of the TA and auxiliary arteries (AX) and halos bilaterally. We fitted 4 models with clinical and laboratory findings. We combined the best CDS and clinical models (according to the Akaike Information Criterion) to identify independent correlates of a TAB diagnostic for GCA and of clinical outcome at 6 months (visual loss + VDI ocular + glaucoma-corticoids > 10 mg/day and/or on immunosuppressants) and performed a 10-fold cross-validation of the model. We validated the clinical outcome model on an independent cohort referred to the fast-track ultrasound clinics of two European rheumatology centres.

Results: We included 135 patients with GCA from TABUL (female: 68%, age 73 ±8) and 72 patients from an independent cohort (female: 46%, age 75±7). The...
best fitting CDS model for TAB used maximum IMT size and bilaterality of plaques at the level of the TA and AX. The best fitting clinical model included raised ESR/ CRP, polymyalgia rheumatica, headache and ischaemic symptoms (jaw/tongue claudication, amaurosis, double vision, stroke). The coefficients from the best fitting models (CDS and clinical) allowed to produce a comprehensive score (CDS-US score) to stratify patients according to the probability of having a positive TAB (Figure 1), Model discrimination was fair (AUC-ROC 0.77, 95%CI 0.68-0.84). None of the considered variables was associated with clinical outcome expressing worse prognosis at 6 months.

Conclusion: We demonstrated that a quantitative analysis of CDS findings adds important diagnostic information with a computable estimate of the probability of positive history, supporting the use of CDS as a surrogate diagnostic tool to replace TAB. A few CDS and clinical findings can be combined into a simple computable risk score to support a diagnosis of GCA.

OP0143 PREDICTORS OF SEVERE CRANIAL ISCHEMIC COMPLICATIONS IN GIANT CELL ARTERITIS

HOCVAR ALOTUA1,2,3, Rek Jese1, Ziga Rata1, Malija Tomsi1,2,3, University Medical Centre Ljubljana, Dept. of Rheumatology, Ljubljana, Slovenia, 1University of Ljubljana, Medical Faculty, Ljubljana, Slovenia

Background: Vision disturbances and ischemic stroke represent severe ischaemic complications of giant cell arteritis (GCA). Despite the fast track GCA pathway since 2011 our secondary/tertiary rheumatology center, about 10% of patients still develop permanent vision loss (PVL) or stroke.

Objectives: We aimed to determine markers predicting severe cranial ischemic complications in GCA.

Methods: We analyzed medical records of prospectively collected GCA patients diagnosed between 01.09.2011 and 31.12.2018 and compared clinical and laboratory characteristics of patients with and without vision disturbances (diplopia, transient vision loss (TVL), PVL) or ischemic stroke.

Results: During the 88-month observation period, we identified 250 new GCA patients (63.2% female, median (IQR) age 74.9 (67.8-79.9) years, 83.3% histologically proven, 79.8% with positive temporal artery ultrasound, 30.3% with extracranial large vessel involvement). Fifty (20.0%) patients developed either vision disturbances (16 diplopia, 10 TVL or 19 PVL) or ischemic stroke (8); isolated vision disturbances in 42, and isolated stroke in 5 patients. Conventional cardiovascular risk factors (obesity, arterial hypertension, hyperlipidemia, diabetes mellitus, and smoking were not associated with severe cranial ischemic complications (Table 1). The patients with severe cranial ischemic complications had more frequently had atrial fibrillation (RR 2.4 (95%CI 1.3-4.4), p<0.011). Twenty-five from 35 patients with atrial fibrillation were already treated with anticoagulants (10/13 in the group with cranial ischemic complication and 15/22 without them). Besides, GCA cases with severe cranial ischemic complications were significantly older (p<0.006) and more commonly reported jaw claudication (RR 1.8 (95% CI 1.4-2.3), p<0.001). We found no significant differences in the median level of C-reactive protein between the compared groups, whereas the erythrocyte sedimentation rate was slightly lower (p=0.032) and haemoglobin concentration higher (p<0.030) in cases with severe cranial ischemic complications.

Conclusion: Increasing age and jaw claudication predicted severe cranial ischemic complications in our GCA cohort. Atrial fibrillation might represent an additional risk factor.

OP0144 MORTALITY IN GIANT-CELL ARTERITIS PATIENTS: A NATIONWIDE POPULATION-BASED STUDY

Niv Ben-Shabat1, Howard Amital1,2,3, Amnon Cohen4,5, Doron Comaneshe1, Shmuel Tissiano1,2, Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel, 3Sheba Medical Center, Medicine B, Tel-Hashomer, Israel, 4Sheba Medical Center, The Zabludowicz Center for Autoimmune Diseases, Tel-Hashomer, Israel, 5Clalit Health Services, Quality Measurements and Research, Chief Physician’s Office, Tel-Aviv, Israel, 6Ben Gurion University of the Negev, Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Beer-Sheva, Israel

Background: Giant cell arteritis (GCA), is the most common type of chronic systemic vasculitis over the age of 50. So far, studies regarding mortality in giant-cell arteritis (GCA) patients had yielded conflicting results.

Objectives: In this large population-based study we aimed to examine whether GCA is associated with increased mortality in different time periods, and in patients diagnosed ≤70 years of age.

Methods: We utilized the medical database of the Clalit-Health-Services in a retrospective cohort study. Follow-up was from January 1st, 2002 and continued until death or end of study follow-up at September 1st, 2018. Incident GCA patients were compared with age- and sex-matched controls. Estimated median survival-times were calculated using Kaplan-Meyer (KM) method and Risk for all-cause mortality in different follow-up periods was obtained by Cox proportional-hazard model, adjusted for age, gender, socio-demographic variables and traditional risk factors.

Results: Our study included 7,294 GCA patients and 34,156 age- and sex-matched controls. The mean age at the start of follow-up was 72.1±9.90 years with 69.2% females. The crude mortality rates for the entire follow-up period was 33.4% amongst GCA patients and 30.2% amongst controls. In KM analysis estimated median survival-time was 13.08 years (95% CI, 12.64-13.52 years) in GCA patients compared to 14.35 years (95% CI 14.09-14.61) in controls (P-value < 0.001). Cox regression demonstrated increased mortality risk in the first 2 years after diagnosis (HR 1.15; 95% CI 1.04-1.26) and >10 years after diagnosis (HR 1.13; 95% CI 1.02-1.32). Risk was higher in patients diagnosed ≤70 years of age [HR 1.66 (95% CI 1.22-2.13) 0-2 years; HR 1.44 (95% CI 1.16-1.79) >10 years].

Conclusion: GCA patients have a minor decrease in long-term survival compared to age-and-sex matched controls. The seen difference is due to excess mortality in the first 2 years, and >10 years after diagnosis of GCA, especially in patients diagnosed ≤70 years of age.

Background: Systemic signs of inflammation such as raised CRP or ESR are a classical feature of PMR, but some patients present with normal acute phase reactants (APR). It is not known whether these patients represent milder forms of PMR, whether their disease is not yet fully expressed, or whether they represent another pathophysiological subset of PMR or another disease. Data on demographic and clinical differences between PMR patients with normal versus elevated APR.

Methods: We conducted a retrospective cohort study of clinical characteristics of newly diagnosed PMR patients (clinical diagnosis) who visited our outpatient clinic between April 2012 and September 2017. Patient with concomitant inflammatory rheumatic disease were excluded. Data on patient-, disease-, and treatment characteristics in PMR patients with normal versus elevated APR were provided in the study.

Objectives: To explore baseline differences in demographics and clinical characteristics in PMR patients with and without elevated APR.

Methods: We conducted a retrospective cohort study of clinical characteristics of newly diagnosed PMR patients (clinical diagnosis) who visited our outpatient clinic between April 2012 and September 2017. Patient with concomitant inflammatory rheumatic disease were excluded. Data on patient-, disease-, and treatment characteristics in PMR patients with normal versus elevated APR were provided in the study.

Results: 454 patients were included (table 1). Sixty-two patients had normal, and 392 had elevated APR. In the group with normal APR, fewer patients had peripheral arthritis (2 versus 9%; p=0.044) and fewer had anemia at diagnosis (17 versus 43%; p=0.001). Furthermore, patients had a longer median duration of symptoms before diagnosis (13 versus 10 weeks; p=0.0196) and were more likely to have a history of PMR (16 versus 8%; p=0.057). No significant differences were found in other clinical characteristics. Conclusion: The results of this cohort indeed suggest that patients with normal APR are a different subset of PMR patients. Fewer cases have peripheral arthritis and anemia at diagnosis, suggesting a milder form of PMR. Secondly, our results do not support the hypothesis that PMR of those with normal APR is not yet fully expressed, as they have a longer symptom duration prior to diagnosis.

**Background:** The development of more potent therapeutic approaches to KD is an urgent need because intravenous immunoglobulin (IVIg) treatment is not effective in 20% of patients, increasing the risk of coronary dilations/aneurysms. The combination of genetic and transcriptomic data revealed the key role of interleukin-1 (IL-1) signaling in KD vasculitis and mouse model of KD has shown that anakinra (IL1RA: IL-1 receptor antagonist) could prevent the development of vascular aneurysms.

**Objectives:**
- To assess as primary objective, the efficacy of anakinra in patients with KD who fail to respond to at least one infusion of IVIg.
- To assess its safety and tolerability and its effect on disease activity, systemic inflammation and coronary lesions.

**Methods:** A 45-day, phase IIa proof of concept study open labeled with anakinra dose escalation, with a target of at least 12 patients completing the study. Eligible patients had KD according to the AHA criteria, duration of fever ≤ 14 days, and were ≥ 3 months and 5 Kg. They had persistent (or relapsing) fever (≥38°C) within 48h of the last IVIG infusion, had not received other alternative treatment including steroids, and had no others exclusion criteria. After informed consent, they received a starting dose of 2mg/kg (patients <10kg and/or <8 months: 8mg/kg), which could be increased every 24h of 2mg/kg until a maximum of 6mg/kg (patients <10kg and/or <8 months: 8mg/kg). In case of persistent fever, Anakinra treatment duration was 15 days. Outcome measures were fever, KD symptoms, blood inflammation and cardiac echography. Total study duration was 45 days. **Clinical trials:** NCT02396596. The study is supported by a grant from the French ministry of health, APHP, national PHRC 2014. IRB approval was obtained and all patients (parents) gave informed consent.

**Results:** 18 patients were screened and 16 were included and 13 have completed the study. Anakinra was started in 16 patients (14 boys, 2 girls) at a median age 2 years (3 months to 6 years) and at a median of 9.5 days after the onset of fever. 4 patients escaped early for SAE, and 1 had sJIA final diagnosis. The maximum dose of anakinra was 6mg/kg in 6 patients, 4mg/kg in 6, and 2mg/kg in 4. Mean PGA decreased from 7.80 (4-10) to 1.2 (0-3) at D14. Median temperature was 37.7°C (36.7-39.7) at day 3 and 37.2°C at D7 (36.7-37.9). Median CRP was 135mg/L at screening and decreased to 9.5 mg/L at D7. 8/14 evaluated patients had coronary dilatation (Z score max >2.5mm) at inclusion, 5/14 at D14 and 3/14 at D45. 3/14 patients who increased 2 score at D14 decreased it at J45. We observed 3 severe adverse events (SAE) where treatment was discontinued: anakinra overdose, MAS in a patient evolving to sJIA and increase of coronary dilatation. Others AE included cytolytic hepatitis (2 patients), hypereosinophilia (1), injection site reaction (1) and pancreatitis (1) without treatment discontinuation.

**Conclusion:** We have realized the first experimental study assessing IL-1 blockade in severe refractory KD. 15 days-duration of anakinra treatment, given early in the course of IVIG-resistant KD, was rapidly effective on KD symptoms, biologic inflammation and coronary dilatations in almost all patients, with a good tolerability. This study calls for further investigation of IL-1 blockade in KD.

**OP0148 METABOLOMICS IN JUVENILE-ONSET SLE: IDENTIFYING NEW BIOMARKERS TO PREDICT CARDIOVASCULAR RISK**

George Robinson1,2, Anna Radziszewska2, Chris Winnoc1, Coiziana Curtiu2, Yiannis Ioannou2, Ines Pineda Torra3, Elizabeth Jury1, Jury Lab. 1University College London, Rheumatology, London, United Kingdom; 2University College London, Centre for Adolescent Rheumatology, London, United Kingdom; 3University College London, Metabolism and Experimental Therapeutics, London, United Kingdom

**Background:** Juvenile-onset systemic lupus erythematosus (JSLE) is an autoimmune disorder characterised by immune dysregulation, chronic inflammation and increased cardiovascular risk (CVR). Cardiovascular disease is the leading cause of mortality in JSLE not attributable to lupus flare. Our findings in adult-onset SLE link immune cell dysregulation with dyslipidemia but little is known about the immune profile or whether abnormal lipid metabolism contributes to disease pathogenesis in JSLE.

**Objectives:** The objective of this study was to investigate dyslipidemia and CVR in a cohort of JSLE patients using in depth metabolomics and relate this to clinical and immune cell profiles and to identify novel biomarkers to predict CVR in these patients.

**Methods:** Metabolic biomarker analysis (NMR) and in-depth immune cell phenotyping (30 subsets by flow cytometry) was performed on serum and PBMCs respectively from a discovery cohort of 35 JSLE patients (median age 19 (14-25), 12 males, 23 females) compared with 39 age/sex matched healthy donors (HCs) (median age 18 (16-25), 17 males, 22 females). Data was analysed using cluster and correlation-correlation and receiver operating characteristic (ROC) analysis.

**Results:** Patient stratification by metabolomic profile using unbiased hierarchical clustering revealed 3 groups that each had a unique lipoprotein profile, immune cell phenotype and clinical presentation. Group-1 had decreased atheroprotective high density lipoproteins (HDL) and increased atherogenic very low and low density lipoproteins (VLDL/LDL) and Group-2 had elevated HDL but reduced VLDL/LDL indicating that these groups could be at high and low CVR respectively. This hypothesis was validated by previously recognised markers of CVR including the atherosgenetic index of plasma, ApoB:A1 ratios and lipid biomarkers we previously identified to be associated with pre-clinical atherosclerotic plaque in adult SLE patients. Patients in Group-1 had a significant increase in plasmablasts and activated T-cells compared to HCs and had clinical features associated with increased disease activity. These immunopathogenic properties were not seen in the...
low CVR Group-2. Patients in Group-3 displayed an intermediate CVR but a pro-inflammatory immune cell profile. This metabolic patient stratification was validated in a separate JSLE cohort. Importantly, ApoB:A1 ratio was identified as a highly predictive biomarker (ROC area under the curve=0.99) distinguishing between JSLE patients in Group-1 and 2, indicating high and low CVR respectively. Finally, longitudinal analysis revealed that the ApoB:A1 ratio biomarker remained stable over time.

Conclusion: ApoB:A1 ratio and metabolic lipoprotein signatures could be new biomarkers to predict CVR in JSLE patients. Patient stratification using these biomarkers could provide an opportunity for tailored disease treatments using lipid modification therapy and/or diet/lifestyle interventions.

CD4+ T CELLS FROM CHILDREN WITH ACTIVE JUVENILE IDIOPATHIC ARTHRITIS SHOW ABERRANT CHROMATIN ORGANIZATION AND CTCF LOCALIZATION ASSOCIATED WITH TRANSCRIPTIONAL ABNORMALITIES

Evan Tarbell1, Kaiyu Jiang2, Teresa R. Hennon3, Lucy Holmes3, Patrick M. Gaffney3, Tao Lu3, Jim Jarvis1,2, 3University at Buffalo, Biochemistry, Buffalo, United States of America; 4University at Buffalo, Pediatrics, Buffalo, United States of America; 5University at Buffalo, Pediatrics, Buffalo, United States of America; 6University at Buffalo, Biochemistry, Buffalo, United States of America; 7University at Buffalo, Pediatrics, Buffalo, United States of America; 8University at Buffalo, Genetics, Genomics, and Bioinformatics Program, Buffalo, United States of America.

Background: Our group and others have shown that peripheral blood cells of children with juvenile idiopathic arthritis (JIA) display numerous transcriptional abnormalities. However, most of these studies have been performed on mixed cell types (peripheral blood mononuclear cells, whole blood). Little cell type specific data is available, making mechanistic inferences and links to disease pathogenesis difficult.

Objectives: To define transcriptional patterns in CD4+ T cells from children with polyarticular JIA and query mechanisms underlying transcriptional abnormalities.

Methods: We studied CD4+ T cells obtained from children with active polyarticular onset JIA and sought to identify epigenetic features associated with altered gene expression. We performed RNA-seq and ATAC-seq on a cohort of patients who had the active disease and were under treatment with methotrexate and eta-nercept (ADT), patients who fit criteria for clinical remission on medication (CRM), and healthy control children (HC). We used standard used the general dispersion protocol in EdgeR to identify differential gene expression. We used our recently developed and validated Hidden Markov Model library for ATAC-seq software to identify differentially accessible regions, comparing ADT, CRM, and HC samples. We integrated ATACseq and RNAseq data using the BETA software package. After preliminary analysis revealed a potential role for the transcriptional regulator, CCCTC binding factor (CTCF) in the observed transcriptional patterns, we performed ChIPseq and HICchip studies on an independent group of JIA CD4+ T cell samples.

Results: We found widespread transcriptomic differences between ADT and either HC or CRM patients. We identified 4,062 genes that showed differential expression between ADT and HC samples. Gene expression patterns from CRM samples were closely correlated to ADT patients, with high and low CVR respectivly. Finally, longitudinal analysis revealed that the ApoB:A1 ratio biomarker remained stable over time.

Conclusion: ApoB:A1 ratio and metabolic lipoprotein signatures could be new biomarkers to predict CVR in JSLE patients. Patient stratification using these biomarkers could provide an opportunity for tailored disease treatments using lipid modification therapy and/or diet/lifestyle interventions.

OP0150

MONOCYTE AND MACROPHAGE TRANSCRIPTIONAL PHENOTYPES IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS REVEAL TRIM8 AS A MEDIATOR OF IFNGAMMA HYPERRESPONSIVENESS AND RISK FOR MACROPHAGE ACTIVATION SYNDROME

Grant Schulert1,2, Thi Dao2, Sanjeev Dhakal2, Nidate Faith2, Mario Medvedovitch2, Nathan Salomonis3,4, Alex Geom2,5, University of Cincinnati, Pediatrics, Cincinnati, United States of America; 6Cincinnati Children’s Hospital Medical Center, Rheumatology, Cincinnati, United States of America; 7University of Cincinnati, Environmental Health, Cincinnati, United States of America; 8Cincinnati Children’s Hospital Medical Center, Biomedical Informatics, Cincinnati, United States of America

Background: Systemic juvenile idiopathic arthritis (SJIA) is a severe and distinct subtype of childhood arthritis. Children with SJIA are at risk for macrophage activation syndrome (MAS), a life-threatening episode of hyperinflammation driven by interferon-gamma (IFNγ). Previous studies in SJIA have demonstrated that proinflammatory and proinflammatory cytokines in SJIA display hyperresponsiveness to IFNγ, but the molecular basis of this remains unclear.

Objectives: Utilize transcriptional profiling of monocytes and macrophages in SJIA to identify polarization phenotypes including features of interferon response

Methods: Bulk RNA-sequencing (RNA-seq) was performed on purified monocytes from 26 patients with SJIA without MAS. In addition, single-cell RNA-seq was performed on isolated bone marrow macrophages from control patients and patients with SJIA and MAS. THP-1 monocytic cells and primary human monocyte-derived macrophages (MDM) were transfected with TRIM8-specific or negative control small-interfering RNA prior to stimulation with IFNγ.

Results: RNA-seq of purified SJIA monocytes revealed marked transcriptional changes between cells from patients with high vs low serum ferritin levels. Pathway analysis demonstrated enriched upregulated gene ontology pathways including Response to External Stimulus (p<2.73x10^-10), Defense Response (p<2.66x10^-10) and Inflammatory Response (p=1.95x10^-11) when comparing the SJIA monocyte signature to well-characterized polarization phenotypes.

Conclusion: Utilize transcriptional profiling of monocytes and macrophages in SJIA to identify polarization phenotypes including features of interferon response

OP0151

MACROPHAGE ACTIVATION SYNDROME PROTEIN ASSEMBLY AND NETWORK ANALYSIS REVEAL TRIM8 AS A MEDIATOR OF HYPERRESPONSIVENESS TO IFNGamma AND RISK FOR MACROPHAGE ACTIVATION SYNDROME

Grant Schulert1,2, Thi Dao2, Sanjeev Dhakal2, Nidate Faith2, Mario Medvedovitch2, Nathan Salomonis3,4, Alex Geom2,5, University of Cincinnati, Pediatrics, Cincinnati, United States of America; 6Cincinnati Children’s Hospital Medical Center, Rheumatology, Cincinnati, United States of America; 7University of Cincinnati, Environmental Health, Cincinnati, United States of America; 8Cincinnati Children’s Hospital Medical Center, Biomedical Informatics, Cincinnati, United States of America

Background: Systemic juvenile idiopathic arthritis (SJIA) is a severe and distinct subtype of childhood arthritis. Children with SJIA are at risk for macrophage activation syndrome (MAS), a life-threatening episode of hyperinflammation driven by interferon-gamma (IFNγ). Previous studies in SJIA have demonstrated that proinflammatory and proinflammatory cytokines in SJIA display hyperresponsiveness to IFNγ, but the molecular basis of this remains unclear.

Objectives: Utilize transcriptional profiling of monocytes and macrophages in SJIA to identify polarization phenotypes including features of interferon response

Methods: Bulk RNA-sequencing (RNA-seq) was performed on purified monocytes from 26 patients with SJIA without MAS. In addition, single-cell RNA-seq was performed on isolated bone marrow macrophages from control patients and patients with SJIA and MAS. THP-1 monocytic cells and primary human monocyte-derived macrophages (MDM) were transfected with TRIM8-specific or negative control small-interfering RNA prior to stimulation with IFNγ.

Results: RNA-seq of purified SJIA monocytes revealed marked transcriptional changes between cells from patients with high vs low serum ferritin levels. Pathway analysis demonstrated enriched upregulated gene ontology pathways including Response to External Stimulus (p<2.73x10^-10), Defense Response (p<2.66x10^-10) and Inflammatory Response (p=1.95x10^-11) when comparing the SJIA monocyte signature to well-characterized polarization phenotypes.

Conclusion: Utilize transcriptional profiling of monocytes and macrophages in SJIA to identify polarization phenotypes including features of interferon response

Disclosure of Interests: None declared

MIRNAS CONTRIBUTE TO DYSREGULATED ROS METABOLISM IN THE INFILTRATED JOINT

Kim Oth1, Patricia Klemm1, Tobias Schwarz2, Federica Raggi3, Alessandro Consolaro3, Joachim Peltz2, Gerd Hornett2, Klaus Tenbrock1, RWTH Aachen University, Pediatric, Aachen, Germany; 2Rehumalinik Sendenhorst, Sendenhorst, Germany; 3IRCCS Istituto Giannina Gaslini, Genova, Italy; 4University at Buffalo, Pediatrics, Buffalo, Buffalo, United States of America

Background: In the last years miRNAs have emerged as critical regulators of innate and adaptive immune responses and an altered expression of function is associated with several inflammatory and autoimmune diseases. Therefore miRNAs are also believed to promote inflammatory processes within the inflamed joint of juvenile idiopathic arthritis (JIA) patients. It is furthermore known that oxidative stress is associated with JIA. Free radicals are implicated in joint damage and play an important role as secondary messengers in immunological responses. How and if miRNAs contribute to dysregulated reactive oxygen species (ROS) metabolism in JIA remains to be elucidated.

Objectives: We aimed to identify miRNAs and miRNA regulated pathways, which contribute to dysregulated immune cell responses within the inflamed joint.

Methods: miRNA profiling was performed on peripheral blood mononuclear cells (PBMCs) from healthy children, PBMCs from 9 JIA patients and synovial fluid mononuclear cells (SFMCs) from the same JIA patients. Subsequently, GO and pathway enrichment analyses were performed on predicted target genes. Upregulation of miRNAs was confirmed in vitro after incubation with synovial fluid by qRT-PCR. Mitochondrial integrity, cellular ROS and Nrf2 protein expression were measured by flow cytometry.

Results: Transcriptome analysis of JIA SFMCs compared to HC PBMCs revealed strongly enhanced expression of miR23a and miR23a, miR27a, miR44a, and miR115, which are involved in oxidative stress processes. In addition, expression of these could be induced in healthy control PBMCs by synovial fluid ex vivo. ROS level in synovial fluid T cells were enhanced, while expression of Nrf2, the main regulator of anti-oxidative responses and a target of miR27a, remained low. Furthermore mitochondrial cycliphiphin, which regulates ROS escape from mitochondria and is suppressed by miR23a, was downregulated in SFMCs as well.

Conclusion: SFMCs within the inflamed joint reveal a distinct miRNA expression profile. Especially miRNAs that are involved in regulation of ROS metabolism are upregulated. In line with this, expression of Nrf2 and mitochondrial cycliphiphin, which are important regulators of cellular ROS metabolism are reduced while production of ROS is enhanced. We suggest that higher abundance of miRNAs, that are involved in oxidative stress pathways, contribute to redox dysregulations within the inflamed joint and thereby contribute to inflammatory processes.

Oligoarticular Juvenile Idiopathic Arthritis (O-JIA) is a common inflammatory joint disease in children, driven by continuous local T-cell activation. [1] T cell activation is counter-balanced via signals generated by co-inhibitory receptors (co-IRs) such CTLA-4, PD-1, LAG-3, and TIM-3. [2] This work was supported by a research grant from PACE EUA Foundation for Research in Rheumatology.

Disclosure of Interests: Endal Sag: None declared, Selcan Demir: None declared, Morten Aagard Nielsen: None declared, Malene Hvid: None declared, Ege Bayan: None declared, Yelda Bilginer: None declared, Selcan Demir: None declared, Joachim Peltz: None declared, Gerd Hornett: None declared, Klaus Tenbrock: Grant/research support from: Pfizer, Novartis, Speakers bureau: Pfizer, Novartis

REFERENCES
[2] T cell activation is counter-balanced via signals generated by co-inhibitory receptors (co-IRs) such CTLA-4, PD-1, LAG-3, and TIM-3.
physiologic circumstances. Enhancers do not always regulate the nearest gene, and may regulate more than one gene. Enhancers typically regulate genes within the same chromatin loop, or topologically associated domain (TAD).

Objectives: To gain a better understanding of the genetics of JIA by examining the broader chromatin architecture that encompasses the known risk haplotypes.

Methods: We used publicly available chromatin conformation HiC data and the online Juicebox software suite to query known JIA risk haplotypes for evidence of physical interactions between putative enhancers within the haplotypes and immunologically relevant genes. We specifically queried 20 haplotypes in which H3K4me1/H3K27ac marks were prominent within both lymphoid and myeloid cells. We queried data from GM12787 (B cell), K562 (lymphoblast), and THP-1 (monocyte/macrophage) cells, as well as human cord blood T cells. To identify TADs associated with specific enhancers, we used a SKB resolution (which allowed us to visualize chromatin loops as peaks), setting the cursor at the center of each putative enhancer. We also identified the genes within the identified chromatin loop domains and used gene ontology (GO) analyses to identify functional associations among genes within the TADs incorporating the JIA risk loci.

Results: We identified at least one chromatin loop structure in all 20 of the JIA risk haplotypes for each of the 4 cell lines we queried. These loops were not cell type specific. That is, almost identical loops structures could be seen in each of the cell lines at each of the loci, suggesting that these enhancers regulate a broad range of chromatin architecture functions. The TADs incorporating the JIA haplotypes invariably included genes of immunologic interest. For example, the TAD incorporating the IL2RA haplotype including IL15 (the alpha chain of the IL15 receptor) and PKCD, a protein kinase C-family enzyme important in both T and B cell activation, was the most complex locus was C50S6 which encompassed 25 genes (including IL2, IL4, and IL13) and 3 miRNA within 4 loops and sub-loops. Genes within the TADs were highly enriched for multiple GO terms for processes involved in leukocyte activation (e.g., MAP kinase signaling cascade), JAK-STAT responses, chemokines, and cytokine-mediated signaling pathways.

Conclusion: These 20 JIA-associated risk loci are situated within complex chromatin regions that show similar features in both lymphoid and myeloid cells. HiC data demonstrate direct physical contacts between putative enhancers within the risk loci and multiple genes of immunologic interest. We hypothesize that at least some of the genes within the haplotype-associated TADs are the long sought "far get genes" of JIA-associated genetic variants. This work emphasizes the importance of broadening our focus beyond the "nearest gene" to the GWAS-identified tag SNPs.

OP0154

A NOVEL RELA TRUNCATION IN A 3-GENERATION FAMILY WITH BEHÇET’S DISEASE ALTERS THE APOPTOTIC RESPONSE TO INFLAMMATORY STIMULANTS

Emma Dorris1, Fahd Adee2, Dylan Lawless3, Wan Lin Ng4, Aqeel Anjum4, Niamh Morgan1, Eoin Cummings5, Sinisa Savic5, Alexander Fraser1, Gerry Wilson1

1University College Dublin, Centre for Arthritis Research, Dublin 4, Ireland
2University Hospital Kerry, Rheumatology, Tralee, Ireland
3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Disease, Leeds, United Kingdom
4University Hospital Limerick, Rheumatology, Limerick, Ireland
5University College Dublin, School of Medicine, Dublin, Ireland

Background: Behçet’s disease (BD) is a heterogeneous multi-faceted autoimmune condition characterised by recurrent episodes of oral and genital ulceration, uveitis and skin lesions, with less frequent involvement of the gastrointestinal tract, large blood vessels and central nervous system. The NF-κB pathway is a ‘master-regulator’ of immune and inflammatory signaling, with the ability to control the expression of key inflammatory genes and genes associated with apoptosis and proliferation.

Objectives: To identify the pathobiology associated with a novel genetic mutation identified in a 3-generation family with Behçet’s-like mucocutaneous ulceration syndrome, primarily involving childhood-onset chronic oral and genital ulcers.

Methods: The novel RELA mutation was identified using whole exome sequencing. Immunoblot of peripheral blood mononuclear cell (PBMCs) lysates from affected family members was used to determine if the predicted truncated protein was expressed. PBMCs were stimulated with TNF: NFκB phosphorylation was measured relative to unstimulated cells form affected and unaffected family members. HEK293T cells transfected with plasmids encoding either wild-type or the novel RELA-mutant and overexpression confirmed via immunoblot. An in vitro model of the RELA truncation was used to observe the effect of the RELA truncation on response to TNF stimulation. Apoptosis protein arrays, western blots, and ELISA assays were used to investigate the effect of TNF on wild-type RELA compared to the mutant protein. Mouse Embryonic Fibroblasts (MEFs) isolated from RELA mice, which do not express endogenous RELA, were transfected with plasmids encoding either wild-type or the novel RELA-mutant. Wild Type MEF cells (with endogenous RELA) were used as a control. Cells were stimulated with LPS (2.5µg/ml) or no treatment control for 12 hours.

Results: A heterozygous cysteine deletion at position 1459 in RELA was detected in all affected individuals as previously reported. This mutation results in a frame-shift His487ThrfsTer7, producing a truncated protein of 492 amino acids. RELA-His487ThrfsTer7 heterozygotes have different phosphorylation kinetics of key NFκB pathway components. Interestingly, TNF was less sensitive to TNF stimulation compared to wild-type controls. Cells overexpressing RELA-His487ThrfsTer7 had increased pro-apoptotic proteins (BAD, cleaved caspase 3 and SMAC) whereas anti-apoptotic proteins (BCL2, CLASP1) were decreased compared to cells transfected with wildtype RELA. Cells transfected with RELA-His487ThrfsTer7 were much less sensitive to TNF stimulation compared to wild-type controls, as measured by induction of TNF-sensitive proteins.

Conclusion: This study gives novel information on both the genetic basis and biological mechanisms of BD in individual families. Familial mutations that induce haploinsufficiency of RELA have recently been associated with BD. However, the IL4, IL15R, IL4, and PKCQ, a protein kinase C-family enzyme important in both T and B cell activation, are also highlighted. The most complex locus was C50S6 which encompassed 25 genes (including IL2, IL4, and IL13) and 3 miRNA within 4 loops and sub-loops. Genes within the TADs were highly enriched for multiple GO terms for processes involved in leukocyte activation (e.g., MAP kinase signaling cascade), JAK-STAT responses, chemokines, and cytokine-mediated signaling pathways.

Transformative care – the future

OP0155-HPR

TARGETS FOR REDUCING PREMATURE MORTALITY IN OLDER RESULTS WITH OSTEOARTHRITIS: RESULTS FROM A NOVEL PATH ANALYSIS WITHIN A COX PROPORTIONAL HAZARDS MODEL

Ross Wilkie1, Simran Parmar, Milica Bucknall. Keele University, Keele, United Kingdom

Background: There is increasing evidence that it is the impact of osteoarthritis rather than the osteoarthritis itself that explains an excess risk of mortality. This indicates that potentially modifiable targets may reduce mortality for those with osteoarthritis. Mediation analysis can be used to investigate pathways, although this has rarely been undertaken using survival analysis due to the challenge of accounting for time. The study uses a novel approach to examine mediation using path analysis with Cox proportional hazard modelling (survival analysis).

Objectives: The objectives of this study were to identify potential mechanisms of the impact of osteoarthritis on mortality and examine the role of modifiable targets (anxiety, depression, insomnia and walking frequency) for health professionals in rheumatology (HPRs).

Methods: A population-based prospective cohort study was conducted using data from the North Staffordshire Osteoarthritis Project (NoSOP), in which primary care medical record data was linked to self-report information collected by questionnaire in adults aged 50 years and over (n=8066). Individuals were defined as having osteoarthritis if they had consulted general practice for osteoarthritis, identified by Read codes in the primary care medical record, and indicated moderate to severe pain interference in daily life in the Medical Outcomes Short Form 36 at baseline (2002). A Cox proportional hazards analysis was performed to determine the total effect (TE) of osteoarthritis on mortality, both with adjustment for confounding variables (age, sex, education, occupation, smoking status, ischaemic heart disease, chronic obstructive pulmonary disease, non-steroidal anti-inflammatory drugs, obesity, cognitive impairment). Within the Cox model, path analysis was used to decompose the TE to assess the indirect (IE) and direct effects (DE) for each of four potential mediators (anxiety, depression, insomnia, walking frequency; all measured by questionnaire) with adjustment for confounders. Results are expressed as adjusted hazard ratios (aHr): bootstrap resampling was used to generate 95% confidence intervals (95% CIs).

Results: Mean age of participants was 65.2 (SD 9.6) years and 51.6% were female. 5266 (29.7%) had osteoarthritis. Participants were followed up over 10 years during which time 1188 (14.7%) died. The rate of mortality was greater in those with osteoarthritis (52 deaths per 1000 person years) compared to those without (38 deaths per 1000 person years). Osteoarthritis was significantly associated with mortality (aHR 1.14; 1.00, 1.28). The relationship between osteoarthritis and mortality was mediated by walking frequency, depression and insomnia (anxiety did not mediate the relationship (IE HR 1.00, 0.98, 1.02)). The strongest mediator was walking frequency (TE 1.14; 1.00, 1.29; DE 1.04; 0.91, 1.16: IE 1.08; 0.98, 1.11), followed by depression (IE 1.06; 1.03, 1.08) and insomnia (IE 1.01; 1.00, 1.03).
Conclusion: This is the first study to examine mediation and highlights the importance of potentially modifiable targets for HPRs to reduce mortality in older adults with osteoarthritis. Encouraging people to maintain levels of physical activity at a population level and targeting a reduction in physical limitation in clinical practice to allow this, is important.

References:
are monitored for serum uric acid less than twice per year. But 79% of patients claim to be satisfied with their current treatment and do not expect better management of their disease.

Conclusion: The results of the survey demonstrate that gout patients in Europe, as providing more information and guidance about what support they can access and receiving psychological support from their healthcare team were (i) lack of optimism about their future with RA or AJA (ii) not knowing what support they can access (iii) finding it difficult to talk about their emotions and asking for help (iv) believing healthcare professionals lack the time and ability to help them (v) believing that discussing emotions and providing psychological support is not on their healthcare team’s agenda, evidenced by a focus on physical rather than psychological health in consultations and (vi) never or rarely being asked about their emotional health in consultations and during the resistance training program. The primary outcome measure was isokinetic (60 °/s) upper leg muscle strength (Nm/kg). In addition, the estimated 1 RM for leg press, leg curl and hip abduction were used as measures for muscle strength. Other outcome measures included severity of knee pain (NRS), self-reported and performance-based activity limitations (WOMAC physical functioning (WOMAC), Get-up-and-go-test (GUG)). Measurements were performed by a blinded assessor prior to the exercise program (T0), directly after the program (T1) and at 6 months follow-up (T36). Additionally, for patients with vitamin D deficiency, measurements were also taken prior to vitamin supplementation or placebo (T-12).

Results: Both the high-intensity group and moderate-intensity group improved in upper leg muscle strength over time. No significant differences between groups were found for isokinetic upper leg muscle strength (p = 0.646) (see figure 1). However, when measured by the estimated 1 RM, significant differences were found between groups in favor of the high-intensity group (p = 0.001) (see figure 1). No between-group differences were found on pain (p = 0.885), or on self-reported and performance-based activity limitations (WOMAC p = 0.868; GUG p = 0.896), although both groups improved (see figure 1). An unexpected finding was that, in the (small sample of) patients with vitamin D deficiency, the placebo group showed significant greater isokinetic upper leg muscle strength over time compared to the vitamin D group (p = 0.001).

Conclusion: No differences between groups were found for isokinetic upper leg muscle strength. With the estimated 1 RM as a measure of muscle strength, high-
intensity resistance training led to greater improvements in muscle strength compared to moderate-intensity resistance training in patients with knee OA. This did not result in greater improvements in pain and physical functioning in the high-intensity resistance group; both groups showed similar clinically important improvements. The added value of vitamin D supplementation on muscle strength in knee OA patients with vitamin D deficiency need further study.

OP016-HPR DOES OCCUPATIONAL THERAPY DELAY OR SHORTEN THE TIME TO CARPOMETACARPAL SURGERY? RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

LONG-TERM EFFECTIVENESS OF CANAKINUMAB IN PATIENTS WITH CRYOPYRIN-ASSOCIATED PERIODIC SYNDROME

J. B. Kuemmerle-Desnuelle1, Norbert Blank2, Michael Borte3, Ivan Foeldvari4, Gesa Homes5, Prasad Oommen6, Catharina Schravan7, Frank Weller-Heinemann8, Julia Weber-Arend3, Tilman Kallinich9, University Hospital, Tübingen, Germany; 2University Hospital, Heidelberg, Germany; 3Hospital St. Georg, Leipzig, Germany; 4Centar Ped Rheumatology, Hamburg, Germany; 5Asklepios Clinic, Sankt Augustin, Germany; 6University Hospital, Düsseldorf, Germany; 7University Hospital, Dresden, Germany; 8Prof. Hess Klinik, Bremen, Germany; 9Novartis, Nuernberg, Germany; 10Charité, Berlin, Germany

Background: Treatment options for autoinflammatory diseases include anti-interleukin (IL)-1 therapies since the IL-1 pathway is crucial in immune dysregulation in patients with monogenic periodic fever syndromes.

Objectives: To gain further insights from routine clinical practice with respect to long-term effectiveness and safety of canakinumab (CAN) in pediatric and adult patients with CAPS (cryopyrin-associated periodic syndrome, including Muckle-Wells syndrome [MWS]), familial cold autoinflammatory syndrome [FCAS], neonatal onset multisystem inflammatory disease [NOMID]/chronic infantile neurologic-cutaneous and arthritic syndrome [CINCA]), FMF (familial Mediterranean fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up enrolling patients aged ≥2 years with clinically confirmed diagnoses who routinely received CAN. 6-monthly clinical assessment and evaluation of patient-reported outcomes is aligned with routine clinic visits. CAPS disease activity was determined by physicians’ and patients’ assessment. Endpoints were effectiveness and safety of CAN under standard clinical practice conditions.
Results: The interim analysis includes 52 CAPS patients with prior long-term CAN treatment (43.1% females) enrolled by September 2018. 44.2% of the patients participated in the RELIANCE study. The mean age was 20.7 years (4.0–79.0 years) at baseline and the mean duration of prior CAN treatment was 5.4 years (0.0–11.0 years). 40 patients (76.9%) were diagnosed with MWS, the other patients had FCAS (2), NOMID/CINCA (7) or atypical CAPS (1) (subtype diagnosis of 2 patients not available). Mutations in Nod-like receptor family pyrin domain-containing-3 were identified in 34 patients (68.0%) including E311K (7), Q703K (5), V198M (5), T348M (5), A439V (4). A baseline screening revealed sensorineural hearing loss (62.0%), papillitis (84.0%) and neurological symptoms (71.4%) in patients which had not been detected previously. The majority of patients had no disease related symptoms at baseline and 6 months demonstrating sustained remission in patients receiving long-term CAN treatment. The following disease related symptoms (mild/moderate and severe) were observed in the analysis cohort (N=31) at baseline and 6 months, respectively – disease symptom: baseline (mild/moderate, severe) vs. 6 months (mild/moderate, severe) – urticarial skin rash: 19.4%, 6.5% vs. 25.8%, 0.0%, arthritis: 32.3%, 0.0% vs. 29.0%, 7.9%, myalgia: 9.7%, 0.0% vs. 16.1%, 0.0%, headaches: 22.6%, 9.7% vs. 19.4%, 19.4%, conjunctivitis: 32.3%, 3.2% vs. 12.9%, 6.5%, abdominal pain: 9.7%, 6.5% vs. 22.6%, 9.7%. Patients’ assessment of disease activity and fatigue did not change between baseline and 6 months. However, at baseline 45.5% and after 6 months 76.0% of patients had no impairment of social life by the disease. Serious adverse events were reported for 2 patients (tonsillitis, delivery at week 31).

Conclusion: The RELIANCE study longitudinally monitors the stability of efficacy and safety of CAN in patients with monogenic periodic fever syndromes. An initial interim analysis including the CAPS subgroup which had prior CAN treatment showed that CAN is an effective and safe treatment in those patients.

RECOMMENDATIONS:

- The efficacy of LEF in combination with GCs therapy was significantly superior to conventional GCs monotherapy in preventing relapses in patients with IgG4-RD.

- Combination therapy of GCs and LEF may be considered as first-line therapy for the induction of remission in IgG4-related disease (IgG4-RD).

- The efficacy of LEF in combination with GCs therapy was significantly superior to conventional GCs monotherapy in preventing relapses in patients with IgG4-RD.

- Combination therapy of GCs and LEF may be considered as first-line therapy for the induction of remission in IgG4-related disease (IgG4-RD).

- The efficacy of LEF in combination with GCs therapy was significantly superior to conventional GCs monotherapy in preventing relapses in patients with IgG4-RD.

- Combination therapy of GCs and LEF may be considered as first-line therapy for the induction of remission in IgG4-related disease (IgG4-RD).

- The efficacy of LEF in combination with GCs therapy was significantly superior to conventional GCs monotherapy in preventing relapses in patients with IgG4-RD.

EULAR RECOMMENDATIONS FOR THE DIAGNOSIS AND THE MANAGEMENT OF RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS DUE TO CANCER IMMUNOTHERAPY

1University of Bordeaux, Bordeaux, France, 2University Hospital of Geneva, Geneva, Switzerland, 3Johannes Hopkins University, Baltimore, United States of America, 4Haga Hospital, the Hague, Netherlands, 5University Medical Centre Mannheim, Mannheim, Germany, 6University of Munich, Munich, Germany, 7Cardiff University School of Medicine, Cardiff, United Kingdom, 8University Hospital Heidelberg, Heidelberg, Germany, 9University Medical Center Utrecht, Utrecht, Netherlands, 10King’s College London, London, United Kingdom, 11Le Kremlin-Bicêtre, Paris, France, 12University Hospital of Strasbourg, Strasbourg, France, 13Pitié-Salpêtrière University Hospital, Paris, France, 14EULAR PARE Patient Research Partner, Netherlands, Netherlands, 15Aarhus University Hospital, Aarhus, Denmark, 16University of British Columbia, Vancouver, Canada, 17Gustave Roussy, Paris, France, 18Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom, 19Netherlands Cancer Institute, Amsterdam, Netherlands, 20Cleveland Clinic, Cleveland, United States of America

Disclosure of Interests: Rheumatic immune-related adverse events (rIAEs) are increasingly recognized musculoskeletal manifestations in cancer patients receiving immune checkpoint targeted immunotherapy (1). Since they represent a spectrum of new clinical entities and a robust evidence base is lacking, a task force was convened to reach a joint expert consensus regarding their identification and management due to the lack of dedicated clinical trials.

Objectives: To develop EULAR recommendations for the diagnosis and the management of rheumatic rIAEs due to cancer immunotherapy, based on literature and expert opinion.

Methods: Recommendations were developed according to the 2014 EULAR Standard Operating Procedures. The task force consisted of 19 clinical experts from Europe and North America (14 rheumatologists, 2 internists and 3 oncologists) in 1 clinical epidemiologist, 1 allied health professional and 2 patient representatives. During the first meeting, the group defined the focus of the task force, the target population, and formulated research questions. A systematic literature research was performed by one fellow (MK) with the help of a librarian. Based on available evidence and using a consensus procedure, recommendations were developed during a second meeting. The level of agreement was determined by an anonymous voting process.

Results: 4 overarching principles and 10 recommendations were developed. The overarching principles define the role of rheumatologists and highlight the shared decision-making process between patients, oncologists and rheumatologists. One recommendation addresses the referral process, two address the diagnosis, and five address the therapeutic strategy of cancer patients experiencing rheumatic, musculoskeletal, and systemic signs or symptoms while receiving immunotherapy. An additional recommendation was included to address pre-existing rheumatic conditions and the last focuses on the diagnostic approach before immunotherapy.

Conclusion: These recommendations provide the basis of a EULAR consensus on the diagnosis and the management of rheumatic rIAEs.

Background: Adult-onset Still’s disease (AOSD) is a systemic inflammatory disease generally responsive to non-steroidal anti-inflammatory drugs (NSAIDs) therapy. Cases of non-responsive CS monotherapy are frequently found in clinical practice. In such cases, metrotexate and/or biologics including TNF-α, IL-1, or IL-6 inhibitors are used [1]. However, further treatment options are required for refractory AOSD patients who are intolerant to meloxicam and/or biologics. Calcineurin inhibitors (CNI) downregulate T cell activation through inhibiting IL-2 transduction and signal transduction. Therefore, they are reasonable therapeutic medication for AOSD considering T cells and subsequently activated macrophages play a pathophysiological role in AOSD [2]. Nevertheless, only a few case series have indicated effects of CNI for difficult AOSD.

Objectives: To evaluate the efficacy of CNI in patients with AOSD.

Methods: This is a multi-centre historical cohort study comprised the consecutive cases of AOSD in accordance with the classification criteria. The primary endpoint was set as the time from the initiation of treatment to event defined as death of any causes or relapse of AOSD requiring an increase of CS dose. Secondary endpoints were set as persistency rate of CNI and safety. Based on the recurrent event data analysis, these endpoints were evaluated for each event. We compared the frequency of events between groups according to the treatment that included calcineurin inhibitors (CNI+) or conventional therapy without calcineurin inhibitors (CNI-).

Results: One hundred seventy-eight patients were enrolled in this study. Mean age was 46.0 years old, and median follow-up period 36 months. Seventy-one events in 56 patients were treated with therapeutic regimen including CNI (CNI+), cyclosporine: 14, tacrolimus: 60, and 176 events in 138 patients were treated with the conventional therapy excluding CNI (CNI-). CNI were used in AOSD patients with recurrent history, high ferritin level, serositis, hemophagocytic syndrome (HPS) and/or disseminated intravascular coagulation (DIC). The CNI+ group had longer event-free survival than the CNI- group (83% versus 75% at 5th

Results: B cells from IgG4-RD patients (i) produced the pro-fibrotic molecule PDGF-B and stimulated collagen production by fibroblasts; (ii) expressed enzymes implicated in extracellular matrix remodeling such as LOXL2; (iii) produced the chemokatic factors CCL-4, CCL-5, and CCL-11; and (iv) induced the production of these same chemokines by activated fibroblasts. Plasmablasts expressed sets of genes implicated in fibroblast activation and proliferation, and therefore represent cells with intrinsic pro-fibrotic properties.

Conclusions: We have demonstrated that B cells, contribute directly to tissue fibrosis in IgG4-RD. These unanticipated pro-fibrotic properties of B lymphocytes, particularly of plasmablasts, might be relevant for fibrogenesis in other fibro-inflammatory disorders and for wound healing processes in physiological conditions.

Background: IgG4-related disease (IgG4-RD) is a fibro-inflammatory condition marked by rapid clinical improvement after selective depletion of B lymphocytes with rituximab. This feature suggests that B cells might participate in fibrogenesis and wound healing (1-3).

Objectives: In the present work we aimed to demonstrate that B lymphocytes contribute directly to tissue fibrosis in IgG4-RD.

Methods: Total circulating CD19+ B-lymphocytes, naïve B cells, memory B cells, or plasmablasts from IgG4-RD patients were cultivated with human fibroblasts. Pro-fibrotic soluble factors and collagen production in the co-cultures were assessed by ELISA and Lumines assays. RNA-sequencing and quantitative RT-PCR were used to assess fibroblast activation in the presence of B cells, as well as the induction of pro-fibrotic pathways in B cell subsets. Relevant pro-fibrotic and inflammatory molecules were confirmed in vitro by functional experiments and on IgG4-RD tissue sections by multi-color immunofluorescence studies.

Results: B cells from IgG4-RD patients (i) produced the pro-fibrotic molecule PDGF-B and stimulated collagen production by fibroblasts; (ii) expressed enzymes implicated in extracellular matrix remodeling such as LOXL2; (iii) produced the chemokatic factors CCL-4, CCL-5, and CCL-11; and (iv) induced the production of these same chemokines by activated fibroblasts. Plasmablasts expressed sets of genes implicated in fibroblast activation and proliferation, and therefore represent cells with intrinsic pro-fibrotic properties.

Conclusions: We have demonstrated that B cells, contribute directly to tissue fibrosis in IgG4-RD. These unanticipated pro-fibrotic properties of B lymphocytes, particularly of plasmablasts, might be relevant for fibrogenesis in other fibro-inflammatory disorders and for wound healing processes in physiological conditions.

Objective: Our aims were to: a) assess long-term post-transplant survival in patients with CTD-ILD and b) compare post-transplant survival of patients with CTD-ILD with patients with idiopathic pulmonary fibrosis (IPF).

Methods: Single center study in a referral center for lung transplant of all patients who underwent lung transplantation for CTD-ILD between 1998 and 2017. This cohort was compared with patients with IPF (group-matched for age, transplant year and basiliximab induction). Cumulative survival rates after transplantation were estimated by the Kaplan-Meier method and compared between groups using the log-rank test.

Results: We studied 26 patients with CTD-ILD matched to 26 patients with IPF. The underlying diseases of patients with CTD-ILD were: Rheumatoid arthritis (6), Scleroderma (6), Sjögren syndrome (4), ANCA-vasculitis (3), Anti synthetase syndrome (2), Dermatomyositis (1), Systemic lupus erythematosus (1). The comparative study of baseline characteristics between both groups is shown in the Table. All of RA patients undergoing transplantation in our study had the histologic subtype of usual interstitial pneumonia (UIP) whereas non-specific interstitial pneumonia (NSIP) was the most common histologic subtype of ILD associated with the rest of CTD. Cumulative survival rates at 5 year post-transplant did not differ significantly between CTD-ILD and IPF [42.4% vs 65.8% (p=0.075)] (FIGURE 1).

Conclusion: Our retrospective analysis showed a trend to lower long-term post-transplant survival than in those with IPF, however no statistical differences were found in cumulative survival rates at 5-years post-transplant. These data support that lung transplantation should be considered in patients with end-stage CTD-ILD.

Background: Interstitial lung disease (ILD) is one of the most serious complications associated with connective tissue diseases (CTD). Patients with ILD have increased mortality and limited treatment options. Lung transplant has been recognized as an option for patients with end-stage CTD-ILD. However, rheumatic diseases are still sometimes considered a contraindication for lung transplant because of concerns for worse outcomes.

[FIGURE 1. Boxplot of SAS and patients' global assessment of disease activity]
Objective: To explore the performance of these provisional criteria in a cohort of Spanish patients with IgG4-RD.

Methods: Data were obtained from the Spanish IgG4-RD registry (REEIRIGG4) from October 2013 to December 2018, including 9 centers. Patients needed to fulfill almost 1 of the available diagnostic criteria sets (pathology consensus and/or comprehensive). Provisional ACR/EULAR classification criteria (PAECC) were applied based on the public information disclosed at the abovementioned meeting.

Results: One hundred patients were included. Thirty-four (34%) were females, median age at diagnosis was 54.8 years (IQR 20.7). The ethnicity of the participants was: Caucasian 83%, Hispanic 12% and North-African/Middle-East 5%. Ninety-two percent were diagnosed with a biopsy. Regarding the diagnostic criteria, 85% met consensus pathology criteria and 94% comprehensive criteria.

Seventy-one individuals (71%) met the PAECC including entry criteria, exclusion criteria, and one full diagnostic criteria set (pathology consensus or comprehensive). Seventy-one percent of the Spanish patients participating in the PAECC (55%) had an inclusion criteria score under 19 points (median 12): 3 patients (4%) did not have a biopsy, 8 (11%) biopsies had partial reports, and 10 subjects (14.3%) had normal serum IgG4 levels. Six (8.5%) of 38 patients who did not meet the PAECC had involvement limited to the head and neck and 3 (19%) had retroperitoneal or aortic involvement.

Conclusion: Seventy-one percent of the Spanish patients participating in the REEIRigG4 met the 2018 PAECC, while all of them met almost one of the available diagnostic criteria sets (pathology consensus and/or comprehensive). Seventy-one percent of the Spanish patients participating in the PAECC had an inclusion criteria score under 19 points (median 12): 3 patients did not have a biopsy, 8 biopsies had partial reports, and 10 subjects had normal serum IgG4 levels. Six of 38 patients who did not meet the PAECC had involvement limited to the head and neck and 3 had retroperitoneal or aortic involvement.

From child to adult care – breaking down the barriers of transition

Disclosure of Interests: None declared

The Erosive hand osteoarthritis (OA) phenotype is associated with more inflammation, localized in the hand and it also seems to be associated with psoriasis. This differentiates from radiographic hand OA. The study was conducted in the Prospective Cohort of Osteoarthritis A Coruña (PROCOAC). This cohort consists of 1107 subjects, of which 747 suffered from radiographic hand OA. We split the cohort into patients with and without erosive hand OA, and analyzed both clinical and demographic data within each group, together with the assessment of the Australian Consortium on Ankylosing Spondylitis Hand (AUSCAN) index. The study consisted in a univariate analysis comparing different variables between both groups, followed by a stepwise logistic regression analysis taking into account the significant confounder variables analyzed in the Univariate approach.

Results:
The mean age of the cohort was 63.23±8.85 years and consisted of 627 females and 120 males. Of the 747 OA patients, 179 had erosive hand OA and 568 did not. The univariate analysis revealed that patients with erosive hand OA were younger (60.25±10 vs 64.16±8.86; p<0.001), smokers (p=0.005), with lower body mass index (p<0.005), increased inflammatory episodes (p<0.001) and, interestingly, showed MetS as a risk factor too (OR=1.25-3.58; p=0.002). Regarding the number of damaged joints, a lower frequency of both knee and hip OA was detected in patients with erosive hand OA compared with non-erosive patients (24.4% vs 54.7% for knee OA prevalence and 11.6% vs 16.7% for hip OA prevalence); however, only knee OA occurred at a significant lower frequency (OR=0.267; 95% CI=0.182-0.393; p<0.001). In addition, the three subscales of the AUSCAN score showed significantly higher mean values in patients with the erosive phenotype: pain (57.67±29.30 vs 43.86±31.45; p<0.001), function (55.61±27.68 vs 40.53±29.48; p<0.001) and stiffness (55.40±32.26 vs 60±36.23; p=0.001).

Conclusion:
The erosive hand OA phenotype is associated with more inflammation in younger patients, and worst AUSCAN score. Contrarily to the non-erosive phenotype, the presence of erosions associates with a lower occurrence of other forms of OA, specially knee OA. In our cohort, erosive hand OA seems to be more localized in the hand and it also seems to be associated with psoriasis. This different profile could serve the clinicians to provide personalized prevention strategies, and the researchers to investigate the pathogenesis of this specific phenotype.

PARTIAL KNEE REPLACEMENT IS ASSOCIATED WITH A LOWER RISK OF VENOUS THROMBOEMBOLISM AND OPIOID USE THAN TOTAL KNEE REPLACEMENT BUT INCREASED RISK OF LONG-TERM REVISION: A MULTINATIONAL, MULTIDATABASE, PROPENSITY SCORE-MATCHED, COHORT ANALYSIS INCLUDING OVER 260,000 PATIENTS

Daniel Pieiro-Alhambra 1, Edward Burn 1, James Weaver 2, Anthony G Gens 3, Henry Morgan Stewart 1, Patrick Ryan 2. 1Centre for Statistics in Medicine, OXFORD, UK; 2Janssen Research and Development, TITUSVILLE, NJ; 3University of Oxford, OXFORD, UK

Background: Knee replacement is one of the few effective treatments for severe knee osteoarthritis. A number of surgical interventions are available, including two main types: partial or total knee replacement.

Objectives: We aimed to assess the outcomes of partial compared to total knee replacement.

Methods: We conducted a multi-database propensity score-matched cohort study. Data was obtained from 4 US claims databases (IBM MarketScan Commercial Database, IBM MarketScan Medicare Supplemental Database, MDVR, Optum), de-identified Clininformatics Datamart, Extended - Date of Death (Optum), and Pharmetrics), and 1 UK primary care electronic medical record database (THIN).

All people aged 40 years or older at the time of knee replacement surgery were included. Data were mapped to a common data model (OMOP), and processed using analytical tools developed by the OHDSI community.

Participants were followed up from the date of their first knee replacement and for up to 5 years. Outcomes included short-term (60-day) post-operative complications (infection, venous thromboembolism, mortality, readmission), opioid use in the 3-12 months post-surgery as a proxy for persistent pain, and 5-year revision risk.

Results: Out of 71 evaluated patients with symptomatic erosive HOA, and 64 matched the inclusion criteria and were randomized. Among them, 32 patients were randomized in the placebo group and 32 in the Methotrexate group. There was no significant difference between the two groups on the primary endpoint at 3 months, with an average decrease in VAS in the placebo group of 8.36 mm (95% CI: 25.15, and 17.47 mm (95% CI: 28.37) in the treatment group (p = 0.1797). At 12 months, no difference was found in the evolution of pain between the two groups (p = 0.6045) as well as in the functional evolution. In subjects taking Methotrexate, joints move more to a remodeling phase undergoing treatment (27%) than placebo subjects (15%) (p = 0.0278). They also seem to evolve less towards erosion when their joints present a space loss (29% become erosive under placebo, against 8% in the Methotrexate group) (p = 0.0879).

Conclusion: Our study does not show superior efficacy of MTX over placebo over pain and function in subjects with erosive HOA. Our results suggest a possible structural effect on the radiological evolution of HOA under Methotrexate.

Disclosure of Interests: None declared

HEALTH-RELATED QUALITY OF LIFE IN HAND OSTEOARTHRITIS PATIENTS FROM THE GENERAL POPULATION AND THE OUTPATIENT CLINIC

Marieke Lodé 1, Wendy Damman 1, Renée de Mulder 1, Frits Rosendaal 2, Margaret Klompenburg 1, 3, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), Epidemiology, Leiden, Netherlands

Background: In osteoarthritis (OA) patients health-related quality of life (HRQoL) is decreased. Whether patients with OA seeking care in a rheumatology outpatient clinic experience more impact on HRQoL than those in the general population is unknown.

Objectives: To investigate the impact of hand OA on physical and mental HRQoL in the general population, and to investigate the difference in impact between patients who have, and who have not been referred to a medical specialist.

Methods: In the population-based Netherlands Epidemiology of Obesity (NEO) study, middle-aged participants were recruited from the greater area of Leiden. In the Hand OSTeoArthritis in Secondary care (HOSTAS) study, patients with a rheumatologist's diagnosis of primary hand OA were recruited from the outpatient clinic at the Leiden University Medical Center, a secondary and tertiary referral center. In both cohorts, hand and knee OA was defined by the ACR clinical classification criteria. Patients with fibromyalgia or inflammatory rheumatic conditions were excluded. For the current analyses, only patients classified with hand OA alone were included. HRQoL was measured with the SF-36 questionnaire; we calculated standardized scores on a scale of 0 to 100 with subsequent application of a norm-based transformation (mean 50, standard deviation 10). Linear regression analyses, corrected for age, sex, education, ethnicity and BMI, were used to study cross-sectional associations between OA and HRQoL. Data are presented as regression coefficients with 95% confidence intervals (CI). Because a suitable reference group without OA was lacking in the HOSTAS study, these patients were compared to the normative value of 50. Previous research concluded a minimal clinically important difference of 2 points on the SF-36 scale, which was used to assess clinical relevance of differences in scores.

Results: Of the 6,334 NEO participants 8% were classified with only hand OA and 4% were classified concurrent hand and knee OA. The HOSTAS cohort consisted of a total of 538 participants with hand OA, of whom 57% fulfilled the ACR criteria for only hand OA and 32% was defined with concurrent hand and knee OA. In the population-based NEO study, mean PCS was reduced with -2.4 (-3.6;-1.3) in participants with only hand OA, compared to participants without hand or knee OA (table 1). The subscales bodily pain and physical functioning were affected with the most with mean differences of -3.4 (-4.8;-2.2) and -2.1 (-3.0;-1.1). Mental HRQoL was not reduced in participants with only hand OA, compared to participants without OA. In the population-based cohort 14% of participants with hand OA reported to have visited a medical specialist for OA. Participants with hand OA that have been referred to a medical specialist showed a lower physical HRQoL with a

METHOTREXATE IN PATIENTS WITH HAND OSTEOARTHRITIS: A RANDOMISED, DOUBLE-BLIND, PLACEBO CONTROLLED TRIAL

Stéphanie Ferrero 1, Ruth Witteck 2, Edem Allado 2, Eric Fontas 2, Coralee Cruzel 2, Liana Euller-Ziegler 1, Damien Loeuille 3, Christian Roux 1. 1University of Nice côte d’azur/CHU Nice, Department of rheumatology, Nice, France; 2Ghent University, Ghent, Belgium; 3University of Oxford, Oxford, United Kingdom

Background: To date, no studies have been published on the effect of Methotrexate (MTX) in hand osteoarthritids (HOA).

Objectives: The aim of our study is to examine the effect of methotrexate on pain in symptomatic erosive HOA, as well as its functional and structural effect using MRI and radiography.

Methods: This prospective, single-center, randomized, double-blind, placebo-controlled study followed patients with HOA over 12 months. Patients were randomized to Methotrexate 10 mg per week or placebo.

The primary endpoint was pain assessment at 3 months, and secondary end-points were clinical (Visual Analogue Scale “VAS” pain at 12 months), and radiographic (radiographic anatomical score, then the Ghent University Score System “GUSS” and MRI).

All subjects aged between 45 and 85 years, who had apparent NSAIDs and pain treatment failure with a VAS greater than 4/10, and at least one erosive joint were included.

Results: Out of 71 evaluated patients with symptomatic erosive HOA, and 64 matched the inclusion criteria and were randomized. Among them, 32 patients were randomized in the placebo group and 32 in the Methotrexate group. There was no significant difference between the two groups on the primary endpoint at 3 months, with an average decrease in VAS in the placebo group of 8.36 mm (95% CI: 25.15, and 17.47 mm (95% CI: 28.37) in the treatment group (p = 0.1797). At 12 months, no difference was found in the evolution of pain between the two groups (p = 0.6045) as well as in the functional evolution. In subjects taking Methotrexate, joints move more to a remodeling phase undergoing treatment (27%) than placebo subjects (15%) (p = 0.0278). They also seem to evolve less towards erosion when their joints present a space loss (29% become erosive under placebo, against 8% in the Methotrexate group) (p = 0.0879).

Conclusion: Our study does not show superior efficacy of MTX over placebo over pain and function in subjects with erosive HOA. Our results suggest a possible structural effect on the radiological evolution of HOA under Methotrexate.

Disclosure of Interests: None declared

mean difference in the PCS of −3.9 (-6.7; -1.2), but no difference in mental HRQoL, compared with participants with hand OA that have not reported consulting secondary care for OA (table 2). In patients with only hand OA from the outpatient clinic, the PCS (-3.5), bodily pain (-4.9), vitality (2.8) and role functioning – physical (2.2) scales were clinically relevantly reduced, but mental HRQoL was not affected.

Conclusion: Participants with hand OA from the general population had a clinically relevant lower physical HRQoL, but not mental HRQoL. Physical HRQoL was further reduced in patients consulting secondary care and in co-occurrence with knee OA. Hence, patients with hand OA in secondary care experience more impact on physical HRQoL than patients in the general population.

1. University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia
2. Monash University Medical School, Department of Epidemiology and Preventive Medicine, Melbourne, Australia

Background: Metabolic syndrome (MetS) has been suggested a crucial role in the pathophysiology of osteoarthritis (OA); however, currently none of studies have examined the associations between MetS and structural changes on MRI.

Objectives: To describe the associations between MetS and its components and structural changes on MRI including knee cartilage volume (CV) loss and bone marrow lesion (BML) change over 10.7 years.

Methods: Longitudinal data on 435 participants (mean age 61 years, 50% of females) from a population-based cohort study were analysed. Blood pressure, glucose, triglycerides, and high-density lipoprotein (HDL) were collected. MetS was defined based on the National Cholesterol Education Program-Adult Treatment Panel III criteria. MRI of the right knee was performed to measure CV and BML. Radiographic knee osteoarthritis (ROA) was assessed by X-ray.

Results: 32% of participants had MetS and 60% had ROA. In multivariable analysis, the following were independently associated with medial tibial CV loss [MetS: β=-0.30%; central obesity: β=-0.26%; low HDL: β=-0.26% per annum]. MetS, hypertriglyceridemia and low HDL were also associated with higher risk of BML size increase in the medial compartment [MetS: relative risk (RR) 1.72, 95%CI 1.22-2.43; Hypertriglyceridemia: RR 1.43, 95%CI 1.01-2.02; low HDL: RR 1.87, 95%CI 1.1-3.1]. After further adjustment for central obesity, MetS and low HDL remained significant with both medial tibial CV loss and BML size increase. The number of components of MetS correlated with greater CV loss and BML size increase (both P for trend <0.05). There were no statistically significant associations in the lateral compartment.

Conclusion: MetS and low HDL are associated with medialized compartment CV loss and BML worsening, suggesting that targeting MetS has the potential to prevent or slow structural change in knee osteoarthritis.

### CARDIOVASCULAR COMORBIDITIES HAVE A DELETERIOUS IMPACT ON KNEE OSTEOARTHRITIS PROGNOSIS AT 5 YEARS: DATA FROM THE PROSPECTIVE KOHALA COHORT

Camille Roubille1, Joel Coste1, Jeremie Sellam2, Anne-Christine Rat2, Francis Guillemin3, Christian Hugy4, Lapérouse Montpellier University Hospital, Laboratoire PHYMEDEXP, INSERM U1046, CNRS UMR 9214, University of Montpellier, Department of internal medicine, Montpellier, France, 2Cochin Hospital, AP-HP, University of Paris Descartes, Biostatistics and Epidemiology Unit, Paris, France, 3Saint-Antoine Hospital, AP-HP, Rheumatology department, Inserm UMR_S_598, Paris, France, 4University of Lorraine, Nancy Hospital, APEMAC, Rheumatology Department, Nancy, France, 5University of Lorraine, APEMAC, Nancy, France, Nancy, France, 6University of Cote d’Azur, Nice Hospital, Rheumatology Department, Laboratoire LAMHESS, EA6312. BEV CNRS IMR 7277 INSERM U1081 UINS., Nice, France

Background: The long-term effect of comorbidities on progression of structural changes in osteoarthritis (OA) remains poorly understood. Patients with knee OA have been reported to be at increased risk of several comorbidities including cardiovascular diseases (CVD). Nevertheless, the impact of all comorbidities on structural progression and on arthroplasty, not only in knee but also in hip OA, should be further defined.

Objectives: The objective of our study was to explore the relationship between comorbidities and the progression of structural changes in symptomatic knee and/or hip OA patients over 5 years.

Methods: The KOHALA (Knee and Hip OsteoArthritis Long-term Assessment) cohort is a French prospective multicenter observational cohort that included 878 subjects, aged 40 to 75 years, with symptomatic hip and/or knee OA at baseline (Kellgren and Lawrence (KL) ≥ 2). The structural progression was defined by the increase of one point of KL (KL+1) or incidence of total knee or hip replacement at 5 years. Various comorbidities were analyzed: cardiovascular diseases excluding hypertension (coronary artery disease, heart failure, stroke, lower limb arteriopathy), hypertension, diabetes, smoking, dyslipidemia, metabolic syndrome, osteoporosis, neurological (e.g. Parkinson’s disease, dementia), digestive (e.g. gastrointestinal reflux disease, ulcer), pulmonary (e.g. asthma, COPD), and psychiatric (depression, anxiety) diseases. Multivariate analysis was performed separately in hip and knee OA adjusted on age, sex and body mass index (BMI). Subjects with a BMI> 30 kg/m² were excluded from the analysis given the close relationship between obesity and the different comorbidities analyzed. Subjects with KL = 4 at the time of inclusion were also excluded from the analysis.

Results: Data from 631 non-obese subjects (BMI<30 kg/m²) were analyzed. At 5 years, cardiovascular diseases were significantly associated with the 5-year KL change in knee OA (OR = 2.6 [1.3-5.7], p<0.02) and with knee arthroplasty (OR = 3.4 [1.1-11.2], p<0.04). Such associations were not found at the hip. Other comorbidities had no significant impact on knee OA structural progression. No significant relationship was found between any type of comorbidities and hip OA structural progression.

Conclusion: This 5-year data analysis of the KOHALA cohort revealed a significant association between cardiovascular comorbidities and structural progression of knee OA in subjects without obesity (BMI<30 kg/m²). Other types of comorbidities do not appear to influence the structural prognosis of OA. These results argue for an integrated management of cardiovascular comorbidities in knee OA patients and highlight the differences between hip and knee OA.

DO DISTINCT PAIN PHENOTYPES HAVE DIFFERENT RISK OF KNEE REPLACEMENT: A 13-YEAR FOLLOW-UP STUDY?

Feng Pan1, Jin Tian1, Ishanka Munugoda1, Stephen Graves2, Michelle Lorimer3, Flavia Cicuttini4, Graeme Jones1, University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; 2Australian Orthopaedic Association National Joint Replacement Registry (AOANJR), Adelaide, Australia; 3South Australian Health and Medical Research Institute (SAHMRI), Adelaide, Australia; 4Monash University Medical School, Department of Epidemiology and Preventive Medicine, Melbourne, Australia

Background: Pain is the main impetus for osteoarthritis (OA) patients to seek healthcare including joint replacement. The pain experience is very heterogeneous and affected by factors across multiple domains—peripheral, psychological, and neurological, which suggests the existence of homogeneous subgroups/phenotypes within OA patients with pain. We recently identified three pain phenotypes using a wide spectrum of factors including main pain dimensions (structural damage on MRI, body mass index (BMI), comorbidities, psychological and multi-site pain (a surrogate of neurological factor)).

Objectives: To examine whether the risk of knee replacement (KR) varied when these three pain subgroups were compared.

Methods: 1099 participants (mean age 63 years; range 51-81 years) from a population-based cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Demographic, psychological and multi-site pain questionnaires at each time-point. Presence of pain (yes/no) in the neck, back, hands, shoulders, hips, knees and feet was also assessed by questionnaire at each time-point. KR up to 13.7 years after recruitment was identified by linking to the Australian Orthopaedic Association National Joint Replacement Registry. Latent class analysis was used to differentiate pain phenotypes by considering sex, BMI, emotional problems, education level, comorbidities, number of painful sites and knee structural damage on MRI. Log-binomial regression was used to evaluate the association between three pain phenotypes and risk of KR.

Results: 963 participants were included in the analysis (BMI 27.7 kg/m², 50% female). Three distinct phenotypes were identified: Class 1: high prevalence of emotional problems and low prevalence of structural damage (25%); Class 2: high prevalence of structural damage and low prevalence of emotional problems (20%); Class 3: low prevalence of emotional problems and low prevalence of structural damage (55%). Participants in Class 1 had greater pain severity than those in Class 2 and 3. During a follow-up of 13.7 years, there were 46 right and 51 left TKR‘ s in 79 participants In multivariable analyses, participants in Class 1 and 2 had higher risk of requiring KR on the right [Class 1 vs. Class 3: relative risk (RR) 6.66, 95% confidence interval (CI) 2.17-20.49; Class 2 vs. Class 3: RR 14.14, 95%CI 4.85-41.22, left] Class 1 vs. Class 3: RR 2.75, 95%CI 1.22-6.19; Class 2 vs. Class 3: RR 3.46, 95%CI 2.64-11.32], and any knee joints (Class 1 vs. Class 3: RR 3.68, 12.60) compared to Class 3, but the associations were stronger with Class 2 than Class 1.

Conclusion: Participants with distinct pain phenotype groups have different risks of KR. This suggests that the identified phenotypes reflect distinct clinical subgroups with different prognoses. As expected the highest risk of KR was found in those with the most structural damage (Class 2). However, those participants with low structural damage have an increased risk of KR when they have high comorbidities. Low emotional problems, indicating that selection of subjects for KR could be improved by screening out those in Class 3.

LOW-DOSE PREDNISOLONE IN PATIENTS WITH HAND OSTEOARTHRITIS (HOPE): RESULTS FROM A RANDOMISED DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL

Féline Krooz1, Marion Kortekaas1, Anneleen Boonen2,3, Stephan Böhringer4, Monique Reijnierse5, Frits Rosendaal6, Naghmeh Riyazi7, Mirian Starman8, Frankien Turkstra9, Jende van Zeben2, Cornelia Allaria1, Margreet Kloppeur6,10,11, LUMC, Rheumatology, Leiden, Netherlands; 2Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands; 3Care and Public Health Research Institute, Maastricht, Netherlands; 4LUMC, Medical Statistics, Leiden, Netherlands; 5LUMC, Radiology, Leiden, Netherlands; 6LUMC, Clinical Epidemiology, Leiden, Netherlands; 7Haga Hospital, Rheumatology, The Hague, Netherlands; 8Zuyderland Medical Center, Rheumatology, Heeren, Netherlands; 9Amsterdam Rheumatology and Immunology center / Reade, Amsterdam, Netherlands; 10Sint Franciscus Vlietland Group, Rheumatology, Rotterdam, Netherlands;

Background: Hand osteoarthritis (OA) is a prevalent joint disease with high disease-burden in need for effective therapeutic options. Studies have shown that synovial inflammation is often present in hand OA and a main determinant of pain and radiographic disease progression.

Objectives: To investigate the efficacy and safety of short-term low-dose prednisolone in patients with painful hand OA.

Methods: This randomised, double-blind, placebo-controlled trial enrolled patients with painful hand OA, fulfilling American College of Rheumatology criteria, and signs of synovial inflammation. Patients with <4 interphalangeal joints (IPJ) with osteoarthritic nodes, >1 IPJ with soft swelling or erythema and >1 IPJ with positive power Doppler signal (PDS) or synovitis grade ≥2 on ultrasound, were eligible. Key exclusion criteria were chronic inflammatory rheumatic diseases, psoriasis, using immune modulating drugs within 90 days before baseline, and predominant thumb base pain. Eligible patients with visual analogue scale (VAS) finger pain ≥30 mm, flaring ≥20 mm upon non-steroidal anti-inflammatory drug washout, were randomised to receive prednisolone 10 mg daily for 6 weeks or placebo, followed by a two-week tapering scheme and 6 weeks without study medication. Outcomes were assessed at 2, 4, 6, and 14 weeks. Primary endpoint was VAS finger pain at week 6 in intention-to-treat analysis. Secondary clinical endpoints included fulfilment of OMERACT-OARSI responder criteria, Australian/Canadian Hand OA index (AUCAIN) pain/function, Functional Index for Hand OA (FIHOA), VAS patient global assessment, Short-Form 36 and grip strength. Imaging endpoints included ultrasound synovitis and PDS.

Results: Of 92 patients (mean (SD) age 63.9 (8.8), 79% women) randomised to prednisolone (n=46) or placebo (n=46), 42 patients in each group completed the study. Baseline characteristics were well-balanced between the groups. The mean (SD) change from baseline to week 6 in VAS finger pain was -21.5 (21.7) in the prednisolone and -5.2 (24.3) in the placebo group, with a mean between-group difference of -16.5 (95% confidence interval (CI) -26.1 to -6.9; figure). At week 6, 33 (72%) patients in the prednisolone versus 15 (33%) in the placebo group fulfilled OARSI responder criteria (odds ratio 5.3, 95% CI 2.0 to 13.6, p<0.001). In analogy with the primary endpoint, prednisolone was superior to placebo in most other secondary clinical endpoints (table). Ultrasound synovitis significantly improved at week 6 in the prednisolone compared to the placebo group, while no difference was observed in PDS (table). After tapering, between-group
RESULTS showed that the IFN muscle signature may play a predominant role in some subgroups but not all IIM groups in the pathogenesis of IIM.

SYNTHETIC PEPTIDES TARGETING CD206 INHIBIT PATHOGENIC MACROPHAGES IN SYSTEMIC SCLEROSIS

Henry Lopez1, Kimi Kumar2, George Martin3, Jesse Jaynes3, James Stanway4, Bahaa Ahmed Abd1, Nikita Arumalla1, Sarah Karrar1, Sian Morris1, Christa Denton1, David Abraham1, Xu Shuwen1, Richard Stray1, 2Riptide Bioscience, 4Suzhou Institute of Systems Medicine, Suzhou, China

Objectives: To determine the macrophage activation signature in SSc assess CD206 as a biomarker of ongoing fibrotic activity, and measure the effect of the peptides on macrophage activation and macrophage-fibroblast cross-talk.

Methods: scCD206 was assayed in plasma (n=50 healthy, 50 limited SSc, 50 diffuse SSC), and suction blister fluid (BF) obtained over active lesions by ELISA, sST2LEC (monocyte interferon signature) and IL-31 (Th2 signature) were assayed for comparison. Cell surface CD206 and DAMP receptor P2X7 were assayed by flow cytometry. The macrophage activation signature was investigated further by qPCR for inflammatory M1, as well as M2-like gene expression (IFNγ, Arg1, CD206). Macrophage-fibroblast cross talk was assessed using media transfer following heat activation to SSc dermal fibroblasts assayed by qPCR for collagen I. The macrophage secretome was determined by LumineX and ELISA

Results: CD206 was significantly elevated in SSc BF (SSC median scCD206 42, HC 31 pg/ml, p<0.041). Plasma scCD206 was raised in diffuse limited SSc (P<0.0103) and was correlated with ESR (R=0.364, p<0.009) and sST2LEC (R=0.244, p<0.05), but not disease duration or IL-31. By flow cytometry both CD206 and P2X7 were highly expressed by SSc macrophages (mean fluorescence SSC, 776.1 SD=409.1, 724.4 SD=455.3 vs HC 632.2 SD=73.7, 472.9 SD=25.4), correlating with modified Rodnan Skin Score (mRSS) (p<0.05, r=0.51). Plasma sCD206 was raised in diffuse versus limited SSc (p=0.037) and showed that 68 interferon-stimulated genes (ISGs) were significantly up-regulated compared to NC and total of 1637 transcripts were differentially expressed (log2 Fold Change >1, Padj < 0.05). Unsupervised hierarchical clustering of these differentially expressed transcripts (DETs) revealed a prevalent interferon (IFN) signature and showed that 68 interferon-stimulated genes (ISGs) were significantly up-regulated in IIM. These 68 ISGs were used to cluster different IIM subgroups and distinct ISG expression was found. The mRNA expression levels of several ISGs (MX1, IFIH1, LAMPI, CMPK2, HERC6) in sequencing cohorts and expanding cohorts also confirmed the diverse ISG expression between different IIM subgroups. An IFN signature scoring system was established to quantify the IFN activity and subsequently IIM could be classified into IFN-Dominant, IFN-Moderate and IFN-Weak respectively based on the IFN intensity and different MSA subgroup. Moreover, the IFN-Dominant group showed much higher MXa expression on muscle biopsy than the IFN-Moderate and IFN-Weak group by immunohistochemistry.

Conclusion: We revealed a prominent IFN signature and MSA-based ISG expression heterogeneity in IIM through muscle transcriptomics. Preliminary

In addition, analysis for transcription factor motif enrichment in the differentially accessible peaks of the ATAC-Seq analysis revealed that motifs for TEAD2, RUNX family, and NFKB2 were less accessible, while motifs for JUN::FOS, NFPL2 and EHF were more accessible due to the chromatin changes. These results indicate that ATAC-Seq could provide a tool to assess the activity of these candidate transcription factors by changing chromatin configuration at the sites of their consensus sequences.

Conclusion: ATAC-Seq in combination with microarray analysis identified candidate mechanisms for the TGFB-regulated proliferotic effects of H19 X including direct effects on chromatin organization and on transcription factors associated with fibrotic pathways.

Inflammmation-dependent Decreased Expression of CD29 on Circulating CD14+ Monocytes Facilitates Adhesion in Systemic Sclerosis

Michal Rudnik1, Michal Stellato1, Przemyslaw Blyszczuk1,2, Karin Klingen1, Jörg Henes4, Carol Feghali-Bostwick5, Oliver Distler1, Gabriela Kania1.

Objectives: We aimed to functionally investigate the role of circulating CD14+ monocytes in the course of SSC with a special focus on monocyte adhesion and the influence of CD29 expression. Methods: Biopsies from the heart, lungs and skin of SSC patients (n=11, 7, 7 respectively) and healthy controls (HC) (n=10, 7, 7 respectively) were analysed by immunohistochemistry for the presence of CD14+ cells. Polya RNA sequencing of CD14+ monocytes isolated from peripheral blood of SSC patients (n=6, age=54.4 ± 16.7), and CD14+ monocytes (n=5, age=51.8 ± 7.2) and age- and sex-matched HC (n=5, age=50.8 ± 9.7) was performed using illumina HiSeq 4000 platform. Differentially expressed genes were computed using DESeq2 algorithm. Gene ontology and pathway analysis were performed using Metacore software and ShinyApp. Expression of adhesion molecules was confirmed on the protein level using flow cytometry. Results: CD29 protein is highly expressed on CD4+ T-cells and plays an important role in the modulation of T-cell receptor signalling. Nevertheless, the function of this protein on monocytes is not completely understood. Objectives: We aimed to functionally investigate the role of circulating CD14+ monocytes in the course of SSC with a special focus on monocyte adhesion and the influence of CD29 expression. RITUXIMAB AND CYCLOPHOSPHAMIDE

**Pathogenicity of Functional Autoantibodies**

Exceeding respective parameter in Group B (p=0.2). The patient percentage with FVC 10% FVC increase was found in the third of the patients thus increase (p=0.034 and 0.000045, respectively), with median increment about 5%.

Evaluation of FVC time course in Groups A and B revealed significant FVC in RTM-treated patients.

During the follow-up period no change of the other studied parameters was revealed.

**Discussion of Results**: None declared.

**Disclosure of Interests**: None declared.

**OP0187**

**RITUXIMAB AND CYCLOPHOSPHAMIDE COMPARISON FOR EFFICACY AND SAFETY IN THE PATIENTS WITH SYSTEMIC SCLEROSIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE**

Olga Konova, Lida P. Ananyeva, Ludmila Garzanova, Oxana Desinova, Olga Osyvannikova, Mayya Starovoytova. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background**: Cyclophosphamide (CyP) is considered as a drug of choice for the treatment of interstitial lung disease (ILD) in the patients with systemic sclerosis (SSc). However, according to the literature the use of CyP leads to rather limited and transient improvement of the pulmonary fibrosis. In this context the search for novel, more efficacious agents has been continued, such as attracting much attention rituximab (RTM).

**Objectives**: To compare the impact of CyP and RTM on SSc clinical manifestation and activity, and the safety of these agents in the open-label prospective non-randomized study.

**Methods**: 107 patients with the confirmed SSc diagnosis and ILD evidence based on HRCT findings were enrolled into the study. All patients received low-dose and moderate-dose prednisolone regimens. 36 patients (Group A) received parenteral CyP for 12±6 months at total dose 10.6±5 g (the average age 47±12 years, females 83%, SSc duration 5.1±4.4 years, diffused/localized forms 1/6.1), 71 patients (Group B) received RTM at total dose 1.43±0.66 g over the follow-up period 13.2±2 months (the average age 46±13 years, females 83%, SSc duration 5.6±4.4 years, diffused/localized forms 1/4.1); to 32 (45%) of them RTM was added to immunosuppressants due to inadequate efficacy of the latter. The time courses FVC (%), modified skin count (mRss, points), activity index (EScSG, points), left ventricle ejection fraction (LVEF, %), mean pulmonary arterial pressure (EchoCG), and cardiac rhythm and conductivity disorders (ECG) were evaluated.

**Results**: In Groups A and B the therapy was associated with significant decrease in mRss (p=0.009 and 0.001, respectively) and EScSG (p=0.000165 and 0.001, respectively). Increase in LVEF (8±1.8% to 8.3±6.7, p=0.02) was observed only in RTM-treated patients. Evaluation of FVC time course in Groups A and B revealed significant FVC increase (p=0.034 and 0.000045, respectively), with median increment about 5%.

In Group A FVC 10% FVC increase was found in the third of the patients thus exceeding respective parameter in Group B (p=0.2). The patient percentage with FVC decrease by ≥10% was similar in both groups.

During the follow-up period no change of the other studied parameters was observed.

The therapy was better tolerated in RTM-treated group; during RTM therapy adverse reactions emerged in significantly lower proportion of the patients (11/14%) compared with CyP-treated group (19/53%), p=0.0000.

**Conclusion**: Both agents effectively alleviated skin induration and EScSG, and significantly improved FVC. However, CyP use for a year slightly more frequently resulted in clinically significant FVC increase, probably due to low RTM cumulative dose. RTM was better tolerated compared to CyP. The study findings substantiate potential use of anti-B-cell therapy both as a first-line agent for ILD treatment in the patients with SSc, and in the event of CyP inefficacy of poor tolerability, especially in the patients with cardiacopathy.

**Disclosure of Interests**: None declared.

**OP0188**

**PATHOGENICITY OF FUNCTIONAL AUTOANTIBODIES AGAINST AT1R IN A MOUSE MODEL OF SYSTEMIC SCLEROSIS**

Junping Yin1, Xiaoqing Wang1, Xiaoyang Yue1, Gabriela Riemekasten2, Xinhua Yu1, Frank Petersen1, 2. Research Center Borstel, Borstel, Germany;

1University of Lübeck, Lübeck, Germany

**Background**: Systemic sclerosis (SSc) is an autoimmune connective tissue disease featured by autoimmunity, fibrosis and vasculopathy. Although many autoantibodies have been detected in the sera of patients with SSc, it is not clear whether they play a role in the pathogenesis of disease. It has been reported that autoantibodies against the angiotensin-II receptor type 1 (AT1R) are present in the sera of SSc patients and are associated with several clinical symptoms of the disease, suggesting that these autoantibodies may act as pathogenic drivers. Recently, our group has developed a novel mouse model for SSc by immunizing mice with human AT1R (hAT1R). From this model we were able to generate functional monoclonal antibodies agonizing AT1R.

**Objectives**: In the current study, we aim to clarify, whether B cells and antibodies directed against AT1R are involved in the pathogenesis of experimental SSc in vivo.

**Methods**: To investigate the role of B cells in the hAT1R-induced mouse model of SSc, we immunized B-cell deficient mice with hAT1R. Nine weeks after the first immunization, mice were sacrificed and sera and tissues were collected for further evaluation. To investigate the pathogenicity of anti-AT1R antibodies in the disease, monoclonal autoantibodies against hAT1R were applied to the ear of C57Bl/6 mice by single or repetitive injection. Mice were sacrificed 24 hours or 14 days after the first injection for single and repeated application, respectively, and ear and lung tissues were collected for further evaluation.

**Results**: Compared to the wild type C57Bl/6 mice, hAT1R-Immunized B-cell deficient mice were resistant against experimental SSc with regard to autoantibody production, inflammation in the lung and skin, and skin fibrosis. Furthermore, both single and repetitive injection of monoclonal antibodies against hAT1R induced inflammation in ears of mice. Despite this local effect, repetitive injection of anti-AT1R monoclonal antibodies provoked also inflammation in the lung of mice.

**Conclusion**: Our data demonstrate that i) B cells are indispensable for the pathogenesis of the hAT1R-induced mouse model for SSc and ii) monoclonal antibodies against hAT1R can induce inflammation in mice. Therefore, our results support a role of autoantibodies against AT1R in the pathogenesis of SSc.

Genetics, epigenetics and immunity

**OP0189 GENETICS OF JUVENILE IDIOPATHIC ARTHRITIS: THE IDENTIFICATION OF A NOVEL RISK LOCUS AND CLINICAL SUBGROUP ANALYSIS**

**John Boxers** Annie Yarwood, Samantha Smith, Damian Tarasek, Wendy Thomson. The University of Manchester, Arthritis Research UK Centre for Genetics and Genomics, Manchester, United Kingdom

**Background:** Juvenile idiopathic arthritis (JIA) is a clinically heterogeneous group of childhood onset inflammatory joint diseases with strong evidence to support a genetic contribution to susceptibility. JIA is divided into seven clinical subgroups based on observed patterns of clinical symptoms using the International League of Associations for Rheumatology (ILAR) classification system. The genetic overlap between these groups is not completely understood and this lack of knowledge typically leads to the different ILAR groups being analysed as discrete entities and reducing the overall power of genetic association studies.

**Objectives:** The aim of this study was to conduct a large case-control association study on susceptibility to JIA to identify novel susceptibility loci and to investigate differences of these associations between the ILAR groups.

**Methods:** JIA participants were genotyped on the Illumina Infinium CoreExome or OmniExpress arrays at The University of Manchester. UK population control genotype data was obtained from the Understanding Society Longitudinal Study. Quality control of data was performed conforming to conventional standards based on call rate, cryptic relatedness and ancestry outliers. Imputation was performed using the Haplotype Reference Consortium panel on the Michigan Imputation Server followed by exclusion of SNPs with low imputation accuracy (R² < 0.5) and low minor allele frequency (< 1%). Association testing of all SNPs was performed with an additive model incorporating imputation uncertainty using SNPTEST. A subset of SNPs independently associated with all JIA (p-value < 5x10⁻⁸) were tested to evaluate if they were specific to a particular ILAR group or shared across multiple ILAR groups using Bayesian multinomial regression and model selection methods implemented in the Trinculo software package.

**Results:** Following quality control the dataset consisted of > 7.4 million SNPs for 3305 JIA cases and 9196 controls. Association testing in a combined dataset of all ILAR groups identified seven SNPs associated at genome-wide significance (5x10⁻⁹); six of these have previously been reported for JIA while one is a novel association. The novel association (rs497523, p-value = 7.12x10⁻⁹, OR 0.85, 95% CI 0.80-0.9) maps to chromosome 16p11 and is located within intron one of the CCDC101 gene. In a subset of 44 independently associated SNPs we found no strong evidence to support association of any SNP to a specific ILAR group with the majority of the SNPs showing evidence for sharing across multiple groups.

**Conclusion:** In the largest case control association study for susceptibility to JIA performed to date, we identified a novel association to a SNP in the intron of CCDC101. This gene is involved in transcriptional regulation through histone acetyltransferase. CCDC101 may be the causal gene at this locus; however introns contain enhancer elements that regulate other genes in the transcriptional domain. Therefore fine mapping with the integration of genomic data is currently being performed for this locus. The results provide little evidence to support ILAR subgroup specificity for any of the associated variants; on the contrary the results support a general model of sharing across multiple groups. The combined analysis of data across subgroups, informed by model sharing, will maximise power to identify novel associations.

**Background:** In recent years, research has consistently proven the occurrence of genetic overlap across autoimmune diseases, which supports the existence of common pathogenic mechanisms in autoimmunity.

**Objectives:** The objective of this study was to further investigate this shared genetic component.

**Methods:** We performed a cross-disease meta-analysis of Immunochip data from 37,159 patients diagnosed with a seropositive autoimmune disease (11,489 celiac disease (CeD), 15,523 rheumatoid arthritis (RA), 3,477 systemic sclerosis (SSc), and 6,670 type 1 diabetes (T1D)) and 22,308 healthy controls of European origin using the R package ASSET.

**Results:** We identified 38 risk variants shared by at least two of the conditions analyzed, five of which represent new pleiotropic loci in autoimmunity. We also identified six novel genome-wide associations for the diseases studied. Cell-specific functional annotations and biological pathway enrichment analyses suggested that pleiotropic variants may deregulate gene expression in different subsets of T cells, especially Th17 and regulatory T cells. Finally, drug repositioning analysis evidenced several drugs that could represent promising candidates for CeD, RA, SSc and T1D treatments.

**Conclusion:** We have been able to advance in the knowledge of the genetic overlap existing in autoimmunity, thus shedding light on common molecular mechanisms of disease and suggesting novel drug targets that could be explored for the treatment of the autoimmune diseases studied.

EPIGENETIC PROFILING OF SYNOVIAL FIBROBLASTS REVEALS STRUCTURAL DNA DYNAMICS AT DISEASE IMPLICATED CHROMOSOME REGIONS

Xiangyu Ge1, Mojca Frank-Bertoncelj2, Amanda Mcgovern1, Gisela Orozco1, Paul Martin1, Caroline Ospel1, Stephen Eyre1. 1Versus Arthritis Centre for Genetics and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, The University of Manchester, UK, Manchester, United Kingdom; 2University Hospital Zürich, Zurich, Switzerland

Background: One of the more striking findings from genome-wide association studies (GWAS) is how the majority of disease associated genetic variants are found within gene regulatory regions, known as enhancers. It is now well established that these enhancers regulate target genes through physical interactions. We, and others, have shown that these interactions can vary between cell types and act over long distances. Therefore, if we are to fully translate GWAS findings, we need link disease associated enhancers to their target genes, in the relevant cell types. So far we only have a limited picture in rheumatoid arthritis (RA) relevant cell types, since synovial fibroblasts (SF) have been omitted from this type of chromatin interaction analysis.

Objectives: Investigate dynamic Hi-C interactions in unstimulated and stimulated SF, mapping RA enhancers to their target genes, and correlating with gene expression.

Methods: We cultured SF from synovial tissues of RA patients. After stimulation of the SF (n=6) with 10 ng/ul TNF for 24h, Hi-C and RNA libraries were generated and sequenced on the Illumina HiSeq 4000. We called dynamic active and inactive regions of the genome (A/B compartments), mapped on RA associated enhancers, linked these to target genes and correlated the interactions with dynamic expression.

Results: We found a region on the chromosome 6q23, intergenic between OLIG3 and TNFAIP3, with an enhancer containing SNPs associated with RA to be dynamically linked to the TNFAIP3 gene through DNA activity, interactions and corresponding gene expression. As shown in figure 1a, the genomic region containing the RA associated variants (red square) only resides in an open, active region of DNA (black bar, compartment A) upon TNF-stimulation of the SF. This region then makes a strong interaction with the promoter of TNFAIP3 (figure 1a) in stimulated cells, which corresponds to a more than 100-fold increase in TNFAIP3 gene expression (figure 1b).

Conclusion: Using independent data, we have indicated how the RA region on 6q23 could influence the expression of TNFAIP3, under stimulatory conditions in SF. This supports previous work, where this particular 6q23 enhancer is preferentially active in RA synovium, compared to osteoarthritis, reflecting the different stimulatory conditions in each disease (Ai et al. 2018). We have successfully linked an RA associated enhancer to its target gene in SF, indicating how the enhancer works over a large distance to interact with and regulate the TNFAIP3 gene. Furthermore we show that this enhancer containing RA associated SNPs is only active upon stimulation with TNF in SF.

DISSECTING THE LONG-RANGE GENE REGULATION OF RHEUMATOID ARTHRITIS ENHANCERS AT THE 5Q11 LOCUS USING THE COMPLEMENTARY APPROACHES OF CRISPRa AND CRISPRi

Kate Duffus1, Oliver Gough1, Gisela Orozco1, Anthony Adamson1, Stephen Eyre1. 1Arthritis Research UK Centre for Genetics and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, The University of Manchester, Manchester, United Kingdom; 1Faculty of Biology, Medicine and Health University of Manchester, Manchester, United Kingdom

Background: Large-scale genome wide association studies (GWAS) in rheumatoid arthritis (RA) have revealed that the majority of associated risk variants lie in non-coding regions of the genome. For RA it has been demonstrated that risk variants are significantly enriched in T cell specific enhancers. One such susceptibility locus known as Sq11 is the third strongest association with RA. At this locus the lead-risk variants lie in two distinct active enhancer elements intrinsic to the ANKRD55 gene. Previous work using chromatin conformation has shown these enhancers make physical contact with the promoter of IL6ST, 150 kb away on the linear chromosome. Whilst ANKRD55 is a gene of unknown function, IL6ST is part of the IL6R complex which regulates the IL6 signalling pathway. Tocilizumab is already an approved drug for RA, which works against the IL6R. CRISPR is an ideal tool to dissect this enhancer-gene relationship to provide us with empirical evidence that the intronic enhancer within ANKRD55 regulates the expression of IL6ST. Understanding how RA risk genetic background affects gene regulation will give us a better understanding of the underlying biology of the disease and can ultimately be used to help repurpose or discover novel drug therapies.

Objectives: To use CRISPR interference (CRISPRi) and CRISPR activation (CRISPRa) to perturb the ANKRD55 intronic enhancer and measure the downstream effect on the expression of IL31RA, IL6ST, ANKRD55.

Methods: We used dead (dCas9) a modified CRISPR Cas9 enzyme that is catalytically inactive, that precisely targets DNA, but does not cut. Instead, effector molecules are fused to the dCas9 (VP64 for activation and KRAB for repression) to alter the transcription of the targeted genes. Two lead functional risk SNPs at the 5q11 risk locus rs10065637 and rs7731626 (R 2 = 0.4472) lie in two distinct enhancer elements separated by 5.5kb. We designed 4 guides across each enhancer, and transduced a T cell line (Jurkat) using lentiviral delivery; first dCas9-KRAB and dCas9-VP64 and subsequently the pool of guides for each enhancer alongside controls. We cultured the cells until confluent and then sorted the top 60% expression of BFP-GFP (KRAB) or MCherry-GFP (VP64). RNA was extracted and then a qPCR was performed (Quantstudio) for IL31RA, IL6ST and ANKRD55.

Results: In the CRISPRa Jurkat cells the guides targeted to both SNP containing enhancers significantly increased the expression of ANKRD55: rs7731626 (p=<0.0001) and rs6859219 (p=0.0003) respectively. They also increased the expression of IL6ST rs7731626 (p=0.0023) and rs6859219 (p=0.01). In CRISPRi Jurkat cells the guides targeted to both SNP containing enhancers significantly decreased the expression of ANKRD55: rs7731626 (p=0.00) and rs6859219 (p=0.0071). When guides were simultaneously used for both enhancers rs6859219+rs7731626 there was also a significant decrease in expression of ANKRD55 (p=0.0001). Only the pool guides against both enhancers significantly decreased the expression of IL6ST (p=0.0001). In both systems no significant effect was seen on the expression of IL31RA (Figure 1).

Figure 1a

Figure 1b

Figure 1
Conclusion: Results from CRISPRi and CRISPRa are concordant and support the idea that inotropic enhancers associated with RA susceptibility, can regulate the expression of both ANKRD55 and also modulate long range gene regulation with JLEST to influence disease risk. These findings are crucial to begin to dissect and translate GWAS findings.

OP0194 CAMP RESPONSE ELEMENT MODULATOR (CREMA) INDUCES DUAL SPECIFICITY PROTEIN PHOSPHATASE (DUSP) THROUGH EPIGENETIC REMODELING, PROMOTING IL-17A AND REDUCING IL-2 EXPRESSION IN T CELLS

Sigrun Hofmann1, Katrin Maebert1, Franz Kapplusch2, Susanne Russ1, Christian Hedrich1,2,3, 1Universitätsklinikum Carl Gustav Carus, TU Dresden, Pädiatrie, Dresden, Germany; 2Institute of Translational Medicine, University of Liverpool, Department of Women’s and Children’s Health, Liverpool, United Kingdom; 3Aöd Hey Children’s NHS Foundation Trust Hospital, Department of Paediatric Rheumatology, Liverpool, United Kingdom

Background: Tissue inflammation and organ damage in systemic lupus erythematosus (SLE) have been linked to effector T cells that are characterized by increased IL-17A and reduced IL-2 production(1). T cells from patients with SLE express increased levels of the transcription factor cAMP response element modulator (CREMa) that contributes to altered cytokine expression(1-3). However, the exact molecular events contributing to dysregulated IL-17A and IL-2 expression are incompletely understood.

Objectives: To investigate molecular events that promote effector T cells in health and disease. The definition of molecular regulators of effector T cell generation and activity may deliver new biomarkers and potential therapeutic targets in disorders characterized by altered effector T cell function, including (but not limited to) SLE.

Methods: Using CRISPR/Cas9 genome editing and lentiviral transduction, we generated CREMa deficient or overexpressing Jurkat T cells. Gene expression profiles in Jurkat and primary human CD4+ T cells were assessed by qRT-PCR and mRNA probe-based hybridization techniques. Gene regulation events were investigated using luciferase reporter assays (trans-activation) and ChIP. Interactions between CREMa and the transcriptional co-activator p300 were assessed using proximity ligation assays and p300 knock-down with siRNAs.

Results: We link CREMa production in effector CD4+ T cells with increased expression of dual specificity protein phosphatase (DUSP4). Using genetically modified Jurkat T cells, we demonstrate that CREMa induces DUSP4 through recruitment of the transcriptional co-activator p300 and histone H3K18 acetylation. Using DUSP4 transfection models and genetically modified Jurkat T cells, we support previous reports suggesting that DUSP4 induces IL-17A while limiting IL-2 expression. Furthermore, we demonstrate that CD4 T cells from patients with juvenile-onset SLE share the phenotype with CREMa over-expressing CD4+ T cells with increased DUSP4 expression that contributes to imbalanced IL-17A and IL-2 production.

Conclusion: Collectively, our results deliver previously unknown CREMa-mediated molecular mechanisms promoting effector T cells and support the central involvement of CREMa in the pathophysiology of SLE. CREMa and DUSP4 may prove valuable as disease biomarkers and/or targets in the search for individualized and target-directed treatments.

OP0195 HISTONE DEACETYLASE 1 (HDAC1): A KEY MEDIATOR OF T CELLS FOR THE PATHOGENESIS OF RHEUMATOID ARTHRITIS

Lisa Göschl1, Victoria Saferding1, Nicole Boucheron2, Johan Backlund3, Alexander Platzer1, Kiyoshi Hirahara1, Hao-Yu Shin1, Patrick Matthäus1, Clemens Scheinecker1, Günter Steiner1, Wilfried Ellmeier2, Michael Bonetti2.
1Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; 2Institute of Immunology, Division of Immunobiology, Vienna, Austria; 3Department of Neurology and Biochemistry, Medical Inflammation Research, Karolinska Institute, Stockholm, Sweden; 4Graduate School of Medicine, Chiba University, Department of Immunology, Chiba, Japan; 5National Institutes of Health, National Institute of Arthritis, Bethesda, United States of America; 6Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland.

Background: Despite enormous efforts to develop new therapeutic strategies for treatment of rheumatoid arthritis (RA), the large number of non responding patients to currently available drugs underlies the unmet need to identify new therapeutic targets. Certain CD4+ T cell subsets, especially those polarized toward the T helper (Th) subset Th1 and Th17, have been shown to be major drivers of inflammation in patients with RA. The expression of their key transcription factors is controlled by histone modifications which includes acetylation of lysine residues mediated by histone deacetylases (HDAC). Indeed, pan HDAC inhibitors have been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underlined the need of more specific HDAC molecules.

Objectives: We addressed the individual role of HDAC1 on the development of collagen-induced arthritis model (CIA), which partially reflects human RA.

Methods: Mice with a T cell specific deletion of HDAC1 (HDAC1 cKO) were generated by using the CD4Cre/LoxP system. At week 8 of age arthritis was induced in wild type (WT) and HDAC1 cKO mice by immunizing with chicken collagen II (CII), emulsified in complete Freund’s adjuvant. After 21 days mice received a booster injection of CII. The animals were 3 times per week scored for paw swelling and grip strength. Anti-CII antibody levels were determined by ELISA. Various cell subsets, including Th cells, where detected in the blood, the spleen and the draining lymph node by FACS analysis. To test antigen-specific T cell activation we performed in vitro restimulation of spleen and lymph node cells with collagen II followed by assessment of cytokine production and quantification of the proliferation rate using 3Hthymidine incorporation.

Results: After 4 and after 10 weeks mice were sacrificed and paraffin sections of the affected joints were analyzed for histomorphologic signs of inflammation, cartilage and bone destruction.

Discussion: Eighty percent of the animals developed serum anti-CII antibodies (IgM and IgG) whereby the antibody levels were a day 21 of disease similar between the HDAC1 cKO and the WT mice. Furthermore, no differences in the production of antibody subclasses, especially of pathogenic IgG2c antibodies, were observed. Enhanced percentages of Th1 and Th17 cells among HDAC1-null CD4+ T cells were detected after immunization with the HDAC1 cKO mice. Nonetheless, and unexpectedly, these mice did not develop any signs of disease at the clinical level while WT mice developed pronounced paw swelling and loss of grip strength. In accordance with the clinical data, histological analysis revealed no signs of inflammation, no bone erosion and no appearance of osteoclasts in the joints of HDAC1 cKO mice. This appeared to be mainly caused by an impaired migratory capacity of HDAC1 cKO CD4+ T cells, so that they were unable to invade the joints.

Conclusion: Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of T cell driven collagen induced arthritis. Therefore it might be considered as an interesting novel therapeutic target in RA.

OP0195 SELECTIVE EXPANSION OF REGULATORY T-CELLS IN HUMANS BY A NOVEL IL-2 CONJUGATE T-REG STIMULATOR, NKTR-355, BEING DEVELOPED FOR THE TREATMENT OF AUTOIMMUNE DISEASES

Christie Fanton1, Suresh Siddhanti1, Neha Dixit1, Lin Lu1, Toufigh Gordi1, Daniel Dickerson2, Jonathan Zalevsky1, Brian Kotzin1, Nektar Therapeutics, San Francisco, United States of America; 2PRA Health Sciences, Lenexa, United States of America

Background: Impaired IL-2 production and dysfunction of regulatory T cells (Tregs) have been identified as key immunological defects leading to the...
breakdown of immune self-tolerance, a causative mechanism implicated in multiple autoimmune diseases. Enhanced sensitivity of Tregs to IL-2 supports the use of low-dose IL-2 therapy; however, this treatment is limited by its short half-life and relatively poor selectivity for stimulation of Tregs versus other T cell types. NKTR-358 is a polyethylene glycol (PEG) conjugate of recombinant human IL-2 (adesleukin sequence with no additional amino acid mutation or substitution). It is differentiated from native IL-2 by its prolonged biological activity as well as its marked and selective stimulation of Tregs in different animal species, including non-human primates.

**Objectives:** Study objectives assessed the safety and tolerability of NKTR-358 in humans administered single ascending doses subcutaneously (SC). In addition, time course and extent of changes in the numbers and percentages of Tregs, conventional CD4+ and CD8+ T cells, NK cells, cytokine levels, and the pharmacokinetics (PK) of NKTR-358 in peripheral blood were investigated.

**Methods:** In this first-in-human, double-blind, single ascending dose study, healthy volunteers received SC doses ranging from 0.3 to 28 ug/kg (9 active:3 placebo per cohort) and subjects were followed for 50 days.

**Results:** All 8 planned cohorts completed dosing. There were no dose-limiting toxicities, serious adverse events, deaths, or clinically significant abnormalities in vital signs, electrocardiograms, or laboratory test values. Adverse events attributed to NKTR-358 were primarily limited to mild (grade 1) injection site reactions. One subject at the highest dose tested demonstrated transient sialyl and mild (grade 1) symptoms of elevated cytokine levels and lymphopenia, which resolved without treatment. No other individual at any dose level had systemic signs or symptoms known to be associated with IL-2 therapy. The first 6 cohorts have been tested for anti-drug antibodies to date and none have been detected. NKTR-358 reached maximum plasma levels 4-6 days after administration, with little change for ~2 weeks, and then decreased with a half-life of ~6-9 days. NKTR-358 exhibited linear PK above the 1.0 ug/kg dose. The primary effect of NKTR-358 was seen on Tregs. In the 3.0 to 28.0 ug/kg dose cohorts, a dose-dependent and sustained increase in the absolute numbers and percentages of circulating CD4+FoxP3+CD25+Bright Tregs were observed. The elevated levels peaked at Days 10-12 and did not return to baseline until ~20 to 25 days following administration. At 28.0 ug/kg, the mean peak increase of 3.5-fold in the percentages and numbers of NK cells at the highest dose tested, but no changes in percentages or numbers of conventional CD4+ or CD8+ T cells were observed. NKTR-358 selectively induced Tregs, evidenced by a 15-fold increase in the mean peak Treg:CD8 ratio over baseline in the 28.0 ug/kg group.

**Conclusion:** Single doses of the IL-2 conjugate T-reg stimulator, NKTR-358, in the dose range tested were well tolerated and safe. NKTR-358 led to a striking and selective dose-dependent increase in circulating CD25Bright Tregs with minimal effects on conventional T cells and with relatively small effects on NK cells. These clinical results extend previous animal studies showing the prolonged and Treg selective action of NKTR-358, and provide strong support for testing NKTR-358 as a new therapeutic in autoimmune diseases, such as systemic lupus.

EVALUATING THE RELATION OF STRUCTURAL MRI-DETECTED STRUCTURAL ABNORMALITIES AND TYPE II COLLAGEN DEGRADATION IN KNEE OSTEOARTHRITIS

Nidhi Sofat1, Vivian Ejindu2, Christine Heron2, Lena Assi3, Anasuya Kuttapitiya4, Guy Whitley5, Soraya Koushesh3, Abiola Harrison1, Franklyn Howe6.

Objectives: In this study we evaluated the relation between structural damage by MRI, clinical and pain sensitisation measures and wet biochemical biomarkers in knee OA.

Methods: We recruited 130 participants fulfilling ACR criteria with advanced OA requiring total knee replacement (TKR) (n=80), mild OA having standard care (n=42) and non-OA controls (n=8). Knee MRI in 90 subjects (72 F, 18 M) was acquired and assessed by two radiologists with the MRI Knee Osteoarthritis Score (MOAKS). Overall MOAKS scores were created for Bone Marrow Lesions (BML), Cartilage Degradation (CD) and effusion/Hoffa synovitis (tSyn). Type II collagen cleavage products (CTX-II) were determined by ELISA. Clinical scoring was performed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) for pain levels (WOMAC_P), Hospital Anxiety and Depression Scale (HADS), Body mass index (BMI) and pain sensitisation with pain pressure thresholds (PPT) of the patella by Quantitative Sensory Testing (QST).

Results: The mild OA group had a mean age of 63 +/- 9 yr and the advanced OA group 69 +/- 9 yr. The advanced OA group had higher levels of pain, with a mean WOMAC_P of 58 +/- 22 compared with the mild OA group who had a mean WOMAC_P of 40 +/- 22. WOMAC_P correlated with the total number of regions with cartilage damage (nCD) (R=0.225, p=0.033) and total number of BMLs (nBML) (R=0.195, p=0.065) using BMI, age and HADS as covariates. Levels of CTX-II correlated with tSyn (R=0.313, p=0.03), nBML (R=0.252, p=0.019), number of osteophytes (R=0.33, p=0.002) and nCD (R=0.218, p=0.042), using BMI and age as covariates. The correlation for urinary CTX-II with tSyn (p=0.006) is shown in Figure 1 using a partial linear regression analysis of MOAKS, BMI and age. We also found CTX-II correlated with lesion load scores (total number of lesions multiplied by MOAKS size by% damage scores) for CD (R=0.277, p=0.009) and BML (R=0.308, p=0.004). PPT correlated with patella MOAKS scores for nBML (R=0.221, p=0.038) and nCD (R=0.279, p=0.009), with HADS, BMI and age as covariates.

Conclusion: There is a direct correlation between the degree of cartilage damage and BMLs with pain in OA. Type II collagen degradation products were higher when there was more severe MRI-detected synovitis, BMLs and cartilage damage in the knee joint, suggesting that the source of enzymes degrading type II collagen in OA, including matrix metalloproteinasenes, are also likely to be produced by synovium and bone (1) and not just cartilage, as previously hypothesised in other studies. There was also a correlation between pain sensitisation and frequency of BMLs and cartilage degradation, suggesting that molecular mediators of pain sensitisation, which we have shown are produced by BMLs (1), are a cause of patient-reported OA pain.

MRI-DETECTED STRUCTURAL ABNORMALITIES AND DEVELOPMENT OF INCIDENT RADIOGRAPHIC KNEE OSTEOARTHRITIS OVER 10 YEARS OF FOLLOW-UP

C. Kent Kwoh1, Frank Roemer2, Leena Sharma3, Erin Ashbeck4, Chengcheng Hu5, Ali Guermazi6, For the Biomarkers of Early Arthritis of the Knee (BEAK) Investigators. 1University of Arizona, Tucson, United States of America; 2University of Erlangen-Nuremberg, Erlangen, Germany; 3Northwestern University, Chicago, United States of America; 4University of Arizona, Tucson, United States of America; 5Boston University, Boston, United States of America

Background: Structural joint pathology on MRI has been found in knees without radiographic evidence of osteoarthritis (OA). We have previously shown that structural abnormalities on MRI may be precursors of disease and associated with the detection of incident radiographic knee OA (ROA) up to 2 years later, and in some circumstances up to seven years later. The prognostic value of structural abnormalities on MRI for knee OA, however, is unknown.

Objectives: Estimate the probability of incident ROA over 10 years of follow-up, according to structural abnormalities detected on baseline MRIs.

Methods: A subcohort of participants (862 knees, one knee/person) from the Osteoarthritis Initiative (OAI) with at least one knee at risk of developing ROA (i.e., Kellgren-Lawrence (KL) 0.1 at baseline) was randomly selected. MRI-detected structural features of the knee were assessed by expert readers using the MRI Osteoarthritis Knee Score (MOAKS). Participants underwent bilateral posteroanterior fixed-flexion weight-bearing knee radiography at baseline and annually through year 10 and then every two years until year 10. Radiographs were centrally read for KL grade, with ROA defined as KL=2. Survival was estimated with the Turnbull non-parametric maximum likelihood estimator, a generalization of Kaplan Meier curves for interval censored data. Survival curves were compared using a log rank permutation test available in the R package interval. Hazard ratios were estimated using Cox models fit using the R package iceReg, designed for interval censored data. Features were considered one at a time, with no adjustments.

Results: Knees with any of the following structural abnormalities had higher estimated probabilities for the development of radiographic OA within two, four and 10 years of follow-up: effusion-synovitis, Hoffa-synovitis, bone marrow lesions in the medial compartment and whole knee, surface area and full thickness cartilage damage in the medial compartment and whole knee, and medial meniscal extrusion (Table 1). Differences in the probability for the development of ROA within two, four, and 10 years of follow-up were significant (post-hoc 95% confidence intervals did not include 0), between knees without the abnormality and knees in the most severe category for all features, with one exception at the two-year follow-up. All of these abnormalities were significantly associated with time to ROA over 10 years of follow-up.

REFERENCES:

Figure 1

Conclusion: Our results demonstrate the prognostic value of effusion-synovitis, Hoffa-synovitis, bone marrow lesions, cartilage damage, and meniscal extrusion
for the development of ROA up to 10 years later. Future directions include developing a predictive model that incorporates multiple features.

Different pathophysiological pathways in axial and peripheral disease: Peripheral and axial spondyloarthritis: to split or to lump?

OP0199

THE HUMAN ENTHESIS HARBOURS RESIDENT ADAPTIVE CD4+ AND CD8+ T-CELLS WITH INCLUDIBLE IL-17A AND TNF PROTEIN THAT IS PHARMACOLOGICALLY SUPPRESSED BY ROR-Γ AND PDE4 INHIBITORS BUT NOT METHOTREXATE IN A NOVEL IN VITRO ENTHESIS MODEL

Abdulla Watad1, Hannah Rowe2, Charlie Bridgewood2, Tobias Russell3, Qiao Zhou2, Almas Khan4, Robert Dunsmuir5, Peter Loughenbury2, Abhay S Rao2, Peter Millner2, Richard Cuthbert2, Dennis McGonagle2, Tel Aviv University, Tel Aviv-Yafo, Israel, 2University of Leeds, Leeds, United Kingdom

Background: Animal models have demonstrated that enthesis is the primary lesion in experimental spondyloarthritis (SpA). In mice, innate lymphocytes were suggested as the major cytokine producers at the enthesis.

Objectives: We tested the hypothesis that the human enthesis harbours tissue resident conventional T-cells. We also assessed their ability to express SpA-related cytokines including TNF and IL-17A and if this could be blocked using psoriasis therapeutic agents (methotrexate (MTX), and phosphodiesterase type 4 inhibitor (PDE4i)) and experimental RORγt inhibitors (RORγt).

Methods: Entheseal spinal process was obtained from patients undergoing elective orthopedic procedures (n=20) and mechanically digested or processed for confocal staining and flow cytometry. CD4+ and CD8+ T-cells were sorted and RNA was isolated and analysed by qPCR. Magnetically isolated cells were stimulated using an anti-CD3/CD2/CD28 bead with and without the presence of MTX, RORγt and PDE4i. Following stimulation IL-17A and TNF were measured by ELISA and intracellular flow cytometry.

Results: CD4+ and CD8+ T-cells represent 35.7% and 23.7% of T-cells in the enthesis, respectively, with topographic confirmation by anti-CD3 immunofluorescence staining. Entheseal tissue contained a higher proportion of CD4+ and CD8+ T-cells expressing a resident memory phenotype (CD69+/CD45RA-) compared to matched blood. Sorted T-cells from entheseal tissue had a gene expression profile consistent with a tissue resident phenotype and CD4+ and CD8+ T-cells showed increased expression immunomodulatory genes including IL-10 and TGF-β compared to peripheral blood T-cells (p<0.001). Following stimulation CD4+ T-cells produced more TNF than CD8+ T-cells (p<0.05), while RORγt only reduced IL-17 secretion (p<0.001). MTX had no significant impact on both TNF and IL-17A production in either cell population. This pattern of inhibition was mirrored in TNF secretion from CD8+ T-cells.

Conclusion: This is the first description of conventional CD4+ and CD8+ entheseal resident T-cells. PDE4i was effective in abrogating induced TNF production and IL-17, whereas RORγt is highly effective for IL-17A production but not TNF. In contrast, MTX had little effect on in vitro enthesis model cytokine production. These findings may have some practical implications in the treatment of subclinical enthesis.

OP0200

A SET OF INFLAMMATORY MARKERS ALLOWING TO DETECT SYSTEMIC INFLAMMATION IN PSORIATIC SKIN, ENTHESEAL AND JOINT DISEASE IN THE ABSENCE OF CRP AND THEIR LINK TO CLINICAL DISEASE MANIFESTATION

Maria Soldatova1,2, Kemal Nas3, Yubin Luo4, David Simon1, Yi Zhao5, Jürgen Rech4, Mario Zais1, Georg Scheel1, 1Friedrich-Alexander University Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 2Lomonosov Moscow State University, Faculty of Medicine, Moscow, Russian Federation; 3Sakarya University School of Medicine, Division of Rheumatology and Immunology, Sakarya, Turkey; 4West China Hospital, Sichuan University, Department of Rheumatology and Immunology, Chengdu, China

Background: Psoriatic disease is composed of skin, entheseal and joint disease, which can manifest isolated or combined. Little is known about the systemic inflammation levels in psoriatic disease as a robust IL-6 signal is missing and therefore acute phase reactants such as C-reactive protein are often normal. Measuring systemic inflammation in the different manifestations of psoriatic disease is therefore a continuous unmet need.

Objectives: To better define systemic inflammation in patients with psoriatic disease limited to the skin (S), the entheses (E) or the joints (arthritis, A) or with a combination of these disease manifestations (SE, SA, EA, SEA).

Figure 1. Effect of different therapeutic agents on the TNF and IL-17A production by resident entheseal T-cells compared to peripheral blood

Figure 2. Gene expression profile of entheseal T-cells (soft tissue and adjacent bone) compared to peripheral blood

Abbreviations: ST, enthesal soft tissue; PEB, peri-enthesal bone.

Disclosure of Interests: Abdulla Watad: None declared, Hannah Rowe: None declared, Charlie Bridgewood: None declared, Tobias Russell Grant/research support from: PhD Project is funded by Novartis., Qiao Zhou: None declared, Almas Khan: None declared, Robert Dunsmuir: None declared, Peter Loughenbury: None declared, Abhay S Rao: None declared, Peter Millner: None declared, Richard Cuthbert: None declared, Dennis McGonagle Consultant for: Lilly, Novartis UCB, Speakers bureau: Lilly, Novartis UCB

Methods: Hypothesis-driven approach selecting makers that are (i) either targets of IL-23/IL-17 pathway activation (β-defensin 2, lipocalin 2, IL-22), (ii) associated with neutrophil/monocyte activation (calprotectin, IL-8) and (iii) achieve serum concentrations sufficient for reliable detection by standard ELISA. Parameters were assessed in 210 individuals comprising 105 healthy controls and 105 patients with psoriatic disease (each 15 for isolated (S, E, A) and composed disease manifestations SE, SA, EA, SEA). Results are expressed as percent positive patients with levels above three standard deviations over the mean level in healthy controls. In addition, 6-months sequential data on levels of these makers were collected in 20 patients treated with secukinumab or adalimumab to test treatment effects.

Results: CRP levels were normal in the majority of individuals. The respective percentages of patients with normal CRP (>0.3 mg/L) were as follows: S: 100%, E: 95%, A: 80%, SE: 93%, SA: 67%, EA: 73%, SEA: 67% (Figure). Thus, CRP is only elevated in a subset of patients with arthritis. In sharp contrast, beta-defensin 2 levels (>1.88 ng/mL) and lipocalin-2 (>24.7 ng/mL) were elevated in the majority of patients with isolated skin and entheseal, but not joint disease. Conversely, elevations of calprotectin (>3.58 mg/mL) and IL-8 (>10.3 pg/mL), were found in the majority of patients with isolated joint disease. IL-22 was elevated (>17.1 pg/mL) in all three manifestations of psoriatic disease. Reflecting a combination of the disease manifestations SE, SA, EA, SEA) showed widespread marker elevation. IL-17 and TNF inhibition differentially lowered and partially normalized elevated markers of inflammation.

Conclusion: Systemic inflammation is detectable in the majority of patients with psoriatic disease, even if CRP is normal. The respective marker pattern depends on the manifestation (skin, entheses, joints) of psoriatic disease, with beta-defensin 2 and lipocalin-2 reflecting skin and entheseal disease, calprotectin and IL-8 joint disease and IL-22 a combination of these disease manifestations.

Thursday, 13 June 2019

My joints hurt and I’m overwhelmingly tired – fatigue in rheumatoid arthritis.

OP0201

FATIGUE IN JUVENILE IDIOPATIC ARTHRITIS AFTER 18 YEARS OF FOLLOW-UP

Ellen Dalen Arntsd1,2, Mia Glurup3, Veronika Rydpdal5,6, Susi Petloniemi6, Maria Ekelund7, Lillemor Berntsson8, Anders Fasth9, Susan Nielsen10, Marek Zak1, Kristina Aalto10, Ellen Nordal11, Troels Herlin11, Pål Richard Romundstad12, Marie Rygg13, Levanger Hospital; Dept. of Pediatrics, Levanger, Norway; 2NTNU – Norwegian University of Science and Technology, Dept. of Clin. and Molecular Med., Trondheim, Norway; 3Aarhus University Hospital, Dept. of Pediatrics, Aarhus, Denmark; 4University Hospital of North Norway, Dept. of Pediatrics, Tromsø, Norway; 5UT The Arctic University of Norway, Dept. of Clin. Med., Tromsø, Norway; 6University of Helsinki, Helsinki, Finland; 7Rybo County Hospital, Dept. of Pediatrics, Jonkoping, Sweden; 8Uppsala University, Dept. of Women’s and Children’s Health, Uppsala, Sweden; 9Institute of Clin. Sciences, Sahlgrenska Academy, University of Gothenburg, Dept. of Pediatrics, Gothenburg, Sweden; 10Rigshospitalet Copenhagen University Hospital, Dept. of Pediatrics, Copenhagen, Denmark; 11Rigshospitalet Copenhagen University Hospital, Copenhagen, Denmark; 12NTNU – Norwegian University of Science and Technology, Dept. of Public Health and Nursing, Trondheim, Norway; 13St. Clavs Hospital, Dept. of Pediatrics, Trondheim, Norway

Background: Fatigue is common in adults with rheumatic disease and has also been shown in adolescents with juvenile idiopathic arthritis (JIA). Knowledge on fatigue in JIA in long-term follow-up is limited.

Objectives: To study the prevalence and severity of fatigue 18 years after onset of JIA.

Methods: In this close to population-based cohort study from defined geographical areas of Norway, Sweden, Denmark and Finland, consecutive cases of JIA with disease onset in 1997 to 2000 were prospectively enrolled (1). At 18-year follow-up, fatigue was measured using Fatigue Severity Scale (FSS, range 0-7) (2), and severe fatigue was defined as FSS >4. General health status was measured with Health Assessment Questionnaire (HAQ) and 36-Item Short Form Health Survey (SF-36). Reduced health was defined as HAQ >0, and SF-36 <40 (according to the physical component summary score/mental component summary score (PCS/MCS)). Pain was measured with 10 cm visual analogue scale (VAS), 0 – no pain, >0 – pain. Remission was defined according to the preliminary criteria described by Wallace. A Norwegian healthy cohort was used for comparison. Multivariable logistic regression analyses were performed.

Results: Among 434 eligible JIA participants 377 completed a Fatigue Severity Scale (FSS) measurement at the 18-year follow-up and were included. Of these 72% were girls, 53% had oligoarticular disease six months after onset, median age at onset was 5.6 (IQR 2.6-9.7) years, and age at the 18-year visit was 23.1 (IQR 20.3-27.2). Mean total FSS (±SD) was 3.2 (±1.5), and participants with active disease scored 3.6 (±1.6) compared to 2.9 (±1.4) for those in remission off medication. The highest total FSS was found in those with SF-36 PCS and/or MCS <40 (4.7 (±1.6) and 4.6 (±1.6), respectively). Severe fatigue was considerably more frequent in participants with active disease (36%, odds ratio (OR) 2.5) compared to those in remission off medication (19%), HAQ score >0 (47%, OR 4.1) compared to HAQ score =0 (18%), SF-36 PCS/MCS <40 (64/61%, OR 7.1/4.9) compared to SF-36 PCS/MCS >40 (20/19%), and VAS pain >0 (36%, OR 3.8) compared to VAS pain ≤0 (13%). The proportion of severe fatigue in a healthy Norwegian control cohort was 12%

Conclusion: At 18-year follow-up fatigue was a prominent symptom in JIA, and we found consistently higher fatigue burden and considerably more severe fatigue among participants with active disease, pain and self-reported health problems, compared to those without. We suggest fatigue to be measured at long-term follow-up both in clinical and research settings.

EFFECT OF RSLV-132 ON FATIGUE IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME – RESULTS OF A PHASE II RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PROOF-OF-CONCEPT STUDY

Benjamin Fisher1, Francesca Barone1, Kerry Jobling2, Peter Gallagher3, Victoria Macrae2, Andrew Filby4, Gillian Hulmes5, Paul Milne5, Emmaurella Traianos6, Valentina Iannizzotto5, Alexandre Dumusc5, Simon J. Bowman5, Jessica Tarn5, Dennis Lendrem5, Daniel Burge7, Benjamin Fisher1, Francesca Barone1, Kerry Jobling2, Paul Gallagher5, Kingdon

Background: Fatigue is the key symptom that leads to poor health related quality of life and loss of work productivity in patients with primary Sjögren’s syndrome (pSS). RSLV-132 is a first-in-class drug comprising RINase1 fused to the Fc region of IgG1. It is designed to increase serum RINase activity to digest RNA associated immune complexes, thereby reducing Toll-like receptor (TLR) activation and subsequent production of type 1 interferon (IFN), B-cell proliferation, and autoantibody production – mechanisms that are key to pSS pathogenesis. IFN pathway dysregulation has also been implicated in fatigue.

Objectives: To explore the clinical efficacy of RSLV-132 in improving patient-reported outcomes (PRO), particularly fatigue among patients with pSS.

Methods: Patients with positive anti-Ro and IFN gene expression signature were randomised: 3:1 to RSLV-132 10 mg/kg IV or placebo (PBO) at weeks 0, 1, 2, and then fortnightly until week 12. Use of hydroxychloroquine, other immunomodulatory therapies or prednisolone >10mg daily were not permitted. There was no minimum entry criteria for EULAR Sjögren’s syndrome disease activity (ESSDAI) or EULAR Sjögren’s syndrome patient reported index (ESSPRI). The primary endpoint was changes in gene or protein expression levels in blood indicative of reduced inflammation. Secondary endpoints, among others, included safety and tolerability, and changes in PRO between baseline and week 14 including ESSPRI, FACIT, Fatigue visual analogue score (0-100), Profile of fatigue (PRO-F) (0-7)) and Neuropsychological tests.

Results: Thirty patients were randomised (RSLV=22, PBO=8). Baseline clinical and demographic characteristics were comparable between groups. Two subjects randomised to active drug withdrew from the study before dosing. Among the patients receiving RSLV-132, the mental component of PRO-F improved by 1.53 points compared to worsening of 0.06 points in the PBO group (p=0.046). Consistently, there was a significant improvement in the RSLV-132 group in their Digital Symbol Substitution Test performance with a reduction of 16.4s in completing the test compared to an increase of 2.8s in the PBO group (p=0.024). The physical component of PRO-F improved by 0.8 points in the RSLV-132 group compared to improvement of 0.06 points in the PBO group (p=0.142). Similar trends were observed for ESSPRI and FACIT-F scores.

Conclusion: RSLV-132 is a promising therapy to improve the symptoms of fatigue in patients with pSS, with a good safety profile. Further investigation of its use in pSS is warranted.

CHARACTERIZING THE EPIGENOMIC LANDSCAPE OF PSORIASIS PATIENTS DESTINED TO DEVELOP PSORIATIC ARTHRITIS

Remy Pollock1, Rohan Machh1, Vinod Chandran2,3,4, Dafna D Gladman1,2

1Krembil Research Institute, University Health Network, Psoriatic Disease Research Program, Toronto, Canada; 2Faculty of Medicine, University of Toronto, Division of Rheumatology, Toronto, Canada; 3University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada; 4Memorial University, Faculty of Medicine, St. John’s, Canada

Background: Approximately 30% of psoriasis patients develop psoriatic arthritits (PsA), typically within 10 years of psoriasis onset. A large proportion of individuals with PsA remain undiagnosed. Epigenetics is potentially a major mechanism through which environmental factors influence PsA risk. An understanding of how the epigenome changes during the transition to PsA could yield predictive biomarkers and facilitate PsA diagnosis. We hypothesize that epigenetic deregulation at the level of DNA methylation occurs early in PsA pathogenesis, prior to overt clinical symptoms, and epigenetic markers can be used as biomarkers for disease prediction.

Objectives: To discover predictive biomarkers of PsA and gain an understanding of the pathogenesis of PsA by characterizing the epigenomic landscape of psoriasis patients who later developed PsA (converters) and comparing it to psoriasis patients who did not develop PsA (non-converters).

Methods: We performed an epigenome-wide comparison of DNA methylation in baseline whole blood samples from psoriasis converters (n=60) and non-converters (n=60) from a longitudinal cohort. Converters and non-converters were matched for age, sex, psoriasis duration, and duration of follow-up. DNA was analyzed on Human MethylationEPIC BeadChips using the Illumina package. Cell type heterogeneity was corrected using RefBaseEWAS. Differentially methylated probes and regions were identified using limma and DRMRcate, respectively. The FEM package was used to infer differentially methylated gene modules within a protein-protein interaction network.

Results: Converter baseline samples were collected a median of 4.2 (interquartile range 1.9-6.3) years prior to the onset of PsA, while non-converters samples were collected a median of 4.3 (1.2-7.3) years prior to the most recent clinic visit. The RefBaseEWAS method estimated that converters had slightly higher proportions of CD4+ T-cells and granulocytes compared to non-converters, however the differences were not statistically significant. After adjustment for cell type heterogeneity, 68 individual CpG sites were found to be differentially methylated between converters and non-converters (FDR<0.05). Differentially methylated regions (DMRs) containing at least 2 significant CpGs were identified in genes such as FBXO27 (beta fold change [FC]=0.06, region-wise adjusted p=4.1x10^-3), a ubiquitin ligase involved in lysosomal degradation, RCAN1 (FC=-0.05, p=5.2x10^-3), a protein which inhibits calcineurin-dependent signaling pathways and is involved in bone homeostasis, and PMAIP1 (FC=0.04, p=6.7x10^-5), which encodes the NOXA protein involved in mediating apoptosis of activated B cells. Several significant CpG sites mapped to protein-protein interaction subnetworks involved in Th17 differentiation (IRF4 and MAFF), TNF alpha signaling (IKKBE, REL, MAVS, IκBKE).
EMAPALUMAB, AN INTERFERON GAMMA (IFN-γ) BLOCKING MONOClonAL ANTIBODY, IN PATIENTS WITH macROPHAGE ACTIVATION SYNDROME (MAS) COMPLICATING SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (SJIA)

Fabricio De Benedetti1, Paul Brogan2, Alexei Grom3, Pierre Quartier4, Rayet Schneider4, Kraft De Graaf5, Philippe Jacquin6, Maria Balabio6, Cristina de Miré1. 1IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy; 2UCL Institute of Child Health, and Great Ormond Street Hospital NHS Foundation Trust, Section Head: Infection, Immunology, and Rheumatology, London, United Kingdom; 3Cincinnati Children’s Hospital, Division of Rheumatology, Cincinnati, United States of America; 4Hôpital Necker, Service de Généétique clinique – Génétique Moléculaire, Paris, France; 5The Hospital for Sick Children, Department of Paediatrics, Division of Rheumatology, Toronto, Canada; 6Novimmune SA, Basel, Switzerland; 7Mns Modelling and Simulation, Dinant, Belgium

Background: MAS is a severe complication of rheumatic diseases, most frequently SJIA, characterized by excessive activation and expansion of T cells and macrophages. It is characterized by fever, hepatosplenomegaly, liver dysfunction, cytopenias, coagulation abnormalities and hyperferritinemia, possibly progressing to multiple organ failure and death. MAS is categorized as a secondary form of HLH. A vast body of evidence points to uncontrolled overproduction of IFNγ as a major driver of hyperinflammation and hypercytokinemia in MAS and HLH. Emapalumab has been shown to effectively control disease activity in patients with primary HLH.

Objectives: To assess the pharmacokinetics (PK), efficacy and safety of intravenous (IV) emapalumab in patients with MAS and confirm the proposed dose regimen.

Methods: This is a pilot open-label single arm international study (NCT03311854). Patients had to have MAS (defined according to the 2016 ACR/EULAR classification criteria), on a background of confirmed, or high presumption of, SJIA, and inadequate response to high-dose IV glucocorticoids. Emapalumab initial dose was 6 mg/kg and treatment was continued at 3 mg/kg, twice weekly for a total of 4 weeks or less upon achievement of complete response. Serum concentrations of emapalumab, IFNΓ-induced chemokine CXCL9 and sIL2R were measured. Safety assessments included adverse events (AEs) and laboratory abnormalities. Efficacy was defined as complete response by week 8, i.e. absence of MAS clinical signs plus white blood cell and platelet counts above lower limit of normal, LDH, AST/ALT<1.5 x upper limit of normal, fibrinogen >100 mg/dl, and ferritin decreased by >50% or to <2000 ng/mL, whichever was lower. Twin protocols are in place to recruit 5 patients each in Europe and North America (trial not started yet). We report data on the 6 patients recruited in the European protocol.

Results: Six patients (5 females, median age 11 years, range: 2-25 years) received emapalumab according to the prescribed dose regimen. Treatment duration ranged from 3 (2 patients) to 4 weeks. Prior to emapalumab, all patients failed methylprednisolone pulses, in 2 patients plus cyclosporine A (CsA) and in 2 patients plus CsA and anakinra. The achieved emapalumab concentrations led to rapid neutralization of IFNγ as indicated by CXCL9 levels and subsequent deactivation of T cells as indicated by sIL2R levels. In all patients, complete response was achieved by week 8, in 4 patients by end of treatment (Table). Systemic glucocorticoids were weaned in all patients. Emapalumab infusions were well tolerated and none of the patients discontinued emapalumab. A CMV reactivation was reported by investigator as a serious event possibly related to emapalumab, but resolved completely with treatment.

Conclusion: Emapalumab administration with the tested dosing regimen led to rapid neutralization of IFNγ as shown by normalization of CXCL9, associated with evidence of decreased T cell activation. In all patients, emapalumab treatment was effective in controlling MAS with a favourable safety profile.

booster while on tocilizumab, 7 on anakinra, and 5 on canakinumab. There was no relation between disease activity, type or duration, sex, age and outcome of vaccinations. No vaccine infection related to measles, rubella, mumps and varicella were reported.

Conclusion: This large, retrospective data collection demonstrates that live-attenuated booster vaccine is probably safe in children with rheumatic diseases, on immunosuppressive therapies. This strengthens the new PRES recommendation: “Vaccination of live-attenuated vaccines in patients on high-dose DMARD, high-dose glucocorticosteroids or biological agents can be considered on a case-by-case basis, weighing the risk of infections against the hypothetical risk of inducing infection through vaccination.” These data provide the basis for a large, prospective data collection study that is planned by the PReS vaccination study group.

Exercise – more than a wonderdrug

OP0206-HPR

BENEFICIAL LONG-TERM EFFECT OF A SUPERVISED EXERCISE PROGRAM ON PHYSICAL ACTIVITY LEVEL IN PATIENTS WITH AXIAL SPONDYLOARTHROPATHIES: 12 MONTHS FOLLOW-UP OF A MULTICENTER RANDOMIZED CONTROLLED TRIAL

Sille Halvorsen Sveaas1, Hanne Solveig Dagfjord2, Melissa Woll Johansen3, Elisabeth Pedersen4, Annelie Bilberg5, Diakonhjemmet Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2Martina Hansens Hospital, Department of physiotherapy, Bamum, Norway; 3University Hospital of North Norway, Department of physiotherapy, Tromsø, Norway; 4University of Gothenburg, Institute of Neuroscience and Physiology, Section of Physical medicine and rehabilitation. 2018;99(2):383-388.e381.

Background: Exercise is recommended in the management of axial spondyloarthritis (axSpA) as it may reduce the burden of the disease. Despite this, patients with axSpA tend to have a low physical activity (PA) level and few patients engage in high intensities of exercise.

Objectives: To investigate the long-term effect of a three months supervised exercise program on PA-level in patients with axSpA.

Methods: 100 patients with axSpA were randomized to either an exercise group (EG) or no-intervention control group (CG). The exercise program participated in a three months high intensity cardiorespiratory and strength exercise program on a case-by-case basis, weighing the risk of infections against the hypothetical risk of inducing infection through vaccination.

Results: A total of 87 of 100 (87%) patients were included in the analyses (table 1). At 12 months follow-up, significantly more patients in the EG than in the CG exercised 2-3 times per week (25 [58%] vs. 15 [34%], p=0.02). Fewer patients in the EG reported to exercise at a low intensity level (low intensity reported by 3 [8%] in the EG vs. 14 [44%] in the CG, p=0.002). The regression analysis showed that participating in the exercise program (p=0.001) and earlier exercise experience (p=0.01) were the factors most associated with being physically active at 12 months follow-up (table 2).

Conclusion: A three month supervised exercise program delivered by physiotherapists had a significant long-term beneficial effect on PA-level in patients with axSpA. As regular exercise is an important part of the treatment recommendations for patients with axSpA, the results indicate that a time-limited supervised exercise program may be used as an effective intervention to succeed in reaching this recommendation.

Getting a grip on the co-morbidities in gout

OP0207

URATE-LOWERING THERAPY WITH VERINURAD AND FEBUXOSTAT REDUCES SERUM URIC ACID AND ALBUMINURIA IN HYPERURICEMIC PATIENTS WITH DIABETES

Robert Terkelthau1, Naïna Dronanraj2, Susanne A Johansson2, Joanna Parkinson3, Eva Johansson4, Fredrik Erlandsson4, Austin Stack4, VA San Diego Healthcare System, UC San Diego, United States of America; 2AstraZeneca RandD, Gaithersburg, United States of America; 3AstraZeneca, Gothenburg, Sweden; 4Department of Nephrology, University Hospital Limerick and Health Research Institute, University of Limerick, Limerick, Ireland

Background: Hyperuricemia is implicated as a major risk factor for chronic kidney disease (CKD), and emerging clinical data suggest that lowering serum uric acid (sUA) may protect kidney function by reducing albuminuria and slowing the rate of CKD progression. We evaluated the efficacy and safety of an intensive sUA-lowering strategy of verinurad (RDEA3170), a novel urate transport inhibitor and febuxostat in patients with Type 2 diabetes mellitus (T2DM) and albuminuria (clinicaltrials.gov: NCT03118739).

Objectives: To compare the efficacy of verinurad + febuxostat to placebo in reducing albuminuria in patients with T2DM.

Methods: A Phase 2 parallel group, randomised, double-blind, placebo-controlled clinical trial. Patients were assigned 1:1 to either verinurad 9 mg + febuxostat 80 mg (n=32) or placebo (n=28). Inclusion criteria: aged ≥18 years, sUA concentration ≥6.0 mg/dL, estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m², urinary albumin-to-creatinine ratio (UACR) 30–3500 mg/g and T2DM diagnosis. Exclusion criteria: history of gout or recent treatment with urate-lowering therapy. The primary endpoint was change in UACR. Secondary endpoints included sUA, renal function biomarkers, and eGFR.

Results: Baseline characteristics were similar between groups. For treatment vs placebo, respectively, mean (SD) sUA was 7.5 (1.6) vs 7.0 (0.8) mg/dL, eGFR was 59.2 (25.3) vs 68.1 (23.2) mL/min/1.73 m², and UACR was 459 (825) vs 412 (548) mg/g at baseline. The study met the primary endpoint as verinurad/febuxostat reduced UACR by 39% vs placebo after 12 weeks of treatment (p=0.07,

Background: The association between serum urate and hypertension continues to be controversial. Animal models and studies in adolescents provided strong support of urate-lowering therapy (ULT) efficacy to improve early hypertension (1), while one recent randomized-controlled study in adults failed to find benefit (2).

Objectives: To test the hypothesis that serum urate reduction with allopurinol would lead to blood pressure reductions in young adults with pre-hypertension.

Methods: Single center, double-blinded, crossover trial in which participants were randomly assigned to allopurinol (300 daily mg) or placebo for a period of one month each. Adults ages 18-40, with baseline systolic blood pressure (SBP) ≥ 120 and < 160 mm Hg or diastolic blood pressure ≥ 80 and < 100 mm Hg, and serum urate ≥ 5.0 mg/dL (297.4 μmol/L) or ≥ 4.0 mg/dL (237.9 μmol/L) (men or women, respectively) were enrolled. Main exclusion criteria included chronic kidney disease, gout, or use of ULTs. The primary outcome was change from baseline in SBP assessed by 24 hour ambulatory blood pressure monitoring. Safety assessments were also conducted.

Results: 95 participants were randomized, and 82 completed study participation. The primary outcome was significant (p=0.001) and by a non-significant -0.04 ± 0.75 mg/dL (2.4 ± 44.6 μmol/L) while taking placebo. SBP changed by -0.71 ± 8.21 mmHg during the period assigned to placebo versus -0.16 ± 7.33 mmHg during the period assigned to placebo. The difference between these changes in SBP was not significant (p=0.52) (Table 2). Changes in diastolic blood pressure and mean ambulatory blood pressure also a not significantly different during allopurinol and placebo exposure periods. In post hoc analyses, there was a trend towards significant blood pressure decreases in the small participant subgroup with serum urate of > 6.5 mg/dL (386.7 μmol/L) at baseline visit. No allopurinol hypersensitivity events or other serious adverse events were observed.

Conclusion: In the intention-to-treat analysis, urate-lowering therapy with allopurinol in young adults did not lead to reductions in blood pressure when compared with placebo. Blood pressure reductions with allopurinol may be limited only to participants with higher baseline serum urate levels.

IMPROVING MENTAL WELLBEING - COACHING PEERS TO USE TOOLKIT FOR MIND

Disclosure of Interests: Angelo Gatto: None declared, David Calhoun: None declared, Elizabeth Rahn: None declared, Suzanne Oparil: None declared, Paul Muntner Grant/research support from: Dr. Muntner declares research grant from Amgen, Peng Li: None declared, David Redden: None declared, Tanja Dudenbostel: None declared, Jeff Foster: None declared, Stephanie Biggers: None declared, Daniel Feig: None declared, Kenneth Saag Grant/research support from: Amgen, Ironwood/AstraZeneca, Horizon, SOBI, Takeda, Consultant for: Abbvie, Amgen, Ironwood/AstraZeneca, Bayer, Gilead, Horizon, Kowa, Radius, Roche/Genentech, SOBI, Takeda, Teijin DOI: 10.1136/annrheumdis-2019-eular.1623

Tina Hongisto, The Finnish Rheumatism Association, Helsinki, Finland

Background: The theme for the Finnish Rheumatism Association for 2019 is Mind and Me. The Age Institute in Finland launched a project called Mental Wellbeing to Promote Older People’s Knowhow to Face Life’s Challenges and the project was piloted at the Finnish Rheumatism Association in 2018. During the pilot project, staff members from the Finnish Rheumatism Association and volunteers from its member organisations were trained as Tools for Mind Coaches. This training gave new tools for peer support targeting older people and their mental wellbeing. The Coaches may use the tools developed by the Age Institute, and these include Mind Tools, Senior Mind Pack of 52 cards, Nature Attraction Path, A Guide for Life Skills Coaches and a pocket book on Mental Wellbeing. The project especially targeted older people and their families in challenging life situations by promoting their mental wellbeing.

Objectives: To disseminate the theme and activities of mental wellbeing in member associations. To utilise the tools for Mind in the activities of the Finnish Rheumatism Association and its member associations. To promote mental wellbeing to members.

Methods: In the pilot project in 2018 the Age Institute organized three mental wellbeing training sessions for peer support group coaches, each lasted 1-2 days. The Finnish Rheumatism Association provided the coaches with some of the Tools for Mind. The training sessions included theory and practices. Participants were introduced how to use the Tools for Mind and they were encouraged to think for other applications of the tools. Also the themes discussed included elements of mental wellbeing, solution-focused approach, organising peer support groups for old people with chronic illnesses and ethical principles for group activities.

Results: There were altogether 11 people from the Finnish Rheumatism Association and its member associations that finished the training for Mind Coaches. Feedback from the participants was positive and the Tools for Mind were not only considered as useful practical tools but they also increased self-confidence and enthusiasm for peer led support groups. Senior Mind Pack of 52 cards were described as multipurpose and having good visual quality. All Tools for Mind were considered as thought-provoking tools to start conversation. Practical tools help
to recognise new aspects of one’s own illness and they can be used to give support to people in different stages of their illness. Participants felt that forming groups and increasing cooperation between trained coaches and local associations need to be supported by the umbrella organisation, Finnish Rheumatism Association. Toools for Mind have successfully been used in a Fibromyalgia group and in senior groups for veterans (who did not have any RMDs).

Conclusion: The Finnish Rheumatism Association is creating new activities to endorse mental wellbeing. The training in 2018 will be used as a model for training coaches in mental wellbeing and it will be introduced in member organisations in 2019. Four training sessions will be arranged around Finland in the spring 2019.

The programme will follow the pilot project programme. Training includes learning how to use the tools for mental wellbeing, going through the elements of mental wellbeing, solution-focused practices, organising peer support groups for old people with chronic illnesses and ethical principles. If possible, it is always good to have a trained Coach in the training, to tell about his/her experiences of using the Tools for Mind, how people have reacted to using the tools, and what kind of challenges and good moments the coach has experienced in group work. In 2019, the tools are utilised for example in monthly tasks concerning mental wellbeing and the Senior Mind Pack of 52 cards are being used in the member organisation visits to start conversation.

Diagnostic challenges in vasculitis

OP0210 FALSE POSITIVES OF ULTRASOUND IN GIANT CELL ARTERITIS. SOME DISEASES CAN ALSO HAVE HALO SIGN
Elisa Fernández, Irene Monjo, Gemma Bonilla, Chamaida Plasencia, Maria-Eugenia Miranda-Carús, Alejandro Balza, Eugenio de Miguel. La Paz University Hospital, Rheumatology, Madrid, Spain

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in the elderly. The halo sign has been shown as an accepted valid test in the diagnosis of GCA in trained units[1-2]. However, to further improve the specificity, the sonographer should know some pathologies that can mimic halo signs since they also produce a hypoechoic increase of the arterial wall thickness.

Objectives: The aim of our study was to identify the causes and diseases that could be associated with the false positive diagnoses of GCA made by color Doppler ultrasound (CDUS).

Methods: Observational study of 305 patients with temporal artery CDUS findings compatible with GCA. The medical histories of these patients were reviewed and demographic, physical examination, clinical and analytical data were collected. The clinical diagnosis based on the long term follow-up of the patient was established as the definitive true diagnosis.

Results: 13 of the 305 cases included (4.3%) were false positives. The characteristics of these 13 patients and their final diagnoses are shown in table 1. 69.2% were women, while 30.8% were men. The mean age was 73.3 ± 8.0 years. Analytically, the mean ESR was 64.8 ± 42.3 mm/h, CRP 50.8 ± 60.0 mg/L, and hemoglobin 12.8 ± 2.0 g/dL. Five patients (38.5%) fulfilled the ACR GCA classification criteria and eight did not (61.5%). A temporal artery biopsy was performed in 8 of the 13 patients (61.5%), with negative results in all of them. Eleven patients had CDUS involvement of superficial temporal arteries. Five had 1 branch involved (38.5%), three 2 branches (23.1%), one 3 branches (7.7%) and two 4 branches (15.4%). In addition, two patients (15.4%) had isolated halo sign in the axillary arteries, one unilateral and the other bilateral. Regarding the definitive diagnosis, four patients were polymyalgia rheumatica (30.8%), three aneurysmatosis (23.1%), and there was one case of non-Hodgkin’s Lymphoma type T, osteomyelitis of the skull base, primary amyloidosis associated with multiple myeloma, granulomatosis with polyangiitis, urinary sepsis and narrow-angle glaucoma.

A percentage of false positives in the CDUS for the diagnosis of GCA is low. Nevertheless, other some diseases can also produce halo sign and the clinician should be aware of this to improve the accuracy of the ultrasound test.

OP0211 ULTRASONOGRAPHY CAN POTENTIALLY BE THE FIRST CHOICE OF IMAGING IN SUSPECTED EXTRA-CRANIAL GCA
Hilde Hop1, Douwe J Mulder1, Maria Sandovic2, Andor Glaudemans2, Arle Van Roon1, Riemer Star1, Elisabeth Brouwer1. 1University Medical Center Groningen, Internal Medicine, Groningen, Netherlands; 2University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Color duplex ultrasonography (CDU) is recommended as first line of imaging in patients suspected for cranial GCA [1]. However, extra-cranial involvement without temporal artery involvement is found in up to 40% of GCA patients [2]. CDU is very suitable to also assess extra-cranial artery inflammation, of which the axillary artery is relatively easy to assess. However, data on the value of CDU in extra-cranial GCA is limited [3].

Objectives: We aimed to [1] evaluate the performance of axillary artery CDU in patients with extra-cranial GCA by comparing CDU findings with [18F]-FDG PET/CT findings. Furthermore, to [2] compare the sensitivity and specificity of adding assessment of axillary arteries to temporal artery CDU, over temporal artery CDU only.

Methods: Consecutive patients suspected of GCA who underwent CDU examination of the temporal and axillary arteries between 2013 and 2017 were

DIGESTIVE INVOLVEMENT IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME FROM THE SJOGRENRENSER SPANISH REGISTRY

Shelia Melchor1, Carlos Sánchez-Piedra2, Monica Fernandez Castro3, Jose Luis Andreu4, Victor Martinez Taboada5, Alejandro Olive6, Jose Rosas7, Patricia Carrera1, SjogrenSer Project.1 Hospital Universitario 12 de Octubre, Rheumatology, Madrid, Spain; 2 Unidad de Investigación SER, Madrid, Spain; 3 Hospital Puerta de Hierro Majadahonda, Madrid, Spain; 4 Hospital Marques de Valdecilla, Santander, Spain; 5 Hospital Germans Trias i Pujol, Barcelona, Spain; 6 Hospital Mariscal Cueto, Alicante, Spain

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands. Among the extraglandular manifestations, digestive involvement (DI) is frequent, and may condition the quality of life of these patients. There are few studies that systematically analyze gastrointestinal involvement in pSS.

Objectives: To describe the prevalence of DI in patients with pSS included in SjogrenRENSER Spanish registry and the phenotype of these patients, and to analyze their association with other clinical manifestations, serological markers, activity index and treatments used.

Methods: Transversal multicenter study that includes all patients of SJOGRENRENSER registry (patients who meet 2002 pSS classification criteria), a study conducted in 33 units of rheumatology in Spain between 2014-2016, which collected demographic and clinical and serological data (1). Patients were classified according to the presence of patients, GCA that included esophagus, stomach, intestine, liver and pancreas). A descriptive analysis was done, with means and standard deviations, frequencies and proportions. Student t for quantitative variables and Chi2 for qualitative ones were performed to evaluate differences between groups. The association of DI with other variables was analyzed by bivariate and multivariate binomial logistic regression analysis. In the multivariate model all variables with p <0.2 in the bivariate were included, and the effect of age and sex was controlled.

Results: From 437 patients included (95% women, median age of 58 years), 59 (13.5%) had some DI (21 (36%) chronic atrophic gastritis, 12 (20%) esophageal dismotility, 3 (5%) lymphocytic colitis, 23 (39%) other), 54% of patients developed DI at the time of pSS diagnosis or later, and 45% before the diagnosis, with a mean age of 49 years at the onset of pSS symptoms. Patients with DI were older, both at diagnosis, onset of pSS symptoms and inclusion in the cohort, than those without it. There were no differences in the ESSDAI index between both groups.

Conclusion: In patients with DI more thyroid involvement and C3 hypocomplementemia. In addition, patients with DI had been treated more frequently with glucocorticoids and immunosuppressants. In the multivariate analysis, DI was significantly associated with older age at diagnosis (OR 1.03 (1.00-1.05); p=0.05), more C3 hypocomplementemia (OR 2.40 (1.0-5.26); p=0.02) and absence of anti-Ro antibodies (OR 0.33 (0.12-0.87) p=0.034). Significant factors for DI were sex, diarrhea and Raynaud.

THURSDAY, 13 JUNE 2019

Difficult to manage Sjögren’s syndrome and Myositis

OP0212

MYOFASCIA-DOMINANT: INFLAMMATION DETECTED ON WHOLE BODY MRI PREDICTS RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE IN PATIENTS WITH DERMATOMYOSITIS

Kohei Kanie, Michihiro Kono, Michiko Kono, Yuichiro Fujieda, Masaru Kato, Toshiyuki Bohgaki, Olga Amengual, Kenji Oku, Shinuke Yasuda, Tatsuya Asumi, Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan

Background: Rapidly progressive interstitial lung disease (RPILD) is a major cause of death in patients with dermatomyositis (DM). Early diagnosis and aggressive immunosuppressive therapy are required in RPILD to improve the prognosis. Clinically amyopathic dermatomyositis (CADM) and anti-melanoma differentiation-associated gene 5 antibody are known as risk factors for RPILD. However, 70% of the patients with CADM do not develop RPILD. Whole-body magnetic resonance imaging (WB-MRI) can detect inflammation of whole muscle and myofascia. Although recent studies have indicated that MRI could be...
useful for assessing disease activity\(^2\), the relation between MRI findings and RPILD has not been investigated.

**Objectives:** In this study, we assessed whether WB-MRI findings are related with RPILD in patients with DM.

**Methods:** This retrospective study comprised 33 patients with DM who underwent WB-MRI in our hospital before the initiation of treatment for myositis. Muscular and myofascial signal abnormalities were scored on 42 muscular groups. The ratio of myofascial score to muscular score (myofascia/muscle ratio) was calculated and used to evaluate myofascia-dominant inflammation. RPILD was defined as the acute onset and rapid worsening of dyspnea, hypoxemia and radiographic ILD/fibrosis within 1 month.

**Results:** Of 33 patients, 16 were CADM, and 24 had ILD, including 8 patients with RPILD. All patients including CADM showed abnormal signal intensity in muscle and myofascia (scores median: 15 and 21, respectively). Muscle scores positively correlated with serum level of creatine kinase (\(r=0.672, p<0.001\)). The patients with RPILD showed a significantly higher myofascia/muscle ratio compared with that in the non-RPILD patients (2.167 vs 1.000; \(p=0.018\)). Logistic regression analysis identified myofascia/muscle ratio >1.53 (odds ratio: 141.90, \(p=0.042\)) and older age (odds ratio: 1.15, \(p=0.041\)) as independent risk factors for RPILD.

**Conclusion:** We newly defined myofascia-dominant inflammation using WB-MRI as a predictor to develop RPILD in patients with dermatomyositis.

Anergy, exhaustion or post-activation in autoimmunity – facts and future consequences

Ana-Luisa Stefanski\(^1,2\), Annika Wiedemann\(^3\), Karin Reiter\(^1\), Andrea Lino\(^1\), Thomas Dörner\(^1\), "Charité Universitätsmedizin, Rheumatology and Clinical Immunology, Department of Medicine and German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany; "University Hospital Inselspital Bern, Rheumatology, Allergology and Immunology, Bern, Switzerland

**Background:** Prior studies on systemic lupus erythematosus (SLE) B cells reported an altered responsiveness to TLR9 stimulation, such as proliferation, cytokine production as well as indications for impaired T and B cell interaction \([1]\). The role of co-inhibitory and co-stimulatory (check-point) molecules in this setting has not been delineated in detail so far.

**Objectives:** Assess the expression of co-inhibitory (PD-1, PD-L1 and PD-L2) and co-stimulatory molecules (CD86 and CD40) by SLE B cells after in vitro stimulation and their potential contribution for B cell hyporesponsiveness in SLE.

**Methods:** PBMCs from 10 SLE patients and 10 healthy donors (HD) were stimulated with IL-2/IL-10, anti (α) - B cell receptor (BCR), CpG and CD40L alone or in combination. Expression of PD-1, PD-L1, PD-L2 as well as CD86, CD40 on CD19 +CD20+ B cell subsets after 48h stimulation was analyzed by FACS. CD71 was employed to measure proliferation of CD19 “CD20” B cells after 48h stimulation.

**Results:** SLE B cells exhibited a substantially decreased upregulation of PD-L1 (\(p=0.0006\)) and CD86 (\(p=0.0188\), Fig.1) associated with significantly reduced B cell proliferation (\(p=0.0039\)) after 48h stimulation with CpG alone and in combination compared with HD. While TLR9 engagement in SLE B cells appeared to be abnormal, activation of CD40 resulted into a consistent upregulation of both, inhibitory and stimulatory molecules. PD-L1 was positively correlated with B cell proliferation (\(p=0.003\)). Notably, the expression of PD-L1 and CD86 correlated inversely with Siglec-1, as surrogate marker for interferon signature (\(p<0.0001\) and \(p=0.0021\)) respectively). PD-L1 expression correlated inversely with cSLE-DAI (\(p=0.0087\)).

**Conclusion:** Hyporesponsive/anergic lupus B cells are characterized by a functionally diminished PD-L1 and CD86 upregulation associated with reduced proliferation and clinical activity. The data mandate evaluations of innovative therapeutic interventions in SLE.

**DOIs:** 10.1136/annrheumdis-2019-eular.3186
Fracture liaison service: an opportunity for prevention

Background: Osteoporosis is a well-known complication of rheumatoid arthritis (RA) (1). NICE advises that health providers do not routinely assess fracture risk in people with RA aged under 50 years unless they have other major risk factors. However, studies suggest that young people with RA are at increased fracture risk even before age 50 (2-4).

Objectives: To measure the incidence and risk of first and subsequent fracture in adults with RA aged under 50 in the UK.

Methods: A retrospective observational cohort study with matched control using data from Clinical Practice Research Datalink (CPRD) of adults ≥18 years with diagnosis of RA recorded from 1987 to 2016. Patients were followed from index date to the first fracture and subsequent fracture. Cases were adults with a new diagnosis of RA with at least one day of follow-up during the period. These cases were matched to 3 controls by age, sex, GP surgery and calendar year. The date of RA diagnosis date is the index date for cases and their matched controls. CPRD data has a high level of data validity in reporting of fractures but subsequent fractures may be recorded more than once. In this analysis when subsequent fractures were of the same body part the fracture had to occur at least 6 months after the previous fracture to be classified as a “subsequent fracture”.

“First fracture” is the first fracture occurring after the index. “Subsequent fracture” is the fracture occurring after the first fracture. “Pre-index fracture” is a fracture that occurs before the index date.

Results: The characteristics of the study population are shown in Table 1.

</table>

The incidence rate of first fracture for cases was 9.02 per 1000-person years (95% CI 8.46-9.61), for controls 6.85 per 1000-person years (95% CI 6.55-7.15). The incidence rate ratio (IRR) for first fracture was 1.32 (95% CI 1.22-1.426; p<0.00). The incidence rate of subsequent fracture was 1.78 (95% CI 1.55-2.05) per 1000-person years for cases and 1.17 (1.05-1.29) per 1000-person years for controls. The IRR for subsequent fracture was 1.53 (95% CI 1.28-1.833; p<0.00). A Cox’s proportional hazards model was used to estimate the hazard (or risk) of first and subsequent fracture for cases and controls stratified by age. Those with a pre-index fracture and with a glucocorticoid prescription prior to the index date had significantly higher hazard ratios for first and subsequent fracture. Women had a higher hazard ratio for first fracture.

Conclusion: This study shows that the incidence of fracture in patients with RA aged under 50 is significantly higher than in matched controls. This is true for the first fracture and for the subsequent fracture and is significantly higher for women in those under 50 for first fractures.

EVALUATION OF PATIENTS’ EXPERIENCES OF AN INTENSIVE SMOKING CESSATION INTERVENTION FOR PEOPLE WITH RHEUMATOID ARTHRITIS

Ida Kristiane Roelsgaard1, Thordis Thomsen2, Mikkel Østergaard3, Grete Semb4, Lena Andersen5, Bernt Appel Esbensen6, Rigs Hosspitalet, Center for Rheumatology and Spine Diseases, Copenhagen Center for Arthritis Research (COPECARE), Gentofte, Denmark; 2Copenhagen University Hospital Herlev; 3Glostrup, Denmark; 4Rheumatology and Spine Diseases, Copenhagen Center for Arthritis Research (COPECARE), Gentofte, Denmark; 5The Danish Rheumatism Association, Gentofte, Denmark

Background: Smoking is considered one of the most important modifiable environmental risk factors to the pathogenesis of rheumatoid arthritis (RA). Smoking may also exacerbate the symptoms of RA. A randomized controlled trial (RCT) testing the effect of an intensive smoking cessation intervention on smoking cessation and disease activity in people with RA is currently being carried out (1).

Objectives: To evaluate how people with RA experienced an intensive smoking cessation intervention.

Methods: We conducted a qualitative study with individual interviews. Participants were recruited consecutively from the intervention group in a smoking cessation RCT after having completed both the smoking cessation intervention and the three-month follow-up visit. The analysis was based on thematic analysis (2). One patient research partner was involved in all phases of the study.

Results: In total 12 patients with RA were included (6 female, mean age 58 years (range 33-71)). We identified seven themes illustrating participants’ experiences of the smoking cessation intervention. The themes were: Instilling hope for smoking cessation referring to the initial invitation to participate in the RCT and the allocation to the intervention group, which participants seized as a chance to stop smoking, Having a fellow traveler on the road to smoking cessation referring to their cooperation with the smoking cessation counselor who was important for maintaining motivation for smoking cessation, Tangible evidence that smoking cessation makes a difference referring to improved carbon monoxide levels which motivated endeavors to quit smoking, Apprehension – fear of a new dependence referring to participants’ fear of becoming addicted to nicotine replacement therapy instead of smoking, Breaking habits referring to ongoing reflection on and efforts to quit smoking using the tools and knowledge obtained from the smoking cessation intervention, Why wasn’t I told? Referring to the lacking provision of information on smoking and RA from health professionals, and Denial referring to neglect of the detrimental impact of smoking on RA symptoms and overall health.

Conclusion: The participants were grateful for the offer to participate in a RCT and a smoking cessation intervention because it created an opportunity for them to stop smoking. They valued getting concrete information about detrimental effects of smoking on RA and RA treatment. Many requested that health professionals focus more proactively on smoking and smoking cessation.

LUPUS EUROPE YOUTH PANEL – WHAT WE LEARNED FROM YOUNG PEOPLE LIVING WITH LUPUS
Alain Cornet1,2, Jeanette Andersen1. 1Lupus Europe, Romford, Essex, United Kingdom; 2CLAIR, St Maur, Belgium

Background: Since 2014, Lupus Europe conducts patient panels, where 10 to 12 persons from all over Europe living with lupus discuss the selected topic guided by facilitators living with lupus themselves. This allows to capture qualitative feedback of relevance, without the obstacle of the “white blouse”. In 2018, 10 Young (18-27) European Lupus patients (8 female, 2 male) with diverse Lupus types met to discuss “Lupus and youth”.

Objectives: Understand specificity of being young with lupus to better include young patients in Lupus groups action plans

Methods: 11 young patients, mostly with little or no involvement in patient groups were recruited through Lupus Europe’s network. They were asked to send ahead of time their top challenges/issues living with lupus as well as their key questions for the panel. This input was used to build the 2 days program itself. Mid May, 10 of the 11 met face-to-face in Brussels, and explored multiple aspects of their input though 7 specifically designed interactive workshops

Results: While they considered taking pills every day as a key problem, they preferred to focus on the collective issues of being understood by friends and family and having to live with limitations.

A big “Wow” was the feeling of guilt expressed by several female participants (guilt of imposing limits to their partners, guilt of not being able to do as much as others, …), a very important underlying dimension of their social and affective life, which is likely much misunderstood by doctors and patient organizations; young people with lupus remain fundamentally more positive on their life with lupus than the average patients. While they perceive lupus as being “all over their lives”, they refuse to be ruled by it.

They view the future of a LUPUS EUROPE youth group as a “virtual group” on social media, with minimal commitment required, but bringing together “friends” around highly visual messages, short stories and the exchange of ideas that could lead to small group gatherings.

On the medical front, when we probed what would drive them to consider joining a clinical trial, clear first media is their lupus doctor, second are national lupus groups and LUPUS EUROPE. Other medias have a very limited impact.

Conclusion: Young patients needs must be addressed in a more aspirational way and using more virtual tools than average patients (more focused on health issues and geographic proximity). The feeling of guilt of young women with regards to their affective life must be further explored to give them confidence and reassurance.

Oligomeric S100A4 induces monocyte innate immune memory

Emmanuel Karuzakas1, Agnieszka Pajak1, Niels Riksen2, Leo Joosten2, Mihai Netea3, Esther Latung4, Eric Stroons2, Adrian Ciurea3, Olivier Deltour1, Mariam Grigorian1, Michel Neidhart1.

1University Hospital Zurich, Zurich, Switzerland, 2Radboud University Medical Center, Nijmegen, Netherlands, 3Academic Medical Center, Amsterdam, Netherlands, 4University of Copenhagen, Copenhagen, Denmark

Background: Trained immunity is a process of innate immune memory in which a primary stimulus such as beta-glucan can enhance the response of monocytes to secondary stimuli. The concept that specific damage associated molecular patterns (DAMPs) in rheumatoid arthritis (RA) could cause trained immunity which is involved in the disease pathogenesis has not been investigated so far. The oligomeric form of S100A4 (oS100A4) is a potent inducer of pro-inflammatory cytokines which is found in the plasma of patients with rheumatoid arthritis (RA).

Objectives: Aims to investigate whether oS100A4 induces trained immunity in monocytes and characterize the molecular pathways involved in this process.

Methods: Monocytes were isolated from peripheral blood of healthy donors using density gradient centrifugation. To induce training, monocytes were stimulated with 2 μg/ml of oS100A4 and 1 μg/ml β-glucan for 24 hours (n=8). We searched for differential gene expression by RNA sequencing in order to identify factors that play a role in the initial stages of trained immunity. On day 4, LPS (10 ng/ml) was added. After 24 hours, IL-6 and TNFα were measured in cell culture supernatants by ELISA. The training protocol was repeated in monocytes transfected with PRDM8 siRNA using Lipofectamine (n=4). In addition, plasma levels of S100A4, CCL5 and IL-6 were measured in a cohort of RA patients (n=36) and healthy controls (n=18) by ELISA and PRDM8 transcripts in RA peripheral blood monocytes were quantified by RT-PCR.

Results: Monocytes primed with oS100A4 showed increased releases of IL-6 and TNFα in response to a subsequent LPS stimulation. RNA-Seq revealed the differential expression of 902 genes upon oS100A4 and 667 upon beta-glucan (mean and median > 2 fold, FDR<0.01). Among the differential genes, 601 were upregulated in S100A4 and 447 in beta-glucan stimulated cells. Upregulated genes included chemokine/cytokine and epigenetic factors. When we compared the upregulated genes from oS100A4 and beta-glucan stimulated cells, 63% of chemokines/cytokines and 50% epigenetic factors were identical. Interestingly, the histone methyltransferase PRMD8 was found to be a major regulator of pro-inflammatory mediators by both stimuli. siRNA knockdown of PRMD8 abolished the training effect of oS100A4 by decreasing the LPS induced release of IL-6 and TNFα (p<0.01). Furthermore, we analyzed a cohort of monocytes taken from RA patients. Higher PRDM8 transcription in RA monocytes was associated with increased plasma levels of CCL5 and IL-6 (r = 0.52 and 0.55, p < 0.01). RA patients in remission versus active patients showed significantly lower PRDM8 transcripts (p = 0.05).

Conclusion: Oligomeric S100A4 induced trained immunity in monocytes similarly to beta-glucan. PRDM8 histone methyltransferase is involved in this process that appears to be activated in monocytes of RA patients.

Disclosure of Interests: Emmanuel Karuzakas: None declared, Agnieszka Pajak: None declared, Niels Riksen: None declared, Leo Joosten: None declared, Mihai Netea: None declared, Esther Latung: None declared, Eric Stroons: None declared, Adrian Ciurea: Consultant for: AbbVie, Celgene, Janssen-Cilag, MSD, Eli Lilly, Novartis, Pfizer, UCB, speakers bureau: AbbVie, Celgene, Janssen-Cilag, MSD, Eli Lilly, Novartis, Pfizer, UCB, Oliver Deltour: Grant/research support from: Prof. Distler has/had consultancy and may even have life-threatening sequelae. This disease is often under-screened, especially in at-risk populations that require multidisciplinary care such as patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS) [1,2,3,4,5,6]. Moreover, a recent study showed that the scoranographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) with a threshold at 145 Hounsfield Units (HU) identified 96.6% of patients in the general population with a vertebral fracture (VF), whereas DEXA (with a T-score ≤ 2.5) identified only 39% of these patients [7].

Objectives: The aim of the study was to identify the prevalence of vertebral fractures (VFIs) and to measure the scoranographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) based on CT-scan examinations of patients with rheumatoid arthritis (RA), patients with ankylosing spondylitis (AS) and in a control group.

Methods: This monocentric and retrospective study included patients who were evaluated between 2009 and 2017 with a diagnosis of RA based on the ACR/EULAR criteria, those with a diagnosis of AS based on the New-York criteria, and a RA-matched control group. All of the patients received a CT-scan. The osteoporosis risk factors, data from dual energy X-ray absorptiometry (DEXA) and clinical characteristics were collected. VFIs were determined via CT-scans according to the Genant classification, and the SBAC-L1 was measured in Hounsfield units (HU). SBAC-L1 ≤ 145 HU (fracture threshold) defined patients at risk of VFIs.

Results: A total of 244 patients were included (105 RA, 83 AS, 56 controls). The AS group was younger and primarily consisted of males. Of the 4,365 vertebrae studied, 66 osteoporotic VFIs were found in 36 patients: 18 (17.1%) patients with RA, 13 (15.7%) patients with AS and 5 (8.9%) controls. The SBAC-L1 was 142.2 ± 10.7 HU. A T-score -2.5 SD and a SBAC-L1 £ 145 HU were significantly lower in the RA and AS groups than in the control group. Furthermore, SBAC-L1 ≤ 145 HU was associated with a VF (OR = 2.35 [95% CI: 1.12-4.92] and 2.06 [95% CI: 1.04-4.10], respectively).

Conclusion: The SBAC-L1 was significantly lower in the RA and AS groups than in the control group. Furthermore, SBAC-L1 ≤ 145 HU was associated with a higher risk of VFIs, with an odds ratio similar to that of a DEXA.

Background: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. We have conducted clinical trials of E6011, a novel humanized anti-FKN monoclonal antibody, for patients with rheumatoid arthritis (RA) in Japan.

This is the first report of efficacy and safety results of E6011 from a Phase 2, multicenter, randomized, double-blind, placebo-controlled, parallel-group comparison study in RA patients inadequately responding to methotrexate (NCT02060438).

Objectives: To evaluate efficacy and safety of three dose of E6011 compared with placebo.

Methods: During the 24-week double-blind period, patients with moderately to severely active RA of inadequate response to MTX were randomly assigned to E6011 100 mg, 200 mg, 400/200 mg, or placebo groups at a 1:2:2:2 ratio. In the E6011 100 mg, 200 mg, and placebo groups, subjects received 100 mg, 200 mg, or placebo at Weeks 0, 1, 2, and every 2 weeks subsequently. In the E6011 400/ 200 mg group, subjects received 400 mg at Weeks 0, 1, 2, 4, 6, 8, 10 and then 200 mg every 2 weeks subsequently.

Results: A total of 190 subjects (54 in the placebo group, 28 in the 100 mg group, 54 in the 200 mg group, 54 in the 400/200 mg group) received study drug. Of the 190 subjects, 169 completed and 21 discontinued study treatment prematurely during the 24-week double-blind period. The ACR20 response rate at Week 12 (non-responder imputation), the primary endpoint, was 37.0% in the placebo group, 39.3% in the 100 mg group, 54.7% in the 200 mg group, and 57.4% for 400/200 mg. In addition, we focused on CD16+ monocytes which highly expressing FKN receptor/CX3CR1 as a blood biomarker that linked to the clinical response to E6011. The whole patient population was divided into 2 groups according to the median value of baseline CD16+ monocyte percentage (Median: 10.35%). Much clearer ACR20 response was observed in a dose dependent manner in the subjects who showed higher baseline CD16+ monocytes over the median at Week 24 (NRI) (30.0% for placebo, 46.7% for 100 mg, 57.7% for 200 mg, and 69.6% for 400/200 mg) although such fashion was obscure dependent manner in the subjects who showed higher baseline CD16+ monocytes over the median at Week 24 (NRI) (30.0% for placebo, 46.7% for 100 mg, 57.7% for 200 mg, and 69.6% for 400/200 mg) although such fashion was obscure in the subjects below the median value. Adverse events that occurred in >5% of subjects in any E6011 group were nasopharyngitis, upper respiratory tract infection, stomatitis, bronchitis, back pain, pharyngitis, and dental caries. As a results, E6011 was well tolerated with no notable safety concerns at doses of 100, 200, and 400/200 mg when administered subcutaneously for 24 weeks.

Conclusion: E6011 provided clinical improvements with a good safety profile in RA patients with inadequately responding to MTX. Especially, a higher efficacy of E6011 was suggested in patients with higher baseline CD16+ monocytes (%).
RESULTS OF A PHASE 2 STUDY OF RG6125, AN ANTI-CADERHIN-11 MONOCONAL ANTIBODY, IN RHEUMATOID ARTHRITIS PATIENTS WITH AN INADEQUATE RESPONSE TO ANTI-TNFALPHA THERAPY

Rebecca Finch1, Alexandre Sostelly2, Kim Sue-Ling3, Angela Blauere2, Guillermette Duchateau-Nguyen5, Lida Ukarma4, Claire Petry5, Patarani Ravra6, Peter Villiger7, Uwe Junker8,1, Roche Products Ltd, Welwyn, United Kingdom; 2Roche Innovation Center Basel, Basel, Switzerland; 3Roche Innovation Center New York, New York, NY; 4United States of America; 5Inselstippen Bern, Bern, Switzerland

Background: Cadherin-11 is expressed on fibroblasts in joints of RA patients and augments local fibroblast-mediated inflammation, pannus formation and tissue invasion (1). RG6125 is a novel humanized monoclonal antibody directed against Cadherin-11.

Objectives: To assess the safety, tolerability and efficacy of RG6125 as adjunctive treatment in patients with moderately to severely active RA and an inadequate response to anti-TNF-alpha therapy.

Methods: The Phase 2 study was conducted as a multicenter, randomized, double-blind, placebo-controlled study. Patients were randomly assigned (2:1) to receive 810 mg of RG6125 or placebo by IV infusion. In the treatment period, patients received RG6125 or placebo IV infusions twice every two weeks and up to 12 doses for a total of 4 dose administrations up to Week 12. The primary efficacy endpoint was the proportion of patients with ACR50 response at Week 12.

Results: Demographics: 109 patients were randomized (98 female) to either placebo (N=37) or RG6125 (N=72) and were included in the efficacy analysis population. 107 patients were included in the safety analysis population (37 placebo, 70 RG6125). The median age was 55 years (22–78), and 52% were female. The median RAMRIS Osteitis Score at baseline was 1.6% (95% CI 1.6, 2.3), while for those with TNFi in utero exposure, it was 2.3% (95% CI 1.6, 3.0). In children born to unaffected mothers, the percentage of serious infections was 1.6% (95% CI 1.6, 1.7).

Conclusion: RG6125 was well tolerated with only mild to moderate AEs. RG6125 did not show a discernible treatment effect in RA patients in combination with anti-TNFalpha-blockers over placebo.

Non-responder imputation used for missing ACR responses. LOCf used for missing SJC/TJC. For ACR missing CRP has been imputed with ESR if available. No imputation for other missing components. No imputation for missing DAS28, CDAI, HAO-Di or MRI RAMRIS scores.

* ANCOVA adjusted for baseline score and prior anti-TNF-alpha therapy duration. MRI RAMRIS score is combination of the wrist and 1-5 MCP joints, and are exploratory endpoints.

SERIOUS INFECTIONS IN OFFSPRING EXPOSED IN UTERO TO NON-TNFI BIOLOGICS AND TOFACITINIB

Evelyne Vinge1, Yvan St-Pierre2, Cristiano Moura4, Jeffrey Curtis2, Sasha Bernadsky1, McGill University, Divisions of Rheumatology and Clinical Epidemiology, Montreal, Canada; 3McGill University Health Centre Research Institute, Montreal, Canada; 4University of Alabama at Birmingham, Birmingham, United States of America

Background: During pregnancy, maternal circulating immunoglobulins G (IgG) are actively transported across the placenta through their Fc portion. Thus, TNFi and other biologics harbouring an Fc part have the potential to transfer across the placenta, often reaching higher fetal than maternal levels.[1] In addition, it is postulated that small-molecule drugs may cross the placenta, although this remains unconfirmed. As fetuses could be exposed to therapeutic (or potentially supra-therapeutic) levels of biologics and small molecules, there are concerns that these agents could cause immune suppression in exposed offspring.

Objectives: We compared the risk of serious infections in children born to mothers with chronic inflammatory diseases who used non-TNFi biologics or tofacitinib during pregnancy, versus unexposed offspring and children exposed to TNFi in utero.

Methods: We identified all women with ≥1 hospitalization for delivery after a diagnosis of rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriasis (PsO), psoriatic arthritis (PsA), or inflammatory bowel diseases (IBD), and a randomly selected group of unaffected mothers, matched: ≥1 for age, year of delivery, and state of residence, using MarketScan data (2011-2016). Only women continuously enrolled within MarketScan for ≥12 months prior to delivery and with available child linkage were included. We defined tofacitinib, TNFi and non-TNFi biologic (i.e. abatacept, rituximab, tocilizumab, ustekinumab, vedolizumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertainment serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographic, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics). For each exposure group, we defined tofacitinib, TNFi and non-TNFi biologic exposure (i.e. abatacept, rituximab, tocilizumab, ustekinumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographics, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics). For each exposure group, we defined tofacitinib, TNFi and non-TNFi biologic exposure (i.e. abatacept, rituximab, tocilizumab, ustekinumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographics, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics). For each exposure group, we defined tofacitinib, TNFi and non-TNFi biologic exposure (i.e. abatacept, rituximab, tocilizumab, ustekinumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographics, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics). For each exposure group, we defined tofacitinib, TNFi and non-TNFi biologic exposure (i.e. abatacept, rituximab, tocilizumab, ustekinumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographics, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics). For each exposure group, we defined tofacitinib, TNFi and non-TNFi biologic exposure (i.e. abatacept, rituximab, tocilizumab, ustekinumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. We also characterized all exposure groups according to maternal demographics, disease type, co-morbidities, pregnancy complications, and drug use (i.e. corticosteroids, DMARDs, biologics). For each exposure group, we defined tofacitinib, TNFi and non-TNFi biologic exposure (i.e. abatacept, rituximab, tocilizumab, ustekinumab) exposure based on ≥1 filed prescription and/or infusion procedure code during pregnancy and/or the conception period. We ascertained serious infections in the offspring based on ≥1 hospitalization with infection as a primary diagnosis, within the first year of life. SOLID TUMOUR OUTCOMES IN PATIENTS WITH RA TREATED WITH ABATACEPT AND OTHER DMARDs: RESULTS FROM A 10-YEAR INTERNATIONAL POST-APPROVAL STUDY

Teresa Simon1, Samy Suissa2, Mary Lou Skovron3, Thomas Friese1, Johan Askling4, Kaleb Michaud5, Sofia Pedrio6, Anja Strangfeld6, Maarten Boers7, Diane Lacalle7, Marc Hochberg8, Andres Gomez9, Bristol-Myers Squibb, Princeton, United States of America; 2McGill University, Montreal, Canada; 3Karolinska Institutet, Stockholm, Sweden; 4University of Nebraska Medical Center, Omaha, United States of America; 5FORWARD, The National Databank for Rheumatic Diseases, Victoria, British Columbia, Canada; 6German Rheumatism Research Centre, Berlin, Germany; 7VU University Medical Center, Amsterdam, Netherlands; 8Arthritis Research Center, Richmond, Canada; 9University of Maryland, Baltimore, United States of America

Background: The abatacept global post-marketing epidemiology programme includes observational studies based on biologic disease registries and healthcare claims database studies to evaluate infection and malignancy risks associated with abatacept treatment, as used in routine clinical practice.

Objectives: To assess the risk of solid tumour malignancies in patients with RA treated with abatacept vs conventional synthetic (cs)DMARDs and other biologic (b) or targeted synthetic (ts)DMARDs.

Methods: Data were analysed from four cohorts: two biologic registries (the Anti-Rheumatic Therapy in Sweden [ARTIS] register and the Rheumatoid Arthritis Observation of Biologic Therapy [RABBIT] German registry), a disease registry (FORWARD, The National Databank for Rheumatic Diseases in the USA) and a healthcare claims database (the population-based British Columbia Canadian RA Cohort [BC]). Exposure defined as “ever exposed” unless specified. Crude incidence rates (per 1000 patient-years of exposure) with 95% CIs were calculated for overall malignancies, breast, lung and lymphoma. Adjusted risk ratios (RRs) with 95% CIs were estimated using multivariable models adjusting for demographics, comorbidities and other potential confounders within each dataset, and were subsequently pooled using a random-effects model for meta-analyses.

Results: Patients treated with abatacept (~5100), csDMARDs (~74K) and other b/tsDMARDs (~74K) and other b/tsDMARDs (~37K) were followed up for a mean of 3.0–3.7, 3.0–6.2 and 3.0–4.7 years, respectively. Patients were mainly female (71–86%), with an age ranging from 55–63 years, and 4–94% had a history of malignancy. A greater number of abatacept-treated patients had been treated with ≥2 prior biologics (abatacept, 44–85%; csDMARDs, 11% [FORWARD] and other b/tsDMARDs, 0–19%). The incidence rate of overall malignancy in abatacept-treated patients was low (Table). Adjusted RRs (95% CIs) for abatacept vs csDMARDs (range: 0.8 [0.2, 3.4] to 1.3 [0.5, 3.3]; pooled estimate: 1.1 [0.8, 1.5]) and abatacept vs other b/tsDMARDs (range: 1.0 [0.4, 2.6] to 1.2 [0.6, 2.3]; pooled estimate: 1.0 [0.8, 1.3]) showed no increased risk in overall malignancy. Although individual registries showed a slight increase in breast (BC), lung (RABBIT) and lymphoma (ARTIS) cancers in patients treated with abatacept, numbers were too low to make an accurate comparative risk assessment.

Conclusion: While the development of malignancy is a potential risk associated with the use of immunomodulators, data from this large, international, post-marketing epidemiology programme suggest that the overall malignancy and breast, lung or lymphoma cancers were not significantly increased in patients treated with abatacept. These data are consistent with the established safety profile of abatacept.

Conclusion: The results of this Phase Ib study showed that GSK3196165 substantially improved the scores of a range of PRO measures among RA patients. In particular, there was a highly significant improvement in pain; a key symptom of RA. These effects were observed despite achieving much lower drug exposure than predicted. Further studies are required to confirm the additional patient relevant benefits that are expected to arise from increased exposure to GSK3196165.

REFERENCES:

Results: 37 patients were randomised to each treatment group. The observed numbers of biosimilars infliximab received; B, risk of treatment interruption according to the presence of anti-drug antibodies (ADA); and C, treatment retention within the observation period.

Background: Phase 3 (P3) clinical trials are the mainstay of drug development in all areas of medicine, including rheumatology, allowing to determine safety and efficacy of new drugs on their way to approval. Historically, efficacy results of P3 trials have often been disappointing with respect to the expectations set by phase 2 (P2) trials. It is unclear whether these observations are reflection of a true bias or merely a play of chance.

Objectives: To systematically compare efficacy results of P2 versus P3 trials in RA and investigate potential determinants of efficacy differences.

Methods: We performed a systematic review of disease modifying anti-rheumatic drugs (DMARDs) tested in P2 trials in rheumatoid arthritis (RA) over the last 20 years for which also P3 trials exist. We searched Medline, EMBASE, and the
Effectiveness of Influenza Vaccine in TNF Inhibitor-Treated Patients

Giovanni Adami, Angelo Fascio, Giovanni Orsolini, Alessandro Giollo, Davide Gatti, Maurizio Rossini. University of Verona, Rheumatology Unit, Verona, Italy

Background: Tumor Necrosis Factor-α inhibitors (TNFi) are immunosuppressive therapies that are known to increase infectious risk. Indeed, patients affected by TNFi requiring conditions are at higher risk of influenza compared with healthy controls. Furthermore, mildly reduced seroconversion rate after influenza vaccination had been reported in TNFi-treated patients. Nonetheless, the immune response is considered large enough to recommend influenza vaccination in all patients affected by rheumatoid arthritis, regardless of treatment. However, there are data showing that patients are not being vaccinated as recommended. In addition, given that subjects with autoimmune conditions treated with TNFi are at higher risk for influenza, the exact number needed to vaccinate (NNV) for this condition is still unknown.

Objectives: We sought to determine the NNV for influenza in TNFi treated patients and the cost for preventing one case of influenza compared with general population.

Methods: The present analysis included data from cohorts of healthy subjects [1] and TNFi treated patients [2]. We calculated NNV for preventing one case of influenza in each cohort. NNV is the required number of patients receiving vaccination to prevent one case of a given infectious disease. NNV is the inverse of the absolute risk reduction (ARR), which is calculated as following: Control Event Rate (CER) – Experimental Event Rate (EER). In addition, the NNV gives us the opportunity to calculate the cost for preventing one case of influenza, assuming a cost per vaccine from 20 to 40 $.

Results: In 71,221 healthy individuals influenza vaccination reduced influenza rate from 2.3% in individuals without vaccination (CER = 0.023) to 0.9% in vaccinated individuals (EER = 0.009). The calculated NNV is 71 (NNV = 1/ARR, ARR = 0.023 – 0.009), namely 71 healthy adults need to be vaccinated to prevent one of them experiencing influenza. The costs to prevent a case of clinical influenza in healthy controls would range from 1,420 to 2,840 $. On 15,132 patients exposed to adalimumab, influenza-related adverse events have been reported in 55 of 382 not-vaccinated patients (CER = 0.14) and in 8 of 179 vaccinated patients (EER = 0.04). In this population (mean age 53.5 years, predominantly white women) the NNV of influenza vaccines is 10 (NNV = 1/ARR, ARR = 0.144 – 0.045) and preventing a case of influenza would cost approximately from 200 to 400 $, which is largely lower when compared to healthy controls’ costs. The relative risk of influenza vaccination in healthy individuals (2.3% to 0.9%, RR 0.41, 95% confidence interval (CI) 0.36 to 0.47) and rheumatoid arthritis patients treated with TNFi (14.4% to 4.5%, RR 0.31, 95% CI 0.15 to 0.64) are similar, while there is a large difference between NNVs (71 vs 10) (Figure 1).

Conclusion: When estimating the effectiveness of vaccinations, clinicians should always include the calculation of the NNV and not only the calculation of relative risk, which might be misleading. The difference in NNV for influenza between healthy individuals and TNFi treated patients is due to a greater absolute risk for influenza in the latter group. The present analysis provides further evidences on the effectiveness of influenza vaccination in patients affected by rheumatoid arthritis receiving treatment with TNFi and should represent a call-to-action for all rheumatologists to consider vaccination in such patients.

How to treat SpA? From physiotherapy to new IL-17 blocking drugs.

OP0231 DUAL NEUTRALISATION OF IL-17A AND IL-17F WITH BIMEKIZUMAB WAS ASSOCIATED WITH IMPROVEMENTS IN PATIENT-REPORTED AND QUALITY-OF-LIFE OUTCOMES IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: RESULTS FROM A PHASE 2B, RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, DOSE-RANGING STUDY

Désirée van der Heijde1, Lianne S. Gensler2, Alou Deodhar3, Xenon Baraliakos4, Denis Poddubnyy5, Mary Katherine Farmer6, Dominique Baeten7, Jason Coane8, Marga Oortgiesen9, Maxime Dougados10.

Leiden University Medical Center, Leiden, Netherlands; 1UCSF, San Francisco, United States of America; 2OHSU, Portland, United States of America; 3Ruhr-University Bochum, Herne, Germany; 4Charité – Universitätsmedizin Berlin, German Rheumatism Research Centre, Berlin, Germany; 5UCB Pharma, Raleigh, United States of America; 6UCB Pharma, Brussels, Belgium; 7Cochin Hospital, Paris, France

Background: Ankylosing spondylitis (AS) is a chronic immune-mediated inflammatory disease primarily affecting the sacroiliac joints and spine, causing pain, stiffness and loss of mobility and function. These manifestations can severely impair patients’ quality of life (QoL).1 Dual neutralisation of IL-17A and IL-17F in addition to IL-17A alone in disease-relevant cell models.2 Results previously reported from this Phase 2b study (NCT02963506) demonstrated that, during the 12-week double-blind treatment period, bimekizumab provided substantial clinical improvements in disease outcome measures, including Assessment of SpondyloArthritis international Society (ASAS)40%, in patients with active AS.3

Objectives: To assess the impact of bimekizumab on patient-reported and QoL outcomes at Week 12 in patients with active AS.

Methods: In this 48-week Phase 2b study (double blind to Week 12 then dose blind to Week 48), 303 patients with active AS (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] ≥ 4; spinal pain ≥ 4 [0–10 numerical rating scale]), fulfilling the modified New York criteria, were randomised 1:1:1:1:1 to receive subcutaneous bimekizumab 16mg, 64mg, 160mg, 320mg or placebo QW for 12 weeks. Prior exposure to one anti-TNF therapy was permitted. Secondary and other endpoints included: BASDAI ≥ 50% improvement in BASDAI (BASDAI 50); ≥ 50% improvement in BASDAI (BASDAI 50); Bath Ankylosing Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life (ASQoL) and Patient’s Global Assessment of Disease Activity (PGA) at Week 12. Safety was also assessed.

Results: Over 287 (95%) patients completed the 12-week double-blind period. Baseline scores on patient-reported and QoL outcomes were similar across treatment groups (Table). At Week 12, BASDAI 50 was achieved by 23.7% of bimekizumab-treated patients versus 11.9% receiving placebo. All bimekizumab doses were associated with greater reductions in individual BASDAI components, including: fatigue (range: -1.6 to -2.5 vs -0.6); neck, back or hip pain (2.0 to -3.3 vs -1.2); discomfort due to tenderness to touch or pressure (-1.6 to -3.0 vs -1.1); level of morning stiffness (-2.5 to -3.5 vs -1.2) and duration of morning stiffness (1.7 to -3.3 vs -1.4) (Table). Compared with placebo, greater reductions from baseline were also achieved with bimekizumab for BASFI (-1.4 to -2.2 vs -1.0), BASDAI 50% improvement in BASDAI (BASDAI 50), Bath Ankylosing Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life (ASQoL) and Patient’s Global Assessment of Disease Activity (PGA) at Week 12. Safety was also assessed.

Conclusion: Dual neutralisation of IL-17A and IL-17F with bimekizumab was associated with improvements in patient-reported and QoL outcomes including pain, fatigue and tenderness in patients with active AS after 12 weeks of treatment. No new safety findings were observed versus previous studies of bimekizumab.3,4

OP0232 NETAKIMAB REDUCES THE DISEASE ACTIVITY OF RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS. RESULTS OF ASTERA STUDY

Inna Gaydukov1, V. Mazurov1, Shandor Edes2, Tatiana Dubinina3, Olga Nesmeyanova4, Elena Ilivanova4, Alena Kuzder2, Nikolaj Sorko4, Aleksander Kastanayany4, Tatjana Povarova4, Elena Zhugrova4, Tatjana Plaksina5, Pavel Sheshteny6, Tatjana Kostopina7, Olga Antipova8, Elena Smolyarchuk9, Oksana Totsa11, Diana Abdulganieva16, Diana Kretchikova17, Ivan Gordeev17, Vadim Tyrenko17, Aleksandra Strekova17, Anna Ereemeeva17, Ekaterina Chemyayeva17, Roman Ivanov17, Metchikov North-Western State Medical University, St-Petersburg, Russian Federation; 2Nasonov Research Institute of Rheumatology, Moscow, Russian Federation; 3Regional Clinical Hospital, Cheyabinsk, Russian Federation; 4Leningrad Region Clinical Hospital, St-Petersburg, Russian Federation; 5Healthcare Institution Municipal Clinical Hospital 1, Minsk, Belarus; 6Scientific and Practical Center of Surgery, Transplantology and Hematology, Minsk, Belarus; 7Rostov State Medical University, Rostov-on-Don, Russian Federation; 8Road Clinical Hospital, Saratov, Russian Federation; 9Municipal Inpatient Facility No.38, St-Petersburg, Russian Federation; 10Nizhny Novgorod Regional Clinical Hospital, Nizhny Novgorod, Russian Federation; 11Krasnoyarsk State Medical University, Krasnoyarsk, Russian Federation; 12Municipal Clinical Hospital, Omsk, Russian Federation; 13Regional Clinical Hospital, Smolensk, Russian Federation; 14City Clinical Hospital No 15, Moscow, Russian Federation; 15Kirov Military Medical Academy, St-Petersburg, Russian Federation; 16Kirov Military Medical Academy, St-Petersburg, Russian Federation; 17JSC BIOCAD, St-Petersburg, Russian Federation

Background: Efficacy and safety of netakimab (NTK), a humanized anti-IL17A antibody, was established in phase 2 clinical trials in patients (pts) with radiographic axial spondyloarthritis (r-axSpA) and psoriasis.2

Objective: The abstract presents 16-week data from ongoing ASTERA study (NCT03447704) in pts with active r-axSpA.

Methods: ASTERA is a phase 3 international double-blind placebo (PBO)-controlled study. 228 adult pts with r-axSpA, active (BASDAI ≥ 4) despite the standard NSAIDs, were randomly assigned (1:1) to receive 120 mg NTK or PBO SC at Week (Wk) 0,1,2 and then qWk through Wk 16. After Wk 16 all pts will start to receive NTK up to Wk 52. Primary endpoint was ASAS40 rate at Wk 16.

Disclosure of Interests: Inna Gaydukov Consultant for: Amgen, Roche, UCB, Lilly, Novartis, Pfizer; Grant/research support from: Lilly, Roche, UCB, Elan, Novartis, Celgene; Employee of: Eli Lilly and Company, Pfizer, Roche, UCB; Dominique Baeten Employee of: UCB Pharma, Shareholder of: UCB Pharma; Consultant for: Abbvie, Amgen, AstraZeneca, BioMed suivant, Celgene, Pfizer, UCB Pharma.
Results: The mean age at baseline was 39.14±9.9 years, the mean symptom duration was 4.3±4.5 years. 76.8% of pts were naïve to biological treatment. At Wk 16 ASAS40 rate was higher in NTK arm compared to PBO: 40.35% versus (vs.) 24.63% pts (95% CI for the difference in ASAS40 rate was [27.37%; 48.07%] (p<0.0001, Figure 1). Efficacy of NTK was also proved by comparison of secondary endpoints (Figure 2); improvement in BASDAI, MASES, BASFI became significant from Wk 4 and remained during the study (no data presented). Most reported adverse events (AE) and treatment-related AEs (TRAE) were mild/moderate (Table 1). The most frequent AEs were anemia, neutropenia, ALT increase. One serious AE (SAE), not related to the treatment (bone fracture), was reported in NTK arm.

Conclusion: NTK at a dose 120 mg is well-tolerated drug with favorable safety profile that leads to decline in r-axSpA activity, function improvement and axial mobility in 16 Wks.

Disclosure of Interests: Inna Gaydukova Grant/research support from: JSC BIOCAD, Olga Tsiupa Grant/research support from: JSC BIOCAD, Diana Abdulganieva: None declared, Diana Kretchikova Grant/research support from: JSC BIOCAD, Ivan Gordeev Grant/research support from: JSC BIOCAD, Vadim Tynenko Grant/research support from: JSC BIOCAD, Aleksandra Steklova Grant/research support from: JSC BIOCAD, Anna Ereemeva Grant/research support from: JSC BIOCAD, Ekaterina Chernyaya Employee of: JSC BIOCAD, Roman Ivanov Employee of: JSC BIOCAD.

Conclusion: EAMs appear to play an important role in the choice of TNFi in axSpA. Patients with previous AAU and IBD are more likely to be prescribed ADA.
and less likely to receive ETA, consistent with the superior efficacy of monoclonal TNFi for these conditions. The presence or absence of EAMS did not influence the use of CZP, although small sample size might explain the lack of associations. Future work will determine whether EAMS influence TNFi survival, or effectiveness, and whether this varies between agents.

Methods: In this phase 3, multicenter, randomized, double-blind, placebo-controlled study conducted in Japan, South Korea and Taiwan, eligible axSpA patients were randomized 1:1 to brodalumab subcutaneously (s.c.) 210 mg or placebo at baseline, weeks 1 and 2, every 2 weeks thereafter. At week 16, all subjects entered an open-label extension phase and received brodalumab 210 mg s.c. Q2W. ASAS 40 (Assessment of SpondyloArthritis international Society) response rate at week 16 was the primary endpoint. Secondary outcomes and safety profiles were also assessed.

Results: A total of 159 patients were randomized, and 77/80 patients in placebo arm were completed the 16 weeks. No suicidal ideation or behavior were observed. Other disease activity parameters demonstrated trend to improvement in therapeutic arm (Table). Brodalumab 210 mg had good safety profile. Most commonly reported adverse event was nasopharyngitis observed in both brodalumab and placebo arm (10.3%) arms. AE rates including SAE rates were comparable between groups. No suicidal ideation or behavior were observed.

Conclusion: Brodalumab s.c. 210 mg Q2W treatment was effective and tolerable in axSpA patients in this 16 week phase 3 clinical trial. Based on the ongoing trial results, brodalumab could be considered as a future therapeutic option for patients with axSpA.

Background: Secukinumab (SEC) has provided significant and sustained improvement in the signs and symptoms of active psoriatic arthritis (PsA) and ankylosing spondylitis.1 Evidence on the efficacy of biologics in the treatment of PsA patients (pts) with axial manifestations affecting 30–70% of PsA pts is limited2, particularly as validated classification criteria for this subtype of PsA are not yet available; an effort to develop criteria is being undertaken by ASAS/GRAPPA. MAXIMISE is an ongoing study evaluating the efficacy and safety of secukinumab 300 or 150mg in managing axial manifestations in PsA pts

Objectives: To report the primary analysis results at Week (Wk) 12 from MAXIMISE (NCT02721966) trial

Methods: This phase 3b, double blind, placebo (PBO)-controlled, multicentre 52-wk trial included 498 pts aged ≥18 years with PsA (CASPAR criteria), clinician-
diagnosed axial involvements, spinal pain VAS >40/100 and BASDAI >4 despite trial of at least two NSAIDs. Pts were randomised to subcutaneous (SC) SEC (300/150 mg) or PBO weekly for 4 wks and every 4 wks thereafter. At Wk 12, PBO pts were re-randomised to SC SEC 300/150 mg. The primary endpoint was proportion of pts achieving ASAS20 response with SEC 300 mg at Wk 12. The key secondary endpoint was ASAS20 response with SEC 150 mg at Wk 12 after superiority of 300 mg was established. Analyses used multiple imputation.

**Results:** Demographic and baseline (BL) disease characteristics were comparable across groups (Table). Primary and key secondary endpoints were met; ASAS20 response rates at Wk 12 were 63.1% (SEC 300 mg; P<0.0001) and 66.3% (150 mg; P<0.0001) vs 31.3% (PBO; Figure). ASAS20 responses in pts using concomitant MTX were 65.1% (300 mg), 67.3% (150 mg) vs 35.9% (PBO) and corresponding values in No MTX group were 60.5%, 64.4% vs 27.1%. The safety profile was similar across groups through Wk 12.

**Conclusion:** MAXIMISE is the first randomised controlled trial evaluating the efficacy of a biologic in the management of the axial manifestations of PsA. SEC 300 and 150 mg provided rapid and significant improvement in ASAS20 responses through Wk 12 in PsA pts with axial manifestations and inadequate responses to NSAIDs.

OP0237 INTERLEUKIN-17 OR TNF BLOCKADE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AFTER WITHDRAWAL OF AT LEAST ONE TNF INHIBITOR
Christoph Tellenbach1, Raphael Micheroli1, Kristina Buerki1, Almut Scherer2, Christoph Tellenbach1, Raphael Micheroli1, Kristina Buerki1, Almut Scherer2

Background: Secukinumab (SEC), an interleukin-17A inhibitor, is approved for the treatment of ankylosing spondylitis (AS) and has been integrated into the current treatment recommendations of patients with axial spondyloarthritis (axSpA) as an alternative to tumor necrosis factor inhibitors (TNFi). The optimal use of one mode of action over the other remains unclear and longitudinal real-life data are lacking.

Objectives: To compare drug survival of SEC versus TNFi in axSpA patients having previously stopped at least one TNFi in a large prospective cohort.

Methods: Patients with a clinical diagnosis of axSpA in the Swiss Clinical Quality Management cohort were included if they had previously stopped treatment with at least one TNFi, initiated therapy with either SEC or a new TNFi after approval of SEC and had a baseline clinical visit. Drug survival was evaluated by Cox proportional hazards models adjusted for sex, age, and number of previous TNFi.

Results: Baseline characteristics of 382 axSpA patients included (N=107 for SEC and N=275 for new TNFi) are shown in Table 1. The proportion of patients with ≥2 TNFi administered previously was significantly higher in the SEC group. Patients starting SEC had higher baseline disease activity, more enthesitis and greater impairment of spinal mobility, function and quality of life. A history of uveitis was more prevalent in the TNFi group. No differences between the groups could be detected with regards to the reason for discontinuation of the previous TNFi.

Conclusion: SEC was predominantly initiated in axSpA after use of at least 2 TNFi. Patients starting SEC had a higher mean disease activity than patients starting a new TNFi. Adjusted drug survival after previous withdrawal of TNFi was comparable for SEC or a new TNFi.

Acknowledgement: Supported by a grant from Novartis.

WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT AMONG PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS/RADIOPHAGIC AXIAL SPONDYLOARTHROPATHY AND TREATED WITH IXEKIZUMAB FOR 16 WEEKS: RESULTS FROM COAST-V AND COAST-W
Annettes Boonen1, Maxime Doudougos2, Bernard Combe3, Theresa Hunter4, Baqin Zhu5, David Sandoval6, Louis Bessonette5, Atul Deodhar7, A. Maastricht University Medical Center, Maastricht, Netherlands; "Hôpital Cochin, Paris, France; "CHU Montpellier, Montpellier University, Montpellier, France; "Eli Lilly and Company, Indianapolis, United States of America; "Laval University and CHU de Quebec, Quebec, Canada; "Oregon Health and Science Univ, Portland, United States of America

Background: Axial spondylarthropathy (axSpA) negatively impacts work productivity and IL-17A antagonists, such as ixekizumab (IXE), may improve paid and unpaid work productivity. Also, it is unknown if improvements with IXE differ between biologic-naive and TNF inhibitor (TNFi) experienced patients.

Objectives: We investigated the effect of IXE treatment for 16-weeks on work productivity and activity impairment among patients with radiographic axSpA (r-axSpA) using data from the biologic-naive and TNFi experienced patients receiving either placebo (PBO), IXE, or adalimumab (ADA), if biologic-naive.

Methods: Both COAST-V and COAST-W investigated the efficacy and safety of IXE among patients with r-axSpA that either were biologic-naive patients (COAST-V, NCT02696785) or TNFi-experienced patients (COAST-W, NCT02696798), as defined by prior inadequate response or intolerance to 1 or 2 TNFi. Patients were required to have a diagnosis of axSpA. Patients fulfilled ASAS criteria for r-axSpA and mNII criteria for ankylosing spondylitis. Activity disease was defined by BASDAI ≥4 on a 0-10 numeric rating scale (NRS). Full eligibility criteria were previously reported. Patients were treated with placebo (PBO), 40-mg adalimumab (ADA) every 2 weeks (Q2W; COAST-V only), 80-mg IXE Q2W (IXE30Q2W) or every 4 weeks (IXE4Q4W) for 16 weeks. Work productivity was investigated using the Work Productivity and Activity Impairment Questionnaire for Ankylosing Spondylitis (WPAI:SpA). Individual and integrated
study data were analyzed using analysis of covariance models. Results reported as least squares mean (LSM) change from baseline: standard error (SE). Integrated data of COAST-V and -W were analyzed for inferential statistics due to small sample sizes in the individual studies. ADA was included in COAST-V as an active reference arm only, and the study was not powered to allow comparisons between the IXE and ADA arms.

**Results:** Overall, 365 (64.5%) PBO- and IXE-treated patients reported paid work (part-time or full-time) at baseline in COAST-V and COAST-W. Based on integrated data, Absenteeism was significantly lower in IXEQ2W treated patients than PBO and Presenteeism, Work Productivity Loss, and Activity Impairment were significantly reduced in IXEQ2W and IXEQ4W treated patients versus PBO (Table 1). WPAI-SpA outcomes for biologic-naïve and TNFi-experienced were similar with some exceptions (Table 2). The active reference arm (ADA) exhibited numerical improvements for presenteeism, work productivity, and activity impairment versus PBO.

**Conclusion:** In this integrated analysis of patients with active r-axSpA, IXE treatment for 16 weeks yielded significant improvements in work productivity and activity impairment versus PBO. The effect is similar in biologic-naïve and TNFi-experienced patients. A limitation for evaluations of work productivity in the individual studies was the relatively low number of employed patients.

**DOI:** 10.1136/annrheumdis-2019-eular.1613

**RESULTS:**

Of 826 SSc-ILD patients were included; 219/826 (26.5%) showed moderate/significant ILD progression at 12±3 months follow-up. Baseline FVC, erythrocyte sedimentation rate, modified Rodnan skin score (mRSS), GERD and disease duration were significantly associated with significant fibrosis in univariate analysis and multivariable modelling (area under curve 0.67). Serial lung function data with median follow-up of 5 yrs were available in 411/826 (49.8%) patients. In 128/411 with initial progressive ILD at 12±3 months, 59/128 (46.1%) showed further progression, while 69/128 (53.9%) were stable. Baseline FVC, mRSS and disease duration were significantly associated with further ILD progression. The incident cumulative frequency of moderate and significant ILD progression was 22.9% (n=189/826) and 28.5% (n=235/826) during the median 5-yr follow-up and time to first progressive event (Figure).

**Conclusion:** This study provides novel insights into the frequency, severity and association of progressive fibrosis in patients with SSc-ILD in the EUSTAR database.

Assessment of Pulse Wave Velocity in Safety and Efficacy of Lenabasum in An...

Background: Systemic sclerosis (SSc)-related vasculopathy is generally thought to occur on a microvascular level. However, some observations also suggest involvement of arterial vessels. Macrovacular involvement (e.g., aorta or upper extremity) can be non-invasively assessed by measuring pulse wave velocity (PWV). Although, several studies have assessed aortic and upper extremity PWV in SSc, studies have not reached a consensus regarding this matter. Furthermore, we hypothesized that the endothelin antagonist bosentan may improve arterial stiffness by its direct endothelial and potential anti-fibrotic effects.

Objectives: The aim of this exploratory study was two-fold. First, we aimed to compare arterial stiffness in patients with SSc and age- and sex-matched healthy controls (HC). Secondly, we will investigate the effect of bosentan on both short-term (three month) and long-term (one-year) PWV.

Methods: Baseline differences between HC and SSc patients were studied in a case-control design. The follow-up of SSc patients was a randomized, prospective, 2-arm parallel group, open-label, (usual care with bosentan versus usual care only), blinded endpoint, intervention study. PWV (Sphygmocor) in meters/second, was measured to assess arterial stiffness in the aorta (carotid-femoral PWV), upper arm (carotid-brachial PWV), and forearm (brachial-radial PWV), adjusted for mean arterial pressure.

Results: Baseline characteristics are shown in Table 1. No significant differences were observed in PWV at all sites between HC and SSc patients. No effect of bosentan on aortic, and upper arm PWV was found. The change in forearm PWV was different between the groups, with a decrease (e.g. lowering arterial stiffness) in the bosentan group (figure 1).

Conclusion: This small study shows that aortic, upper arm, and forearm arterial stiffness does not appear to increase in patients with SSc, as compared to age- and sex-matched healthy controls. To the best of our knowledge, this is the first study to investigate the concept of potential effects of an endothelin receptor antagonist on macrovascular involvement in SSc. Although the results demonstrate no effects on aorta and upper arm arterial stiffness, they may indicate a beneficial effect on the stiffness of the smaller arteries of the forearm. Future studies are needed to further investigate the potential effect of bosentan on these smaller arteries.

1University of Groningen, University Medical Center Groningen, Internal Medicine, division Vascular Medicine, Groningen, Netherlands; 2Medical Center Leeuwarden, Netherl...
immunosuppressive drugs. At the time of data cut-off, all subjects who entered OLE completed 12 months of dosing. Nineteen (95%) of subjects experienced at least 1 AE, with 59 AEs occurring among the subjects during the OLE to date. The majority of AEs were mild (n = 16, 80%), with 1 severe AE (fatigue) considered unrelated to lenabasum reported. AEs occurring in ≥ 2 subjects were: dermatomyositis worsening, dizziness, fatigue, herpes zoster, nasopharyngitis, nausea, upper respiratory tract infection, and urinary tract infection. No serious AEs related to lenabasum have been reported. Improvement was seen in multiple physician- and patient-reported efficacy outcomes; selected outcomes are presented in Figure 1. Mean (SE) changes from study start at Week 52 in the OLE were: CDASI activity score = -17.6 (SD), Patient Skin Activity VAS = -2.6 (SD); Skindex-29 Symptoms Domain = -21.6 (SD); Patient Itch VAS = -2.8 (SD); Physician Overall Disease VAS = -3.0 (SD); and Patient Pain VAS = -2.3 (SD). Improvements were seen in other efficacy outcomes, 12 subjects had no changes in immunosuppressive drugs during the OLE, 3 reduced chronic steroids, 2 reduced mycophenolate, 3 were switched from methotrexate to mycophenolate, 1 started methotrexate, and 1 had a burst and taper of steroids.

Conclusion: Lenabasum continues to have a favorable safety and tolerability profile in the OLE of the Phase 2 trial JBT101-DM-001 with no serious AEs or study discontinuations related to lenabasum. The CDASI activity score and multiple other physician and patient-reported outcomes improved, although limitations of attributing efficacy to lenabasum in the setting of open-label dosing is acknowledged. These data support further testing of lenabasum for the treatment of DM, and a Phase 3 study of lenabasum in DM has started.

SAFETY PROFILE OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE AND IDIOPATHIC PULMONARY FIBROSIS

Kristin Highland1, Oliver Didier2, Martina Gahlentenn3, Arata Azuma4, Areyh Fischer5, Maureen Mayes6, Ganesh Raghu7, Wiebke Sauter8, Manna Girard9, Veronika Kohlbrenner10, Emmanuelle Clerisme-Beaty11, Susanne Stowell1, Masataka Kukwana2, Toby M Maher12,13, SENSCIS trial investigators, 1Respiratory Institute, Cleveland Clinic, Cleveland, Ohio, United States of America, 2Dept of Rheumatology, University Hospital Zurich, Zurich, Switzerland, 3Boehringer Ingelheim (Schweiz) GmbH, Basel, Switzerland, 4Dept of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan, 5University of Colorado School of Medicine, Denver, Colorado, United States of America, 6Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, Texas, United States of America, 7University of Washington, Seattle, United States of America, 8Boehringer Ingelheim Pharma GmbH and Co. KG, Biberach an der Riss, Germany, 9Boehringer Ingelheim France S.A.S., Reims, France, 10Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, Connecticut, United States of America, 11Boehringer Ingelheim International GmbH, Inge, Germany, 12Dept of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, 13National Heart and Lung Institute, Imperial College London, UK, and National Institute for Health Research Clinical Research Facility, Royal Brompton Hospital, London, United Kingdom

Background: Nintedanib has been investigated in patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD) in the SENSCIS trial and idiopathic pulmonary fibrosis (IPF) in the two INPULSIS trials. These patient populations differ in age, sex, disease characteristics and comorbidities.

Objectives: To compare the safety and tolerability of nintedanib in patients with SSc-ILD and IPF.

Methods: Adverse events that occurred over 52 weeks of treatment in the SENSCIS and INPULSIS trials were assessed descriptively in subjects who received ≥1 dose of trial drug.

Results: A total of 576 subjects were treated in the SENSCIS trial (288 nintedanib; 288 placebo) and 1061 in the INPULSIS trials (638 nintedanib; 423 placebo). At baseline, mean (SD) age was 54.0 (12.2) and 66.8 (8.0) years in SENSCIS and INPULSIS, respectively. The proportion of females was 24.6% and 79.3%, respectively. Over 52 weeks, 19.4% and 10.8% of patients treated with nintedanib and placebo discontinued treatment in SENSCIS, compared with 24.5% and 18.9% of patients treated with nintedanib and placebo in INPULSIS. Gastrointestinal adverse events were the most frequently reported adverse events with nintedanib and placebo, and, as expected based on the underlying disease, were more frequent in patients with SSc-ILD than IPF in both treatment groups (Table). Diarrhoea adverse events were reported in 75.7% and 31.6% of patients treated with nintedanib and placebo in SENSCIS, and 62.4% and 18.4% of patients treated with nintedanib and placebo in INPULSIS, respectively.

Conclusion: The safety and tolerability profile of nintedanib in patients with SSc-ILD is similar to that observed in patients with IPF.

EFFICACY OF PIRFENIDONE IN SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE – A RANDOMISED CONTROLLED TRIAL

Nuopur Asharya1, Debashish Mishra1, Sahajal Dhoria2, Varun Dhi1, Sanjay Jain1, Shefali Khanna Sharma1, 1Post Graduate Institute of Medical Education and Research, Chandigarh, Internal medicine, Division of Rheumatology, Chandigarh, India, 2Post Graduate Institute of Medical Education and Research, Chandigarh, Pulmonary Medicine, Chandigarh, India

Background: Interstitial lung disease (ILD) is a major cause of morbidity and mortality in systemic sclerosis(SSc). (1) Lung fibrosis in systemic sclerosis shares...
similar pathogenesis as idiopathic pulmonary fibrosis. (2) Pirfenidone slows the decline in lung functions in idiopathic pulmonary fibrosis. (3) Therefore, pirfenidone may be efficacious in SSc-ILD.

**Objectives:** To compare the efficacy and safety of pirfenidone with placebo in SSc-ILD.

**Methods:** This was a double-blind, randomised, placebo controlled trial. We enrolled 34 consecutive subjects of SSc-ILD with forced vital capacity (FVC) >50% of predicted value and diffusion capacity of lung for carbon monoxide > 30% of predicted value. Subjects were randomly assigned in a ratio of 3:1 to receive either pirfenidone (n = 17) or placebo (n = 17) and followed up for 6 months. Pirfenidone was started at 600 mg/day and increased to 2400 mg/day over one month and continued for the trial period. Primary outcome was to compare the proportion of patients with stabilisation or improvement in lung functions (FVC). Secondary outcome was to compare the change in FVC, Mahler’s dyspnea index, 6 minute walk distance (6MWD), modified Rodnan skin score (MRSS) and change in serum levels of tumour necrosis factor a (TNF-α) and tissue growth factor (TGF-β) at the end of 6 months. Trial was registered with clinical trials registry of India (CTRI/2018/01/011449).

**Results:** By intention-to-treat analysis, 16 (94.1%) patients in treatment group showed stabilisation of lung function compared to 13 (76.5%) in control group (p = 0.335). The median change in FVC was -0.55% (IQR = -4.75% to 1.75%) and 1.0% (IQR = -8.5% to 5%) in the treatment and control groups respectively (p = 0.654). The median change in 6MWD was -15 (IQR = -42.5 – 13.75) meters and 0.0 (IQR = -50 – 30) meters in treatment and control groups respectively (p = 0.601). The median of focal scores for transitional dyspnea index in both the treatment and control groups were 3.0 (IQR = 0 – 3) (p = 0.838). Median change in MRSS was 0.0 (IQR = -2.0 – 1.0) and -1.0 (IQR = -4.0 – 0.0) in treatment and control groups (p = 0.628). Difference in TNF-α levels were -5.14 (IQR = -14.6 – 0.29) pg/ml in the treatment and -2.94 (IQR = -5.51 – -2.35) pg/ml control group (p = 0.918). Difference in TGF-β levels in the treatment and control groups were 186.73 (IQR = 731.43 – 64.6) pg/ml and 24.29 (IQR = -233.21 – 382.0) pg/ml respectively (p = 0.093). The mean tolerated dose of pirfenidone was 1700 ± 644 mg/day. Adverse events were mild, most common among them were gastrointestinal side effects followed by skin rashes. Only one serious gastrointestinal adverse effect was documented.

**Conclusion:** We failed to demonstrate a beneficial effect of pirfenidone over placebo in stabilising FVC, functional status, or skin disease after 6 months of therapy. A larger study with longer follow up period may be further required.

**Efficacy and Safety of Low-Dose IL-2 in Patients with Multiple Myositis/Dermatomyositis**

He-Hua Sun1, Sheng-xiao Zhang1, Jia Wang1, Yu-Fei Hao1, Guang-Ying Liu1, Caihong Wang1, Chong Gao2, Li-Xiao Feng1. 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2B Brigham and Women’s Hospital, Harvard Medical School, Department of Pathology, Boston, United States of America

**Background:** Dermatomyositis (DM) and polymyositis (PM) are rare chronic inflammatory disorders with significant associated morbidity and mortality despite treatment (1, 2). Characterized by subacute onset of proximal muscle weakness, elevated muscle enzymes, and inflammatory infiltrates on muscle biopsy. Although several hypotheses have been proposed for triggers of inflammation in the diseases (4), growing evidences have focused on the immune disorders (5). However, the quantitative changes of lymphocyte subsets in DM/PM are unclear and whether low-dose IL-2 could rebalance the lymphocyte subsets and further benefit to remission disease activity of DM/PM patients is unknown.

**Objectives:** To investigate the quantitative status of peripheral blood lymphocyte subsets in the patients for the exploration of pathogenesis and evaluate the safety and efficacy of low-dose IL-2 therapy in patients with DM/PM.

**Methods:** From February 2016 to October 2018, total 147 patients with PM/DM and 129 gender and age matched healthy individuals were enrolled in this study. The absolute numbers of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Treg cells in peripheral blood of these individuals were detected by flow cytometry combined with standard absolute counting beads. Patients in IL-2 group (n=31) were not only given traditional treatments, but injected subcutaneously human IL-2 (alde-skulin) at 50 IU/ml per day for a 5-day course. The demographic features, clinical manifestations and laboratory indicators were compared before and after the treatment.

**Results:** Patients with PM/DM had lower levels of Treg cells as well as T, CD4+T, CD8+T, Th1, Th2, Th17 and Th17 compared with those of the healthy controls (P < 0.05), which was correlated with disease activity (P < 0.05). After IL-2 administration, the absolute numbers of peripheral lymphocyte subsets in patients were significantly increased (P < 0.05), leading to a better remission compared with the patients received conventional therapy (P < 0.05).

**Conclusion:** The difference status of peripheral lymphocyte subsets, especially Tregs, between PM/DM patients and healthy individuals suggests that lymphocyte subsets may be involved in and play an important role in the pathogenesis of patients. Low-dose IL-2 can effectively increase the level of Treg cells as well as other lymphocytes to some degree and maintain the immunologic balance, which may help for PM/DM patients’ symptoms remission without over-treatment and evaluated side effect. But long-term benefits of IL-2 therapy are required to further study.

Background: The anti–IL-6 receptor-α antibody tocilizumab (TCZ) demonstrated numerical improvement in modified Rodnan skin score (mRSS) and clinically relevant preservation of lung function (LF) (assessed by forced vital capacity [FVC]) in systemic sclerosis (SSc) patients (pts) in a ph 2 trial.1

Methods: Pts from the double-blind period of ph 3 trial (NCT02453256). BL%-predicted FVC at wk 48 was 75.6%. Mean BL computer-assisted quantitative lung fibrosis of the most affected region was 20.4, ppFVC 82.1%, and ppDLCO 82.5%. Mean BL computer-assisted quantitative lung fibrosis of the most affected lobe (QLF-LM) was 4.7% for the PBO group and 5.5% for the TCZ group. At wk 48, the primary endpoint was non-inferiority of BL% predicted FVC (pfFVC) and time to Tx failure (time from first study treatment) (Tx) to first occurrence of death, decline in FVC >10%, increase in mRSS >20% and ppFVC <5, or occurrence of predefined SSc-related Cx). Chest high-resolution computed tomography (HRCT) and ACR Combined Response in SSc (CRSS) were exploratory endpoints.

Results: Of 106 PBO- and 104 TCZ-treated pts, 81% were women and 31% had previous or concurrent interstitial lung disease based on history. BL mean values were age 48 yrs, SSc duration 23 mts, mRSS 20.4, pfFVC 82.1%, and ppDLCO 75.6%. Mean BL computer-assisted quantitative lung fibrosis of the most affected lobe (QLF-LM) was 4.7% for the PBO group and 5.5% for the TCZ group. At wk 48, the primary endpoint was non-inferiority of BL% predicted FVC (pfFVC) and time to Tx failure (time from first study treatment) (Tx) to first occurrence of death, decline in FVC >10%, increase in mRSS >20% and ppFVC <5, or occurrence of predefined SSc-related Cx). Chest high-resolution computed tomography (HRCT) and ACR Combined Response in SSc (CRSS) were exploratory endpoints.

Conclusion: The primary mRSS endpoint was not met; however, TCZ Tx resulted in clinically relevant differences in FVC with preservation of LFS and improvement in fibrosis, measured by HRCT, in SSc pts.

Background: The recently validated Lupus Low Disease Activity State (LLDAS) definition has been shown to have utility as a target to treat endpoint in SLE, whereby LLDAS attainment is associated with reduction in permanent damage accrual. Robust evaluation is required to ensure this protective association is not simply reflective of milder disease phenotypes being over-represented among LLDAS attainers.

Objectives: To assess the effect of attainment of LLDAS on damage accrual in patients with active disease at baseline. SLEDAI-2K<6 was chosen as this reflects clinical trial entry criteria.

Methods: A prospective multinational cohort study was undertaken in 13 centres between 2013-2017. Patients with SLE who were recruited, SLEDAI-2K, SELENA flare index, PGA, and medication data collected at every visit, and damage score (SLICC-ACR damage index (SDI)) collected annually. Subgroup analyses were performed to assess the effect of LLDAS on damage accrual in patients who had active disease at baseline (SLEDAI-2K<6)-Time-dependent hazards regression models were used to assess the association of attainment of LLDAS at any time point, and proportion of time in LLDAS at the 50% observed time cut-off, with occurrence of irreversible permanent end-organ damage.

Results: 1,735 patients were followed for (mean ± SD) 2.2 ± 0.9 years, totalling 1,735 patients were followed for (mean ± SD) 2.2 ± 0.9 years, totalling 3,761 patient-years. LLDAS attainment was less frequent in patients with active disease at baseline (901 of 3,835 visits in LLDAS, 23.5%), compared to patients with SLEDAI-2K<6 at baseline (519 of 8845 visits in LLDAS, 5.7%), p<0.001. In contrast, compared to those with baseline SLEDAI-2K<6, patients with active disease at baseline demonstrated a stronger association of LLDAS attainment with reduction in risk of damage accrual, in visit by visit analysis (HR 0.49, 95% CI 0.28-0.86, p 0.01 vs HR 0.72, 95% CI 0.52-0.99, p 0.05), and in analysis of cumulative time spent in LLDAS (HR 0.52, 95% CI 0.33-0.83, p 0.01 vs HR 0.65, 95% CI 0.47-0.91, p<0.01).

Conclusion: Despite lower attainment of LLDAS in patients with higher disease activity at baseline, the magnitude of association of LLDAS attainment with lower damage accrual was greater in this subgroup of patients compared to those less active baseline disease. This supports the validity of LLDAS as an outcome measure, in a population similar to that typically selected into clinical trials, and further highlights the potential impact of achieving a target outcome in SLE patients with active disease.

**ATTAINMENT OF THE LUPUS LOW DISEASE ACTIVITY STATE IS ASSOCIATED WITH PROTECTION FROM DAMAGE ACCRUAL IN PATIENTS WITH ACTIVE DISEASE AT BASELINE**

**EFFECT OF IMMUNOSUPPRESSIVE DRUG WITHDRAWAL ON DAMAGE PROGRESSION AND FLARE OCCURRENCE IN SLE PATIENTS IN REMISSION**
The impact of exercise on hand function and quality of life of SLE patients: a randomized controlled trial

Kyriaki Keramitou1,2, Christos Anagnostou2, Antonios Galanos3, Evagelia Kakatsi1,2, Maria Tekikou2,3, National and Kapodistrian University of Athens, Medical School, Athens, Greece; 2Thriassio Hospital, Eresina, Greece; 3National and Kapodistrian University of Athens, Athens, Greece; 4National and Kapodistrian University of Athens, Medical School, Athens, Greece; 5National and Kapodistrian University of Athens, Medical School, Athens, Greece

Background: Systemic Lupus Erythematosus (SLE) has a significant impact on the ability to perform daily activities and patients’ quality of life. To date, no studies have examined the effect of exercise on hand function and quality of life of SLE patients.

Objectives: To determine the effect of exercise on hand strength, dexterity and performance of daily activities, and the quality of life of SLE patients.

Methods: A randomized, 24-week follow-up trial was designed. A total of 240 consecutive SLE patients fulfilling the SLICC classification criteria were evaluated. Sixty two patients who met the inclusion criteria [age >18 years, upper limb arthralgias, DASH (Disabilities of the Arm, Shoulder, and Hand) score >10 and stable drug regimen for >3 months], were randomly assigned to the exercise group (n=120) or the routine care (control) group (n=120). Patients in the exercise group received by the hand therapist a 30 min daily program at home of strengthening and stretching upper limb exercises for 12 weeks. Performance of daily activities was evaluated with the DASH and HAQ questionnaires, the grip and pinch strength with the Jamar dynamometer and pinch gauge respectively.

Results: There were no statistically significant differences between two groups in baseline age (39.2 vs 39.6 years, p=0.806). Thirty participants (93.75%) from the exercise group completed the 12-week exercise program and 28 (87.5%) were re-evaluated at 24 weeks; 30 (p=0.044) and 26 (p=0.001) in the exercise group compared to control group at all-time points. More- patients (100%) of control group completed the 24-week study.

Conclusion: In our SLE cohort, the withdrawal of IS therapy in remitted patients did not seem to influence damage progression in the medium-term.

Background: Antiphospholipid antibodies (aPL) have been associated with organ damage and certain features in SLE patients.

Objectives: Our aim was to investigate the differences between SLE patients according to the presence of aPL and/or clinical antiphospholipid syndrome.

Methods: Patients from the RELESSER-T registry were included. RELESSER-T is a multicenter, hospital-based registry, with retrospective cross-sectional collection of data from a large representative sample of adult non-selected patients with SLE attending Spanish rheumatology services from the public national health system.

Results: We included 3651 SLE patients and 1368 were positive for aPL (44.9%). 9% of patients were positive for anticardiolipin antibodies, 27.3% showed positivity for anti b2glycoprotein I and 24% for lupus anticoagulant. Overall 2283 patients were classified as SLE no aPL, 528 as SLE-aPL and 840 as SLE-APL.

All values are presented as median (interquartile range). DASH=Disabilities of the Arm, Hand, and Shoulder; HAQ=Health Assessment Questionnaire; LUPUS-QoL=Lupus Quality of Life; PH=physical health domain, DH=dominant hand, JAW=joint pain, COM=combination.

Disclosure of Interests: None declared

Conclusion: SLE-APS patients show a more severe clinical profile with higher frequency of major organ involvement and more damage accrual than SLE-aPL.

Background: T2T is routine in RA, but no comparable standard has been defined for SLE. In 2015, the definition of Lupus Low Disease Activity State (LLDAS) was generated by Asia-Pacific Lupus Collaboration, and the preliminary validation demonstrated its attainment to be associated with improved outcomes in SLE. A SLEDAI-2K score lower than 4 is the main criteria for LLDAS. SSDM is an interactive mobile disease management application, including application systems for both the doctors and patients. The patients can perform self-assessment, including SLEDAI and medical records entry through the mobile application. The data is synchronized to the SSDM of authorized rheumatologists and stored in cloud database.

SLE PATIENTS FROM NORTH AMERICA ARE OLDER WITH LESS SEROLOGIC ACTIVITY THAN OTHER POPULATIONS IN INTERNATIONAL CLINICAL TRIALS

Ewa Olech1, Eduard van Rijen2, Ali Ashrafzadeh3, Alexander Kant4, Joan T. Menter5, IQVIA, Rheumatology Center of Excellence, Las Vegas, United States of America, 6Oklahoma Medical Research Foundation, Oklahoma City, United States of America

Background: Regional differences have been identified as potential confounders of SLE clinical trial results. Recently, no difference between treatment and placebo was observed in the US lupus patients when a significant treatment effect was observed in Europe.

Objectives: To compare SLE serologic features/markers of active disease between different geographic regions in recent multinational clinical trials.

Methods: Laboratory data of 1005 subjects from four global randomized SLE clinical trials at baseline were examined. Mean/median C3 and C4 complement levels, prevalence of low C3 or C4 (Low C3/C4), positive anti-double stranded DNA (DNA), anti-Extractable Nuclear Antibodies (ENA), and high-titer Antinuclear Antibody (ANA $>\text{t}1:50$) in North America (NA) patients were compared to Asia (AS), Latin America (LA), Africa (AF), Western Europe (WE), and Eastern Europe (EE).

Results: NA patients were significantly older than patients in LA, AF, or AS but not WE or EE. Not surprisingly, they also had higher complement levels and the lowest rates of low C3/C4, DNA, ENA, and ANA $>\text{t}1:640$. Our data confirm that age is an important factor in the prevalence of low complement and autoantibodies. However, there remained a marked difference in serologic activity between NA and EE, despite being close in age.
Asian patients were the youngest, had the lowest complement levels and the highest rate of ENA & DNA consistent with high disease activity. Low complement, but not DNA, was relatively common in Europe. LA patients, like Asians, had high rates of serologic activity but less incidence of low C3/C4, suggesting that this population may have intrinsic disease severity without being as acutely active. *Mann-Whitney Rank Sum **Chi-square *One-way ANOVA on ranks; Med-median p p value C-comparator ns-not significant; Data not corrected for multiple comparisons

Conclusion: SLE patients entering studies from North America are strikingly less likely to have markers of active disease than other regions, raising concerns for their suitability for trials. This appears to be associated, at least in part, with age, although more aggressive treatments cannot be ruled out. Asian subjects have the greatest prevalence of autoantibodies and low complement. Latin American patients have high prevalence of ANA; 1:640 and other autoantibodies, but less evidence of low complements. These findings may help to explain regional differences in treatment/placebo responses and emphasize the importance of geographical stratification and improved methods to screen out patients unsuitable for SLE trials.

Background: Central nervous system (CNS) involvement accounts for over 90% of neuropsychiatric (NP) events compared to involvement of the peripheral nervous system (PNS) which accounts for most of the other events. Although there is a large body of work on CNS disease in SLE patients, involvement of the PNS is less well established.

Objectives: In a multi-ethnic/racial, prospective SLE inception cohort, to determine the clinical characteristics, associations and outcomes in different types of peripheral nervous system (PNS) disease.

Methods: Patients were evaluated annually for 19 NP events including seven types of PNS disease. Standardized case definitions and attribution models for each type of PNS event were used. SLE disease activity (SLEDAI-2K), organ damage (SLICC/ACR damage index), autoantibodies, patient (SF-36) and physician (Likert score) assessment of outcome were measured. Time to event and linear regressions were used as appropriate.

Results: Of 1,827 SLE patients, 68.8% were female, 48.8% Caucasian. The mean±SD age was 35.1±13.3 years, disease duration at enrollment 5.6±4.2 months and follow-up 7.6±4.6 years. There were 161 PNS events in 139.1,827 (7.6%) patients. The predominant events were peripheral neuropathy [68/161 (41.0%), mononeuropathy [44/161 (27.3%)] and cranial neuropathy [39/161 (24.2%)] and the majority were attributed to SLE. Multivariate Cox regressions suggested longer time to resolution in patients with prior history of neuropathy, older age at SLE diagnosis, higher SLEDAI2K scores, and for peripheral neuropathy versus other neuropathies. Neuropathy was associated with significantly lower SF-36 physical and mental component summary scores versus patients without NP events. By physician assessment, the majority of neuropathies...
resolved or improved over time and this was associated with improvements in SF-36 summary scores for peripheral neuropathy and mononeuropathy.

Conclusion: PNS disease is an important component of total NPSLE and has a significant negative impact on health related quality of life. The outcome is favourable for most patients, but several factors associated with longer time to resolution were identified.

In medium to long-term juvenile dermatomyositis, proinflammatory and profibrotic cytokines are differently associated with pulmonary involvement in active vs inactive disease

Hennieter Marster1,2, Thomas Schwartz2,3, Trond M Kaaalaker2, May Britt Lund3, Berit Flat3,4, Ivar Sjaastad1,2, Hege Aspanger3,4, Center for Cardiac Research, Oslo, Norway, Oslo University Hospital, Institute for Experimental Medical Research, Oslo, Norway, 1Oslo University Hospital, Department of Rheumatology, Oslo, Norway; 2Oslo University Hospital, Respiratory Medicine, Oslo, Norway; 3Oslo University Hospital, Department of Rheumatology, Oslo, Norway; 4University of Oslo, Institute for Clinical Medicine, Oslo, Norway; 5Birkens university college, Oslo, Norway

Background: Knowledge about associations between cytokines and lung involvement in juvenile dermatomyositis (JDM) is scarce.

Objectives: To examine associations between cytokines and pulmonary involvement in JDM assessed after medium to long-term follow-up.

Methods: 58 JDM patients examined median 17y after disease onset were stratified in active and inactive disease by the updated PRINTO criteria (Ref 1). Serum levels of cytokines were analyzed by Luminex or ELISA. Pulmonary function tests (PFT) included forced vital capacity (FVC), total lung capacity (TLC) and diffusing capacity for carbon monoxide (DLCO) (hbg adjusted). PFT variables are expressed as% of predicted. High resolution computed tomography (HRCT) scans were scored for interstitial lung disease (ILD), calcinosis in chest wall and airway disease. Associations between lung involvement and cytokines are presented as Spearman’s correlation coefficient (rs).

Results: Table 1. Characteristics, PFT, HRCT findings and cytokines

Numbers are mean (SD) if not stated otherwise, *unit: pg/ml

No significant differences were found between active and inactive patients in tbl. 1

Associations between cytokines and PFT/HRCT findings

Numbers are rs, all p’s < 0.05

In patients total, TGFb1 and PDGF correlated with TLC and FVC (r = 0.38 - 0.30).

For TGFb1 correlations with TLC and FVC were -0.62 and -0.59 in the inactive group, whereas PDGF correlated with FVC in the active group (r = 0.48).

IP-10 correlated with TLC in active patients only (r = 0.35).
In patients total and active patients, eotaxin correlated with DLCO% (0.39 and 0.52). In inactive patients, MIF1b correlated with DLCO% (0.47).

In patients total, IP-10 correlated with any HRCT finding and Airways disease (0.37 and 0.44), which were also present in active patients (0.34 and 0.61). In patients total, MCP-1 correlated with any HRCT finding and calcinosis (0.34 and 0.40); in active patients MCP-1 and calcinosis correlated (0.34). Eotaxin correlated with ILD in both patients total and active patients (0.37 and 0.38).

The following cytokines correlated with HRCT findings in inactive patients only; IL-17 with any HRCT findings and ILD (0.61 and 0.52), MIF1a with any HRCT findings (0.63) and IL-5 with ILD (0.42).

Conclusion: In JDM, lung involvement was associated with mainly proinflammatory cytokines in active and pro-inflammatory/proinflammatory cytokines in inactive patients. The association between higher eotaxin and better gas diffusion was interesting, since we have previously demonstrated an association between higher eotaxin and cardiac dysfunction (Ref 2).

**OP0257 CHILDHOOD-ONSET MONOGENIC SYSTEMIC LUPUS ERYTHEMATOSUS NOT DUE TO COMPLEMENT DEFICIENCY: ASYSTEMATIC REVIEW OF 90 CASES**

Natalia Cabrera1, Pauline NakHieh2, Jean-Christophe Lega1, Alexandre Belot2.
1University Lyon 1, UMR-CNRS 5558 (LBBE), Villeurbanne, France; 2Hospital Woman Mere Enfant – Hôpital National Réferral Centre for rare Juvenile Rheumatological and Auto-immune Diseases (RAISE), Bron, France

Background: The paediatric SLE (pSLE) are estimated 10 to 17% of SLE (1). Studies comparing pSLE with adult-onset SLE reported high prevalence of neuropsychiatric organ damage at diagnosis due to the diagnosis delay, more severe disease course with high disease activity resulting in worse prognosis in pSLE (1,2). Recently, whole exome sequencing and next-gen sequencing have facilitated the identification of rare monogenic variants associated with SLE and lupus-like phenotypes with high penetrance (3,4).

Objectives: To reporting the whole spectrum of monogenic pSLE according to pathway abnormalities, using a meta-analysis (MA) approach.

Methods: A systematic review of studies focused on monogenic pSLE were analysed. To be included in the systematic review, studies had to meet simultane-
ously all the following criteria: (i) reported at least 1 case of SLE (ii) started before the age of 16 (iii) with clearly description of the diagnosis criteria and (iv) provided genetic data of the case.

We pooled the genes into three main groups of signalling pathways: (i) genes that affect adaptive immunity pathways including the lymphocyte apoptosis (FAS, KRAS, PTPN11, SHOC2) and the B and T cell development checkpoints (PRKCD, RAG2, IKZF1, DDX4, WASP), (ii) genes containing type I interferon (IFN) pathways (IRF5, TREX1, SAMHD1, RNASEH2A, RNASEH2B, RNA-SEH2C, IFIH1, DNASE1L3, DNASE1, TMEFF173, Terasomy 9), and (iii) metabolism pathways including both amino acid metabolism (PEPD, SLC7A7, MAN2B1) and oxidative metabolism (NCF2). Clinical and laboratory data were analysed according to the SLICC classification.

Results: We included 42 articles encompassing 88 patients, plus 2 additional unpublished cases of one author (AB). The MA process were carried out according to the PRISMA statement. According to the SLICC classification, the blood disorders were significantly higher in the group of the metabolism pathway as well as the positivity of direct Coombs test. The positivity of antibodies anti-Sm was also a distinguishing element for this group, while the positivity of ALP antibodies was the only manifestation to distinguish the adaptive immunity pathway from the others. Fever, recurrent infections, hepatosplenomegaly, and pulmonary diseases were significantly predominant in the metabolism pathways. In the group of the IFN pathway, the most distinctive criteria were the neurological manifestations and bone changes. There were no statistically significant differences in all groups concerning all other clinical or immunological criteria.

Conclusion: This is the first quantitative analysis of multiples cases reports, comparing the whole spectrum of monogenic pSLE according to three different pathways. Our results suggest that abnormalities in signaling pathway delimitate different SLE juvenile subset. The clinical and biological differing between the three signaling pathway were not specific, but our results may help to detect phenotypes requiring targeted genetic investigations. Subsets of SLE syndrome have to be identified to drive the treatment and propose personalized medicine.

**OP0258 LESSON FROM EUROFEVER REGISTRY AFTER THE FIRST TEN YEARS OF ENROLLMENT**

Martina Ferrari, Ilaria Gueli, Joost Frenkel, Seza Ozan, Helen J. Lachmann, Fabrizio De Benedetti, Isabelle Kneu-Pauly, Carine Wouters, Paul Brogan, Hermann Girschick, Benedicte Neven, Alberto Martini, Nicolo Ruferto, Marco Gattorno, IRCSS Istituto Gianna Gaslini, UCSID Centro Malattie Autoinflammatorie e Immunodeficienze, on the behalf of the Paediatric Rheumatology International Trials Organisation (PRINTO) and the Eurofever Project, Genoa, Italy

Background: In 2008 the Paediatric Rheumatology European Society (PReS) promoted an International Project for the study of Autoinflammatory Diseases (AIDs) named Eurofever, whose main purpose is to create a web-based registry for the collection of information in AIDs patients.

Objectives: To assess the impact of the Eurofever Registry on scientific community with particular interest in the geographical coverage, diagnostic delay, access to treatment and publications.

Methods: The data analyzed in the study were extracted from the Eurofever registry, which is hosted in the PRINTO website.

Results: Up to date 4175 patients have been enrolled from 62 countries (3843 of them with complete demographic data). Most of patients (72%) are resident in Western Europe, 8% in Central-Eastern Europe, 11% in Southern-Eastern Mediterranean, 2% in South America and 7% in other countries. Compared to the first Eurofever report (Toplak et al, 2012) we have observed an increase of enrolled patients from 1388 to 2651 in Western Europe, from 106 to 313 in Central-Eastern Europe, from 284 to 406 in Southern-Eastern Mediterranean. The median onset age is 4 years (range 1 month – 78 years), the median diagnosis age is 6 years (range 1 month – 78 years). The median diagnostic delay observed in 2012 was 7.3 years (range 0.3–76), from patients enrolled after 2012 it was 1.9 years (range 0.57). Comparing the mean diagnostic delay from 1980 to 2018, we have observed an encouraging constant reduction of period between AIDs onset and diagnosis (from a mean diagnostic delay value of 20 years for patients born before 1980, to a mean value of 1 year for patients born after 2011, Figure 1). Complete information on access to treatment were available in 2430 patients. DMARDs were used in 1031 (42%), biologics in 396 (16%) patients. According to the number of enrolled patients, biologics were used in 361/7182 (20%) of Western europeans, 17/342 (5%) of Central-Eastern europeans, 6/259 (2%) of Southern-Eastern Mediterranean patients. Regarding Eurofever impact on Scientific Communication, during this first 10 years the Registry provided 12 papers with more than 800 citations. Detailed analysis of clinical features collected in Eurofever database allowed to perform studies with large cohort of patients, to propose new classification criteria (Federici et al, 2015), to validate damage and activity score (Piram et
Conclusion: In the last years we have observed an encouraging increase of involved Countries, with a greater number of patients coming from geographic area poorly represented in the first epidemiologic study of Toplak et al. Eurofever data analysis has confirmed an improvement of diagnostic ability during the last years, with a significant reduction of mean diagnostic delay. Longterm studies will help understand the efficacy and safety of different treatments used in these rare conditions.

Background: Patients with juvenile idiopathic arthritis (JIA) may have a different body composition associated with reduced muscle mass and increased fat mass [1]. They display decreased physical fitness, perform less strenuous physical activities, and spend more time sleeping than do healthy children. A lower level of physical activity is associated with deconditioning and functional deterioration, favoring an inactive lifestyle. The risk of overweight might be further increased by the glucocorticoid treatment.

Objectives: Since obesity can increase inflammatory processes, cause early atherosclerotic changes and promote metabolic disorders, the objectives were a) to determine the prevalence of overweight and obesity in children and adolescents with JIA, and b) to examine the association between overweight and health-related parameters in this population.

Method: A cross-sectional analysis of physicians’ recorded body weights and heights of patients with JIA enrolled in the NPRD in the year 2016 was performed. Overweight was defined as BMI >90th sex- and age-specific percentile and obesity as BMI >97th percentile. For comparison with data from the general German population [2], patients aged 3 to 17 years were considered. A linear regression model was used to explore the association between overweight and both clinical as well as self-reported outcomes.

Results: In total, data from 6.860 children and adolescents with JIA (age 11.5 ± 4 years, disease duration 4.6 ± 3.6 years, 67% girls, 39% persistent oligoarthritis) were analyzed. Overweight was found in 14% (including 6% obesity) of JIA cases. Comparative data from the German general population report an overweight prevalence of 15% (including 6% obesity). In contrast to the general population, overweight rates in JIA differed between girls and boys (girls 14% vs. boys 16%, p=0.05). Patients with psoriatic arthritis (20%) and systemic JIA (18%) showed the highest overweight rates. In multivariate analyses, age (OR 1.06; 95%CI: 1.04-1.09), male sex (OR 1.21; 95%CI: 1.01-1.44), functional limitations (OR 1.29; 95%CI: 1.04-1.59), as well as therapy with biological DMARDs (OR 1.48; 95%CI: 1.22-1.80) and systemic glucocorticoids (OR 1.40; 95%CI: 1.14-1.71) were significantly associated with overweight.

Conclusion: The prevalence of overweight and obesity in young patients with JIA is similar to that of children and adolescents in the general population. The overweight rate increases with age and is strongly associated with functional restrictions and treatment with glucocorticoids. The role of overweight in the long-term outcome of JIA is an issue that still needs to be addressed.
VACCINATION SAFETY AND COVERAGE IN AN ITALIAN COHORT OF AUTOINFLAMMATORY DISEASES

Sara Signa, Caterina Matucci Cerinic, Enrica Toniolo, Marta Bastuffa, Matteo D’alessandro, Stefano Volpi, Roberta Caorsi, Leonardo Oliveira Mendonca, Marco Gattorno. IRCCS Istituto Giannina Gaslini, Clinica pediatrica e neonatologia, Genova, Italy

Background: Vaccine-preventable diseases are again emerging in our population after anti-vaccine campaign has started. In autoinflammatory diseases (AID), vaccine triggered disease is a well known phenomenon for Hyper-IgD/Mevalonate-Kinase Deficiency (MKD). In CAPS, severe flares have been experienced after pneumococcus vaccine, while PFAPA patients did not achieve sufficient and protective levels of antibodies. This evidence has raised doubts in physicians and families about the safety of vaccines.

Objectives: To evaluate, in a cohort of Italian AID, the vaccination coverage of the Italian Vaccination Schedule and the prevalence of adverse reactions and disease flares induced by vaccinations.

Methods: An anamnestic questionnaire was applied to AID patients referring to the AID Unit of the Istituto Giannina Gaslini from August 2017 to August 2018. Acquired data were revised for quality of information. Data about disease triggers in AID were obtained from the EUROFEVER registry for statistical reference.

Results: Triggers in AID Eurofever Registry: In August 2018 a total of 3783 patients were enrolled in the EUROFEVER registry (1908 female, 50.43%). The mean age of symptoms at disease onset was 7.04 +/- 9.48 SD yrs, (minimal 0 - maximum 75.92 yrs). The distribution among the periodic hereditary fevers was: 28,75% FMF (n=1081); 17,66% TRAPS (n=271) and 5,39% MKD (n=204). Triggers were observed in the disease of 70% of the MKD, while PFAPA, TRAPS and UND had a rate of reactions of 20%. This was also found in 12,34% of CAPS, whereas FM and inflammatory bone disorders had a rate of 6% and 3%, respectively. Excluding other causes of reactions, and isolating just vaccines as a cause, MKD had a higher percentage of reactions (7,14%), while PFAPA and UND had 1% and CAPS, TRAPS, FM and inflammatory bone disorders had less than 1%. Triggers in IGG cohort: 150 questionnaires were distributed with 70% rate of response. Quality of data was 100% for coverage and adverse reactions. 105 patients were identified: PFAPA (n=26); CAPS (n=5); TRAPS (n=6); FM (n=14); MKD (n=6); Inflammatory Bone Disorders (CRMO and PAPA, n=4) and UND (n=4). Rate of coverage was lower than 90% for Hib3 (83.11%), MMR/ MMRV (88.9%) and for Rota C (1.85%). DTP3, Hep3, PCV3 and IPV the rate of coverage was higher than 90% for all vaccines. 11 moderate/severe reactions were observed as following: 5 after DTPA+IPV (1 PFAPA; 2 TRAPS, 1 MKD and 1 UND); 1 after Hib (PFAPA); 1 after P10/13 (PFAPA); 1 after MPR (PFAPA); 1 after MMR (1 TRAPS, 1 MKD and 1 UND). The general rate of severe reactions/shot was 0.68 for 1000 shots and no severe infection, death, persistent or significant disability or life-threatening condition was observed. Just one MKD patient had a severe disease flare requiring hospitalization following pneumococcal vaccine.

Conclusion: Data show that in AID patients vaccines may more frequently trigger the disease. Therefore, vaccination in AID may be considered a peculiar public health problem. Specific recommendations for vaccination in AID are warranted as well as further investigations for immunologic protection.

FACTORS ASSOCIATED WITH ACUTE ANTERIOR HYDROXYCHLOROQUINE DOSING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: ANALYSIS OF THE BSRBR-AS REGISTRY DATABASE

Mohammad H. Derakhshan1, Linda Dean2, Gareth T. Jones2, Gary J. Macfarlane2, Stefan Siebert1, Karl Gaffney3, University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2University of Aberdeen, Epidemiology Group, Aberdeen, United Kingdom; 3Norfolk and Norwich University Hospital, Rheumatology Department, Norwich, United Kingdom

Background: Acute anterior uveitis (AAU) is one of the key extra-articular manifestations in axial spondyloarthritis (axSpA). The presence of AAU may influence the decision to start and the choice of biological therapy.

Objectives: To examine the factors associated with AAU in patients with axSpA in the British Society for Rheumatology Biologics Register in Ankylosing Spondylitis (BSRBR-AS).

Methods: Clinical and patients-reported outcomes of 2420 patients with axSpA from 83 rheumatology centres in the United Kingdom were collected as part of the BSRBR-AS. Patients with AAU diagnosed by an ophthalmologist were compared to those without AAU in relation to demographic and lifestyle factors. The associations were analysed using univariable and multivariable logistic regression models, considering necessary interaction terms and sensitivity analyses.

Results: 568 (23.5%) patients in the cohort had at least one episode of AAU. The male/female ratio was 2.0:1 and group’s median (IQR) age was 51 (41 – 61) years. Factors associated with higher odds of AAU in univariable analyses were HLA-B27 positivity [OR 2.32 (95%CI: 1.66 – 3.23)], univerisity degree [OR 1.44 (95%CI: 1.53 – 1.79)], age [OR (per year) 1.02 (95%CI: 1.01 – 1.03)] and axSpA disease duration [OR (per year) 1.02 (95%CI: 1.01 – 1.03)]. Ever-smoking was inversely associated with AAU [OR 0.71 (95%CI: 0.59 – 0.89)]. Ever-alcohol drinking (p=0.213), BMI (p=0.325) and gender (p=0.317) did not show any associations.

In multivariable analysis, the magnitude of associations remained significant for HLA-B27 positivity, age, and axSpA disease duration, as did the inverse association with smoking (see Table). Analysis restricted to patients with inflammatory bowel disease did not alter the relationship between AAU and the above risk factors.

Table 1. Factors associated with AAU in axSpA, multivariable analysis

Conclusion: The odds of having a diagnosis of AAU is high in axSpA patients with positive HLA-B27, and longer disease duration (having controlled for age). The negative association with smoking in this large cohort contrasts with previous published data and warrants further evaluation.

Acknowledgement: British Society of Rheumatology

Disclosure of Interests: Mohammad H. Derakhshan: None declared, Linda Dean: None declared, Gareth T. Jones Grant/research support from: Have received research grants (not current) from Abbvie and Pfizer.

Conclusion: A significant fraction of patients with rheumatic disease on HCQ received doses greater than those recommended by the AAO, with large differences across practices and states. Patients with low body weight are consistently at increased risk of receiving a higher dose. Although further studies are required to

OP0263 HYDROXYCHLOROQUINE DOING IN PATIENTS WITH RHEUMATIC DISEASE ACROSS THE U.S.: DATA FROM THE RHEUMATOLOGY INFORMATICS SYSTEM FOR EFFECTIVENESS (RISE) REGISTRY

Zara Izaz1, Milena Gianfrancesco2, Michael Evans1, Julia Kay1, Laura Trupin1, Gabriela Schmajuk1, Michelle A Patel1, Jinoo Yazdany1, University of California, San Francisco, San Francisco, United States of America; 2Johns Hopkins University, Baltimore, United States of America

Background: The risk of retinal toxicity and subsequent visual loss from hydroxychloroquine (HCQ) is dependent on daily dose and duration of use. Although further efficacy and safety studies are required to understand optimal dosing strategies, real-world application of existing American Academy of Ophthalmology (AAO) recommendations in a population-based sample of patients with rheumatic disease has never been described.

Objectives: The objectives of this study were to assess application of AAO dosing recommendations across the U.S. and identify patient and practice-level risk factors for receiving higher than recommended doses using data from the ACR’s RISE registry.

Methods: RISE is a national, EHR-enabled registry that passively collects data on all patients seen by participating practices, reducing the selection bias present in single-insurer claims databases. As of December 2017, RISE held validated data from 1,257 providers in 236 practices, representing about 36% of the U.S. clinical rheumatology workforce. We included adult patients with at least one order for HCQ in 2017. For patients with multiple orders, the most recent order was included in the analysis. We excluded weights that appeared to be outliers and practices with <30 patients receiving HCQ. Instructions were interpreted to yield an average daily dose per patient. We investigated practice-level and state-level variation by calculating the proportion of patients who received a dose >5 mg/kg/day by practice and the proportion of patients who received a dose >6.5 mg/kg/day (AAO’s 2011 recommendation) by state. We tested whether prescribing a dose exceeding the AAO recommendations was associated with patient-level demographics (age, sex, race/ethnicity, insurance) or practice characteristics (type, size) using multivariate mixed-effects regression.

Results: We included 45,712 patients (85% female, 53% Caucasian, with mean age 57±15) from 96 practices (34% single specialty group practice, 76% with 1-5 providers). The patient average daily dose of HCQ ranged from 57 mg to 800 mg, with a median of 400 mg. Overall, 40% and 9% of patients received a HCQ dose >5 mg/kg/day and >6.5 mg/kg/day, respectively. Practice-level variation ranged from 6-66% for receiving a dose >5 mg/kg/day (Figure 1) and 0-28% for receiving a dose >6.5 mg/kg/day. State-level variation was also significant (p<0.001, Figure 2). After adjusting for demographics and practice characteristics, low body weight (<78 kg, the sample median) was strongly associated with receiving doses >5 mg/kg/day (+64%, p<0.001) and >6.5 mg/kg/day (+18%, p<0.001). In the same model, female gender was also associated with doses >6.5 mg/kg/day (+5%, p<0.001). Practice characteristics were not statistically significantly associated with receiving a higher dose.

Conclusion: A significant fraction of patients with rheumatic disease on HCQ received doses greater than those recommended by the AAO, with large differences across practices and states. Patients with low body weight are consistently at increased risk of receiving a higher dose. Although further studies are required to

Disclosure of Interests: Mohammad H. Derakhshan: None declared, Linda Dean: None declared, Gareth T. Jones Grant/research support from: Have received research grants (not current) from Abbvie and Pfizer.
achieve consensus on optimal dosing of HCQ, these data suggest that patients with low body weight should be targeted for toxicity monitoring regardless of the dosing cut-off used.

Disclaimer: This data was supported by the ACR’s RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

OP0264 REFINING THE PRIMARY CARE CCP+ PATIENT PATHWAY
Leticia Garcia-Montoya, Jacqueline Nam, Kulveer Mankia, Laurence Duquenne, Peta Pentony, Andrea Dimatteo, Paul Emery. NIHR Leeds Biomedical Research Centre, Chapel Allerton Hospital, Leeds, United Kingdom

Background: It is known that the presence of anti-CCP antibodies (CCP+) is associated with the development of rheumatoid arthritis (RA). Between 0-9% of the general population test positive [1], but only a small percentage of them will develop the disease. Previous work [2] showed that the selection of individuals with non-specific musculoskeletal symptoms, without clinical synovitis enriched the prevalence of anti-CCP positivity and also the likelihood of imminent progression to inflammatory arthritis.

Objectives: To assess for other factors which are associated with disease progression in patients testing CCP+ in order to optimise primary care referrals to Rheumatology.

Methods: A prospective observational study recruiting patients over 18 years old with a new musculoskeletal complaint and no clinical synovitis was conducted. Patients were recruited from primary care centres across the UK from July 2007 until February 2018. Those testing CCP+ in anti-CCP2 assay (immunocap method, Phadia assay) were invited to come to Leeds for assessment and follow-up including a baseline musculoskeletal ultrasound. Patients unable to attend were sent questionnaires 12 months later and were contacted in January 2019 to assess their status.

Results: 5702 eligible patients were recruited from primary care. 2.99% (171/5702) patients tested CCP+ and data from 150 patients was available for analysis: 5702) patients tested CCP+ and data from 150 patients was available for analysis: 148 (64) of 150 progressed to inflammatory arthritis (IA), predominantly RA. The mean time of progression was 242 days and 91% progressed in less than 12 months. The absence of pain in the hands or feet had a negative predictive value of 0.97) of patients with CCP+ high titre (p<0.001). All low titre progressors had pain in hands and feet and history of smoking exposure. 114 patients came to secondary care for assessment and a baseline musculoskeletal ultrasound scan was performed in 72 of them: the presence of PD in hands/feet was associated with progression to IA with a RR 2.4 (95%CI 1.27-4.58, p=0.01).

Conclusion: CCP+ patients without clinical synovitis who do not have pain in the hands or feet are unlikely to progress to IA especially if they have low titre antibodies. A high anti-CCP titre, new pain in hands/feet and PD in these joints are associated with rapid progression. These data may help optimise the primary care referrals to Rheumatology.

OP0265 FRAILITY, DISABILITY, AND WORK DISABILITY IN PEOPLE WITH OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS
Michael Cook1, Guzzane Verstappen1, Terence Oreel1,2. 1The University of Manchester, Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom, 2Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom

Background: Frailty is a clinical syndrome associated with adverse health outcomes. Frailty and disability can co-occur though are distinct entities. There are few prospective data looking at the occurrence and development of frailty, disability, and work disability in people with osteoarthritis (OA) and rheumatoid arthritis (RA).

Objectives: To determine the odds of prevalent and incident frailty, disability, and work disability in people with OA or RA, compared to people without these diseases.

Methods: Subjects aged 40-69 were recruited to the UK Biobank cohort. Data, including self-reported physician-diagnosed OA and RA, were collected at baseline (2007-10) and, in a subset, at follow up (2012-16). Frailty was measured using a modified Fried phenotype comprising five components: self-reported weight loss, exhaustion, low physical activity, slow usual walking pace, and low measured grip-strength (1). Participants were classified as robust if none of the components were present, pre-frail if 1-2 components were present and frail if ≥3 components were present. Participants were classified as having a disability if they indicated receiving a disability allowance/benefit. Participants indicating that they were unable to work due to disability or illness were classified as work disabled. Incident frailty was defined as frail at follow up and robust or pre-frail at baseline. Incident disability or work disability, respectively, was defined as receiving a disability benefit or indicating work disability at follow up but not at baseline.

Results: The mean (SD) age of the 465,379 participants at baseline was 56.5 (8.1) years and 54.3% were female. At baseline, 8.0% of the cohort reported that they had OA and 1.1% RA. At baseline, the prevalence of pre-frailty and frailty was 45.9% and 3.1%, respectively. 3.4% of the cohort indicated receiving a disability benefit, and 3.6% being work disabled. In a model adjusted for age, sex, smoking status and deprivation, compared to those without OA, those with OA were more likely to be pre-frail, odds ratio (OR) (95% CI), 1.8 (1.7,1.8), or frail, OR 4.5 (4.3,4.7), than robust. The adjusted OR (95% CI) for pre-frailty and frailty in those with RA (vs no RA) was 2.8 (2.6, 3.0) and 10.6 (9.7, 11.6), respectively. The adjusted OR (95% CI) for disability benefit was 3.9 (3.8, 4.1) in people with OA (vs no OA) and 7.7 (7.2, 8.2) in people with RA (vs no RA). The adjusted OR (95% CI) for work disability at baseline was 3.5 (3.3, 3.6) in people with OA and 4.8 (4.4, 5.2) in people with RA.

Data were available for 26,932 participants at follow up. The mean (SD) follow up time was 5.3 (1.5) years. Of those without frailty at baseline, 573 participants developed frailty during follow up. There were 292 incident cases of disability benefit and 137 incident cases of work disability. The adjusted OR (95% CI) for incident frailty in people with OA and RA at baseline was 2.3 (1.8, 2.9) and 3.3 (1.9, 5.7), respectively. The adjusted OR (95% CI) for incident disability benefit in people with OA and RA at baseline was 2.7 (2.0, 3.6) and 3.2 (1.7, 6.2), respectively. The adjusted OR (95% CI) for incident work disability in people with OA and RA at baseline was 2.3 (1.3, 3.9) and 3.7 (1.3, 10.1), respectively.

Conclusion: People with OA and RA have an increased risk of being, or becoming, frail, disabled, or work disabled. Further work is needed to determine effective

Discipline: Rheumatology

OP266 RISK OF HOSPITALIZED INFECTION IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIS TREATED WITH BIOLOGICAL DRUGS – A MATCHED COHORT STUDY

Simon Krabbe1,2, Kathrine L. Gran1,2, Bente Glintborg1,3, Frank Mehner4, Dorthe E. Jarbel5, Mikkel Østergaard1,2, Merete L. Heitland1,2. 1The DANBIO Registry and Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; 2Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; 3Center for Rheumatology and Spine Diseases, Gentofte Hospital, Hellerup, Denmark; 4Department of Clinical Epidemiology, Aarhus University, Aarhus, Denmark; 5Department of Public Health, University of Southern Denmark, Odense, Denmark

Background: Patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) treated with biological drugs (bDMARDs) have increased risk of hospitalized infection (i.e. infection causing admission to hospital) compared to the general population. Since patients with RA, axSpA and PsA have different age distributions, and age is an important predictor for infection, we found it of interest to quantify the excess burden of hospitalized infection in patients with inflammatory arthritis treated with bDMARDs compared to the general population and to investigate whether risk depended on age and diagnosis.

Objectives: To compare the risk of hospitalized infection in bio-naïve patients with inflammatory arthritis, who started treatment with a bDMARD with that of the general population, and to explore how this risk was influenced by age and diagnosis.

Methods: Matched cohort study based on data from The Danish Rheumatology Register (DANBIO) linked with The Danish National Patient Register and The Danish National Prescription Register. Patients with a diagnosis of RA, PsA or axSpA were matched with controls from the general population. For each patient, 10 controls from the general population, matched by age, sex, postal code and date were obtained. Infection risk in patients and matched controls were compared in analyses stratified by age and diagnosis, with Cox proportional hazards models accounting for matching. Follow-up time was 12 months irrespective of whether treatment was continued or changed during follow-up.

Results: In total, 11,372 patients and 113,715 controls were included. Overall, hospitalized infection was observed during follow-up in 4.6% of patients and 1.3% of controls; hazard ratio 3.7 (95% confidence interval (CI): 3.4-4.1).

The absolute risk was highest in RA patients, followed by PsA, axSpA and controls (unadjusted comparison). When stratified by age, the absolute risk increased with age, but was largely similar across diagnoses (Figure). In the stratum ≥60 years, RA patients appeared to have higher risk than axSpA patients, but the subgroup of axSpA patients ≥60 years was small.

Conclusion: The risk of hospitalized infection during 12 months of follow-up was approximately four times higher in bio-naïve patients with inflammatory arthritis who started treatment with a biological drug (bDMARD) compared to matched controls from the general population. When stratified by age, the absolute risk was largely similar across the diagnoses RA, axSpA and PsA. Thus, attention to preventive strategies such as vaccination seems prudent in these patients, especially those ≥60 years of age.

OP267 INACTIVATED INFLUENZA VACCINATION DOES NOT ASSOCIATE WITH DISEASE FLARES IN AUTOIMMUNE RHEUMATIC DISEASES: A SELF-CONTROLLED CASE SERIES STUDY USING DATA FROM THE CLINICAL PRACTICE RESEARCH DATALINK

Georgina Nakafere1, Matthew Grainger2, Puja Myles3, Christian Mallen3, Weiya Zhang1, Michael Doherty1, Jonathan Nguyen-van-Tam1, Abhishek Abhishek1, 1University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom; 2University of Nottingham, Epidemiology and Public Health, Nottingham, United Kingdom; 3Keele University, Keele, United Kingdom

Background: Concerns about vaccination with the seasonal flu vaccine associating with increased risk of autoimmune rheumatic disease (AIRD) activity, and anecdotal reports of the seasonal flu vaccine triggering diseases such as vasculitis are barriers to flu vaccination in this population1. 2 This is despite reports of stable disease activity following flu vaccination provided disease modifying anti-rheumatic drug therapy is continued in the peri-vaccination period3. Previous studies generally include patients with stable disease activity, and as far as we are aware, a real world study evaluating the association between inactivated influenza vaccine (IIV) administration and AIRD activity has not been conducted.

Objectives: To examine the association between IIV administration and primary case control vaccination for joint pain, fatigue, rheumatoid arthritis (RA) flare, corticosteroid prescription, and incident vasculitis in people with AIRDs.

Δελτίο Ελέης
**Methods:** We undertook within-person comparisons using self-controlled case-series (SCCS), AIRD cases who received IV and had an outcome of interest in the same influenza cycle, between 1st September of one year and 31st August of the next year, between 2006 and 2016 were ascertained within the Clinical Practice Research Datalink. The influenza cycle (1st September of one year to 31st December of the next year) was partitioned into five exposure periods (1-15 days pre-vaccination, and 0-14, 15-30, 31-60, and 61-90 days post-vaccination), with the remaining time period classified as non-exposed. Incidence rate ratios (IRR) and 95% confidence intervals (CI) were calculated to compare the frequency of outcomes in different periods.

**Results:** Data for 14,928 AIRD cases (69% women, 80% with RA) were included. There was no association between IV administration and primary-care consultation for RA flare, corticosteroid prescription, and vasculitis (Table 1). Vaccination associated with reduced primary-care consultation for joint pain in the 90-day post-vaccination period (IRR (95%CI) 0.91(0.87-0.94)), and fatigue (IRR (95%CI) 0.90(0.87-0.94)) in the 61-90 days post vaccination Table (1).

*New corticosteroid prescription on the same date as consultation for either RA flare, or joint pain, or fatigue.

**Conclusion:** The administration of IV was not associated with flare of the underlying AIRD and its association with reduced disease activity warrants further investigation. Nevertheless, these data add to the accumulating evidence to support seasonal influenza vaccination in people with AIRDs.

**OPO268-HPR** THE PREVALENCE AND IMPACT OF FATIGUE IN PEOPLE WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME: A MIXED METHODS STUDY

Lindsay Beamer1, David O’Dowd2, Sophia Georgopoulou2, Louise Neil3, Julie Beiles1, Josie Andrews1, Katrine Stolark1, Thomas Williamson1, Beatriz Santana-Suarez2, Amy Tully1, Heidi Lempp2, 1King’s College London, Department of Population Health Sciences, London, United Kingdom; 2King’s College London, Department of Inflammation Biology, London, United Kingdom; 3Guy’s and St Thomas’ NHS Foundation Trust, The Louise Codres Unit, London, United Kingdom

**Background:** Primary antiphospholipid syndrome (PAPS) is a prothrombotic disorder associated with increased mortality and morbidity. Symptoms include fatigue but the prevalence and impact of fatigue is unknown.

**Objectives:** To explore the prevalence, relationships and impact of fatigue in adults with PAPS.

**Methods:** This mixed methods study recruited participants from one public hospital, UK. Inclusion criteria comprised: adults with >6 month history of PAPS (Sydney classification criteria) and sufficient written and spoken English. Exclusion criteria included: other autoimmune rheumatic/inflammatory disorders; cancer; active chronic infections, positive Antinuclear antibody, pregnancy/breast-feeding, drugs/alcohol dependency and BMI>30.

Consenting participants completed seven questionnaires to record sociodemographic characteristics, fatigue (Fatigue Severity Scale (FSS), FACIT-Fatigue subscale, (FFS)), social support (Multi-Dimensional Perceived Social Support Scale (MDPSS), mood (Patient Health Questionnaire (PHQ-9), quality of life (EQ-5D-5L), sleep quality (Pittsburgh Sleep Quality Index (PSQI) and physical activity (International Physical Activity Questionnaire (IPAQMETs)). The relationship between (FSS) and predictor variables were explored using Spearman’s Rho correlation coefficients and backward stepwise regression analyses. Audio recorded, semi structured interviews were conducted with a subset of participants by two researchers with an agreed topic guide. Interviews were transcribed verbatim, anonymised, and analysed thematically with NVivo 10. The data was validated by a subsample of participants, cross-referencing the emergent codes and themes.

**Results:** 103 participants were recruited (87 complete datasets; mean (standard deviation) 50.3 (10.4) years, 8 men, 49 thrombotic APS). 69% of participants reported clinically relevant fatigue (FSS>3) and 62% of participants indicated severe fatigue (FSS>4). FSS was positively associated with PSQI (r (0.67-0.269 p=0.025), PHQ9 (r (0.83-0.620 p<0.001) and negatively associated with EQ-5D-5L (r (0.83)-0.055 p=0.001). F (r (0.82)-0.656 p=0.001) and IPAQMETs (r (0.80)-0.243 p=0.028) but not MDPSS. The best fit model explained 62% of the variance in FSS (adjusted R²=0.617, F (0.82)-22.63.p=0.001) and included FS, MDPSS, PHQ9, and IPAQMETs as significant predictors. For every 1 unit increase in FS, MDPSS, IPAQMETs and PHQ9, FSS decreased by -0.087 points, -0.084 points and -9.7*10^-3 MET minutes or increased by 0.090 points respectively.

Twenty participants (10 obstetric/10 thrombotic pAPS) completed interviews (duration 20-50 minutes). Participants with obstetric PAPS were younger. Five themes were identified across both subgroups: 1. Unpredictability of fatigue 2. Impact on daily life 3. Physical activity matters 4. Individual coping strategies 5. Acknowledgement and help with fatigue from clinicians.

**Conclusion:** Fatigue is a common, overwhelming, unpredictable symptom of PAPS which is a challenge to manage. Social support, mood and physical activity predicted fatigue severity. Interviewees tended not to discuss fatigue with clinicians due to lack of observed response or empathy. Participants perceived physical activity as important but difficult to complete regularly. Interventions to manage fatigue and support physical activity are needed for adults with PAPS.

**REFERENCE:**

Background: Fatigue is common in RA (ERA) and some patients experience improvement in fatigue when disease is well controlled, others experience persistent fatigue associated with work disability, poor QoL, and depression.

Objectives: To compare patterns and predictors of improved vs. persistent fatigue in the first year of ERA.

Methods: Data were from ERA patients (symptoms <1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) from 01/2007 to 03/2017. All met ACR1987 or 2010 ACR/EULAR criteria, had active disease, were on DMARDS, and complete fatigue (0-10) data over ≥12 months. Patients were classified at baseline with low (<4) or high (≥4) fatigue; high fatigue patients were categorized at 12-months as improved (1-2) or persistent (≤1). Multivariable logistic regression was used to identify predictors of improved vs. persistent fatigue at 12 months in those with high baseline fatigue.

Results: The 1002 pts were mostly white (81%), female (71%), with a mean (SD) symptom duration of 5.7 (2.9) months in those with high baseline fatigue. Among those with initial high fatigue, 30% had persistent fatigue at 12 months and was associated with obesity, comorbidities, higher disease activity (Table 1). Among those with initial high fatigue, 30% had persistent fatigue at 12 months and was associated with obesity, comorbidities, FM, longer symptom duration, and slightly lower baseline fatigue.

Table 1. Descriptive Statistics

Predictors of improved fatigue in multivariable models were BMI<30 (OR 0.6; 95% CI 0.3-0.9), MTX<20 mg (OR 1.7; 95% CI 1.0-2.7) and higher pain (OR 1.1; 95% CI 1.0, 1.2) after controlling for other variables.

Conclusion: Fatigue is common in ERA and associated with active disease, worse pain and disability, obesity, depression, major stressors, poor sleep and OA backpain. In high fatigue, those who are not obese, have higher pain, and take >20 mg MTX are more likely to improve over the first year. Optimizing weight, sleep, physical and emotional use and MTX use may improve persistent fatigue beyond control of RA inflammation.

Disclosure of Interests: Susan J. Bartlett Consultant for: Pfizer, UCB, Lilly, Novartis, Merck, Jansen, Abbvie, Orit Schieir: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared, Marie-France Valois: None declared.
Conclusion: Child’s psychosocial adjustment is likely to be related with school attendance. When the attendance decreases, problems such as social functioning and isolation can occur. The fact that families and children agreed on the reasons about not to go to school but their functional and psychosocial status were good may have been due to different reasons. It was thought to normalize and encourage children to go to school. In addition, families should motivate their children with positive reinforcements.

ASSESSMENT OF MUSCLE MASS RELATIVE TO FAT MASS AND ITS ASSOCIATION WITH DISEASE ACTIVITY STATUS AND PHYSICAL FUNCTIONING IN RHEUMATOID ARTHRITIS

Rafaela Cavalheiro do Espírito Santo1, Jordana Miranda de Souza Silva1,2, Joshua Baker1, Vanessa Haix1, Clariton Brenol2,3, Lidiane Filippin2,3, Priscila Lora3, Ricardo Xavier1,2,4
1Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; 2University of Pennsylvania, Philadelphia, United States of America; 3Universidade La Salle, Canoas, Brazil; 4Universidade do Vale do Rio dos Sinos, São Leopoldo, Brazil

Background: Rheumatoid arthritis (RA) is an autoimmune, chronic, progressive, inflammatory disease characterized by symmetrical, destructive polyarthritis and is accompanied by systemic manifestations. RA patients show low appendicular lean mass index (ALMI) and higher fat mass index. Impaired physical function is associated greater with fat mass and the adiposity is an important confounder that may mask true relationships between physical functioning and ALMI (1).

Objectives: To assess muscle mass relative to fat mass and verify associations this parameter with disease activity status, functional capacity and biologics treatments.

Methods: 115 RA patients, aged between 40 and 70 years, were recruited and followed for 12 months. Body composition was assessed by total body dual-energy x-ray absorptiometry for measurement of appendicular lean mass index (ALMI, kg/m2) and fat mass index (FMI, kg/m2). Age-, sex-, and race-specific Z-Scores and T-Scores were determined by comparison to published reference ranges. ALMI values were adjusted for FMI (ALMI/FMI) using a published method. Disease activity was assessed by Disease Activity Score-28 with erythrocyte sedimentation rate (DAS28). RA patients were divided in non-remission (DAS28≥2.6) and in remission (DAS28<2.6). Physical functioning was assessed by Health Assessment Questionnaire (HAQ).

Background: Public health recommendations for physical activity (PA) advice that exercise programs include all four fitness dimensions, i.e. cardiorespiratory, muscle strength, flexibility and neuromotor exercise training at well-defined

Fitness Status of People with Axial Spondyloarthritis (ASxPA): First results after implementation of fitness assessments in ASxPA exercise groups

Karina Niedermann1, Anne-Kathrin Rausch1, André Meichtry1, Béatrice Walker2, René Bramer1, Adrian Ciurea2,3, Zurich University of Applied Sciences, School of Health Professions, Winterthur, Switzerland; 2Analyzing Spondylitis Association of Switzerland, Zurich, Switzerland; 3University Hospital, Rheumatology, Zurich, Switzerland

Background: Public health recommendations for physical activity (PA) advice that exercise programs include all four fitness dimensions, i.e. cardiorespiratory, muscle strength, flexibility and neuromotor exercise training at well-defined

frequency, intensity and duration/repetitions, and regular evaluations (1). The 2018 EULAR recommendations for PA (2) state that this is also effective, feasible and safe for people with rheumatic diseases. Therefore, the Ankylosing Spondylitis Association of Switzerland (SVMB) has started to implement assessments of all four fitness dimensions in their exercise groups (n=68). Criteria for selection of an assessment was its psychometric properties and feasibility for group setting, i.e. low costs and material requirements: Chester step test (CST) for cardiorespiratory fitness (3); adapted Core Strength Endurance test battery (CSE) for muscle strength (4); Bath AS Metrology Index (BASMI) for flexibility (5); Single-Leg Stance test (SLS) for balance (as proxy for neuromotor activities) (6). For all assessments, except CSE, norm values for healthy people are available.

Objectives: To assess the fitness status of people with axSpA across four volunteering pilot groups and evaluate if between-subject variables of interest are associated with fitness status.

Methods: Participants were assessed at baseline and after 6 months on all four fitness dimensions. For each dimension, a linear mixed model with random intercept was fitted to the data with the within-subject variables time and measurement condition and the between-subject variables age, disease duration, disease activity (Bath AS Disease Activity Index, BASDAI) and PA level (weekly Metabolic Equivalent of Task MET) as explanatory variables.

Results: Of 30 patients assessed, 10 (33%) were women, mean age was 58.5 (SD 7.68) years, mean disease duration was 32.6 (SD 9.68) years, mean disease activity was 3.1 (SD 2.36) and mean PA per week was 5013 (SD 3479.77) METs. Estimated VO2max for cardiorespiratory fitness was 35.2 (SD 6.59). Disease activity was negatively (slope=-1.49, p<0.01) and PA level positively (slope=3.28, p=0.01) associated with cardiorespiratory fitness. Mean core muscle strength endurance was 78.8 (SD 51.98) seconds. PA level was positively associated with core muscle strength (slope= 6.82, p=0.05). Mean flexibility score was 3.1 (SD 2.36), with age being positively associated with flexibility (slope=0.10, p=0.04). Mean balance was 43.1 (SD 21.09) and 7.7 (SD 5.84) seconds with open and closed eyes respectively. Age was negatively associated with balance (slope= -0.84 (p=0.00).

Conclusion: The SVMB has made an important step by implementing regular fitness evaluations in their axSpA exercise groups. The test scores of the assessed people with axSpA were lower than in healthy people but within the norms. PA level was positively associated with cardiorespiratory fitness and core muscle strength. Disease duration and disease activity were negatively associated with cardiorespiratory fitness only, but not with the other fitness dimensions, which may be different from what is usually assumed.

FUNDAMENTAL EXERCISE FOR ADULTS WITH CHRONIC NON-SPECIFIC LOW BACK PAIN: A RANDOMIZED CONTROLLED TRIAL

Emilia Moreira, Anamaria Jones, Eider Da Silva Lima, Fabio Jennings,
Jamil Natour. Universidade Federal de Sao Paulo, Rheumatology Division, Sao Paulo, Brazil

Background: Exercise therapy is part of the recommendation for the treatment of chronic non-specific low back pain (LBP). Functional exercise may be an alternative for the treatment, no studies assessing its effectiveness were found.

Objectives: To assess the effectiveness of the functional exercise program for pain, functional capacity, general health, kinesiophobia and perceived exertion in adults with chronic nonspecific LBP.

Methods: A randomized controlled clinical trial with intention-to-treat analysis and 24-week follow-up was performed. Eighty-four patients were randomly assigned to an experimental group (EG) or control group (CG). The EG participated in the functional exercises program performed twice a week for twelve weeks. The functional exercise program was composed by global exercises that worked the group of muscles of the trunk and lower and upper limbs with progression every 4 weeks. The two groups received an informative class on the disease and were advised to use analgesic if necessary. Primary outcome was LBP measured by numeric rating scale (NRS). Secondary outcomes included was functional capacity by Oswestry and Roland Morris questionnaires, 6-minute walk and TUG tests, kinesiophobia (FABQs), general health (SF-36), perceived exertion (BORG). Evaluations were performed at baseline, after 6, 12 (end of intervention) and 24 weeks by a blind evaluator.

Results: The groups were homogeneous for all parameters at baseline. Compared with the CG, the EG statistically improved pain, functional capacity, kinesiophobia, some domains of general health and perceived exertion - Table 1.

Conclusion: The functional exercise program was effective to improve pain, functional capacity, kinesiophobia, general health and perceived exertion in adults with chronic nonspecific LBP.

DEVELOPMENT OF GENERIC CORE COMPETENCES OF HEALTH PROFESSIONALS IN RHEUMATOLOGY: A SYSTEMATIC LITERATURE REVIEW INFORMING THE 2018 EULAR RECOMMENDATIONS

George E. Fragoulis1, Lisa Edelaar2,3, Valentin Schäfer4, Jan Schoones3, Christos G. Angelopoulou5, Anna Maria Ignaocco2, Thea Viet Vliet1, Elena Nikiforou1,2,1 University of Glasgow, Institute of infection, immunity and inflammation, Glasgow, United Kingdom;2 Amsterdam Rehabilitation Research Center, Amsterdam, Netherlands;3 Leiden University Medical Center, Walaues Library, Leiden, Netherlands;4 University Hospital Bonn, III. Medical Clinic, Department of Oncology, Hematology and Rheumatology, Bonn, Germany;5 Academic Rheumatology Centre, Dipartimento di Scienze Cliniche e Biologiche, Turin, Italy;6 Leiden University Medical Center, department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands;7 King’s College, Department of Information Biology, London, United Kingdom

Background: Acquisition and maintenance of competences by Health Professionals in Rheumatology (HPRs) is important to ensure the best care for people with
rheumatic and musculoskeletal diseases (RMDs). HPRs’ competencies have never been systematically evaluated, nor international recommendations provided. A EULAR Task Force (TF) was formed for this purpose.

**Objectives:** To perform a systematic literature review (SLR) on the core competences of HPRs with a focus on nurses, physiotherapists (PT) and occupational therapists (OT) to inform the “EULAR recommendations for the generic core competences of Health Professionals in Rheumatology”

**Methods:** Thirteen main themes identified by the TF and translated into research questions, formed the basis of the SLR. Existing literature was systematically evaluated using the following databases (PubMed/Medline, Embase, Cochrane library, CENTRAL, Embcare, PsychINFO, Academic Search Premier, Web of Science, Google Scholar, ERIC and National Science Digital Library) from 1/1/1990 to 20/02/2018. Relevant search terms for competences, RMDs and HPRs were used. In addition, EULAR HPR national presidents were invited to share any documents describing HPRs’ competences. Inclusion criteria were: studies on competences or roles, knowledge, attitudes, skills or educational needs relevant for the management of people with RMDs, of HPRs in general or specifically of nurses, PTs or OTs, at post-graduate level. Exclusion criteria were: HPRs’ competences for children’s care or for concuring co-morbidities; extended roles of HPRs; a very specific clinical intervention or an intervention clearly attributable to only one profession or studies written in a language other than English or Dutch.

All abstracts were screened to identify eligible studies for full text inclusion. The methodological quality of the studies was scored using appropriate tools (Table).

**Results:** From 591 unique references reviewed, 79 studies were included. Twenty studies addressed competences of multiple HPRs. The methodological quality of most papers was high to medium (Table). The identified studies underpinned a range of HPRs’ competences, including: communication skills, promotion of physical activity, basic knowledge about RMDs and education of patients and other health providers. Competences more relevant to specific professions (e.g. musculoskeletal system examination skills for PTs and assessment of house and work environment for OTs) were also recorded. Heterogeneity in the HPR desired competences and practice across countries highlighted the need for further education of HPRs to acquire certain competences.

**Conclusion:** High-quality literature is available on the competences of HPRs for the management of people with RMDs. This literature supports the formulation of evidence-based recommendations for the core competences for HPRs by a EULAR Task Force.

**COP275**

**THE PI3Kδ INHIBITOR INCBO50465 AMELIORATES SALIVARY GLAND PATHOLOGY AND REDUCES AUTOANTIBODY FORMATION IN A MURINE MODEL OF SJÖGREN’S SYNDROME**

Brittany Fay, Monika Scuron, Niu Shin, Yan-Ou Yang, Eddy Yue, Andrew Combs, Julian Oliver, Felicia Thomas, Roni Page, Eduardo Huarte, Paul Smith, Incyte Corporation, Wilmington, United States of America

**Background:** Sjögren’s syndrome (SS) is a chronic autoimmune exocrinopathy affecting the glands that produce tears, saliva and vaginal and bronchial

**secrets. SS represents a complex interaction between the adaptive immune system and specific tissue regions of exocrine glands. Germinal ectopic lymphoid structures that are rich in autoimmune B-cells are thought to play an important role in local chronic B-cell activation and clonal expansion, autobody production, and Ig class switching in SS. Genetic deletion or pharmacological inhibition of PI3Kδ leads to defective B-cell activation, reduced proliferation and functional suppression. INCBO50465, an oral small molecule selective PI3Kδ inhibitor, is currently being evaluated in clinical trials for the treatment of B-cell driven autoimmune diseases: SS and autoimmune hemolytic anemia (NCT03627065 & NCT03538041).

**Objectives:** To evaluate INCBO50465 efficacy as a monotherapy in a spontaneous murine model of Sjögren’s syndrome.

**DENDRITIC CELL-DERIVED IL-27 REGULATES THE MAGNITUDE OF INDUCIBLE ECTOPTIC GERMINAL CENTRES BUT FAILS TO DOWNMODULATE IL-17 PRODUCTION IN CD4 T CELLS FROM PATIENTS WITH SJÖGREN’S SYNDROME**

David Lucchesi1, Rachel Coleby2, Elena Pontarini3, Edoardo Prediletto1, David Hill2, Alicia Derrac Soría1, Felice Rivelles1, Costantino Pitzalis2, Simon Jones3, Gareth Jones3, Michele Bombardieri1, William Harvey Research Institute, Queen Mary University of London, Experimental Medicine and Rheumatology, London, United Kingdom; 2Cardiff University, School of Medicine, Cardiff, United Kingdom; 3University of Bristol, School of Cellular and Molecular Medicine, Bristol, United Kingdom

**Background:** Approximately 30% of Sjögren’s Syndrome (SS) patients develop Ectopic Lymphoid Structures (ELS) in their salivary glands (SG). ELS play an active role in autoimmunity and contribute to the development of MALT lymphoma. Interleukin 27 (IL-27) exerts key immunomodulatory actions on CD4 T cells with both pro- and anti-inflammatory roles but its role in the formation and regulation of ELS in the salivary glands of SS is unknown.

**Objectives:** We first used a murine model of inducible SG ELS to elucidate the role of IL-27 and its interaction with IL-17 in the regulation of ELS formation and function. We then extended our observations on a cohort of SS patients to identify IL-27 cellular source, target cells and functional properties in modulating peripheral and lesional CD4 T cells function.

**Methods:** To trigger ELS formation a single dose of reporter-encoding adenovirus was delivered directly to the SG of wild-type (WT) and IL-27-deficient (KO) mice. For IL-17 blockade anti-mouse IL-17A antibody was administered systemically. ELS development and peripheral immune responses were tracked by immune-blot histopathology, FACS, and qPCR. Minor SG biopsies were collected from SS and non-specific sialadenitis (sicca) patients. Peripheral blood mononuclear cells (PBMC) isolated from patients and age-sex matched healthy donors (HD). For in vitro experiments PBMCs, isolated CD4 T cells and parotid gland MCs were incubated with IL-27 and analysed by FACS for CD4 T cell subsets while cytokines levels were measured intracellularly by FACS and in tissue supernatants. Tissue IL-27 was assessed in SS SG sections by multicolour immunofluorescence to identify IL-27 producing cells.

**Results:** In WT mice, SG ELS formation was preceded by an upregulation of IL-27 and infiltration of IL-27 producing cells (CD4+IL-27(IFN-γ)). In KO mice, IL-27 was increased in the ELS+ subset of SS, it consistently failed to downregulate Th17 response in the SG by restricting Th17 expansion. Both in murine inducible ELS and in patients with SS, higher expression levels of IL-27 transcripts and protein, respectively, compared to sicca, while IL-27 was selectively increased in the ELS+ subset of SS. Immunofluorescence staining for IL-27 revealed its presence primarily in the T cell rich areas of SS ELS with frequent co-localization with DC-LAMP+ dendritic cells. Finally, while IL-27 was able to significantly downregulate IL-17 production in HD, CD4 T cells from patients with SS failed to downregulate IL-17 but showed an aberrant IFNγ release upon IL-27 incubation. We did not observe any difference in IL-27R expression or downstream STAT1/3 phosphorylation between SS and HD.

**Conclusion:** The role of IL-27 in the development of the IL-27/IL-17 axis play an important role in ELS formation in this condition. SG IL-27 was increased in the ELS+ subset of SS, it consistently failed to downregulate Th17 response in the SG by restricting Th17 expansion. Both in murine inducible ELS and in patients with SS, higher expression levels of IL-27 transcripts and protein, respectively, compared to sicca, while IL-27 was selectively increased in the ELS+ subset of SS. Immunofluorescence staining for IL-27 revealed its presence primarily in the T cell rich areas of SS ELS with frequent co-localization with DC-LAMP+ dendritic cells. Finally, while IL-27 was able to significantly downregulate IL-17 production in HD, CD4 T cells from patients with SS failed to downregulate IL-17 but showed an aberrant IFNγ release upon IL-27 incubation. We did not observe any difference in IL-27R expression or downstream STAT1/3 phosphorylation between SS and HD.

**Disclosure of Interests:** None declared.

**Acknowledgement:** This work was supported by FOREUM, SYSCID and ERC-Advanced Grant.
in UST-NR or PBO patients. IGS levels were elevated in 67% of patients at baseline versus healthy controls. Serum IFN-γ levels and IGS levels in blood were not modulated by UST treatment through week 24. Baseline IFN-I signature status did not associate with response to UST, as the treatment effect size (UST vs PBO) was similar in IFN-I (n=27%) and high (n=28%) patients.

Conclusion: Response to UST was associated with reductions in IFN-γ levels, whereas IL-17A, IL-17F, IL-22 and IFN-I remained largely unchanged. While these findings require confirmation in an ongoing Phase 3 study, these data imply the involvement of the IL-12 pathway and suggest a novel mechanism of action for UST-R in SLE.

A UNIQUE IL-21 SIGNATURE CHARACTERIZES LESIONAL AND CIRCULATING T-FOLLICULAR HELPER CELLS IN SJÖGREN’S SYNDROME PATIENTS WITH ECTOPIC GERMINAL CENTRES AND MALT LYMPHOMA

Elena Pontarini1, William Murray Brown2, Cristina Croia2, Davide Lucchesi2, Felice Rivellese2, Liliane Fossati-Jimack2, Elena Pontarini1, William Murray Brown2, Cristina Croia2, Davide Lucchesi2, Felice Rivellese2, Liliane Fossati-Jimack2, Elena Pontarini1, William Murray Brown2, Cristina Croia2, Davide Lucchesi2, Felice Rivellese2, Liliane Fossati-Jimack2, Elena Pontarini1, William Murray Brown2, Cristina Croia2, Davide Lucchesi2, Felice Rivellese2, Liliane Fossati-Jimack2, Elena Pontarini1, William Murray Brown2, Cristina Croia2, Davide Lucchesi2, Felice Rivellese2, Liliane Fossati-Jimack2

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that can affect multiple organs, including the skin, joints and kidneys. The disease is characterized by the development of skin lesions, autoantibody production and inflammation-induced glomerulonephritis. The skin is involved in SLE cases1. In the MRL/lpr spontaneous mouse model of SLE, disease symptoms also include lymphocyte hyper-proliferation, resulting in lymphadenopathy and splenomegaly. The evolutionary conserved Janus kinase-signaling transducer of activators of transcription (JAK-STAT) pathway constitutes a rapid mechanism to nuclear signaling modality that affects key biological aspects of the mammalian immune system2. Janus kinase 1 (JAK1) is involved in the downstream signaling pathway of type I interferons (IFNs), and high levels of type I IFNs are associated with SLE3. INCB054707 is an oral small molecule JAK1 selective inhibitor currently being evaluated in clinical trials for the dermatological disease hidradenitis suppurativa (NCT03569371 & NCT03607487). We hypothesized that INCB054707 should reduce IFN signaling and ameliorate cutaneous lesions in SLE.

Objective: To determine the effectiveness of INCB054707, a selective JAK1 inhibitor, in a preclinical model of cutaneous lupus erythematosus.

Methods: Female MRL/lpr mice were randomized to treatment groups at 11 weeks old to receive twice daily oral doses of vehicle (0.5% methyl cellulose) or INCB054707 at 10, 30, or 90 mg/kg for 10 weeks. Efficacy was determined by weekly scoring of the changes in skin, lymph node size, and proteinuria. At study termination (week 21), inguinal lymph nodes and spleens were excised and weighed, skin lesions and kidneys were excised and fixed for histopathologic analysis, and serum was collected for pharmacokinetic analysis and ELISA. Autoantibody presence in the serum was detected using a commercial anti-dsDNA ELISA kit.

Results: IL21 and IL21R expression, together with CD4+CD45RO+PD1+ICOS+ Tfh cells were strongly enriched in ELS- vs ELS- SS Gs. Tfh cells densely infiltrated B cell rich areas and, within ectopic GC, acquired BCL6 expression, both in ELS+ and MALT-L. Tfh infiltration significantly correlated with SG IL21 mRNA level, which in turn was associated with high T (CD4+) and plasma cells (CD138+) IHC scores and significantly correlated with CXC13L1, LTj, BAFF, AID and Pax5 gene expression. MALT-L samples displayed 10-fold higher IL21 mRNA and twice as much PD1+ICOS+BCL6+ Tfh-cells/field in comparison to ELS+ SS samples. Within the SGs, IL21 and IFNγ production by Tfh in the peripheral compartment showed a positive correlation with IgG serum levels.

Conclusion: Within the SG of SS patients Tfh cells closely segregated with lesional IL21 expression, localize within ELS and are strongly enriched during MALT-L development, which is supporting their role in sustaining B cell activation and malignant transformation. High production of IL21 by Tfh in peripheral blood selectively identifies SS patient with ectopic GC in the SG, suggesting a role for IL21+ Tfh cells as surrogate markers of SG histopathology in SS.

ELEVATED EXPRESSION OF BAFF-RECEPTOR IN PERIPHERAL MONOCYTES PROMOTES B CELL ACTIVATION AND CORRELATES WITH CLINICAL MANIFESTATIONS OF PRIMARY SJÖGREN’S SYNDROME

Keiko Yoshimoto, Katsuya Suzuki, Yumi Ikeda, Eriku Takei, Tsutomu Takeuchi. Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Primary Sjögren’s syndrome (pSS) is an idiopathic autoimmune disease whose major clinical manifestations are xerostomia and keratoconjunctivitis sicca, and is often accompanied with hypergammaglobulinemia. Several lines of evidence suggest that a focal lymphocytic infiltrate of the exocrine glands is responsible for lesion formation, IgG production and subsequent dysfunction of the glands. It is well known that B cell activating factor (BAFF) and its receptor, BR3, are deeply involved in the pathogenesis of pSS, and hence BAFF and BR3 are promising targets to treat the disease. We have reported that the abnormally elevated expression of BR3 in monocytes is associated with overproduction of inflammatory cytokines, such as IL-6, by monocytes of pSS patients. Our in vitro experiments suggest that BAFF-stimulated monocytes contribute to IgG overproduction by pSS B cells. We also found that the population of a specific subset of B cells overexpressing BR3 was abnormally increased in pSS patients and that the proportion of the subset was positively and significantly correlated with serum levels of autoantibodies and total IgG as well as ESSDAI, one of the indicators of disease activity of pSS. Our results collectively suggest that the elevated expression of BR3 in pSS monocytes results in B cell activation and subsequent overproduction of IgG. However, the relationship between the abnormalities of peripheral cells and clinical manifestations of pSS has not been fully understood.

Objective: To elucidate possible roles of abnormal monocytes in the development of clinical manifestations of pSS.

Methods: The expression level of BR3 in peripheral monocytes of patients with pSS (n = 65) and healthy controls (HC: n = 38) was analyzed by FACS. Peripheral B cells were cultured with BAFF-stimulated monocytes in the presence or absence of an anti-IL-6 receptor antibody, and the proportion of CD38hiIgD- cells among CD19+ cells, and IgG production were analyzed by FACS and ELISA, respectively. The serological data and focus scores by lip biopsy of the patients were collected by clinical records.

Results: FACS analysis revealed that the expression level of BR3 in pSS monocytes was significantly higher than that of HC (p < 0.001). Moreover, the expression level of BR3 in peripheral monocytes was positively and significantly correlated with serum levels of IgG (p = 0.01) and IgM (p = 0.02) of the patients. Notably, BR3 expression in monocytes from focus score-positive pSS patients was significantly higher than that from negative patients (p = 0.006). In addition, BR3 expression in pSS monocytes was elevated in anti-SS-A and/or anti-SS-B positive patients as compared to negative patients. When B cells prepared from pSS patients were mixed with autologous monocytes and co-cultured in vitro in the presence of BAFF, the proportion of CD38hiIgD- cells, which are plasmablasts and/or plasma cells, among CD19+ positive cells and IgG produced by the cells were drastically enhanced by BAFF-stimulation, whereas the stimulation showed only marginal effects when B cells were solely cultured in vitro. In addition, an anti-human IL-6R antibody significantly inhibited the proportion of CD38hiIgD- cells and IgG production. These data strongly suggest that IL-6 produced by BAFF-stimulated monocyte plays a pivotal role in B cell differentiation and the IgG overproduction in pSS patients.

Conclusion: Our data strongly suggest that accelerated signal transduction through a BAFF-BAF3 axis in monocytes is involved in the pathogenesis of pSS and associates with clinical manifestations of the disease. These results also suggest that BAFF and the BAFF signaling pathways through BR3 are the possible therapeutic targets for pSS.
OBSTETRIC ANTIPHOSPHOLIPID SYNDROME (OAPS) VS. WITH OBSTETRIC MORBIDITY RELATED WITH ANTIPHOSPHOLIPID ANTIBODIES (OMAPS): A SURVEY OF 1650 CASES FROM EUROAPS REGISTRY

Jaume Alijotas-Reig1, Enrique Esteve-Valverde2, Elisa Llurba3, Raquel Ferrer-Oliveras4, Domingo Ruiz-Hidalgó5, Luis Sáez-Comet6, Cristina Belizna7, Arseni Mekinian8, Elmina Lefkou10, Gerard Espinosa10, EUROAPS study group. 1Systemic Autoimmune Disease Unit, Department of Internal Medicine, Vall d’Hebron University Hospital, 2Department of Medicine, Universitat Autònoma, Barcelona, 3Barcelona, Spain; 4Internal Medicine Department, Althaia Healthcare Network of Manresa, Systemic Autoimmune Disease Unit, Manresa, Barcelona, Spain; 6Obstetrics and Gynaecology Department, High Risk Unit, University Hospital of the Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain; 8Obstetrics and Gynaecology Department, High Risk Unit, Vall d’Hebron University Hospital, Universitat Autònoma Barcelona, Barcelona, Spain; 9Internal Medicine Department, Althaia Healthcare Network of Manresa, Manresa, Universitat Autònoma Barcelona, Barcelona, Spain; 10Internal Medicine Department, Miguel Servet University Hospital, Zaragoza, Spain; 11Vascular and Coagulation Department, University Hospital Angers, Angers, France; 12AP-HP, Hopital Saint-Antoine, service de médecine interne and Immunoimmunopathology-Immunotherapy-Biotherapy Department (DHU i2B), Sorbonne Universités, UPMC Univ Paris 06, Paris, France; 13Haematology Unit, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece. 14Systemic Autoimmune Diseases Service, Hospital Clinic, Universitat de Barcelona, Barcelona, Spain

Background: The obstetric antiphospholipid syndrome is an autoimmune systemic disorder related to antiphospholipid antibodies and pregnancy morbidity. There exist many patients that do not fulfil the Sydney classification criteria. Those cases may be defined as Obstetric Morbidity related with antiphospholipid antibodies (OMAPS). Objectives: To compare clinical features, laboratory data and foetal-maternal outcomes, between 1000 women with obstetric antiphospholipid syndrome and 640 women with aPL-related obstetric complications not fulfilling Sydney criteria. Methods: Retrospective and prospective multicenter study from the European Registry on Obstetric Antiphospholipid Syndrome. Results: 1650 women with 5251 episodes were included of which 3601 were historical and 1650 were latest episodes. 1000 cases (OAPS group) fulfilled the classification criteria and 650 (OMAPS group) did not. Ten OMAPS cases were excluded because they presented a thrombosis during follow-up. In the OMAPS group, 172/640 (26.67%) did not fulfill Sydney clinical criteria (subgroup A), 179/ 640 (27.96%) had a low titer and/or non-persistent aPL positivity but fulfilled clinical criteria (subgroup B), and 289/640 (45.15%) had a medium or high aPL titer but did not fulfill Sydney clinical criteria (subgroup C).

Conclusion: Significant clinical and laboratory differences were found between groups. Foetal-maternal outcomes were similar in both groups when they were treated. The results suggest that we could improve our clinical practice with closed defining and monitoring OMAPS patients.

A DUTCH RESEARCH AGENDA DEVELOPED BY PEOPLE WITH RMDs: WHAT ARE THE MAIN PROBLEMS PEOPLE WITH RMDs FACE AND WHAT ARE THEIR MAIN WISHES FOR RESEARCH AND DEVELOPMENT?

Patricia Penning MSc1, Renate Verkaik2, Henrieke Kappen2, Hennie Boeije1, 1National Association ReumaZorg Nederland, Nijmegen, Netherlands; 2NIVEL Netherlands Institute for Health Services Research, Utrecht, Netherlands

Background: In the Netherlands much progress has been made with regard to patient participation in research. More and more researchers are finding their way to patient organizations for collaboration. This is also the case for the National Association ReumaZorg Nederland where more and more researchers are asking for the opinion of our patient-experts on their written research proposals. However, this happens mostly because ‘asking for the patient’s view’ is an obligatory (last) part of the submission process of their proposal. ReumaZorg Nederland wants to take patient participation in research to the next level. A level where ‘what matters most to patients’ is taken into account before a proposal is written. Only then will the patient’s voice really be heard in the very heart of a research project.

Objectives: To identify the main problems people with RMDs face in their daily lives and to prioritize their wishes for future research and development. To investi-gate whether these problems and wishes vary between patients with different types of RMDs. To encourage researchers and product-developers to take these wishes into account at the very start of their research proposal or product-plan.

Methods: Independent and professional research was needed to develop this research agenda. NIVEL, the Dutch Institute for Health Services Research, performed a 7 month research project which consisted of several steps. First, a literature search was performed on scientific publications in PubMed, Embase and Psycinfo on search strings focusing on living with RMDs, problems and wishes of people with RMDs and other known research agenda’s for people with RMDs. The second step consisted of 3 focus group sessions: inflammatory RMDs (group 1), osteoarthritis & fibromyalgia (group 2) and soft tissue- & systemic RMDs (group 3). In addition, a combined session of representatives of each focus group (12 participants) was organized to compare and complement the results of the 3 focus groups. In the third step, an online survey (277 respondents) was held to explore how these problems and research wishes were recognized and prioritized within the Dutch community of people with RMDs. After data-analysis in step 4, a stakeholders session was held in step 5 to discuss results amongst patients, researchers, rheumatologists and project-developers.

Results: Among the 89 problems that were recognized, the main problems people with RMDs face are:

1. Uncertainty about their future.
2. Having to cope with fatigue.
3. Having to cope with the unpredictability of RMDs.
4. Preserving boundaries/staying balanced.
5. Having to cope with the impact of RMDs on social life with family and friends.

Among the 85 wishes for research and development, the main wishes of people with RMDs are:

1. To develop treatments of RMDs other than surgery.
2. To develop an accessible and affordable network of physical exercise activities under professional supervision.
3. To investigate the cause of inflammatory RMDs.
4. To investigate the cause of fatigue with RMDs and how to cope.
5. To investigate alternative forms of therapy and their effect on specific types of RMDs.

All results were described in the first Dutch research agenda made by people with RMDs. 1

Conclusion: Remarkably, the main problems people face with RMDs are not necessarily the same as the wishes they have for further research or development. The problems people face have to do with issues regarding living and cop-ing with RMDs in everyday life, whereas their research-wishes are more medical. Fatigue is, however, an issue that is highly prioritized as a problem as well as a subject for further research. This goes for people with all types of RMDs.

THE INFLUENCE OF FUNCTIONAL TRAINING AND PSYCHO-SOCIAL SUPPORT

Nenad Nedčić, Mirjana Lapčević. Belgrade, Belgrade, Serbia

Background: Treatment of chronic noncontagious diseases in which we include RMD implies usage of medicines and non medicine (changing bad lifestyle habits like losing nutrition, physical activity, smoking…). Unwanted cardiovascular and cerebrovascular states are the most common cause of shortening of life of people with RMD. None of the chemical drugs can replace physical activity. Physical activity dosage is individual, and depends on aerobic capability and heart rate increase, taking in account age, type of noncontagious diseases, level of tissue and organs damage as well as the type of work the person is engaged in.

Patients with RMD have common symptoms, such as stiffness, fatigue, poor mobility, joint pain and muscle pain, anxiety and depression, and lack of fitness. In addition to physical medicine and rehabilitation and balneoklimatology, various forms of physical activity are recommended, such as walking, swimming, functional training. Today, moderate physical activity is known to help reduce fatigue, strengthen muscles and bones, improve flexibility and endurance of the joints, and improve general health. It is necessary to find the best combination of rest, activities and exercise programs to prevent deformities of the joints, the development of disability, improve the quality of life, and the mental health of patients with RMD.

Objectives: 1. By practicing Cigong, an increase in the volume of movement in the joint, the strengthening of joint muscles and the improvement of general condition, pain relief, fatigue reduction is achieved and also, it helps patients look and feel better.
2. The goal of Yoga is to neutralize and remove all obstacles that stand in the way and disturb the function of the body and the mind and achieves inner peace.
3. Changing the psychological state during exercise also led to a positive way of thinking.
4. Psycho-physical support for the people with RMD.

Methods: From 2011, we organize twice a week functional training of Cigong. Since January 2016, twice a week persons with RMD have been practicing Yoga.

From 2015, one per week four psychologists volunteer hold workshops for psycho-social support for persons with RMD.

Participants of the training and psycho-social sessions took a survey.

Results: 1. Joint pain reduction ~ 50% of total number of participants
2. Joint mobility increase ~ 95% of total number of participants
3. General fitness improvement ~ 73% of total number of participants
4. Less pronounced negative emotions ~ 59% of total number of participants

Conclusion: Practicing cigong, yoga and psycho-social support workshops help patients look better and feel better. Changing the psychological state during exercise also led to a positive way of thinking. All of this increased the effectiveness of drug treatment and improved the quality of life of patients with RMD.

the management of chronic illnesses, such as diabetes treatment, including good users’ acceptance and an increase in their knowledge. Knowledge acquisition is generally seen as a necessary condition for behavioral change. Applications with virtual humans offer a dynamic, interactive and easily accessible approach to enhance users’ knowledge. We did not find published literature on the use of virtual humans to educate people with OA.

Objectives: To develop a web application to support education of caregivers and people with OA.

Methods: This is a proof of concept study, which builds on our previous experience with virtual assistant applications. For example, “Virtual Pharmacy” is intended to improve self-medication consultation skills between students/pharmacy professionals and community pharmacy clients, whilst “VASelfCare” aims to facilitate self-care of older people with type 2 diabetes (REF?). The main principle underpinning the development of our application is the use of gamification embedded in a narrative with a double purpose of maintaining user engagement and enhancing the play experience. This option has in consideration that OA is more prevalent among the seniors and is supported by a study showing that embedding narratives in mobile games enhances the play experience of this age group.

In our approach, the narrative comprises dialogues aiming to ease and stimulate the search for new knowledge, and to educate for disease management and health promotion.

Results: So far, we have developed NOA, a virtual assistant that interacts with users through speech (voice and subtitles) plus facial and body animations. NOA is a 2D cartoon female model that plays the role of a character who suffers from OA and provides information about her own experiences with the disease. At the end of each dialogue, a quiz tests users’ knowledge. Awarding points and digital badges for correct answers, or showing the right answers when the user fails, are expected to motivate users to play and learn more. This application will be placed in the “Portuguese League Against Rheumatic Diseases” website to convey easy access.

Conclusion: Development of a virtual assistant web application to promote education on OA, resorting to a narrative approach and gamification principles, is ongoing. Future work includes testing the application with experts and patients.

WHAT DO YOUNG PEOPLE THINK ABOUT CONTINUOUS DATA COLLECTION IN CLINICAL RESEARCH AND THE TYPES OF ELECTRONIC DEVICES?

Laura Lund1,2, Stephanie Shoop-Worrall3,4, Sonia Kharon3,5, Imogen Bolw2, Antonio L. Fartana3,5, Mary A Short3, Janet McDonagh1,2,3,4,5, NHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; 2BANNAR Your Rheum, The University of Manchester, Manchester, United Kingdom; 3The University of Manchester, Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom; 4The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom; 5Elli Lilly and Company, Indianapolis, United States of America

Background: The use of wearable devices are of increasing interest to enable continuous data collection during drug trials. This is particularly pertinent when involving young people who are “digital natives” and have grown up with such technologies.

Objectives: To ascertain opinions from young people regarding the design of wearable devices and the use of continuous data collection for a future clinical drug trial for juvenile idiopathic arthritis (JIA).

Methods: A three hour face-to-face patient involvement session was held in a young person friendly venue in central Manchester on the 8th December 2018. Young people with a rheumatic disease were invited to participate using event flyers provided in local rheumatology clinics. Members of a national youth advisory panel, Your Rheum, were also invited to attend. Data was collected in both large and small group discussions and included a ranking exercise involving the use of voting cards, emojis and pictures of electronic devices to aid conversations. In addition, an online survey was also developed and uploaded to http://yourheim.org for young people to complete if they could not attend the event in person. Open questions (requesting free text answers) ranged from general thoughts and concerns about continuous data collection, device preferences and features, to examples of unattractive devices.

Results: Eight young people attended the event (M=5, F=3, 11-19 age range). All males were under 14 years of age. One young person completed the online survey (F=1). All participants regularly used some form of an electronic device and were generally willing to use a wearable device for continuous data collection, although consideration of school regulations (e.g. uniform policies) and potential bullying was necessary. Participants reported that they would choose a device based on its viability, look, comfort and functionality. For instance, the device would need to be discrete in terms of size, muted (no sounds or vibrations) and removable. The preference of device type differed by gender though a watch and patch were in the top three favourite devices for all. Key features included the

OP0287-PARE

SETTING UP A EUROPEAN FEDERATION OF SJÖGREN’S SYNDROME PATIENT ASSOCIATIONS: HOW WE BUILT UP SJÖGREN EUROPE IN LESS THAN ONE YEAR

Alice Grosjean1, Ana Vieira2, Coraile Bouillot3, Jenny Inga Diaz4, Mascha Oosterbaan5, Joyce Koelewijn-Tukker5, Isabelle Lesuisse6.

Mascha Oosterbaan5, Joyce Koelewijn-Tukker5, Isabelle Lesuisse6.

Methods: Sjögren Europe was conceived during the 2018 ISSS and the decision to address the lack of visibility and the unmet needs, foster patient training and involvement in research and articulate patient voices throughout Europe. To set up a perennial European Federation of SS patient associations, a task force was set to set a mindset and to communicate on a regular basis to ensure a common spirit. We set priorities and down-to-earth objectives and focus on them. Although there is a leader for supervision and to take final decisions, the governance is mainly based on shared leadership sustained by trusted connections. Personal initiatives are encouraged, and failure is considered as a learning experience. We build a culture of compromise. As members experience debilitating fatigue, they achieve the tasks they can, whenever they have time and energy, and report them to the others: Sjögren Europe adapts to its members. We also welcome anyone sharing our mission principles and wanting to be involved in the project.

Results: On the 23rd of February 2019, Sjögren Europe was officially set up with more than 8 countries as founders. Being flexible not only allows patients with debilitating fatigue to work for the federation but also leads to lean and efficient procedures and tasks. An enthusiastic and supportive environment makes the commitment sustainable and meaningful. Face to face meetings, a good network and collaboration are imperative. The way we respond to mistakes is also crucial for motivation.

Conclusion: This project empowers the SS patient community, brings hope, injects a new energy in patient advocacy and breathes motivation for collaboration to researchers, scientists and clinicians. This presentation aims to share our story and the key learning points about the way we work and to spread the positive atmosphere.

ability to switch devices on and off, send reminders, chat to other young people and to track their own data. As well as personal preferences, age specific considerations were highlighted by the young people. It is therefore imperative not only to involve young people as research participants but also to involve them at early stages of research including trialing design to ensure acceptability of data collection methods including the design of any devices proposed.

Acknowledgement: Your Rheum is the national youth advisory panel of the Barbara Ansell National Network for Adolescent Rheumatology BANNAR. We would like to thank all of the young people who took part and other individuals who facilitated their involvement including BANNAR members and Versus Arthritis Young People Coordinators.

Background: Despite the availability of several treatment options, some Rheumatoid Arthritis (RA) patients do not reach low disease activity. There thus remains a need for differentiated new therapies. Prior studies identified a series of biphenylsulphonamides with bone protecting and anti-inflammatory activity which might meet this need.

Objectives: To evaluate the selectivity of a novel small molecule, MBS2320, in myeloid and lymphoid cells, characterise its selectivity for osteoclasts versus osteoblasts and characterise its effects on synovitis and osteoprotection compared to an anti-TNFα agent in a therapeutically administered collagen-induced arthritis (CIA) mouse model.

Methods: Viability, proliferation or cytokine production were assessed in human primary monocytes, lymphocytes or a Mixed Lymphocytes Reaction (MLR). Human primary osteoclasts (OCs) were differentiated from CD14+ monocytes with M-CSF and RANKL. Mature OCs were stained with tartrate-resistant acid phosphatase (TRAP) and quantified by light microscopy. Osteolytic activity was assessed on mineral-coated surfaces. Osteoblasts were derived from mesenchymal stem cells by differentiation in the presence of RANKL and BMSCs were differentiated from CD14+ monocytes assessed by Alizarin Red S staining. CIA was induced in DBA/1J mice by collagen immunisation. MBS2320 and etanercept were dosed once daily after onset of disease. Arthritis Index (AI) was scored throughout the dosing period after which serial paw sections were assessed for inflammation, synovitis, stromal cavity osteolysis, pannus hyperplasia, osteoid layering and bone resorption foci.

Results: MBS2320 reduced the production of cytokine from monocytes and inhibited T-cell proliferation, and cytokine production in a MLR. MBS2320 also reduced primary OC differentiation and function in vitro to a greater degree than alendronate but showed no effect on the differentiation of primary osteoblasts. MBS2320 (0.3 mg/kg) and etanercept (10 mg/kg) inhibited the onset and severity of CIA arthropathy, synovitis, pannus infiltration and osteolysis, with equivalent efficacy. In addition MBS2320 showed anatomically appropriate osteoid layering with conservation of the tide mark, and the bone marrow showed no cell atypia, with all progenitor classes present although reduced in number and distribution. In contrast, osteoid formation in the etanercept group was multi-focal with atypia, with all progenitor classes present although reduced in number and distribution.

Conclusion: MBS2320 selectively inhibits myeloid and lymphoid activity/differentiation, whilst sparing mesenchymal cells, in vitro. In murine CIA, MBS2320 treatment led to the formation of anatomically appropriate osteoid layering indicating an anti-osteolytic effect of osteoclasts conditioned by biomechanics. By contrast, osteoid formation due to etanercept was more ‘reactive’ and secondary to suppression of inflammation. The data suggest that MBS2320 offers equivalent anti-inflammatory activity, but a broader spectrum of osteoprotective efficacy in CIA compared to TNFα inhibition and may offer an alternative therapeutic approach to improving bone quality in RA.

OP297
ABERRANT ADENOSINE TO INOSINE RNA EDITING IN ACTIVE RHEUMATOID ARTHRITIS

Nikolaos Vlachogiannakis 1,2, Alkaterini Gatsiou 1, Kimon Stamateopoulos 1, Maria Tektonidou 1, Petros Sfikakis 1, Konstantinos Siollos 1, National and Kapodistrian University of Athens Medical School, First Department of Propaedeutic Internal Medicine and Joint Rheumatology Program, Athens, Greece; Newcastle University, Faculty of Medical Sciences, Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom; National and Kapodistrian University of Athens Medical School, Department of Clinical Therapeutics, Athens, Greece

Background: Adenosine to inosine (A-to-I) RNA editing is a widespread post-transcriptional RNA modification mainly located in repetitive Alu elements and mediated by the enzyme adenosine deaminase acting on RNA-1 (ADAR1). A-to-I RNA editing controls various aspects of RNA metabolism, which may affect tissue-specific gene expression. Although deregulation of RNA editing has been previously reported in various human diseases including cardiovascular disease and cancer (Stellos et al., 2017; Liu et al., Nat Med 2019 and Ishizuka et al., Nature, 2019), its role in autoimmune diseases and especially in rheumatoid arthritis (RA) remains unknown.

Objectives: To study whether A-to-I RNA editing is involved in the pathogenesis or to determine the impact of anti-rheumatic treatment on RNA editing.

Methods: We first analysed the expression of ADAR1 in 185 RA synovial tissues versus 76 healthy/osteoarthritic synovia derived from 4 independent RNA-sequencing and microarray datasets. We validated the findings in peripheral blood mono-nuclear cells (PBMCs) derived from 19 patients with active RA vs 14 controls and performed an additional ADAR1-isofrom analysis (ADAR1p110/ADAR1p150) by RT-qPCR. Further, we studied in single nucleotide level the A-to-I RNA editing levels of the pro-inflammatory gene cathepsin S (CTSS) 3’-translated region (3’UTR), a matrix degradation enzyme which is a well-established target of ADAR1, by AU Sanger sequencing and RNA editing analysis. Last, we examined the effect of anti-rheumatic treatment on RNA editing.

Results: Expression of the RNA editor ADAR1 was significantly increased in RA synovium compared to healthy or osteoarthritic synovium. Similarly, a significant increase of ADAR1, mainly due to an increase of the interferon-inducible ADAR1p150 isoform, was observed in PBMCs from active RA. Next, we studied the RNA editing levels in PBMCs from active RA patients before and after 12-week treatment versus controls. RNA editing of CTSS 3’UTR AluSx+ was increased in active RA (6.47% increase in editing rate of 8 individual adenines, P<0.05). Increased CTSS mRNA expression in RA PBMCs was associated with both ADAR1p150 expression (r=0.623, P=0.004) and RNA editing rate of 12 individual adenines (r=0.45-0.72, P<0.05 for all) located within the CTSS 3’-UTR AluSx+. The correlation between CTSS and ADAR1 was also observed in synovial tissue. Notably, ADAR1p150 expression and RNA editing rate reached control levels after 12-week treatment with methotrexate and/or biologics in patients with good clinical response (EULAR responders) but remained unchanged in the EULAR moderate/non-responders.

Quantification of histological markers did not show differences in population of macrophages, plasmocytes, T and B Cells, across pairs of joints. After correction for multiple comparisons, no transcripts were differentially expressed between large and small joints. Similarly, we did not find any significant differences in the expression of transcripts involved in pathogenesis and cell division specifically overexpressed in RA compared to OA synovial tissue.

In order to increase our ability to observe pair-wise differences in gene expression patterns we studied transcripts significant in expression in RA compared to OA joints with a fold change ≥ 2 (n = 581) and clinical or biological markers of disease activity (DAS28, CRP, CRP, Physician Global Assessment of disease activity). Similar patterns of correlations indicated that disease activity was not driven by different pathways in small versus large joints.

Conclusion: This study is an important methodological milestone in the field of synovial biopsies, as it indicates that cellular and molecular alterations occurring in RA synovials are similar across small and large joints from the same patient. Hence, biopsy of a single joint is representative and can be used to explore pathogenic processes or potential biomarkers in RA.

90% of ACPA-IgGs harbour N-linked glycans in the antibody variable (V) domain. The corresponding N-glycosylation sites in the amino acid backbone of ACPA V-regions result from somatic hypermutation, a T cell-dependent process. Notably, both genetic evidence and data obtained from the analysis of serum ACPA indicate that T-cells drive the maturation of the ACPA-response prior to the onset of arthritis.

Objectives: We investigated whether ACPA-IgG carry V-domain N-glycans prior to the development of arthritis and whether the occurrence of such glycans predicts the transition from pre-disease autoimmunity to overt RA.

Methods: Two independent sets of serum samples were obtained from RA patients and from ACPA-positive first-degree relatives (FDR) of RA-patients (n=126) of an Indigenous North American (RNA) population with high incidence rates of ACPA-positive RA. These samples comprised cross-sectional and longitudi-
Conclusion: ADAR1-mediated RNA editing is increased in active RA inducing the expression of pro-inflammatory genes thus representing a novel drug response biomarker and a potential therapeutic target in EULAR moderate/non-responders.

PCSK9 IN ATHEROSCLEROTIC INFLAMMATION OF LUPUS PATIENTS AND MURINE MODEL OF LUPUS WITH ATHEROSCLEROSIS

Chenglong Fang1, Tingting Luo2. 1Second Affiliated Hospital of Fujian Medical University, Department of Rheumatology, Quanzhou, China; 2Second Affiliated Hospital of Fujian Medical University, Quanzhou, China

Background: Systemic lupus erythematosus (SLE) patients have tendencies of accelerated atherosclerosis (AS), which is refractory to statins. Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a new therapeutic target for AS for its dual mechanisms in lipids metabolism and inflammation. PCSK9 inhibitors had proved to be highly promising cardiovascular disease (CVD) drugs [1]. Our previous study suggested that Toll-like receptor 4 (TLR4) signal participates in the atherosclerotic inflammation of murine model of lupus with AS [2].

Objectives: To investigate the role of PCSK9 in atherosclerotic process of lupus and the association between TLR4 and PCSK9 in atherogenic inflammation of murine model of lupus with AS.

Methods: 90 SLE patients and 50 healthy controls were included. According to carotid intima-media thickness (cIMT), SLE patients were further divided into SLE-AS and SLE-NonAS subgroups (cut-off point: 1.0mm). Traditional CVD risk factors, inflammatory biomarkers and PCSK9 concentrations were compared between: (I) SLE patients and controls; (II) SLE-AS subgroup and SLE-NonAS subgroup. Correlational analysis and multivariate linear regression analysis were applied to analyze the association between PCSK9 levels and disease parameter, and the predictors of PCSK9 levels in SLE patients. Effects on PCSK9 concentrations by monotherapy with hydroxychloroquine (HCQ), which is thought having protective effects against CVD in SLE, were investigated by follow-up analysis in 15 SLE patients with inactive disease (SLEDAI=2). In animal experiment, murine model of SLE with AS was set up by intraperitoneally injection of lipopolysaccharides (LPS) in ApoE−/− mice. 30 female ApoE−/− mice were respectively administrated with LPS (SLE+AS group, n=10), saline (AS group, n=10) and LPS plus injection of lentivirus-PCSK9 small hairpin RNA targeting the mouse PCSK9 gene into the tail vein to interfere PCSK9 expression (SLE+AS+PCSK9 group, n=10). 10 female C57BL/6 mice were included as controls. Serum concentrations of PCSK9 and inflammatory biomarkers including TNF-α and IL-1β, atherosclerotic lesion, lipids parameters, expression of PCSK9, TLR4 and NF-κB p65 in atherosclerotic plaque were assessed.

Results: Characteristics of SLE patients and controls were listed in Table 1. SLE patients had significantly elevated serum PCSK9 levels than controls, especially in SLE-AS subgroup, accompanied with higher ratio of cIMT thickening. Correlational analysis showed PCSK9 concentrations correlated with C-reactive protein (CRP) levels, age and erythrocyte sedimentation rate (ESR), but not lipids parameters. Univariate and multivariate linear regression revealed that only CRP, but not age or ESR was positive predictors of PCSK9. Monotherapy with HCQ for 3 months significantly reduced PCSK9 levels in inactive SLE patients (Table 2, Figure 1). Mice in SLE+AS group had significantly higher serum PCSK9 concentrations than mice in AS group and C57BL/6 mice. Immunohistochemistry showed that PCSK9 over-expression was observed in SLE+AS mice than those in AS group and SLE+AS+PCSK9 group. Mice in SLE+AS+PCSK9 group exhibited decreased inflammatory cell infiltration in atherosclerotic plaque, alleviated atherosclerotic lesion, lower serum TNF-α and IL-1β levels and attenuated expression of TLR4 and NF-κB p65 in atherosclerotic plaque than SLE+AS group. PCSK9 silencing had no significant effects on lipids parameters in SLE+AS mice (Figure 2).

ASSESSMENT OF ROLE OF URINARY HEPARANASE IN LUPUS NEPHRITIS PATIENTS AND ITS CORRELATION WITH DISEASE ACTIVITY

Mustafa Abou-Alfa1,2, Rasha Abdel Noor3, Haifa Nagy2, Nesreen Kotb4. 
1Tanta University, Internal Medicine, Tanta, Egypt; 2GOTHI, Internal Medicine Nephrology unit, Cairo, Egypt; 3Tanta University, Clinical Pathology Department, Tanta, Egypt

Background: Lupus nephritis (LN) is one of the commonest and serious complications of Systemic Lupus Erythematous (SLE) and assessment of its activity is crucial. Heparanase has been proposed to be important in the pathogenesis of lupus nephritis and correlate with protein excretion. Annals of the Rheumatic Diseases. 2013;71(Suppl 3):548-9.

Objectives: To assess the ability of urinary heparanase to identify SLE with nephritis and the relation of this marker to lupus activity.

Methods: This cross sectional study was carried out on 90 subjects; 70 patients with SLE and 20 healthy volunteers as a control. All patients and controls were subjected to full history taking and complete clinical examination, routine investigations. Immunological assay and assessment of disease activity by systemic lupus erythematous disease activity index (SLEDAI) score, renal SLEDAI (r-SLEDAI) were done for lupus nephritis group. The lupus patients were divided according to SLEDAI score into 4 groups; 20 with active lupus nephritis, 17 with non-active LN, 18 with active lupus without renal involvement, 15 with non-active lupus without renal involvement. Urinary Heparanase levels were measured by ELISA for all groups.

Results: The level of urinary heparanase was significantly higher in LN groups than non-LN groups and control. It was also significantly higher in active LN than non-active LN patients. There was a significant positive correlation between urinary heparanase and 24 hours urinary proteins, total SLEDAI, and r-SLEDAI; and significant negative correlation between urinary heparanase and C3 & C4. ROC curve analysis revealed that urinary heparanase predicted presence of lupus nephritis activity with a sensitivity of 80%, and a specificity of 91.43%.

Conclusion: Urinary heparanase levels are increased in patients with active LN and correlate with disease activity markers, indicating that it can serve as a new useful biomarker for lupus nephritis activity.

Thrombotic and atherogenic processes contributing to cardiovascular disease. (2) However, the role of NETs in cardiovascular disease in human gout is not known.

**Objectives:** Our objective is to investigate the association between neutrophil activation and cardiovascular risk in gout patients. We hypothesize that neutrophil activation mediates inflammation, as well as activation and damage to endothelial cells, partaking in atherosclerosis development.

**Methods:** Plasma samples from 75 gout patients participating in the ‘Reade gout cohort Amsterdam’ were analyzed. Patient data was collected on disease activity, demographics, gout history, comorbidities, medication use and cardiovascular risk assessments. Measurements included anthropometry, vital parameters (RR, HF), ECG and lab variables. Levels of NETs, and NET-derived markers (cell-free DNA and peroxidase activity) were analyzed using a MPO-DNA ELISA, as well as fluorometry. Levels of calprotectin (S100A8/A9) were analyzed by ELISA. Markers of NETosis were related to clinical markers of cardiovascular risk, including BMI, smoking, blood pressure, lipid profile and 10 year risk of cardiovascular mortality (SCORE EU).

**Results:** No associations were found between markers of cell death (cDNA and NETs) and cardiovascular risk. However, markers of neutrophil activation, including peroxidase activity correlated with BMI (r=0.31, p =0.008), waist-hip ratio (r=0.52, p<0.001), cholesterol ratio (r=0.51, p<0.001), and triglycerides (r=0.42, p<0.001). These associations were even stronger in patients with chronic, polyarticular gout. Peroxidase activity was associated with the 10 year risk of cardiovascular comorbidity (r=0.47, p<0.001, Figure 1A). Calprotectin levels were elevated in hypertensive patients (p<0.005) and diabetes (p=0.02), with calprotectin levels associating with diabetes independently on BMI (OR=6.2, p=0.04). Finally, we constructed a neutrophil risk score ranging from 0-2 based on positivity for peroxidase and/or calprotectin to identify patients with a ‘neutrophil activation signature’. The neutrophil risk score strongly associated with CVD risk (Figure 1B). Patients with neutrophil activation signature (risk score 1-2) had markedly elevated cardiovascular risk score (p<0.001), with 67.7% of the patients having high cardiovascular risk, versus 32.3% of the patients without a neutrophil activation signature (OR=2.9, p=0.03).

**Conclusion:** We have demonstrated, for the first time, that neutrophil activation markers are associated with several risk factors of cardiovascular disease, including hyperlipidemia, hypertension and diabetes in a large cohort of gout patients. Furthermore, the presence of a neutrophil activation signature is strongly associated with a 10-year risk of cardiovascular comorbidity.

Methods:
was used in murine air pouch model to assess the effects of 2DG and Glut1 inhibition in crystal-mediated inflam-
results: In vitro, both MSU and mCPPD crystal-induced IL-1β secretion and
Asc speck formation were inhibited when cells were cultured in glucose-free medium or in presence of 2DG.Similarly, MSU and mCPPD crystal-induced inflammation was abrogated in mice treated with 2DG.In THP-1 cells stimulated by MSU and mCPPD crystals, metabolic analysis displayed alteration of glycolysis pathway and Krebs cycle and decrease of intracellular ATP production. Interestingly, MSU and mCPPD crystals increased glucose uptake in vitro, ex vivo and in vivo. Crystal-induced IL-1β secretion was decreased by STF-31 and in THP-1 cells transfected with Glut1 siRNA. Next, we observed that MSU and mCPPD crystals increased membrane localization of Glut1 in THP-1, BMM and neutrophils infiltrated in air pouch lavages and membranes. Glut1 membrane localization was positively correlated with IL-1β production. Moreover, during gout flare, the proportion of Glut1 positive neutrophils was higher in synovial fluid neutrophils than in circulating neutrophils. Finally, STF-31 treatment decreased, in vitro, glucose uptake induced by MSU and mCPPD crystals, and in vivo MSU and mCPPD crystal-induced inflammation.
Conclusion: Glucose uptake through Glut1 transporter enhanced IL-1β production induced by MSU and mCPPD crystals. Studies to decipher how these crystals induced Glut1 membrane localization are ongoing. Similarly, we investigate how glycolysis regulates NLRP3 and ASC activation. Decreasing Glut1 membrane localization might be a potential target to dampen crystal-induced inflammation.

Background: Cardiovascular (CV) disease is one of the main causes of mortality in axial spondyloarthritis (axSpA). The higher incidence of CV risk factors and sys-
temic chronic inflammation increase CV risk in axSpA. This is enhanced by a dysregulation of adipokines. Low levels of omentin, an anti-inflammatory adipokine, have been associated with metabolic dysfunction and CV disease in general population and conditions different from axSpA. 1,2,3
Objectives: To evaluate the implication of omentin in CV risk and subclinical artherosclerosis in axSpA at the genetic and functional (mRNA and protein) level.
Methods: 382 patients fulfilling the ASAS classification criteria for axSpA and 84 controls were included. Carotid ultrasound was performed to evaluate the pre-
ence of subclinical atherosclerosis. Serum omentin levels were assessed by ELISA. mRNA expression of ITLN1, coding omentin, was evaluated by RT-qPCR. ITLN1 rs12409609 (C/T), in complete linkage disequilibrium with a polymorphism
previously associated with coronary artery disease,6 was genotyped by TaqMan probes. Results were adjusted by potential confounding factors (STATATA v.11.1).

Results: Serum and miRNA levels of omentin were lower in axSpA compared to controls (p<0.001). Low omentin serum levels were observed in obese patients, patients with inflammatory bowel disease (IBD) and in those with an atherogenic index indicative of dyslipidemia (p=0.002, 0.006 and 0.004, respectively). Interestingly, the C allele of rs12409609 (both when alleles and genotypes were assessed) was associated with low mRNA levels of omentin in axSpA (p<0.001).

No association was observed between omentin and markers of subclinical athero-atherosclerotic disease. Interestingly, the C allele of rs12409609 (both when alleles and genotypes were assessed) was associated with low mRNA levels of omentin in axSpA (p<0.001).

Background: High levels of the damage-associated molecular pattern (DAMP) S100A8/A9 are produced in the inflamed synovium during experimental and human rheumatoid arthritis (RA), which have been implicated in sterile inflammation-induced bone resorption. We and others have previously shown that stimulation of mature osteoclasts with S100A8/A9 increases their bone-resorptive capacity. In agreement, reduced bone destruction was observed after induction of experimental RA models in S100A8−/− mice. However, its effects on the differentiation of osteoclasts from their precursors remains elusive.

Objectives: Here, we investigated the effects of S100A9 on osteoclast differentiation from CD14+ circulating precursors.

Methods: CD14+ monocytes were isolated from buffy coats of healthy donors and differentiated towards osteoclasts with macrophage colony-stimulating factor (M-CSF) and receptor activator of nuclear factor kappa-B (RANK) ligand in the presence or absence of S100A9. Differentiation state of osteoclasts was determined by tartrate-resistant acid phosphatase (TRAP) staining and resorption capacity was quantified using hydroxyapatite-like-coated plates. RNA expression was analyzed with RNA sequencing and qPCR. RANK expression was assessed using FACS. Underlying epigenetic programming was studied using chromatin immunoprecipitation. Secretion of pro-anti-inflammatory mediators was analyzed with Luminex analysis

Results: S100A9 stimulation during monocyte-to-osteoclast differentiation resulted in a strong decrease in the numbers of multinucleated osteoclasts, underlined by a decreased resorptive capacity. The thus differentiated cells showed a high production of pro-inflammatory factors, such as interleukin (IL)-1α, IL-6, IL-8, and tumor necrosis factor-α (TNFα) after 16h of stimulation. In contrast, at day 4, the cells showed a decreased expression of the osteoclast-promoting factor TNFα. Interestingly, we showed that S100A9 stimulation only during the first 16h of culture was sufficient to reduce osteoclastogenesis. To determine the mechanism of how this short S100A9 stimulation might reduce the osteoclast differentiation, we determined the protein expression of RANK. We observed that within this 16h time frame, S100A9 inhibited the M-CSF-mediated induction of RANK, which we found to be associated with changes in various histone marks at the epigenetic level. This S100A9-induced reduction in RANK could be partially reversed by blocking TNFα using etanercept, but not by blocking interleukin-1 (IL-1) with the IL-1 receptor antagonist.

Conclusion: Whereas S100A8/A9 was previously shown to stimulate the resorptive capacity of mature osteoclasts, we here show that early S100A9 stimulation impedes monocyte-to-osteoclast differentiation via reduction of RANK expression that is partially TNFα-mediated. This suggests that the timing of exposure to S100A8/A9 is an important determinant for monocyte-to-osteoclast differentiation.

and hospital organisation factors. Geographical Information Systems are used to display maps describing adjusted estimates of variation in outcomes across NHS CCG areas.

Variation in outcome of surgery across Clinical Commissioning Groups. (2014-2016)

Results: 210,725 primary TKR/UKR were identified nested in 207 clinical commissioning group areas. 57% of patients were women, with an average age 70 years (SD ±9 years). Whilst we identified a number of factors that predicted outcomes of surgery (e.g. age, gender, co-morbidity, deprivation, baseline function, surgical volume, numbers of orthopaedic surgeons, beds, operating theatres), these factors did not explain the observed geographical variations in outcomes across surgery CCGs. The absolute predicted change in OKS varied from 13.0 to 18.8, predicted 6-month complication rate from 2.9% to 5.8%, predicted revision from primary TKR/UKR undertaken in 2014-2016 0.7% to 1.8%, predicted mean length of stay 2.9 to 6.6 days, bed-day cost £4758 to £6893 (Figure).

Conclusion: We have identified potentially unwarranted variations in patient outcomes of knee replacement surgery. This variation cannot be explained by differences in patients case mix, surgical factors, or hospital organisational factors. This information is informative to patients in making a decision in where they have their surgery, and to commissioners in monitoring variations in outcomes of surgery.

STANDARDS OF CARE FOR RHEUMATOID ARTHRITIS: GAPS IN IMPLEMENTATION EXPERIENCED BY PATIENTS AND RHEUMATOLOGISTS ACROSS 33 EUROPEAN COUNTRIES

Rachel Meinders1, Polina Putrik1,2, Sofia Ramiro2, Monika Hifiger1,2, András Keszei1, Yvonne van Eijk-Husings2, Anthony Woolf3, Josef S. Smolen6, Tanja Stamn3, Michaela Stoffer-Manx3, Till Ulhig3, Rikke Helene Mor4, Maarten de Wit6, Annelies Boonen5, 2, Implementation of Standards of Care in Europe Working Group. Maastricht University, CAPHRI, Maastricht, Netherlands; 4MUMC, Rheumatology, Maastricht, Netherlands; 5LUMC, Rheumatology, Leiden, Netherlands; 6RWTH, Medicine, Aachen, Germany; 7Royal Cornwall Hospital, Cornwall, United Kingdom; 8Medizinische Universität Vienna, Vienna, Austria; 9Diakonessenhuis Hospital, Oslo, Norway; EULAR PRP, Amsterdam, Netherlands

Background: EuMusc.net, a EULAR and EU supported initiative (which took place from 2009 to 2013) aimed to raise and harmonize quality of care for patients with rheumatic and musculoskeletal diseases across European countries. As part of EuMusc.net, 16 user-focused standards of care (SoC) for rheumatoid arthritis (RA) were developed.

Objectives: To evaluate gaps in quality of care using the EuMusc.net SoCs among patients and rheumatologists across Europe and to investigate the contribution of individual- and country-level characteristics to care gaps.

Methods: Fifty RA patients and 50 rheumatologists from each of 33 countries were invited to participate in a survey. For each SoC, levels of importance and care were rated for received by patients or provided by rheumatologists on a scale from 0 to 10 (=best). Care gaps were calculated as difference from the maximum score for care received multiplied by the score for importance of care (0 (no gap) – 100), when the gap = 30 and importance >6. Individual- and country-level (GDP in tertiles) determinants of care gaps were analysed in multilevel logistic regression models, with patients clustered in country of residence. For patients, individual factors included gender, age, disease duration (years), level of education (low, high), work status (retired, disabled, working, not working), literacy, patient organisation membership and overall health (0-10). For rheumatologists, individual factors were gender, age, years of experience and work setting (university hospital and non-university hospital/private practice).

Results: In total, 1,422 patients from 27 and 1,044 rheumatologists from 33 European countries, respectively, were included. Patients had a mean (SD) age of 57.2 (13.2) years and 74% were female. For rheumatologists, the mean age was 47.7 (10.5) and 53% were female. After ranking the SoCs on percentage of problematic gap, the 7 SoCs in the top 10-ranks for both patients and rheumatologists (Table) were: diagnosis within 6 weeks, information about patient organisations, availability of treatment plan, receiving a schedule of regular assessment, vaccination-related information, information about adequate physical exercise and training on aids, devices and ergonomic principles. The least frequent problematic SoC for both patients and rheumatologists was adequate DMARD received (6% and 3%).

Multilevel analyses revealed large variation across countries for patients (all models p <0.01) and for the majority of analyses for rheumatologists, despite adjustment for individual characteristics. In addition, patients with higher education and lower self-reported health experienced problematic gaps more frequently. Among rheumatologists, patterns in determinants across SoCs were less consistent. For example, rheumatologists from lower GDP countries identified problematic gaps more often compared to those from medium or high GDP countries about half of the SoCs, rheumatologists from lower GDP countries identified problematic gaps more often compared to those from medium or high GDP countries.

Table: Frequencies and determinants of care gaps perceived by patients and rheumatologists (top-7 SoCs with highest % of respondents reporting a problematic gap)

**Conclusion:** For most SoCs, problematic gaps were identified in essential aspects of RA care, and substantial differences across countries were observed.
QUALITY OF CARE PREDICTS OUTCOME IN SYSTEMIC LUPUS ERYTHEMATOSUS – CROSS SECTIONAL ANALYSIS OF A GERMAN LONG-TERM STUDY (LULA COHORT, 2011–2015)

Anna Kernder1, Jutta Richter1, Rebecca Fischer-Betz2, Borgi Winkler-Rohlling2,
Mathias Schneider1, Gamal Chehab1, Heinrich-Heine-University Düsseldorf,
Policlinic of Rheumatology andiller Research Unit, Düsseldorf, Germany;
German Lupus Self-Help Community, Wuppertal, Germany

Background: Systemic lupus erythematous (SLE) is a chronic disease, which is still associated with significant morbidity and mortality.1 Recommendations for the management of SLE patients exist2-5, but information on its implementation and the resulting impact on long-term outcome remain unclear.

Objectives: Our aim was to study the quality of SLE medical care in Germany to understand gaps and to analyze the association to long-term outcome parameters.

Methods: In the Lula-study information on demographics, clinical and medical care parameters are assessed annually by self-reported questionnaires among a representative sample of SLE patients in Germany (Lula cohort, n=572). In 2013 additional questions on the management of care, as mentioned in current guidelines and recommendations, were surveyed. Ten items predicting a good clinical care (quality measures) were evaluated and an overall score with a minimum of 0 points and a maximum of 10 points was calculated. The ten items are taking anti-malarials, osteoporosis protection at a dose above 7.5mg prednisolone equivalent per day or taking 5mg per day, vaccination, blood pressure, fat metabolism counseling, urine examination and blood test once a year, treatment of comorbidity, fat metabolism disorder, osteoporosis and hypertension. Health related quality of life (Short Form Survey, SF-12/36), damage (Brief Index of Lupus Damage, BILD) and activity (Systemic Lupus Activity Questionnaire, SLAQ) were chosen as relevant proxies for long-term outcome.

Using linear regression, we examined the relationship between the quality measures and outcome parameters, adjusted for age, disease duration and gender.

Results: 65.9% of the patients consulted a rheumatologist as a main contact for their disease. On average 6.1 points of the 10 quality measures were met (SD 1.7). The fulfillment of these quality measures varied between 22.8% (fat metabolism counseling) and 97.8% (osteoporosis protection at a dose above 7.5mg prednisolone equivalent per day or ≤ 7.5mg per day). Fulfilling more clinical care items in 2013 was predictive for high disease-related quality of life (SF-36, p=0.004), low progress in disease-related damage (BILD, p=0.048) and low disease activity (SLAQ, p=0.046) in the subsequent years.

Conclusion: Our study illustrates a strong link between the quality of care and important SLE outcome parameters: quality of life, disease-related damage and disease activity assessed by a self-reported questionnaire. Consistent considerations of these care parameters, which are recommended in several management guidelines, yield a positive effect on outcome. An interdisciplinary approach with general practitioners and other specialists is certainly beneficial and warranted.

IMPLEMENTATION OF TNF-BIOSIMILARS (INFLEXIMAB AND ETANERCEPT) IN DANISH DEPARTMENTS OF RHEUMATOLOGY

Thomas Bo Jensen1, Dorthe Bartels2, Eva Aggerholm Saedder3, Birgitte Klintzb Poulsen4, Stig Ejdrup Andersen5, Mette Marie H. Christensen6, Lars Nielsen7, Hanne Roalghed Christensen8. 1 Copenhagen University Hospital Bispebjerg, Department of Clinical Pharmacology, Copenhagen, Denmark; 2Amgros – The Regions’ Pharmaceutical Organisation, Copenhagen, Denmark; 3Aarhus University Hospital, Department of Clinical Pharmacology, Aarhus, Denmark; 4Aalborg University Hospital, Department of Clinical Pharmacology, Aalborg, Denmark; 5Zealand University Hospital, Clinical Pharmacology Unit, Roskilde, Denmark; 6Odense University Hospital, Department of Clinical Biochemistry and Pharmacology, Odense, Denmark; 7The Hospital Pharmacy of The Capital Region of Denmark, Herlev, Denmark

Background: The use of expensive biological drugs in rheumatology is rapidly increasing and has led to substantial increases in drug expenditures. A considerable reduction of drug costs is possible by using biosimilars as soon as they become available and carrying out non-medical shifts to biosimilars (i.e. switching a patient well treated on a biooriginator to the biosimilar). Research on biosimilars has focused on interchangeability and safety outcomes, but little focus has been on nationwide implementation and the direct economic consequences on drug expenses.

In Denmark, TNF-inhibitors are solely given in an in-hospital setting and bought through national tenders. The Danish in-hospital organization includes Regional Drug and Therapeutics Committees that ensures regional implementation of treatment guidelines and close collaboration between hospital pharmacies and regional clinical pharmacologists. Furthermore, the implementation of TNF-inhibitor biosimilars was preceded by careful preparations from among others a newly established national biosimilar task force.

Objectives: The aim of this study was to describe the implementation of the two first TNF-inhibitor biosimilars (infliximab and etanercept) in Danish departments of rheumatology.

Methods: Monthly data on drug sales to Danish rheumatology departments were used to assess the biosimilar uptake rate and subsequent changes in the drug expenditures during the implementation in Denmark.

Results: Shifts to biosimilars were begun within a few months following end of biooriginator patent, vertical lines in the figure. Use of the infliximab biosimilar was begun in April 2015, and in August 2015 biosimilar uptake was 92.9% of total infliximab use. Similarly use of etanercept biosimilar was begun in April 2016, and in June 2016 the biosimilar uptake was 91.6% of total etanercept use. In January 2015 the total use in Defined Daily Doses (DDD) were 42.4 thousand DDD’s for infliximab and 37.5 thousand DDD’s for etanercept. The use increased steadily and was in January 2018 138.4 thousand DDD’s for infliximab and 62.1 thousand DDD’s for etanercept (equivalent to increases of 226.6% and 66.8%). The increases in DDD’s were not reflected in total drug costs due to the shift to biosimilars. The total drug cost for infliximab in January 2015 was 6.7 million DKK but was reduced to 5.4 million DKK in January 2018 (-19.4%). A corresponding cost reduction was seen for etanercept (11.3 million DKK in January 2015, 8.1 million DKK in January 2018, -28.7%).

Conclusion: Danish departments of rheumatology experienced a fast and near-complete switch of infliximab and etanercept biooriginators to biosimilars. At the same time the use of the drugs increased substantially, but due to large price reductions the total drug cost decreased despite the increasing use. We believe that a thorough preparation and an organizational setting supporting the implementation was crucial for the successful implementation. The Danish structure, with its national tendering, probably contributed to the substantial drug discounts obtained. The implementation will be used for future biosimilars in Denmark.

VARIABILITY IN BIOLOGIC PRESCRIPTION PATTERNS
COST-EFFECTIVENESS OF A JAK1/JAK2-INHIBITOR

Figure 1

Disclosure of Interests: Milada Cvancarova Småstuen Grant/research support from: I have received a Research grant from Pfizer, Randdeep Madia Employee of: Pfizer, still employed, Oddvar Solli Employee of: Pfizer, still employed by Pfizer, Erik Helvin Employee of: Pfizer, still employed by Pfizer

Figure 2

Disclosure of Interests: Celine van de Laar1, Martijn Oude Voshaar1, Walid Falhoun2, Lilianna Zaremba-Pechmann3, Francesco de Leonardi3, Inmaculada De La Torre4, Mart van de Laar1,2, 3, 4, 5.

Background: Biologics account for a substantial portion of drug spending in rheumatoid arthritis (RA). Variability in the U.S. in biologic prescribing patterns (and therefore variability in cost of care), and factors that correlate with that variability, remain largely undefined.

Objectives: We used data from the RISE registry to perform a cross-sectional analysis among U.S. rheumatologists of prescription patterns for biologic DMARDs and tofacitinib and their relationship to RA disease activity.

Methods: RISE is a U.S. registry that passively collects data on all patients seen by participating practices, thereby reducing selection bias present in single-insurer claims databases. As of December 2017, RISE held validated data from 1,257 providers in 236 practices, representing an estimated 25% of the U.S. clinical rheumatology workforce. We identified patients with available demographic and disease activity information who were assigned ≥2 codes for RA ≥30 days apart between January and December 2017. Practices with <20 RA patients (15/104 practices providing all necessary data) were excluded. We tallied the proportion of patients in each practice prescribed a TNF inhibitor, abatacept, rituximab, tocilizumab, or tofacitinib at least once during 2017. Patients prescribed >1 of these drugs were assigned to the first drug prescribed and therefore counted only once. We used a hierarchical linear model to predict the probability of receiving a prescription for a biologic based on the patient’s most recent disease activity score (moderate or high disease activity vs. low disease activity or remission) and age from 2016, accounting for clustering by practice.

Results: We analyzed 53,850 patients from 104 practices. Overall, 29% of patients were prescribed a biologic DMARD or tofacitinib in 2017. TNF inhibitors were most commonly prescribed, followed by abatacept (4.5% of patients), tofacitinib (4.2%), tocilizumab (3.4%), and rituximab (2.5%). We found significant variation within practices in the proportion of patients prescribed any of these drugs (range 0%-100%). In the adjusted analysis, we found that patients with higher disease activity in 2016 were more likely to receive biologics in 2017 (OR 1.56, 95% CI (1.51, 1.62)). Within a practice, as shown in the figure, the risk-adjusted likelihood of receiving a biologic prescription still showed significant variation (between 0%-83%) of patients in each practice received a biologic; model c-statistic 0.61.

Conclusion: In this large sample of U.S. rheumatology practices, higher RA disease activity correlated with the likelihood that a patient would receive a prescription for a biologic, but did not account for all of the variability in biologic prescription patterns. These results suggest that there may be other factors in addition to RA disease activity that account for practice-to-practice variability in biologic prescription patterns. Disclaimer: These data were collected from the ACR’s RISE Registry; however, the views expressed represent those of the authors, not necessarily those of the ACR.

Disclosure of Interests: Celine van de Laar: None declared, Martijn Oude Voshaar: None declared, Walid Falhoun: None declared, Lilianna Zaremba-Pechmann: None declared, Francesco de Leonardi: None declared, Inmaculada De La Torre: None declared, Mart van de Laar: Research support from: Investigator initiated award from Pfizer from 2015-2018, unrelated to this work, Consultant for: Eli Lilly and Company, Indianaroid, United States of America; Arthritis Center Twente, Enschede, Netherlands.

Background: Treating Rheumatoid Arthritis (RA) to an a priori defined disease activity target (T2T) is recommended in EULAR guidelines. This involves a step-up approach in which it is first attempted to achieve the target with a combination of conventional synthetic (cs) DMARDs. Baricitinib is a JAK1/JAK2-inhibitor approved for treatment of patients suffering from RA. EULAR and ACR guidelines currently position JAK1/JAK2-inhibitors and bDMARDs at the same level in the therapeutic treatment sequence for csDMARD2 Inadequate Responders (IR). Cost-effectiveness assessment of different T2T strategies, especially ones...
including new treatments, and integrating health economic considerations is of importance to the decision-making process as it incorporates the societal perspective in the longer run.

Objectives: To compare the cost-effectiveness of the previously evaluated DREAM T2T strategy csDMARD combination therapy (csDMARDs) - first bDMARD (adalimumab) - next bDMARD (TNFi/non-TNFi) with the comparable strategy in which baricitinib is placed instead of adalimumab in csDMARDs IR using a Markov model. All analyses were performed from the societal perspective. Costs and effects over five years were compared between the two strategies to provide insight into the differences in economic considerations between treating patients with strategies including either JAK1/JAK2-inhibitor (baricitinib) or 1st bDMARD (adalimumab).

Methods: A Monte Carlo microsimulation model was developed to conduct cost-utility analysis from the societal perspective over 5 years. Health states were based on the DAS28-ESR categories. Effectiveness of baricitinib was retrieved from clinical trials and (1) and corrected for differences between RCT and real-world setting. Effectiveness of all other treatments, health state utilities, medical costs, and productivity loss were retrieved from DREAM cohorts (2) and the Dutch institute for Health. Annual discount rates of 1.5% for utility and 4% for costs were used, as advised in Dutch guidelines. All analyses were run using probabilistic sensitivity analysis (PSA) to incorporate uncertainty around all parameters and assess result robustness.

Results: PSA results showed the baricitinib strategy yielded lower costs and higher utility over a 5-year period and is cost-effective and dominant over the DREAM T2T strategy. Scenario analyses showed the baricitinib strategy to be cost-effective in both the moderate and severe at baseline RA populations analysed together and separately.

LONG TERM TRAJECTORIES OF CHRONIC WIDESPREAD PAIN: A 21-YEAR PROSPECTIVE COHORT LATENT CLASS ANALYSIS

Katarina All1,2,3, Paul Campbell4,5, Zoe A Michaeli4, Victoria Y. Strauss5, Kelvin Jordan7, Arnn Breanmander1,6, Peter Croft4,5, Stefan Bergman1,5, RandD Spenshult, Halmstad, Sweden; 2Halmstad University, School of Health and Welfare, Halmstad, Sweden; 3Karolinska Institute, institute of Environmental Medicine, Stockholm, Sweden; 4Keele University, Research Institute for Primary Care and Health Sciences, Keele, United Kingdom; 5Midlands Partnership NHS Foundation Trust, Stafford, United Kingdom; 6University of Oxford, CSM, NDORMS, Oxford, United Kingdom; 7Keele University, Centre for Prognosis Research, Keele, United Kingdom; 8University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 9University of Gothenburg, Institute of Medicine, Gothenburg, Sweden

Background: Chronic widespread pain (CWP) is common (population prevalence of approximately 10%) and has a significant impact on the individual, health-care, and society. Currently little is known about the actual course of CWP over time, in particular the pathways to the development and maintenance of CWP. One useful way to understand these pathways is to identify common clusters of people who share pain trajectories. Such information is clinically useful to identify factors that predict development, persistence, and resolution of CWP.

Objectives: To identify different longitudinal pain trajectories over a period of 21 years.

Methods: A 21-year longitudinal open-population cohort of n=1858 adults (aged 20-74) who completed surveys relating to their pain status in at least three of the five time points 1995, 1998, 2003, 2007, and 2016. Pain status (presence of persistent pain) was ascertained from a report of painful regions (0-18) on a pain mannequin and categorised into: NCP (no chronic pain), CRP (chronic regional pain), and CWP (chronic widespread pain). Latent Class Growth Analysis (LCGA) was carried out based on these categories. Participants were assigned to a trajectory cluster where the posterior probability was the highest. Model fit was assessed by statistical indices and clinical interpretations of clusters.

Results: LCGA identified five clusters describing different pathways of CWP, CRP and CWP over the 21 years. The cluster “Persistent CWP” was the most common pathway (n = 1052, 57%) and had a significant impact on the individual, health-care, and society. Currently little is known about the actual course of CWP over time, in particular the pathways to the development and maintenance of CWP. One useful way to understand these pathways is to identify common clusters of people who share pain trajectories. Such information is clinically useful to identify factors that predict development, persistence, and resolution of CWP.

Conclusions: This study showed that whilst half of adults report no chronic pain over 21 years, a substantial proportion develop CWP or have persistent CWP over this time period. Whilst a common trajectory was movement from chronic regional pain to no chronic pain, a pattern of improving CWP was not seen suggesting this is an uncommon trajectory. This is the first study to show long-term trajectories for CWP, and further work is now required to understand factors that may identify individuals at risk of worsening pain status and factors that might promote improvement. These identified pathways of chronic pain over a lifespan improve the understanding of long-term development of chronic pain and chronic widespread pain.

ACHIEVING A LOW DISEASE STATE WITHIN FIRST 3 MONTHS IN EARLY RHEUMATOID ARTHRITIS

RESULTS IN LOWER FATIGUE OVER 5 YEARS

Melissa Holden1, Orit Schieir2, Susan J. Bartlett3,4, Louis Bessette5, Gilles Boire1,6, Glen Hazlewood1, Carol Hitchon6, Edward Keystone7, Diane Truere 8

1McGill University/MUHC, Montreal, Canada; 2Johns Hopkins Medicine, Baltimore, United States of America; 3University de Laval, Quebec City, Canada; 4University de Sherbrooke, Sherbrooke, Canada; 5University of Calgary, Calgary, Canada; 6University of Manitoba, Winnipeg, Canada; 7University of Toronto, Toronto, Canada; 8Southlake Regional Health Center, Newmarket, Canada; 9Hospital for Special Surgery, New York, United States of America; 10Weill Cornell Medical College, New York, United States of America

Background: Up to 80% of rheumatoid arthritis patients report clinically relevant fatigue. Fatigue is complex multi-factorial process that can result in adverse affects on patients’ physical and emotional well-being.

Objectives: To examine the relationship between disease activity and fatigue over time in early rheumatoid arthritis (ERA).

Methods: Data were from patients with ERA (symptoms < 12 months) enrolled in the Canadian Early Arthritis Cohort (CATCH). CATCH participants completed repeat clinical assessments, laboratory investigations and self-reported questionnaires including rating their fatigue over the past week using a 10 point numerical rating scale (NRS). Fatigue severity was classified as low (<2); moderate (>2 but ≤5) and high (>5) based on other published RA studies. Bivariate relationships between disease activity measures and fatigue over 5 years of follow-up were estimated using the Pearson correlation coefficient. T-tests and repeated measures analysis were used to compare differences in fatigue ratings in patient who did vs. did not achieve a low disease state (DAS28 <3.2) within 3-months of cohort entry.

Results: Of the 1864 patients included, 1640 (88%) met criteria for RA, 1342 (72%) were women and most had moderate-high baseline disease with a mean (SD) DAS28 of 4.9 (1.5). Fatigue was common with 19% reporting moderate or high fatigue throughout 5 years of follow-up compared to those with moderate or high fatigue (p<0.001). Patients who achieved DAS28 REM or LDA within 3-months of entry had significantly lower mean fatigue compared to those with more active disease throughout 5 years of follow-up (p<0.001) (Figure 1).

Conclusion: Fatigue is common in ERA and is most strongly correlated with pain and patient global ratings (r 0.56-0.67, p<0.001), positively and moderately correlated with DAS28 (r 0.35-0.49, p<0.001), and positively but more weakly correlated with tender/swollen joint count, physician global assessment, ESR and CRP (r 0.10-0.39, p<0.01) throughout the first year of follow-up. Patients who reported low fatigue severity by three months continued to have significantly lower fatigue throughout follow-up compared to those with moderate or high fatigue (p<0.001). Patients who achieved DAS28 REM or LDA within 3-months of entry had significantly lower mean fatigue compared to those with more active disease throughout 5 years of follow-up (p<0.001).

Optimizing the access to new treatments for RMD patients

COST EFFECTIVE INTERVENTION TO IMPROVE QUALITY OF CARE MEASURES FOR RHEUMATOID ARTHRITIS PATIENTS IN AN UNDERSERVED COMMUNITY

Yvan Maque-Acosta1, Juliana Hirsch2, Qingying Lai3, Rachel Kalpou1, Beverly Johnson4,1

1Jacobi Medical Center/Albert Einstein College of Medicine, Internal Medicine, Bronx, United States of America; 2Mt. Sinai St. Luke’s-West Hospital, New York, United States of America; 3Hackensack University Medical Center, Hackensack, United States of America; 4Jacobi Medical Center/Albert Einstein College of Medicine, Rheumatology, Bronx, United States of America

Background: Quality of care measures for rheumatoid arthritis (RA) have been endorsed by the American College of Rheumatology and the CDC. Similar quality indicators have been studied and recommended by the European League Against Rheumatism. Improving quality metrics in an underserved community is a problem given the lack of resources.

Objectives: To identify quality metrics for RA patients with need for improvement in our underserved urban public hospital, and to establish an effective intervention.

Methods: An initial retrospective chart review established baseline data from patients with RA seen in our clinic (July 2015 - July 2016), they were identified by ICD-9/10 coding. We identified 3 RA measures needing improvement: (a) tuberculosis screening (TBsc) 12 months prior to starting a new biologic agent, (b) documentation of clinical disease activity index (CDAI) in ≥50% of encounters, and (c) appropriate pneumococcal vaccination. We then planned an intervention by placing index cards at computer stations to remind providers to check these measures. We collected data on these 3 variables prior to the intervention (December 2016 - July 2017) and 30+ days after (August 2017 - December 2017). We also compared these results by provider type (attendings and fellows).

RESULTS: Baseline data included 240 patients, prior analysis to the intervention included 86 patients, and after the intervention included 131 patients. CDAI documentation was improved from 72.1% to 86.3% (Figure 1, p=0.01), however, when stratifying the analysis by provider type, this improvement was only significant in attendings (p=0.005) and not in fellows (p=0.43). Further analysis by including only the same fellows in both pre and post intervention moments (some fellows graduated) showed a significant difference in both groups (attendings: p=0.005; fellows: p=0.024). In terms of TBsc, baseline data showed 73.1% compliance, however we already found a compliance of 100% prior to the intervention (Figure 2, p=0.002 when compared with baseline data). Finally, there was no difference in
compliance with pneumococcal vaccination between baseline data, prior and post intervention (p=0.895).

Conclusion: Placing a card reminding providers to check 3 RA quality measures significantly improved CDAI documentation after 30 days of starting the intervention. The compliance with TBsc prior to starting a new biologic agent was 100% even before the intervention, which was better compared to baseline data, likely due to providers being aware there was a problem after initial data was collected. We did not find improvement in pneumococcal immunization rate, most likely because there are multifactorial components to motivating patients to get the vaccine. Our results suggest that interventions as simple as raising provider awareness to a problem such as TB screening, and an index card to remind people to document CDAI can be effective to improve I3 measures in RA patients in underserved communities.

OP0317
ASSOCIATION OF PATIENT SATISFACTION WITH HEALTHCARE UTILIZATION, COST, AND QUALITY OF LIFE IN RHEUMATOID ARTHRITIS
Nasim Khan1,2, Fawad Aslam1, Wais Atta1, Chenghui Li1. 1University of Arkansas for Medical Sciences, Little Rock, United States of America; 2Central Arkansas Veterans Healthcare System, Little Rock, United States of America; 3Mayo Clinic, Phoenix, United States of America

Background: Patient satisfaction and experience with care is being used as a surrogate marker of quality and value of healthcare delivery. No study has evaluated the association of patient satisfaction with healthcare utilization and cost, and quality of life in RA patients.

Objectives: To examine the association of RA patient satisfaction with healthcare utilization and cost, and quality of life.

Methods: 2010-2015 longitudinal files from the Medical Expenditure Panel Survey (MEPS), a nationally representative survey of the US civilian non-institutionalized population were used to identify patients with self-reported RA diagnosis. MEPS has overlapping panel design with participants interviewed up to 5 rounds over a 2- year period. In rounds 2 and 4, patient satisfaction is assessed by the four items about physician interaction – listened carefully, explained things well, showed respect, and spent enough time; and one item for overall satisfaction with quality of care received. A patient satisfaction score was constructed from standardized composite score of these items, and classified as most satisfied (patient satisfaction quartile 4) and less satisfied (patient satisfaction quartiles 1-3). The outcome measures were assessed in year 2: healthcare utilization (any emergency department visit, any inpatient stay, number of visits to office-based providers, outpatient department, and prescription drugs); total healthcare expenditures (measured in 2015 dollars), and quality of life (QoL, measure using 12-item Short Form healthy survey (SF-12)). Two statistical approaches were used: a standard logistic regression comparing most satisfied with less satisfied, and propensity score matching. Propensity scores were estimated using a logistic regression approach yielded similar results.

IS PSYCHOLOGICAL SUPPORT REACHING THOSE IN MOST NEED? A SURVEY OF PEOPLE WITH RHEUMATOID ARTHRITIS AND ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS:
Hayley McBain1, Matthew Bezzant2, Ailsa Bosworth1. 1City, University of London, London, United Kingdom; 2National Rheumatoid Arthritis Society (NRAS), Maidenhead, United Kingdom

Background: Rheumatoid arthritis (RA) and adult juvenile idiopathic arthritis (AJIA) is associated with a significant impact on psychological well-being.1-2 UK guidelines for the management of RA3-5 state that psychological interventions should be offered to people with RA to help them adjust to living with their condition and manage their psychological well-being. Three in four rheumatology units in the UK however, rate their overall provision of psychological support as inadequate.6

Objectives: To establish levels of anxiety and depression in people with RA or AJIA and how this relates to the prevalence of diagnosed mood disorders and receipt of psychological support.

Methods: The 2018 National Rheumatoid Arthritis Society (NRAS) ‘Emotional Health and Well-being Matters’ survey was designed by patients and researchers. This included a questionnaire designed to capture self-reported comorbidities, receipt of psychosocial support and the Hospital Anxiety and Depression Scale (HADS).7 Participants were recruited by NRAS via their social media platforms, membership and non-membership lists and in newsletters and forums. The survey was open from May–July 2018. Recruitment was focused on those diagnosed with RA or AJIA aged 18 years and over and living in the UK.

Results: A total of 1565 people with RA and 55 AJIA completed the survey. Although mean scores on the HADS were within the normal range in both populations, over 25% of the samples were experiencing clinical levels of anxiety or depression. Over half of those reporting clinical levels of anxiety or depression had never received a formal diagnosis. Most concerning however, was that 1 in 2

Background: The OMERACT Ultrasound (US) in calcium pyrophosphate deposition disease (CPPD) sub-task force has been working on the assessment of the utility of US in CPPD since 2014 first creating definitions for CPPD identification and then demonstrating that US is a reliable tool[1].

Objectives: Objective of this study is to assess the diagnostic accuracy of US in CPPD

Methods: This is a multicentre international diagnostic accuracy study involving 17 centres from 9 countries. We enrolled in this study consecutive patients waiting to undergo knee replacement surgery due to severe osteoarthritis. Each patient underwent US examination of the knee, focusing on the menisci and the hyaline cartilage, the day prior to surgery, scoring each site according to the presence/absence of CPP as defined by OMERACT[1]. After surgery, the menisci and the condyles were collected and examined microscopically. Six samples were collected, both from the surface and from the internal part of menisci and cartilage trying to cover a large part of the structure. All slides were observed under transmitted light microscopy and by compensated polarised microscopy. A dichotomous score was given for the presence/absence of CPP crystals. US and microscopic analysis were performed by blinded operators. Sensitivity and specificity of US were calculated using microscopic findings of the menisci and cartilage as the gold standard.

Results: These preliminary analyses include 30 patients. The mean age was 71yrs (SD9.1), 19 (63%) were females. 17 patients were positive at US analysis and 12 at microscopic analysis. Diagnostic accuracy results of US at patient level, are presented in figure 1.

Conclusion: These preliminary results demonstrate that US is a sensitive exam for identification of CPPD with acceptable specificity. US is the first diagnostic technique with consistent reliability and validity to be applied for non-invasive screening for CPPD in clinical practice.

SUCCESSFUL EVALUATION OF A PREDEFINED SET
OF ANATOMIC SITES IN THE PELVIS OF PATIENTS
WITH POLYMYALGIA RHEUMATICA SHOWING
EXTRACAPSULAR INFLAMMATION AS VISUALIZED
BY CONTRAST ENHANCED MAGNETIC RESONANCE
IMAGING:

Martin Fruth1, J Kozik1, P Martin-Seidel1, Annika Seggewiss1,
Xenofon Baraliakos2,3, Juergen Braun2,3. 1Radiology, Herne, Germany;
2
Rheumazenrum Ruhrgebiet, Herne, Germany; 3Ruhr-University, Bochum,
Germany
Background: The diagnosis of polymyalgia rheumatica (PMR) is based on a
thorough clinical evaluation of the patient - including exclusion of other diseases,
since there is no decisive diagnostic test. A characteristic pattern of extracapsular
inflammation in the pelvis of patients with PMR as assessed by contrast enhanced
magnetic resonance imaging (MRI) has been recently described (1)
Objectives: To evaluate the performance of a predefined set of anatomic sites in
the pelvis of patients with PMR vs. controls.
Methods: A total of 120 pelvic MRI scans of patients who had presented to our
tertiary center with pelvic girdle pain in the last 3 years, including 40 patients with
an expert rheumatologist diagnosis of PMR and 80 controls with other reasons of
pelvic pain was evaluated by 3 radiologists blinded to clinical diagnosis and
patient demographics. The experts scored the presence or absence of contrast
enhancement at 19 predefined tendinous and capsular pelvic structures. Different
patterns of involvement were compared and statistically evaluated by ROC analysis. Kappa statistics were applied to calculate inter- and intrareader agreement.
Results: Mostly bilateral peritendinitis and capsulitis including uncommon sites
such as the proximal origins of the muscles rectus femoris and adductor longus
were found almost exclusively and, thus, typically in PMR patients: the difference
in the mean number of sites showing contrast enhancement was significantly different with 13.4±2.7 for PMR vs 4.0±2.3 for controls. A cut-off of 10 inflamed
sites discriminated very well between the groups resulting in a sensitivity and specificity of 95.8% and 97.1%, respectively. Just concentrating on the most frequently involved anatomic sites bilateral inflammation of proximal M. rectus
femoris or adductor longus tendons together with at least 3 other bilaterally
inflamed sites performed even better with a sensitivity and specificity of 100% and
97.5%, respectively.
Conclusion: This study strongly confirms that the previously described pattern of
extracapsular pelvic inflammation as assessed by contrast enhanced MRI is very
typical for patients with PMR. In addition, the high sensitivity and specificity of the
set of anatomic sites evaluated suggest their definite potential for use as a confirmatory diagnostic test.
REFERENCE:
magnetic resonance imaging of the pelvis to describe changes at different
anatomic sites which are potentially specific for polymyalgia rheumatica.

The benefits of involving patients in health
technology assessment
OP0321-PARE

A NOVEL APPROACH TO REACH PATIENTS FOR
EDUCATIONAL PURPOSES – VIRTUAL CONFERENCE
REUMANET

Mitchell Silva, Nele Caeyers. ReumaNet, zaventem, Belgium
Background: Every two years, ReumaNet organises a physical conference for
patients addressing various topics of rheumatic and musculoskeletal diseases
(RMD). Traditionally, about 200 individuals attend this event. For the last edition
however, ReumaNet swapped the physical event with a virtual one. This allowed
us to reach far more people, who could attend the ‘conference’ online whenever
they wanted, over a period of four weeks.
Objectives: The objective was to assess the impact, reach and patient experience of such a virtual event.
Methods: In this virtual event, more than twenty presentations were pre-recorded
and put into an online system. Virtual booths were offered to partner organisations
to offer educational material in pdf’s or in video format.
The board of ReumaNet set up an interesting program, covering the following
aspects:
.
.
.
.

Medical evolution in RMD’s: explanation about new treatments in various
indications, information on new medication
Living with an RMD: information about the psychological, vocational, social
and physical aspects of having an RMD
The future of healthcare: information on the changing technology in
healthcare and sustainability of the healthcare system
Testimonials: video testimonials of patient advocates

All information was pre-recorded and integrated into an online portal. The lectures
showed both speaker and the slide set, moving along with the presentation.
Registration was free and anonymous. Only email was required in order to validate the registration. Visitors also had the option to answer surveys on various
topics and score every video presentation. All material could be downloaded
(PowerPoint presentations, brochures, videos).
This virtual symposium was accessible from mid-September till mid-October, covering four weeks around World Arthritis Day. People could come and go, and log
in at any other point in time from different devices, so it was not necessary to view
all at once.
Results: The results were very promising, having over 1.300 registrations (compared to 200 registrations at a physical event). The social media reach was over
140.000 and the event also increased the visibility of the Facebook page of ReumaNet. On the platform itself there were over 5000 video views and over 3000 visits of the virtual booths of partner organisations. General satisfaction rates were
high: 96% of the visitors indicated they were most likely to visit a similar event in
the future. Over 80% gave the event a + 4 star rating out of 5.
Conclusion: This event was considered to be very successful. The results
showed that this virtual event exceeded our expectations and had an impact on
the visibility of our organisation via social media. This type of event has been
expanded towards sister organisations in rheumatology, such as the Belgian
organisation for healthcare professionals and can serve as an innovative way for
other European patient organisations to attract new profiles and increase awareness of RMDs among the broad public.
Disclosure of Interests: Mitchell Silva Consultant for: For Pfizer, MSD, Janssen,
Merck, BMS, Sanofi, Novartis, AstraZeneca, Speakers bureau: For Pfizer, MSD,

GRASSROOTS CAMPAIGN FOR DUTCH RMDFRIENDLY MUNICIPALITIES

Margot Feith, Nique Lopuhaä, Sija De Jong. Dutch Arthritis Society, Patient
Advocacy, Amsterdam, Netherlands
Background: Following the decentralisation of healthcare in 2014, Dutch municipalities were assigned a key role in providing healthcare support to local residents. ReumaNederland used the 2018 council elections to start a campaign to
raise awareness for RMD-friendly council policies.
Objectives: The campaign aimed to raise awareness for suitable RMD healthcare policies across municipalities.


Cannabis for arthritis: Hype or hope?

**Method:** Evaluation of clinical correlates of cannabis use in arthritis patients.

**Results:** Cannabis use was reported by 20% of patients. Use was associated with a younger age, higher education level, and a lower prevalence of pain and depression.

**Conclusion:** Cannabis use is common among arthritis patients and may be associated with better quality of life.

---

**OP0324**

**CANNABIODI ELEVATES INTRACELLULAR CALCIUM AND INDUCES APOPTOSIS IN HUMAN ARTICULAR CHONDROCYTES**

**Background:** Osteoarthritis (OA) is a major public health problem among the increasing aged and obese population, therefore development and investigation of therapeutic treatment of joint diseases has emerged.

**Objectives:** Cannaβidiol (CBD) is the most abundant non psychoactive compound of Cannabis sativa extracts and has been shown to have antiarthritic potency in animal models [2, 3]. In the present study we investigated the effects of CBD on the cell viability and Ca2+ homeostasis in human articular chondrocytes.

**Methods:** Cell viability, discrimination of intact, apoptotic and necrotic cells and caspase 3/7 activity were determined by Resazurin assay, Annexin-V/7-AAD staining followed by flow cytometry and caspase-Glo 3/7 assay respectively. Intra-cellular Ca2+ was monitored by time-lapse fluorescence imaging. The perfomed whole-cell patch clamp technique was used for measuring the cell membrane potential. Western blot analysis was performed for the quantification of Erk1/2 phosphorylation.

**Results:** C28/i2 and human primary chondrocytes showed a significantly reduced viability with an apoptosis maximum at 10μM CBD after treatment with rising amounts of CBD. This apoptotic effect was accompanied by an increase of caspase 3/7 activity. Flow cytometry analysis of AnnexinV/7-AAD stained cells revealed a decline of intact cells and a significant dose dependent increase of the early apoptotic cell population after treatment with CBD.

**Conclusion:** Cannaβidiol is a promising agent for the treatment of OA.

---

**OP0323**

**USEFULNESS OF UNIVERSAL ANTINUCLEAR ANTIBODIES TESTING IN EARLY ARTHRITIS REFERRALS**

*Mariana Luís, Luisa Brites, Ana Rita Prata, Tânia Santiago, José Antionio P. da Silva, Cátia Duarte. Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*

**Background:** The CHUC Early Arthritis Clinic, founded in 2011, intends to provide a prompt response to patients with recent onset of symptoms suggestive of an inflammatory rheumatic disease (IRD). By research protocol, all patients are screened at baseline for the presence of antinuclear antibodies (ANA). An analysis was performed to evaluate the usefulness of universal ANA testing in these patients.

**Objectives:** To evaluate the prevalence and clinical correlates of ANA positivity in early arthritis referrals.

**Methods:** A retrospective study of consecutive patients referred to the Early Arthritis Clinic between 2011 and 2018 was conducted. Referral is based on the fulfillment of specific criteria: presence of arthritis or clinically suspected arthralgia beginning in the previous 12 months plus suggestive laboratory abnormalities (rheumatoid factor, C-reactive protein or erythrocyte sedimentation rate). ANA titer (positive ≥ 1:160) and cellular staining patterns were assessed by indirect immunofluorescence (Hep-2 cells). Positive (PPV) and negative predictive values (NPV) of an ANA positive test for the diagnosis of an IRD or an ANA related rheumatic disease (ARD) were determined, along with PPV for the other referral criteria.

**Results:** 207 patients were included in the analysis (64.3% female, aged 53.9 ± 18.2 years). The diagnosis of an IRD was confirmed by the rheumatologist in 61.4% of cases, including 11.8% cases of ARD. The most prevalent diagnosis was rheumatoid arthritis (21.7%), followed by unclassified arthritis (8.7%), psoriatic arthritis, osteoarthritis and fibromyalgia (6.8% each). The prevalence of ANA positivity in our cohort was 64.2%, most frequently in low titer (1:160 in 33.8%, 1:320 in 19.2%, 1:640 in 8.7% and 1:1280 in 2.4%) and with a dense fine speckled pattern (45.1%). ANA-positive patients were older (53.7 ± 17.9 versus 47.9 ± 18.5, p<0.05), more likely to have an IRD (72.9% versus 40.5%, p<0.001) but not an ARD (9.0% versus 4.1%, p=0.186). PPV for ARD was 9.0% for the 1:160 cut-off titer and 15.6% for the 1:320. Squeeze test (PPV 13.5%), erythrocyte sedimentation rate (PPV 9.9%) and rheumatoid factor (PPV 20.0%) as referral criteria, all performed better at predicting an ARD, compared to an ANA positive testing.

**Conclusion:** Early Arthritis Clinic referred cohort has a high prevalence of IRD but a low prevalence of ARD which explains the poor predictive value of ANA in this setting, especially when considering lower titers and when compared with specific referral criteria. Thus, universal ANA testing in Early Arthritis Clinic referrals seems unjustified, given its costs and added value. Studies designed to optimize the use of ANA in this context are warranted.

**Disclosure of Interests:** None declared

mediated by the CB1 receptor indicated by an increased cell viability and reduction of caspase activity after combined treatment with CBD and CB1 antagonist AM251. Since CBD induced Erk1/2 phosphorylation seems to be independent of CB1 signalling, the involvement of other signalling pathways and/or a crosstalk with other Ca2+ channels or receptors seems likely and will be the focus of further investigations.

11Corbus Pharmaceuticals, Inc., Norwood, United States of America

Background: Lenabasum is a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses and limits fibrosis in animal models of SSc. Lenabasum had acceptable safety and tolerability, and improved efficacy outcomes in the 16-week, double-blind, randomized, placebo-controlled Part A of Phase 2 trial JBT101-SSc-001 (NCT02465437) in dCSSC subjects.

Objectives: To provide long-term open-label safety and efficacy data in dCSSC subjects in study JBT101-SSc-001.

Methods: Subjects who completed Part A were eligible to receive oral lenabasum 20 mg BID in an open-label extension (OLE) that assessed safety and efficacy at 4 weeks, then every 8 weeks.

Results: 38/39 (97%) eligible subjects enrolled in the OLE, with mean interval of 134 (range 33-392) days or 19.1 weeks from end of dosing in Part A to start of OLE when subjects received only standard-of-care drugs. 34/36 (94%) subjects were on stable doses of immunosuppressive drugs. At safety data cut-off, 31/38 (81%) eligible subjects enrolled in the OLE, with mean interval of 134 (range 33-392) days (18 months) from end of dosing in Part A to start of OLE when subjects received only standard-of-care drugs. At efficacy data cut-off, 30/36 (83%) subjects had completed each.

Conclusions: Lenabasum continues to have a favorable safety and tolerability profile in the OLE of Phase 2 trial JBT101-SSc-001 with no lenabasum-related serious AEs or study discontinuations. Only 7 (19%) subjects had an AE related to lenabasum in ≥18 months of OLE dosing. ACR CRISSE score, mRSS, Physician Global Assessment, and multiple patient-reported outcomes show continued improvement, although background therapy, potential for spontaneous improvement, and open-label dosing limit what can be definitely attributed to lenabasum.

DEVELOPMENT OF A STANDARDIZED MINIMAL CORE DATA SET FOR PREGNANCY REGISTERS IN RHEUMATOLOGY – RESULTS OF A EURAL TASK FORCE

Yvette Meißner1, Rebecca Fischer-Betz2, Laura Andreoli3, Nathalie C oste doat-Chalumeau6, Diederik De Cock4, Radboud Dolhain7, Frauke För ger8,9, Doreen Goll10, Anna Moltó11, Rebecca Özdemir12, Luigi Raio6,9, Catherine Nelson-Piercy13,14, Sebastian C Rodriguez-Garcia14, Savino Sciascia15, Marianne Wallenius16, Astrid Zibden17, Angela Zink17,18, Anja Strangfeld19, German Rheumatism Research Centre, Berlin, Germany; 2Heinrich-Heine University, Düsseldorf, Germany; 3University of Brescia, Brescia, Italy; 4Université Paris-Descartes, Paris, France; 5Hospital Cochin, Paris, France; 6KU Leuven, Leuven, Belgium; 7Erasmus University Medical Center, Rotterdam, Netherlands; 8University Hospital, Bern, Switzerland; 9University of Bern, Bern, Switzerland; 10Patient partner, Berlin, Germany; 11INSEERM Unit 1153, CRESS, Paris, France; 12Patient partner, Duisburg, Germany; 13St. Thomas Hospital, London, United Kingdom; 14Hospital Clinic Barcelona, Barcelona, Spain; 15University di Torino, Torino, Italy; 16University Hospital and Norwegian University of Science and Technology, Trondheim, Norway; 17Chantel University Medicine, Berlin, Germany

Background: Results from individual data collections on drug safety during pregnancy and outcomes of pregnancy in patients with inflammatory rheumatic diseases (IRD) are often limited due to small number of cases. Joint data analyses from different data sources could solve this problem.

Objectives: The aim of this EURAL task force was to define a core data set to facilitate joint analysis of pregnancy registers in rheumatology.

Methods: Scope and core areas of the core data set have been developed according to COS-STAR recommendations by consensus. An initial list of data items possibly relevant for pregnancy registers was generated based on (I) a systematic literature search, (II) data items already collected by European pregnancy registers and (III) a survey amongst patient representatives. Consensus about the importance of each data item to be included in a core data set was reached by interviews and standardized safety form. Efficacy on GI symptoms was measured using the UCL A GIT 2.0 score questionnaire. Patients were defined as responders if reported symptom improvement was equivalent to the UCL A GIT definition of “minimally clinically important difference”. Secondary and explorative endpoints included changes in relative abundance of total, immunoglobulin (Ig)A- and IgM-coated fecal bacteria measured by 16s rRNA sequencing; changes in modified Rodnan skin score, lung function, CRP, ESR, and patient and physician global. Descriptive statistics were applied for clinical endpoints and linear mixed models for microbial analysis.

Results: Ten patients with limited cutaneous SSC randomized to ACHIM (n=5) or placebo (n=5) were included. All patients were female with clinical apparent GI symptoms, mean age of 62 years and mean time from diagnosis of 12 yrs. Two placebo controls experienced procedure-related serious adverse events; one developed laryngospasms at first gastroduodenoscopy necessitating study exclusion and one duodenal perforation at final gastroduodenoscopy. Improvement in total GIT score was reported by 3/5 FMT patients compared to 2/4 placebo controls at weeks 4 and 16 (Figure 1). FMT effects were most pronounced on lower GI symptoms, with improvement reported by 3/5 FMT patients with diarrhea, distention/ bloating and/or fecal incontinence compared to baseline at 2/4 placebo controls (Figure). Clinical secondary endpoints showed no differences and other side effects (stomach discomfort, bloating and diarrhea) were mild and transient. Fecal microbiota diversity (observed number of operational taxonomic units) was increased after FMT compared to placebo treatment at week 16 (p<0.006). Moreover, abundant bacterial genera in ACHIM were present within the total, and IgA- and IgM-coated fecal bacteria at both week 4 and 16 in the FMT group (Figure) but not in the placebo controls.

Conclusion: The consensus process resulted in an extensive list of data items recommended by experts to be collected as a minimum by pregnancy registers in rheumatology. This core data set applies to all pregnant women irrespective of the underlying IRD. The EURAL task force plans to find consensus on additional disease specific advice.
Conclusion: FMT of commercially-available ACHIM in patients with SSc appeared safe, effectively reduced lower GI symptoms, altered gut microbiota composition, richness and diversity and appeared to affect the mucosal immune system.

Calming the cytokine storm in children and adults_
Remission – the holy grail? Looking across diseases.

**CONTRAST OF THE EFFECTS OF DORIS REMISSION AND LUPUS LOW-DISEASE ACTIVITY STATE (LLDAS) ON DISEASE OUTCOMES IN A MULTINATIONAL PROSPECTIVE STUDY**

**Background:** The Definitions of Remission in SLE (DORIS) group has proposed multiple definitions of remission, but these are infrequently attained and have not been prospectively evaluated in relation to protection from damage accrual. In contrast, the Lupus Low Disease Activity State (LLDAS) is more attainable, and has been shown to be associated with improved patient outcomes.

**Objectives:** To compare the attainability, variability, and outcomes, of LLDAS and remission in a prospective multicentre study.

**Methods:** A prospective multinational cohort study was undertaken in 13 centres between 2013-2017. Time dependent Cox proportional hazards models were used to compare LLDAS and DORIS definitions of remission in terms of impact on disease flares and damage accrual.

**Results:** 1735 SLE patients were recruited, and followed for (mean±SD) 2.2±0.9 years, totalling 12,717 visits. LLDAS was achieved in 47.2% of observed visits. In contrast, remission was achieved in 1.1%±15.4% of visits depending on the stringency of remission definition. LLADS attainment at any visit was associated with significantly reduced subsequent flare (HR 0.65, 95%CI 0.56-0.75, p<0.001) and damage accrual (HR 0.59, 95%CI 0.45-0.76, p<0.001). In contrast, only the least stringent remission definition was associated with reduced damage accrual (HR 0.58, 95%CI 0.39-0.79, p<0.001). Only remission definitions including serological remission were significantly associated with reduction in subsequent flares. Patients who spent >50% of their observed time in LLDAS had reduction in damage accrual (HR 0.54, 95% CI 0.40-0.70, p<0.001) compared to patients with <50% of observed time in LLADS; again, only the least stringent remission definition, or the related definition excluding serology, were associated with reduced damage (HR 0.59, 95% CI 0.45-0.76, p<0.001; HR 0.59, 95% CI 0.40-0.83, p<0.001; HR 0.69, 95% CI 0.48-0.99, p<0.05, respectively).

**Conclusion:** LLDAS was more attainable than any remission definition, whilst still conferring significant reduction in flares and damage accrual. Only the least stringent remission definitions could be shown to be associated with significantly lower damage accrual, likely reflecting a low frequency of remission attainment overall. LLDAS is a valid treatment target for SLE and is more achievable than remission.

**Background:** Progression of structural joint damage occurs in 20-30% of patients with rheumatoid arthritis (RA) in clinical remission1. Magnetic resonance imaging (MRI)-detected synovitis and in particular osteitis/bone marrow edema (BME) are known predictors of structural progression in both active RA and in remission, but the predictive value of adding MRI tenosynovitis assessment as potential predictor in patients in clinical remission has not been investigated.

**Objectives:** To investigate the predictive value of baseline MRI inflammatory and damage parameters on 2 year MRI and X-ray damage progression in an RA cohort in clinical remission, following MRI and conventional treat-to-target (T2T) strategies.

**Methods:** 200 RA patients in clinical remission (DAS28-CRP<3.2 and no swollen joints) on conventional DMARDs, included in the randomized IMAGINE-RA trial2 (conventional DAS28 + MRI-guided T2T strategy targeting absence of BME vs conventional DAS28 guided T2T strategy) had baseline and 2 years contrast-enhanced MRIs of the dominant wrist and 2nd-5th MCP joints and X-rays of hands and feet performed, which were evaluated with known chronology by two experienced readers according to the OMERACT RAMRIS scoring system and Sharp/ van der Heijde method, respectively.

The following potentially predictive baseline variables: MRI BME, synovitis, tenosynovitis, MRI and X-ray erosion and joint space narrowing (JSN) score, CRP, DAS28, smoking status, gender, age and patient group were tested in univariate logistic regression analyses with 2-year progression in MRI combined damage score, Total Sharp Score (TSS), and MRI and X-ray JSN and erosion scores as dependent variables. Variables with p<0.1, age, gender and patient group were included in multivariable logistic regression analyses with backward selection. 

**Results:** Based on univariate analyses MRI BME, synovitis, tenosynovitis, x-ray erosion and JSN, gender and age were included in subsequent multivariable analyses. Independent MRI predictors of structural progression were BME (MRI progression) and tenosynovitis (MRI and X-ray progression), see table.

* Odds Ratio (95% confidence interval; CI) p-value: MRI combined damage score: sum score of MRI erosion and JSN scores.
Conclusion: This is the first to report that MRI tenosynovitis independently predicts both X-ray and MRI damage progression in RA patients in clinical remission. Further studies are needed to confirm MRI-determined tenosynovitis as predictor of progressive joint destruction in RA clinical remission.

WHAT SEROLOGIC PROFILING PROVIDES OPTIMAL ENTRY CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS CLINICAL TRIALS?

Ewa Olech1, Eduard van Rijen1, Alexander Kant1, Ali Ashrafzadeh1, Joan T Merrill2.

1IQVIA, Durham, United States of America; 2Oklahoma Medical Research Foundation, Oklahoma City, United States of America

Background: A major concern for SLE clinical trials is the possibility that some patients who technically meet entry criteria may not have active disease. Antinuclear antibody (ANA) is known to lack specificity for SLE, permitting inclusion of inappropriate patients. Typically, ANA ≥ 1:80 and/or positive anti-double stranded DNA (DNA) are required screening elements, but largely other autoantibody variables have been utilized.

Objectives: To examine serologic features that promote entry of active SLE patients into trials while supporting reasonable recruitment rates.

Methods: Serologic features of 1411 individual subjects who had full laboratory data at screening (N = 783) and/or baseline (N = 1019) in 4 phase 2 multicenter SLE trials were examined. Complement levels, percent of patients with low C3 or C4, and elevated DNA were used as markers of active disease. Serological profiles consistent with active SLE were tested on screened population for effects on potential screen failure rates.

Results: Of 1019 patients who qualified for the studies (baseline population), 399 (39.2%) were positive for DNA and 670 (65.8%) had anti-Extractable Nuclear Antibodies (ENA). Patients with positive DNA or ENA (even in absence of DNA) had lower complement levels and were more likely to have low C3/C4 (Table 1). In patients at screening, higher titers of ANA were associated with lower complement levels and were more likely to have low C3/C4, and elevated DNA were used as markers of active disease. Serological profiles consistent with active SLE were tested on screened population for effects on potential screen failure rates.

Conclusion: The following entry criteria may help increase the likelihood that trial subjects have active SLE: ANA ≥ 1:640, or DNA, or low C3 or C4. To the extent that a modest loss of recruitment increases the probability of entering true, active SLE patients, these alternative constructs should be considered in future SLE trials.

A PROSPECTIVE CLINICAL AND MRI STUDY OF COMMONLY USED DRUGS IN RHEUMATOLOGY MAY ALTER ANTI-TUMORAL RESPONSE TO IMMUNE CHECKPOINT INHIBITORS

Marie Kosting, Eleonora Mauric, Thomas Barmetche, Léa Rouxel, Caroline Dutiaux, Léa Dousset, Sorlits Frey, Marie Beylot-Barré, Julien Seneschal, Rémi Veillon, Charlotte Vergnenegre, Amaury Daste, Charlotte Domblices, Baptiste Sionneau, Marine Gouz-Goupil, Alain Ravaud, Edouard Forcade, Bernard Barnwarth, Marie-Elise Truchetel, Christophe Richez, Nadia Merssen-Cetie, Thierry Schaeverbeke, on behalf of the FHU ACRONIM, Bordeaux University Hospital, Bordeaux, France

Background: Immune checkpoint inhibitors (ICls) are revolutionizing the treatment of some advanced cancers. Gut microbiota has emerged as an important component of anti-tumoral response and can also be related to the occurrence of immune-related adverse events (irAEs). It has recently been shown that antibiotic treatment given at the initiation of ICI therapy had a dramatic impact on microbiota that compromised the anti-tumoral effect of ICls (1).

Objectives: To evaluate whether co-medications known to have a potential impact on gut microbiota may alter ICI efficacy and/or irAE occurrence when given at ICI onset.

Methods: This was a retrospective cohort study including all cancer patients who received ICIs at our institution from May 2015 to September 2017. Co-medications given to the patients within one month before or one month after the first administration of ICI were extracted from medical records on the basis of a predefined list of medications known to impact gut microbiota. The tumour response, occurrence of irAEs and patient outcomes were assessed on a regular basis. Overall survival (OS) has been considered from the start of ICI therapy.

Results: 635 patients (70% male, mean age 64.5 years) were included, of whom 293 had melanoma, 150 had advanced non-small cell lung cancer and 83 had renal carcinoma. A previous autoimmune disorder was present in 8% of patients, mainly rheumatic and endocrine diseases. Psychotropic drugs (41.1%), proton pump inhibitors (PPIs) (37.3%), angiotensin-converting enzyme (ACE) inhibitors and/or angiotensin II receptor blockers (ARBPs) (32%), glucocorticoids (GC) (24.2%), antibiotics (21.4%), statins (20.8%) and morphine (20.6%) were the most co-prescribed medications. Baseline GC use, when >10mg of prednisone equivalent, was associated with a significant decrease in OS (median 4.5 months versus 24.3 months; p=0.0001) and a less frequent tumour response (55% versus 73%; p=0.0001). When given after ICI onset for the management of irAEs, GC did not influence ICI efficacy (Figure A). Baseline PPIs use also altered both OS (median 10.9 versus 24.3 months; p=0.0001) and tumour response (62% versus 71%; p=0.02) (Figure B). We confirmed the detrimental impact of antibiotics when given at ICI onset, and also found worse outcomes for patients receiving baseline psychotropic drugs (median OS 9.3 versus 19.4 months; p=0.0001). No significant difference was observed with baseline use of NSAIDs, aspirin, statins and ARBs/ACE. Furthermore, co-medication with antibiotics, GC, PPIs, morphine, NSAIDs, aspirin and psychotropic drugs was associated with decreased occurrence of irAEs.

Conclusion: As many of these treatments are used by rheumatologists, one should be aware of their potential detrimental effect when used at ICI initiation, that sometimes could have been avoided.

ORTHOTIC TREATMENT: IS IT IN OR OUT?

Hilda Oliveira, Anamaria Jones, Fabio Jennings, Mariana Vassallini, Andre Rosenfeld, Jamil Natour. Universidade Federal de São Paulo, São Paulo, Brazil

Background: Morton’s neuroma (MN) is a benign enlargement of the third common digital branch of the medial plantar nerve. The most common symptom is buming pain in the plantar foot, located between the metatarsal heads, often radiating to the two corresponding toes. Treatment can be surgical or conservative, which consists of decreasing nerve pressure and irritation through therapies that promote analgesia, patient education, and plantar orthosis. The custom insole prescriptions are aimed at relieving the pressure in the MN region, and to redistribute pressure throughout the sole of the foot. There is no study evaluating the effect of insoles in patients with MN.

Objectives: The aim of the present study was to assess the effectiveness of a customized insole with metatarsal and arch support on pain in patients with Morton’s neuroma and the impact of this insole on function, load distribution in the plantar region, gait, quality of life and satisfaction with insole use.

Methods: A randomized, controlled, double-blind, clinical trial was carried out with intent-to-treat analysis. Seventy-two patients with MN were randomly allocated into a study group (n=36) and control group (n=36). One week following the baseline evaluation, the study group received a customized insole with metatarsal and arch support made of ethyl vinyl acetate and the control group received a flat insole of the same material, color and density. The groups were evaluated after 6, 12 and 24 weeks of insole use. The following assessment parameters were employed: pain when walking, on palpation and at rest (END); paresthesia (ENP); quality of life (SF-36); foot function (FFI and FHSQ); six-minute walk test (6MWT) and foot pressure analysis using the AM Cube FootWalk Pro program.

Results: The groups were homogeneous regarding the majority of variables at baseline. In the comparisons over time, statistically significant differences between the groups were found for pain when walking (p=0.048), in the general health of the foot) and quality of life (limitation by physical aspects, bodily pain and vitality), we observed improvement in both groups with no statistically significant difference between them. No change was observed in the baropodometry parameters with the use of the insole.

Conclusion: A customized insole with metatarsal and arch support reduce pain when walking and improve function of patients with MN.

CURRENT TREATMENT OF VASCULITIS

Xiaoning Liu, Gejin Chen. The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: The lack of CD4+CD25+Foxp3+ T regulatory cell (Treg) has been associated with human systemic autoimmune diseases, such as rheumatoid arthritis (RA). IL-2 is an essential growth and survival factor for Treg cells. However, the significance of Treg cells in the pathogenesis and the effect of low dose IL-2 on Behcet’s disease (BD) are rarely reported.

OBJECTIVES: To investigate the significance of Treg cells and the effect of low dose IL-2 on BD.

Methods: Eighty patients with BD and seventy healthy donors were enrolled. CD4+ T cell subsets in peripheral blood mononuclear cells from these people were measured by multicolour flow cytometry. Twenty-six patients were treated daily with subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days. CD4+ T cell subsets were analysed before and after treatment by flow cytometry.

Results: Compared to health control, the absolute counts of circulating Treg cells were significantly decreased in patients with BD (median:29.93 cells/ul VS median:33.16 cells/ul, P=0.039) and it is negative correlation with disease activity. While the ratios of TH17/Treg in patients with BD (median:0.29) were significantly higher than those of health control (median:0.2). No difference in the absolute counts of circulating TH17 cells (CD4+IL-17) between patients with BD and health control. Treatment of patients with BD with a low-dose IL-2 selectively increased the absolute counts of Treg cells, from a median of 18.97 cells/ul to 74.88 cells/ul (at 5 days) (P<0.001). No significant difference was observed in the absolute counts of circulating TH17 cells after IL-2 treatment.

Conclusion: TH17/Treg cells may play a role in the pathogenesis of patients with BD, low-dose IL-2 proposes a selective biological treatment strategy by restoring immune tolerance.

LOW-DOSE IL-2 SELECTIVELY RESTORES REGULATORY T CELLS IN PATIENTS WITH BEHÇET’S DISEASE

Xiaoning Liu, Gejin Chen. The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: The lack of CD4+CD25+Foxp3+ T regulatory cell (Treg) has been associated with human systemic autoimmune diseases, such as rheumatoid arthritis (RA). IL-2 is an essential growth and survival factor for Treg cells. However, the significance of Treg cells in the pathogenesis and the effect of low dose IL-2 on Behcet’s disease (BD) are rarely reported.

Objectives: To investigate the significance of Treg cells and the effect of low dose IL-2 on BD.

Methods: Eighty patients with BD and seventy healthy donors were enrolled. CD4+ T cell subsets in peripheral blood mononuclear cells from these people were measured by multicolour flow cytometry. Twenty-six patients were treated daily with subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days. CD4+ T cell subsets were analysed before and after treatment by flow cytometry.

Results: Compared to health control, the absolute counts of circulating Treg cells were significantly decreased in patients with BD (median:29.93 cells/ul VS median:33.16 cells/ul, P=0.039) and it is negative correlation with disease activity. While the ratios of TH17/Treg in patients with BD (median:0.29) were significantly higher than those of health control (median:0.2). No difference in the absolute counts of circulating TH17 cells (CD4+IL-17) between patients with BD and health control. Treatment of patients with BD with a low-dose IL-2 selectively increased the absolute counts of Treg cells, from a median of 18.97 cells/ul to 74.88 cells/ul (at 5 days) (P<0.001). No significant difference was observed in the absolute counts of circulating TH17 cells after IL-2 treatment.

Conclusion: TH17/Treg cells may play a role in the pathogenesis of patients with BD, low-dose IL-2 proposes a selective biological treatment strategy by restoring immune tolerance.

SATURDAY, 15 JUNE 2019
Workshop: #ConnectToday and tomorrow: The campaigning continues.

OP0340-PARE #SEE ME – RAISING AWARENESS AND UNDERSTANDING OF JUVENILE IDIOPATHIC ARTHRITIS IN IRELAND

Brian Lynch, Arthritis Ireland, Dublin, Ireland

Background: For those living with juvenile idiopathic arthritis (JIA), it is a doubly confounding condition. The popular perception that arthritis is an old person’s disease leaves little room for understanding that children can also get the disease in its impact. There are 1,200 children and young people under 16 living with JIA in Ireland.

In this campaign, Arthritis Ireland sought to capture people’s attention by subverting typical associations around arthritis. The campaign had to speak to and draw upon youth culture. Once people’s attention was captured, this created an opportunity to communicate key pieces of information about the disease and highlight the challenging situation regarding access to Irish paediatric rheumatology services.

Objectives:
- To raise awareness that children and young people can get arthritis;
- To increase awareness and understanding of what it’s like to live with JIA;
- To increase political support for the provision of enhanced paediatric rheumatology services.

Methods: #SeeMe was launched during Ireland’s National Arthritis Week (9-15 April 2018) and encompassed social media, public affairs and media relations. A key element of the campaign was the creation of a unique media asset, a short music video, which would speak directly to young people and encourage them to get involved in the campaign. The video communicated how JIA can impact enjoyable, everyday teenage activities such as dancing. A dedicated microsite was created which housed all of the campaign assets.

A campaign petition called on the Government to implement the Model of Care for Paediatric Rheumatology. It was extremely successful, gathering more than 17,000 signatures and far exceeding the target of 5,000. The petition also harvested powerful testimony from supporters who were able to share their own stories of living with JIA.
Personal patient stories were leveraged throughout the campaign by the involvement of #SeeMe Ambassadors. These were children and young people living with JIA who were willing to share their experience publicly. National and regional media were successfully targeted, securing considerable coverage. Subsequently, the campaign progressed to a third phase of activity as young people raised awareness of JIA through their own schools, social clubs and social media networks.

An infographic was developed to communicate key medical information about JIA and paediatric rheumatology services in a clear, accessible way.

Results: 

• 87,000 people viewed the campaign video;
• 17,000 people signed the #SeeMe petition;
• 820,000 people were reached by the social media campaign;
• 35 pieces of media coverage on television, radio and print were achieved;
• Lobbying of politicians by patients and their families prompted 12 TDs and senators to raise this issue;
• In May 2018, the Government committed to the appointment of an additional paediatric rheumatologist in 2019, with plans to recruit a multidisciplinary team.

Conclusion: This campaign set out to give a voice to those living with JIA and to increase awareness and understanding of the disease. The campaign highlighted the challenges in paediatric rheumatology services and proved an effective vehicle in harnessing public opinion; resulting in over 17,000 people signing the petition calling for the implementation of the Model of Care for Paediatric Rheumatology.

In the wake of the campaign, the announcement by the Irish Government to invest in paediatric rheumatology services represents an important step forward. While much remains to be done, this is progress and highlights the important role played by patient organisations, and their public education and advocacy work.

Tackling inflammatory bone disorders in children and adults

OP0342

IDENTIFYING CANDIDATE ITEMS TOWARDS THE DEVELOPMENT OF CLASSIFICATION CRITERIA FOR CHRONIC NONBACTERIAL OSTEOMYELITIS (CNO) AND CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS (CRMO)

Melissa Oliver1, Eveline Wu2, Raymond Naden3, Matthew Hollander4, Polly Ferguson5, Fatma Dedegul7, Seza Özen, Yongdong Zhao1, 2. 1Riley Hospital for Children at Indiana University Health, Indianapolis, United States of America; 2University of North Carolina at Chapel Hill, Chapel Hill, United States of America; 3University of Iowa Stead Family Children’s Hospital, Iowa City, United States of America; 4University of Vermont Children’s Hospital, Burlington, United States of America; 5University of Iowa Stead Family Children’s Hospital, Iowa City, United States of America; 6Boston Children’s Hospital, Boston, United States of America; 7Hacettepe University, Ankara, Turkey; 8Seattle Children’s Hospital, Seattle, United States of America

Background: Chronic nonbacterial osteomyelitis (CNO) is a severe and occult autoinflammatory bone disease of unknown cause. Early diagnosis is challenging, and CNO may debilitate affected children when left untreated. Currently, evidence-based and validated diagnostic and classification criteria for CRMO/CNO are lacking. The insidious disease course, increasing disease incidence, and significant delay in diagnosis highlight the need for the development of classification criteria that leads to more precise and early selection of patients for clinical trials. 1, 2

Objectives: To identify candidate items towards developing classification criteria for CNO using anonymous survey and nominal group technique.

Methods: An international collaborative effort was formed within the pediatric and adult rheumatology communities to conduct the following phases: 1) to generate candidate criteria items by a Delphi survey among international rheumatologists; 2) to reduce candidate criteria items through consensus processes involving physicians managing CNO and patients or caregivers of children with CNO. This study was approved by Seattle Children’s Hospital Institutional Review Board.

Results: In Phase 1, 259 pediatric rheumatologists (30%, N=865) participated in an online questionnaire about features most relevant to the classification of CNO. Of those, 77 (30%) practiced in Europe, 132 (51%) in North America, and 50 (19%) in other continents. A total of 138 (53%) responders had >10 years of practice experience and 106 (42%) had managed >10 CNO patients. There were 33 candidate criteria items initially identified. In Phase 2, candidate items were presented to 39 rheumatologists and 7 parents and items were refined or eliminated through item reduction techniques. Seventy-seven (94%, N=82) workgroup members then participated in a second survey to rank the remaining items by their distinguishing power of CNO from mimicking conditions. Figure 1 shows the mean score for the remaining 31 candidate criteria. Multifocal lesions, ruling out malignancy and infection and typical location on imaging had the greatest means. CRP and/or ESR greater than 3x the normal upper limit had the greatest negative means.

Discriminatory Score: +3/-3 (increases/decreases the likelihood of CRMO the most)
+2/-2 (increases/decreases the likelihood of CRMO moderately)
+1/-1 (increases/decreases the likelihood of CRMO slightly)
0 (no difference)

Conclusion: Through surveys and consensus technique, candidate items towards developing classification criteria for CNO were identified. This list of items will guide the design of a feasible patient data collection form towards weighting of each item in the classification criteria.

LONGITUDINAL ASSESSMENT OF MRI OF THE SACROILIAC JOINTS IN THE ASAS CLASSIFICATION COHORT: EVOLUTION OF DIAGNOSTIC FEATURES AND PREDICTIVE UTILITY FOR AXIAL SPONDYLOARTHRITIS

Walter P Maksymowych1, 2, Xenofon Baraliakos3, Anna Ghadir2, Martin Fruhth2, Uta Kiltz1, Juergen Braun1.

Background: Follow up of the ASAS Classification Cohort (CC) indicated a high positive predictive value for the CC criteria derived from baseline patient and imaging data. Moreover, diagnosis of axSpA was changed by the rheumatologist in only 11.2% of patients after 4.4 years. This has raised potential concerns regarding diagnostic ascertainment bias.

Objectives: To determine the evolution of MRI features of axSpA in ASAS-CC cases by central readers, whether this reflects diagnostic assignment by the rheumatologist, and the predictive utility of baseline MRI features of axSpA.

Methods: MR images were available from 108 cases in the ASAS-CC at baseline and follow up (mean 4.4 years) and also had a rheumatologist diagnostic assessment at both time points. Eight readers from the ASAS MRI group recorded MRI lesions that were quantified by the ASAS MRI group. MRI data from >2 readers and from the majority of readers (≥5/8) was used to calculate positive and negative predictive values (PPV, NPV).

Results: MRI was considered diagnostic of axSpA in 52/108 (48.1%) cases at baseline and in 47/86 (54.7%) diagnosed at baseline as axSpA by the rheumatologist. Change in MRI diagnosis was recorded in 10/108 (9.3%) of cases (2 from yes to no, and 4 from no to yes for axSpA) according to agreement by ≥2 readers and in only 3 cases according to >5/8 readers (Table 1). Change in rheumatologist diagnosis was recorded in 9/108 (8.3%), 2 of which had a change in MRI diagnosis. Baseline MRI lesions considered typical of axSpA had very high PPV for follow up diagnosis of axSpA (Table 2).

Conclusion: The infrequent change in diagnostic ascertainment of rheumatologists over follow up of the ASAS-CC is supported by this central reader evaluation of MRI scans. A positive MRI at baseline had very high PPV for a follow up diagnosis of axSpA.

OP0344 WHICH MAGNETIC RESONANCE IMAGING LESIONS OF THE SACROILIAC JOINTS ARE OF DIAGNOSTIC VALUE FOR AXIAL SPONDYLOARTHRITIS?

Xenon Baraliakos1, Anna Ghadir2, Martin Fruhth2, Uta Kiltz1, Juergen Braun1.

1Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany;
2Radiologie Herne, Herne, Germany

Background: Classification of patients as having axial spondyloarthritis (axSpA) by the imaging arm of the ASAS criteria relies partly on the detection of bone marrow edema (BME) suspicious of SpA on magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ). Fatty lesions (FL) and erosions on SIJ-MRI have been sug- gested to be genuinely related to SpA in the context of interpretation of a ‘positive’ MRI in case of doubtful BME cases (1).

Objectives: Evaluate the role of different SIJ-MRI lesions for diagnosing axSpA in daily routine practice.

Methods: Consecutive patients with chronic back pain (duration >3 months) starting before age 45 and clinical suspicion of axSpA underwent a complete diagnostic workup including SIJ-MRI. All clinical, laboratory and imaging data were available to experienced rheumatologists for diagnosing axSpA or not (non-SpA). In parallel, two experienced readers, blinded to all patients’ information and diagnosis, evaluated the MRIs and made a diagnostic judgement based only on imaging. Furthermore, radiologists quantitatively assessed MRIs for BME (Berlin Score), FL, erosions, sclerosis and ankylosis. Results: A total of 300 consecutive patients were recruited. AxSpA was diag- nosed by the rheumatologist in 131 patients (43.7%) with mean age of 34.5±7.2 years, 73% HLA-B27+, mean symptom duration 35.6±9.5 months, vs. 169 non- SpA patients with mean age of 34.7±7.4 years, 21% HLA-B27+, mean symptom duration 33.9±45.1 months. The ASAS classification criteria were fulfilled by 99/ 131 patients diagnosed with axSpA (75.6%) vs. 70/169 patients diagnosed vs. non-SpA non-SpA (41.4%).
In 97/162 patients, rheumatologists and radiologists agreed on a diagnosis of axSpA and non-SpA (overall agreement: 86.3%). However, 34/131 (28.1%) patients were diagnosed by axSpA by rheumatologists but not by radiologists. According to radiologists, BME alone was critical for diagnosis in only 7/97 patients (7.2%) with axSpA as agreed by both, rheumatologists and radiologists, in contrast to chronic lesions alone (30/97, 30.9%) or the combination of both lesion types (60/97, 61.9%).

While the sensitivity of BME for diagnosing axSpA did not change, the specificity improved when chronic lesions were also present (Tab.1). In addition, based on rheumatologists’ diagnosis, the respective odds ratio (OR) for identifying axSpA by MRI was higher when chronic lesions were present (Tab.1). MRI scores were significantly higher in axSpA vs. non-SpA patients, indicating that axSpA is associated with deeper BME or chronic lesions (Tab.2).

Conclusion: The combination of structural changes and BME lesions as assessed by MRI performed best in the process of diagnosing axSpA in consecutive patients in a real-life setting presenting to our center. The discrepancy in diagnosis between rheumatologists and radiologists reflects the increasing insecurity of including only BME of SIJ as the major criterion for diagnosing axSpA.

COP0245

DOES IMMUNOLOGICAL REMISSION, DEFINED AS DISAPPEARANCE OF AUTOANTIBODIES, OCCUR WITH CURRENT TREATMENT STRATEGIES? A LONG-TERM FOLLOW-UP STUDY IN RHEUMATOID ARTHRITIS PATIENTS WHO ACHIEVED A SUSTAINED DMARD-FREE STATUS

Debbie Boeckers1*, Leonie Burgers1, Rene Toes1, Annette van der Helm - van Mi1,2, 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: Sustained disease modifying antirheumatic drug (DMARD)-free status, the sustained absence of synovitis after cessation of DMARD-therapy, is infrequent in autoantibody-positive RA, but approximates cure (i.e. disappearance of signs and symptoms). It was recently suggested that immunological remission, defined as disappearance of anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF), underlies this outcome.1 However, the association between seroreversion and cure of disease has not been extensively studied before.

Objectives: To determine in a long-term observational study if autoantibodies disappear in RA-patients who achieved sustained DMARD-free remission.

Methods: We studied 95 ACPA- and/or RF-positive RA-patients who achieved DMARD-free remission after median 4.8 years and kept this status for the remaining follow-up (median 4.2 years). Additionally, 21 autoantibody-positive RA-patients with a late flare, defined as recurrence of clinical synovitis after a DMARD-free status of ≥1 year, and 45 autoantibody-positive RA-patients who were unable to stop DMARD-therapy (during median 10 years) were studied. Anti-CCP2 IgG, IgM and RF IgM levels were measured in 587 samples obtained at diagnosis, before and after achieving DMARD-free remission.

Results: 12.8% of anti-CCP2 IgG positive RA-patients had seroreverted when achieving remission. In RA-patients with a late flare and with persistent disease this was 8.3% and 5.7%, respectively (p=0.63, Figure). For anti-CCP2 IgM and RF IgM similar results were observed. Evaluating the estimated slope of serially measured levels revealed that RF-levels decreased more in patients with than without remission (p<0.001); the course of anti-CCP2 levels was not different (p=0.66).

Conclusion: Sustained DMARD-free status in autoantibody-positive RA was not paralleled by an increased frequency of reversion to autoantibody-negativity. This form of immunological remission should therefore not be a treatment target.

MRI OF THE WRIST IN EARLY RHEUMATOID ARTHRITIS AFTER 1-YEAR TREAT-TO-TARGET STRATEGY

XIAO Fan1*, James F Griffith1, Lai-Shan Tam2. 1Prince of Wales Hospital, The Chinese University of Hong Kong (SAR), Imaging and Interventional Radiology, Hong Kong, Hong Kong (SAR); 2Prince of Wales Hospital, The Chinese University of Hong Kong (SAR), Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)

BACKGROUND: There are two types of remission in rheumatoid arthritis. The first, and most commonly applied, is clinical remission. Imaging remission is another aspect to consider given that (a) the correlation between clinical and imaging is present at relatively modest levels (1), (b) imaging can show subclinical inflammation not evident clinically and (c) imaging evidence of inflammation can predict structural damage (1). In this study, we compared clinical and imaging remission in early rheumatoid arthritis (ERA) patients after one year of standard treatment.

OBJECTIVES: To semi-quantitatively and quantitatively measure the degree of inflammation (synovitis, tenosynovitis, bone marrow oedema) and structural change (erosions, joint space narrowing) on MRI in early RA patients following treat-to-target strategy treatment for one year and to compare this with changes in clinical parameters.

METHODS: Prospective cross-sectional study of 70 ERA patients underwent treat-to-target strategy treatment for one year, DAS28-ESR remission (DAS28-ESR score c<3.2), 2011 ACR/EULAR definition of remission, SDAI remission (SDAI ≤ 3.3) and Boolean remission was measured before and after treatment. High resolution MRI of the most symptomatic wrist was performed before and after treatment. MRI parameters including RAMRIS subscores, synovial volume (synovitis and tenosynovitis), synovial perfusion (max enhancement, enhancement slope) were measured.

RESULTS: 55 (%) out of 70 ERA patients completed baseline and one-year clinical and MRI assessments. Remission rates for DAS28-ESR, SDAI and Boolean were 60% (33), 44% (24) and 33% (18) respectively. Eight (24%) out of 33 patients with DAS28-ESR remission, showed progression in bone erosion. Fourteen (16.7%) of 24 patients with SDAI remission showed progression in bone erosion while 1 (5%) of 18 patients with Boolean remission showed progression in bone erosion. Patients who achieved remission after treatment had a greater reduction in all MRI-evident inflammation as well as bone erosion. At month 12, MRI-evident joint synovitis, tenosynovitis and bone marrow oedema was still frequently seen in ERA patients with clinical remission though patients who achieved Boolean remission had the lowest levels of joint synovitis (RAMRIS Synovitis= 2.6±0.8 (2.9±1.3 for DAS28-ESR remission and 3±1.2 for DAS28-ESR remission)); synovitis volume= 1298±1217 mm³ (1480±1367 mm³ for SDAI remission and 1520±1584 mm³ for DAS28-ESR remission); synovitis perfusion of max enhancement= 38±22% (41±25% for SDAI remission and 41±25% for DAS28-ESR remission)), bone marrow oedema (RAMRIS BME score= 0.9±1.1 (1.3±2.6 for SDAI remission and 1.4±2.3 for DAS28-ESR remission)) as well as bone erosion (RAMRIS bone erosion score= 4±5.8 (4.6±5.5 for SDAI remission and 4±3.4 for DAS28-ESR remission)) for all patients at one year.

CONCLUSION: MRI detected inflammation is common even in patients with clinical remission. Patients with Boolean remission had overall less residual inflammation than DAS28-ESR or SDAI remission patients as well as lowest number of patients who had bone erosion progression in remission group at month 12. Treat to target protocols should ideally target Boolean remission.

Restless lives: Managing fatigue, sleep and pain

THE INFLUENCE OF PAIN ON SLEEP PROBLEMS, MENTAL HEALTH AND USE OF STRONG PAINKILLERS AMONG PATIENTS WITH ARTHRITIS

Lene Mandrup Thomsen. The Danish Rheumatism Association, 2820, Denmark

Background: Chronic pain is a part of daily life for many people with RMD and leads to reduced quality of life, high risk of losing work ability, impaired functions and a poor social life. The chronic pain also means that many patients need painkillers. In Denmark there is a very high consumption of strong painkillers (opioids) compared to the other countries in Scandinavia. Therefore, the authorities have a great focus on reducing this and are urging the doctors to reduce the prescription of strong painkillers to patients with chronic pain, including patients with RMDs. In the Danish Rheumatism Association, we have many inquiries to our professional helpline from patients regarding pain. Especially about the use of painkillers, sleeping problems caused by pain, and the negative influence that pain has on one’s mood. The patients experience side effects and discomfort associated with the painkillers. Some must phase out their consumption of strong painkillers, because of the authorities’ focus on this - and have problems with this. In order to get a more detailed knowledge about the influence of pain among patients with RMD, the Danish Rheumatism Association made this study.

OBJECTIVES: To investigate the influence of pain on sleeping problems, mental health and the use of strong painkillers among members of a user-panel.

METHODS: The study was carried out in November 2018 as an online questionnaire survey sent to 1328 members of a user-panel in The Danish Rheumatism Association. 69% answered the questionnaire. The user-panel consists of people at least one RMD. It is not representative of patients with RMD in Denmark.

RESULTS: The most important results are.

Sleep: 67% rarely or never feel fully rested when they wake up in the morning, and 36% takes painkillers to improve their sleep. 69% have experienced that the quality of their sleep has affected their pain negatively.

Mental health: During the past four weeks, 58% have felt that everything is unmanageable for them due to pain, 11% indicated having had thoughts of taking their own life due to pain, and 45% have not wanted to be together with other people because of their pain.

Use of strong painkillers: 83% have pain on a daily basis or several times a week. Among these, 46% have received strong painkillers over the last year, and 78% have not been offered alternatives to strong painkillers.

More results from the survey will be presented on EULAR.

Conclusion: The study indicates that pain and poor quality of sleep, has surprisingly large influence on patient’s daily life. More than one third takes painkillers to improve their sleep. Pain seems to have a severe negative influence on their sleep and reversed - poor sleep worsens their pain. Surprisingly many are still using strong painkillers, despite the authorities focus on reducing prescription of strong painkillers, and the patients’ state, that they are not been given an alternative to strong painkillers. Finally, the study shows that pain has a surprisingly negative influence on mental health and the patients’ hope for the future. In general, it has been a surprise for the Danish Rheumatism Association, that pain has such a huge impact on the participants’ daily life, especially on their mental health. Therefore, the organization has been using the result of this study in our political work for better treatment and support to patients with chronic pain in our healthcare system, and in our political campaigning about the importance of a focus on pain among patients with RMDs. It is to be explained on EULAR, how we more concretely have applied the results of the study in our political work.

FACE ARTHRITIS: WHAT SITUATIONS AFFECT EMOTIONALLY THE PATIENT WITH RHEUMATOID ARTHRITIS AND HOW TO RESOLVE THEM EFFECTIVELY

Santos Castañeda1, José Bernardo Negrón2, D María, Navarro Rubio2, L José, Baquero Ubeda4, Loreto Carmona5, Spanish Forum of Patients and ConArtritis.

1Hospital de La Princesa, Rheumatology, Madrid, Spain; 2Instituto de Musculoskeletal Health – InMusc, Madrid, Madrid, Spain; 3Hospital Sant Joan de Déu, Barcelona, Barcelona, Spain; 4Foro Español de Pacientes, Madrid, Madrid, Spain; 5Instituto de Salud Musculosquelética, Madrid, Spain

Background: Who defines health as a state of physical, psychological and social well-being. However, patients with rheumatoid arthritis (RA) declare that
treatment is mainly aimed at combating physical affectation and hardly focusses on emotional and social aspects.

Objectives: To identify the situations that produce the greatest negative emotional impact in RA patients and to assess the coping strategies used.

Methods: A previous phase (Project OpinAR) identified situations with negative emotional and social impact. In this project, 2 stages were developed: a) A nominal group of patients, following the McMillan method, selected the most emotionally affected situations from the previous list; b) Voting of patients and rheumatologists to assess the assumed effectiveness of 8 coping strategies for each situation with a Likert scale of 1 to 10 (minimum and maximum): proactive resolution, self-criticism, emotional expression, desiderative thinking, social support, cognitive restructuring, avoiding problems and social withdrawal. The median, interquartile range (IQR), and statistical significance of the differences between patients and physicians (Student’s T test) were calculated with a cut-off value of p<0.05. The strategies valued with 8, 9 and 10 were recommended and those valued as 1, 2 or 3 were discouraged. The study was approved by the Ethical Research Committee of the Hospital of La Princesa.

Results: 107 patients from all the Autonomous Communities and 31 expert rheumatologists from 13 Autonomous Communities were recruited, of which 100 (93%) and 17 (55%) participated in the study in a valid way, respectively. The four situations that most negatively affect them, in the opinion of patients and their doctors are: i) The patient feels that his disease evolves worse than what the doctor says, ii) The patient does not know aspects of the control and monitoring of his disease, iii) The patient feels that he does not really participate in the decision making, and iv) The patient is dissatisfied with the overall treatment received. Regarding coping strategies, doctors recommended using proactive resolution in all situations more frequently than patients (p<0.05 for all situations, low variability, with IQR <2 among physicians) as well as emotional expression (p<0.05 for 3 situations, high variability, with IQR >3). Other strategies were less valued by doctors and patients, but with similar responses. There was a lot of dispersion (IQR >1) in most cases.

Conclusion: The situations with the greatest negative emotional impact on RA are those that put the doctor and the patient at odds with regard to the perception of the disease and its control and should be treated during visits. The most recommended strategies are proactive resolution and emotional expression. The most discouraged are self-criticism and the avoidance of the problem. Anyway, there is a great variability of opinions and doctors tend to give more extreme responses. Doctors and patients should have a space and willingness to discuss and exchange opinions on how they emotionally face RA.

OP0349 NEURAL NETWORKS FOR AUTOMATED SCORING OF JOINT DISEASE ACTIVITY ON DOPPLER ULTRASOUND IMAGES

Jakob K. H. Andersen1, Jannik S. Pedersen1, Martin S. Laursen1, Kathrine Holz1, Jakob Grauslund2, Thiusius Rajeeth Savarimuthu1, OMERACT-EULAR Synovitis Scoring (OESS) system, is a major step forward in the use of ultrasound in the diagnosis and monitoring of patients with inflammatory arthritis. The variation in interpretation of disease activity on US images can affect diagnosis, treatment and outcomes in clinical trials.

Objectives: To investigate if we could utilize neural network architecture for the interpretation of disease activity on Doppler US images, using the OESS scoring system.

Methods: Two state-of-the-art neural networks were used to extract information from 1342 Doppler US images from Rheumatoid Arthritis (RA) patients. One neural network that divided images as either healthy (Doppler OESS score 0 or 1) or diseased (Doppler OESS score 2 or 3). The other to score images across all four of the OESS systems Doppler US scores (0-3). The neural networks were hereafter tested on a new set of RA Doppler US images (n=170). Agreement between rheumatologist’s scores and network scores was measured with the kappa statistic.

Results: For the neural network assessing healthy/diseased score, the highest accuracies compared to an expert rheumatologist were 86.4% and 86.9% with a sensitivity of 0.864 and 0.875 and specificity of 0.864 and 0.864, respectively. The other neural network developed to four class Doppler OESS scoring achieved an average per class accuracy of 75.0%, and a quadratically weighted kappa score of 0.919.

Conclusion: This study is the first to show that neural network technology can be used in the scoring of disease activity on Doppler US images according to the OESS system.

OP0350 ULTRASOUND POWER DOPPLER SEMI-QUANTITATIVE SCORING, IS IT TIME WE MOVED TO A RED PIXEL DENSITY ALGORITHMIC PROGRAM TO DETERMINE TRUE TREATMENT RESPONSE?

Nirupam Purkayastha1, Samba Ismaï2, Peter C. Taylor3, Costantino Pitzalis4, Stephen Kelly5, 1Queen Mary University, William Harvey Research Institute, EMRI, London, United Kingdom; 2King George Hospital, General inernal medicine, London, United Kingdom; 3University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 4Barts Health NHS Trust, Rheumatology, London, United Kingdom

Background: The introduction of the semi-quantitative (SQ) grey-scale and power Doppler (PD) 0-3 scoring system, as agreed by the EULAR-OMERACT ultrasound (US) working group (1, 2), has undoubtedly been the most recognised and accepted method in both clinical practice and trials. Studies have suggested that the SQ scoring method is reliable as the quantitative when scoring the grey-scale (3, 4). Additional studies have shown that the use of red pixels in determining the PD signal in tenosynovitis, compared to SQ scoring was not different (5). However, the distribution of the PD SQ score over estimated the percentage compared to the quantitative score, which could reflect treatment responses inaccurately (6).

Objectives: 1. To describe how a quantitative pixel density score maps to a SQ PD score. 2. Can using a 0-4 PD grading scale better distribute the PD percentages, as determined by pixel count, than 0-3 scale?

Methods: Patients were selected from an observational study of 122 DMARD naïve patients (PEAC study REC: 05/00703/198); IRAS Project ID 60271) and 60 DMARD failure patients treated with anti-TNF (THERAPY study, MREC: 15/SC/0045; IRAS Project ID:147240). All patients were classified according to the 1987 ACR or 2010 ACR/EULAR criteria for rheumatoid arthritis. In total 334 images were analysed, from a total of 127 patients. The calculator for the US PD signal/ synovial area ratio was created on software MATLAB 2018b. PD was scored according to the SQ definitions for the visual grade 0-3 and 0-4 scoring systems (Figure 1A). Agreement between two readers using 80 US images: ICC SH —0.82 (interval 0.79-0.9), ICC PD —0.93 (interval 0.9-0.95), calculated using SPSS software. The results were analysed using R v3.4.2.

Results: The SQ grade 3 score was shown to over estimate PD signal/synovial area ratio, with a mean ratio of only 40.8%. Figure 2A, illustrates how the spread in PD signal varied with a single grade, in this case SQ grade 3. Figure 1B showed that adding a SQ grade 4 reduced the SD in the SQ grade 3 group but increased the SD overall by causing a larger SD in SQ grade 1, 2 and 4 grades.

A k-means (KM) clustering algorithm was used to find the most efficient ratio cut off points for a SQ grade 3 scoring system. The SQ grades are not taken into account for this scoring system, it is based on the mathematically optimum cut off points (Figure 1C). It is seen that the SD was drastically reduced in the KM score and the 95% confidence interval and grade overlaps.

When comparing the KM score with the SQ score it was shown to be significantly dependent (Pearson’s Chi squared p-value <2.2e-16) and strongly positively correlated (Spearman’s 0.84, p-value <2.2e-16), this is shown in Figure 2B and C. Furthermore, the KM score was seen to have a stronger linear correlation (Pearson’s 0.95, p-value <2.2e-16) when compared to the SQ score (0.82, p-value <2.2e-16).
Conclusion: The 0-4 SQ grade was not equivalent to that of the 0-3 SQ grade used PD scoring and it increased the variance in the majority of SQ grades. This study does show that the PD pixel algorithm has a stronger linear correlation when compared to the SQ grading, suggesting a more accurate method at interpreting treatment response, as the intervals between grades are more equal. Therefore, built in algorithms to detect PD signal in US machines are the future for drug monitoring in inflammatory arthritis.

Background: Filgotinib (FIL), an orally administered, potent, selective inhibitor of Janus kinase 1 (JAK1), has shown good efficacy and was well tolerated for treatment of rheumatoid arthritis (RA).

Objectives: To compare efficacy and safety of FIL with and without methotrexate (MTX) in patients with RA who were naïve to MTX therapy.

Methods: This phase 3, double-blind, active-controlled study randomized patients with moderately to severely active RA (2:1:1:2) to FIL 200mg daily + MTX weekly (up to 20mg), FIL 100mg + MTX, FIL 200mg (+placebo [PBO]), or MTX (+PBO) for up to 52 weeks; results through week 24 are presented. Primary efficacy endpoint was proportion of patients achieving ACR20 response at week 24; additional assessments included ACR50 and ACR70 responses; DAS28-CRP score ≤3.2 and <2.6, and changes in van der Heijde mTSS, HAQ-DI, SF-36 PCS, and FACIT-Fatigue. Safety endpoints included types and rates of adverse events (AEs). Logistic regression adjusting for stratification factors with nonresponder imputation was used for treatment comparisons for ACR response and other binary endpoints. Mixed-effect model adjusting for baseline value, stratification factors, treatment, visit, and treatment by visit interaction as fixed effects with observed cases was used for continuous endpoints.

Results: Of 1,252 randomized patients, 1,249 received study drug (416 FIL 200mg+MTX; 207 FIL 100mg+MTX; 210 FIL 200mg monotherapy; 416 MTX monotherapy) and were analyzed; 1,130 completed week 24. At week 24, significantly more patients in the FIL 200mg +MTX (81.0%; P<0.001) and FIL 100mg+MTX (80.2%; P<0.05) arms achieved an ACR20 response compared to MTX monotherapy (71.4%)(Table 1). Compared to MTX monotherapy, more patients receiving FIL with or without methotrexate (MTX) in patients with RA who were naïve to MTX therapy.

Scientific Abstracts
Saturday, 15 June 2019 259

Scientific Abstracts Saturday, 15 June 2019 259
Methods: ORAL Shift (NCT02831655) was a global Phase 3b/4 study in pts aged ≥18 years with moderate to severe RA and an inadequate response to MTX. Pts received open-label (OL) tofacitinib MR 11 mg QD with MTX (tofacitinib + MTX) for 24 weeks. Pts achieving LDA (CDAI ≤50) at Week (W)24 entered the 24-week double-blind (DB) MTX withdrawal phase and were randomised 1:1 to receive tofacitinib MR 11 mg QD with placebo (tofacitinib monotherapy; ie underwent blinded MTX withdrawal) or continue tofacitinib + MTX. The primary endpoint was least squares mean change from W24 to W48 (Δ DB phase) in DAS28 4(ESR).

Non inferiority of tofacitinib monotherapy vs tofacitinib + MTX was declared if the upper bound of the 95% two-sided confidence interval (CI) for the difference in ΔDAS28 4(ESR) between arms was <0.6. Secondary endpoints included ΔΔDAS28 4(ESR), ΔΔDAS28 4(ESR), ΔΔDAS28 4(ESR), ΔHAQ-DI; rates of ACR20/50/70 response, HAQ-DI response, ΔΔDAS28 4(ESR)- and CDAI-defined LDA and remission, and ACR-EULAR Boolean-defined remission (W48), and safety (OL and DB phases).

Results: Of 694 pts in the OL phase, 530 achieved CDAI-defined LDA at W24 and were treated in the DB phase (tofacitinib monotherapy; n=264; tofacitinib + MTX; n=266). Demographics and pt characteristics at OL-phase baseline were similar between treatment arms. The difference (95% CI) between arms in ΔΔDAS28 4(ESR) (primary endpoint) was 0.30 (0.12, 0.48; Table 1) at W48, demonstrating that tofacitinib monotherapy was non-inferior to tofacitinib + MTX. Consistent with the primary endpoint, ΔΔΔDAS28 4(ESR)/SADI/CDAI were greater for tofacitinib monotherapy vs tofacitinib + MTX, but these differences were not clinically meaningful; ACR/HAQ-DI response and LDA rates were generally similar between arms (Table). Remission rates were also similar between arms and generally did not change after MTX withdrawal in the DB phase, rates of AEs, serious AEs, discontinuations due to AEs and AEs of special interest were generally comparable between arms (Table 1).

Conclusion: Pts receiving tofacitinib MR 11 mg QD + MTX who achieve LDA may withdraw MTX up to W48 without significant worsening of disease activity. Pts in remission tend to remain in remission after MTX withdrawal. Safety appeared consistent with the known profile of tofacitinib.

REFERENCE

Acknowledgement: Study sponsored by Pfizer Inc. Medical writing support was provided by C Vogelmann of CMC Connect and funded by Pfizer Inc.
Background: There have been few head-to-head clinical trials comparing different biologic disease-modifying anti-rheumatic drugs (bDMARDs) in patients (pts) with psoriatic arthritis (PsA).

Objectives: To report 24-week (wk) results of a study directly comparing efficacy and safety of ixekizumab (IXE), an IL-17A inhibitor, and adalimumab (ADA), a TNF inhibitor, in bDMARD-naive pts with PsA.

Methods: The study (NCT03151551; SPIRIT-H2H) included pts with active PsA and PASI100. Additional PsA, skin, composite treat-to-target (T2T: MDA, DAPSA 4), enthesitis resolution (Figure 1), and skin-related quality of life (Table 2). No unexpected safety signals were observed.

Results: 566 pts were randomised (283 to IXE and 283 to ADA). Baseline demographics and disease characteristics were generally well balanced between groups (Table 1). All primary and key secondary efficacy endpoints at wk 24 were met (Figure). The proportion of pts achieving both ACR50 and PASI100 was significantly greater for IXE than ADA (36% vs 28%, p<0.05). IXE was non-inferior to ADA for ACR50 response and superior for PASI100 response (Figure). While improvements from baseline were achieved with both treatments, significantly better results were seen with IXE vs ADA for skin and composite T2T outcomes, enthesis resolution (Figure 1), and skin-related quality of life (Table 2).

Conclusion: In bDMARD-naive pts with active PsA and skin disease, IXE showed superior efficacy to ADA based on simultaneous achievement of ACR50 and PASI100 responses at wk 24. Greater improvements with IXE vs ADA were also attained in individual PsA domains and composite T2T outcomes.

Disclosure of Interests: Philip J Mease Grant/research support from: AbbVie, Amgen, Bristol-Myers Squibb, Celgene, Galapagos, Gilead, Janssen, Eli Lilly, Merck, Novartis, Pfizer, Sun Pharmaceutical Industries, Inc., and UCB; Consultant for: AbbVie, Amgen, Bristol-Myers Squibb, Celgene, Galapagos, Gilead, Janssen, Eli Lilly, Merck, Novartis, Pfizer, Sun Pharmaceutical Industries, Inc., and UCB.

Additional PsA, skin, composite T2T outcomes, and safety were assessed. 2. Mease PJ, Smolen JS, Behrens F, et al. In bDMARD-naive pts with active PsA, IXE showed superior efficacy to ADA based on simultaneous achievement of ACR50 and PASI100 responses at wk 24. Greater improvements with IXE vs ADA were also attained in individual PsA domains and composite T2T outcomes.
SUBCUTANEOUS SECUKINUMAB 300MG AND 150MG PROVIDES SUSTAINED INHIBITION OF RADIOGRAPHIC PROGRESSION IN PSORIATIC ARTHRITIS OVER 2 YEARS: RESULTS FROM THE PHASE 3 FUTURE 5 STUDY

Philip J. Mease1, Robert B.M. Landewé2, Proton Rahman3, Hasan Tahir4, Atul Singh5, Elke Boeticher5, Sandra Navarra6, Aimee Reader6, Shephard Mpfou7, Eumorphia Maria Delicha7, Luminita Pricop7, Désirée van der Heijde8,1,9,10,10 Swedish Medical Centre and University of Washington, Seattle, Washington, United States of America; 2University of Amsterdam and Amsterdam Medical Centre, Amsterdam, The Netherlands; 3Memorial University, Newfoundland and Labrador, Canada; 4Whips Cross Hospital, London, United Kingdom; 5Southwest Rheumatology, Dallas, United States of America; 6Rheumazentrum Favoriten, Vienna, Austria; 7University of Santo Tomas Hospital, Manila, Philippines; 8Novartis Pharmaceuticals Corp., East Hanover, United States of America; 9Novartis Pharma AG, Basel, Switzerland; 10Leiden University Medical Centre, Leiden, Netherlands

Background: Secukinumab (SEC) provided sustained clinical efficacy, and inhibition of radiographic progression over 52 Weeks (Wks) in patients (pts) with psoriatic arthritis (PsA) in the FUTURE 5 study 1.

Objectives: To report the effect of SEC on radiographic progression at Wk 104 (2 years) in PsA pts in the FUTURE 5 study.

Methods: Adults (N=996) with active PsA, stratified by prior anti-TNF therapy (naïve and inadequate response/intolerance [IR]) were randomised 2:2:2:3 to subcutaneous SEC 300mg with loading dose (LD; 300mg), 150mg LD (150mg), or SEC no LD (150mg no LD). Concomitant (naïve and inadequate response/intolerance [IR]) were randomised 2:2:2:3 to SEC; 150mg groups include pts who had dose escalated to 300mg. Concomitant MTX (≤25 mg/week) was allowed. Radiographic progression (mean change in van der Heijde-modified total Sharp score [vdH-mTSS]) and its components: erosion and joint space narrowing [JSN] scores, was based on hand/ wrist/foot X-rays obtained at BL and Wk 104, and assessed by two blinded readers (plus an adjudicator if required). Other efficacy endpoints included ACR20/50, PASI90 and resolution of dactylitis and enthesitis.

Results: Overall, 84.7% (300mg), 82.3% (150mg) and 75.2% (150mg no LD) pts completed 2 years of treatment. A total of 86 (39%) and 92 (41%) pts had their dose escalated to 300mg in the 150mg and 150mg no LD groups, respectively. Inhibition of radiographic progression was sustained with SEC through 2 years (Table 1). Proportions of pts with no radiographic progression (change from BL in mTSS ≤0.5) with SEC were 89.5% (300 mg), 82.3% (150 mg), and 81.1% (150 mg no LD) at 2 years; corresponding proportion of pts for change from BL in mTSS ≤0.0 were: 81.2%, 69.1% and 73.4%, respectively. Clinical responses were also sustained over 2 years (Table 1).

Conclusion: Subcutaneous secukinumab provided sustained inhibition of radiographic progression and sustained clinical responses through 2 years of treatment in pts with active PsA.

SUBCUTANEOUS TANZEUMAB FOR OSTEOARTHRITIS PAIN: A 24-WEEK PHASE 3 STUDY WITH A 24-WEEK FOLLOW UP

Francis Bierenbaum1, Francisco J. Blanco2, Ali Guermazi3, Eric Vignon4, Kenji Miki5, Takaharu Yamabe6, Lars Viktrup7, Rod Jonun8, William Carey9, Mark Brown9, Ken Verburg3, Christine Weste3, 1Sorbonne Universite, INSERM, AP-HP Hospital Saint Antoine, Paris, France; 2RHRC-Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain; 3Boston University School of Medicine, Boston, United States of America; 4Université Claude Bernard, Lyon, France; 5Osaka Yukioka College of Health Science, Hayashi Hospital, Osaka, Japan; 6Pfizer Inc, Groton, United States of America; 7Eli Lilly & Company, Indianapolis, United States of America; 8Pfizer Ltd, Tadworth, United Kingdom

Background: Tanezumab, a monoclonal antibody against nerve growth factor, is in development for treatment of osteoarthritis (OA) pain. Tanezumab, a monoclonal antibody against nerve growth factor, is in development for treatment of osteoarthritis (OA) pain.

Objectives: To assess efficacy and safety of tanezumab in patients with moderate to severe OA pain who have not responded to or cannot tolerate standard of care analgesics.

Methods: A randomized, double-blind, placebo-controlled study (24 week treatment; 24 week follow-up) was conducted in patients in Europe and Japan with moderate to severe OA pain of the knee or hip and history of insufficient pain relief or intolerance to acetaminophen, oral nonsteroidal anti-inflammatory drug, and either tramadol or opioids (or unwilling to take opioids). Patients received subcutaneous tanezumab (2.5 or 5 mg) or placebo at baseline, week 6, and week 10. Co-primary endpoints were change from baseline in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain, WOMAC Physical Function, and Patient Global Assessment of OA (PGA-OA) scores at week 24. Safety, including independent adjudication of joint safety events, was assessed.

Results: Tanezumab 5 mg met all co-primary endpoints (Fig. 1). Tanezumab 2.5 mg met WOMAC Pain and Physical Function endpoints but not the PGA-OA endpoint; thus, this dose did not meet pre-specified efficacy criteria. The occurrence

*70% and 50% no head area include 86 and 50 pts, respectively, who were dose escalated to 70% or 50%.
**N number of pts on each column, n number of pts with data at BL and wk 24.
**Data from pts with ≥44 joints 25% body surface area, ≤5 in knees, ≤10 in OA.

of adverse events (AEs) and discontinuations due to AEs were similar across groups, though serious AEs occurred more frequently in both tanezumab groups relative to placebo. Two deaths in the 5 mg tanezumab group were deemed unrelated to treatment. The only AE occurring in ≥3% of patients in any group, and more frequently (>1% difference) in both tanezumab groups relative to placebo, was OA. Total joint replacements (TJR) occurred in 6.7%, 7.8%, and 7.0% of patients in the placebo, tanezumab 2.5 mg, and tanezumab 5 mg groups, respectively. Joint safety events, including TJRs, were mostly adjudicated as normal progression of OA (58/79; 73.4%). Pre-specified joint safety events occurred in 0% and 2.5% (n = 14) of patients in the placebo and tanezumab (2.5 mg = 1.8%; 5 mg = 3.2%) groups, respectively. These 14 events in the tanezumab groups included rapidly progressive OA (2.5 mg n = 4; 5 mg n = 8), subchondral insufficiency fracture (2.5 mg n = 1), and primary osteonecrosis (5 mg n = 1).

Conclusion: Tanezumab 5 mg significantly improved all co-primary endpoints of pain, physical function, and PGA-OA. Tanezumab 2.5 mg significantly improved pain and physical function, but did not reach significance on PGA-OA. AEs are consistent with previous studies of tanezumab in OA. A similar number of TJRs were reported across groups, though overall joint safety events were more frequent with tanezumab than placebo.

Methods: The MR was implanted in 14 patients with active RA and prior insuffi-
cient response to ≥2 bDMARDs or JAK inhibitors with ≥2 different modes of
action; all patients remained on stable background of methotrexate. Three weeks
after implantation, the first 3 subjects were stimulated 1 min QD and, following
safety review board approval, the remaining 11 patients were implanted with the
MR and randomized to 1 min of sham, QD, or QID stimulations for 12 weeks. Patients,
rheumatologists, joint assessors and monitors were fully blinded to treat-
ment arm. Subjects randomized to sham had their devices activated after the pri-
mary endpoint at 12 weeks. Clinical efficacy was measured by DAS28-CRP
response and contrast-enhanced MRI (RAMRIS QMERCAT). The pharmacody-
namic response to VNS was assessed in blood using cytokine production in an
ex-vivo bioassay (TruCulture).

Results: 14 patients were enrolled (mean prior bDMARDs= 4.8, mean DAS28-
CRP= 5.94). Implantation and stimulation were generally well tolerated. There
were no device or treatment-related SAEs and 2 surgery related adverse events
(left vocal cord paralysis, Horner’s syndrome) that resolved without clinically sig-
nificant sequelae. DAS28-CRP change at week 12 was (mean ± SEM): Open
label QD= -1.44 ± 0.64, QD= -1.24 ± 0.88, QID= 0.38 ± 0.71, Sham=0.16 ± 0.21.
Of QD stimulated patients, 4 of 6 had a EULAR good or moderate response. MRI
measures of synovitis or osteitis did not change after 12 weeks of stimulation.
RAMRIS erosion scores correlated with EULAR response (change ± SEM in ero-
sion scores in EULAR responders = -2.2 ± 1.4 vs. 2.4 ± 0.96 in EULAR non-
responders). The pharmacodynamic response to VNS was confirmed in actively
stimulated groups with >30% decrease from baseline in bioassay levels of IL-1β,
IL-6, and TNF-a at week 12.

Conclusion: The novel MR device and stimulation was well tolerated independ-
ent of the two surgery-related events. MR associated stimulation reduced signs
and symptoms of RA in a meaningful number of highly drug-refractory subjects.
No clinical improvement was observed in the sham group. These initial pilot data
support the use of the MR in a larger blinded sham-controlled study in patients
who have failed biologics or targeted oral therapies as a novel approach for treat-
ment of RA and other chronic inflammatory diseases.

LB0009
FIRST-IN-HUMAN STUDY OF NOVEL IMPLANTED
VAGUS NERVE STIMULATION DEVICE TO TREAT
RHEUMATOID ARTHRITIS

Mark C. Genovese1, Norman Gaylis2, David Sikes3, Alan Kovitz4, Diane
M Horowitz2, Charles Peterly4, Yaakov Levine4, David Chernoff5

5 SetPoint Medical, Valencia, United States of America

Background: The inflammatory reflex plays a role in regulating innate and adap-
tive immunity through cellular and molecular pathways1. Activation of this neuro-
immune reflex by electrical vagus nerve stimulation (VNS) reduced systemic
inflammation and improved disease activity in a 17 subject rheumatoid arthritis
(RA) proof-of-concept study using a reprogrammed epilepsy stimulator2. A novel
miniaturized neurostimulator, the “MicroRegulator” (MR), was developed for a
first-in-human pilot study in multi-drug refractory RA.

Objectives: To assess the safety and efficacy of the MR in a double-blind study in active RA patients.
case series even lower doses might be sufficient for maintenance treatment, potentially improving safety and decreasing costs. (1)

Objectives: To compare effectiveness of RTX retreatment with ultra-low doses (1 × 500mg or 1 × 200mg) to standard low dose (1 × 1000mg).

Methods: A 6-month double-blind randomised controlled non-inferiority trial (REDO study (2)) was performed in 5 centres in the Netherlands. Patients with RA responding well to RTX (based on DAS28-CRP 2.9 or clinical judgement) were randomised (1:2:2) to 1 × 1000mg, 1 × 500mg or 1 × 200mg RTX respectively. DAS28-CRP and peripheral CD19+ B-cells were measured at baseline, 3 and 6 months. Primary analysis (per protocol with LOCF) consisted of a hierarchical testing procedure comparing ultra-low doses (1 × 500mg at 3 and 6 months, then 1 × 200mg at 3 and 6 months) to 1 × 1000mg using a non-inferiority margin of 0.6 (on DAS28-CRP). DAS28-CRP change of study groups was compared using linear regression, adjusted for baseline DAS28-CRP, RF/ACPA status and concomitant csDMARD use.

Results: The projected inclusion was met (n=142, table 1a). In both ultra-low dose groups 2 patients received an extra dose of 1000mg RTX due to a flare. The 500mg dose was non-inferior to 1000mg at 3 months (0.04 (95% CI -0.39 to 0.30)), but not at 6 months (0.31 (95% CI 0.05 to 0.68). The 200mg dose was non-inferior to 1000mg at both time points. Because of our pre-defined hierarchical testing, non-inferiority could not formally be inferred for the 200mg dose. Mean DAS28-CRP scores remained low in all groups throughout the study, and B-cell counts decreased similarly at 3 months (figure 1). In the 200mg group, more patients received intramuscular corticosteroid injection(s) compared to the 1000mg group (table 1b).

Conclusion: Non-inferiority of retreatment with 1 × 500mg or 1 × 200mg rituximab versus 1 × 1000mg after 6 months could not formally be established. However, ultra-low doses appear similarly effective in the majority of RA patients, judged by DAS28-CRP course over time and B-cell results, with use of slightly more co-medication.

HEADLINE RESULTS FOR A PHASE 4, 52-WEEK, RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY TO ASSESS ADVERSE EVENTS OF SPECIAL INTEREST (AESI) IN ADULTS WITH ACTIVE, AUTOANTIBODY-POSITIVE SYSTEMIC LUPUS ERYTHEMATOUS (SLE) RECEIVING BELIMUMAB

Saira Sheikh1, Morton Scheinberg2, James Cheng-Chung Wei3, Dana Tegzova4, William Stohl5, Tamara Mucenic6, Roger Levy7, Damon Bass1, Jorge Ross Terrés1, Rajesh Punwaney7, Julia Harris8, Kevin Thorneloe7, Beulah Ji8, David Roth7.

1University of North Carolina, Chapel Hill, United States of America; 2Centro de Pesquisas Clínicas do Hospital Abreu Sodré, São Paulo, Brazil; 3Chung Shan Medical University, Taichung City, Taiwan, Republic of China; 4Institute of Rheumatology, Prague, Czech Republic; 5University of Southern California Keck School of Medicine, Los Angeles, United States of America; 6Hospital Monhos de Vento, Porto Alegre, Brazil; 7GSK, Philadelphia, United States of America; 8GSK, Uxbridge, United Kingdom

Background: Belimumab (BEL) is approved in adults with active, autoantibody-positive SLE. Phase 2, 3 and long-term extension studies showed a favourable benefit-risk profile. However, numerical differences in the incidence of mortality, infections, hypersensitivity reactions and some psychiatric events warranted a large, focused safety study to assess these events, along with potential for malignancy.

Objectives: To evaluate all-cause mortality and AESI in patients with SLE receiving intravenous (IV) BEL vs placebo (PBO) over 52 weeks.

Methods: This study (BASE; BEL115467; NCT01705977) randomised adults with SLE (1:1) to monthly BEL 10 mg/kg IV or PBO, plus standard of care, for 48 weeks. No minimum SELENA-SLEDAI disease activity was required and no exclusions for previous psychiatric conditions were made. Differences in rates (95% CI) of mortality and other pre-specified AESI (malignancies, serious infections, opportunistic infections and other infections of interest, serious depression, suicidality [C-SSRS], and serious infusion/hypersensitivity reactions) on-treatment (first to last dose +28 days) were assessed. For on-treatment serious suicidal ideation/behaviour and self-injury events (per sponsor adjudication), and on-study (first dose to end of Week 52 study follow-up) suicidal ideation/behaviour (C-SSRS), differences (95% CI) vs PBO were calculated post hoc.

Results: 4003 patients received ≥1 dose. Baseline demographics and disease characteristics were similar between groups. On-treatment mortality and pre-specified AESI rates are shown in the Table 1 below. Overall rates of on-treatment AESIs were similar between groups, except for serious depression and serious infusion/hypersensitivity reactions.

On-treatment deaths were most frequently caused by infection (3 [0.15%] PBO vs 9 [0.45%] BEL); on-study deaths occurred in 22 (1.10%) PBO and 13 (0.65%) BEL patients (difference [95% CI]: -0.45 [-1.03, 0.13]). On-treatment serious suicidal ideation/behaviour and self-injury events were reported for 5 (0.25%) PBO and 15 (0.75%) BEL patients (difference [95% CI]: 0.50 [0.06, 0.94]); on-study suicidal ideation/behaviour (C-SSRS) occurred in 39 (1.96%) PBO and 48 (2.43%) BEL patients (difference [95% CI]: 0.47 [-0.44, 1.38]). No suicide-related deaths were reported.

Conclusion: In this double-blind, placebo-controlled (1:1) safety study, which is the largest SLE clinical study to date with 4003 patients, on-treatment all-cause mortality, infection and malignancy AESI rates were similar between BEL and PBO, with imbalances observed in serious depression, serious suicidal ideation/behaviour and self-injury events, and serious infusion/hypersensitivity reactions.

Innate immunity in rheumatic diseases

THU0001 CIRCULATING INNATE LYMPHOID CELLS IN IGG4-RELATED DISEASE

Mikael Ebbo1,2, Benjamin De Sainte Marie1, Christelle Piperoglou1, Nathalie Banzet2, Aurélie Gradics2, Catherine Farnarier3, Matthieu Groh2, Benjamin Terrier2, Jean- Robert Harlé1, Nathalie Costedoat-Chalumeau1, Frédéric Vély2,3, Nicolas Schleinitz2, Hôpital de la Timone, AP-Hôpital, Internal Medicine, Marseille, France, Aix Marseille Univ, CNRS, INSERM, CMI, Marseille, France, APHIM, Hôpital de la Timone, Marseille Immunopôle, Immunology, Marseille, France, CH de Niort, Internal Medicine, Niort, France, Hôpital Choc, Internal Medicine, Suresnes, France, 1Paris Descartes University, Hôpital Cochin, AP-Hôpital, Internal Medicine, Paris, France

Background: IgG4-related disease (IgG4-RD) is characterized by lymphoplasmacytic infiltrates, IgG4 plasma cells, fibrosis and frequent ectopic lymphoid structures (ELS). Excessive Th2 cytokines production and role of T follicular helper (Tfh) cells have been reported. In innate cells (ILCs), a heterogeneous population of non-B non-T lymphocytes lacking antigen-specific receptors, are able to produce type 2 cytokines (ILC2s) or to participate to ELS formation (ILC3s) and could contribute to IgG4-RD lesions.

Objectives: To analyze circulating blood ILCs in IgG4-RD.

Methods: IgG4-RD patients were identified according to the Comprehensive Diagnostic Criteria. Patients treated with steroids or DMARDs within 3 months or rituximab within 6 months prior inclusion were excluded. Peripheral blood mononuclear cells were isolated and analyzed by flow cytometry. ILCs were defined as lymphoid CD45+Lineage(Lin)-CD127+ cells. Among ILCs, 3 subsets were defined according to CRTH2 and CD117 expression. In some patients, transcription factor expression (T-bet, GATA3, RORyT) as well as cytokine production (IFNγ, IL-4/IL-13, IL-17A/IL-22) after different stimulations were analyzed in ILC subsets. Results were compared to healthy controls (HC), correlated to clinical and biological characteristics, and compared before and after treatment.

Results: Twenty patients with active untreated IgG4-RD and 30 HC were included. In IgG4-RD group, mean age was 64 years and sex ratio 1:4. Serum IgG4 levels were >1.35 g/l for 85% of patients and median eosinophil count 410/mm3. Most patients (65%) were analyzed at diagnosis. Main organs involved were lymph nodes (n=15), pancreas (n=5), salivary glands (n=8), biliary tree and kidney (n=5), lung and retroperitoneum (n=4), with ≥3 organs involved in 50% of cases. Number of blood ILCs was not modified in IgG4-RD patients (1.2 ± 2.6 x10^7/ml vs 1.5 ± 1.3 x10^7/ml in HC, p=0.07). CRTH2+ ILC2s were increased in IgG4-RD patients (60%±13% vs 24%±10% in HC, p=0.002) and an increase in ILC3s (51.4% [33.8-66.7], p=0.0009, proportions). ILC2s (274/ml [152-594]) vs 554/ml [82-1000], p=0.045) and ILC3s (214/ml [120-620] vs 599/ml [336-908], p=0.04) numbers were decreased in IgG4-RD patients. No correlation was found between the proportion of total ILCs or any ILC subsets and clinical or biological characteristics such as age, number of organ involved, IgG4-RD Responder Index or serum IgG4. No correlation was found between Tfh and ILC3s, or between eosinophils and ILC2s numbers. As human ILC3s and ILC2s contribute to ILCs subset distribution observed. GATA3 or RORyT are produced by Th2 cytokine production, ELS formation and fibrosis, needs further investigations.

Conclusion: Circulating ILC2s and ILC3s are decreased in IgG4-RD. Recruitment of ILC2s or ILC3s in tissues, where they could participate to Th2 cytokine production, ELS formation and fibrosis, needs further investigations.

THU0002 THERAPEUTIC ANTI-TNF BIOLOGIC AGENTS EXHIBIT FUNCTIONAL DIFFERENCES IN BLOCKING TNF-INDUCED EFFECTS ON HUMAN MONOCYTES IN VITRO

Bohdan Harvey, Zehra Kaymakcalan, AbbVie Bioresearch Center, Global Biologics, Worcester, United States of America

Background: Therapeutic anti-TNF biologic agents can be distinct in their structure, such as etanercept, a human TNFRII-Fc fusion protein, as compared to adalimumab, a human IgM molecule, and/or in their binding to TNF as shown by crystal structures of adalimumab as compared to infliximab in the presence of TNF. Whether these differences can affect the functional properties of these biologics in direct comparison to each other has not been thoroughly investigated.

Objectives: To determine the equivalency of all anti-TNF biologic agents currently approved for the treatment of RA in preventing a variety of TNF-induced effects on human monocytes in vitro.

Methods: Human mononcytic U937 NF-κB luciferase reporter cell line was incubated with 100 ng/ml TNF-α increasing conc (0.15-338 nM) of adalimumab (ADA), etanercept (ETN), infliximab (IFX), golimumab (GOL) or certolizumab pegol (CZP) as pre-formed complexes generated for 1 h. at 37°C. Surface TNF-R1 and -RII levels were monitored by flow cytometry following 1 h. incubation. Luciferase activity was measured in cell lysate after 4 h, to assess NF-κB activation. After 24 h., U937 cells were analyzed by flow cytometry for surface levels of ICAM-1, an NF-κB induced adhesion molecule shown to contribute to monocyte migration and arthritis. Apoptosis was assessed by time-lapse microscopy and flow cytometry using caspase 3/7 fluorescent substrate. Alpha-2,6 sialylation (Sia), a glycosylation modification shown to regulate TNF-RI internalization and apoptosis induction, was evaluated by flow cytometry using FITC-labeled Sambucus nigra lectin (SNA). Human PBMBC were incubated with TNF-α + pre-formed complex with anti-TNF biologics for 24 h. and then stained with CD14 and ICAM-1 Abs for flow cytometry.

Results: Surface levels of TNF-R1 and -RII on U937 cells were both reduced by 2.4-fold in presence of TNF. TNF-R1 was maintained at baseline levels by 16.7 nM ADA or CZP as pre-formed complexes with TNF; however, those complexes with ETN, IFX or GOL were only partially effective (48%, 61% and 52% reduction, respectively). All anti-TNF biologics were equally effective in preventing loss of surface TNF-R1. TNF stimulation of U937 NF-κB reporter cells led to a 122-fold increase in luciferase activity which was reduced to baseline by only ADA or CZP with largest conc. range tested. Partial reduction by 3, 7 and 11-fold was observed with ETN, IFX or GOL, respectively. TNF-α enhanced ICAM-1 surface expression (3-fold increase) on U937 cells was reduced to baseline by 16.7 nM ADA or CZP, whereas ETN, IFX or GOL were only partially effective (48%, 61% and 59% reduction, respectively). Exposure of CD14+ primary monocytes to ADA:TNF or CZP:TNF complexes not only prevented TNF induction of ICAM-1 but significantly reduced its level below that of baseline, whereas those with GOL or IFX brought ICAM-1 levels to baseline and those with ETN were only 46% effective. Both ADA:TNF and CZP:TNF complexes also completely inhibited TNF-induced apoptosis in a dose dependent manner unlike ETN, IFX and GOL, which were less effective (42%, 32% & 42% reduction, respectively). According to SNA staining, alpha-2,6 Sia surface levels dropped and GOL, which were less effective (42%, 32% & 42% reduction, respectively). All anti-TNF biologics were equally effective in preventing a variety of TNF-induced effects on human monocytes in vitro.

Conclusion: For each of the conditions tested in vitro, many resembling features associated with RA pathogenesis, the pre-formed complexes of ADA:TNF and CZP:TNF complexes not only prevented TNF induction of ICAM-1 but significantly reduced its level below that of baseline, whereas those with GOL or IFX brought ICAM-1 levels to baseline and those with ETN were only 46% effective. Both ADA:TNF and CZP:TNF complexes also completely inhibited TNF induced apoptosis in a dose dependent manner unlike ETN, IFX and GOL, which were less effective (42%, 32% & 42% reduction, respectively). According to SNA staining, alpha-2,6 Sia surface levels dropped in presence of TNF specifically on the subset of cells undergoing apoptosis and this subset was reduced proportionately to the inhibitory properties of anti-TNF biologics on apoptosis.

THU0003 CRYSTALLINE SILICA IMPAIRS EFFEROCYTOSIS CAPACITIES OF HUMAN MONOCYTE-DERIVED MACROPHAGES THROUGH RHOA-ROCK ACTIVATION

LESCOAT Aloïs, Alice Ballerier, Marie Lelong, Marie Lelong Yu Augagneur, Claudine Morzadec, Stéphane Jouneau, Patrick Jégou, Olivier Fardel, Laurent Vernhet, Valérie Lequerre, Univ Rennes, CHU Rennes, Rennes, EHEOSP, Inser (Institut de recherche en santé, environnement et toxicologie) – UMR S 1085, F-35000 Rennes, France, Rennes, France

Background: Inhalation of crystalline silica can lead to pulmonary diseases and systemic autoimmune disorders, such as systemic sclerosis (SSc), systemic lupus erythematosus or rheumatoid arthritis (1). A failure of apoptotic cell clearance, also called effectorcytosis, is reported in autoimmune diseases and, impaired effectorcytosis in macrophages from SSc patients has especially been described recently (2). However, the precise

Scientific Abstracts
Thursday, 13 June 2019 267
mechanisms linking crystalline silica exposure and autoimmune disorders is still to be determined.

Objectives: This study explored the effects of crystalline silica on efferocytosis abilities of human macrophages.

Methods: Monocyte-derived macrophages (MDM) were exposed in vitro to crystalline silica for 4 hours. Their ability to phagocyte CFSE-positive apoptotic and non-apoptotic Jurkat cells and their polarization profile after silica exposure were assessed by flow cytometry. Efferocytosis capacities of MDM from SSc were also evaluated using the same methods.

Results: Crystalline silica exposure impaired efferocytosis capacities of human MDM in a specific and dose-dependent manner. This effect of silica required the expression of SR-B1 and, was associated with a decreased membrane expression of the M2 polarization markers CD206, CD204 and CD163. Their expressions after silica exposure were similar to those of M1 polarized MDM. Silica increased F-actin staining, RhoA activation and phosphorylation of myosin phosphatase subunit 1 (MYPT1), a known ROCK target. Y27632, a Rho kinase (ROCK) inhibitor, reversed the F-actin staining, the phosphorylation of MYPT1 and, at least in part, the silica-induced impairment of efferocytosis. Moreover, efferocytosis abilities of MDM from SSc patients were similar to those of silica-exposed MDM and, a treatment of SSc-MDM with Y27632 significantly increase their efferocytosis capacities, suggesting an activation of the RhoA/ROCK pathway in SSc MDM also.

Conclusion: These findings demonstrate that silica impairs efferocytosis in MDM via an activation of RhoA/ROCK pathway. These results also suggest a therapeutic potential of drugs targeting this pathway and advance the hypothesis that silica exposure may contribute to the impaired efferocytosis capacities of macrophages from SSc patients, a silica-associated systemic disorder still without curative treatment to date.

MICRORNA-223 NEGATIVELY REGULATE GOUTY INFLAMMATION BY TARGETING THE NLRP3 INFLAMMASOME WITHOUT INFLUENCING IL-37 AND TGF-B1

Yu-Feng Qing1,2, Dan Zhu1, Ting Yi2, Jian-Xiong Zheng2, Qin Xiong3, Quan-Bo Zhang1. 1Institute of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology and Immunology, nanchong, China; 2Institute of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, nanchong, China; 3Institute of Rheumatology and Immunology, Department of Geriatrics, affiliated Hospital of North Sichuan Medical College, nanchong, China

Background: MicroRNA-223 (miR-223) serves as an important regulator of inflammatory and immune responses and is implicated in several autoinflammatory disorders[1]. To date, no relevant studies have reported the expression levels of miR-223 in gout patients or assessed whether miR-223 participates in negatively regulating gouty inflammation via regulating cytokines (such as IL-1β, tumor necrosis factor (TNF)-α, IL-37 and TGF-β1) by targeting the NLRP3 inflammasome.

Objectives: To determine the function of miR-223 in monosodium urate (MSU)-induced gouty inflammation.

Methods: miR-223 was detected among 107 acute gout patients (AG), 58 intercritical gout patients (IG), and 75 healthy subjects (HC). RAW264.7 macrophages were cultured and treated with MSU. Over-expression or under-expression of miR-223 was inducted in RAW264.7 macrophages to investigate the function of miR-223. Real-time quantitative PCR, ELISA and western blotting were used to determine the expression levels of miR-223, cytokines and the NLRP3 inflammasome.

Results: 1. Expression of miR-223 in PBMCs among the AG, IG and HC groups(Figure1)

Abstract THU0004 Figure 1.

2. Altered expression of miR-223, the NLRP3 inflammasome and cytokines in MSU-induced RAW264.7 murine macrophage inflammation (Figure2)

Abstract THU0004 Figure 2.

3. Effect of miR-223 on cytokine secretion from RAW264.7 macrophages treated with MSU(Figure3)
Conclusion: Our findings suggest that miR-223 provides negative feedback regulation of gouty inflammation development by suppressing production of IL-1β and TNF-α, but not by regulating IL-37 and TGF-β1, and that miR-223 regulates cytokine production by targeting the NLRP3 inflammasome. These findings provide novel insight into the regulatory role of miR-223 in the spontaneous resolution of acute gouty inflammation. Finally, these results suggest that targeting miR-223 in macrophages might be an effective therapeutic strategy for the treatment of gout flare.

THU0005   PTX3 AS A UNIVERSAL MARKER OF VASCULAR INFLAMMATION IN MULTIPLE IMMUNE-MEDIATED DISEASES

Giuseppe Alvise Ramirez1,2,3, Enrico Tombetti1,2,3, Patrizia Rovere-Querini1,3, Miriam Blasi1,2,3, Mattia Baldini1,2,3, Rebecca De Lorenzo1,2,3, Enrica Bozzolo4, Roberto Leone4,5,6, Angelo Manfredi1,2,3, 1Università Vita-Salute San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; 2IRCCS Ospedale San Raffaele, Division of Immunology, Transplantation and Infectious Immunity, Milan, Italy; 3Humanitas Clinical and Research Center – IRCCS, Rozzano (MI), Italy; 4Humanitas University, Rozzano (MI), Italy; 5The William Harvey Research Institute, Queen Mary University of London, London, United Kingdom

Background: Pentraxin-3 (PTX3) is a prototypic innate humoral pattern recognition receptor with a multi-functional role in tissue homeostasis from host defence to fertility, cancer biology, autoimmunity, regulation of angiogenesis and tissue repair. PTX3 is selectively expressed at sites of inflammation and rises in the circulating blood during disease activity in many (but not all) immune-mediated inflammatory conditions. Research on PTX3 as a biomarker has so far focused on single diseases.
4. Cytokines and inflammatory mediators

**THU0006**

**PROINFLAMMATORY RESPONSES IN THE JAK-STAT PATHWAY IN SYNOVIAL FIBROBLASTS ARE STIMULUS-SPECIFIC AND ONLY PARTIALLY INHIBITED BY THERAPEUTIC DOSES OF TOFACITINIB**

Ana Župančič, Blaž Burja, Kerstin Klein, Raphael Micheroli, Oliver Distler, Caroline Ospelt, Mojca Frank-Bertoncelj. University Hospital Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Schilling, Switzerland

**Background:** The Jak-STAT signalling pathway has a key role in the pathogenesis of rheumatoid arthritis (RA). First Jak inhibitors, including tofacitinib, have been approved for the treatment of RA. Whereas Jak inhibitors exert pleiotropic effects on the immune system, their in situ activities on synovial fibroblasts (SF), the resident synovial cells, are less well understood.

**Objectives:** To characterise the Jak-STAT pathway and its inhibition by tofacitinib in RA synovial tissues and SF from different joints across diverse pro-inflammatory stimuli.

**Methods:** Synovial tissues and SF were isolated from knee (n=4), shoulder (n=4), and hands (n=4-6) joints of RA patients undergoing joint replacement surgery. To activate and inhibit the Jak-STAT pathway, SF were stimulated with TNF (0.1 ng/ml, 1ng/ml) + IL-6 receptor (IL-6R, 50ng/ml) or IL-6 (50ng/ml) + IL-6R for 24h in the presence or absence of 80ng/ml, 180ng/ml, and 1000ng/ml tofacitinib. 80ng/ml and 180ng/ml tofacitinib mimic the plasma drug concentrations in subjects on therapeutic doses of tofacitinib. 1000ng/ml is the in vitro used tofacitinib concentration. Gene expression in synovial tissues and SF (n=12 each) was measured using the low-density gene expression arrays containing 6 housekeeper genes and 90 probes for the core components, inhibitors and target genes of the Jak-STAT pathway. Clustering analysis of the array data [principal component analysis (PCA), heatmap] was performed using the ClustVis web tool. PCA identified one outlier SF sample, driven by distinct housekeeper gene expression that was omitted from further analysis. The production of IL-6 was determined by ELISA.

**Results:** RA synovial tissues and quiescent SF exhibited highly similar expression of the core components of the Jak-STAT signalling pathway, suggesting that SF contribute significantly to the synovial expression of JAK and STAT genes. Clustering analysis of the array data showed that SF stimulated with 0.1ng/ml TNF+IL-6R, SF treated with IL-6+IL-6R and quiescent SF formed separate clusters (Figure 1), pointing towards stimulus-specific transcriptional outputs in the Jak-STAT pathway. Moreover, TNF+IL-6R increased the expression of multiple core components in the Jak-STAT pathway (IL6ST, JAK2, JAK3, STAT3, STAT4) with simultaneous downregulation of pathway inhibitors (PIAS1, PIAS2) (p<0.05). SF produced different amounts of IL-6 under distinct proinflammatory stimuli, including 0.1ng/ml TNF-IL-6R (2.7±1.5 ng/ml), 1ng/ml TNF (2.8±1.7 ng/ml) and 1ng/ml TNF + IL-6R (5.0±2.7 ng/ml). Specifically, the addition of IL-6R to 0.1 ng/ml TNF increased the production of IL-6 in SF to the levels observed with 1ng/ml TNF alone and this response was further exacerbated in the presence of IL-6R + 1 ng/ml TNF. 80nm, 180nm and 1000nm tofacitinib decreased the IL-6 production by 20-30%, 50% and 60% respectively, suggesting a limited anti-inflammatory effect at average plasma concentrations (80nm). The inhibitory effect of tofacitinib on IL-6 production in SF was thus dose dependent, however highly similar across distinct proinflammatory conditions (0.1ng/ml or 1ng/ml TNF ± IL-6R).

**Conclusion:** Here we show that soluble IL-6R strongly augments the pro-inflammatory effects of TNF in SF. Furthermore, percent inhibition of the IL-6 production by tofacitinib remained constant across diverse proinflammatory conditions despite different amounts of IL-6 being produced. Thus, higher pre-treatment inflammatory responses to TNF ± IL-6R predict higher residual inflammatory activity in SF following Tofacitinib therapy, pointing towards a saturation of anti-inflammatory effects of Tofacitinib in SF in RA.

IL-26 PROMOTES OSTEOCLASTOGENESIS IN RHEUMATOID ARTHRITIS

Sang-Heon Lee1, Kyung Ann Lee2, Hae-Rim Kim1. 1Konkuk University Medical Center, Seoul, Korea, Rep. of (South Korea); 2Soonchunhyang University Seoul Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: IL-26 is a 171-amino acid protein, which is classified as a member of the Th17 cytokine family. The role of IL-26 in osteoclastogenesis in RA is needed to be clarified to understand the pathogenesis of RA.

Objectives: To examine the functional role of interleukin-26 (IL-26) in the expression of RANKL and induction of osteoclastogenesis in rheumatoid arthritis (RA).

Methods: The expression of IL-20Rα and IL-26 was measured in a human monocyte cell line in response to human recombinant IL-26. The expression of GM-CSF messenger RNA (mRNA) and protein was measured in human monocytes by real-time polymerase chain reaction and ELISA. Human peripheral blood mononuclear cells were cocultured with macrophage colony-stimulating factor (M-CSF) and IL-26, after which osteoclastogenesis was evaluated by counting the number of tartrateresistant acid phosphatase-positive multinucleated cells. Osteoclastogenesis was also evaluated after monocytes were cocultured with IL-26-prestimulated FLS.

Results: The IL-26 concentration in the FLS was higher in RA patients than in patients with osteoarthritis (OA). In IL-26-stimulated FLS, the expression of RANKL mRNA and protein was increased in a dose-dependent manner. IL-26 increased the expression of RANKL in RA-FLS, and the IL-26-induced RANKL expression decreased by the inhibition of IL-20Rα. IL-26-induced RANKL expression was down-regulated significantly by the inhibition of SHP-1, ERK, JNK, STAT3, c-jun or p38 MAPK/ NF-κB signaling. When monocytes isolated from human peripheral blood were cultured with IL-26, they were differentiated into osteoclasts in the absence of RANKL. Monocytes were also differentiated into osteoclasts when they were cocultured with IL-26-pretreated RA-FLS.

Conclusion: IL-26 has a direct effect on osteoclastogenesis in RA: 1) direct induction of osteoclastogenesis from monocytes and 2) up-regulation of RANKL production in RA-FLS. This IL-26-RANKL axis could be a potential therapeutic target for bone destruction in RA.

GM-CSF PATHWAY SIGNATURE IDENTIFIED IN TEMPORAL ARTERY BIOSPES OF PATIENTS WITH GIANT CELL ARTERITIS

Maria C. Cig1, Rohan Gandhi2, Marc Corbera-Bellalta1, Sujatha Muralidharan3, John F. Paolini4. 1Hospital Cliníc, University of Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Research Unit, Department of Autoimmune Diseases, Barcelona, Spain; 2Kiniksa Pharmaceuticals, Lexington, United States of America

Background: Giant Cell Arteritis (GCA) is a type of large vessel vasculitis that can cause blindness and aortic aneurysms. Significant unmet medical need remains in GCA, as current treatment options are limited, and relapse increases corticosteroid (CS) exposure and toxicity. The primary role of macrophages/dendritic cells (DCs) and T(H)1/T(H)17 lymphocytes in GCA pathogenesis has been highlighted previously. Granulocyte-macrophage colony stimulating factor (GM-CSF) may contribute to GCA pathogenesis by stimulating giant cell formation. GM-CSF produced by CD4+ T helper T(H)1 and T(H)17 cells can stimulate conventional DCs and promote differentiation of monocyte-derived DCs. GM-CSF may drive DCs to program naïve CD4+ T cells to T(H)1, T(H)17, and T follicular helper phenotypes (IFNγ/IL-17/IL-21). Notably GM-CSF RNA has been reported in GCA lesions and in peripheral blood mononuclear cells of symptomatic patients.

Objectives: We hypothesized elevation of the GM-CSF pathway signature in GCA versus controls.

Methods: Two independent sources of temporal artery biopsies were utilized. First, GCA (n=17) and control (symptomatic patients suspected for GCA, but with a normal temporal artery biopsy) (n=5) biopsies were analyzed for 15 mRNA transcripts representing T(H)1, T(H)17, and GM-CSF-signaling (RNAscope; RS) and for mRNA transcripts representing the autoimmune panel (Nanostring; NS). Semi-quantitative scoring was performed on RS images, and fold-change of representative T(H)1, T(H)17 and GM-CSF-related mRNA transcripts were calculated via NS nCounter analysis. Additional GCA and control biopsies were obtained and analyzed by RT-PCR for a subset of transcripts (n=10 each) and by confocal microscopy for GM-CSF and GM-CSF-Rx protein (n=2 each).

Results: The GM-CSF-signaling pathway molecular signature was confirmed to be upregulated by 4 independent analyses. GM-CSF-associated and T(H)1-associated genes were upregulated in GCA biopsies versus control (GM-CSF: 3-4x RS; GM-CSF-Rx: 6.7x NS, 6x RS; and C3D8: 3.9x NS, 6x RS; TFFx: 2x NS, 3x RS; IFNγ: 2x RS; IL-1β: 6x RS). T(H)17 associated genes were not elevated, potentially due to concomitant CS treatment.

Upregulation of both GM-CSF (12x) and GM-CSF-Rx (3x) mRNA was confirmed in a separate cohort of biopsies from GCA patients vs. controls by RT-PCR (Figure). GM-CSF and GM-CSF-Rx proteins were detected in the luminal endothelium, neovessels and inflammatory cells of GCA patients. In normal temporal arteries, GM-CSF protein was not detected, and some GM-CSF-Rx expression was observed in the luminal endothelium.

Conclusion: GM-CSF and T(H)1 pathway signatures were demonstrated in GCA patient temporal arteries by independent analytical techniques. Active GM-CSF signaling in diseased tissue is evidenced by increased expression of Pu.1 in the vessel wall. These data implicate the GM-CSF pathway in GCA pathophysiology and increase confidence in rationale for targeting GM-CSF in GCA.

Abstract THU0008 Figure 1.
ASSOCIATIONS BETWEEN CYTOKINE LEVELS AND TH17/TREG IMMUNE BALANCE IN PATIENTS WITH BEHÇET’S DISEASE

Yue Liu1, Yan Yang2, Rui Su3, Xinyu Zheng4, Li Xiaoleng4, Caihong Wang4. 1The Second Hospital Of Shanxi Medical University, The Department of Rheumatic Immunology, Taiyuan, China; 2The Second Hospital Of Shanxi Medical University, The Department of Rheumatic Immuno-ology, Taiyuan, China; 3The Second Hospital Of Shanxi Medical University, The Department of Rheumatic Immunology, Taiyuan, China; 4The Second Hospital Of Shanxi Medical University, The Department of Rheumatic Immunology, Taiyuan, China

Background: Behçet’s disease (BD) is a chronic systemic vascular inflammatory disease. Autimmune imbalance associated with genetic and infectious factors promotes the immune response of neutrophils and T cells, which is BD’s important pathogenesis. Several studies indicate that the Th17/Treg immune imbalance may play an important role in BD pathogene-sis. Although the proportion of Th17 cells was notably increased, which was accompanied by an increased levels of IL-17, IL-23, whether other cytokines are associated with Th17/Treg immune balance is unclear.

Objectives: The aim of this study was to examine associations between levels of a broad selection of cytokines and Th17/Treg immune balance in patients with BD.

Methods: The study included 66 BD patients and 66 healthy controls. The absolute counts of lymphocyte subsets and CD4+ T cell subsets were detected by flow cytometry for all participants. Serum levels of the following 6 cytokines were determined in the same samples using a cytokine beads array (Interleukin-2 (IL-2), Interleukin-4 (IL-4), Interleukin-6 (IL-6), Interleukin-10 (IL-10), Interferon-γ (INF-γ)) and Tumor Necrosis Factor-α (TNF-α) for all BD patients. T tests was used to compare continuous measures. Correlations between cytokines and Th17/Treg were assessed by Spearman’s rank correlation tests.

Results: (1) Compared to healthy controls, the absolute counts of T cells were increased (P<0.048), the absolute counts of CD8+ T cells were also increased (P=0.031) in BD group, the absolute counts of Th1 and Th17 cells were significantly increased (P<0.05) in BD group, the absolute counts of Th2 cells were decreased (P<0.001) in BD group, the ratio of Th1/Th2 was increased (P<0.001), and the ratio of Th17/Treg were increased (P<0.001) in BD group. There were no differences between the absolute counts of the two groups of B, NK, T+ B+NK, CD4+ T and Treg cells. (2) Among the investigated cytokines, the differences between the levels of IL-2, IL-6, INF-γ and normal range have statistical significance (P=0.001). Finally, two cytokines were positively correlated with Th17/Treg, i.e., IL-2 (r=0.279, P=0.023) and IL-4 (r=0.260, P=0.035)/P<0.2 for all other cytokines).

Conclusion: Our research shows that T cell homeostasis perturbation, especially Th1 and Th17 expansion and Th17/Treg immune imbalance, is the cornerstone of BD pathogenesis. These findings suggest that immune responses associated with increased levels of IL-2 and IL-4 may promote Th17/Treg immune imbalance. This also highlights the role of IL-2 and IL-4 in maintaining a balance in the Th17/Treg ratio. Further studies are required to evaluate these preliminary findings in different patient populations and also examine the possible molecular mechanisms behind our observations.

THE ANTI-INFLAMMATORY CYTOKINE INTERLEUKIN 37 IS AN ENDOGENOUS INHIBITOR OF TRAINED IMMUNITY

Guglielmo Cavali1,2,3, Mark Gresnigt4, Rob Arts2, Travis Nemkov5, Angelo D’ Alessandro6, Silvia Gugliano7, Elan Eisenmesser8, Lorenzo Dagnà9, Leo Joosten10, Mihai Netea11, Charles Dinarello12,3, Giulio Cavalli1,2,3, Mark Gresnigt4, Rob Arts2, Travis Nemkov5, Angelo D’alessandro6, Silvia Gugliano7, Elan Eisenmesser8, Lorenzo Dagnà9, Leo Joosten10, Mihai Netea11, Charles Dinarello12,3, Vita-Salute San Raffaele University, Milan, Italy; 2Radboud University Medical Centre, Nijmegen, Netherlands; 3University of Colorado Denver, Aurora, CO, United States of America; 4Leibniz Institute for Natural Product Research and Infection Biology, Jena, Germany; 5Humanitas University, Milan, Italy

Background: Trained immunity (TI) is a de-facto innate immune memory program induced in monocytes/macrophages by exposure to pathogens or vaccines, which evolved as a protective mechanism against infections. TI is characterized by rewiring of functional, epigenetic and metabolic programs of innate immune cells such as monocytes and macrophages, which sustain enhanced production of pro-inflammatory cytokines. Since aberrant activation of TI is implicated in inflammatory diseases, tight regulatory mechanisms are likely in place, but the mechanisms responsible for this modulation remain elusive.

Objectives: Scope of this study was to evaluated the role of IL-37, an anti-inflammatory cytokine that curbs inflammation as well as modulates metabolic pathways, as an endogenous regulator of trained immunity.

Methods: The effects of recombinant IL-37 were evaluated in a mouse model of TI induced by the administration of beta-glucan in vivo (survival to a lethal inoculum of infectious agents, production of inflammatory cytokines, recruitment of inflammatory cells at the sites of infection). Subsequently, the effects of IL-37 were evaluated in vivo in bone marrow monocytes (production of inflammatory cytokines, metabolic analysis of the activation status of the main pathways of cellular energy metabolism),
Finally, we evaluated the association between IL-37 gene polymorphisms and the induction of TIE1 in monocytes of healthy donors with in vitro functional studies.

Results: The exogenous administration of IL-37 abrogated the pro-inflammatory effects of TIE1, significantly reducing the production of pro-inflammatory cytokines and the survival of experimental animals subjected to a model of disseminated infection. The inhibitory effects of IL-37 on TIE1 were also associated with reduced recruitment of neutrophils at sites of inflammation. IL-37 and TIE1 programs had differential and opposite effects on the modulation of cellular energy metabolism of monocytes. In humans, polymorphisms in the IL-37 gene were associated with reduced activation of TIE1 programs and reduced production of inflammatory cytokines by healthy donor monocytes.

Conclusion: In conclusion, IL-37 emerges as an endogenous regulator of TIE1, which makes this cytokine a potential therapeutic target in immune-mediated pathologies.

THU0011 PEFICITINIB (ASP015K) INHIBITS MONOCYTE CHEMOTACTIC ACTIVITY VIA PRONFLAMMATORY CYTOKINE PRODUCTION IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES
Yuzo Ikari, Takeo Itozaki, Tatsuyoshi Kasama. Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan

Background: Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway has been identified as an important signaling pathway in rheumatoid arthritis (RA) of various cytokines (e.g. IL-6). Janus kinase (JAK) is a cytokine/protein tyrosine kinase associated with various cytokine receptors. Molecules of signaling pathways such as the JAK family are thought to be promising targets for RA treatment. Peficitinib (ASP0150K) is a novel JAK inhibitor in development for the treatment of RA. Peficitinib has been suggested for its effectiveness in clinical trials, but clarification of the mechanism of RA for the inflammatory pathology is still inadequate.

Objectives: We clarified the effect of peficitinib on RA fibroblast-like synoviocytes (FLS).

Methods: To determine whether JAK1, JAK2 and JAK3 were expressed in RA ST and FLS, immunohistochemistry was performed. To confirm if IL-6 and IL-6 receptor (IL-6R) activate JAK-STAT pathway in FLS, western blot analysis was performed. RA FLS were stimulated with IL-6 (100 ng/ml) and IL-6R (100 ng/ml) for 10 minutes or 30 minutes. Next, we investigated effect of peficitinib on IL-6 and IL-6R responses in RA FLS. RA FLS were stimulated with IL-6 (100 ng/ml) and IL-6R (100 ng/ml) after treated peficitinib (0.1, 1, 5µM) for 24 h. Furthermore, we performed a proliferation assay of FLS and chemotaxis assay using THP-1 (human acute monocye leukemia cell line) and peripheral blood mononuclear cells (PBMC) to perform functional analysis by peficitinib. In the same procedure as Western blot analysis, peficitinib (5 µM) was added to FLS and stimulated with IL-6 and IL-6R. Finally, we investigated whether peficitinib suppresses the secretion of FLS inflammatory mediator using ELISA. The amounts of RANTES/CCL5, MCP-1/CCL2, MMP-3, fractalkine/CX3CL1, ENA78/CXCL5 and IL-8 in IL-6 and IL-6R stimulated peficitinib treated RA FLS conditioned medium were determined compared with IL-6 and IL-6R stimulated non-treated RA FLS conditioned medium.

Results: We found JAK1, JAK2 and JAK3 were expressed in RA STs and FLS. JAK1 and JAK3 were observed in RA ST lining layers. JAK2 was expressed entirely in RA ST cell nucleus. JAK1, JAK2 and JAK3 were detected in RA FLSs. It was confirmed that JAK1, JAK2 and JAK3 is expressed in FLSs of ST. Representative western blotting showing expression of phospho STAT1, phospho STAT3 and phospho STAT5 were increased 10 minutes after stimulation with IL-6 and IL-6R. Phosphorylation of STAT1, STAT3 and STAT5 in RA FLS was suppressed by concentration-dependence of peficitinib. It was proved that peficitinib suppress the activation of JAK-STAT pathway. Furthermore, peficitinib treated RA FLS conditioned medium reduced THP-1 migration compared to non-treated RA FLS conditioned medium (number of THP-1 cells migrated ± SEM; 42 ± 3 and 66 ± 6 cells migrated, respectively, p<0.05). Peficitinib treated RA FLS conditioned medium also reduced PBMC migration compared to non-treated RA FLS conditioned medium (number of PBMC migrated ± SEM; 36 ± 5 and 63 ± 9 cells migrated, respectively, p<0.05). In addition, peficitinib treated RA FLS showed a 14 ± 2% decrease in proliferation of RA FLS compared with nontreated RA FLS. Finally, we found peficitinib suppress the secretion of inflammatory mediators in RA FLS. MCP-1/CCL2 in RA FLS supernatant was suppressed in peficitinib compared to nontreated(mean ± SEM; 160.1 ± 65.6 and 646.0 ± 107.1 pM, respectively, p=0.05). From these results, suppression of chemokinesis of THP-1 and PBMC was also observed through suppression of MCP-1/CCL2 in RA FLS supernatant. Conclusion: Peficitinib suppressed the JAK-STAT pathway of RA FLS and was involved in the suppression of monocyte chemotaxis and the proliferation of FLS through suppression of inflammatory cytokines. These results suggest that peficitinib acts on FLS and suppresses inflammatory pathology.

THU0012 ESTROGEN REGULATES MICRO RNA BIOPROCESSING AND PRODUCTION OF IL9 CYTOKINE WITHIN LEUKOCYTES IN RHEUMATOID ARTHRITIS
Cal I Davies1,2, Malin C. Ertendarson1,2, Sofia Törnt Gyllensward1, Karin Me Andersson1,3, Maria I Bokarewa1,2. 1Universitet, 2Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 3Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Rheumatoid arthritis (RA) is more prevalent in females. It is reported to be alleviated during pregnancy, and increase in severity during menopause, which implies estrogen as an important contributor in RA pathogenesis. Micro-RNA (miR) are short, non-coding RNAs, that act within a RNA-induced silencing complex. miRs have recently emerged as important epigenetic controls of leukocyte maturation and function.

Objectives: To study the epigenetic effect of estrogen on the transcription of microRNA and their bio-processor enzymes in RA patients.

Methods: The leukocytes of 145 female RA patients split for estrogen receptor alpha (ERa) (qct 9.57) were analyzed for the expression of Dicer, Drosha and DGR8 mRNA by RT-PCR and serum levels of TGFb-dependent cytokines IL4 and IL9. Micro-RNA transcription array was performed by 3D-Genetm microarray measuring >2560 miRs (TATAA Biocenter, Gothenburg) in human primary leukocytes, fat tissue and plasma. The samples were split by expression of estrogen receptor alpha (ERa, qct 9.57), a proxy of an active estrogen signaling, and used to identify miRs of interest. Bioinformatic analysis was performed using DIANA, miRDB, miRTarBase and Ensembl, using microRNA nucleotide sequences obtained from miRBase, to predict signaling pathways and gene targets of miR. To confirm estrogens effect on miR processing, leukocyte cultures of RA patients were exposed to estrogen and subjected to miR, gene and protein analysis.

Results: Comparing leukocytes with different ERa, we identified 214 miRs with high and 7 miRs with low expression when ERa was high. Cross-analysis in the fat and serum sample miR array identified most of those miRs. Bioinformatic analysis of the upregulated miRs confirmed that 16miRs were involved in the estrogen signaling pathway (p=0.0063) and 15 TGFb signaling pathway (p<0.0001), where these miRs had 61 common predicted gene targets.

To study if transcription of these predicted targets was dependent on estrogen signaling, we took advantage of the clinical RA material. Patients with high ERa were significantly younger (51y vs 61y, p<0.00001), which confirmed active estrogen signaling. High ERa had significantly higher expression of miR bioprocessing enzymes Dicer (p=0.0197), Drosha (p=0.0454), DGR8 (p=0.0192) and lower disease activity (DAS28, p=0.0023; ESR p=0.005, ILE, p=0.0129).

Conclusion: High ERa expression can be considered a significant regulator of miR transcription in leukocytes. miR and bio-processors regulated by estrogen could be of importance in the pathogenesis on RA by targeting pathways responsible for regulation of inflammation and the non-protective elements of RA development; explaining the ameliorating effects of estrogen.

IL-17A AND IL-17F ARE SECRETED BY ENTHESIS T CELLS AND SYNERGIZE WITH TNF TO INDUCE CCL20 FROM ENTHESAL STROMAL CELLS

Charlie Bridgewood1, Tobias Russell2, Abdulla Watad3, Hannah Rowe3, Qiao Zhou4, Almas Khan2, Peter Loughenbury2, Abhay S Rao2, Peter Millner2, Robert Dunsmuir5, Richard Cuthbert6, Dennis Mcgonagle1. 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 2Department of Medicine, University of New South Wales, Sydney, Australia; 3Department of Medicine, Sheba Medical Center, Tel-Hashomer, Israel, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel; 4The Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, Leeds, United Kingdom

Background: Enthesis or inflammation of tendon/ligament anchorage points is the cardinal lesion in spondyloarthritis (SpA). Human SpA is thought to be driven by IL-17 producing T-cells and can be successfully therapeutically targeted with anti-IL-17A and more recently anti-IL-17F[2]. The CCR6-CCL20 axis is thought to be crucial to tissue recruitment of IL-17 producing T-cells, however it is presently unknown if CCR6+ T-cells reside at the healthy human enthesis[3]. Moreover, the ability of IL-17 to drive CCL20 production and hence to promote further T-cell migration to the enthesis has not been tested. Objectives: To determine if enthesis T cells secrete IL-17A and IL-17F. To determine if CCR6+ T-cells reside at the normal human enthesis. To study the effect of both IL-17A and IL-17F on CCL20 induction from entheseal stromal cells. Methods: Normal spinous process enthesis was obtained from patients undergoing spinal decompression or surgery for scoliosis correction. Normal PEB and ST were also analysed for the presence CCR6+ T-cells by multiparameter flow cytometry. Stromal cells were isolated from both the peri-entheseal bone (PEB) and enthesis soft tissue (ST). Stromal cells were stimulated with combinations of IL-17A or IL-17F and TNF and subsequently CCL20 was measured by ELISA. Normal PEB and ST were also analysed for the presence CCR6+ T-cells by multiparameter FACs including CD4+ and CD8+ cells. Results: Enthesal CD4+ cells secreted IL-17A and IL-17F following stimulation. When used as single agents IL-17A, IL-17F and TNF were able to induce minimal CCL20 from entheseal stromal cells, but great synergy was reported for IL-17A/IL-17F, IL-17A/TNF and IL-17F/TNF. No synergy was reported for IL-17A/TNF and IL-17F/TNF. No synergy was observed between IL-17A and TNF or IL-17F and TNF. Conclusion: Resident CD4+ T cells at the enthesis secrete IL-17A and IL-17F following stimulation. The normal human enthesis contains CCR6+ T cell populations, suggesting a CCR6+/CCL20 axis is important to entheseal homeostasis. IL-17A/TNF dramatically synergizes with TNF to induce CCL20 from entheseal stromal cells, which would be well placed to mediate further migration of IL-17 producing lymphocytes to enthesis tissues. TARGETING ACTIVATED ASK1 IN SYNOVIAL FIBROBLASTS IN COMBINATION WITH JAK1 INHIBITION ENHANCES EFFICACY IN RAT CIA

Paqui Gonzalez-Traves, Christian Franci, Julie A. Di Paolo. Gilead Sciences, Inc., Foster City, United States of America

Background: Despite improved therapy, rheumatoid arthritis (RA) remains an area of unmet medical need. Current therapies have improved disease control by targeting inflammatory pathways. However, treatments rarely induce remission, highlighting the need for new therapies. Figitibin (FIL) is an oral selective JAK1 inhibitor that has demonstrated clinical efficacy in RA trials.1,2 Apoptosis signal-regulating kinase 1 (ASK1) is a member of the MAPK6 family that activates p38 and c-jun and has recently been shown to modulate human RA fibroblast-like synoviocyte (FLS) invasion, proliferation, and migration in vitro.3 We hypothesize that by dual targeting of JAK-dependent inflammatory pathways with FIL, and ASK1 signaling in FLS with an ASK1 inhibitor, we can demonstrate an increase in efficacy in a rat collagen-induced arthritis (CIA) model.

Objectives: To evaluate the individual and combination activity of JAK1 and ASK1 inhibition in the rat CIA model by oral dosing with FIL and an ASK1 inhibitor. Methods: The in vivo efficacy of FIL and an ASK1 inhibitor were tested individually or in combination in a therapeutic rat CIA model. Dosing was initiated at the onset of disease (day 11) and continued until day 18. Efficacy evaluations were based on animal body weights, daily ankle caliper measurements, ankle diameter (expressed as area under the curve), terminal hind paw weights, and histopathology of the ankles and knees. Results: Administration of FIL individually significantly reduced ankle diameter and final paw weights by 51% and 52%, respectively (p<0.05). There was no change in body weight loss or in histological measures with treatment. Conversely, ASK1 inhibition did not reduce inflammation as measured by ankle diameter or paw swelling, but resulted in a 48% reduction in ankle histopathological score (p<0.05). The combination of FIL and the ASK1 inhibitor showed significantly greater effects on all measured parameters including paw weight (81% reduction), ankle diameter (78% reduction), and ankle and knee histopathology scores (69% and 87% reduction, respectively) than either agent alone. Body weight loss was also significantly reduced with the combination, and increased toward normal weight gain compared to the monotherapy arms. Conclusion: Combining FIL with ASK1 inhibition significantly improved clinical and histopathology scores, and reduced body weight loss in this model. These data suggest that simultaneously targeting JAK and ASK1 pathways can provide orthogonal activities that can enhance overall disease control. REFERENCES:

VARIATION IN MACROPHAGES DIFFERENTIATION AND SREBF1 EXPRESSION BETWEEN INFRAPATELLAR FAT PAD AND SUBCUTANEOUS TISSUES FROM RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS PATIENTS

Shuhe Ma1, Kosaku Murakami1, Motomu Hashimoto2, Masao Tanaka2, Koichi Murata2, Kohei Nishitani3, Hiromu Ito3, Tsuneyo Mimori1. 1Kyoto University Graduate School of Medicine, Dept. of Rheumatology and Clinical Immunology, Kyoto, Japan; 2Kyoto University Graduate School of Medicine, Advanced Medicine of Rheumatic Disease, Kyoto, Japan; 3Kyoto University Graduate School of Medicine, Dept. of Orthopedic Surgery, Kyoto, Japan

Background: Sterol regulatory element-binding protein 1 (SREBP1) has been known to upregulate the expression levels of regulators of ω-3 fatty acids in the resolution phase of macrophages, and this would in turn repress the production of pro-inflammatory cytokines. In OA joints, adipocytes might participate in inflammatory process. We are interested to investigate the proportion of CD14 positive cells as well as M1 and M2 macrophages in SVF of Hoffa and SC, and explore contribution of SREBF1 to rheumatic disease pathological processes of RA and OA.

Objectives: To investigate the proportion of CD14 positive cells as well as M1 and M2 macrophages in SVF of Hoffa and SC; and to explore contribution of SREBF1 to rheumatic disease pathological processes of RA and OA.

Methods: After treated with collagenase, macrophages (CD14 positive cells) in SVF were counted by flow cytometry. Then they were divided, half for calculating the ratio between CD80 positive cells (M1 macrophages) and CD163 positive cells (M2 macrophages), and half for performing qRT-PCR.

Results: Characteristics of the patients

OA: osteoarthritis; RA: rheumatoid arthritis; CRP: C-reactive protein; BMI: body mass index; Underweight: BMI <18.5; overweight: BMI >24.9; normal BMI: 18.5-24.9; obesity: BMI >30.0

More CD14 positive cells exist in Hoffa comparing to SC, and M2 macrophages show higher proportion. A comparison of proportion of CD14 positive cells between Hoffa and SC showed significance both from OA and from RA. To M2 macrophages proportion, higher percentages of M2 macrophages (OA: 26.3±5.5%, RA: 22.5±2.4%) exist in Hoffa from both OA and RA patients, but no significance was found between the diseases. However, the proportion of M1 macrophages (OA: 15.6±1.7%, RA: 11.3±2.1%) indicated significance.

Srebf1 expressed less in Hoffa than in SC

Results show that in Hoffa, srebf1c expressed less in RA patients than that in OA patients, but no significance was indicated. In the proportion of expression levels between Hoffa and SC, both srebf1a and srebf1c showed significance, and more IL-6 and IL-1β expressed in Hoffa than in SC.

Conclusion: In RA patients, more M2 macrophages exist in Hoffa than in SC. Lower expression levels of srebf1c in Hoffa from RA patients suggest that macrophages differentiation can be reprogrammed by fatty acid metabolism.

ALTERED EXPRESSION OF FUNCTION OF P2X7 RECEPTOR IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Anna Lisa Giulian1, Federica Furini2, Alessandra Bortoluz2, Marcello Govoni2, Francesco Di Virgilio1. 1University of Ferrara, Morphology, Surgery and Experimental Medicine, Ferrara, Italy; 2University of Ferrara, Medical Science, Ferrara, Italy

Background: Extracellular ATP (eATP) is one of the most diffuse danger associated molecular patterns (DAMPs) released actively through specific mechanisms from intact cells, or passively from damaged or dying cells. An implication for eATP has been found in SLE. Among receptors for eATP, P2X7R is deeply involved in inflammatory and immune processes and its activation drives different intracellular pathways such as NLRP3-inflammasome activation, IL-1β maturation and release, IL-6 and TNF-α production, regulation of lymphocyte proliferation and cell apoptosis. Previous studies pointed out a possible relationship between P2X7R signaling pathways and SLE pathogenesis. A marked inflammatory condition characterize serositis, that are among the most common manifestations of SLE, and chloroquine is one of the main drugs employed.

Objectives: The aim of this study was to investigate P2X7R expression and activity in SLE.

Methods: 48 SLE patients, and 20 healthy control (HC) subjects were enrolled. Among SLE patients, 16 (SLE-S) presented, and 32 (SLE-NS) did not present history of serositis. All subjects gave written informed consent to peripheral venous blood withdrawal after approval by the local ethic committee. Plasma samples were used to measure IL-1β, IL-6 and TNF-α levels by ELISA. Mononuclear cells were isolated from blood samples by Ficoll gradient sedimentation and employed as follow: i) assessment of IL-1β, IL-6 and TNF-α release after stimulation with lipopolysaccharide (LPS) and/or Benzoyl ATP (BzATP); ii) evaluation of P2X7R mRNA expression by RT-PCR; iii) measurement of P2X7R activity as BzATP-induced increase of intracellular Ca²⁺ concentration using the Fura2/AM probe.
Results: In SLE patients respect to HC, plasma IL-1β levels were unmodified whereas IL-6 was higher, resulting significantly increased in SLE-S. Monocytes isolated from SLE patients released lower quantities of IL-1β after stimulation with BzATP, whereas the release of both IL-6 and TNF-α was significantly augmented in SLE-NS respect to both HC and SLE-S subjects after all types of stimulation. RT-PCR showed reduced P2X7R and augmented NLRP3 mRNA expression in SLE patients. Accordingly, P2X7R activity was significantly reduced in all SLE patients and did not appear to be influenced by a chloroquine pre-treatment.

Conclusion: In SLE patients, compared to HC subjects, we found reduced P2X7R mRNA expression, increased NLRP3 mRNA, as a possible compensating mechanism, and correspondingly, significantly lower BzATP-induced intracellular Ca2+ increase, without an apparent influence by chloroquine, one of the drugs most diffusely used for SLE treatment. The in vitro IL-1β release was reduced, whereas plasma IL-1β was unaltered, indicating an alternative source than monocytes, of this cytokine. Conversely, IL-6 and TNF-α levels were increased in vitro, and IL-6 was present in plasma at higher levels. The possible consequences of reduced P2X7R, mainly on cytokines network deregulation and lymphocyte proliferation, will be further investigated as well as the role of IL-6 and TNF-α as possible therapeutic targets.

THU0017 IN VITRO MECHANISTIC STUDIES DEMONSTRATE FILGOTINIB ACTIVITY THAT HAS POTENTIAL IMPLICATIONS FOR DIFFERENTIATION AMONG JAK INHIBITORS

Pei Han, Amy Meng, Nevena Mollova, Yuanjiang Yu, Julie A. Di Paolo. Gilead Sciences, Inc., Foster City, United States of America

Background: Inhibition of the Janus kinase-signal transducers and activators of transcription (JAK-STAT) pathway has demonstrated efficacy in immune-mediated diseases and has been identified as a therapeutic target for the treatment of rheumatoid arthritis (RA). Differences in JAK inhibitor specificity for JAK1, JAK2, JAK3, and TYK2 may influence their safety profiles, but the mechanism is not known. Selective JAK1 inhibition by filgotinib (FIL) may modulate a subset of proinflammatory cytokines associated with RA pathogenesis and improve the risk-benefit profile by minimizing other non-JAK1-related adverse events. JAK2 inhibition is associated with cytokine upregulation, while JAK3 inhibition has been associated with increased risk for opportunistic infections (eg, tuberculosis and herpes zoster) and chronic low-grade inflammation. In clinical trials, FIL did not negatively impact hemoglobin, LDL/HDL ratios, or natural killer (NK) cell counts.1,2

Objectives: To compare the in vitro profile of JAK inhibitors with different JAK selectivity profiles, for effects on erythroid progenitor cell expansion, NK cell proliferation, and liver X receptor (LXR) agonist-induced cholesterol ester transfer protein (CETP) expression, an enzyme responsible for the conversion of HDL to LDL.

Methods: JAK inhibitors (FIL, FIL metabolite [GS-829845], baricitinib [BARI], tofacitinib [TOFA], and upadacitinib [UPA]) were evaluated in vitro in human cell-based assays: growth of erythroid progenitors from human cord blood CD34+ cells using a HemaTox™ liquid expansion assay, IL-15-induced NK cell proliferation, and LXR agonist-induced CETP expression in the hepatic cell line (HepG2). Using IC50s generated from these assays and the reported human plasma concentrations of the JAK inhibitors from clinical studies,3-6 we calculated the target coverage for each compound. The activity of FIL in humans was based on a PK-PD modeling algorithm7 of FIL + GS-829845.

Results: In vitro assay results are described in the table. Based on these results, human exposure data, and modeled PK-PD relationships, FIL 100 mg and FIL 200 mg result in lower calculated cellular inhibition than the other JAK inhibitors at clinical exposures. Notably, FIL 100 mg and FIL 200 mg, but not the other inhibitors, are calculated to reduce CETP expression by 17% and 27%, respectively, while BARI, TOFA, and UPA are not expected to alter CETP levels.

4 Weak stimulation of LXR agonist-induced CETP expression.

Conclusion: JAK1 selectivity of FIL and GS-829845 resulted in less inhibition of erythroid progenitor expansion and NK cell proliferation compared with BARI, TOFA, and UPA. FIL also reduced LXR agonist-induced CETP expression, while the other inhibitors did not alter these levels. These results provide a potential mechanistic link to the observed reduction of CETP concentration and activity following FIL treatment, and the observed reduction in LDL-HDL in RA patients.8

THU0018 ANTI-GALECTIN-9 ANTIBODY AS A NOVEL TREATMENT OPTION IN RHEUMATOID ARTHRITIS TARGETING PATHOGENIC FIBROBLAST-LIKE SYNOVIOCYTES

Ditte Köster1, Malene Hvid2, Aida Sahaj Hansen1, Tue Wendel Krågstrup1, Ditte Nielson1,2, Aarhus University, Biomedicine, Aarhus, Denmark; 2Aarhus University, Clinical Medicine, Aarhus, Denmark; 3Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 4UMR 8126, CNRS, VillejulxFrance; 5Université Paris-Saclay, Gustave Roussy, Villejuif, France; 6Université Paris-Saclay, Univ Paris Sud, Le Kremlin-Bicêtre, France

Background: Fibroblasts-like synoviocytes (FLS) present in the stromal environment are key effector cells in the persistence of synovial inflammation and joint damage in rheumatoid arthritis (RA). A particular subset of FLS characterized as Thy1+Podelparin/CD34 is significantly expanded in RA patients and has been described to be disease-associated.1 Currently, no treatment targeting the stromal environment in RA is available2.

Objectives: To identify a novel treatment option targeting the stromal environment in RA to modify the disease-associated subset of fibroblasts.

Methods: An in vitro model was established with FLS derived from synovial fluid mononuclear cells (SFMC) from RA and osteoarthritis (OA) patients (n=6). FLS between passage 2-5 were used for further analyses. Untreated FLS in cultures were analyzed by flow cytometry for expression of
of the surface proteins CD34, CD45, Thy-1 and Podoplanin. The potential effect of cell detachment solutions on the expression of the surface proteins was examined by applying either tropsin or lidocaine. To evaluate on the inflammation status of the FLS, MCP-1 levels in supernatants from FLS in mono-cultures stimulated with either antibodies targeting galectin-9 (Gal-9), an anti-Gal-9 antibody-matched isotype control, LPS or steroid were analyzed by ELISA and compared to culture medium alone. Cell viability were examined using an MTT assay. Data are expressed as mean (95% CI) and analysed by a paired t-test. P-values <0.05 were considered statistically significant.

Results: FLS derived from SFMC were characterized as CD34+CD45- and declared, Aida Solhøj Hansen: None declared, Tue Wenzel Kragstrup Ditte Køster: None declared, Malene Hvid: None declared.

THU0019 INHIBITION OF FUCOSYLATION IN ENDOTHELIAL CELLS REDUCES RHEUMATOID ARTHRITIS ANGIOGENESIS
Takeo Isozaki, Shinichiro Nishimi, Tsuyoshi Kasama, Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan

Background: Glycosylation has been reported to associate with tumor invasion and metastasis. Fucosylation is involved in the biological functions of adhesion molecules and growth factor receptors. In regards to arthritis, we have previously reported that fucosylated proteins were expressed in rheumatoid arthritis (RA) synovial tissues. However, a direct role for fucosylated cytokines in RA has not been demonstrated.

Objectives: To confirm that fucosylated proteins are expressed in RA and involved in RA angiogenesis.

Methods: Total glycans in serum were significantly higher than in NL serum [mean ± SEM; 477 ± 24 pmol/μl (n=10) and 339 ± 14 pmol/μl (n=10), p<0.05, respectively]. In addition, total glycans in RA serum were significantly decreased with tocilizumab treatment at 24 weeks. Total glycans in RA serum were also correlated with DAS28 (ESR). Percent of fucosylated proteins in total glycans were decreased with TCZ treatment at 24 weeks. 2-d Gal treated HUVEC tube formed towards RA synovial fluids (n=6 patients) were decreased compared with nontreated HUVEC tube formed (number of tube formed: 7 ± 1 and 25 ± 2, p<0.05, respectively). We found that 2dGal treated HUVECs showed decreased migration compared with nontreated HUVECs, towards RA SF (numbers of HUVEC migrated; 3 ± 1 and 34 ± 4, n=5 patients, p<0.05). Fractalkine, CXCL1, CXCL6, or IL-8/CXCL8 in 2-d Gal treated HUVEC conditioned medium were decreased compared with in non-treated HUVEC conditioned medium but not MCP-1/CCL2, ENA-78/CXCL5, or VEGF.

Conclusion: These data indicate that glycoproteins are involved with RA, and play a role in angiogenesis in RA and suggest that targeting glycosylation especially fucosylation may provide a method by which to decrease inflammation and potentially treat other inflammatory diseases.

THU0200 COMPARATIVE STUDY OF THE PHOSPHODIESTERASE TYPE 5 INHIBITOR SILDAFIL AND THE PROSTACYCLIN ANALOGUE ILOPROST ON IP10 MODULATION IN SYSTEMIC SCLEROSIS
Clara Crescioli1, Valeria Riccieri2, Katia Stefanon1, Clariass Corinaldesi1, Massimiliano Valsec3, Franco Maramport, Guido Valesi2, Andrea Lenz2, Luigi Di Luigi3, Cristina antonini1.1 University of Rome Foro Italico, Rome, Italy, 2Sapienza University of Rome, Rome, Italy

Background: Systemic sclerosis (SSc) is an autoimmune disease ending in multorgan fibrosis. Vascular damage, relevant for the vascular alteration and disruption, has been suggested to play a key role in disease maintenance and progression [1]. Recent data demonstrated that high serum levels of the interferon (IFN)-γ-induced protein 10 (IP-10) in SSc patients correlated with peripheral vascular injury and increased in association with nailfold capillaroscopic pattern worsening and digital ulcers presence [2, 3]. Between the vasoactive drugs used for SSc treatment, the prostacyclin analogue iloprost (I) and PDE-S inhibitor sildenafil (S) seem to have high vasodilatory and immunomodulatory actions [4-6].

Objectives: To investigate and compare the ability of S and I to modulate: IP-10 circulating levels in SSc patients under different treatments; IP-10 release by human endothelial (Hfaec) cells subjected to Th1-related inflammatory stimuli.

Methods: Sera of 28 patients satisfying ACR/EULAR 2013 classification criteria for SSc were analyzed by ELISA. IFN-γ+TNFα-induced activation of NFκB, STAT1, JNK, ERK1/2 and AKT in Hfaec after S or I was tested by Western blot.

Results: The treatment with S significantly reduced IP-10 serum levels vs. treatment with (DMARDS) and corticosteroids (CCs) (184.1±65.10 vs. 880.9±339.0 pg/ml and vs. 426.5±101.7, respectively, P<0.01); while no significant difference has been found vs. 1 (184.1±65.10 vs. 282.7±46.6 pg/ml). In Hfaec, S and I differently counteracted the IFN-γ+TNFα-induced phosphorylation of JNKs (respectively 61.0±20.1% and 31.6±7.9% of phosphorylation vs. I+T-induced taken as 100%), STAT1 (respectively 49.2±15.8% and 93.4±1.2% of phosphorylation vs. I+T-induced taken as 100%), and AKT (respectively 27.3±4.4% of phosphorylation vs. I+T-induced taken as 100%)

Conclusion: In vivo results show that S and I have more effect in targetting serum IP-10 in SSc patients than other therapeutic treatments. In vitro data show different inhibitory drug-induced effects on pathways under-virulent production, dependent on intracellular targets. S could be a potential pharmacological tool as effective as I to control IP-10 in blood or at endothelial cell level in SSc.

References:
Background: Obesity is a condition that prolongs chronic inflammation and promotes synthesis and secretion of pro-inflammatory factors by adipose tissue, such as classical cytokines, tumor necrosis factor-α (TNF-α), adipokines (leptin, adiponectin, resistin) and other newly identified pro-inflammatory factors (hemin, lipokain, serum amyloid protein 3) [1,2,3,4,5]. Nowadays one of the most actively studied adipokines is nicotinamide phosphoribosyltransferase (visfatin, Nampt).

Objectives: We investigated the relationship the effect of weight loss over 5 kg on the clinical manifestations of OA and Nampt serum levels in patients with OA.

Methods: We observed 160 patients with different forms of OA ranged in age from 36 to 78 years, of whom there were 104 (65%) women (mean age 52.08 ± 1,58 years), and 56 (35%) of men (mean age - 54.07 ± 2.0 years) and the control group (60 healthy persons) with no complaints of pain in the joints over a lifetime, and without clinical signs of OA. Nampt level in serum was determined by ELISA using a commercial test systems.

Results: As overweight patients were recruited in the study, hypocaloric diet low in animal fats and physiotherapy has been recommended to all participants. The positive dynamics in body weight loss over 5 kg within 3 months has been achieved by 36 patients (23%). All patients were divided into two groups to study the effect of weight loss on the clinical manifestations of OA. These data proves that obesity may be an important risk factor for OA progression. As a result, weight loss results in decreasing metabolic disorder severity. In the second group of patients we have seen a decrease in all the parameters, but a significant difference has been observed only in the level of CRP, level of pain at rest and during walking according to VAS scale and total index on the WOMAC. However, patients with weight loss over 5 kg had significantly greater positive dynamics of clinical parameters than in the second group, without weight loss. This fact is probably explained by the decreased activity of inflammatory process after OA therapy and weight reduction.

Conclusion: Thus, as a result of our study patients with OA with weight loss of more than 5 kg had more obvious pain relief than patients with the original weight. These findings suggest that there is a possible role of visfatin in the pathogenesis of osteoarthritis. All patients with OA with a BMI over 25 kg/m² are recommended to lower their weight to decrease the mechanical stress on the joints, and also to reduce the severity of inflammation and metabolic disorders.

ETANERCEPT INCREASES AUTOPTOSIS AND REDUCES APOPTOSIS INDUCED BY TNF-ALPHA EXPOSURE IN ENDOTHELIAL CELLS IN VITRO

Alessandra Ida Cella, Cristina Barbat3, Fulvia Ceccarelli, Tania Colasanti, Annarca Finucci, Carlo Piericone, Mariangela Speziali, Francesca Romana Spinelli, Marta Vomero, Fabrizio Corti, Guido Valesini, Cristiano Alessandri. Sapienza University of Rome, Roma, Italy

Background: Rheumatoid arthritis (RA) is associated with high incidence of cardiovascular events, mainly due to accelerated atherosclerosis and endothelial dysfunction (1). Apoptosis in endothelial cells has been associated with vascular wall damage, contributing to atherosclerotic plaque formation (2). At the contrary, apoptosis may play a protective role in preventing development of atherosclerosis. However, the exact mechanism which controls the apoptotic effect of endothelial cells is still unknown. Tumor necrosis factor alpha (TNF-α) is one of the leading cytokines involved in the pathogenesis of RA. Several evidences suggest a pro-atherogenic effect of TNF-α in patients with RA. Etanercept (ETA) and other TNF-α inhibitors are effective treatments for joint inflammation in RA, but their effect on endothelial dysfunction is still not well understood.

Objectives: The aim of this study was to investigate in vitro, the effects of ETA treatment on endothelial cells exposed to TNF-α, with particular attention on apoptosis levels and autophagy pathway.

Methods: In vitro effects of ETA and TNF-α on endothelium were evaluated using human umbilical vein cell line EA.hy926. Cells were treated with ETA (15μg), TNF-α (10 ng/ml), alone or in combination. An untreated control cell culture was also performed. After 24 hours, apoptosis levels and autophagy have been evaluated. Apoptosis was analyzed by flow cytometry using a FITC-conjugated annexin V and propidium iodide apoptosis detection kit (3); autophagy was analyzed by western blot for the expression level of the autophagic markers LC3-II and p-62 (4).

Results: TNF-α treatment significantly increased apoptosis in endothelial cells compared both to untreated and ETA-treated cells (p= 0.0087 and p= 0.00187 respectively) [Figure 1]. The co-treatment with TNF-α and ETA significantly reversed the increase of apoptosis levels (p= 0.001 versus TNFα alone). Both ETA and TNFα treatments significantly increased the expression level of LC3II in treated cells when compared to untreated cells (p=18 and p=3 respectively). The co-treatment induced an additive effect on apoptosis levels (p< 0.0001 versus untreated cells). At last, the expression level of p-62 showed an inversely proportional trend to LC3II levels [ETA (p=0.0001), TNF-α (p<1), ETA+TNF-α (p<5)] versus untreated cells, respectively [Figure 2].

Conclusion: Our results show that treatment with Etanercept have a protective effect on endothelial cells in vitro, reversing the apoptosis induced by TNF-α. Moreover, this is the first study that supports a possible effect of Etanercept in increasing autophagy level in endothelial cells. Reducing TNFα-induced apoptosis, Etanercept treatment may lead to an improvement of endothelial function and to a reduction of accelerated atherosclerosis.

THU0023 PARADOXICAL EFFECT OF INTERLEUKIN 1 BETA CYTOKINE ON COLLAGEN TYPE I SYNTHESIS IN OSTEOSTABL-LIKE CELLS

Nur Adeelah Che Ahmad Tantowi, Jemma Kerns. Lancaster Medical School, Lancaster, United Kingdom

Background: Osteoblasts are the bone forming cells that are responsible for the synthesis of collagen type I and mineralization of bone during initial bone formation and later bone remodeling. Abnormalities in osteoblasts phenotype and activity occur in common bone diseases including osteoarthritis (OA). Studies showed that osteoarthritic osteoblasts secrete a colla-gen type I homotrimer of α1 chains, which is phenotypically distinct from the normal heterotrimer formed by two α1 chains and one α2 chain. Cytokines released during OA initiation or progression may interfere with osteoblastic function in the bone matrix. Interleukin 1 beta (IL-1β) is one of the major inflammatory cytokines implicated in the pathogenesis of OA; however, the biological response of osteoblasts to the cytokine is only partly understood.

Objectives: Our aims were to clarify the effects of IL-1β on collagen type I synthesis in osteoblast-like cells and to explore further possible relationship between collagen type I synthesis and mineralization.

Methods: At confluence, MG63 osteoblast-like cells in osteogenic media were stimulated with low (1 ng/ml) or high (10 ng/ml) dose of recombinant human IL-1β at several incubation times: 1, 2, 3, 4 and 5 hours. Non-stimulated MG63 cells were grown as control at indicated time points. Cell viability was tested by using the PrestoBlue reagent. Total collagen production was evaluated by Picro-sirius red precipitation method. Secretion of homotrimer collagen type I α1 (COL1A1) and mineralization at exposure time of 1-, 3- and 5-hour were determined by immunofluorescence staining of COL1A1 antibody and Alizarin Red S staining, respectively.

Results: IL-1β showed no statistical evidence in influencing cell viability at the time and dose tested compared to control. We found that IL-1β significantly (p<0.05) increased collagen content at short exposure time (1-hour), while significantly (p<0.05) decreased collagen content at longer exposure time (5-hour), in a dose-dependent manner. Immunofluorescence staining showed increased of homotrimer COL1A1 at 1-hour exposure and decreased of homotrimer COL1A1 at 5-hour exposure of IL-1β in the MG63 cells. IL-1β stimulated the formation of mineralized nodules at all exposure time.

Conclusion: We demonstrated for the first time of the paradoxical effect of IL-1β on collagen type I synthesis in osteoblast-like cells. Increased mineralization in low and high homotrimer type I collagen condition may possibly explain the abnormal mineralization in osteoarthritic bone.

TNF-α, tumor necrosis factor-α; HAAF, human aortic adventitial fibroblasts. Data are shown as mean ± SD of 3 independent experiments, each in triplicate. *P < 0.001, **P < 0.01 vs. control group(0 ng/ml T-614) within each group alone.

Conclusion: T-614 can inhibit the proliferation of HAAF and promote IL-8 production; therefore, it may provide a new immunotherapeutic intervention for TA.

REFERENCES:
synovial fibroblasts (SF) are known key effector cells of cartilage destruction in inflammatory arthritides such as RA, tenocytes are a major component of tendons and entheses and play a central role in tendon inflammation observed in PsA.

**Objectives:** To investigate whether PsASF and tenocytes show significant interactions while being stimulated with the above cytokines alone as well as in combination with the aim to find out whether these may contribute to thepathogenesis of PsA.

**Methods:** SF were isolated from patients with PsA undergoing joint surgery. Human tenocytes were acquired commercially and isolated from hamstring tendon tissue of patients undergoing hamstring tendon ACL reconstruction. PsASF and tenocytes were stimulated with IL-1β, TNF-α, IFN-γ, IL-15 and IL-23 alone and in combination. Direct cell co-culture experiments were performed at a 1:1 ratio of both cell types in parallel to experiments with single cell type cultures. IL-6 levels were measured by ELISA to quantify the immunological activation of the cells.

**Results:** PsASF as well as tenocytes showed strong responses to IL-1β (tenocytes 1173-fold, n=3; PsASF 156-fold, n=3) and TNF-α (tenocytes 10-fold, n=3; PsASF 9-fold, n=3) stimulation regarding IL-6 secretion. IFN-γ alone had only minimal effects on both cell types but acted synergistically when applied together with IL-1β (tenocytes 218-fold, n=3; PsASF 1129-fold, n=3) and TNF-α (tenocytes 24-fold, n=3; PsASF 119-fold, n=3). IL-15 and IL-23 alone showed no effect but the data suggest a small antagonistic effect against IL-1β (tenocytes IL-15 21% IL-23 27%, n=3; PsASF IL-23 19%, n=3) and TNF-α induced IL-6 secretion. Overall, PsASF and tenocytes showed similar responses in the single cell type stimulation experiments. Co-culturing PsASF and tenocytes did not reveal any synergistic or antagonistic interactions in regards to any of the cytokines used.

**Conclusion:** Our data suggest that tenocytes and PsASF do not interact in a way that would promote inflammation within the synovio-enthesal complex. Also, as far as the induction of IL-6 is concerned, PsASF and tenocytes are not major target cells of IL-15 and IL-23. IFN-γ, however, may be able to promote inflammation in combination with other cytokines in both cell types.

**ANALYSIS OF POTENTIAL INTERACTIONS BETWEEN TENOCYTES AND SYNOVIAL FIBROBLASTS AFTER STIMULATION WITH CYTOKINES EXPRESSED WITHIN THE SYNOVIO-ENTHESAL COMPLEX**

Felix Dechant 1, Klaus Frommer 1, Neil L Millar 2, Iain McInnes 2, Stefan Rehart 2, Ulf Müller-Ladner 1, Elena Neumann 1. 1 Justus-Liebig-University Giessen, Dept. of Rheumatology and Clinical Immunology, Bad-Nauheim, Germany; 2 University of Glasgow, Inst. of Infection Immunity and Inflammation, Glasgow, United Kingdom; 3 Agaplesion Markus Hospital, Dept. of Orthopaedics and Trauma Surgery, Frankfurt, Germany.

**Background:** Psoriatic arthritis (PsA) is frequently associated with enthesitis. It has been proposed that inflammatory processes at the synovio-enthesal complex are involved in the pathogenesis of inflammatory arthritides including especially PsA. Besides IL-1β and TNF-α, IL-15, IL-23 and IFN-γ are cytokines expressed within the synovium, tendons and entheses and some of which are already used as therapeutic targets.

**Objectives:**

1. To study the effect of different JAKi on the proliferation of RASF.
2. To investigate whether PsASF and tenocytes show significant interactions while being stimulated with the above cytokines alone as well as in combination.
3. To find out whether these may contribute to the pathogenesis of PsA.

**Methods:** Human RASF were isolated and pretreated with JAKi. After stimulation with IL-1β, TNF-α, IFN-γ, IL-15 and IL-23, the effect of different JAKi on proliferation of RASF was determined by a BrdU-incorporation assay. The influence of peficitinib on migration of RASF was determined by a Transwell assay. The levels of IL-6 and MMP-3 were measured in supernatants by ELISA.

**Results:**

- **Proliferation:** The effect of different JAKi on proliferation of RASF was determined by a BrdU-incorporation assay. The results showed that peficitinib and filgotinib offer a benefit in treatment of rheumatoid arthritis.
- **Migration:** The influence of peficitinib on migration of RASF was determined by a Transwell assay. The results showed that peficitinib and filgotinib offer a benefit in treatment of rheumatoid arthritis.
- **Cytokine Levels:** The levels of IL-6 and MMP-3 were measured in supernatants by ELISA. The results showed that peficitinib and filgotinib offer a benefit in treatment of rheumatoid arthritis.

**Conclusion:** Our data suggest that tenocytes and PsASF do not interact in a way that would promote inflammation within the synovio-enthesal complex. Also, as far as the induction of IL-6 is concerned, PsASF and tenocytes are not major target cells of IL-15 and IL-23. IFN-γ, however, may be able to promote inflammation in combination with other cytokines in both cell types.

**Disclosure of Interests:** Felix Dechant: None declared, Klaus Frommer: None declared, Neil L Millar: None declared, Iain McInnes Grant/research support from: AstraZeneca, Celgene, Compugen, Novartis, Roche, UCB Pharma, Consultant for: Alexion, Lilly, Novartis, Pfizer; UCB Pharma, Stefan Rehart: None declared, Ulf Müller-Ladner Grant/research support from: Projekt supported by an unrestricted educational grant from Celgene GMBH, Elena Neumann: None declared DOI: 10.1136/annrheumdis-2019-eular.7148
the MMP-3 levels induced by IL-1β by 88% (n=7, p<0.001) at 5 μM and by 31% at 1 μM (n=7, ns). In direct comparison to tofacitinib and baricitinib, peficitinib exerted the strongest decrease of about 70% (p<0.001, n=4) and it was the only inhibitor attenuating the proliferation of RASF by 38% at 1 μM and by 92% at 5 μM. The observed effects were not mediated by apoptosis and even after 48h peficitinib did not act cytotoxic on RASF. In contrast to migration, short-term adhesion onto a plastic surface was not affected by peficitinib.

Conclusion: Peficitinib and filgotinib were only moderately decreased the IL-1β-induced response of RASF. Peficitinib also inhibited the proliferation and the migration of RASF. Therefore, especially peficitinib could be able to reduce the aggressive pannus formation in RA patients.

THU0027

INHIBITION OF TH17 CELLS IN PSORIATIC ARTHRITIS THROUGH ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR IS DEPENDENT UPON DISEASE ACTIVITY

Amara Ezeoneyi1,2, Michael Ehrenstein1.1 University College London, London for Rheumatology, London, United Kingdom; 2St George’s University Hospital NHS Trust, London, United Kingdom

Background: Th17 cells have been implicated in the development of psoriatic arthritis (PsA) and psoriasis and are a major target for therapy. Th17 cells exhibit plasticity and can transdifferentiate to other effector cell types. Th17 cells that lose expression of IL-17 in favour of IFN-γ (non-classical Th1 cells) contribute to the pathogenesis of autoimmune diseases and are found in the joints of patients with inflammatory arthritis.

Conversely, induction of IL-10 in Th17 cells has been shown to suppress their pathogenic potential. The Aryl Hydrocarbon Receptor (Ahr) is a nuclear receptor with pleiotropic effects on immune function. The AHR ligand, faloquin hydroxylated (3,2-bjercarboxyl (FICZ) has been shown to induce or suppress Th17 cell differentiation and promote generation of tolerogenic Foxp3+ Treg cells in a regulatory cell type (Tr1) that produce IL-10. FICZ also induces proinflammatory IL-21 in a model of skin inflammation through AHR activation. FICZ could thus play a regulatory role to control inflammation in PsA.

Objectives: To evaluate the immunomodulatory effects of FICZ on IL-17, IL-10 and IFN-γ production from human CD4+ T cells in PsA and healthy controls (HC).

Methods: Whole PBMCs and purified CD4+ T cells were isolated from HC, untreated or DMARD treated (UNT/DMARD) PsA patients and anti-TNFα (adalimumab and etanercept) treated patients. Cells were stimulated with anti-CD3/CD28 (εCD3/εCD28) (1 μg/ml) and cultures were maintained in the presence or absence of FICZ (250nM). To some cultures 2,3,7-Tetachlorodibenzo-p-dioxin (TCDD) (10nM) was used as a control AHR ligand, and IL-21 (30ng/ml) as a positive control for IL-10 production. Cells were then re-stimulated with PMA/ionomycin and intracellular production of IL-17, IFN-γ and IL-10 measured by FACs.

Results: The percentage of IL-17+ CD4+ T cells was reduced in the peripheral blood of HC and PsA patients after 3 days (healthy p=0.0098, UNT/DMARD p=0.0001, anti-TNFα p=0.0019) and 5 days (healthy p=0.0005, UNT/DMARD p=0.0012, anti-TNFα p=0.0012). The percentage of IFN-γ+ CD4+ T cells was increased in HC and PsA patients (HC p=0.016, UNT/DMARD p=0.001, anti-TNFα p=0.001) after 3 days culture with FICZ but this effect was only sustained for HC patients (p=0.02) and anti-TNFα treated patients (p=0.01) after 5 days of culture. No ligand specific difference in IL-17 suppression was seen between FICZ and TCDD. No difference in baseline IL-10 expression was seen between treatment groups. However, IL-10 production was significantly enhanced by FICZ in the anti-TNFα patients group (p=0.02). This effect was not seen with TCDD nor IL-21 alone. The addition of IL-21 to cultures from anti-TNFα patients treated with FICZ further enhanced IL-10 expression (p<0.01). Increase in IL-10 by FICZ was associated with a reduction in IL-17. Upon stratifying patients by swollen joint count (SJC) and Psoriasis Area Severity Index (PASI) into high (SJC≥3, PASI≥5) and low (SJC<3, PASI≤5) disease activity, the percentage of IL-17+ CD4+ T cells after 3 days culture with FICZ was reduced for patients with low PASI score (p=0.02). A similar trend was seen for those with low SJC (p=0.06). In contrast, stimulation with FICZ did not regulate Th17 cells in patients with high PASI score or SJC.

Conclusion: The AhR ligand FICZ suppresses IL-17 production in CD4+ T cells of PsA patients and HC and IFN-γ in HC and anti-TNFα treated patients. FICZ promotes IL-10 production in CD4+ T cells from anti-TNFα treated patients and this effect is enhanced in the presence of IL-21. CD4+ T cells from patients with high disease activity are more resistant to FICZ mediated IL-17 suppression. Use of AhR ligands may thus be a useful therapeutic adjunct to conventional and biological therapy in PsA.

similarly effective in abolishing the synergistic effect of IL-17A + TNF-\(\alpha\) in RASF and PsASF.

**Conclusion:** According to our data, the differences in the therapeutic effectiveness of the anti-IL17A biologic secukinumab cannot be attributed to differential SF responses since the response to IL-17A alone and IL-17A together with TNF-\(\alpha\) is not stronger for PsASF than for RASF and since secukinumab was similarly effective for both SF types. Furthermore, in a proinflammatory milieu with increased TNF levels, both IL-17A and IL-17F can contribute to promoting inflammation in the pathophysiology of PsA and RA.

**FAS LIGAND REGULATES THE GENE EXPRESSIONS OF VARIOUS KEY MOLECULES IN RHEUMATOID SYNOVIAL FIBROBLASTS**

Koifuku, Y., Yasushi Miura,1,2, Shinya Hayashida,1, Yoshishita Maeda,1, Ryosuke Kuroda,1  

1Kobe University Graduate School of Medicine, Department of Orthopaedic Surgery, Kobe, Japan; 2Kobe University Graduate School of Health Sciences Division of Orthopedic Science, Department of Rehabilitation Science, Kobe, Japan.

**Background:** Fas ligand (FasL) is a member of tumor necrosis factor superfamily (TNFSF6) and reported to contribute to synovial hyperplasia of rheumatoid arthritis (RA). Apoptosis of RA synovial cells through Fas/Fasl pathway was inhibited by pro-inflammatory cytokines present within the synovium [1]. We previously reported that decoy receptor 3 overexpression in rheumatoid synovial fibroblasts (RA-FLS) stimulated by TNFalpha protects the cells from Fas-induced apoptosis [2].

**Objectives:** In this study, we investigated the gene expression profiles regulated by FasL in RA-FLS to reveal how Fasl is involved in the pathogenesis of RA.

**Methods:** RA-FLS were obtained during total knee replacement surgery from patients with RA. Four individual lines of primary cultured RA-FLS were incubated either with 1000 ng/ml of recombinant human FasL protein or the same volume of phosphate buffered saline as unstimulated control in reduced serum medium for 12h. Gene expressions were detected by microarray assay (Human Genome U133 Plus 2.0, GeneChip® 3 Expression Array; Thermo Fisher Scientific).

**Results:** Microarray data analysis revealed that FasL up-regulated or down-regulated the expression of various genes in RA-FLS. The function of regulated genes included transcriptional activator activity, positive regulation of metabolic process, positive regulation of cellular metabolic process, positive regulation of macromolecule metabolic process, positive regulation of nitrogen compound metabolic process, regulation of phosphorylation, positive regulation of biological process, regulation of phosphate metabolic process, regulation of MAPK cascade, and regulation of multicellular organismal process. The most up-regulated 3 genes by FasL were dual specificity phosphatase 6 (DUSP6), epiregulin (EREG) and interleukin11 (IL-11). The most down-regulated 3 genes by FasL were angiotropin-like 7 (ANGPTL7), protein inhibitor of activated STAT2 (PIAS2) and growth differentiation factor 5 (GDF5).

**Conclusion:** DUSP6 regulates CD4+ T-cell activation and differentiation by inhibiting the T-cell receptor-dependent extracellular signal-regulated kinases 1 and 2 activations [3]. EREG is increased in patients with RA and associated with the development of cytokine-induced arthritis [4]. IL-11 regulates the growth and development of hematopoietic stem cells and decreases the pro-inflammatory cytokines and nitric oxide productions [5]. ANGPTL7 is pro-angiogenic factor [6] and promotes pro-inflammatory responses through the PI3K signaling pathway [7]. PIAS proteins inhibit the activated STAT and are involved in the pathogenesis of RA [8]. GDF5 is associated with joint destruction of patients with OA and RA [9]. FasL regulates the expression of various genes in RA-FLS. Therefore, FasL may affect the pathogenesis of RA by regulating gene expressions of these molecules in RA-FLS.

**THE DIFFERENTIAL EFFECT OF TNF-A AND IL-6R BLOCKERS ON THE EXPRESSION OF IL-17 AND ACTIVATED CD4+CD25+ T CELLS IN PATIENTS WITH PSORIATIC ARTHRITIS**

Smadar Geitel,1,2, Ari Polacheck,1,2, Victoria Furer,1,2, Daphna Paran,1,2, On Elkahamy,1  

1Tel Aviv Sourasky Medical Center, Department of Rheumatology, Tel-Aviv-Yafo, Israel; 2Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel

**Background:** TNF-\(\alpha\) blockers are effective drugs for the treatment of psoriatic arthritis (PsA) and rheumatoid arthritis (RA). On the other hand, while interleukin-6 receptor (IL-6R) blockers have emerged as effective drugs in the treatment of RA, their effect in PsA has been disappointing. We hypothesized that the differential effect of TNF-\(\alpha\) and IL-6R blockers in PsA may be mediated by the effect of these drugs on IL-17 expression, a cytokine profoundly involved in PsA and by their influence on activated CD4+CD25+ T cells.

**Objectives:** To evaluate the differential effect of adalimumab (ADA) (representing TNF-\(\alpha\) blockers) and tocilizumab (TCZ) (IL-6R blocker) on the expression level of IL-17 and on the frequency of activated CD4+CD25+ T cells.

**Methods:** Levels of IL-17 mRNA expression were measured following in vitro co-culture of peripheral blood mononuclear cells (PBMC) derived from PsA patients with, ADA, TCZ at 10ug/ml or with medium alone as control for 3 days. Next, RNA was extracted and real-time PCR for IL-17 mRNA expression was performed. In addition, after 5 days incubation with the biologic agents the frequency of activated CD4+CD25+ T cells were analyzed by flow cytometry.

**Results:** The differential effect of ADA and TCZ on IL-17 mRNA expression and modulation of activated CD4+CD25+ T cells in culture of PBMC derived from PsA patients is shown in Figure 1. We found that IL-17 mRNA expression in PsA patients derived PBMC (n=20) was down-regulated by ADA. This down grading was significant in comparison with TCZ and respectively (p<0.0001, p<0.0003). On the other hand, TCZ significantly up-regulated the expression of IL-17 as compared to medium control (p<0.05) (Figure 1A). The frequency of activated CD4+CD25+ T cells was down-regulated by ADA as compared to medium and TCZ, respectively (p<0.03, p<0.005), whereas activated CD4+CD25+ T cells were up-regulated by TCZ (although not significantly) as compared to medium control (n=60) (Figure 1B).

**Conclusion:** Our data highlight the differential effect of ADA and TCZ on IL-17 expression level and on frequency of activated CD4+CD25+ T cells in culture of peripheral immune cells derived from PsA patients. This data suggest a new mechanism of action of ADA and provide a possible explanation of the inefficacy of TCZ in PsA.

**FILGOTINIB TREATMENT PROVIDES RAPID AND SUSTAINED REDUCTION OF INFLAMMATORY BIOMARKERS IN MODERATE TO SEVERE PSORIATIC ARTHRITIS (PSA) PATIENTS**

Dafna D. Gladman,1 Rene Gallien,2 Corrine Jamouli,3 Mona Trivedi,4 Neelufar Mozaffarian,5 Orhyu Yoon,6 Wendy Jiang,7 Jiyun Kim.8 1University of Toronto and Krembil Research Institute, Toronto Western Hospital, Toronto, Canada; 2Galapagos SASU, Romainville, France; 3Galapagos NV, Mechelen, Belgium; 4Gilead Sciences Inc, Foster City, United States of America

Background: PsA is a chronic inflammatory musculoskeletal disease characterized by joint and skin inflammation, enthesitis, dactylitis, and nail lesions. In the recent EQUATOR study, filgotinib (FIL), an oral, selective Janus kinase 1 (JAK1) inhibitor, produced significant and sustained improvements on the signs and symptoms of PsA compared to placebo (PBO). As targeted JAK1 inhibition by FIL has potential to simultaneously block multiple inflammatory pathways, we analyzed biomarker samples from EQUATOR using exploratory multiplex biomarker panels.

Objectives: To evaluate the impact of targeted JAK1 inhibition on the circulating biomarkers in patients with active PsA.

Methods: Design and results of the EQUATOR study—a 16-week, double-blind, multicenter, phase 2 study in subjects with active PsA (NCT03101670)—have been published. Subjects were randomized 1:1 to 200 mg FIL (n = 65) or PBO (n = 66) once daily. Serum samples (FIL n = 60 and PBO n = 61) were collected at baseline (BL), week 1, week 4, and week 16, and analyzed using 135 multiplex biomarker screening panels. Biomarker changes from BL were analyzed on all time-paired subject data and reported for weeks 1, 4, and 16.

Results: FIL treatment produced significant reductions serum concentration of multiple biomarkers associated with PsA disease activity. We identified 4 clusters of biomarker response based on the kinetics and magnitude of changes from BL (Figure): Cluster 1: rapid, substantial and sustained reduction (>25% from BL by week 1); Cluster 2: rapid and moderate reduction (5%–15% from BL by week 1); Cluster 3: delayed reduction (significant reduction by week 4); and Cluster 4: moderate increase (5%–10% from BL). Although initial grouping was based on the speed and magnitude of biomarker response, a number of biomarkers formed sub-clusters representing discrete biological functions. Cluster 1 included 2 acute phase reactants (CRP, SAA) while Cluster 2 included inflammatory mediators (TNFR1, CXCL10, IL-12/-23; CXCL10 and IL-12/-23 reached full reduction by week 1). Cluster 3 was the largest group and represented inflammatory markers and inflammation in RA and the effect of antirheumatic therapy on adipocytokine levels in patients with early RA is discussed.

Objectives: To assess the dynamics of adipocytokine levels (adiponectin, leptin, etc.) involved in the pathogenesis of rheumatoid arthritis (RA). The relationship of adipocytokines with activity markers and inflammation in RA and the effect of antirheumatic therapy on adipocytokine levels in patients with early RA is discussed.

Methods: The study included 47 patients with early RA (criteria ACR/EULAR, 2010), 57 [46; 62.0] years, disease duration 6.0 [5.5;15.5] months, seropositive for IgM RF and anti-CCP, with highly active RA (DAS28 5.5 [5.1; 5.9]; SDAI 32.4 [22.4; 41.7]; CDAI 29.0 [19.7; 39.5]). At study entry, all patients received methotrexate (MTX) [10 [10-15] mg/week], after 12 weeks, with inefficiency of MT, adalimumab (ADA) was administered 40 mg 1 time in 2 weeks. Serum concentration of adipokines (adiponectin, leptin) was measured with ELISA.

Results: By the 24th week of therapy, 23 (49%) patients with early RA (initial and after 24 weeks) using various treatment regimens: methotrexate monotherapy (MT) and combination therapy (MT + adalimumab (ADA)).

RNA PROFILING OF HEALTHY AND RHEUMATOID ARTHRITIS SUBJECTS TREATED WITH TOFACITINIB MONOTHERAPY

Angela Hadjipanayis, Xing Chen, Julie Lee, Sharrong Zhao, Weidong Zhang, David Martin, Mateusz Maciejewski, Daniel Ziemek, Lori Fitz, Craig Hyde, David von Schack, Pfizer Inc, Cambridge, MA, United States of America

Background: The Janus kinase (JAK) family of tyrosine kinases includes JAK1, JAK2, JAK3 and TYK2 which signals through type I and type II cytokine receptors. Tofacitinib is an oral JAK inhibitor approved for the treatment of rheumatoid arthritis (RA). In cellular settings where JAKs signal in pairs, tofacitinib preferentially inhibits signalling by heterodimeric receptors associated with JAK1 and/or JAK3 and has functional selectivity over JAK2. Next generation sequencing (i.e. RNA sequencing) offers an unbiased analysis of the whole transcriptome, pharmacology.

Objectives: To profile the transcriptome in whole blood samples collected in a Phase 1 healthy volunteer (HV) study and a Phase 2 study with RA subjects treated with placebo, 5 mg, 10 mg or 15 mg of tofacitinib monotherapy.

Methods: In the HV study, a total of 93 Paxgene RNA tubes were obtained from 30 subjects collected at screening, at baseline on day 1, and at 2 hours post dosing on day 15. HVs were treated daily with tofacitinib (10 mg BID) for 15 days. In the RA study (NCT00550446), a total of 239 RNA samples were obtained from 25–31 subjects at baseline and day 28 who were treated with tofacitinib 5 mg BID, 10 mg BID or 15 mg BID daily for 84 days. RNAseq libraries were generated using a polyA based mRNA kit and sequenced to a depth of ∼40 million paired-end reads. Upstream processing included alignment of sequences, gene quantification and data quality control. The raw reads were normalised using the Trimmed Mean of M values (TMM) method in the edgeR package. Log2 fold-changes (FC) and corresponding false discovery rate (FDR)-adjusted p-values (padj) were calculated using the voom function in the Limma package (vers 3.8) in R 3.5.1. In particular, the correlations between baseline and measurements at each visit per patient were estimated by Limma’s duplicateCorrelation function. Genes were considered significant after multiple test correction with FDR, or padj <0.1 within each study.

Results: Modulation of the JAK-STAT signalling pathways was observed as exemplified by gene expression differences in cytokine-inducible SH2-containing protein (CISH) (p-value=4.64E-41 in the HV study and p-value=1.2E-8 in the RA study) and suppressor of cytokine signalling (SOCS2) protein (p-value=1.38E-18 in HV study and p-value=2.27E-7 in the RA study). Gene expression of CISH, a member of the SOCS family, was decreased from its baseline value at day 15 in HV (FC from baseline=-0.52) and day 28 in RA subjects (FC from baseline=-0.42) when comparing tofacitinib treatment (HV:10 mg, RA:15 mg) to baseline or placebo, respectively. SOCS2 gene expression was also decreased at day 15 in HV (FC from baseline=-0.40) and at day 28 in RA subjects (FC from baseline=-0.52) when comparing tofacitinib treatment (HV:10 mg, RA:15 mg) to baseline or placebo, respectively. Other changes observed in the HV study included 201 genes were upregulated and 168 genes were downregulated when comparing 2 hours post dose on day 15 to baseline. In the RA study, 643 genes were upregulated and 801 genes were downregulated when comparing the 15 mg dose to placebo at week 4. Preliminary pathway level analysis shows overall a broader modulation of cytokine and chemokine signalling pathways by tofacitinib treatment in RA compared to what we observe in HV.

Conclusion: The results of this post hoc analysis demonstrate that tofacitinib induces measureable changes in the modulation of the JAK-STAT signalling pathway as well as effects on inflammatory cytokines and chemokines. The existence of overlapping but also unique JAK-STAT pathway inhibition due to tofacitinib between the HV and RA studies, as well as ongoing work, will provide a better understanding of response/non-response to tofacitinib and future drug developments.

THU0034 IRAK4 INHIBITION SUPPRESSES TLR7, TLR9, AND SLE SERUM-INDUCED IFNA PRODUCTION IN PRIMARY HUMAN PLASMACYTOID DENDRITIC CELLS

Angie Hammonds, Sean S. Parghi, Stacey Drabric, Nathan Wright, Ethan Grant, James Taylor, Matthew R. Warr. Gilead Sciences, Inc., Foster City, United States of America

Background: A hallmark of lupus is the presence of antinuclear autoantibodies, including those against RNA-protein complexes and double-stranded DNA (dsDNA).1,2 FC/r-FcR-mediated internalization of these nucleic acid/autoantibody immune complexes results in endosomal activation of TLR7 and TLR9, respectively, and the production of IFNs from plasmacytoid dendritic cells (pDCs).3,4 The importance of this pathway is underscored by the majority of SLE patients having a peripheral interferon- stimulated gene (ISG) signature.3 IFAK4 is a serine/threonine kinase at the top of the signaling cascade downstream of TLRs, including TLR7 and TLR9. As such, inhibition of IRAK4 represents a promising therapeutic target for lupus.

Objectives: To investigate the effect of a highly selective IRAK4 inhibitor on IFNα production from pDCs stimulated with TLR7 and TLR9 agonists, SLE serum, and nucleic acid/autoantibody immune complexes.

Methods: Primary human pDCs were preincubated with an IRAK4 inhibitor followed by stimulation for 24 hours. Stimulation agents included TLR7 and TLR9 agonists, human SLE serum, and nucleic acid/autoantibody immune complexes. Supernatants were then assessed for secretion of IFNα by MSD.

Results: TLR7 and TLR9 stimulation of pDCs resulted in the secretion of IFNα from pDCs as expected. Treatment with an IRAK4 inhibitor resulted in dose-dependent inhibition of TLR7- and TLR9-induced IFNα with high potency. Human SLE serum was tested to extend findings to physiological SLE-relevant stimuli. Several SLE serum samples, which had positive ELISA titers to the antinuclear antibodies, stimulated production of IFNα in pDCs after 24 hours in culture. No induction of IFNα was observed with healthy volunteer serum samples. Treatment with an IRAK4 inhibitor effectively blocked secretion of IFNα from SLE serum-stimulated pDCs in a dose-dependent manner. Additional antigen (either RNP or dsDNA) was added to SLE samples that yielded titers for autoantibodies but failed to elicit IFNα production. Addition of RNP or dsDNA to anti-RNP and anti-dsDNA-positive SLE serum activated IFNα production, and this response was blocked with IRAK4 inhibition. No induction was seen with SLE serum that was negative for both anti-RNP and anti-dsDNA.

Conclusion: This work demonstrates the effects of IRAK4 inhibition on IFNα production in primary pDCs downstream of disease-relevant stimuli and highlights the potential for IRAK4 inhibition as a promising treatment for lupus.

THU0035 DOMINANCE OF DRUG TARGET MECHANISMS IN RHEUMATOID ARTHRITIS

Jérôme Paul1, Pierre Grammel1, Thibault Helleputte1, DNAlytics, Louvain-la-Neuve, Belgium

Background: Biological and Targeted Synthetic Disease-Modifying Anti-Rheumatic Drugs (b- and tsDMARDs) have been developed over the years for rheumatoid arthritis (RA). They can be grouped into families of drugs according to their mechanisms of action. Here we focus specifically on anti-TNFs, anti-IL6s, anti-IL1s, T or B Cells inhibitors and JAK inhibitors. There is still a significant proportion of patients
ACTIVATED MEMORY T CELLS PRODUCE LIGANDS THAT CAUSE NF-κB-DEPENDENT INFLAMMATORY ACTIVATION OF THE ENDOTHELIUM: IDENTIFICATION OF NOVEL THERAPEUTIC TARGETS

Kim Jeukers1,2, Jan Piet van Hamburg2, Sander W. Tas1,2, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; 2Amsterdam UMC, Experimental Immunology, Amsterdam, Netherlands

Background: Endothelial cells (EC) are important contributors to inflammation via expression of inflammatory mediators, including cytokines, chemokines and adhesion molecules. Production of these inflammatory mediators can be induced via canonical and NF-κB-inducing kinase (NIK)-dependent noncanonical NF-κB signalling. The ligands activating these pathways are well studied, but less is known about the cells producing ligands that can activate NF-κB signalling in EC.

Objectives: To study the effects of factors produced by activated memory T (Tcm) cells on NF-κB dependent inflammatory activation of EC.

Methods: CD4+CD45RO+ memory T cells were isolated from healthy PBMC using MACS sorting and cultured in presence of anti-CD3 and anti-CD28 for 72h, after which supernatant was harvested. Endothelial cells were stimulated for 72h with 50% Tcm supernatant (Tm sup) after which protein and RNA was harvested by analysis of NF-κB signalling and downstream expression of inflammatory mediators using qPCR and western blot. Culture supernatants were analysed by ELISA for various inflammatory mediators. To repress canonical NF-κB signalling an inhibitor of IKKβ (iIKKβ) was used and to repress NIK-dependent NF-κB signaling an inhibitor of NIK (iNIK) was used.

Results: Stimulation with Tm sup led to activation of both canonical NF-κB signalling (increased levels of phosphorylated IκBα) and noncanonical NF-κB signalling (increased p100 to p52 processing). After stimulation with Tm sup EC had increased mRNA levels of all tested inflammatory mediators compared to non-treated cells. Gene expression of chemokines, cytokines, and growth factors (CCL1, CXCL5, IL6, IL8 and GM-CSF) in Tm sup stimulated EC was significantly reduced after treatment with iIKKβ and to a lesser, but still significant, extent after treatment with iNIK. Treatment with iIKKβ also led to a reduction in mRNA levels of the adhesion molecules VCAM-1 and ICAM-1, while this effect was less pronounced after iNIK treatment. Of note, treatment with either iIKKβ or iNIK led to a significant reduction of CXCL5 in the culture supernatant of Tm sup stimulated EC.

Conclusion: This study provides new insights into the cellular interactions leading to production of inflammatory mediators by EC. Our findings demonstrate that activated Tcm cells produce factors that can cause NF-κB-dependent inflammatory activation of EC. Targeting canonical NF-κB signaling via IKKβ or NIK-dependent NF-κB signaling reduces inflammatory activation of the endothelium and may be a potential novel therapeutic target.

ACTIVATED MEMORY T CELLS PRODUCE LIGANDS THAT CAUSE NF-κB-DEPENDENT INFLAMMATORY ACTIVATION OF THE ENDOTHELIUM: IDENTIFICATION OF NOVEL THERAPEUTIC TARGETS

Kim Jeukers1,2, Jan Piet van Hamburg2, Sander W. Tas1,2, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; 2Amsterdam UMC, Experimental Immunology, Amsterdam, Netherlands

Background: Endothelial cells (EC) are important contributors to inflammation via expression of inflammatory mediators, including cytokines, chemokines and adhesion molecules. Production of these inflammatory mediators can be induced via canonical and NF-κB-inducing kinase (NIK)-dependent noncanonical NF-κB signalling. The ligands activating these pathways are well studied, but less is known about the cells producing ligands that can activate NF-κB signalling in EC.

Objectives: To study the effects of factors produced by activated memory T (Tcm) cells on NF-κB dependent inflammatory activation of EC.

Methods: CD4+CD45RO+ memory T cells were isolated from healthy PBMC using MACS sorting and cultured in presence of anti-CD3 and anti-CD28 for 72h, after which supernatant was harvested. Endothelial cells were stimulated for 72h with 50% Tcm supernatant (Tm sup) after which protein and RNA was harvested by analysis of NF-κB signalling and downstream expression of inflammatory mediators using qPCR and western blot. Culture supernatants were analysed by ELISA for various inflammatory mediators. To repress canonical NF-κB signalling an inhibitor of IKKβ (iIKKβ) was used and to repress NIK-dependent NF-κB signaling an inhibitor of NIK (iNIK) was used.

Results: Stimulation with Tm sup led to activation of both canonical NF-κB signalling (increased levels of phosphorylated IκBα) and noncanonical NF-κB signalling (increased p100 to p52 processing). After stimulation with Tm sup EC had increased mRNA levels of all tested inflammatory mediators compared to non-treated cells. Gene expression of chemokines, cytokines, and growth factors (CCL1, CXCL5, IL6, IL8 and GM-CSF) in Tm sup stimulated EC was significantly reduced after treatment with iIKKβ and to a lesser, but still significant, extent after treatment with iNIK. Treatment with iIKKβ also led to a reduction in mRNA levels of the adhesion molecules VCAM-1 and ICAM-1, while this effect was less pronounced after iNIK treatment. Of note, treatment with either iIKKβ or iNIK led to a significant reduction of CXCL5 in the culture supernatant of Tm sup stimulated EC.

Conclusion: This study provides new insights into the cellular interactions leading to production of inflammatory mediators by EC. Our findings demonstrate that activated Tcm cells produce factors that can cause NF-κB-dependent inflammatory activation of EC. Targeting canonical NF-κB signaling via IKKβ or NIK-dependent NF-κB signaling reduces inflammatory activation of the endothelium and may be a potential novel therapeutic target.

ASSOCIATION BETWEEN PRO-INFLAMMATORY CYTOKINE POLYMORPHISMS AND JUVENILE IDIOPATHIC ARTHRITIS

Jae Hyun Jung, Jae-Hoon Kim, Sung Jae Choi, Gwan Gyu Song, Korea University College of Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic arthritis of childhood and has a variety of subtypes, but the etiology is unclear. Proinflammatory cytokines such as interleukin (IL)-1, IL-6 and tumor necrosis factor (TNF)-α play a major role in the development of JIA. Single nucleotide polymorphisms (SNPs) may be associated with susceptibility, phenotype, progression, and treatment of JIA, and the relevance of more than 20 SNPs and JIA has been studied.

Objectives: We investigated whether IL-1, IL-6, and TNF-α polymorphisms were associated with susceptibility to JIA.

Methods: A meta-analysis was conducted on the associations between IL-1α-889 C/T, IL-1β-511 C/T, IL-6-174 G/C, and TNF-α-308 G/A and -238 G/A polymorphisms, and JIA. A literature search was performed using PubMed and Embase. The strength of the association between these cytokine polymorphisms and risk of JIA was estimated using the crude odds ratio (OR) and 95% confidential interval (CI). We performed meta-analyses using 1) allelic contrast, 2) recessive, 3) dominant, and 4) additive models. The heterogeneity between studies was assessed with the Cochran Q test, and the heterogeneity among studies was tested with the F statistic.

Disclosure of Interests: Jérôme Paul Grant/research support from: The data analysis included in this work has been financially supported by Sanofi Genzyme., Pierre Gramme Shareholder of: Shareholder of DNAlytics., Grant/research support from: The data analysis included in this work has been financially supported by Sanofi Genzyme., Thibault Helleputte Shareholder of: Founder of DNAlytics., Grant/research support from: The data analysis included in this work has been financially supported by Sanofi Genzyme.

Results: A total of 27 studies included 4,678 JIA cases and 7,634 control subjects. There were 23 studies on Caucasians, 3 on Asians, and 1 on Africans. Seventy studies were on IL-1α-899 C/T, 5 were on IL-1β-511 C/T, 6 were on IL-6-174 G/C, 19 were on TNF-α-308 G/A, and 14 were on TNF-α -238 G/A polymorphisms. Meta-analysis of IL-1α-899 C/T, IL-1β-511 C/T, IL-6-174 G/C, and TNF-α-308 G/A and -238 G/A polymorphisms revealed no significant associations between JIA and minor alleles (OR 0.99, 95% CI 0.87–1.22, P = 0.5; OR 1.04, 95% CI 0.91–1.19, P = 0.57; OR 1.01, 95% CI 0.87–1.37, P = 0.46; OR 0.85, 95% CI 0.63–1.13, P = 0.26). Subgroup analysis was conducted on the relationship between JIA and proinflammatory cytokines based on ethnicity. In Caucasians, there was no significant association between IL-1α-899 C/T, IL-6-174 G/C, and TNF-α-308 G/A and -238 G/A polymorphisms and JIA; however, there were significant relationships between JIA and recessive (TT vs. CT + CC) and additive (TT vs. CC) models of IL-1β-511 C/T polymorphisms (OR 1.48, 95% CI 1.09–2.00, P = 0.01; OR 1.46, 95% CI 1.05–2.03, P = 0.02).

Conclusion: IL-1α-899 C/T, IL-1β-511 C/T, IL-6-174 G/C, and TNF-α-308 G/A and -238 G/A polymorphisms were not significantly associated with overall JIA susceptibility in all ethnicities. However, differences according to ethnicity were observed, and the TT genotype of IL-1β-511 C/T was associated with a high prevalence of JIA in Caucasians.

Disclosure of Interests: Marcel Gabathuler: None declared, Monika Krosel: None declared, Christoph Kolling: None declared, Matija Tomsic: None declared, Oliver Distler: Grant/research support from: Prof. Distler received research funding from Actelion, Bayer, Boehringer Ingelheim and Mitsubishi Tanabe to investigate potential treatments of scleroderma and its complications, Consultant for: Prof. Distler had a consultancy relationship within the last 3 years with Actelion, AnaMar, Bayer, Boehringer Ingelheim, ChemomAb, espeRare foundation, Genentech/Roche, GSK, Inveniva, Italfarmaco, iQvia, Lilly, medac, MedImmune, Mitsubishi Tanabe Pharma, Pharmacies, Novartis, Pfizer, Sanofi, Serodapharm and UCB in the area of potential treatments of scleroderma and its complications.

Background: The two coactivators of transcription cAMP-response element binding protein (CREB) binding protein (CBP) and p300 are close homologues. They are widely accepted as redundant proteins and unique functions have not been investigated in depth. Both proteins contain a histone acetyltransferase (HAT) activity for writing of cell type specific activating H3K27 histone acetylation marks, and a bromodomain, which functions as a reader of acetylated lysine residues on histone tails. Inhibitors targeting the bromodomains are in drug development for inflammatory and malignant diseases.

Objectives: To analyze individual functions of CBP and p300 in regulating the inflammatory response of rheumatoid arthritis (RA) synovial fibroblasts (SF).

Methods: SF were isolated from knee, shoulder and hand joints of RA patients undergoing joint replacement surgery. The expression of CBP and p300 was silenced by transfection of antisense LNA gapmeRs (12.5 nM), 24h after transfection, cells were stimulated with TNF-α (10 ng/ml, 24h). mRNA levels of H3K27ac in SF were analyzed by Western blotting (n=7). Transcriptomes were determined by RNA-seq (Illumina NovaSeq 6000, n=6). Pathway enrichment analysis of RNAseq data was performed using DAVID bioinformatic resources (fold change > 1.5, FDR < 0.05, top 3000 genes included). Changes in the mRNA expression of potential target genes were confirmed by quantitative Real-time PCR (n=12–14).

Results: Silencing of p300 reduced the levels of H3K27ac by 30% in unstimulated SF, and by 61.4% (p<0.05) in presence of TNF-α, whereas silencing of CBP reduced H3K27ac by 43.5% only in presence of TNF-α. In line with the changes in the H3K27ac, silencing of p300 affected the expression of 6026 and 5138 genes in unstimulated and stimulated SF, respectively. In contrast, only 285 and 1191 genes were affected by CBP silencing in unstimulated and stimulated SF, respectively. 13.5% of overlapping genes were affected by both, CBP and p300, in unstimulated SF, with 9.2% of genes being regulated in opposite directions. 13.5% of overlapping genes affected by CBP and p300 were regulated in opposite directions in TNF-α-stimulated SF. Principal component (PC) analysis of RNAseq data separated TNF-α-stimulated from unstimulated SF (PC1) and p300 gapmeR-transfected SF (PC2) from controls and CBP gapmeR-transfected SF, which clustered together. The top pathways regulated by CBP were ‘cell cycle’ and ‘focal adhesion’ in unstimulated cells and ‘DNA replication’ and ‘cell cycle’ after stimulation with TNF-α. Top pathways regulated by p300 in presence and absence of TNF-α were ‘proteasome’, ‘spliceosome’ and ‘focal adhesion’. The expression of 16 chemokines and cytokines was changed in RNaseq data (fold change >1.5, p<0.05) by either silencing of CBP or p300. Whereas silencing of CBP reduced the expression of all of them, silencing of p300 had pro- and anti-inflammatory effects. We further confirmed expression changes in cytokine and chemokine expression by Real-time PCR. Silencing of CBP reduced the expression of IL6, CCL2 (p<0.01), CX3CL1 (p<0.05), and CXCL10. Silencing of p300 reduced the expression of CCL2 and CX3CL1 (p=0.001) but increased the expression of IL8 (p<0.001) and CXCL2 (p<0.05).

Conclusion: Our results suggest that p300 is the major writer for H3K27ac marks in SF. We have identified overlapping and distinct functions for CBP and p300 in SF. CBP inhibition has anti-inflammatory effects. In contrast, p300 inhibition has pro- and anti-inflammatory functions.

THE RELATION BETWEEN THE INFLAMMATORY STATUS OF HUMAN END STAGE OSTEOARTHRITIC SYNOVUM AND LEVELS OF LOW DENSITY LIPOPROTEIN

Nik Kušnirčič-Bergen, Martijn van den Bosch, Niels Cremers, Arjen Blom, Peter van Lent, Nijmegen, Radboudumc, Nijmegen, Netherlands

Background: High systemic levels of low density lipoprotein (LDL) is a shared metabolic risk factor for osteoarthritis (OA) and cardiovascular disease (CVD), which may point to common biochemical pathways. One of the key events in atherosclerosis is formation and uptake of oxidized LDL (oxLDL) as a consequence of macrophage-mediated inflammation. Studies performed in our lab have previously shown that in mice, high LDL levels enhance synovial activation and ectopic bone formation during development of collagenase-induced OA. Furthermore, injection of oxLDL in naïve macrophage depleted joints led to infiltration of myeloid progenitor cells. Although these results strongly indicate towards (ox)LDL-mediated events that enhance OA severity, these processes have not yet been shown to occur in human osteoarthritic synovium.

Objectives: In the present study, we investigated whether the inflammatory status of OA synovium is associated to systemic and local levels of (ox)LDL.

Methods: Blood was collected from patients planned to undergo total knee replacement and LDL serum levels were determined (n=16). After surgery, synovial explants from the same patients (2-8 per patient) were collected and incubated at 37°C for 24 hours in presence of LDL (50 µg ApoB/mL), oxLDL (50 µg ApoB/mL) or control medium. Levels of IL-1β, TNF-α, IL-10 and MCP-1 secreted in the conditioned medium were measured using Luminex. Levels of S100A8/A9 were measured using ELISA. Concentrations of secreted factors were normalized for tissue sample weight. Synovial explants were further processed for histological analysis. Immunohistochemical staining of ApoB was performed to assess presence and uptake of (ox)LDL in the synovium. Hematoxylin & eosin-stained sections were used to arbitrarily score cellular infiltration and synovial hyperplasia.

Results: Around 50% of the patients in our cohort showed synovial activation exemplified by high secretion levels of IL-1β, TNF-α and IL-10. Cellular infiltration and synovial hyperplasia was observed in the majority of synovial tissue samples, their grades did however not correlate with cytokine secretion. Secretion levels of IL-1β positively correlated with serum levels of LDL and total cholesterol and did not correlate with BMI, suggesting a link that runs via systemic metabolic processes rather than increased weight-mediated joint loading. Considering that around 50% of OA patients suffers from synovitis characterized by increased macrophage presence and activity, high LDL in these patients may trigger oxLDL for-accumulation in these cells. Unexpectedly, presence of high concentra- tions of LDL or oxLDL during incubation of synovial explants did not sig-nificantly affect secretion of IL-1β, TNF-α, IL-10 and MCP-1, whereas presence of LDL but not oxLDL negatively affected secretion of S100A8/ A9.

Conclusion: IL-1β secretion by end stage OA synovium is associated to systemic levels of LDL. Intervention with high concentrations of LDL or oxLDL for 24-hours after synovium extraction did however not alter cyto-kine secretion, suggesting that LDL and synovitis are linked through more long-term local interactions, or alternatively via systemic inflammatory factors.

USING A NOVEL BEAD-BASED IMMUNOASSAY FOR SIMULTANEOUS DETECTION OF AUTOANTIBODIES AGAINST SERUM AMYLOID A1 AND ALPHA1 ACID GLYCOPROTEIN

Tadeja Kuret1,2, Katja Lakota3,4, Polonca Maš5, Matija Tomšič1,5, Sasa Cucič2, Snejža Sodin-Šečer5,6,1, University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 2University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia; 3University of Primorska, FAMNIT, Koper, Slovenia; 4Blood Transfusion Centre of Slovenia, Ljubljana, Slovenia; 5University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: Naturally occurring autoantibodies (Abs) against acute phase proteins (APPs), such as anti-serum amyloid A1 (SAA1) Abs have already been identified in sera of healthy individuals, as well as in patients with autoimmune diseases (1). Currently however, no method exists for simultaneous detection of multiple Abs against APPs.

Objectives: To develop a bead-based duplex immunosassay for simultane- ous detection of IgG anti-SAA1 and anti-alpha 1 acid glycoprotein (AGP) Abs and quantify their levels in sera of healthy blood donors (HBD), and patients with systemic autoimmune diseases, as well as in intravenous immunoglobulin preparation (IVIg).

Methods: Fluorescently labeled MagPlex microspheres (Luminex Corp) were used to covalently bind SAA1 and AGP. Sera samples (diluted 1:20) were added to a 96-well microtiter plate and incubated with SAA1- and AGP-coupled microspheres for 2h. Subsequently, PE-conjugated anti-human IgG Abs were added to each well, incubated for 30 min, resus- pended in PBS-1%BSA and analysed using the MagPix system (Biomed- ica, GmbH).

Abstract THU0040 – Figure 1. Levels of antibodies against SAA1 (A) and AGP (B) in HBD as compared to patients with systemic autoimmune diseases. Shown is median and IQR. 95th and 90th percentile of MFI values in HBD are indicated with dotted lines; *p<0.05; **p<0.01. SAA1, serum amyloid A1; AGP, alpha 1 acid glycoprotein; MFI, median fluorescence intensity; HBD, healthy blood donors; GCA, patients with giant cell arteritis; IgAV, immunoglobulin A vasculitis; SLE, systemic lupus erythematosus; SSC, systemic sclerosis; APS, antiphospholipid syndrome; ERA, early rheumatoid arthritis.

Abstract THU0040 – Figure 2. Presence of antibodies against SAA1 and AGP in IV Ig. IVIg, intravenous immunoglobulin G; SAA1, serum amyloid A1; AGP, alpha 1 acid glycoprotein; MFI, median fluorescence intensity.

Sera samples were collected from HBD (n=55), patients with giant cell arteritis (GCA; n=20), immunoglobulin A vasculitis (IgAV; n=30), systemic lupus erythematosus (SLE; n=20), systemic sclerosis (SSc; n=27), anti- phospholipid syndrome (APS; n=19) and early rheumatoid arthritis (ERA; n=20). Ab levels were determined also in IVIg (Octapharma AG).

Results: We observed the presence of both, anti-SAA1, and anti-AGP Abs in sera of HBD, as well as in patients with GCA, IgAV, SLE, SSC, APS and ERA.

GCA patients had significantly higher anti-SAA1 levels (median (IQR) MFI was 2163 (1131-3048)) as compared to SSc (816 (480-1462); p<0.01) and ERA (886 (722-1596); p<0.05) patients. Levels of anti-AGP Abs were also significantly higher in sera of GCA patients (495 (298-872)) as compared to ERA (213 (130-338); p<0.01) and APS (264 (154-399); p<0.05) patients. No difference in anti-SAA1 or anti-AGP levels was observed between HBD and the tested groups of patients (Figure 1).

Scientific Abstracts

Thursday, 13 June 2019 287
Substantial amounts of anti-SAA1 Abs were observed in serially diluted IgV, while there were 4-fold less anti-AGP Abs detected (Figure 2), which corresponds also to the ratio found in HBD (Figure 1).

Conclusion: Serum IgGs against SAA1 and AGP present in HBD, patients with systemic autoimmune diseases and in IgV can be simultaneously quantified using a customized bead-based multiplex assay. These natural autoAbs found in IgV could be endogenous immune-regulators of the acute phase response.

MESENCHYMAL STEM CELLS OF DIFFERENT ORIGINS
EXHIBIT UNIQUE RESPONSES TO DIFFERENT INFLAMMATORY STIMULI

Blaz Burić1, Ariana Bartić2, Andreja Erman2, Matija Tomić1,2, Katija Mrak-Poljakić1, Snežna Sodin-Šemrl2,3, Katja Lakota1,3.
1University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 2Educare Ltd., Trzin, Slovenia; 3University of Ljubljana, Faculty of Medicine, Institute of Cell Biology, Ljubljana, Slovenia.

Background: Mesenchymal stromal/stem cell (MSC) - based therapies represent promising avenues for treatment of various inflammatory and autoimmune diseases. Currently, a variety of fetal and adult tissues represent a good source of MSC, however further characterization of their effects, especially in an inflammatory environment, is needed.

Objectives: Firstly, to characterize MSC from different origins, namely bone marrow (BM), adipose tissue (AT) and umbilical cord (UC), after stimulation with TNFα, IL-1β and serum amyloid A (SAA). Secondly, to determine the effects of MSC secretome on migration, proliferation and apoptosis of lung fibroblasts.

Methods: BM-, AT- or UC-MSC were isolated each from 3 healthy donors. The expression and secretion of analytes were studied in each cell type at basal level and following TNFα (1 ng/ml), IL-1β (1 ng/ml) and SAA (12 µg/ml) stimulation using qPCR (SDF, CCL5, VCAM, PDE, PGC, IDO, VEGF, IGF) and Luminex technology (IL-6, IL8, MCP-1, ICAM, CHSL1, MMP1, MMP3, tenasin, uPA, HGF, VEGF), respectively. Normal healthy lung fibroblasts (NHLF) were used in the wound scratch assay and treated for 24h with 20% of MSC-conditioned media. For evaluation of BM-, AT- and UC-conditioned media effects on proliferative and apoptotic activity, Ki-67-immunolabeled mitotic cells and caspase-3-immunolabeled cells were counted using fluorescence microscopy. Results: Treatment of MSC with pro-inflammatory cytokines increased mRNA levels of SDF, CCL5, VCAM1, PGC and IDO, while levels of PDE-5A were down-regulated. The greatest increase in expression was observed in TNFα-stimulated MSCs, namely of two immunomodulatory molecules, CCL5 and IDO in AT-MSC (4396- and 928-fold change increase respectively). Secretome analysis showed highest secretion levels of IL-6, IL-8 and MCP1 after IL-1β-activation in all 3 tissue sources. AT- and BM-derived conditioned media increased NHLF scratch closure, while UC-MSC decreased it. In non-inflammatory conditions, UC-, BM- and AT-MSCs conditioned media decreased the number of mitotic events in NHLF by an average of 40%. Importantly, only the conditioned medium derived from inflammatory cytokine-treated AT- and BM-MSC significantly decreased the mitotic rate of NHLF (p<0.01). The number of apoptotic cells increased 3- to 8-fold after treatment with all MSC conditioned media, with UC-MSC showing the highest effect (p<0.01).

Conclusion: Our results highlight specific roles of MSC from different tissue origins, as well as their response to environmental inflammatory stimuli and suggest that source selection might be critical for the success of treatment approaches in different diagnoses.

EFFECT OF SPLEEN TYROSINE KINASE (SYK)-INHIBITORS ON RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

Jeanna Pietriette Lalich Missirama1, Magnus Diller2, Rebecca Hasseli3,
Stefan Rehart4, Ulf Müller-Ladner5, Elena Neumann1, Justinus-Liebig-university Giessen, campus kerkhoft, dept. of rheumatology and clinical immunology, Bad Nauheim, Germany; 2Agaplesion Markus Hospital, Dept. of orthopedics and trauma surgery, Frankfurt, Germany

Background: The spleen tyrosine kinase (syk) is an intracellular protein kinase involved in signal transmission processes of immune cells and non-hematopoietic cells, such as fibroblasts. Various syk-inhibitors are therefore currently being tested in preclinical and clinical studies, e.g. for the treatment of different types of cancer as well as autoimmune diseases. In preclinical studies, syk-inhibitors showed a pronounced anti-inflammatory effect on synovial fibroblasts (SF) from patients with rheumatoid arthritis (RA). These cells play an important role in the pathogenesis of RA by mediating matrix destructive processes. On the other hand, clinical trials have been only moderately successful due to the side effects and the limitation regarding increase in dosage. However, further inhibitors such as RO9021 or TAK-659 have been developed. They are characterized by a more specific kinase profile and therefore side effects could potentially be less severe. Whether these inhibitors also convey an anti-inflammatory effect on RASF has not yet been investigated.

Objectives: This study examines the effect of syk-inhibitors on the inflammatory response and functional behavior of activated RASF.

Methods: RASF were isolated from synovial tissue of patients with known rheumatoid arthritis during joint replacement surgery. RASF were pre-treated with different concentrations of RO9021 and TAK-659 and their vehicle control for 2h and additionally stimulated with IL-1β (10 ng/ml) for 17h or with oncostatin M (OSM, 100 ng/ml) for 24h. Supernatants were collected and the concentration of IL-6 and MMP3 were determined by ELISA. The measurement of cell viability, cytotoxicity and apoptosis was performed to exclude possible cytotoxic or apoptotic effects of the syk-inhibitors. The RASF proliferation assay was performed by a BrdU-incorporation assay. The effect of syk-inhibitors on cell migration towards a FCS-gradient was measured by cell culture inserts. Results: Both TAK-659 and RO9021 showed a significant reduction of the release of the pro-inflammatory cytokine IL-6 and the production of MMP3 in IL-1β stimulated RASF. However TAK-659 showed a stronger effect on IL-6 reduction (48%, p<0.005) than RO9021 (25%, p<0.05) at 10µM. MMP3 decrease was also stronger with TAK-659 (92%, p<0.001) than with RO9021 (59%, p<0.001). This effect was apparently not restricted to IL-1β because both inhibitors also decreased the OSM-induced IL-6 release of RASF by 85% (p<0.01) with TAK-659 and 30% with RO9021 at 10µM. The proliferation of RASF was also reduced by both syk-inhibitors at 5µM and higher. The highest effect could be observed with TAK-659 for 80% and with RO9021 by 50% both at 15µM. The migration of RASF was also decreased by TAK-659 at 10µM (p<0.01, n=3). The effects were not mediated by induction of apoptosis or cytoxicity.

Conclusion: The syk-inhibitors TAK-659 and RO9021 at concentrations above 5µM reduce the inflammatory response, the migration and proliferation of RASF. If appropriate concentrations can be reached in vivo, these syk-inhibitors could offer a possibility to modulate the aggressive phenotype of RASF.

THU0043

IL-25 ALLEVIATES RHEUMATOID ARTHRITIS BY INHIBITING TH17 IMMUNE RESPONSE

dan Liu1,2, LV Yanan3, Xi’an No. 5 Hospital, Department of Rheumatology and Immunology, Xi’an, China; 2Xi’an No. 5 Hospital, Department of Rheumatology and Immunology, Xi’an, China

Background: Rheumatoid arthritis (RA) is a prevalent common autoimmune disease characterized by chronic inflammation of the joint and synovial hyperplasia and progressive destructive articular cartilage and bone. Accumulating evidence highlighted that an imbalance between pro-
and anti-inflammatory cytokines may be a key mechanism for disease progression in RA. IL-25 is reported to play an anti-inflammatory role in autoimmune and inflammatory diseases through the downregulation of Th1 and Th17 cell responses. However, the exact role of IL-25 in the pathogenesis of RA remains to be elucidated.

**Objectives:** Explore the role of IL-25 in the pathogenesis of RA, and provide evidence of the scientific importance of IL-25 relevant biological agent.

**Methods:** 1. The study was first to analyze the relationship between IL-25 and DAS28 score, CRP and anti-CCP in RA patients. Tests IL-1β, IL-6, IL-17A, TNF-α and IFN-γ through ELISA, then analyze the relationship with IL-25. CD4+ T cells from PBMCs of the 5 RA patients and 5 HCs were isolated under the manual of EasySep™ Human CD4+ T Cell Isolation Kit and stimulated with anti-CD3 plus anti-CD28 in the presence or absence of rhIL-25. 2. A CIA model was established to explore the mechanism of IL-25. The expression of CII specific IgG1 and IgG2a, as well as IL-1β, IL-6, IL-17A and TNF-α in CIA serum were examined using ELISA assay. The ROR-γT, -β, GATA-3 mRNA levels in knee joints and spleen were assessed by real-time qPCR analysis. In vitro, CD4+ T cells from spleen were isolated from CIA mice and cultured with or without recombinant mouse (rm)IL-25 for 24h to control the expression IL-17A. Cells were stimulated with plate-bound anti-CD3 plus anti-CD28 in the presence or absence of recombinant mouse (rm) IL-25 with different dose for 24 h.

**Results:** 1. The expression of IL-25 was upregulated in the serum and synovial fluid in RA patients. Serum IL-25 levels were positively associated with DAS28 score, ESR and C-reactive protein. However, no significant correlation was observed between serum IL-25 levels, RF and anti-CCP. IL-25 serum levels was positively correlated with the concentrations of IL-1β, IL-6, IL-17A and TNF-α, respectively. However, no significant correlation was observed between serum IL-25 and IFN-γ level. 2. IL-25 can alleviate inflammatory response of CIA mice and inhibit IL-17 differentiation. The serum levels of IL-1β, IL-6, IL-17A and TNF-α in IL-25-treated mice were markedly reduced compared with those in WT mice, except IFN-γ. RT-qPCR also demonstrated that the transcription levels of IL-17A and ROR-γt were decreased in the synovial tissue of IL-25-treated mice. RmIL-25 treatment significantly inhibited IL-17A production in a dose-dependent manner, and the mRNA level of the key TFs for Th17 cells (ROR-γt), as well as IL-17A, were also decreased.

**Conclusion:** IL-25 is upregulated in the serum and synovial fluid of RA patients. High levels of IL-25 was associated with disease severity and inflammation response in RA patients. IL-25 inhibits CD4+ T-cell activation and differentiation into Th17 cells, without affecting Th1 cells in RA. Systemic administration of IL-25 attenuates arthritis onset and joint damage in CIA mice. IL-25 of multi-target regulation further be used in the clinical treatment of RA.

**DOI:** 10.1136/annrheumdis-2019-eular.8357
Background: Pathogenesis of Granulomatosis with polyangiitis (GPA) is still unknown. However, it has been observed a skewing of circulating CD4+ T cells toward the Th17 and Th2 phenotype. The pro-inflammatory cytokine interleukin 25 (IL-25) is a member of IL-17 cytokine family associated to the Th2 immune phenotype. Through the receptor IL17RB, IL-25 further sustains the Th2-type immune response and elicits the expansion of the type 2 innate lymphoid cells (ILC2) and M2 macrophages. A pathogenic role of the innate lymphoid cells in GPA has been recently demonstrated; however, the relevance of IL-25 in this condition remains unexplored.

Objectives: Aim of the study was to evaluate the expression of IL-25/IL-25R axis and its functional relevance in patients with granulomatosis with polyangiitis (GPA).

Methods: Thirty patients with a diagnosis of GPA fulfilling the Chapel Hill Consensus Conference and ACR classification criteria, and 20 age-matched healthy controls (HC) were included in this study: age range 30-66 years, 40% female in GPA group and 32-63 years, 20% female in HC. IL-25 and IL-33 serum levels were measured by ELISA at the diagnosis and after Rituximab (RTX) therapy (n=15). Immunohistochemical staining for IL-25, IL-33, IL-17B was performed on sections of renal biopsies obtained from GPA patients (n=10). Kidney ILC2 infiltration was assessed by confocal microscopy. Frequencies ILC1, ILC2 and ILC3 were evaluated by flow cytometry analysis by CD45, CRTH2, GATA3, Tbet, CD56, NKp44, IL-22, IL-23R, RORc. Expression levels of IL-5 and IL-13 in kidney were quantified by quantitative real-time PCR (qRT-PCR).

Results: Increased pre-RTX serum levels of IL-25 and IL-33 at baseline were observed in GPA compared to HC (p<0.0001). Both serum IL-25 and IL-33 correlated with the Birmingham Vasculitis Activity Score (BVAS) (r^2=0.51 p<0.0001 and r^0.14 p<0.05 respectively). IL-25, IL-17B and IL-33 expressing cells were increased in GPA renal biopsies vs HC (p<0.0001). Frequencies of circulating ILC1 and ILC3 were not significantly increased in GPA. Conversely, the frequency of ILC2 was expanded in GPA vs HC (p<0.0001) and correlated with BVAS (r^2=0.60 p<0.0001). The number of IL-2 and the levels of expression of IL-5 and IL-13 in GPA kidney were increased (p<0.0001). RTX therapy led to a reduction in IL-25 and IL-33 serum levels and in the frequency of circulating ILC2.

Conclusion: Our data confirm the increases in IL-33 levels previously demonstrated; however, the relevance of IL-25 in this condition remains unexplored.

IA-14069, a novel small-molecule inhibitor directly targeting tumor necrosis factor-α, attenuates collagen-induced arthritis

Sung-Dong Park1, HyungGun Maeng2, Yeon-Hwa Park3, Kye-Jung Shin1,2, Tae-Hwee Heo1,2. 1ILab Inc., College of Pharmacy, The Catholic University of Korea, Bucheon, Korea. Rep. of (South Korea); 2The Catholic University of Korea, Integrated Research Institute of Pharmaceutical Sciences, College of Pharmacy, Bucheon, Korea. Rep. of (South Korea)

Background: Rheumatoid arthritis (RA) is systemic autoimmune disease that is characterized by autoreactive immune cells and various cytokines-mediated inflammation in multiple joints, leading to cartilage degradation, bone erosion and finally irreversible joint destruction1. The inflammatory cytokine tumor necrosis factor-α (TNF-α) is known to play a central role in several chronic immune-mediated inflammatory disorders2.

Objectives: Despite the great success of anti-TNF-α biological drugs in the treatment of RA, no chemical drug targeting TNF-α is available. Here we report that IA-14069, a novel small molecule inhibitor, binds directly to TNF-α and inhibits TNF-α activities both in vitro and in vivo.

Methods: IA-14069 was screened and identified by competitive binding to TNF-α and neutralization activity of IA-14069 against TNF-α was determined using MTT assay. The direct binding IA-14069 to TNF-α was demonstrated by surface plasma resonance and bead pull-down assays. The inhibition of TNF-α-TNFFR interactions by direct binding of IA-14069 to TNF-α was analyzed by flow cytometry. Levels of phosphorylated IκBα (p-IκBα) and NF-κB p65 were analyzed by western blot. IA-14069 was orally administered to TNF-α transgenic (TNF-α-Tg) RA mice at three or 33 mg/kg twice per week or at 25, 50 or 100 mg/kg 3 times per week for preventive or therapeutic effect, respectively. In vivo therapeutic efficacy of IA-14069 or methotrexate was evaluated in collagen-induced arthritis (CIA) mice immunized with bovine type II collagen (CII) emulsified in complete Freund’s adjuvant, and boosted with CII emulsified in incomplete Freund’s adjuvant.

Results: IA-14069 potently inhibits both TNF-α-induced cytotoxicity (IC50 < 0.7 μM) which directly binds to TNF-α and TNF-α-triggered signaling (p-IκBα and NF-κB p65) activities. The therapeutic as well as preventive anti-RA effects of IA-14069 were demonstrated in TNF-α-Tg and CIA models. IA-14069 and MTX had synergistic effects in the CIA therapeutic model. According to pharmacokinetic analysis, IA-14069 showed significant bioavailability. In addition, no in vivo toxicity was observed even under treatment of excessive amount of IA-14069.

Conclusion: The data indicate that IA-14069 can be a novel and potential TNF-α inhibitor for the treatment of RA and other inflammatory diseases.

2ND LINE TREATMENT WITH LESINURAD AND ALLOPURINOL VERSUS FEBUXOSTAT FOR MANAGEMENT OF HYPERURICEMIA: A COST-EFFECTIVENESS ANALYSIS FOR SPANISH PATIENTS

Maria Presa1, Fernando Perez-Ruiz2, Itziar Oyagüez1. 1Pharmacoconomics and Outcomes Research Iberia (PORIB), Madrid, Spain; 2Hospital Universitario Cruces, Rheumatology Division, Bilbao, Spain

Background: Lesinurad, a medication that inhibits uric acid reabsorption, has been recently approved in combination for the treatment of patients with gout who do not reach therapeutic serum urate target with xanthine oxidase inhibitors monotherapy.

Objectives: To assess the incremental cost-effectiveness ratio of adding lesinurad to allopurinol as 2nd line therapy, compared to febuxostat for the management of patients with gout in Spain.

Methods: A Markov model comprising 6 health-states representing the disease evolution was used to estimate in 6-months cycles, the lifetime accumulated cost and benefits in terms of quality-adjusted-life-year (QALY) in an hypothetical cohort of patients stratified according to serum uric acid levels observed on pooled CLEAR trials: 18.8% (<6 mg/dL); 63.7% (6-8 mg/dL); 15.2% (8-10 mg/dL) and 2.3% (>10 mg/dL). During the simulation, patients could either continue with 2nd line treatment with lesinurad (200mg/daily) plus allopurinol (400mg/daily) or febuxostat (80mg/daily), switch to allopurinol monotherapy (271mg/daily) in case of intolerance or discontinue treatment. Proportion of topheaceous gout (18.9%) was considered at each health-state. The efficacy of treatments was captured in the transition probabilities between health states which were derived from findings on CLEAR 1, CLEAR 2 and EXCEL clinical trials. Quality of life related to gout severity (topheaceous or non-topheaceous) and flare frequency was considered by means of utilities estimated from SF-36 scores of the pooled CLEAR trials which were mapped to EQ-5D values. The total cost estimation (€, 2018) included drug acquisition cost (retail prices with mandatory deduction applied), disease monitoring (€377.03 for first 6-month periods, €329.95/795 (subsequent year) and flare management cost (€301.69). Unitary costs derived from local cost databases and literature. A 3% annual discount rate was applied for cost and outcomes. Sensitivity analyses (SA) were carried out.

Results: Lesinurad added to allopurinol provided higher QALYs (14.79) than febuxostat (14.69). Total accrued cost per patient were lower (€6,819.13) with lesinurad and allopurinol (€4.695.27) compared to febuxostat (€5.478.40). Lesinurad plus allopurinol resulted a dominant option (more effective and less costly) compared to febuxostat. SA results confirmed the model robustness.

Conclusion: These results suggest that treatment with lesinurad 200 mg/day plus allopurinol 400 mg/day compared to febuxostat 80mg/day is an effective second option for the management of hyperuricemia in patients with gout who did not reach therapeutic serum urate target to previous allopurinol monotherapy, associated to cost-savings for the Spanish National Health System.

CORRELATION BETWEEN IL-6 AND OSTEOCALCIN SERUM LEVELS WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS (RA) PATIENTS

Ervin Papadaki1, Teuta Baka2, Artur Zoto3, Ermina Zioishi1, Lediana Nuhaj1, Vlbona Sako1, Indira Xhemali1
1Indira Xhemali, Rheumatology Service, Tirana, Albania; 2German Polincic, Rheumatology Service, Tirana, Albania; 3Published in

Background: IL-6 plays a significant role in RA pathophysiology. It is considered nowadays as an important inflammation marker and it is responsible for a wide range of articular and extra-articular manifestations in RA patients. Osteocalcin is a protein (non-collagenous) that can be found in the bones extracellular matrix, as well as in the circulating blood serum. This protein is a marker of bone formation and turnover.

Objectives: Evaluating IL-6 and osteocalcin serum levels in RA patients and their correlation with disease activity.

Methods: We examined 126 patients previously diagnosed with RA according to the ACR/EULAR 2010 criteria. To all patients it was measured the IL-6 serum level (<4.0 pg/mL) and also the osteocalcin serum level using the ELISA-OSTEO kit method (1346ng/ml) and the disease activity was defined according to the DAS28. By using this activity score index the patients were divided in three groups: group I with active disease scoring > 5.1 (43 patients); group II with moderate disease activity scoring between 3.2 - 5.1 (52 patients); and group III with no disease activity scoring <3.2 (31 patients).

Results: IL-6 serum level resulted elevated in patients group I (1.9±0.6pg/ml) and group II (0.9±0.3pg/ml) and normal in patients group III (0.35 ±0.1pg/ml). Osteocalcin serum level resulted elevated in the three groups but with higher serum levels in patients group I and II (62±1.9ng/ml); 49.2±2.6ng/ml) and less higher serum levels in group III (44.5±1.7ng/ml). IL-6 serum level correlates best with osteocalcin serum level in patients group I and II (r=0.9). IL-6 serum level correlates with disease activity in group I and II (r=0.9) but not with disease activity in group III (r=0.4).

Conclusion: There is a significant correlation between IL-6 serum level and disease activity according to DAS 28 in RA patients. The elevation of osteocalcin serum level correlates with disease activity in RA patients with high and moderate disease activity which is an important finding of the intense bone remodelling, whereas in patients with no disease activity bone remodelling tent to slow down.

IMPLICATIONS OF THE DIFFERENT RESPONSES OF NK CELLS AND MONOCYTES TO IL-6 AND IL-10 IN THE PATHOGENESIS OF ADULT-ONSET STILL’S DISEASE

Koito Sato, Yoshimi Aizaki, Hiroaki Yazawa, Yoshihide Mimura, Sataima Medical University, Department of Rheumatology and Applied Immunology, Saitama, Japan

Background: Adult-onset Still’s disease (AOSD) is a systemic inflammatory disease, the cause of which is largely unknown. AOSD has recently been classified as one of the autoimmune diseases in which innate rather than acquired immunity plays an important role in the pathogenesis. Serum IL-18 has been shown to be highly elevated in AOSD patients [1,2].

Objectives: We attempted to quantify the levels of multiple cytokines in the serum of AOSD patients and to evaluate the effects of the cytokines detectable in the AOSD serum on natural killer (NK) cells and monocytes, since these are cells critical to innate immunity.

Methods: We examined 126 patients previously diagnosed with RA according to the ACR/EULAR 2010 criteria. To all patients it was measured the IL-6 serum level (<4.0 pg/mL) and also the osteocalcin serum level using the ELISA-OSTEO kit method (1346ng/ml) and the disease activity was defined according to the DAS28. By using this activity score index the patients were divided in three groups: group I with active disease scoring > 5.1 (43 patients); group II with moderate disease activity scoring between 3.2 - 5.1 (52 patients); and group III with no disease activity scoring <3.2 (31 patients).

Results: IL-6 serum level resulted elevated in patients group I (1.9±0.6pg/ml) and group II (0.9±0.3pg/ml) and normal in patients group III (0.35 ±0.1pg/ml). Osteocalcin serum level resulted elevated in the three groups but with higher serum levels in patients group I and II (62±1.9ng/ml); 49.2±2.6ng/ml) and less higher serum levels in group III (44.5±1.7ng/ml). IL-6 serum level correlates best with osteocalcin serum level in patients group I and II (r=0.9). IL-6 serum level correlates with disease activity in group I and II (r=0.9) but not with disease activity in group III (r=0.4).

Conclusion: There is a significant correlation between IL-6 serum level and disease activity according to DAS 28 in RA patients. The elevation of osteocalcin serum level correlates with disease activity in RA patients with high and moderate disease activity which is an important finding of the intense bone remodelling, whereas in patients with no disease activity bone remodelling tent to slow down.

OFF-LICENSE USE OF ANAKINRA IN CRITICALLY ILL ADULTS WITH SUSPECTED HAEMOPHAGOCYTOSIS – A SINGLE CENTRE EXPERIENCE

Shabnam Shabbir, Ahmad Ali-Abdulla, Anne Kinderlehrer, Mamta Sohal, Mark Layton, Peter Hill, Richard Corbett, Liz Lightestone, Tom Cairns, Justin Mason, Nichola Cooper, Taryn Youngstein. Imperial College Healthcare NHS Trust, London, United Kingdom

Background: Anakinra is a recombinant interleukin-1 receptor antagonist licensed in Europe for the treatment of rheumatoid arthritis, periodic fever and auto-inflammatory syndromes. It is increasingly recognised as an adjunct in the treatment of macrophage activation syndrome/secondary haemophagocytic lymphohistiocytosis (HLH).[1]

Objectives: To analyse the indication, patient demographic and outcomes of critically unwell patients receiving anakinra for suspected HLH.

Methods: Retrospective cohort analysis of adult patients who received anakinra over a 12-month period at Imperial College Healthcare NHS Trust, London.

Results: Eleven patients received anakinra (both sub-cutaneous and intra-venous, dose range 100–460 mg daily), ten alongside conventional treatments for HLH. 64% were male. Median age at presentation was 32 years (range 27-73 years). Serum ferritin was significantly elevated (median 17371 [range 3435 – 160,664 micrograms per litre]) in all cases. Ten of eleven cases underwent bone marrow examination which showed haemophagocytosis in all cases. Underlying diagnoses were: T-cell Lymphoma (n=3), Mantle Cell Lymphoma (n=1), gastric MALT Lymphoma (n=1), infection (n =3: Group A streptococcus in a patient with inflammatory arthritis (bone marrow not performed), EBV and CMV), retained products of conception (n=1), post-transplant-related lymphoproliferative disorder in a case of systemic lupus with renal transplant (n=1), unknown (n=1).

Overall mortality was 55%. The underlying diagnoses were: T-cell Lymphoma (n=3), gastric MALT Lymphoma (n=1), CMV infection in a post-renal transplant immunosuppressed patient (n=1, sarcoidosis underlying diagnosis), unknown (n=1). 100% of cases with T-cell lymphoma as the cause of HLH died, despite two of the three receiving standard chemotherapy to treat the lymphoma. The third case was diagnosed with non-haptenespecific gamma delta T-cell lymphoma post-mortem. In the five cases that survived, anakinra led to rapid recovery in three cases (underlying diagnoses: Mantle Cell lymphoma (managed entirely steroid free), HLH secondary to retained products of conception, and inflammatory arthritis with Group A streptococcal pneumonia). The two remaining cases had underlying PTLV and EBV-driven HLH. Anakinra led to rapid resolution of fever, improvement in respiration and dramatic decreases in serum ferritin (up to 98% reduction in three weeks).

There were no identifiable complications from anakinra use. One case remains on anakinra, a young male with inflammatory arthritis and Group A Streptococcal pneumonia, who rapidly flared again two days after cessation with full recovery once anakinra was re-instigated.

Conclusion: Anakinra can be a useful adjunct in the treatment of suspected HLH but appears to be less efficacious in those with underlying haematological malignancy, where mortality remains high. In critically ill

PERSISTENCE OF CITSTAT AND TACROLIMUS IN MTPP PATIENTS – A SINGLE CENTRE EXPERIENCE

Catherine Burrows, Fintan Horan, Mark Wilson, Seamus Bodden, Tanya Mcnulty, Paul Murphy, Brian Mcgegan, Andrew Mcgegan, Christina Mcgegan. St James’s Hospital, Dublin, Ireland

Background: Infliximab is licensed for the treatment of adult patients with malignancy, where mortality remains high. In critically ill

Disclosure of Interests: None declared

patients we have used it intravenously, and in higher doses, where the half-life is shorter and twice daily dosing is required. Anakinra was well tolerated and its short half-life makes it ideal for use in suspected sepsis-driven HLH. One case was managed entirely steroid-free using anakinra. This allowed for the identification of an underlying lymphoma which may have missed had high-dose steroids been used. Larger studies will help us ascertain whether earlier anakinra use may spare steroid and chemotherapy side-effects and improve patient outcomes.

Ustekinumab and Guselkumab Treatment
Results in Differences in Serum IL17A, IL17F and CRP Levels in Psoriatic Arthritis Patients: A Comparison from Ustekinumab PH3 and Guselkumab PH2 Programs

Stefan Siebert1, Matthew J Loza2, Qingxuan Song2, Iain McInnes1, Kristen Sweet3, 1Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom; 2Janssen Research and Development, LLC, Spring House, United States of America

Background: Ustekinumab (UST) is a monoclonal antibody (mAb) that binds the p40 epitope which is shared by IL12 and IL23, whereas guselkumab (GUS) is a mAb that selectively binds the p19 subunit of IL23. In recent studies, both UST (Phase 3 programs)1 and GUS (Phase 2 program)2 have demonstrated a reduction in musculoskeletal clinical signs and symptoms and improvement of psoriatic lesions in patients with active psoriatic arthritis (PsA), implicating the IL12/23 pathway in disease pathogenesis.

Objectives: To explore the post-treatment pharmacodynamic changes of IL17A, IL17F, and CRP with GUS and UST in the context of PsA.

Methods: Serum protein levels of IL17A, IL17F, and CRP were measured in 142 subjects and 38 matched healthy controls from the GUS Ph2 study3 at Weeks 0, 4, and 16. In the UST Ph3 studies1, biomarkers were assayed at Weeks 0, 4, and 24 as follows: IL17A (n=474), IL17F (n=237), CRP (n=927). IL17A and IL17F were assayed using Single Molecule CountingTM Human Immunoassay Kits (formerly Singulex). CRP was measured using CardioPhase hsCRP assay (UST studies) or Meso Scale Discovery Platform (GUS study).

Results: At baseline, the Th17 effector cytokines IL17A and IL17F were elevated in the serum of PsA subjects in the GUS Ph2 cohort compared to healthy controls. IL17A and IL17F levels significantly correlated with affected skin body surface area, but not swollen or tender joint scores, in both studies. While none of the baseline levels of evaluated cytokines were associated with American College of Rheumatology (ACR) or Psoriasis Area Severity Index (PASI) clinical responses to UST, baseline IL17F levels were modestly associated with ACR20 response to GUS at week 24. Both UST and GUS treatment resulted in pharmacodynamic decreases in IL17A, IL17F, and CRP levels, with GUS treatment restoring IL17A and IL17F levels to that of healthy controls by week 16. Consistent with being a component of ACR scores, CRP changes were significantly associated with ACR20 responses to both UST and GUS treatment. Weeks 4 and 16 changes in IL17F with GUS treatment were significantly associated with ACR20 response at week 24. Week 24 PASI75 response to GUS was significantly associated with week 4 changes in IL17A, with a similar trend observed at Week 16.

Conclusion: These results underscore the relevance of the IL23/Th17 pathway in PsA, with GUS treatment providing a stronger suppression of the pathway than UST treatment. The significant associations of changes in IL17A in IL17F levels with GUS treatment with PASI75 and ACR20 response, respectively, support the importance of the IL23/Th17 pathway for both skin and joint pathologies. The associations of reduction in CRP levels with both UST and GUS treatment also reinforce the role of acute phase inflammation in joint pathology.

APREMLAST INHIBITS THE TGFB1 MEDIATED TRANSITION OF CULTURED HUMAN SKIN FIBROBLASTS INTO PROFIBROBLASTIC MYOFIBROBLASTS: IN VITRO STUDY

Maurizio Cutolo1, Paola Montagna1, Giulia Martinelii1, Samuele Tardito1, Claudio Coral11, Nicola Giordano2, Emanuele Cozzani3, Carmen Pizzoni3, Sabrina Paolino1, Massimo Patané4, Alberto Sulii1, Elsa Alessandri1, Vanessa Smith1,2, Stefano Soldani1, 1University of Genova, IRCCS Polyclinic San Martino Hospital, Research Laboratory and Academic Division of Rheumatology, Department of Internal Medicine, Genoa, Italy; 2University of Siena, Scleroderma Unit, Department of Medicine, Surgery and Neurosciences, Siena, Italy; 3University of Genova, IRCCS Polyclinic San Martino Hospital, Department of Health Science, Unit of Dermatology, Genoa, Italy; 4Ghent University Hospital, Department of Internal Medicine, Ghent, Belgium; 5VIB Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium

Background: Fibroblast-to-myofibroblast transition and extracellular matrix (ECM) is a perpetually recurring fundamental event in chronic inflammation, that characterise several diseases, including psoriasis (1,2). Transforming growth factor-β1 (TGFB1), plays an important role as a profibrotic mediator (3).

Phosphodiesterases (PDE4) act as proinflammatory enzymes via degradation of cAMP. PDE4 are expressed in normal skin fibroblasts (Fs) and overexpressed in psoriatic skin Fbs and myofibroblasts (2).

Objectives: This study investigated how apremilast (an oral PDE4 inhibitor small molecule used for the treatment of psoriasis and psoriatic arthritis) might interfere with intracellular signalling for the fibroblast-to-myofibroblast transition and the synthesis of profibrotic ECM proteins induced by TGFB1 in primary cultures of healthy human skin Fbs.

Methods: Human skin Fbs isolated from Non-cultured healthy subjects after signing informed consent and EC approval. The cultured Fbs were stimulated with TGFB1 10ng/ml alone or in combination with apremilast 1μM and 10μM for 4, 16, and 24 hours. Other aliquots of Fbs were also previously stimulated with TGFB1 for 4 hours and then treated with apremilast 1μM and 10μM for 4, 16, and 24 hours always in the presence of TGFB1. Genes and related protein expression of α-smooth muscle actin (αSMA), type I collagen (COL-1) and fibronectin (FN) were investigated by qRT-PCR and Western blotting (WB). Smad proteins (the main signal transducers for receptors of TGFB1) and extracellular signal-regulated kinases (ERKs), which are implicated in mediating TGFB1 effects, were investigated by WB after 15, 30 and 60 minutes of apremilast 1 stimulation.

Results: Apremilast significantly downregulated the phosphorylation of Smad 2 and 3, at 15 minutes, and that of Erk1/2, after 30 minutes (p<0.05), both induced by TGFB1 stimulation in cultured skin Fbs. Apremilast significantly downregulated the TGFB1-induced increase in the gene expression of αSMA, COL-1 and FN at 4 and 16 hours, and the related protein synthesis after 24 hours (p<0.05) in cultured skin Fbs (treated in combination with TGFB1). Similar effects were observed in differentiated myofibroblasts treated with apremilast.

Conclusion: Apremilast inhibited the fibroblast-to-myofibroblast transition in vitro, as well as the profibrotic activity induced by TGFB1 in cultured skin Fbs by downregulating specific intracellular signalling pathways Smad 2/3 and Erk1/2. These results might partially explain some of the downregulating effects on skin Fbs overactivity during treatment of skin lesions of psoriasis and that of psoriatic patients with apremilast.

THU0053

APREMLAST INHIBITS THE TGFB1 MEDIATED TRANSITION OF CULTURED HUMAN SKIN FIBROBLASTS INTO PROFIBROBLASTIC MYOFIBROBLASTS: IN VITRO STUDY

Thursday, 13 June 2019 293

Scientific Abstracts
THE SYNOVIAL FLUID FROM RHEUMATOID ARTHRITIS PATIENTS CONTAINS SOLUBLE TAM RECEPTOR TYROSINE KINASES OF WHICH SOLUBLE TYRO3 AND ITS LIGAND GAS6 CORRELATE WITH THE PROINFLAMMATORY CYTOKINE LEVELS

Julia Vulling, Claire Waterborg, Marjole Koenders, Peter van Lent, Peter van der Kraan, Fons van de Logt, Radboud Institute for Molecular Life Sciences (RIMLS), Rheumatology, Nijmegen, Netherlands

Background: We recently showed that the tyrosine-protein kinase receptors MER and AXL, both members of the TAM (including TYRO3) receptor family, play a protective role in mouse models of rheumatoid arthritis (RA) [1, 2]. In both humans and mice, TAM receptors can be proteolytically cleaved from the cell membrane and shed as a soluble (s) receptor. These sTAM receptors may act as decoy receptors, bind their ligands Growth Arrest-Specific 6 (GAS6) and Protein S (PROS1), and thereby inhibit the immunoregulatory and anti-inflammatory effect of TAM receptor activation, and prevent TAM receptor-mediated phagocytic clearance of dying cells.

Objectives: To determine the soluble TAM receptor levels in synovial fluids from RA and osteoarthritis (OA) patients and correlate this to the inflammatory process.

Methods: The level of sMER, sAXL, sTYRO3, GAS6, IL-8, TNFα and IL-1β was measured in synovial fluids of RA (n = 28) and OA patients (n = 12) by ELISA or multiplex array. Synovial explants were cultured for 24 hrs and the release of sMER and GAS6 was measured by ELISA. Human synovial explants of RA (n = 15) and osteoarthritis (OA) (n = 17) patients were immunostained for MER.

Results: Soluble MER and sTYRO3 were significantly enhanced in synovial fluids (P = 0.0001 and P = 0.0042) of RA patients as compared to OA patients. The sAXL and GAS6 levels in synovial fluid of RA and OA patients was equally high (P = 0.267 and P = 0.074). In RA patients, but not in OA patients, the synovial fluid levels of sTYRO3 and GAS6 (a ligand for all three TAM receptors) positively correlated with TNFα (r=0.555, r=0.477), IL-1β (r=0.597, r=0.481) and IL-8 (r=0.567, r=0.529). Soluble MER levels, however, did not correlate with local inflammatory markers. Although synovial explants from RA released more sMER into the culture media than explants from OA (P = 0.0045), the explants of both RA and OA patients contained comparable amounts of immunopositive MER cells.

Conclusion: We showed that synovial fluid sTYRO3 and GAS6 levels correlates with higher proinflammatory cytokine levels in RA but not in OA patients. This is in line with the recent observation done by Xu et al. [3], that circulating levels of sTYRO3, but not sMER or sAXL, correlates with disease activity and bone destruction in RA patients. In accordance to serum, the synovial sMER levels were significantly higher in RA than in OA patients with sAXL levels comparable between both patient groups. Interestingly, only for sMER the synovial fluid levels were much higher than in serum suggesting local production as we confirmed in the synovial explants cultures. This illustrates that release of soluble TAM receptors is either the results of different processes (enzymatic shedding or alternative splicing isoforms) or reflect the different cell populations in the arthritic joint. We found that naive macrophages express high MER and inducible AXL, while synovial fibroblast express high AXL and TYRO3. Further studies are warranted to determine if sMER levels impair the clearance of apoptotic cells in the arthritic joint as we have found in our mice studies. Our study shows that synovial sTYRO3 is a marker for joint inflammation and possibly a novel therapeutic target for RA.

THU0055 TPL2 INHIBITION SUPPRESSES MEK-ERK INFLAMMATORY SIGNALING AND PROINFLAMMATORY CYTOKINE PRODUCTION IN PRIMARY HUMAN MONOCYTES

Matthew R. Warr, Angie Hammond, Grace Park, Nathan Wright, James Taylor, Gilead Sciences, Inc., Foster City, United States of America

Background: Tumor progression locus 2 (TPL2, also known as MAP3K8) is a mitogen-activated protein kinase kinase kinase and the primary regulator of ERK-mediated gene transcription downstream of multiple proinflammatory stimuli including bacterial products (eg, LPS and bacterial peptidoglycans), damage-associated molecular patterns (DAMPs), TNFα, and IL-1β.1 Dysregulated signaling downstream of these inflammatory signals can drive uncontrolled immune cell activation and inflammation, which is associated with multiple chronic inflammatory and autoimmune diseases. As such, TPL2 inhibition represents a strategy to modulate inflammation in a variety of disease settings.

Objectives: We evaluated the effect of a highly selective TPL2 inhibitor on inflammatory signaling and cytokine production in LPS and TNFα-stimulated primary human monocytes.

Methods: Monocytes were precultured with a TPL2 inhibitor and stimulated with LPS or TNFα, and phospho-signaling and cytokine production were then evaluated at 30 minutes and 4 hours poststimulation. A431 cells (human epidermoid carcinoma cell line) were stimulated with TNFα or EGF and phospho-ERK was evaluated after 30 minutes.

Results: TPL2 inhibition selectively inhibited LPS and TNFα-stimulated phosphorylation of TPL2, MEK, and ERK, with little to no inhibition of phosphorylated p38, JNK, or p65 observed. TPL2 inhibition similarly inhibited both the RNA production and secretion of TNFα, IL-1β, IL-6, and IL-8 following LPS stimulation in primary human monocytes. To confirm TPL2 requirement for inflammation, but not Ras-mediated (growth factor stimulated) ERK signaling, A431 cells were stimulated with either TNFα or EGF. Although TPL2 inhibition reduced TNFα-stimulated pERK, no effect on ERK activation downstream of EGF was observed.

Conclusion: This work demonstrates the selective effects of TPL2 inhibition on ERK-mediated signaling and proinflammatory cytokine gene transcription in primary human monocytes and highlights the potential for TPL2 inhibition to treat diseases associated with dysregulated inflammatory signaling and chronic inflammation.

THU0056  EFFECTS OF CX3CL1 INHIBITION ON MURINE BLEMÖYCM-INUCDED INTERSTITIAL PNEUMONIA
Sochi Yamada1,2, Shin Miyoshi1,2, Natsuko Kusunoki1,2, Hiroshi Sato1, Yoshikazu Kubo1, Kana Hoshino-Negishi1, Naoto Ishii1, Toshiro Inami1, Tetsuo Mikami1, Hiroyasu Nakano1, Shinichi Kawai1, Toshihiro Nanki1,2. 1Toho University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 2Toho University Graduate School of Medicine, Department of Internal Medicine, Tokyo, Japan; 3Toho University School of Medicine, Department of Respiratory Medicine, Tokyo, Japan; 4Toho University School of Medicine, Department of Biochemistry, Tokyo, Japan; 5Toho University School of Medicine, Department of Inflammation and Pain Control Research, Tokyo, Japan; 6KAN Research Institute, Inc., Kobe, Japan; 7Toho University School of Medicine, Department of Pathology, Tokyo, Japan

Background: Pathological findings of interstitial pneumonia (IP) reveal the accumulation of inflammatory cells and proliferation of fibroblasts in lung tissue. Although a treatment has not yet been established for IP, particularly for IP with collagen diseases, chemokines may play a role in the pathogenesis of IP for inflammatory cell infiltration. We previously reported that chemokine (C-X-C motif) ligand 1 (CXCL1, also known as fractalkine) has potential as a therapeutic target for rheumatoid arthritis (RA).1,2,3 Humanized anti-human CX3CL1 monoclonal antibody (mAb) is currently undergoing clinical trials for RA.4

Objectives: In the present study, we examined the therapeutic effects of CX3CL1 blockade in amurine model of IP.

Methods: Bleomycin (BLM)-induced IP was developed by the intratracheal administration of BLM to C57BL/6 mice. The murine lung was stained with hematoxylin and eosin, and the expression of CX3CL1 and CX3CR1, a receptor for CX3CL1, was examined with immunohistochemistry. Mice were treated with anti-CX3CL1 mAb for 2 weeks. Collagen eluted from the lung was quantified using the Sircol Collagen Assay. The expression of CX3CL1 and CX3CR1 by mouse lung fibroblasts (MLFs) was examined with quantitative RT-PCR and Western blotting, respectively. Cell movement was investigated using the scrape motility assay.

Results: The expression of CX3CL1 and CX3CR1 was upregulated in BLM-induced IP. The treatment with anti-CX3CL1 mAb did not significantly alter inflammatory cell infiltration. However, collagen in the lung was decreased by the treatment with anti-CX3CL1 mAb. Stimulation with CX3CL1 did not alter the in vitro production of collagen by MLFs, but significantly enhanced cell movement.

Conclusion: CX3CL1 may be involved in increasing collagen in IP and the cell movement of MLFs. The present results suggest that CX3CL1 plays an important role in fibrosis in IP.

Cell movement was investigated using the scrape motility assay.

THU0057  PLASMACYDID DENDRITIC CELLS IN THE ENTHESIS: PHENOTYPIC AND FUNCTIONAL INVESTIGATION
Qiao Zhou1, Richard Cutbrell1, Abdulla Watabd,2, Tobias Russell1,2, Hannah Rowe1, Almas Khan1, Peter Millner1, Peter Lougherub, Abhay S Rao1, Robert Dunsmit1, Charlie Bridgewood1, Dennis Mogonagle1. 1Leeds Biomedical Research Centre and Leeds Institute of Rheumat and Musculoskeletal Medicine, Leeds, United Kingdom; 2Sichuan Provincial People’s Hospital, Rheumatology and Immunology, Chengdu, China; 3Tel Aviv University, Tel Aviv-Yafo, Israel; 4Leeds General Infirmary, Leeds Teaching Hospitals NHS Trust, Department of Neurosciences, Leeds, United Kingdom

Background: Plasmacytoid dendritic cells (pDCs) play an important role in linking innate and adaptive immune responses and selectively express Toll-like receptor (TLR) 7 and TLR9 that sense RNA and DNA respectively thus regulating the secretion of type I interferons (IFN) and other inflammatory cytokines such as TNF.1,2 pDCs have been directly implicated in psoriasis immunopathology and are activated following anti-viral vaccination, with vaccination also linked to psoriatic arthritis onset.3,4 Inflammation of the enthesis (enthesitis) is a cardinal spondyloarthritides associated lesion so we hypothesized the presence of enthesis resident pDCs

Objectives: To investigate whether the human enthesis contains a resident pDC population and to compare the responses of TLR7/9 agonists on entheseal pDCs function relative to peripheral blood derived pDCs.

Methods: Normal interspines process enthesis and matched peripheral blood (PB) were obtained from patients (n=11) undergoing spinal decompression or sclerosis corrective surgery. Cells were isolated from peritenethese bone by mechanical digestion. Cells were stimulated with either TLR7 agonist (imiquimod) or TLR9 agonist (ODN-2216). Flow cytometry was used to phenotype pDCs, and intracellular staining used to measure IFNα and TNF. IFNα from supernatant was also measured by ELISA.

Results: pDCs were identified in the human enthesis with a typical phenotype (CD45+HLA-DR+CD123+CD303+CD11c+). By intracellular FACS, following ODN or imiquimod stimulation, IFNα and TNF was detected in entheseal pDCs and also PB. IFNα and TNF induction trended upwards in entheseal pDC when compared with unstimulated pDCs. IFNα was also detected by ELISA following ODN or imiquimod stimulation of entheseal derived pDCs.

Conclusion: The human enthesis contains a resident population of pDCs that produce IFNα and TNF following induction with relevant TLR agonists. For the first time, our findings provide a link between viral infection and vaccination and pivotal innate immune cell production of IFNα and TNF.

TUNALPHA INDUCES NECROTOPSIS-LIKE DEATH OF MACROPHAGES AND PROMOTES EXTRACELLULAR RELEASE OF 14-3-3TA

Guilah Shimizu1, Kaoru Yamagata1, Shigeru Iwata1, Tong Zhang2, Fumi Uemura1, Minoru Satoh3, Michelle Zaharia4, Norma Bilin5, Shinaro Hirata6, Shingo Nakayama7, Yoshiya Tanaka8, University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan; 2University of Occupational and Environmental Health, Japan, Department of Clinical Nursing, School of Health Sciences, Kitakyushu, Japan; 3Augurex Life Sciences Corp, North Vancouver, BC, Canada; 4Hiroshima University Hospital, Hiroshima, Japan

Background: 14-3-3α is an intracellular protein detected in the serum and synovial fluid of patients with rheumatoid arthritis (RA) [1]. While presence of 14-3-3α is both diagnostic for early and established RA [2,3], and prognostic for radiographic progression [3], the mechanism of 14-3-3α externalization in RA remains unclear.

Objectives: To clarify the mechanism of externalization of 14-3-3α into the extracellular space using human PBMC-derived macrophages (Mϕ).

Methods: Distribution of 14-3-3α in synovial tissue of patients with RA or osteoarthritis (OA) was examined by immunohistochemistry; cellular morphology was studied by confocal microscopy and electron microscopy (EM). Mϕ were stimulated with TNF-α, Diamide (induces ligand-independent TNF signalling) or IL-6/sIL-6R. Western blotting was used to detect S-358-phosphorylated MLKL (a mediator of necroptosis) and presence of 14-3-3α in Mϕ culture supernatants.

Results: Dense and punctuate staining of 14-3-3α was detected in Mϕ, but not OA, synovial tissues. 14-3-3α and peptidylarginine deiminase 4 (PAD4) co-localized in CD68+ cells (Mϕ) from RA synovial tissue; 14-3-3α was not detected in CD68+ cells from RA lung tissue or CD4+ cells (T cells) from RA synovium. The outer space around the nucleus of healthy control Mϕ treated with TNF-α or Diamide, but not IL-6/sIL-6R, demonstrated abnormal actin distribution by phalloidin staining and presence of cellular and organelle swelling by EM. Further, magnified images showed partial destruction of the cell membrane in TNF-α and Diamide-treated cells. Phosphorylation of MLKL was observed between 20 min and 24 h after stimulation of healthy control Mϕ with TNF-α, with maximum signal at 8 h post-stimulation, but was not observed upon IL-6/sIL-6R stimulation at any time point. After 8 h of stimulation no 14-3-3α was detected in the culture supernatant of healthy control Mϕ endogenously expressing 14-3-3α or Mϕ stimulated with IL-6/sIL-6R, while a high concentration of 14-3-3α was detected in culture supernatants in Mϕ treated with TNF-α or Diamide.

Conclusion: 14-3-3α protein was abundant in RA, but not OA, synovial tissues and co-localized with PAD4 in CD68+ synovial Mϕ; this close proximity to PAD4 may promote citrullination of 14-3-3α in vivo. Treatment of healthy control Mϕ with TNF-α induced phosphorylation of MLKL and cell swelling and disintegration of the plasma membrane characteristic of necroptosis, correlated with the release of intracellular 14-3-3α protein into cellular supernatants. Our results shed light on mechanism of externalization of 14-3-3α and how it achieves elevated levels in RA synovial fluid.

B CELL SYNOVITIS AND CLINICAL PHENOTYPES IN RHEUMATOID ARTHRITIS AT DIFFERENT DISEASE STAGES

Felice Rivellesi1, Frances Hubmyr2, Liliane Fossati-Jimack1, Hasan Rizvi3, Davide Lucchesi1, Gloria Lliso Ribera1, Alessandra Nerviani1, Rebecca Hands1, Giovanni Giorli1, Barbara Fris6, Edyta Jaworska1, Katriona Goldmann1, Myles Lewis2, Antonio Manzo3, Michele Bombardieri2, Costantino Pitzalis1, Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom; 3University of Pavia, IRCSS Policlinico San Matteo Foundation, Pavia, Italy; 4Barts Health NHS Trust, Department of Pathology, London, United Kingdom

Background: The role of B cells in the pathogenesis of Rheumatoid Arthritis (RA) is well recognised and has been reinforced by the established efficacy of B cell depleting treatments. However, B cell infiltration in synovia is highly variable and their association with clinical disease activity has been inconsistently reported, with contrasting results possibly linked to the lack of standardization in quantitative and qualitative assessment of B cell synovitis. In particular, the presence of B cells in synovia has never been systematically assessed in large cohorts.

Objectives: To evaluate B cells and their association with clinical phenotypes in the synovia of patients with RA at various disease stages.

Methods: A total of 432 synovial biopsies from the following cohorts of RA patients were analysed: i. early (<1 year) treatment-naïve RA (n=165), ii. Synthetic Disease-Modifying Anti-Rheumatic Drugs (SDMARDs) responders (SDMARDS-ir) (n=103), iii. TNF-Infinites inhibit responders (TNFi-ir) (n=164). Haematoxylin and eosin staining was used for the assessment of synovitis according to a previously validated score (Krenn). Upon immunohistochemical staining for CD20, semi-quantitative (Sq) scoring (0-4) was used to classify patients into B cell rich (≥ 2) and poor (< 2) and automated digital image analysis (DIA) to calculate the B cell area fraction. B cell expression markers, including CD20 mRNA counts and a composite B cell module, were obtained by RNA-sequencing from early RA synovial biopsies (n=91).

Results: Semi-quantitative synovial B cell scores positively correlated with the B cell area fraction obtained by DIA (Spearman r 0.93 in early RA and 0.88 in TNFi-ir, p<0.0001). Accordingly, B cell rich patients (Sq score ≥ 2) had a significantly higher B cell area fraction (p<0.0001). RNA-sequencing from 91 patients with early RA showed a positive correlation between the Sq B cell scores and CD20 mRNA counts and the B cell module (Spearman r=0.6 and 0.67, respectively, p<0.0001). Similarly, a positive correlation was found between the B cell area fraction obtained by DIA and CD20 mRNA counts and B cell module (r=0.67 and 0.69, respectively, p<0.0001). When comparing B cell presence in the three cohorts, B cell-rich synovitis was present in 35% of early RA, 36% of SDMARDS-ir and 47.1% of TNFi-ir (p=0.025 comparing early RA vs late-stage TNFi-ir patients). Finally, while B cell-rich patients showed significantly higher synovial inflammatory scores across all cohorts, higher disease activity (number of active joints, DAS28) and higher prevalence of autoantibody positivity (ACPA and RF) in B cell-rich patients were observed exclusively in the early RA cohort.

Conclusion: We here describe a robust and validated synovial B cell score that can potentially contribute to patient stratification in RA, as it helps identifying an enrichment of B cell synovitis in established disease, uncoupled from clinical disease activity.

DANBIO, nationwide, Denmark

Background: Biologics have improved several clinical, patient-reported and radiological outcomes in patients with rheumatoid arthritis (RA), but little is known about the potential impact on the need for joint replacement surgery.

Objectives: To investigate the incidence of joint replacement surgery among biologics treated compared with biologics naïve patients with RA.

Methods: A nationwide, register-based propensity score matched cohort study. RA patients registered between 2006 and 2016 in the DANBIO register with a disease duration ≤ 2 years were identified. Patients initiating their first treatment series with biologics were followed up to 10 years for a first joint replacement of the hip, knee, shoulder, elbow and finger/wrist. Biologics naïve patients were followed up for the same outcome from their first clinical visit registered in DANBIO. Following a 1:1 propensity score matching, Cox-models were undertaken to calculate the hazard ratio (HR) for a first joint replacement surgery among biologics compared with non-biologics treated RA patients. Further, subgroup analyses based on within-strata propensity score matched patients were carried out. All information on surgical outcomes was obtained in the Danish National Patient Registry.

Results: In total, 1187 biologics treated were matched with 3666 non-biologics treated patients (See Table).

Abstract THU0059 – Table1. Baseline characteristics of biologics treated and biologics naïve patients with rheumatoid arthritis and a disease duration < 2 years registered in DANBIO between 2006 and 2016.

Disclosure of Interests: René Cordtz: None declared, Samuel Hawley: None declared, Daniel Prieto-Alhambra Grant/research support from: Grants from Amgen, UCB Biopharma and Servier outside the submitted work, Consultant for: UCB Biopharma, Speakers bureau: Amgen, Lars Erik Kristensen Grant/research support from: UCB, Biogen, Janssens Pharmaceuticals, and Novartis, Consultant for: Consultant for Abbvie, Amgen, Biogen, BMS, Cellgene, Eli Lilly, Janssens Pharmaceuticals, MSD, Novartis, Pfizer, Roche, Sanofi, and UCB Pharma., Speakers bureau: Pfizer, Abbvie, Amgen, UCB, BMS, Biogen, MSD, Novartis, Eli Lilly and Company, and Janssens Pharmaceuticals, Søren Overgaard: None declared, Anders Odgaard: None declared, Lene Dreyer Consultant for: MSD, UCB and Janssens Pharmaceuticals, Speakers bureau: MSD, UCB and Janssens Pharmaceuticals, Speakers bureau: UCB, MSD, Eli Lilly and Janssens Pharmaceuticals.

Methods: Synovial tissue (ST) was sampled by Parker-Pearson needle biopsy from 67 RA patients who had completed one year follow-up from a prospective RA cohort. ST from 13 patients with orthopedic arthropathies (Orth. A) with arthropathy or arthroscopy were used as control. Expression of MUC1 in ST was assessed by immunohistochemistry (IHC). Radiographic assessments of hand/wrist at baseline and month 12 were performed with the Sharp/van der Heijde-modified sharp score. Radiographic joint damage (RJD) was defined as total modified Sharp score (mTSS) >10. Radiographic progression (RP) was defined as a change of mTSS more than 0.5 units.

Results: 1. Both nuclear and cytoplasmic MUC1 expression were observed in lining and sublining cells of synovium. The percentage of MUC1+ lining cells was significantly higher in RA (median 65.4%, IQR 53.6% 73.2%) than that in Orth. A (median 43.1%, IQR 34.1% 68.4%, P <0.05).

2. Thirty-five (52%) RA patients showed RJD at baseline and their MUC1expression in lining layer was significantly enhanced compared with RA patients without RJD (median 69.6%, IQR64.5% 76.8% vs. median 58.9%, IQR 39.8% 67.9%, P <0.01). Spearman’s rank order correlation test showed significantly positive correlations between the percentage of MUC1+ lining cells with mTSS, joint space narrowing (JSN) and joint erosion (JE) subcore at baseline (r =0.303-0.426, all P < 0.05).

3. Furthermore, twenty-two(33%) patients suffered from one-year RP and they showed significantly higher percentage of MUC1+ lining cells than non-progressive patients (median 71.2%, IQR 55.2% 75.2% vs. median 64.1%, IQR 55.2% 75.2%, r <0.01). The percentage of MUC1+ lining cells was positively correlated with JSN, JSN and JE subcores at month 12 (r =0.310-0.405, all P <0.05). ROC curve analysis showed that the tradeoff value of MUC1+ lining cells for predicting one-year RP was 69% with sensitivity 72% and specificity 71% (AUC=0.661, 95% CI:0.516-0.805, P=0.034). Univariate logistic regression analysis showed that high MUC1+ lining cells was a significant predictor of one-year radiographic progression (OR: 5.893, 95%CI: 1.934-17.956, P=0.002).

Conclusion: Our data showed elevated MUC1expression in RA synovial lining cells was positively correlated with joint damage and predicted one-year radiographic progression, which imply that MUC1 might be involved in the pathogenesis of RA joint destruction.

THU0061

IN OVERWEIGHT SUBJECTS, SERUM ADIPONECTIN PREDICTS THE DEVELOPMENT OF RHEUMATOID ARTHRITIS INDEPENDENTLY OF OTHER ADIPOKINES

Yuan Zhang1, Linda Johansson2, Anna Rudin1, LenaCarlsson1, Solbritt Rantapää Dahlqvist1, Cristina Maglio1.

1University of Gothenburg, Department of Rheumatology and Inflammation research, Gothenburg, Sweden; 2University of Umeå, Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden

Background: Adipokines, such as adiponectin, leptin, resistin and visfatin, are cytokines produced by the adipose tissue and involved in metabolism and inflammation1. Adiponectin is elevated in both serum and synovial fluid of subjects with rheumatoid arthritis (RA), suggesting a possible role of this adipokine in the pathogenesis of RA 2-3. Circulating levels of leptin, resistin, and visfatin are also higher in subjects with RA compared to controls.

Objectives: Aim of this study was to determine if adiponectin, leptin, resistin, and visfatin predict the development of RA.

Methods: Two nested-case control studies were performed including pre-symptomatic participants of two cohorts from Sweden: the Swedish Obese Subjects (SOS) study and a cohort of individuals identified within the Medical Biobank of Northern Sweden. The SOS is a clinical trial including 4047 subjects with obesity4. During a follow-up for up to 29 years, 92 subjects developed RA. Among those 92 subjects, 82 subjects with available serum at baseline were matched 1:5 with 410 subjects who did not develop RA during follow-up. Matching was based on baseline age, sex, body-mass index (BMI), bariatric surgery yes/no, year of inclusion, and smoking. A nested case-control study of 88 sex- and age-matched pairs was performed within the Medical Biobank of Northern Sweden using blood samples donated before the onset of the first RA symptoms. The pre-dating time before onset of symptoms of RA was 8.5±5.0 years5.

Baseline serum levels of adiponectin, leptin, resistin, and visfatin were measured using the Quantikine ELISA kit from R&D Systems (Wiesbaden, Germany). Visfatin could not be measured in the Biobank cohort, due to lack of serum. Both binary logistic as well as conditional logistic regression analyses were used to determine if adipokines were elevated years before the onset of RA.

Results: In a multivariable analysis including adiponectin, leptin, resistin, visfatin performed in the SOS cohort, serum adiponectin was associated with a higher risk for RA independently of other adipokines (Odds ratio, OR, 1.1, 95% confidence interval, CI, 1.0-1.1, p value=0.01). Leptin, resistin and visfatin levels were not associated with the risk of RA.

In the Biobank cohort, no association between adipokines and risk for RA was detected. However, when stratifying the population according to BMI, in the subgroup having BMI≥25 (n=109), adiponectin levels were associated with higher risk for RA (OR 1.2, 95% CI 1.0-1.36, p=0.03), independently of leptin and resistin levels. Virtually the same results were obtained in both the SOS and the Biobank cohorts when conditional logistic regression analysis was used.

Conclusion: Our results suggest that higher serum adiponectin levels predict the development of RA in subjects with overweight/obesity.

Background: Antibodies against citrullinated proteins (ACPA) are present months to years before the clinical manifestation of rheumatoid arthritis (RA). ACPA+ individuals are at 8-10x higher risk of developing RA compared to seronegative individuals. EUULAR characterised individuals with arthralgia suspicion for progression to RA based on their clinical features (clinically suspect arthralgia, CSA).

Objectives: The alteration of natural killer (NK) cells and monocyte subpopulations in patients with established RA has been previously described. We therefore aimed to study the lymphocyte and monocyte subpopulations in the preclinical phase of RA.

Methods: Our study included 49 individuals with arthralgia (mean age 45.9±7.119.5 years; 92% females) and 80 age and gender matched healthy controls (HC). Leukocytes from peripheral blood were analysed by flow cytometry. Lymphocyte subpopulations were defined as B (CD19

PRE-MRNA SPlicing ALTERATIONS IN POLYPOLYGLUTAMATE SYNTHETASE IN BLOOD CELLS OF EARLY RHEUMATOID ARTHRITIS PATIENTS ARE ASSOCIATED WITH UNRESPONSIVENESS TO METHOTREXATE

Ittai Muller1, Marry Lin1, Willem Lems2,3, Marieke Ter Wee2,3, Jacqueline Cloos4, Yehuda Assaraf5, Gerrit Jansen2, Robert De Jonge1.

1Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Clinical Chemistry, Amsterdam, Netherlands; 2Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Rheumatology, Amsterdam, Netherlands; 3Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Infection and Immunity Institute, Amsterdam, Netherlands; 4Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands; 5Aalborg University, Aalborg Universitet Hospital, Aalborg, Denmark

Background: Low-dose methotrexate (MTX) serves as the first-line treatment for rheumatoid arthritis (RA). Conversely, for hematological malignancies, high-dose MTX treatment is indicated in combination with folinic acid/leucovorin to prevent untoward toxicity. For both disease modalities, efficient pharmacological response critically depends on the retention and accumulation of intracellular MTX. The latter process is mediated by the enzyme poly(ADP-ribose)polymerase (PARP) through MTX conversion into MTX-polyglutamates (MTX-PG). As such, decreased FPGS activity has been recognized as a mode of MTX resistance, but the underlying molecular mechanism has not yet been pinpointed [1,2]. Recently, aberrant pre-mRNA splicing of FPGS in acute lymphoblastic leukemia cells was associated with reduced FPGS activity, decreased MTX-PG accumulation and lower overall survival. Specifically, a partial retention of FPGS intron 8 (8PR) was identified as a prominent splice variant causing FPGS dysfunction [3].

Objectives: To investigate whether the expression of the FPGS pre-mRNA variant partial retention of intron 8 is associated with MTX unresponsiveness in RA patients over 3-6 months of MTX therapy.

Methods: Patients were enrolled from the COBRA-light trial comprising MTX treatment [4]. After informed consent, blood was obtained from 38 patients in either the COBRA (n=15) or the COBRA-light (n=23) treatment arm [4] and collected in Paxgene tubes for RNA isolation. Two patients were excluded due to insufficient sample quality. Quantitative PCR techniques were used to assess the ratios of FPGS 8PR over wild type FPGS (8WT) expression in whole blood RNA. Remission was defined as a DAS44 < 1.6.

Results: Baseline ratios of 8PR/8WT were associated with a decline in DAS44 at T3 (p=0.001) and T6 (p=0.13) in the COBRA-light patients. T3 ratios were also associated with DAS44 at T6 (p=0.001) and DAS44 at T6 (p=0.26). Logistic regression analysis showed that in COBRA-light patients baseline ratios of 8PR/8WT were associated (p=0.05) with the probability of T3 remission but not T6 remission. T3 ratios of 8PR/8WT in COBRA-light patients were similarly associated with T6 remission but not with T3 remission. COBRA patients also showed a significant association between baseline 8PR/8WT ratios and DAS44 at T6 (p=0.04) while T3 ratios of 8WT/8PR were significantly associated with DAS44 at T3 (p=0.03) and B2 (p=0.05). However, analysis of COBRA patients showed no significant associations between baseline 8PR/8WT ratios and T3/T6 remission, nor associations between T3 ratios and T3/T6 remission.

Conclusion: These results demonstrate that a higher expression of an intron 8 retention of FPGS mRNA is associated with a higher DAS44 at T3 and T6 in COBRA-light patients, and at T6 for COBRA patients. Moreover, in COBRA-light patients, baseline expression of WT/8PR is significantly associated with remission at T3 or T6. This study is the first to show the impact of FPGS pre-mRNA splicing alterations in relation to unresponsiveness to MTX treatment in RA.

REFERENCE:
the model were excluded. Furthermore, the patients with both RA and diabetes were not included in the analysis (n=33). Participants with neither RA nor diabetes were defined as controls.

RA patients, diabetes patients and controls were compared using Cox proportional hazard regression modelling, with age as the time scale. The model was adjusted for sex, smoking status, previous CVD, body mass index (BMI), hypertension, total cholesterol and creatinine. To obtain proportional hazards, an interaction term with age ≤75 years vs >75 years was included for diabetes, smoking and previous CVD. The effects of the groups were compared using overlap of confidence intervals.

Background: Recent studies have shown divergent associations between rheumatoid arthritis (RA)-associated autoantibodies and RA onset phenotype. Whereas some studies report more inflammation in seronegative patients [1, 2], others report that rheumatoid factor (RF) associates with high baseline disease activity [3].

Objectives: To define how individual RA-associated autoantibodies associate with individual disease activity score (DAS28, DAS28CRP) components at the time of RA diagnosis.

Abstract THU0066 – Figure 1

effect of RF on ESR increased with the number of individual ACPO activities present, most prominently for IgM RF (figure).

Conclusion: In early RA, ACPO associate with low counts of affected joints and IgM RF associates with elevated ESR in an ACPO-dependent manner. The latter finding relates to in vitro studies showing enhanced inflammatory effect of ACPO immune complexes with addition of RF[4, 5]. Future RA studies relating autoantibodies to disease activity may benefit from evaluating the impact of individual antibodies as well as distinct DAS components separately.

THU0067 THREE-MONTH RADIOLOGICAL CHANGES IN WRIST JOINT MEASURED BY MRI AND HR-PQCT CAN PREDICT 12-MONTH CHANGES IN EROSION AND FUNCTIONAL OUTCOMES AFTER MTX AND ANTI-TNF TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS: A MULTI-MODALITY IMAGING STUDY

Kenri Mamoto1,2, Tomohiro Shimizu3, Matthew Tanaka4, Valentina Pedoia4, Andrew Burghardt4, Ursula Heilmeier4, Thomas Link5, Jonathan Graf5, John Imboden6, Li Xiaojian7. Cleveland Clinic, Biomedical Engineering, Program of Advanced Musculoskeletal Imaging (PAMI), Cleveland, United States of America; 2Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; 3Hokkaido University Medical School, Orthopaedic Surgery, Sapporo, Japan; 4University of California San Francisco, Radiology and Biomedical Imaging, Musculoskeletal Quantitative Imaging Research, San Francisco, United States of America; 5University of California San Francisco, Medicine, Division of Rheumatology, San Francisco, United States of America

Background: Magnetic resonance imaging (MRI) provides noninvasive methods to quantify joint inflammation and early cartilage degeneration in patients with rheumatoid arthritis.

Methods: Seventeen RA patients with MTX treatment were recruited into a cohort and evaluated their association with the presence of other autoantibodies and disease activity and severity.

Results: Anti-Carbamylated antibodies (Anti-CarP) represent a novel autoantibody family present in sera of patients with rheumatoid arthritis (RA) with high specificity.

Objectives: To investigate if changes in MR measures from baseline to 12-month (12M) in RA patients receiving methotrexate (MTX) and anti-tumor necrosis factor alpha (Anti-TNFa) therapy using MRI and HR-pQCT.

Conclusions: The results suggest that multimodality quantitative imaging with MRI and HR-pQCT provides powerful tools for evaluating early changes and predicting disease progression and therapy response after treatment in RA. Large scale studies with larger sample size are warranted to confirm the observations.

THU0068 ANTI-CARBAMYLATED ANTIBODIES ARE ASSOCIATED WITH TOBACCO AND POOR OUTCOMES IN RHEUMATOID ARTHRITIS

Raul Castellanos-Moreira1, Sebastian C Rodriguez-Garcia1, Virginia Ruiz2, Oscar Camacho1, Julio Ramirez3, Andrea Cuervo3, Cristina Garcia-Moreno2, Rosa Morla1, José Gomez Puerta1, Juan D. Calero1, Isabel Hard3, Raimón Sannart4, 1Hospital Clinico de Barcelona, Rheumatology, Barcelona, Spain; 2IOAC-CSIC, Unit of Synthesis and Biomedical Applications of Peptides, Barcelona, Spain

Background: Anti-carbamylated protein antibodies (Anti-CarP) represent a novel autoantibody family present in sera of patients with rheumatoid arthritis (RA) with high specificity.

Objectives: To analyse the prevalence of Anti-CarP in an established RA cohort and evaluate their association with the presence of other autoantibodies and disease activity and severity.

Conclusions: Cross-sectional study. Presence of Anti-CarP was analyzed in a cohort of patients with established RA (n: 158) by a home-made ELISA test using fetal calf serum. We investigated the demographic, radiological and current and at disease onset clinical features. Rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) status were also assessed.

Results: Anti-CarP were positive in 46.2% of the patients in our cohort and in 15.1%, 19.2% and 9.1% of the patients negative for ACPA, RF and both respectively. Demographic and clinical features are shown in table 1. The mean titer of ACPA (1361±1054 U/mL vs. 918 ± 1092 U/mL) and RF (258 ± 255 AU vs. 174 ± 205 AU) were significantly higher in Anti-CarP positive patients. No difference in symptoms at RA onset was observed. Current (24.7% vs. 11.6%) and previous (54.8% vs. 37.0%) smoking consumption were significantly associated with Anti-CarP antibodies. Anti-CarP positive patients presented a higher CRP values (1.0±1.6 mg/dL vs. 0.5±0.8 mg/dL), swollen joint count (1.3±2.2 vs 0.7 ±1.8) and patient global health assessment VAS (34.8 ±21.5 mm vs. 26.4 ±17.1 mm); although no between-group differences in disease activity (DAS28, CDAI, SDAI and RAPID3) or demographic features were observed. Anti-CarP positive patients presented significantly higher scores in Larsen index (23.6 ± 15.7 vs. 15.7 ± 12.6) and disability (HAQ-DI >1) (23.3% vs. 8.3%).

Conclusion: Anti-CarP were present in approximately half of the RA cohort and were also detected in seronegative (RF and/or ACPA) test. Linear regression models were used to evaluate whether changes in imaging measure changes from BL to 3M predict changes in erosion volumes and patient outcomes (DAS28-CRP, HAQ, MHO) from BL to 12M, after adjusting for age, gender, disease duration and therapy (Anti-TNFa added or not).

Results: Anti-TNFa therapy in the high DAS group resulted in significant decreases of SYN, BMEL at 3M and DAS28-CRP, HAQ and MHO at 3M and 12M from BL (Table.1). The low DAS group in contrast, displayed significant increases in SYN and DAS-CRP at 3M and bone erosion volume at 3M and 12M from BL despite low disease activity (Table.1). Changes in SYN, not BMEL, T1rho or bone erosion, from BL to 3M were significantly correlated with changes in HAQ and MHO from BL to 12M (P < 0.05), and with changes in DAS-CRP from BL to 12M with marginal significance (P=0.053) (Figure 1). Changes in erosion volumes from BL to 3M were significantly correlated with changes from BL to 12M (P<0.05) (Figure 1).

Conclusion: Despite the low disease activity, patients on MTX only showed significantly increased erosion volumes as measured by HR-pQCT at 3M and 12M; on the other hand, patients with MTX+Anti-TNFa treatment showed decreased erosion volumes at 3M and 12M, implying erosion repair. In this study, changes in erosion (but not other MR measures including synovitis and bone marrow edema) within the first 3M predicted changes in erosion at 12M. On the other hand, changes in synovitis volumes predicted patient functional outcomes at 12M. These results suggest that multimodality quantitative imaging with MRI and HR-pQCT provides powerful tools for evaluating early changes and predicting disease progression and therapy response after treatment in RA. Large scale studies with larger sample size are warranted to confirm the observations.
patients. In our cohort, patients with Anti-CarP antibodies presented higher tobacco consumption and poorer disease outcomes.

RHEUMATOID CACHEXIA ASSESSED BY BODY COMPOSITION IS ASSOCIATED WITH WORSE DISEASE IN RHEUMATOID ARTHRITIS PATIENTS WITH NORMAL BODY MASS INDEX

Jian-Zi Lin, Lijuan Yang, Le-Feng Chen, Li Qian-Hua, MA Jianda, Yingqian Mo, Lie Dai; Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

Background: Abnormal body composition (BC) has been reported in rheumatoid arthritis (RA) patients with normal body mass index (BMI). Rheumatoid cachexia (RC) was found in RA patients with a decrease in muscle mass and an increase or limited change in fat mass, resulting in no or limited changes in BMI. However, there is no consensus on the clinical criteria for its diagnosis, and the clinical significance of RC has not been well known until now.

Objectives: To investigate the characteristics of BC in RA patients with normal BMI and the association between RC and disease characteristics.

Methods: Consecutive RA patients were recruited and clinical data including disease activity, function and radiographic assessment were collected. BC was assessed by bioelectric impedance analysis. RC was defined as those with concurrent overweight (body fat percentage ≥25% for men and ≥35% for women) and myopathy (appendicular skeletal muscle mass index ≤7.0 kg/m² in men and ≤5.7 kg/m² in women) in this study. Multivariate logistic regression analysis was performed to identify the association between disease characteristics and RC in RA patients with normal BMI, following the step-forward selection rule that variables were included in the equation when the P value was <0.05 or removed when the P value was >0.10.

Results: 1. There were 516 RA patients recruited, with 13.8% RC as well as 17.4% underweight, 56.4% normal weight, 22.5% overweight and 3.7% obese respectively. Among 71 RA patients with normal BMI, while 2.8% underweight, 22.5% overweight and 1.4% obese. Among 48 patients with normal BMI (n=291), 17.9% patients showed RC. 28.1% showed normal fat but myopathy, 1.4% showed overweight but myopathy, while 52.6% showed both normal fat and non-myopenia. 2. For RA patients with normal BMI, compared with those with both normal fat and non-myopenia, RA patients with RC were older with longer disease duration, higher disease activity indicators including 28TJC, PtGA, PainVAS, ESR, CRP, DAS28-2CRP, SDAI and CDAI, higher functional indicators including HAQ-DI and rate of functional limitation, higher radiographic assessment including mTSS, JCN and JE scores, higher rate of previous use of glucocorticosteroids (75.0% vs. 52.3%), and higher prevalence of hypertension (25.0% vs. 7.8%). Further compared with those with normal fat but myopathy, RA patients with RC showed the similar results with significantly longer disease duration, higher CRP, HAG-DI, mTSS, JCN subscore, JE subscore, and higher rate of previous use of glucocorticosteroids (all P<0.0167, bonferroni correction). 3. Multivariate logistic regression analysis showed that CRP (OR=1.024, 95%CI: 1.009-1.040), mTSS (OR=1.017, 95%CI: 1.010-1.025), previous use of glucocorticosteroids (OR=2.605, 95%CI: 1.217-5.575), and suffering from hypertension (OR=3.462, 95%CI: 1.448-8.274) were positively associated with RC in RA patients with normal BMI.

Conclusion: Our data show that rheumatoid cachexia is associated with worse disease including RA disease activity, functional limitation and radiographic joint damage, which imply that RC should be emphasized especially in RA patients with normal BMI.

WHAT IS THE ADDITIONAL VALUE OF MRI OF THE FOOT TO THE HAND IN UNDIFFERENTIATED ARTHRITIS TO PREDICT RHEUMATOID ARTHRITIS DEVELOPMENT?

Yousra Dakkah1, Debbie Boeters1, Ailed Boets1, Monique Reijnierse2, Annette van der Helm - van Mil3,1, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; 3Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: MRI-detected subclinical joint inflammation in hand-joints of patients with undifferentiated arthritis (UA) predicts progression to rheumatoid arthritis (RA). It is unknown if adding MRI of the foot increases predictive accuracy compared to the hand alone.

Objectives: To assess whether MRI-detected inflammation of the foot is predictive for RA-development, and whether combining MRI-detected inflammation of the foot to that of the hand is of additional value.

Methods: 1.5T-contrast-enhanced MRI of unilateral foot (MTP-1-5), and hand (MCP-2-5 and wrist) was performed in 123 patients presenting with UA (not fulfilling 2010 RA-criteria) and scored for bone marrow edema (BME), synovitis and tenosynovitis. Symptom-free controls (n=193) served as a reference for defining an abnormal MRI. Patients were followed for 1-year, defined as fulfilling classification criteria or initiation of disease modifying anti-rheumatic drugs because of the expert opinion of RA. The added predictive value of foot-MRI to hand-MRI was evaluated.

Results: 52% developed RA. Foot tenosynovitis was predictive (OR 2.55, 95%CI 1.03-6.43), independent of BME and synovitis (OR 3.29, 95%CI 1.01-10.53), but not independent of CRP and number of swollen joints (OR 2.14, 95%CI 0.77-5.95). Hand tenosynovitis was also predictive independent of BME and synovitis (OR 3.99, 95%CI 1.64-9.69) and independent of CRP and swollen joints (OR 2.36, 95%CI 1.04-5.38). Adding foot tenosynovitis to hand tenosynovitis changed sensitivity from 72% to 73%, specificity from 59% to 54% and AUC from 0.66 to 0.64, the net reclassification index was -3.5.

Conclusion: MRI-detected tenosynovitis of the foot predicts progression to RA. However adding MRI of the foot does not improve predictive accuracy compared to MRI of the hand alone. In view of cost-reduction, performance of foot-MRI for prognostic purposes in UA can be omitted.

ULTRASOUND PREDICTS IMMINENT PROGRESSION TO ARTHRITIS IN ANTI-CCP POSITIVE AT-RISK INDIVIDUALS

Laurence Duguayonn1,2, Kulveer Mankii1,2, Jacqueline Nam1,2, Peta Pentony3,4, Leticia Garcia-Montoya5, Andrea Dimattio6,7, Laura Hunt8,9, Paul Emery10,11, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 5NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Ultrasound (US) Power Doppler (PD) signal is predictive for the development of inflammatory arthritis (IA) in anti-cyclic citrullinated protein antibodies positive (CCP+) individuals with musculoskeletal (MSK) symptoms but no clinical synovitis (CS) [1]. Our previous data showed a large increase in the overall US inflammation before arthritis development, suggesting that a sub-clinical phase of synovitis could be detected [2]. This abstract describes the prediction of PD abnormalities in the months following US scan.

Objectives: 1. Presence of PD in one joint is predictive of imminent progression to IA in the next 3 months. 2. A rise in the number of joints with presence of PD increases the odds of progression to IA.

Methods: In a single-centre prospective observational cohort between June 2008 and December 2018, 307 CCP+ patients with a new MSK symptom but no synovitis were followed until CS occurred. Clinical and US findings were analysed. Following our previous study, we compared progression in the 3, 12 or >12 months after a US scan. 38 joints were included in the analysis (MTPs, hands, wrists, elbows, ankles and knees). Patients with palindromic rheumatism were excluded.

Results: From 96 CCP+ at-risk patients who developed CS (progressors) compared to 211 CCP+ patients who did not (non-progressors). Age and gender are similar, the mean follow-up of the non-progressors is higher, with significantly more smokers and higher titre CCP in the progressors group (Table1).

Overall, progressors have more joints with PD than non-progressors (Figure). Patients with PD in one joint are more likely to develop CS in the following 3 months compared to those without PD (OR 7.52) and this remain significant when only the hands and wrists are included.

The clinical characteristics of rheumatoid arthritis at presentation become milder over time? Results from a nationwide study over three decades in Sweden

Jon Einansson, Tor Olufson, Olafur Palsson, Johan K Wallman, Melha C Kapetanovic. Lund University, Department of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden

Background: The course of rheumatoid arthritis (RA) has become milder during the last decades, which could at least partly be attributed to major advances in the pharmacological treatment of the disease and the implementation of “treat to target”-strategies (1,2). It has also been suggested that RA is already milder at presentation (3).

Objectives: To investigate whether the clinical status, markers of inflammation, functional status, and patient and evaluator reported disease activity measures in patients with newly diagnosed RA, have improved over the recent decades.

Methods: Baseline data on all DMARD-naive patients with early RA (<6 months duration) included in the nationwide Swedish Rheumatology Quality registry (SRQ) between 1991 and 2014 were retrieved. The RA diagnosis relied on the clinical judgement of the treating physician and the information comprised swollen and tender joints count (SJC; TJC), markers of inflammation (CRP; ESR), functional status (HAQ; DASH), patient’s and evaluator’s assessment of global disease activity (PtGA; EGA) and patient’s assessment of pain (on a visual analog scale, VAS; 0-100 mm). Baseline demographic and disease characteristics were compared between patients with disease onset 1991-2000 vs. those with onset 2011-2014, using Mann-Whitney U test and Pearson’s chi-squared test.

Results: A total of 6559 early RA patients were included. Over the study period of 23 years the majority of the patients were women (68%), and the mean age at inclusion increased from 57.4 to 59.1 years. Results are summarised in Table 1. Mean CRP, ESR, TJC and SJC all increased significantly between the time periods. Furthermore, time from symptom onset to inclusion was shorter 2011-2014.

Conclusion: In Swedish patients with early RA, baseline joint counts and inflammatory markers improved over the last three decades. This could partly be explained by shorter symptom duration at diagnosis but also suggests that, at onset, RA might be an inherently milder disease today. However, pain and patient’s global assessment and evaluator’s global assessment of disease activity increased over the same period of time, possibly indicating changes in both patients’ and evaluators’ expectations for management of early RA today.

[2] Pentony P. et al., Sequential US shows a late increase in inflammatory burden in anti-CCP positive patients with non-specific MSK symptoms just before progression to IA. Ann Rheum Dis, volume 77, year 2018
EVALUATION OF MEDICATION PERSISTENCE IN EARLY VERSUS DELAYED START OF BARICITINIB IN RA is a systemic disease driven by pathogenic autoantibodies and inflammatory cytokines that can involve tissues and organs as well as synovial joints. Sjögren’s syndrome (SS) and interstitial lung disease (ILD) are frequently reported extra-articular manifestations of RA. However, there are currently limited data on the persistency of non-TNF inhibitor (TNFi) biologic (b)DMARDs and targeted synthetic DMARDs, such as tofacitinib (TOF), in patients (pts) with SS and ILD secondary to RA (RA-SS and RA-ILD).

Objectives: To compare medication persistence between non-TNF-DMARDs including abatacept (ABA), TOF and tocilizumab (TOC) in RA-SS and RA-ILD.

Methods: Pts (≥18 years) from the Truven MarketScan™ administrative claims database with RA ≥2 prescription claims for RA identified with International Classification of Diseases (ICD)-9 or ICD-10) being treated with a non-TNF DMARD from Jan 2006 to Sep 2017 were included. The date of the first claim for a drug of interest on or after diagnosis of RA was considered the index date. Pts were required to have at least 6 months of continuous enrollment prior to the index date (baseline). Pts with claims for other bDMARDs on the index date were excluded from the study. Pts with a diagnosis of SS or ILD any time in the baseline or follow-up periods were included in the RA-SS or RA-ILD cohorts, respectively. Persistence was defined as the number of days from index date to first switch or discontinuation of the index date DMARD, or end of the study period, or end of enrolment, whichever came first. Pts in both cohorts were stratified by prior TNFi use (TNFi-naïve or TNFi-experienced) (OS) use. Pairwise comparison of persistence between the non-TNF DMARDs was performed with ABA as the reference, using the Kruskal–Wallis test for both cohorts separately. A p value of <0.05 was considered statistically significant.

Results: A total of 2503 and 3856 pts satisfied the inclusion and exclusion criteria for the RA-SS and RA-ILD cohorts, respectively. In the RA-SS cohort, 1767, 378 and 358 pts were taking ABA, TOF and TOC, respectively; in the RA-ILD cohort, these numbers were 2937, 343 and 358, respectively. The majority (90% in RA-SS and 75% in RA-ILD) of the study population was female. In the RA-ILD cohort, the proportion of pts with prior CS use was significantly lower in pts taking ABA (vs TOF). In the RA-SS cohort, the commodity index between treatment cohorts was similar; however, ABA pts had significantly lower pulmonary nodules vs TOF pts (Table 1). In the RA-ILD cohort, the commodity index was significantly lower for ABA (vs TOF and TOC), with differences in types of comorbidities at baseline (Table 1). In the RA-SS cohort, the mean time on therapy for pts taking ABA was longer compared with TOC. Persistency of ABA was higher compared with TOC in the TNFi-naïve cohort.

Conclusion: Based on the analysis of a large US claims database, pts with RA-SS prescribed ABA (vs TOF) had higher persistency, and pts with RA-ILD prescribed ABA (vs TOC) had higher persistency. Further analysis of medication persistence, adjusting for pt characteristics, is warranted.

THU0075 – EARLY VERSUS DELAYED START OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A PHASE 3 TRIAL OF PATIENTS NAIVE TO METHOTREXATE TREATMENT

Roy Fleischmann1, Michael Schiff2, Tore K. Kvien3, Gern Gabay4, Patrick Durez5, Anabela Cardoso6, Jinglin Zhong7, Yun-Fei Chen6, Jennifer Workman6, Roy Fleischmann1, Michael Schiff2, Tore K. Kvien3, Cem Gabay4, Patrick Durez5, Anabela Cardoso6, Jinglin Zhong7, Yun-Fei Chen6, Jennifer Workman6, Tsutomo Takeuchi8, 1University of Texas Southwestern Medical Center, Dallas, United States of America; 2University of Colorado, Denver, United States of America; 3University of Oslo, Oslo, Norway; 4University of Geneva, Geneva, Switzerland; 5UCL Saint Luc, Bruxelles, Belgium; 6Eli Lilly and Company, Indianapolis, United States of America; 7IQVIA, Morrisville, United States of America; 8Keio University School of Medicine, Tokyo, Japan

Background: Baricitinib (bari) is an oral Janus kinase (JAK)1/JAK2 inhibitor approved to treat moderately to severely active rheumatoid arthritis (RA) in adults in over 50 countries including European countries, the US and Japan. In the 52-week (wk) Phase 3 RA-BEGIN study, bari 4-mg alone or in combination with methotrexate (MTX) showed clinical improvements compared to MTX monotherapy for MTX-naive patients (pts) with early active RA.1

Objectives: To assess if pts who receive bari monotherapy early attain enhanced clinical, functional and radiographic outcomes compared to pts who initiated MTX and switched to bari at wk 52.

Disclosure of Interests: Jon Einarsson: None declared, Tor Olufsson: None declared, Olafur Palsson: None declared, Johan K Wallman Consultant for: AbbVie, Colgene, Eli Lilly, Novartis, and UCB Pharma, Melina C Kapetanovic: None declared. DOI: 10.1136/annrheumdis-2019-eular.2167

THU0075
Methods: In RA-BEGIN, 588 pts (mean disease duration 1.4 years) were randomized 4:3:4 to MTX, bari 4-mg once-daily, or combination MTX and bari 4-mg. At Wk 52, pts could elect a 1-year extension study in which all pts received open-label bari 4-mg. Pts initially randomized to bari-4 mg monotherapy were defined as early-start and MTX pts who switched to bari 4-mg at Wk 52 were defined as delayed-start for this analysis. Change from baseline using mixed model repeated measures and mean scores were assessed for the Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), Disease Activity Score 28-joints-erythrocyte sedimentation rate (DAS28-hsCRP), Disease Activity Score 28-joints–erythrocyte sedimentation rate (DAS28-ESR), Health Assessment Questionnaire-Disability Index (HAQ-DI), and modified total Sharp Score (mTSS) to compare early- vs delayed-start groups between Wks 0 and 100 (Wks 52-100 for mTSS). Percent of pts achieving low disease activity (LDA, SDAI ≤11) and remission (SDAI ≤3.3) were also assessed.

Results: LDA and remission response rates in the delayed-start group increased from 60% to 78% and 18% to 31%, respectively, within 4 wks after switching to bari 4-mg. Remission rates reached 47% within 1 year after switching, but were not different from the group that initiated bari (Figure 1). Similar results were seen for CDAI, DAS28-ESR, and DAS28-hsCRP (only up to Wk 40 for DAS28-ESR) (data not shown). Pts initially randomized to bari 4-mg had significantly greater change from baseline, observed as early as Wk 1 and up to Wk 52, for HAQ-DI than pts treated with MTX (Figure 2). After switching to bari, the delayed-start group showed a rapid improvement in HAQ-DI with similar improvement at Wk 56 – 4 wks after switching to bari. Upon initiating bari, there was a reduction in the rate of structural damage; however, delaying initiation of bari for 1 year resulted in numerically higher mTSS.

Conclusion: In early MTX-naïve pts, improved clinical, functional, and radiographic efficacy with bari 4-mg vs MTX was observed in most outcome measures up to 52 wks. Switching from MTX to bari at Wk 52 provided a rapid clinical response, allowing a majority of pts to achieve similar results 4 wks post-switch. However, if the goal of therapy is to achieve rapid and sustained control of disease activity, the differences noted here for HAQ-DI and especially structural progression support earlier switch to bari for pts who do not obtain disease control with MTX. Further analysis may be needed to explore prognostic factors, such as hsCRP and disease duration (< or >6 months), baseline erosion, or anti-citrullinated protein antibody positivity, which may help clinicians identify pts who may benefit from earlier treatment with bari.

THU0076 THE IMPACT OF VARYING EXCLUSION CRITERIA ON TREATMENT RESPONSE: REAL-WORLD EVIDENCE TO GUIDE THE DESIGN OF FUTURE CLINICAL TRIALS

Thomas Friesel1, Scott Jelinsky2, Mark Peterson3, Johan Askling1 1Karolinska Institutet, Solna, Sweden; 2Pfizer Research Technology Center, Cambridge, United States of America

Background: Clinical trials of novel pharmaceuticals in Rheumatoid Arthritis routinely use strict inclusion/exclusion criteria aimed at selecting a defined homogeneous population and producing a non-confounded demonstration of the agent’s clinically relevant pharmacologic effect. However, the act of strictly defining numerous individual criteria has the potential...
for impacting the observed response rates, while the effect upon limiting the pool of eligible subjects is often poorly understood. Unnecessarily restrictive criteria may limit the generalizability of trial results to real world patient populations. Conversely, certain patient characteristics may be associated with high or low probabilities of response to active treatment or to placebo.

Objectives: To assess the impact of applying a range of different exclusion criteria on the proportion eligible subjects, and on the observed treatment response rates, in a large real-world patient population.

Methods: Data on RA characteristics, demographics, and co-morbidities among RA patients were identified by linking the Swedish Rheumatology register (SRQ) to the nationwide and virtually complete Swedish census and healthcare registries. Representing an early RA trial scenario, we identified patients starting methotrexate monotherapy as first ever DMARD (N=41) between 2007 and 2016. The cohort was assessed overall and stratified by baseline DAS28. Treatment outcome was defined as the proportions reaching (1) EULAR Good Response and (2) Low Disease Activity, and the change in (3) HAQ and (4) CDAI at 3 and 6 months. Exclusions were made based on age, baseline disease activity, sex, RF, predefined comorbidities, degree of healthcare utilization history, education, and taxed income level (cut-offs for continuous variables were based on distributions from recent clinical trials of tocilizumab). In total, 165 different definitions of exclusion criteria were evaluated.

Results: Within the entire cohort, 50% of patients achieved EULAR DAS28 good response at 3 months. Exclusions based on age, sex, RF status, or duration of RA symptoms before RA diagnosis generally lead to large reductions in number of eligible subjects but did not appreciably affect (< 5% change) the proportion of EULAR good responders. Exclusions based on HAQ had a noticeable drop in the proportion of EULAR good response (~10%, see Figure), although exclusions above 80% was necessary to observe an effect. Similar patterns were observed for TJC, patient’s global health and ESR but exclusions based on SJC or CRP did not impact EULAR response.

Exclusions of specific comorbidities, such as history of myocardial infarction, history of joint replacement, generally had no or modest impact on the observed response rate. Exclusions based on health care use (total number of drugs, hospitalizations), affected response rates (+/- around 5%), while exclusions based on educational level, work ability, or income did not.

The impact of exclusions was very similar on the 3 and 6 month responses.

Conclusion: Exclusions in a range of criteria commonly used in clinical trials had only a modest impact on observed treatment outcome, while impacting on the enrollment pool – sometimes dramatically. More extreme restrictions (excluding well above half the potentially eligible patients) were generally necessary to shift the proportion EULAR Good Response by more than 5 percentage points. This should not be a surprise given the lack of identified strong predictors of treatment outcome in RA, but may raise the question of whether the lowered generalizability and impacts on enrollment rates caused by strict inclusion criteria in clinical trials is warranted by the aspiration to increase chances of demonstrating clinically meaningful effects.

THU0077 RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS CLINICAL TRIALS: HOW TO ENCOURAGE PATIENT PARTICIPATION? RESULTS FROM A REAL-WORLD STUDY CONDUCTED VIA CARENITY, A WORLDWIDE ONLINE PATIENT COMMUNITY

teni gauchoux, Anthony Boisbouvier, Roman Dos Santos, Lise Rasoszczyki.

CARENITY, Paris, France

Background: Involving patients affected with rheumatoid arthritis or ankylosing spondylitis in clinical trials may be highly challenging: in a worldwide context of competitive rheumatoid arthritis and ankylosing spondylitis clinical research, patient engagement is key to optimize medical research and increase participation rates.

Objectives: The aim of this study was to identify patients’ motivations for and hindrances to joining a clinical trial in order to increase participation rate by implementing tailored services and information.

Methods: An online questionnaire was submitted from August 2017 to October 2017 to Carenity’s French members affected with rheumatoid arthritis or ankylosing spondylitis.

Results: 136 patients affected with rheumatoid arthritis (n = 55, 40%, mean age = 55 y/o, 71% of women) or ankylosing spondylitis (n = 81, 60%, mean age = 48 y/o, 80% of women) participated in the study. 10 patients (7%) already participated in a clinical trial.

Non-participants (n=126) exposed the incentives that may increase participation rate: reimbursing the expenses related to the clinical trial can improve their motivation (median weight on motivation to join a trial = 10/10) as well as a better medical follow-up (9/10) or leveraging the trial’s investigator notoriety (8/10). Patients’ healthcare practitioners could be leveraged as well: their favorable opinion turns patients on to clinical trials (7/10). On the contrary, a doctor’s negative opinion may strongly deter patients from joining a trial (median weight on reluctance to join a trial = 8/10). Communication should aim at reassuring them about side effects (9/10), potential risks for their health (8/10) and more generally the risk that the new treatment would not be better than their current one (8/10). Logistic challenges should also be taken into account: the trip between patients’ home and the site of the clinical trial is perceived as an important burden (8/10).

Implementing tailored services and information would be an efficient way to reassure patients and increase their willingness to participate. 81% of non-participants would be enticed to participate if they had access to a website to exchange with healthcare professionals or to follow the results of the trial. 79% would be interested in participants’ testimonials and 74% in a 24-hour phone helpline. Spreading and clarifying information before the trial is also critical: 6/10 patients who participated in a clinical trial did not understand clearly if they will have out-of-pocket costs and 5/10 patients were also unclear on the terms and conditions for leaving the clinical trial. Informing patients via convenient channels is key: 88% of participants and non-participants think that an online patient community is a relevant medium to convey information about clinical trials and 81% of non-participants would like to have access to an information brochure about the trial process.

Conclusion: This real-world study allowed to identify concrete levers to reassure patients affected with rheumatoid arthritis or ankylosing spondylitis about the benefits/constraints balance and to clarify information at each stage of the trial (before, during, after), which is essential to accelerate clinical trial recruitment.

THU0078 SAFETY PROFILE OF BARICITINIB FOR THE TREATMENT OF RHEUMATOID ARTHRITIS UP TO 7 YEARS: AN UPDATED INTEGRATED SAFETY ANALYSIS

Mark C. Genovese1, Josef S. Smolen2, Tsutomu Takeuchi3, Gerd Rüdiger Burmester4, Dennis Brinker5, Terence Rooney6, Jinglin Zhong7, Daqun Mo8, Chadi Sallan9, Anabela Cardoso10, Maher Issa11, Wen-Shuo Wu12, Kevin Winthrop29,13,22,15,16,27,28,29,30 Stanford University Medical Center, Palo Alto, United States of America;2 Medical University of Vienna, Vienna, Austria;3 Keio University, Tokyo, Japan;4 Charité – University Medicine Berlin, Berlin, Germany;5 Eli Lilly and Company, Indianapolis, United States of America;6 IQVIA, Rockville, United States of America;7 Oregon Health Sciences University, Portland, United States of America

Background: Baricitinib (bari), is an oral, selective inhibitor of Janus kinase (JAK) 1/JAK 2, to treat moderately to severely active RA in adults.

Objectives: To update bari’s safety profile with data from an additional Phase III trial and a real-world long-term extension (LTE) study.

Methods: Long-term safety of once-daily bari was evaluated in the All-Bari RA dataset: all patients (pts) exposed to any bari dose from 9

randomized trials (5 Ph3, 3 Ph2, 1 Ph1b) and 1 LTE (data to 13-Feb-2018). Placebo (PBO) comparisons were evaluated to Week 24 from 7 Ph2/3 trials; pts randomized to PBO, bari 2-mg or 4-mg, with censoring at rescue/treatment switch. Dose responses were evaluated in the 2-mg/4-mg extended dataset from 4 Ph2/3 trials; pts randomized to 2- or 4-mg LTE data included; data censored at rescue/dose change (as-treated analysis) and, due to latent period for malignancy, analyzed without censoring (as-randomized analysis). Incidence rates (IR) per 100 patient-years (PY) were calculated.

Results: 3770 pts received bari (10127 PYs); maximum exposure was 7 yrs (Table). No significant differences were seen for bari 4-mg vs PBO in adverse events leading to permanent drug discontinuation, death, malignancy, serious infection, or major adverse cardiovascular events. Herpes zoster IR was significantly higher for bari 4-mg vs PBO (3.0 vs 0.9) and numerically higher for bari 2-mg (2.1). IRs for deep vein thrombosis/pulmonary embolism were numerically higher in bari 4-mg vs PBO; IRs were similar by dose in 2-mg/4-mg-extended dataset. Malignancy (excluding non-melanoma skin cancer) IRs were 0.8 (2-mg) and 1.0 (4-mg: as-randomized analysis). Fewer than 1% of pts discontinued due to abnormal laboratory results.

Conclusion: In this updated integrated analysis of pts with active RA exposed to bari for up to 7 yrs, across safety topics, bari maintained a safety profile similar to that previously reported and acceptable in the context of demonstrated efficacy.

REFERENCE:

Background: At the group level, the classification criteria for rheumatoid arthritis (RA) developed in 2010 identify patients earlier than the 1987 criteria. However, performance of the new criteria in subjects negative for rheumatoid factor (RF) and anti-citrullinated protein autoantibodies (ACPA) is not consistent with [1]. Therefore, patients’ classification may be missed despite severe joint and systemic inflammation.

Objectives: To evaluate disease characteristics and arthritis persistence in autoantibody-negative patients with early polyarthritis fulfilling only 5 of the 10 points of the 2010 classification criteria for RA.

Methods: We included early arthritis patients from our Early Arthritis Cohort with at least one clinically swollen joint, symptoms for less than 12 months, no other explanation of arthritis and naïve to glucocorticoids and disease modifying anti-rheumatic drugs (DMARDs) at presentation. At baseline, fulfillment of each specific domain of the 1987 and the 2010 criteria was recorded. RF and ACPA were centrally determined on baseline sera. RF and ACPA-negative patients achieving a total score of 5 in the 2010 criteria was compared to patients fulfilling RA criteria for baseline characteristics and for arthritis persistence (28-joints disease activity score [DAS28] >3.2) after 2 months of follow-up.

Results: Of the total population of 882 patients with new-onset inflammatory arthritis, comprehensive evaluation of the fulfilment of the 1987 and the 2010 criteria was available in 771 cases (87.4%). Of these, 476 patients fulfilled the 2010 criteria was available in 771 cases (87.4%). Of these, 476

THU0080

DEVELOPMENT OF ULTRASOUND DETECTABLE ARTHRITIS AMONG ACPA POSITIVE SUBJECTS WITH MUSCULOSKELETAL SYMPTOMS: THE RISK RA PROSPECTIVE STUDY

Aase Hensvold1,2, Yogan Kisten3, Alexandre Circiumaru2, Monika Hansson2, Meng Sun2, Guozhong Fei3, Nancy Vivar1, Hamed Rezaei2, Lars Klareskog2, Aleksandra Antovic1, Anca Catrina1,2. 1Center for Rheumatology, Academic Specialist Center, Stockholm Health Services, Stockholm, Sweden; 2Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

Background: Retractive studies have shown that anti-citrullinated protein antibodies (ACPA) are a risk factor for the development of clinical arthritis. Objectives: We aimed to investigate in a prospective setting if ACPA and other biomarkers could predict development of ultrasound detectable arthritis.

Methods: Subjects with positive ACPA-test referred from primary care to the Rheumatology clinic that lacked arthritis in hands, feet and any other symptomatic joints by clinical and ultrasound examination (according to EULAR-OMERACT definition), were recruited into the Risk-RA research program during 2015-2016 and were followed up to the end of 2017. At inclusion a detailed clinical examination was performed and blood samples were analyzed for 13 specific ACPA reactivities (using a custom made peptide microarray) as well as 92 inflammation-associated protein biomarkers (using a multiplex immunoassay with Olink proximity extension technology). Presence of HLA-SE was analyzed using DR low-resolution technology. Univariate and multivariate analysis were used to investigate the association between clinical and laboratory parameters and development of ultrasound detected arthritis adjusting for the follow-up time.

Results: 42% (27/65) of the Risk RA subjects developed ultrasound detectable arthritis during a median follow up of 8 months. The remaining 58% (38 out of 65) were followed for a median of 25 months (range 12-44) without any signs of ultrasound detectable arthritis. Subjects developing arthritis had higher prevalence of HLA-SE (89% vs 56%) and increased occurrence of ultrasound detected tenosynovitis (44% vs 5%), compared to those not developing arthritis. ACPA reactivities to citrullinated vimentin peptides (cit vim 2-17: 22% vs 6%; and cit vim 60-75: 70% vs 43%) and citrullinated histone peptides (cit H4 31-50: 99% vs 49%; and cit H3 21-44: 48% vs 23%) were a more common occurrence in subjects developing ultrasound detectable arthritis. Backward selection in a Cox regression model showed that ultrasound detectable arthritis could be predicted in a model including HLA-SE, tenosynovitis and ACPA reactivity to cit H4 31-50. Hazard ratio compared to the reference group (not developing arthritis) were 3.4 (95% CI 1.0-12, p 0.06) for HLA-SE carriers, 2.9 (95% CI 1.3-6.7, p 0.01) for tenosynovitis and 4.1 (95% CI 1.2-14, p 0.02) for Anti-citrullinated H4 31-50 positivity. Only modest differences were observed for few of the tested inflammatory markers in those developing as compared to those not developing ultrasound detectable arthritis.

Conclusion: This prospective study shows that ultrasound detected arthritis can be predicted in a model including HLA-SE, tenosynovitis and ACPA reactivity to cit H4 31-50.

THU0081

ELEVATED SERUM TREM-1 LEVELS ARE ASSOCIATED WITH DAS28 AND PERIODONTITIS IN RHEUMATOID ARTHRITIS

Nevsun Inanc1,2, Gonca Mumcu2, Menyem Can2, Haner Direskeneli3, Naghan Boistanci1, Marmara University, School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; Marmara University, Faculty of Health Sciences, Department of Health Management, Istanbul, Turkey; Medipol University, Medical Faculty, Department of Rheumatology, Istanbul, Turkey; Karolinska Institutet, Section of Periodontology and Dental Hygiene, Division of Oral Diseases, Department of Dental Medicine, Stockholm, Sweden

Background: The Triggering Receptor Expressed on Myeloid cells 1 (TREM-1) along with its putative ligand peptidoglycan recognition protein 1 (PGLYRP1) are involved in the propagation of the inflammatory response to microbial exposure(1). Periodontal disease (PD) has been suggested as an environmental risk factor for rheumatoid arthritis (RA), yet further studies are required to dissect the mechanisms underlying the association between the two(2).

Objectives: The present study aimed to investigate whether serum levels of TREM-1 and PGLYRP1 in patients with RA correlate with the presence and severity of PD, as well as bacterial load in saliva.

Methods: Serum and saliva samples were collected from 65 individuals with RA (F/M: 48/17), under sDMARD treatment for more than 6 months and never used biologic treatment), with Behcet syndrome (BS, n= 45, F/M: 33,8%) compared to BS (20,9%) and HC (5,1%). Total bacterial load in saliva was assessed by quantitative real-time polymerase chain reaction and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA, while total oral bacteria in saliva and PGLYRP1 were measured by ELISA.

Results: Patients with RA presented with a smaller number of teeth than the BS and HC groups (18.6±7.8, 4.22±3.7; 25.3±6.3, 3.83, respectively) (p<0.001). Prevalence of severe periodontitis was higher in the RA group (33.8%) compared to BS (20.9%) and HC (5,1%). Total bacterial load was significantly higher in saliva of RA than HC (p<0.05). Serum TREM-1 and PGLYRP1 levels were significantly higher in RA (167,1±50,0 pg/ml; 157,5±228,8 pg/ml) than BS (102,6±44,4 pg/ml; 52,4±26,1 pg/ml) and HC (52,4±26,1 pg/ml).
EFFECT OF TREAT-TO-TARGET STRATEGY ON ROLE OF CLINICAL IMPACT, DISEASE-SPECIFIC KNOWLEDGE AND BELIEFS ABOUT MEDICATION ON TREATMENT OUTCOMES IN RHEUMATOID ARTHRITIS: AN INTEGRATIVE STRUCTURAL EQUATION MODELING APPROACH

Georgie Karouzas1, Elizabeth Hernandez2, Yibeeke Strand3, Sarah Ormsett4.
1Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America; 2Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America; 3Stanford, Immunology/Rheumatology, Palo Alto, United States of America

Background: Treatment of rheumatoid arthritis (RA) to remission is the optimal way to ensure control of symptoms, prevention of structural damage, optimization of function and quality of life. Adherence to medical treatment is, therefore, an integral part of a comprehensive and successful management of RA.

Objectives: We interrogated the influence of three distinct domains of RA clinical impact (disease activity, functional limitations, mood disturbance), patient knowledge and beliefs about medications on RA treatment adherence.

Methods: We evaluated 285 patients with established RA from a single center. In the proposed model, RA-specific knowledge was not significantly associated with mediational multi-group structural equation modeling evaluated the model separately in patients treated with bDMARDs and those only receiving csDMARDs.

Results: RA-specific knowledge was not significantly associated with medication beliefs or adherence and therefore was dropped from the model. Modification indices suggested addition of two supplementary paths (dashed lines) that significantly improved the proposed model fit for both

Abstract THU0082 – Figure 2

THU0082 EFFECT OF TREAT-TO-TARGET STRATEGY ON DISEASE ACTIVITY AND RADIOLOGIC OUTCOMES IN RHEUMATOID ARTHRITIS: RESULTS FROM A 9-YEAR CHINESE COHORT

Lanlan Ji1, Wenhui Xie1, LI Guangtao1, Zhuoli Zhang1.
1Peking University First Hospital, Beijing, China

Background: Treat-to-target (T2T) strategy has been implied in clinical practice for 9 years. However, a recent study showed that the radiologic outcome didn’t associate with the adherence to protocolized treatment in clinical practice[1]. Furthermore, in clinical practice, nonadherence to a T2T protocol has been reported[2]. The reasons varied. In our previous study, there was a substantially decrease of RA activity over 8 years after tight control applied[3]. However, whether T2T strategy can improve the radiological outcome is still unknown.

Objectives: the arm of our study was to determine the effect of treat to target (T2T) protocol on disease activity and radiographic outcomes in a 9-year Chinese RA cohort.

Methods: RA patients who were followed-up for more than 1 year in a 9-year Chinese RA cohort.

Results: There were 209 patients enrolled in our study. The median interval of two radiographs was 31.0 (17.0, 50.0) months. 45.0% of the patients followed the time schedule to clinic. Adherence rate of the patients was evaluated by the calculation of the percentage of whether the patients followed the time schedule to clinic. Adherence rate >0.7 was defined as adherent to T2T. The overall disease activity was evaluated by time adjusted mean (TAM) method. The radiological change was evaluated by radiographs of the hands regularly, and the interval between 1 and 3 years. We defined the primary radiological outcome as modified total Sharp score (mTSS) >3 over the follow-up time.

Conclusion: The mTSS progression was associated with baseline HDA and bone erosion existing also independently associated with erosion progression [HR=1.90 (1.12, 3.23), p=0.018]. When divided the adherence rate into three subgroups, we can find that patient not following the T2T protocol were more easily to get radiological progression. There was statistically significant difference among three groups (p=0.004 using log rank, and p=0.001 using Tarone ware). To our surprise, increased adherence rate didn’t provide more benefit when adherence rate was more than 0.9 (Figure 2). In patients who got overall clinical remission, we found none of these variables correlated with the radiological outcome.

Abstract THU0086 – Figure 1

The Long-term Outcome of Intra-articular Glucocorticoid Injected Joints on Radiographic Changes in Patients with Rheumatoid Arthritis: A Real World Data from a Single Center

Jung Hee Koh\textsuperscript{1}, Hanna Lee\textsuperscript{2}, Ji-Won Kim\textsuperscript{3}, Seung Geun Lee\textsuperscript{2}, 1Bucheon st.Mary’s hospital, The Catholic university of Korea, Division of Rheumatology, Department of Internal Medicine, Bucheon, Korea, Rep. of (South Korea); 2Pusan National University Hospital, Division of Rheumatology, Department of Internal medicine, Busan, Korea, Rep. of (South Korea); 3Daegu Catholic University Medical Center, Division of Rheumatology, Department of Internal medicine, Daegu, Korea, Rep. of (South Korea)

Background: Intra-articular glucocorticoids injections (IAGI) have been an important part of a treat-to-target strategy in patients with Rheumatoid arthritis (RA). However, it is not known the long-term outcome of glucocorticoids-injected joint.

Objectives: To explore the long-term outcome of IAGI, the impact on the radiographic joint space narrowing and erosion in patients with RA.

Methods: We performed a retrospective cohort study of IAGI for patients with RA. We identified 88 RA patients who received IAGI into wrists or hand joints determined by ultrasound and had pre-injection and follow-up hand radiographs from a rheumatology department in a tertiary hospital. As a comparator, 88 RA patients who had not received IAGI although they had clinical synovitis (defined as both tender and swollen joint) in wrist or hand joint were randomly selected (Non-IAGI group). Hands radiographs scored using the van der Heijde-modified Sharp Score (HSS) method was used to assess radiographic progression ($\Delta$HSS $\geq$ 1 in joint areas of synovitis). Multivariable Cox regression estimated the hazard ratio (HR) and 95% confidence interval (95% CI) for radiographic progression of joint with synovitis.

Results: Among 88 RA patients who received IAGI (median age, 60 years, 42 (48%) patients had radiographic progression of triamcinolone-injected joint, while 38 patients (43%) in non-IAGI group (median age, 57 years) presented radiographic progression of joint area suffered clinical synovitis (not significant) in the median 2 years follow-up. At baseline, IAGI group presented longer disease duration, lower acute phase reactant levels and less involvement of proximal interphalangeal joints than non-IAGI group. In the IAGI group, a median number of 1 (IQR, 1–2) joint was injected. After 3 months from IAGI, 63.5% of patients reported improvement of injected joint and 16.5% of patients received a second or more IAGI. The radiographic progression of injected joint (Figure 1) was pronounced at the wrists (87.8% of radiographic progressor). The level of C-reactive protein at active arthritis, baseline HSS and power Doppler grade in ultrasound was higher in radiographic progressor than in non-radiographic progressor. A high baseline HSS of hands (HR, 1.021 [95% CI, 1.002–1.040]), wrist joint involvement (HR, 5.365 [95% CI, 1.705–16.813]) and use of NSAIDs (HR, 0.373 [95% CI, 0.179–0.776]) were associated with radiographic progression in joint areas which suffered active synovitis.

THU0085 RHEUMATOID ARTHRITIS AND ALLERGIC DISEASES

Vanessa Kronzer1, Cynthia S. Crowson2, Jeffrey Sparks3, Robert Vassallo4, John Davis5, 1Mayo Clinic, Rochester, United States of America; 2Brigham and Women’s, Boston, United States of America

Background: Historically, RA was considered a TH1 disease while asthma and allergy were considered TH2 diseases (1). However, several studies have shown an association between RA and asthma (2), and more recently, allergic disease (3).

Objectives: We first aimed to determine the association between RA and asthma after controlling for important confounders including allergic disease, urban environment, and passive smoke exposure. Second, we aimed to determine the association between RA and various allergy types.

Methods: This case-control study identified 1,023 cases of RA (175 incident) within a single-center biobank population using a rules-based algorithm that combined self-report with two diagnosis codes. Exposures were defined) within a single-center biobank population using a rules-based algorithm that combined self-report with two diagnosis codes. Exposures were defined as part of a treat-to-target strategy in early rheumatoid arthritis: impact of joint area, repeated injections, MRI findings, anti-CCP, IgM-RF and CRP. Annals of the rheumatic diseases 2012, 71(6):851-856.

THU0086 PREDICTING TNFALPHA INHIBITOR TREATMENT RESPONSE USING SERUM CYTOKINES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Marissa Lassere1, Sue Baker2, Jenny Gu3, 1UNSW Sydney, St George Hospital SESLHD, Sydney, Australia; 2UNSW Sydney, Sydney, Australia

Background: Tumour necrosis factor-alpha inhibitors (TNFαi) are the main biologics (b-MARDs) used to treat active rheumatoid arthritis (RA) in patients that have failed disease modifying treatment (DMARD). However, 10% of patients do not respond to therapy, TNFα inhibitors in all. Patients are continued on this treatment for several months risking side-effects in the hope that the therapy will work. Another 40% of patients respond partially to this treatment and have to also be treated with other drugs such as methotrexate and prednisone in addition to treatment with TNFαi. Biomarkers offer an opportunity to identify before starting or soon after starting treatment with TNFαi which patients will be responders and whether prednisone and other drugs can be reduced and optimise the risk-benefit of treatment.

Objectives: We undertook a series of experiments with the following objectives: determine whether cytokine biomarkers will predict which patients with rheumatoid arthritis will respond to DMARD early treat-ment responders (b) sustained TNFαi early treatment responders, (c) TNFαi early treatment failures.

Methods: We used the Millipore’s MILLIPLEX MAP Human Th17 Magnetic Bead kit for the simultaneous quantification of the following cytokines: IL-1β, IL-2, IL-4, IL-5, IL-6, IL-9, IL-10, IL-12p70, IL-13, IL-15, IL-17A, IL-17E, IL-25, IL-27, IL-28α, IL-28β, IL-29, IL-33, GMCSF, IFNγ, MIP-3α, TNFα and TNFβ. We evaluated 14 patients with RA starting on a DMARD and 26 patients with RA starting on a TNFαi after failing DMARDs. These cytokines were assayed monthly 2 or 3 months prior to starting a TNFαi to evaluate month-to-month cytokine variability and every month up to 5 months after initiation of treatment. RA disease activity was measured using the RA Disease Activity Score (DASCRP28) which includes joint counts, CRP and a patient-reported outcome of health status. All samples were blocked with Heteroblock to reduce rheumatoid factor and other hetero-philic antibodies. Rheumatoid factor was measured before and after blocking. The same negative and positive controls were included across all plate runs. All assays were done in singlet to accommodate longitudinal samples. Mixing studies were undertaken to evaluate whether cytokine results could be analysed using quantitative statistics.

Results: We had 67 serum samples in the DMARD treated group and 202 serum samples in the TNFαi treated group because of the longitudinal study design. Using mixed effects linear regression to account for longitudinal data in a model that included all 25 cytokines, treatment-time and treatment type (DMARD or TNFαi/D-MARD), we found that in patients on DMARDs, IL-6, IL-1β, IL-28α, and TNFβ were associated with treatment response. However, in TNFαi treated patients, TNFα, GM-CSF and IL-6 were associated with treatment response. Only p values <0.005 are reported given that 25 cytokines were included in the model.

Conclusion: In this study of treatment response comparing DMARDs and TNFαi in a longitudinal cohort of 26 patients with a total of 202 samples measuring TNFαi and GM-CSF may predict early TNFαi responders.

THU0087 UTILITY OF INFRARED THERMOGRAPHY FOR THE EVALUATION OF RHEUMATOID ARTHRITIS

Jesús Loarce-Martos1, Javier Bachiller-Corral1, Iñaki Fernández Cuevas2, Manuel Sillero Quintana3, Mónica Vázquez Díaz1, 1ThermoHuman, Madrid, Spain; 2ThermoHuman, Madrid, Spain; 3Universidad Politécnica de Madrid, Madrid, Spain

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory disease, which predominantly affects the hands. Currently in clinical practice, we explore the number of swollen and painful joints in order to evaluate the activity of the disease. Infrared thermography (IT) is a non-invasive, lacking ionizing radiation, operator-independent and low-cost technique that allows to measure the temperature of the cutaneous surface through the taking of a photograph.

Objectives: To determine the utility of IT in the evaluation of hands in patients with RA.

Disclosure of Interests: None declared.

Methods: A cross-sectional study was performed, including patients with RA according to 2010 ACR/EULAR criteria attended in our Hospital between February and March 2018. Demographic, clinical and analytical characteristics of patients were registered. Number of painful and swollen joints were assessed for each patient, including wrist, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints. Subsequently, a standardised photograph of the dorsal aspect of both hands was taken with a thermal camera (FLIR T250 model) (Figure 1). With this technique mean temperature (MeanT) and maximum temperature (MaxT) were assessed at each joint. Also, differential temperature (DiffT) was assessed (mean temperature at joint - temperature at forearm skin).

Results: We included a total of 42 patients. 76% were women, mean age at diagnosis was 56.7 years old. 29 patients were positive for rheumatoid factor and 31 for anti-citrullinated peptide antibody. At the time of the assessment, median CRP was 9.19 mg/L and ESR was 14.77 mm/h. MeanT for the 65 swollen joints was 1.5°C higher than the 847 non-swollen joints (p<0.000). Independent analysis for each joint level (wrist, MCP and PIP) revealed higher temperature in swollen joints (Table 1). Similar results were obtained for painful joints. ROC curves and areas under the curve (AUC) were calculated for wrist, MCP and PIP joints, obtaining the most favorable results for DiffT in wrist and MCP joints, and for MaxT in PIP joints, allowing to calculate a cut-off point at each joint level (Table 2).

Figure 1. Selective temperature increase over third PIP of the left hand.

Table 1. Correlation between swollen joints and MeanT, MaxT and DiffT.

Conclusion: In patients with RA, there is a statistically significant relationship between joint temperature measured by thermal imaging and the presence of swollen and painful joints in the assessment by the rheumatologist. The ROC curves indicate an acceptable sensitivity and specificity and allow to determine cut-off temperatures for clinical use. Infrared thermography could be a useful tool in the assessment and monitoring of arthritis in RA patients.

THU0088 BASELINE ADIPONECTIN LEVELS PREDICT FUTURE DEVELOPMENT OF RHEUMATOID ARTHRITIS IN SUBJECTS WITH OBESITY

Cristina Maglio1, Yuan Zhang1, Christian Herder2, Anna Rudin1, LenaCarlsson3.
1University of Gothenburg, Department of Rheumatology and Inflammation research, Gothenburg, Sweden; 2German Diabetes Center, Düsseldorf, Germany; 3University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden

Background: Adiponectin is a cytokine produced by the adipose tissue and is involved in both metabolic and inflammatory processes1. In obese subjects, serum adiponectin levels are surprisingly low2. On the contrary, adiponectin levels are increased in serum and synovial fluid of subjects with established rheumatoid arthritis (RA)1,3.

Objectives: By exploiting a longitudinal study enrolling more than 4000 obese subjects, we aim to determine if serum adiponectin levels are a risk factor for the development of RA in obese subjects.

Methods: The Swedish Obese Subjects (SOS) study is a longitudinal controlled trial on the effect of bariatric surgery on the incidence of obesity-related diseases. It includes 4047 obese subjects whereof 2010 underwent bariatric surgery and 2037 constituted the matched control group4,5. SOS study participants who developed RA were identified by searching the Swedish National Patient Register. Eleven subjects with prevalent RA at baseline are excluded by the analyses. Patients were followed up until diagnosis of RA, death, migration or end of follow-up (December 2016). Total adiponectin was measured using the Quantikine ELISA kit from Bio-Techne (Minneapolis, MN, USA).

Results: Adiponectin measurement at baseline was available for 3691 subjects. Among those subjects, 82 subjects developed RA during a follow-up for up to 29 years. High serum adiponectin levels at baseline were associated with the incidence of RA, independently of bariatric surgery, sex, age, body-mass index, smoking, and C-reactive protein and erythrocyte sedimentation rate levels (adjusted Hazard Ratio HR per 10 µg/mL adiponectin 1.70, 95% confidence interval CI 1.12-2.60, P value=0.01). When stratifying the population according to the median of erythrocyte sedimentation rate, serum adiponectin levels were associated with the incidence of RA, independently of bariatric surgery, sex, age, body-mass index, smoking, and C-reactive protein and erythrocyte sedimentation rate levels (adjusted HR per 10 µg/mL adiponectin 1.70, 95% CI 1.12-2.60, P value=0.01). When stratifying the population according to the median of baseline adiponectin, subjects with adiponectin greater than 6.8 µg/mL had a higher risk to develop RA during follow up (log-rank P 0.028, unadjusted HR 1.64, 95% CI 1.05-2.56, P=0.03, Figure 1).

Conclusion: In a large cohort of obese subjects followed up for up to 29 years, serum adiponectin levels were associated with the incidence of RA years before the onset of clinical signs. The association between adiponectin and the incidence of RA was independent of other risk factors, including C-reactive protein, smoking and bariatric surgery.

ASSOCIATION OF ANTI-PAD4 ANTIBODIES WITH MORTALITY OVER UP TO 14 YEARS FOLLOW-UP IN RA

Laura Martinez-Prat1,2, Victor Martinez-Taboada3, Marcos Lopez-Hoyos4, Michael Mahler5, Inova Diagnostics, Inc., Research and Development, San Diego, United States of America; 1Francisco de Vitoria University – Madrid, Health Sciences, Pozuelo de Alarcón, Spain; 2Hospital Universitario Marqués de Valdecilla – IDIVAL, Rheumatology, Santander, Spain; 3Hospital Universitario Marqués de Valdecilla – IDIVAL, Immunology, Santander, Spain

Background: Novel biomarkers have been described in rheumatoid arthritis (RA) patients, including antibodies to carbamylated proteins (anti-CarP) and to protein-arginine deiminases (PAD). Anti-PAD4 antibodies are associated with anti-citrullinated protein antibodies (ACPA) and worse baseline radiographic joint damage [1]. A subset of anti-PAD4 antibodies that cross-react with PAD3 and are associated with erosive disease, ACPA and progression despite treatment has also been described [1].

Objectives: To evaluate several novel RA markers in a cohort of RA and controls and their association with erosive disease and biological treatment use in RA.

Methods: Sera from 116 RA patients [63 young onset RA (YORA) and 53 elderly onset RA (EORA)] and 155 controls [134 polymyalgia rheumatica (PMR) patients and 21 healthy individuals (HI) older than 60 years old] were included. Information on erosion status and biological treatment was available for 56 of the RA patients. The samples were tested for anti-PAD3 and anti-PAD4 IgG using the novel particle-based multi-analyte technology (PMAT, research use only, RUO), as well as for ACPA (CCP3 IgG ELISA and chemiluminescent immunoassay (CIA)) and anti-CarP IgG (ELISA, RUO).

Results: Significantly higher levels of anti-PAD3, anti-PAD4 and ACPA were observed in YORA vs. EORA (p<0.0001 for anti-PAD3 and ACPA ELISA and CIA, p=0.0016 for anti-PAD4). In the RA patients with erosion and treatment information available, anti-PAD4 antibody levels, but not ACPA, anti-CarP or anti-PAD3, were significantly higher in patients on biologic treatment vs. patients that were not on biologics (p=0.0017). Anti-PAD4 positive patients, were 10.1 [95% CI 2.5-52.0, p=0.0002] times more likely to be on biologic treatment vs. patients that were not on biologics.

Conclusion: Anti-PAD3, anti-PAD4 and ACPA are associated with disease onset at an early age. Anti-PAD4 are associated with erosive disease and biological treatment use in RA and represent a useful marker for better patient stratification.

MORTALITY OVER UP TO 14 YEARS FOLLOW-UP IN MTX-REFRACTORY PATIENTS RANDOMIZED TO A STRATEGY STARTING WITH ADDITION OF INFliximab OR ADDITION OF SULFASALAZINE AND HYDROXYCHLOROQUINE

Heather Miller1, Johan K Walliman2, Ingemar Petersson3, Saedis Saevardsdottir4, Jonas Söderling3, Sofia Ernemast5, Johan Askling1, Ronald van Vollenhoven6, Martin Neovius1, Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden; 2Lund University, Department of Rheumatology, Clinical Sciences Lund, Lund, Sweden; 3Lund University, Department of Orthopaedics, Clinical Sciences, Lund, Sweden; 4Karolinska Institutet, Stockholm, Institute of Environmental Medicine, Stockholm, Sweden; 5Academic Specialist Center, Stockholm Health Services, Stockholm, Sweden; 6University of Amsterdam, Amsterdam Rheumatology and immunology Center, Amsterdam, Netherlands

Background: Longevity is the ultimate health outcome measure, incorporating treatment effectiveness as well as treatment safety. Randomized controlled trials (RCT) in rheumatoid arthritis (RA) have received lecture fees from AstraZeneca, MSD and Johnson&Johnson.

Disclosure of Interests: Laura Martinez-Prat Employee of: Inova Diagnostics (Not pharmaceutical, diagnostics company), Victor Martinez-Taboada: None declared, Marcos Lopez-Hoyos Consultant for: Inova Diagnostics (Not pharmaceutical, diagnostics company), Michael Mahler Employee of: Inova Diagnostics (Not pharmaceutical, diagnostics company)

Abstract THU0090 – Figure 1. Association of anti-PAD4 antibodies with joint erosion status (A) and to biological treatment use (B). Results are in Median Fluorescence Intensity (MFI). P-values of the Mann-Whitney analysis are shown in red. Dashed line indicates the preliminary cut-off of the assay. Number of positives and % within each subgroup are shown.
controlled trials tend to report data only on short term effects, while extended follow-up of long-term mortality data of treatment strategies are scarce.

Objectives: To compare mortality risk over up to 14 years of follow-up in MTX-refractory patients with early RA, randomized to a strategy starting with addition of infliximab versus addition of sulfasalazine and hydroxychloroquine.

Methods: We used data from a 2-arm, parallel, randomized, active-controlled, open-label trial (Swefot), in which patients with early RA (symptom duration <1y) were recruited from 15 rheumatology clinics in Sweden from 2002-2006. Patients who did not achieve low disease activity after 3-4 months of MTX were randomized to receive additional biological treatment with infliximab (n=128) or conventional combination treatment with sulfasalazine and hydroxychloroquine (n=130). By linking the trial database to the Swedish Total Population Register and Cause of Death Register, we collected complete data on all-cause mortality and emigration until August 31, 2017. Participants were followed until death, emigration, or end of follow-up, whichever came first. Analyses were by intention to treat.

Results: Over a total 1477 and 1504 person-years of follow-up in the infliximab and the conventional combination treatment group there were 13 and 16 deaths, respectively (8.8 [95%CI 0.0-25.1] versus 10.6 [95%CI 0.0-28.4] deaths per 1000 person-years; mortality hazard ratio 1.2 [0.6-2.5]; P=0.62; Figure). After 5 years, approximately 50% of patients in the infliximab arm remained on biologic therapy and 50% in the conventional combination arm remained on synthetic DMARDs.

Conclusion: No increased or decreased mortality risk could be observed over up to 14 years of follow-up in patients with MTX-refractory early RA, randomized to a strategy starting with addition of either infliximab or conventional combination DMARD treatment. At the end of the extended follow-up, a minority of patients remained on their assigned therapy, reflecting the treat to target paradigm.

Disclosure of Interests: Heather Miller: None declared, Johan K Wallman Consultant for: Consultant for AbbVie, Celgene, Eli Lilly, Novartis, and UCB Pharma., Ingemar Petersson: None declared, Saedis Saevarsdottir Consultant for: Consultant for AbbVie, Celgene, Eli Lilly, Novartis, and UCB Pharma., Rosa Morla1, Mariam Riai2, Theodore Pincus2, Isabel Castrejon2. 1Fundació Clinic, Barcelona, Spain; 2Rush University Medical Center, Chicago, United States of America

Background: Depression in patients with rheumatoid arthritis (RA) may be pre-existent, amplified, or newly-developed after onset of RA. Together with other comorbidities, socioeconomic, or affective factors can influence perception of pain, functional disability, and health status. The prevalence of depression in RA patients is 19% and affect remission rates according to a classical composite index.

Objectives: We compared patient self-reported scores included on the Multidimensional Health-Assessment Questionnaire (MDHAQ) and levels of remission according to RAPID3 in patients who self-reported depression versus no depression.

Methods: All patients complete a MDHAQ at each visit, which includes physical function (FN), three 0-10 visual analogue scales (VAS) for pain (PN), patient global estimate (PATGL), fatigue (FT), RADAI self-report joint count, a review of 60 symptoms (ROS) on a checklist, three evaluations for depression, anxiety and sleep quality (0-3.3), and demographics. RAPID3 (0-30) is the sum of FN, PN, and PATGL; being remission RAPID3 <3. Patients with RA (ICD10) were classified according to self-reported depression on the ROS. Agreement between MDHAQ-depression and by the Patient Health Questionnaire (PHQ-9) was evaluated in 57 patients. Demographic and clinical characteristics were compared by self-reported depression status using Student t-test and chi-square test.

Results: 464 RA patients were studied: 118 (25%) self-reported depression. In 57 patients, who also completed the PDQ-9, agreement with MDHAQ depression was 93% (kappa=0.80 95% CI 0.61-0.99). Only 37 (31%) of all patients reporting depression had evidence in the medical record of treatment and/or specialist evaluation for depression. No differences between depression groups were seen for mean age or sex. Patients reporting depression had lower education level (12.5 vs 14.3, p<0.001) and poorer scores for physical function, pain, and patient global leading to higher RAPID3 and lower percentage of patient in remission (12.4 vs 4%, p<0.001) (Table). Depressed patients also reported higher scores for fatigue, number of painful joints, number of symptoms, and more difficulty with sleep, and anxiety.

Table: MDHAQ patient self-report scores in patients with RA according to depression status. Data are presented as mean (SD) and percentages. p<0.001

MDHAQ/RAPID3: Patient self-report scores

| Physical function (0-10)  | 2.4 (2.0)             | 3.4 (1.9)*             |
| Pain (0-10)               | 5.3 (3.0)             | 6.8 (2.6)*             |
| Patient global estimate (0-10) | 4.9 (3.0)            | 6.6 (2.7)*             |
| RAPID3 (0-30)             | 12.6 (7.2)            | 16.6 (6.4)*            |
| % patients in RAPID3 remission | 12.4%               | 4%*                    |
| Fatigue (0-10)            | 4.2 (3.2)             | 6.3 (3.0)*             |
| Self-reported joint pain-RADAI (0-48) | 12 (10)             | 18 (12)*               |
| Review of Symptoms (0-60) | 8 (7)                 | 18 (9)*                |
| Sleep problems (0-3.3)    | 1.1 (0.9)             | 1.9 (0.9)*             |
| Dealing with depression/feeling blue (0-3.3) | 1.1 (0.9)            | 1.9 (0.9)*             |
| Dealing with anxiety/being nervous (0-3.3) | 0.1 (0.4)            | 0.7 (0.4)*             |

Conclusion: The prevalence of self-reported depression in our RA patients was 25%, with only 31% treated for this condition. RA patients with self-reported depression exhibit higher scores for all MDHAQ scores, and a lower rate of RAPID3 remission. MDHAQ may be useful to identify patients with depression in busy clinical settings.

**THU0093**

**BASAL METABOLIC RATE AND CHARLSON COMORBIDITY INDEX ARE INDEPENDENT PREDICTORS OF METABOLIC SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Dong-Jin Park, Haimuzi Xu, Sung-Eun Choi, Ji-Hyou Kang, Shin-Seok Lee.

Cheonnam National University Hospital, Gwangju, Korea. Rep. of (South Korea)

**Background:** Metabolic syndrome (MetS) is associated with 2-fold increase in cardiovascular disease (CVD) and 1.5-fold increase in all-cause mortality in the general population. The overall pooled prevalence of MetS in the meta-analysis of rheumatoid arthritis (RA) patients is 30.65%. Along with high prevalence of MetS in RA, several studies showed the contribution of MetS to the increased risk of CVD or cardiovascular mortality in RA patients. Although controversial, the inflammatory activity of RA was significantly associated with MetS in several cross-sectional studies. However, no prospective studies have confirmed an increased risk of MetS development during the course of RA.

**Objectives:** This 2-year prospective study investigated the predictors of metabolic syndrome (MetS) in patients with rheumatoid arthritis (RA).

**Methods:** We recruited 319 consecutive RA patients who did not have MetS at baseline. MetS was defined according to the modified NCEP/ATP III 2005 for Asian populations. Predictors of MetS were assessed using univariate and multivariate logistic regression analyses.

**Results:** Of the 247 RA patients who finished 2-year follow-up, 37 (15.0%) developed MetS. At baseline, the patients who developed MetS were older and had higher BMI (P = 0.002), higher waist circumference (P = 0.011), higher waist-hip ratio (P = 0.035), greater skeletal muscle mass (P = 0.005), higher body fat mass (P = 0.011), higher percent body fat (P = 0.004), lower basal metabolic rate (P = 0.004) and higher Charlson comorbidity index score (P < 0.001). The percent of diabetes (P = 0.007) and hypertension (P < 0.001) were higher in patients with MetS than without MetS. And they also had elevated glucose (P = 0.004), triglyceride levels (P < 0.001), and a lower low-density lipoprotein cholesterol (LDL-C) (P < 0.001). The patients who were more likely to take less hydroxychloroquine (P = 0.044), more oral hypoglycemic agents (P < 0.001) and had a lower EQ-5D score (P = 0.025). In the multivariate analysis, when variables that belong to the composition of MetS were excluded, basal metabolic rate (OR = 0.205, 95% CI: 0.078–0.541, P = 0.001) and Charlson comorbidity index score (OR = 2.191, 95% CI: 1.280–3.751, P = 0.004) remained significant predictors of MetS.

**Conclusion:** The development of MetS in RA patients was associated with basal metabolic rate and Charlson comorbidity index at baseline. Physicians should pay more attention to RA patients who have these risk factors to avoid CVD and cardiovascular mortality.

**DEFINING A LEARNING CURVE FOR CLINICIANS PERFORMING ULTRASOUND-GUIDED NEEDLE SYNOVIAL BIOPSIES: A RETROSPECTIVE ANALYSIS OF THE EXPERIENCE AT THE EXPERIMENTAL MEDICINE AND RHEUMATOLOGY, QUEEN MARY UNIVERSITY OF LONDON**

Alessandra Nerviani1, Frances Humby2, Gloria Lisso Ribera1, Felice Rivelles1, Stephen Kelly2, Rebecca Hands, Costantino Pitzalis1. William Harvey Research Institute, Queen Mary University of London, United Kingdom; Centre for Experimental Medicine and Rheumatology, London, United Kingdom; 2Barts Health NHS Trust, Rheumatology, London, United Kingdom

**Background:** Despite the significantly better outcome reached by patients with Rheumatoid Arthritis following the introduction of the biologics, the absence of predictors of individual response to the available agents constitutes a huge unmet clinical need. The histological analysis of the diseased synovial tissue (ST) may represent a valuable prognostic tool. The ultrasound-guided needle synovial biopsy (US-nSB) is a safe, effective and increasingly used method to retrieve ST from both large and small joints. Therefore, assessing the ‘learning curve’ for clinicians training in this technique is critically important.

**Objectives:** To retrospectively evaluate the learning curve for clinicians performing US-nSB at the Centre for Experimental Medicine and Rheumatology, Queen Mary University of London.

**Methods:** The performance of 5 clinicians has been evaluated from their first to >20 procedures based on the training phase (Table). The standard teaching method included: US/US-guided injections; observation of US-nSB; initial procedures occurring under the strict active supervision of an expert.

**Results:** The total number of ST fragments retrieved during the procedure did not significantly change during the learning phase (17.3 ± 3.5 from 1st to 10th biopsy vs 17.2 ± 3.4 if expert performer). Independently of the training phase, a significantly higher number of samples were retrieved from knees/wrists in comparison with metacarpo-, metatarso-, and proximal inter-phalangeal joints. The average weight of a ST fragment at the beginning of the learning curve was comparable with the mean weight of US samples retrieved by expert performers (3.7±2.5mg from 1st to 10th biopsy vs 2.9±2.4mg if experts). ST from knees had a significantly higher mean weight, which could be explained by the more frequent use of a 14G (rather than 16G) needle. At the beginning of the learning curve, 48.9%±5.5% of the retrieved ST-samples were considered histologically ‘gradable’ (visible lining and/or clear sub-lining based on H&E/CD68 IHC staining); the rate of gradable ST progressively increased and remained >60% when >20 procedures have been performed. The duration of the US-nSB significantly decreased during the learning time (49 ± 18 min from 1st to 10th biopsy vs 30 ± 9 min if expert). No serious adverse events (AEs) such as haemarthrosis or joint infection have occurred during the learning time. The overall rate of minor AEs (e.g., minor bleeding) was not the highest at the beginning of the training. During the 1st-10th procedures, 18.2% of the patients reported severe pain compared to the average 8.4%.

**Conclusion:** In this single-centre retrospective study we showed that, with an appropriate training and the presence of the initial strict supervision, performing US-nSB is safe and effective since the beginning of the learning curve. Further prospective and multi-centre studies are needed to confirm the optimal learning time and training method.

**REFERENCES:**

Methods: The CareRA trial included 379 patients with early RA (<1 year) fulfilling 1987 or 2010 ACR criteria and naïve to disease modifying anti-rheumatic drugs (DMARDs). Patients were randomized to one of four different intensive treatment strategies based on methotrexate (MTX) monotherapy or synthetic (cs)DMARD combinations with or without glucocorticoid (GC) bridging. Before randomization, stratification into a high- or low-risk group according to classical poor prognostic markers (presence of erosions, positivity to rheumatoid factor (RF) and/or anti-citrullinated protein antibody (ACPA), and elevated disease activity) was conducted. One of these strategies, COBRA Slim, a combination of MTX and a prednisone remission induction scheme stepping-down from 30 mg QD, was initiated in 141 patients from both risk strata, of which 38 were negative for both RF and ACPA (seronegative). Following the treat-to-target principle, using the disease activity score in 28 joints with C-reactive protein (DAS28CRP), treatment adaptations were steered at low disease activity (<2.6), while aiming for remission (<2.6) as final outcome.

The “as observed” population was analysed for differences in disease activity and radiographic progression between seronegative and seropositive patients at several time points during the 2-year study using independent sample t-test, Mann Whitney-U or adjusted X² (Yate’s correction for small samples). Survival analysis using Kaplan Meier was employed for time to first response to treatment. First response to treatment was defined as achieving first remission (DAS28CRP<2.6) or first relevant improvement (ΔDAS28CRP>1.2) after screening. Sensitivity analyses were applied on the complete CareRA cohort.

Results: Seronegative patients starting COBRA Slim (n=38), had similar age (53 vs 51 years, p=0.52), body mass index (25.5 vs 26.7, p=0.08), symptom duration (7.9 vs 7.2 months, p=0.23), presence of erosions (24% vs 23%, p=0.99) and gender distribution (82% vs 63%, p=0.06), compared to seropositive patients (n=103). However, parameters of disease activity were higher in seronegative patients at screening: DAS28CRP (5.1 vs 4.5, p=0.01), 28 swollen joint count (8.2 vs 5.7, p=0.02) and 28 tender joint count (10.3 vs 6.9, p=0.006). These results were corroborated when analysing the entire CareRA cohort.

The mean disease activity was significantly higher in seronegative patients at the first stages (week 8 and 16), but became comparable by year 1 and 2 (Table 1). There was a significant difference in time to first treatment response between seronegative and seropositive patients, despite being treated with the same strategy, as depicted in the inverted Kaplan Meier plot (Figure 1).

Conclusion: In conclusion, CareRA participants with seronegative RA had a higher initial disease activity, longer time to experience a first treatment response, but achieve comparable remission status as seropositive patients with COBRA Slim, a combination of MTX with moderate dose GC bridging. This provides further evidence that, seronegative RA can no longer be considered a milder form of disease and requires an equally intensive initial treat-to-target therapy as seropositive RA.

Results: At T1, 104 patients (44.6%) were classified as IR to MTX. In univariate analysis, factors significantly associated with IR were: female
In this RA cohort, the condition of current smoker was the only predictor of IR to MTX. This observation, together with the lack of association between previous smoking habit and IR to MTX, further prompted to recommend cessation of cigarette smoking in patients with RA who begin treatment with MTX.

THU0097 PERSISTENT HIGH DISEASE ACTIVITY IN THE ANTI-CARBAMYLATED PROTEIN ANTIBODY POSITIVE EARLY ARTHRITIS PATIENTS INDEPENDENTLY OF TREATMENT

Christina Requeiro1, Ana Ortiz2, Laura Nuño3, Diana Peiteado3, Alejandro Villalba4, Dora Pascual Salcedo5, Ana Martinez-Feito6, Alejandro Balsa7, Isidoro González-Alvaro8, Antonio González9, Instituto de Investigacion Sanitaria-Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain; Instituto de Investigacion Sanitaria del Hospital de la Princesa (IDIPAZ), Madrid, Spain; Instituto de Investigacion Sanitaria-Hospital Clinico Universitario de Santiago, Experimental and Observational Rheumatology, Santiago de Compostela, Spain; Orgentec Diagnostika GmbH, Mainz, Germany; Instituto de Investigacion del Hospital de La Paz (IDIPAZ), Madrid, Spain; Instituto de Investigacion del Hospital de La Princesa (IIS-IP), Madrid, Spain

Background: There is great interest in the identification of prognostic bio-markers informing early therapeutic decisions for the improvement of rheumatoid arthritis (RA) evolution. Promising results in early arthritis (EA) patients indicate the anti-carbamylated protein antibodies (ACarPA) may serve this function. In effect, they are associated with high baseline disease activity and, in our patients, with less improvement in the first 6-months of follow-up. This association was independent of sex, age at diagnosis, time since symptoms onset, smoking and the year of onset.

Objective: We aimed to explore the influence of the initial treatment on the persistent high disease activity associated with the presence of ACarPA in EA patients.

Methods: Samples were obtained at the first visit of two EA cohorts from Hospital Universitario La Paz and Hospital Universitario La Princesa, which recruit patients within one year from the clinical onset. Information on the initial treatment and the disease activity at the baseline and at 6-months of follow-up was available from 546 patients. Treatment was categorized according to the use of corticosteroids, methotrexate (MTX) and other DMARDs, and considering changes in the first 6 months. In addition, MTX dose was considered either quantitatively or as a dichotomous variable (≥ 12.5 mg and < 12.5 mg). Main effects general linear regression was used for analysis, including the treatment and the other confounders as covariates.

Results: A large fraction (83%) of the EA patients received specific treatment from the initial visit. It comprised DMARD (50.1%), corticosteroids (10.6%), or a combination of both (39.3%). The most common DMARD was MTX (82.2%), whereas less frequently used medications included sulfasalazine (5.4%), leflunomide (3.2%), hydroxychloroquine (8.1%) and celecoxib (10.6%). The 35.5% of the treated patients (n=193) during the 6-month follow-up. The presence of ACarPA was associated with a 0.45 higher mean baseline DAS28 and with less decrease of DAS28 (ΔDAS28) from the baseline to 6 months of follow-up (β = 0.08, p = 0.016), as already communicated. This latter association persisted without modification after accounting for the initial treatment (DMARD, corticosteroids, and changes in treatment). In addition, it was independent of the consideration of all DMARDs in a single group, or separated into two categories: MTX and the other. Similarly, the association was independent on MTX dose, defined both as a categorical or a quantitative variable.

Conclusion: The association of ACarPA with a persistently increased disease activity in EA patients is independent of the initial treatment. These results reinforce the possibility that ACarPA can be useful as prognostic biomarkers for the first 6 months of evolution and indicate the need for personalized management of the patients carrying ACarPA.

THU0097 VALUEOF ANTIBODIES AGAINST ACETYLATED PEPTIDES FOR THE CLASSIFICATION OF PATIENTS WITH EARLY ARTHRITIS

Lorena Rodriguez-Martinez1, Holger Bang2, Laura Nuño3, Diana Peiteado4, Ana Ortiz5, Alejandro Villalba6, Dora Pascual Salcedo5, Ana Martinez-Feito6, Alejandro Balsa7, Isidoro Gonzalez-Alvaro8, Antonio Gonzalez9, Instituto de Investigación Sanitaria-Hospital Clínico Universitario de Santiago, Experimental and Observacional Rheumatology, Santiago de Compostela, Spain; Orgentec Diagnostika GmbH, Mainz, Germany; Instituto de Investigación del Hospital de La Paz (IDIPAZ), Madrid, Spain; Instituto de Investigación del Hospital de La Princesa (IIS-IP), Madrid, Spain

Background: Patients with rheumatoid arthritis (RA) achieve the best response when they receive adequate treatment as soon as possible. This fact motivated the modification of the classification criteria by the ACR and the EULAR in 2010 to enable early detection. One of the changes is the increased weight conferred to the autoantibodies: rheumatoid factor and anti-citrullinated protein antibodies. As these antibodies are not present in all patients, other antibodies could provide similar information. In this regard, the antibodies that recognize an acetylated peptide from mutated vimentin (Acylated Peptide Antibodies or AAPA) stand out [1].

Objectives: We aimed to evaluate the AAPA predictive value at the baseline visit for the classification of early arthritis patients.

Methods: A total of 438 patients with available samples and information were randomly selected from two early arthritis clinics. The AAPA were determined in baseline sera as previously described [1]. Two peptides were included, one acetylated at a lysine (anti-AcLys) and the other at an ornithine (anti-AcOrn) and considered either individually or combined. The sensitivity, specificity, predictive positive (PPV) and negative (NPV) values and the AUC of the ROC curve were assessed. Logistic regression was also applied adjusting for age, sex, the centre of origin, anti-CCP, and RF. The study was approved by the ethics committee of the Hospital Universitario La Paz, the Hospital Universitario La Princesa, and the Andronic de Galicia.

Results: The AAPA at baseline were sensitive and specific for the classification of the patients fulfilling RA criteria (46.8%) at the end of the 2-year follow-up (table 1). Specifically, the anti-AcOrn antibodies were slightly
more sensitive and specific than the anti-AcLys ones. The two and their combination showed a preserved specificity for the seronegative patients, but a lower sensitivity than for the seropositive ones. Consequently, the PPV for the seronegative patients was low, although the NPV was high. In the same vein, the AUC was insufficient for the seronegative patients. The regression analysis including the anti-CCP and RF revealed a significant contribution of the anti-AcOm antibodies (OR = 2.1, 95% CI = 1.1 - 4.0, P = 0.02), but not of the anti-AcLys antibodies. On the other hand, the inclusion of the AAPA in the classification resulted in an increase in sensitivity of 5.4%, at the cost of a 13.7% lower specificity, which is an improvement over the anti-carbamylated protein antibodies.

**Abstract THU0097**

</tbody>
</table>

Conclusion: The AAPA show high specificity and sensitivity for RA in early arthritis patients. However, their contribution to RA classification is minor once RF and the anti-CCP antibodies have been considered. But nevertheless, AAPA supports the drive to close the diagnostic gap in this early disease phase and to increase the likelihood of successful therapy.

**THU0098 WHICH FACTORS INFLUENCE ACHIEVEMENT OF TREATMENT SATISFACTION IN RHEUMATOID ARTHRITIS?**

**Martin Schaefers, Jörn Kekow, Karin Rockwitz, Anke Liebhaber, Angela Zink, Anja Strangfeld. 1German Rheumatism Research Center, Berlin, Germany; 2Scientific Advisory Board, Vogelsang-Gommern, Germany; 3Rheumatologist, Goslar, Germany; 4Rheumatologist, Haller/Saale, Germany**

**Background:** The satisfaction of RA patients with their pharmacological therapy is a relevant patient reported outcome which influences treatment adherence and continuation. However, it has not been investigated frequently, and almost never in large studies.

**Objectives:** To assess factors exerting a potential influence on the satisfaction with the pharmacological treatment and to quantify this influence.

**Methods:** The German register RABBIT is a prospective longitudinally followed cohort of RA patients enrolled with a new start of a DMARD after at least one csDMARD failure. This analysis comprises patients who were enrolled with start of a DMARD between 01/2009 and 04/2018, who were observed for at least 12 months and had been on the therapy prescribed at enrolment for at least six months.

**Conclusion:** Satisfaction with the applied treatment was measured in four categories from "very satisfied" to "very unsatisfied". Logistic regression combined with multiple imputation of missing values was performed to calculate odds ratios (ORs) for factors which might have an influence on treatment satisfaction.

**Results:** At treatment onset, 55% of the 8,177 patients were "very" or "rather" satisfied (in the following: "satisfied"), while the rest was "very" or "rather" unsatisfied (in the following: "unsatisfied") with their therapy. After one year of treatment, 86% of patients were satisfied with their treatment. Factors with positive impact on whether patients reached the target of treatment satisfaction were satisfaction at baseline, reduction of DAS28-BSG, pain and glucocorticoid dose as well as the increase of physical function. Depression, obesity as well as a prior treatment failure of bDMARDs had a negative influence on the outcome (see Table 1). The DAS28 component most influential on treatment satisfaction was the patient global health assessment. Regarding glucocorticoid therapy, being still treated with either 5 to 15 mg (OR: 0.66, 95% CI: 0.55; 0.79) or > 15 mg glucocorticoids (OR: 0.25, 95% CI: 0.15; 0.41) had a negative impact on the achievement of therapy satisfaction (data not shown).

**Conclusion:** Reductions in disease activity, pain and glucocorticoid dosage as well as improvement of physical function increase the chance to achieve treatment satisfaction. On the other hand, depression and obesity as well as prior treatment failures with bDMARDs are obstacles to therapy satisfaction. For physicians, these results suggest that efforts to taper glucocorticoid doses are worthwhile to improve patient’s satisfaction.

**Acknowledgement:** Disclosure: RABBIT is supported by a joint, unconditional grant from AbbVie, Bristol-Myers Squibb, Celtrion, Hexal, Lilly, MSD Sharp & Dohme, Pfizer, Roche, Samsung Bioepis, Sanofi-Aventis, and UCB.
Background: Rheumatoid Arthritis (RA) is a progressive inflammatory disease which causes pain, joint damage and disability. Patients with RA may experience disease-specific distress (DSD), which is related to the burden of living with their life-long illness. This phenomenon has been identified in patients with RA, as an entity distinct from other forms of psychological distress. They may also experience disease-specific distress (DSD), which causes pain, joint damage and disability. Patients with RA may experience disease-specific distress (DSD), which is related to the burden of living with their life-long illness. Disease-specific distress (DSD) is important: as they may have different perspectives about their health condition that researchers and/or health care professionals may not have considered. Previous secondary data analysis of patient interviews has suggested that DSD does seem to exist in people with RA, as an entity distinct from other forms of psychological difficulties.

Objectives: The aim of this study was to develop a PGOM, based on previously reported domains of distress, to identify DSD in people with RA for use in clinical and research practice. The study aimed to involve patients in the development of the new outcome measure.

Methods: A three-phase qualitative study was conducted. In Phase 1 items were generated from secondary data analysis of patient interviews. In Phase 2, a focus group of people with RA was consulted with the aim to establish initial face and content validity of the measure and perform item reduction. In Phase 3, individual cognitive interviews (n=9) with people with RA were conducted to further establish face and content validity of the Scale, refine items if necessary and ensure the questionnaire ‘made sense’ to participants. A psychometrician was consulted to consider the development of the new Scale.

Results: In Phase 1, 44 items were initially created to form the Rheumatoid Arthritis Distress Scale (RADS). After Phase 2 and 3 focus group and cognitive interviews respectively, items were reduced from 44 to 39 and three additional supplementary questions were created, to include items such as time since diagnosis and disease activity. Dimensions were classified into five domains of RA distress. Overall participants reported the content of the RADS to be clear and relevant, and that DSD is a valid concept in RA, distinct from clinical depression or anxiety.

Conclusion: DSD appears to be an important concept in RA. The 39-item RADS currently demonstrates acceptable face and content validity in this patient group. It may be beneficial to establish face and content validity in a more diverse patient sample before proceeding with further psychometric testing. The RADS may be a useful tool for healthcare professionals to identify DSD in patients with RA. Direct patient involvement and their commitment have been instrumental in the development of new outcome measures.

THU0101

TORQUE TENO VIRAL LOAD FOR MONITORING OF BIOLOGICAL THERAPIES IN RHEUMATOID ARTHRITIS

Paul Studenic1, Gregory Bond2, Andreas Kirschbaumer2, Manuel Becede3, Karel Pavelka4, Dmitry Karateev4, Jutta Stieger5, Rudolf Puchner6, Rudiger Muller7, Elisabeth Puchhammer-Stickl8, Martin Durechova9, Andrea Rubbert-Roth5, Jun-Fei Chen6, and Andreas Kniep1

Background: The apathogenic and highly prevalent Torque Teno Virus (TTV) of Experimental Rheumatology, 1st Faculty of Medicine, Institute of Rheumatology, Prague, Czech Republic; 5Hietzing Hospital, 2nd Department of Medicine, Vienna, Austria; 10Charles University in Prague, Department of Experimental Rheumatology, 1st Faculty of Medicine, Institute of Rheumatology, Prague, Czech Republic; 2Rheumatologist in private practice, Wels, Austria; 3Kantonsspital Aarau, Division of Rheumatology, Aarau, Switzerland; 4Medical University of Vienna, Center for Virology, Vienna, Austria; 5Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; 6Charles University in Prague, Department of Experimental Rheumatology, 1st Faculty of Medicine, Institute of Rheumatology, Prague, Czech Republic

Method: To identify different treatment trajectories, based on CDAI and DAS28 line characteristics.

Results: TTV was measured in 95 RA patients [INF (n=23), TCC (n=22), ABA (n=27) or RTX (n=23)]. Median TTV levels at baseline were 4.2x10^9 c/ml with no difference between the treatment groups. After 3 months of treatment with patients with INF (p=0.018), ABA (p=0.071) and RTX (p=0.001) showed an increase in TTV levels compared to baseline. There was no change in TTV in patients with TCZ, who were omitted from further analyses. TTV at 3 months after treatment was higher in patients achieving a SDAI85 response at month 6, 0.001) Levels of above 5.8x10^9 c/ml at month 3 showed a 67% specificity and 81% sensitivity for a SDAI85 response at month 6, corresponding to a positive likelihood ratio of 2.6 (95% CI: 1.6-4.1). Patients in the top tertile of month 3 TTV (>7.8x10^9 c/ml) had lower SDAI, CDAI and DAS28 and higher SDAI85 response rate at month 6 (OR: 1.41-16.42; p=0.012). The highest non-response rates were found in patients within the lowest TTV tertile (Table A), and the highest remission rates were found in the highest TTV tertile (Table B). No patient below a TTV value of 2.7x10^9 c/ml at month 3 showed SDAI85 treatment response at month 6.

Conclusion: Our data suggest that TTV levels in patients with RA treated with INF, ABA or RTX at month 3 are associated with clinical responses at month 6, and thus may constitute a biomarker for therapeutic monitoring.

THU0102

PATIENT DISEASE TRAJECTORIES IN BARICITINIB-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO METHOTREXATE

Peter C. Taylor1, Paul Emery2, Michael E. Weinblatt3, Eduardo Myster4, Andrea Rubbert-Roth5, Bochao Jia6, Luna Sun7, Yushi Liu8, Yun-Fei Chen9, Anabela Cardoso9, Yoshiya Tanaka10, 1University of Oxford, Oxford, United Kingdom; 2University of Leeds, Leeds, United Kingdom; 3Brigham and Women’s Hospital, Boston, United States of America; 4Organización Médica de Investigación, Buenos Aires, Argentina; 5Kantonsspital St. Gallen, St. Gallen, Switzerland; 6Eli Lilly and Company, Indianapolis, United States of America; 7University of Occupational and Environmental Health, Kitakyushu, Japan

Background: In RA-BEAM phase 3 study, baricitinib (bari) 4mg demonstrated clinical efficacy in patients (pts) with rheumatoid arthritis (RA) and an inadequate response to methotrexate. Bari, a selective Janus kinase 1/2 inhibitor, is approved for the treatment of moderate to severe active RA in adults in >50 countries. For improved treatment strategy, it is important to understand whether the pt population is composed of distinct pt groups with differing treatment responses and associated baseline characteristics.

Objectives: To identify different treatment trajectories, based on CDAI improvement, in bari 4mg treated pts over 52 weeks; and examine the associated clinical disease measures, structural damage score and baseline characteristics.

Methods: Growth Mixed Model (GMM), a novel latent class mixed model, was used to classify the longitudinal disease patterns instead of

Conclusion: Baseline severity is associated with different treatment trajectories. With bari treatment, majority of pts achieved LDA and had no structural progression. Pts with high baseline disease activity were associated with longer time to achieve LDA. Pts with higher baseline structural damage in addition to high disease activity were less likely to achieve LDA, but consistent with the other groups, had similar low rate of joint damage progression. Long-term maintenance and continued improvement in CDAI were observed with bari treatment.
OBJECTIVES: We aimed to identify a metabolite signature with consistently high accuracy for RA.

CONCLUSION: Three distinct groups of persistent responders with early RA were identified based on their 1-year PRO profile. The majority of patients were well-synchronized, reporting very low pain and fatigue levels in concordance with their well-controlled disease activity. One in 5 persistent responders, however, seemed to have unmet needs. In view of early identification of patients at risk of poor wellbeing despite good disease control, early pain and fatigue levels and certain coping behavior and illness perceptions were recognized as potential targets for future interventions.

Disclosures of Interests: Xinran Wang: None declared, Joel Paschke: None declared, Rana Dadashova: None declared, Edna Hutchings: None declared, Liang Li: None declared, Walter P Maksymowych: Grant/research support from: AbbVie, Pfizer, Janssen, Novartis, Consultant for: AbbVie, Eli Lilly, Boehringer, Galapagos, Janssen, Novartis, Pfizer and UCB Pharma; Chief Medical Officer for Canadian Research and Education Arthritis.

measures, the power Doppler joint count (UPDJC), which demonstrates hyper vascularization of the synovium, and the 12-multibiomarker disease activity test (MBDA), which incorporates 12 biomarkers in an algorithm leading to a single disease activity score. The UPDJC includes scoring at six dorsal wrist and six dorsal MCP sites [2]. The average duration of RA in patients at this clinic is > 10 years.

**Results:** Fifty two patients were found to be in inadequate control at the clinic and were started on Tofacitinib. Ten patients discontinued treatment with Tofacitinib within the first year, four because of an inadequate response, and four because of adverse effects (two deaths, one with lung cancer and one with colon cancer), and two because of noncompliance or loss to follow up.

Forty two patients remained on treatment with Tofacitinib for at least one year, and at this point in time, 21 patients have remained on the drug for two or more years. The DAM assessments and selected changes in certain laboratory parameters for two yearly time points are shown for these patients in Table 1. Clinical significance was determined by Paired-samples T tests.

**Conclusion:** Patients showed sustained significant clinical responses for two or more years by all three diverse DAMs and several other common measures of clinical response. The initiation of Tofacitinib in a Rheumatology clinic utilizing a T2T strategy clearly showed sustained clinical responses for up to two years for a significant number of patients. Significant changes in some of the cytokine components of the MBDA were also noted, including increases in leptin levels. The use of the T2T strategy offers a unique opportunity to obtain real time data in patients treated with specific therapeutic agents at a community rheumatology clinic.

**SYSTEMIC IMMUNE-INFLAMMATION INDEX IN RHEUMATOID ARTHRITIS PATIENTS: RELATION TO DISEASE ACTIVITY**

**Takahiro Yoshikawa,** Tetsuya Funukawa, Masao Tamura, Teppei Hashimoto, Mai Morimoto, Naoto Azuma, Masayasu Kitano, Kiyoshi Matsui. Hyogo college of Medicine, Division of Rheumatology, Department of Internal Medicine, Nishinomiya-city, Japan

**Background:** Among the immune system elements, neutrophils, lymphocytes and platelets play a role in the regulation of inflammation while also undergoing changes secondary to inflammation. Recently, the neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) have been used as markers of systemic inflammation including rheumatoid arthritis (RA). It was reported that systemic immune-inflammation index (SII) is positively correlated with neutrophil and platelet counts and inversely correlated with lymphocyte count.

**Objectives:** We investigated whether SII in RA patients and compare between active cases and those in remission.

**Methods:** This research is a cross-sectional study. In 734 RA patients registered in the database of our department from January to April in 2016, a total of 574 eligible RA patients were included in this study, excluding 160 patients whose neither RA disease activity or laboratory data were available. Correlations of SII with the disease activity of RA were evaluated. SII was calculated by the following calculation formula: SII = Neutrophils (%)/Lymphocyte (%) * Platelets (G/L).

**Results:** The median age of patients was 65.0 (IQR: 53.0-73.0) years and the median of disease duration was 9.0 (6.0-14.0) years. The DAS28-ESR was median 2.65 (1.90 - 3.37). SII was 612.0 (400.6 – 951.8). There was a significant correlation between SII and DAS28-ESR (r=0.322, P<0.0001), and SII was significantly elevated as disease activity increased (median 513.6 in remission group, 605.7 in low disease activity group, 793.8 in moderate disease activity group and 1367.1 in high disease activity group, respectively; P<0.0001). In contrast to SII, in NLR no significant difference was observed in all groups. The cut-off of SII was 635.9, 688.6 and 912.5 for DAS28-ESR remission, low disease activity and high disease activity. In multiple regression analysis of LogSII, compared to conventional DMARDs treatment, anti-cytokine therapy such as anti-IL-6 receptor inhibitor or anti-TNF inhibitor showed a significant negative correlation, but no significant differences were observed with abatacept or JAK inhibitor.

**Conclusion:** In this study, for the first we demonstrated that SII was more strongly related to disease activity than NLR. SII is an emerging inflammatory biomarker which could be used to evaluate disease activity in RA patients. A larger scale longitudinal study is recommended to confirm the present results and further demonstrate the relation to medications received and disease outcome.

**BARIATRIC SURGERY DOES NOT PREVENT THE DEVELOPMENT OF RHEUMATOID ARTHRITIS IN OBSESE SUBJECTS**

**Yuan Zhang**, Anna Rudin1, Cristina Maglio1, Lena Carlsson2,1. University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden;2 University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden

**Background:** Obesity is among the risk factors for rheumatoid arthritis (RA)2,3. In subjects with RA, bariatric surgery-induced weight loss has been associated with a lower disease activity, a decrease in inflammatory markers and a lower use of disease-modifying antirheumatic drugs4. However, the effect of bariatric surgery on the prevention of RA is not known. We have previously shown that bariatric surgery reduces the risk of gouty arthritis and psoriasis in obese subjects4,5.

**Objectives:** By exploiting a longitudinal study enrolling more than 4000 obese subjects, we aim to determine if bariatric surgery prevents the incidence of RA.

**Methods:** The Swedish Obese Subjects (SOS) study is a longitudinal controlled trial on the effect of bariatric surgery on the incidence of obesity-related diseases. It includes 4047 obese subjects: 2010 underwent bariatric surgery and 2037 constituted the matched control group5. Seven Swedish local ethics review boards approved the study protocol. SOS study participants who developed RA were identified by searching the Swedish National Patient Register. Eleven subjects with prevalent RA at baseline are excluded by the analyses. Patients were followed up until diagnosis of RA, death, migration or end of follow-up (December 2016).

**Results:** During a follow-up for up to 29 years, 92 subjects developed RA. Fifty-one individuals (55%) had a seropositive RA (serostatus was unknown for 17 subjects). Forty-seven subjects (2.3%) developed RA in the surgery group compared to 45 subjects (2.2%) in the control group. Bariatric surgery was not associated with the incidence of RA during follow up (log-rank P=0.88; unadjusted Hazard Ratio-HR 1.03, 95% Confidence Interval-CL 0.69-1.55, P=0.88, Figure 1). Similar results were
obtained if only subjects with seropositive RA were included in the analysis. Adjustment for confounding factors did not affect the results (HR for bariatric surgery after adjustment for confounding factors 0.92, 95% CI 0.58-1.45, P=0.72).

Conclusion: In a large cohort of obese subjects followed up for up to 29 years, bariatric surgery did not affect the incidence of RA years.

REFERENCES:

Background: Involving patients with rheumatoid arthritis (RA) in the assessment of their disease may increase adherence to treatment, improve disease outcomes and reduce consultation time.

Objectives: To evaluate the concordance between physician and patient assessment of disease activity in RA using Disease Activity Score (DAS-28).

Methods: During the routine consultation, patients were briefed about DAS-28 by their rheumatologist. Using a standard DAS-28 mannequin, physicians, patients and nurses reported the number of tender and swollen joint, inflammatory markers and global health on a 0-10 Likert scale. Concordance between physician- and patient-DAS categories was calculated using weighted kappa (WK) for category comparison. Concordance between physician- and patient-DAS was estimated using the Bland-Altman method. Predictive factors of positive concordance between physician and patient-DAS were identified using logistic regression.

Results: Four hundred and twenty patients from 7 Middle-Eastern countries were included, with a mean age of 49 years (SD 12), 84% of females, disease duration of 11 years (SD 8). Mean physician-DAS-28 was 4.03 (SD 1.51), 65% had positive rheumatoid factor, 58% had positive ACPA, 30% had erosive disease and 34% were on biotherapies. Agreement between physician- and patient-DAS categories was 89%, WK was 0.84. WK were 0.80 for DAS physician-nurse, 0.79 for DAS patient-nurse, 0.83 for CDAI physician-patient and 0.88 for SDAI physician-patient agreements respectively. All activity measures were higher in patients compared to physicians, except for the swollen joints count. The mean difference between physician- and patient-DAS was -0.09 [95% CI -0.14; -0.04] and was smaller in patients in remission (Figure 1: Bland Altman plot). Concordance was statistically associated with CRP and patient SDAI.

Conclusion: Concordance between patient and physician assessment of disease activity in RA was excellent and was higher using SDAI followed closely by DAS-28 and CDAI. Self-assessment of disease activity should be decided according to the physician’s clinical judgment.

INCREASED MODIFIED HEALTH ASSESSMENT QUESTIONNAIRE (MHAQ) SCORE IS INDEPENDENTLY ASSOCIATED WITH HIGH RISK OF SEVERE INFECTION IN RHEUMATOID ARTHRITIS (RA) PATIENTS

Yui Yoshida1, Shiro Ohshima2, Eri Oguro1, Kentaro Kuzuya1, Yasukata Okita1, Hitoshi Matsuoka1, Satoru Teshigawara1, Maiko Yoshimura1, Kentaro Isoda1, Yoshihito Harada1, Jun Hashimoto1, Yukihiko Saeki2.

1National Hospital Organization Osaka Minami Medical Center, Rheumatology and Allergology, Osaka, Japan; 2National Hospital Organization Osaka Minami Medical Center, Clinical Research, Osaka, Japan

Background: Severe infections that complicate rheumatoid arthritis may cause significant morbidity and mortality. The Modified Health Assessment Questionnaire (MHAQ) is one of the scores most used for measuring the functional status of rheumatoid arthritis (RA) patients. However, the relationship between the MHAQ score and severe infection risk has not been well studied [1].

Objectives: To examine the relationship between disease-associated functional status (MHAQ) and severe infection events (SIE) in rheumatoid arthritis patients.

Methods: We used data from the “MIRAi” cohort in Japan. In total, 2174 RA outpatients were examined at the Osaka Minami Medical Center between January 2012 and October 2017. The risk factors were identified and evaluated by multivariate logistic regression, linearity analysis. Interactions of SIE risk between MHAQ and treatment were also observed.

Results: The cohort contributed to 8206 patient-years of follow-up. Overall, 251 SIEs were observed and the incidence of SIE was 3.0 infections per 100 patient-years. The mean age at first observation was 61.7 years and the mean disease duration was 10.3 years. The use of glucocorticoids (GCs), methotrexate (MTX), and biologic and targeted synthetic disease-modifying antirheumatic drugs (bDMARDs/tsDMARDs) was 59.2%, 63.8%, and 40.3%, respectively. The mean Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), Disease Activity Scores of 28 joints (DAS28), and Simplified Disease Activity Index (SDAI) were 300.0, 200.0, and 250.0, respectively.

Conclusions: The MHAQ score was independently associated with SIE risk (OR: 1.02 for each increase of 0.1, 95% CI: 1.01–1.03, p=0.015). The MHAQ score was an independent risk factor for infection in RA patients.

Background: Angiogenic T cells (Tang) are responsible of vascular repair and homeostasis. Decreased Tang frequencies have been reported in rheumatoid arthritis (RA), in association with disease activity and previous history of cardiovascular (CV) disease. However, excess of CV risk is already present during the early stage of RA. Whether Tang cells are associated with subclinical vascular abnormalities remains unknown.

Objectives: To evaluate whether Tang cells could be associated with subclinical CV endpoints (subclinical atherosclerosis and vascular stiffness) in the very early stage of RA.

Methods: Patients were recruited upon early referral to the rheumatology department. All patients were untreated at the time of sampling. Tang (CD3+CD31+CXCR4+) frequency was assessed by flow cytometry in peripheral blood samples. Plaque occurrence, CIMT and stiffness parameters were analyzed by Doppler ultrasound in internal carotid, middle cerebral and basilars arteries.

Results: 53 patients were recruited, 47 fulfilling 2010 ACR/EULAR classification criteria for RA (36 women, 26 FR+ and 26 ACAP+), 6 fulfilling criteria for Clinically Suspect Arthralgia (CSA) (6 women, 3 RF+ and 3 ACPA+), Tang frequency did not differ between RA and CSA (p=0.382) and it was negatively associated with DAS28 (r=-0.448, p<0.001) and SDAI (r=-0.385, p=0.006), but not with duration of the symptoms (r=0.053, p=0.713)). Tang levels were not related to individual traditional CV risk factors, body mass index, waist circumference (all p>0.050) nor the modified SCORE (r=-0.173, p=0.244) or Framingham Risk Score (r=-0.127, p=0.399). Neither atherosclerosis plaque occurrence (r=0.631) nor the cIMT (r=0.070, p=0.652) were associated with Tang levels.

Conclusion: Tang frequency paralleled carotid peak systolic velocity (r=0.399, p=0.008) and end diastolic velocity (r=0.332, p=0.034) in internal carotid artery. Moreover, Tang positively correlated stiffness parameters: vascular strain (VS, r=0.428, p<0.010), vascular distensibility (VD, r=0.479, p<0.004), vascular stiffness (VSF, r=0.519, p<0.001) and pressure-strain elastic modulus (PSEMD, r=0.531, p=0.015) in left internal carotid artery. Finally, Tang frequency was an independent predictor of stiffness parameters after adjusting for mSCORE, body mass index, DAS28, RF and ACPA positivity: VS (β=0.451, p=0.045), VD (β=0.462, p=0.026), VSF (β=0.422, p=0.035) and PSEM (β=0.446, p=0.026). Tang cells may have a very early role on vascular stiffness in RA. These results point to the Tang subset as the missing link between disease activity and vascular abnormalities during the first stage of the disease.

THU0112

SECULAR TRENDS IN THE INCIDENT RISK OF ACUTE MYOCARDIAL INFARCTION IN RHEUMATOID ARTHRITIS RELATIVE TO THE GENERAL POPULATION

Kiana Yazdani, Hui Xie, Antonio Avila, Yufei Zheng, Michael Abrahamowicz, Diane Lachal. Arthritis Research Canada, Richmond, Canada

Background: Recent studies have demonstrated a declining trend in RA mortality relative to the general population (1). This improvement in mortality could be due to improvement in incident risk of cardiovascular events that are the leading cause of excess deaths in RA (2).

Objectives: Our objective was to assess secular trends in ten-year incident risk of acute myocardial infarction (AMI) in incident cohorts of RA versus general population controls, using administrative health data.

Methods: We conducted a retrospective study of a population-based cohort of incident RA cases who first met previously published RA criteria between 01/01/1997 and 31/12/2004 in British Columbia, followed until 12/31/2014, with general population controls matched 2:1 on gender, age, and index year. Individuals were excluded if they had a diagnosis of MI prior to index date. Incident AMI was defined as first AMI during follow-up using ICD codes (ICD-9 code 410/ICD-10 code I21) in Hospital Discharge data or death certificate in Vital Statistics data. RA and general population cohorts were stratified according to year of RA incidence.
defined according to first RA visit, using a 7-year wash-out period. Inci-
dent rates (IRs) of AMI for RA and general population cohorts, as well as
ingcident rate ratios (IRRs), with 95% confidence intervals (CI) were
calculated per calendar years of incidence. Multivariable Cox Proportional
Hazard models with left truncation were used to estimate risk of AMI in
RA relative to general population while controlling for potential confound-
ers, with contribution of person time of follow-up starting from index date
(second RA visit) to avoid immortal time bias and censoring at ten years
from incident year, or last health care utilization. To examine whether
secular trends differed in RA relative to general population, an interaction
term was tested between the RA indicator and year of RA incidence. To
account for non-linear effect of cohort year, we compared cox regression
models with linear, quadratic, and flexible spline forms of the cohort-year
effects and the model with the best AIC was used to interpret the data.
Results: 23,231 RA individuals (66.4% female; mean [SD] age 59[16.88]
years) and 46,474 controls experienced 1,133 and 1,646 incident AMI,
respectively. Cox Proportion model with the lowest AIC best fit the data.
Risk of AMI was significantly higher in RA vs. general population [aHR
(95% CI): 1.21(1.10, 1.32); p<0.001]. A significant decline was observed
in risk of AMI over calendar year of incidence in both RA [0.94(0.92,
0.97); p<0.001] and controls [0.93(0.91, 0.95); p<.0001]. The decline in AMI
risk did not differ significantly in RA vs. general population [interac-
tion p=0.555].
Conclusion: Our finding suggests that the risk of AMI has significantly
decreased over time in RA and general population cohorts. However, the
decreling trend was not significantly different in RA compared to the gen-
eral population.

THU0114 MITIGATING MEDICATION RISK AVERSION IN THE
CONFIDENT TREATMENT DECISIONS FOR LIVING WITH
RHEUMATOID ARTHRITIS TRIAL

Maria Danila1, Lang Chen2, Justin Owensby3, Ronan O’beirne2, Josh Melnick3,
Eric Ruderman, Leslie Harrold4, Jeffrey Curtis1. 1University of Alabama at
Birmingham, Medicine, Birmingham, United States of America; 2Northwestern,
Chicago, United States of America; 3University of Massachusetts, Waltham, United States of America

Background: Controlling disease activity in RA using a treat-to-target
(T2T) strategy can optimize clinical and patient-important outcomes. Yet,
many patients are not familiar with T2T and report medication risk aver-
sion as a major barrier to changing therapy.

Objective:s To develop and evaluate an educational, direct-to-patient
video intervention aimed at improving willingness of patients to appropri-
tely escalate treatment in RA.

Methods: We conducted a controlled, randomized trial of our intervention
among US patients with self-reported RA enrolled in the ArthritisPower
patient registry. We recruited participants by email, and surveyed their
satisfaction with disease control, values about RA medications, decisional
coping, and willingness to change RA treatment change. We compared the dif-
ference in pre-post differences in willingness to change RA treatment bet-
ween the two groups using t-test.

Results: We invited 1264 RA patients by email. We reached our enroll-
ment goal in 8 weeks. Study participants (N=208) were 90% Caucasian,
90% women, with mean (SD) age 50 (11) years, in good health (51%); 52%
reported familiarity with T2T. A majority (89%) reported having values
that favored RA medications. We observed no differences in baseline
sociodemographics, patient global assessment of disease activity, health
IS INCIDENT RHEUMATOID ARTHRITIS INTERSTITIAL LUNG DISEASE ASSOCIATED WITH METHOTREXATE TREATMENT? RESULTS FROM A MULTIVARIATE ANALYSIS IN THE ERAS AND ERAN INFECTION COHORTS:

KIELY Patrick1, Amanda Busby2, Elena Nikiphorou3, Keith Sullivan3, Adam Young2, 1St George’s University Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom, 2University of Hertfordshire, Center for Health Services and Clinical Research and Post Graduate Medicine, Hatfield, United Kingdom; 3King’s College, London, Academic Rheumatology, London, United Kingdom

Background: Rheumatoid arthritis interstitial lung disease (RA-ILD) is a rare but significant manifestation of RA, with high mortality. Methotrexate (MTX) is known to cause hypersensitivity pneumonitis, but its effect on the onset of RA-ILD is less clear.

Objectives: To assess predictive factors for rheumatoid arthritis interstitial lung disease (RA-ILD) in two early RA inception cohorts with a focus on MTX exposure.

Methods: Patients with new diagnosis of RA recruited to the early RA study (ERAS) and the early RA network (ERAN). Standardised data including demographics, drug therapies and clinical outcomes including the presence of RA-ILD were collected at baseline, within 3-6 months, at 12 months and annually for up to 25 years thereafter. Primary outcome was the association of MTX exposure with incident RA-ILD. Secondary outcomes were the association of demographic, comorbid and RA specific factors on incident RA-ILD using univariate and multivariate analyses and the association of MTX exposure on time to RA-ILD diagnosis using time to event Cox proportional hazards analysis.

Results: Of 92 eligible ILD cases, 39 occurred in 1578 (2.5%) MTX exposed and 53 in 1114 (4.8%) non-MTX exposed cases. The primary analysis of incident RA-ILD cases only developing after any csDMARD treatment (n=67) showed MTX exposure not to be associated with incident RA-ILD (OR 0.85 CI 0.49, 1.49 p=0.578) and a non-significant trend for delayed ILD diagnosis (O.R. 0.54 CI 0.28, 1.06 p=0.072) (see Figure). In an extended analysis including all RA-ILD cases (n=92, including those present pre csDMARD exposure), MTX exposure was associated with a significantly reduced risk of incident RA-ILD (O.R. 0.48, CI 0.3, 0.79 p=0.004) and longer time to ILD diagnosis (O.R. 0.41, CI 0.23, 0.75 p<0.004). Other independent baseline associations with incident RA-ILD were higher age of RA onset, ever smoking, nodules, RF positivity, male gender, ESR, and a longer time from first RA symptoms to first secondary care visit. There is no association between MTX treatment and incident RA-ILD. MTX may have a protective role in delaying the onset of RA-ILD.

Conclusion: In ERAS/ERAN, incident RA-ILD is significantly associated with older age of RA onset, ever smoking, nodules, RF positivity, male gender, ESR, and a longer time from first RA symptoms to first secondary care visit. There is no association between MTX treatment and incident RA-ILD. MTX may have a protective role in delaying the onset of RA-ILD.

THU0116

COMPARATIVE SAFETY OF BIOLOGIC DMARDS AND ABATACEPT IN RHEUMATOID ARTHRITIS WITH COPD: A REAL-WORLD POPULATION-BASED OBSERVATIONAL STUDY

Samy Sussa1, Marie Hudson1, Pierre Emms1, Sophie Shen2, Teresa Simon2, 1McGill University, Montreal, Canada, 2Bristol-Myers Squibb, New Jersey, United States of America

Background: The biologic DMARD abatacept has been associated with respiratory adverse events in patients with RA who have chronic obstructive pulmonary disease (COPD) in the ASSURE trial (NCT00048932), based on only 54 patients with RA and COPD. A large observational study of patients with RA and COPD, involving over 1,800 patients using abatacept did not find an increased incidence of respiratory adverse events with abatacept compared with other biologic DMARDs. 2 It remains uncertain, however, whether this potential respiratory risk affects all biologic DMARDs, including abatacept, when compared with non-biologic DMARDs.

Objectives: To assess in a real-world observational setting whether patients with RA and COPD treated with biologic DMARDs, including abatacept, have an increased risk of serious respiratory adverse events compared with similar patients treated with non-biologic DMARDs.

Methods: The Truven MarketScan® Commercial and Supplemental Medicare databases were used to identify patients diagnosed with RA and COPD, treated with a biologic or non-biologic DMARD between January 2007 and December 2015. A prevalent new-user cohort design was used to match each new user of a biologic DMARD with a new user of a non-biologic DMARD on time-dependent propensity scores. Patients were followed up from new use until the end of enrolment or 31 December 2015. The Cox model was used to estimate the hazard ratios (HRs) of respiratory adverse events associated with biologic DMARDs compared
with non-biologic DMARDs, further adjusted for confounders found to be unbalanced despite matching on propensity scores.

Results: The study cohort included 7,424 new users of biologic DMARDs matched to 7,424 new users of non-biologic DMARDs, followed for up to 9 years. The adjusted HR (95% CI) of the combined respiratory endpoint, including severe COPD exacerbation, bronchitis and severe pneumonia or influenza, with biologic DMARD use relative to non-biologic DMARDs was 1.06 (0.91-1.24). For severe COPD exacerbation it was 0.88 (0.64-1.21), 1.02 (0.82-1.27) for bronchitis, while for pneumonia or influenza it was 1.18 (0.90-1.54) if hospitalized and 1.01 (0.89-1.14) as outpatient. For users of abatacept relative to non-biologic DMARDs, the HR of the combined respiratory endpoint was 1.06 (0.80-1.42). Results remained unchanged with sensitivity analyses.

Conclusion: In this large real-world study of patients with RA and COPD, the risk of pre-specified serious respiratory adverse events was not significantly increased in patients using biologic DMARDs, and specifically abatacept, compared with those using non-biologic DMARDs. This study does not support the safety signal for abatacept from the ASSURE trial.

TREATMENT OF RHEUMATOID ARTHRITIS WITH COMBINATION THERAPY USING A BIOLOGIC AGENT AND METHOTREXATE LOWERS THE RISK OF DECREASING KIDNEY FUNCTION COMPARED TO METHOTREXATE MONOTHERAPY

MWA YUSUKE, Nobuyuki Yajima, Sakiko Isejima, Ryo Yanai, Mika Hatano, Yoko Miura, Nao Oguro, Tomoki Hayashi, Kosuke Sakurai, Tsuyoshi Kasama.

Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan

Background: Rheumatoid arthritis (RA) is associated with reduced kidney function, possibly due to chronic inflammation or the use of nephrotoxic therapies. However, little is known about the effects of novel non-nephrotoxic biologic agents (biological disease-modifying antirheumatic drugs [bDMARD]) on the risk of decreasing kidney function.

Objectives: To elucidate the effects of bDMARDs on decreasing kidney function.

Methods: We recruited a cohort of 1058 patients with RA from the All Showa University of RA database. The following background factors were analyzed: age, sex, type of bDMARD, methotrexate and prednisolone dosages, use of conventional synthetic DMARDs and nonsteroidal anti-inflammatory drugs, body mass index, smoking history, diabetes status, hypertension status, dyslipidemia status, serum creatinine (Cr) level, CRP level, and matrix metalloproteinase-3 level. Furthermore, we used the simplified disease activity index (SDAI) for the evaluation of the disease activity of RA. The estimated glomerular filtration rate (eGFR) was calculated using the serum Cr level and age, sex. We divided the patients into two groups according to the treatment, as follows: bDMARD with methotrexate (MTX) treatment (combination group) (744 patients) and MTX monotherapy group (314 patients). The patients followed the same treatment plan for 1 year. Patients who had primary and secondary failures, adverse effects of drugs, and missing data and those who relocated or withdrew from the study were excluded. Propensity scores were calculated based on the following factors: age, sex, prednisolone dosage, MTX dosage, SDAI, Cr level, eGFR, diabetes status, hypertension status, and dyslipidemia status. Overall, 285 patients in each group were identified by propensity score matching. The primary end-points were the eGFR values before treatment and 6 months and 1 year after treatment. Significance was determined using the repeated-measures analysis of variance (ANOVA).

Results: The eGFR (mL/min/1.73 m2) decreased from 88.5 ± 21.8 to 86.1 ± 21.5 and 83.7 ± 21.0 at 6 months and 1 year, respectively, in the combination treatment group and from 86.3 ± 37.3 to 79.5 ± 19.1 and 78.5 ± 19.5 at 6 months and 1 year, respectively, in the MTX monotherapy group. No interaction was observed between the groups. A significant difference was observed between the groups (p < 0.0066) and even during the treatment period (p < 0.001) by repeated-measures ANOVA.

Conclusion: The decrease in eGFR was smaller in the combination treatment group than in the MTX monotherapy group. bDMARD use may lower the risk of decreasing kidney function in patients with RA.

SUCCESSFUL PSYCHOPHARMACOTHERAPY OF ANXIETY AND DEPRESSIVE DISORDERS IMPROVES RHEUMATOID ARTHRITIS REMISSION RATE AT FIVE YEARS FOLLOW-UP

Anton Abramkin1, Tatiana Listysyna1, Dmitry Yeltschenkov2, Olga Seravinaya2, Oksana Kovalevskayaa2, Svetlana Glukhova1, Evgeny Nasonov1. 1-V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2-Moscow Research Institute of Psychiatry, «National Medical Research Center of Psychiatry and Narcology» Ministry of Health of Russia, Stress disorders, Moscow, Russian Federation

Background: Anxiety and depressive disorders (ADD) affect rheumatoid arthritis (RA) disease activity and remission rate. Psychopharmacotherapy (PPT) of ADD attempts to improve the remission rate.

Objective: To determine factors associated with RA remission rate.

Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47.4±11.3 (Me±SD) yrs. All pts met the full ACR criteria for RA. Remission was defined as DAS28<2.6. Mean RA activity by DAS28 was high (5.27±1.78) at baseline. 69.4% RA-pts were already taking prednisone (9 [5; 10] mg/day (Me (25%; 75%)), 84.4% - conventional disease-modifying antirheumatic drugs (cDMARDs), 7.8% - biologic DMARDs (bDMARDs) - anti-TNFα - 6.3%, rituximab - 1.6%. ADD were diagnosed in 123 (96.1%) of RA-pts in accordance with ICD-10 in semi-structured interview. Severity of depression and anxiety was evaluated with Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A). RA-pts with ADD were divided into the following treatment groups: 1 – cDMARDs (n=39), 2 – cDMARDs + PPT (sertraline or mianserin) (n=43), 3 – cDMARDs + bDMARDs (n=32), 4 – cDMARDs + bDMARDs + PPT (sertraline or mianserin) (n=9). Biologics treatment duration varied from 1 to 6 years, antidepressants – from 6 to 96 weeks. Logistic regression analysis was conducted to determine factors associated with RA remission rate.

Results: At 5-yrs endpoint in 83 RA-pts remission rate was 22.9% (8.3%, 34.5%, 19.0% and 33.3% in groups 1, 2 and 3, respectively). Significantly higher proportion of patients achieved remission in cDMARDs + PPT group vs cDMARDs group (34.5% vs 8.3%, RR 1.8 (95%CI 0.35 – 9.2), p=0.024). By univariate logistic regression model, sex, younger age, smoking RA-pts, RA duration, RF and ACPA negativity, lower baseline DAS28 and HAQ, absence of extraarticular RA manifestations and depression at the beginning of the study, and remission of anxiety and depressive symptoms at the end of the study were significantly associated with RA remission (table 1). These variables were subjected to multivariate stepwise logistic regression. Only lower baseline DAS28 (OR 0.636 (95%CI 0.515 – 0.785), p=0.001) and remission of anxiety and depressive symptoms at 5-yrs endpoint (OR 0.689 (95%CI 1.826 – 21.29), p=0.007) were independently associated with RA remission at 5-yrs follow-up.

Table 1. Factors associated with RA remission at 5 years (univariate logistic regression).

RHEUMATIC DISEASE COMORBIDITY INDEX IMPACT ON DISEASE ACTIVITY IN PATIENTS ENROLLED IN KUWAIT REGISTRY OF RHEUMATIC DISEASES (KRRD)

VASER Ali1,2, Khudood Saier2, Ahmed Enzi2, Fatemah Alouabi3, Adel Al-Awdih3, Waelid Al-Kandari3, Eman Hasan4, Hebah Altahain4, Mohammed Hussain5, Ahmed Alsaber6, Ali Adeed4, Adeeba Herz7, Aqeel Ghanem7, 1Mubarak Al Kabeer Hospital, Rheumatology, kuwait city, Kuwait; 2Farwania Hospital, kuwait city, Kuwait; 3AJ Jahs Hospital, kuwait city, Kuwait; 4Amin Hospital, kuwait city, Kuwait; 5Kuwait Technical college, Department of Mathematics, kuwait city, Kuwait

Background: Its known that the presence of certain comorbidities in patients with Rheumatoid arthritis (RA) can have an impact on the chance of achieving low disease activity (LDA).

Objectives: The purpose of this study was to examine the association of different comorbidities with low disease activity index in patients enrolled in KRRD.

Methods: The database of KRRD was used to include patients with RA and multiple visits. Comorbid conditions were collected at enrollment by the treating rheumatologist and modeled using the Rheumatic Disease Comorbidity index (RDCI) score, and by individual comorbidity condition. Disease activity (DAS28) was assessed at routine clinic visits. Associations of comorbidity measures with disease activity over 4 years of follow-up were examined using multivariable linear models. The odds of ever achieving DAS28 low disease activity (<3.2) were examined using multivariable logistic regression.

Results: Among 1511 participants with mean age of 52 (SD 12) years, RA duration 8 (SD 6) years, 60.7% female, 77.1% RF positive, 64.6% anti-CCP positive, and 10.8% with smoking history, 1.29 had a RDCI. Hypertension (21%), diabetes mellitus (21%), hyperlipidemia (12%), cardiovascular (CV) disease (3.6%) and interstitial lung disease (ILD) (1.1%), were the most prevalent comorbidities. Select individual comorbidities, including DM, kidney disease and COPD, were more closely associated with unfavorable longitudinal disease activity, and achievement of low disease activity status. Correlation test between DAS28 and all comorbidities showed significant negative association for achieving low disease activity if the patient has history of diabetes mellitus, COPD or kidney disease. Conclusion: DM, kidney disease and COPD but not composite comorbidity scores, are associated with higher measures of disease activity and lower odds of achieving low disease activity status in RA patients enrolled in KRRD registry.

CIRCULATING FIBROBLAST GROWTH FACTOR-23 IS ASSOCIATED WITH DYSLIPIDEMIA IN RHEUMATOID ARTHRITIS PATIENTS

Antonio Alvarez de Cifuentes1, Lucia Cantero-Nieto2, José Alberto Garcia-Gomez2, Gema Robledo3, Marta Trigo3, Javier Martin Ibanez4, Miguel A Gonzalez-Gay5, Norberto Orteco7, 1Vega Baja Hospital, Rheumatology, Orihuela, Spain; 2Santa Ana Hospital, Emergency, Granada, Spain; 3Hospital General Universitario de Elx, Elche, Spain; 4Institute of Parasitology and Biomedicine López-Neyra IPBLN-CSIC, Granada, Spain; 5Hospital San Cecilio, Internal Medicine, Granada, Spain; 6IDIVAL, Santander, Spain; 7Hospital Universitario San Cecilio, Internal Medicine, Granada, Spain

Background: In rheumatoid arthritis (RA) patients an increased risk of morbidity and mortality from cardiovascular (CV) events as a result of accelerated atherosclerosis. The bone-derived fibroblast growth factor-23 (FGF23) is a novel marker of chronic kidney disease (CKD)-associated mineral bone disorder, which increases progressively with declining renal function. FGF23 is associated with left ventricular hypertrophy, impaired left ventricular function, endothelial dysfunction, heart failure and progression of renal failure in adult CKD.
**Objectives:** The objectives of this study were to: compare serum FGF-23 levels between RA patients and healthy controls and investigate possible associations between FGF23 as surrogate measures of cardiovascular disease.

**Methods:** This cross-sectional study was performed in Vega-Baja Hospital, Orihuela (Spain) from November 2016 to May 2018. We prospectively enrolled 63 consecutive women patients affected by RA and followed up at the Vega-Baja Hospital (Orihuela, Spain) and 65 matched healthy women controls. All patients included in this study had normal serum creatinine (Cr) levels and met the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for RA. Total cholesterol and triglyceride levels were determined by fully enzymatic techniques. High-density lipoprotein (HDL) was determined by precipitation of apolipoprotein B (apoB)-containing lipoproteins with magnesium sulfate, and lipase. Lower-density lipoprotein (LDL) was calculated using the Friedewald formula. Serum FGF-23 was measured using ELISA.

**Results:** The mean serum total cholesterol, HDL-C, LDL-C, and triglycerides were 212.74±41 mg/dL, 69.92±19.45 mg/dL, 120.18±29.24 mg/dL, and 112.93±55.67 mg/dL, respectively. There was no significant differences in FGF-23 levels between the patients and controls [85.7 (5.2-275.4) vs. 81.2 (2.6-269.9) pg/ml; P=0.4316], but we found that FGF23 levels were positively associated with total cholesterol (p <0.05), low-density lipoprotein (LDL-c) level (p <0.05) and smoking (p = 0.008) in patients with RA.

**Conclusion:** We report an association between circulating FGF-23 and LDL-c in RA patients, representing a novel pathway linking high FGF23 to an increased cardiovascular risk.

females. Only few data are available specifically focused on differences in drug use according to gender.

Objectives: To evaluate gender differences in treatment approaches in RA patients treated with bDMARDs (biological DMARDs).

Methods: We included RA patients aged ≥18 years, with disease duration ≥1 years, with a stable bDMARD treatment (≥12 months) in a monocentric cohort in the North-East of Italy. Social, demographic, and clinical features in addition to treatments were considered. To assess variables independently associated with gender, all variables achieving a p<0.20 in univariate analysis were included in a multivariate regression model.

Results: Among 721 RA patients, 514 patients were eligible for the analysis and 407 were females. Compared with males, females had a lower BMI, a higher DAS28, a higher number of conventional synthetic DMARDs (cDMARDs) used before the start of bDMARDs, a higher number of bDMARDs with different mechanism of action (MoA), a larger use of prednisone and a lower rate of combination with MTX (Table 1). After adjustment for confounding factors, females had an increased probability of prednisone and a lower rate of combination with MTX (Table 1). After adjustment for confounding factors, females had an increased probability of taking ≥2 DMARDs before bDMARDs (OR 2.21, 95% CI 1.25-3.93, p=0.007) and a lower BMI (per 5-unit increase, OR 0.70, 95% CI 0.56-0.87, p=0.001) compared to males (Figure 1).

Conclusion: In a cohort of Italian RA patients, females were treated with a higher number of cDMARDs before starting a bDMARD compared to males and a trend toward the use of more bDMARDs with different MoA. Further insight is needed regarding possible differences in the accessibility to bDMARD treatment and reasons for unsatisfactory treatment control in females.

THU0123 INFLUENCE OF AUTOIMMUNE VASCULITIS ON LUNG DISEASES IN RHEUMATOID ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGICAL STUDY OF 161 PATIENTS

Miklós Bély1, Ágnes Apáthy2. 1Hospital of the Order of the Brothers Saint John of God in Budapest, Department of Pathology, Budapest, Hungary; 2St. Margaret Clinic, Budapest, Department of Rheumatology, Budapest, Hungary

Background: Complications of rheumatoid arthritis (RA) may modify the clinical course and symptoms of allied disorders leading to missed diagnosis or late recognition of associated diseases.

Objectives: The aim of this study was to determine the possible role of classic complications of RA: systemic autoimmune vasculitis (AV), AA amyloidosis (AAa), lethal cardiac insufficiency (CI), caused by endo-, myo- or pancarditis, with or without interstitial pneumonitis, furthermore lethal septic infection (SI) on prevalence and mortality of coexistent associated diseases: arteriosclerosis (Ath), hypertension (HT), type 2 diabetes mellitus (DM), and tuberculosis (Tb) with milary dissemination (mTb).

Methods: 234 non-selected autopsy patients with RA were studied. RA was confirmed clinically according to the criteria of the ARA. The presence of AV, AAa, CI and SI was determined at autopsy and confirmed by a detailed review of extensive histological material. The prevalence and mortality of associated diseases Ath, HT, DM, Tb or mTb were determined and analyzed retrospectively, reviewing the clinical and pathological reports.

The link between AV, AAa, CI or SI and Ath, HT, DM, Tb or mTb was analyzed by (χ²) test.

Results: RA was complicated by AV in 43 (18.4%), by AAa in 48 (20.5%), by CI in 15 (6.4%), and by lethal SI in 33 (14.1%) of 234 patients.

RA associated with severe Ath in 106 (45.3%), with HT in 41 (17.5%), with DM in 41 (17.5%), with Tb in 28 (11.9%) and with mTb in 9 (3.8%) of 234 patients.

As a basic disease Ath led to death in 61 (26.1% of 234), HT in 2 (0.9% of 41), DM in none (0% of 41) and Tb with mTb in 3 (1.3%) of 28 patients. Tb without milary dissemination was not lethal in our patient population.

The statistical links (’p’ values of significance) between complications of RA and prevalence or mortality of allied disorders are summarized in Table. (*) indicates a negative value of associations of inverse relationship.

</tbody>
</table>

Conclusion: The inverse correlations between AV, AAa, CI and Ath, HT, DM, Tb or mTb indicate that the prevalence and mortality of allied disorders were not influenced basically by the complications of RA. The consequently inverse and (in most cases) significant correlations between prevalence of AV, AAa, CI and SI the prevalence and mortality of Ath show that these are independent entities in RA. The AV, AAa, CI and SI are the most important complications of RA, and are characterizing severe forms of disease, mostly involving younger patients, with an earlier onset (without pronounced arteriosclerosis); while Ath is basically an age dependent phenomenon, characteristically present in RA patients with advanced age. RA patients with Ath may represent a special group of RA, characterized by lower incidence of AV, AAa, CI or SI, and a better prognosis.

Disclosure of Interests: None declared

Background: Rheumatoid arthritis increases the risk of cardiovascular disease (CVD). Less is known about the direct influence of CVD and CVD risk factors (RF) on RA outcomes, but higher comorbidity burden has been suggested to adversely affect RA treatment response.1

Objectives: We tested our hypothesis that CVD RFs influence RA disease activity and disability in RA.

Methods: The Ontario Best Practices Research Initiative (OBRI) is a clinical registry of RA patients followed in routine care. RA subjects with complete data to calculate disease activity according to the Disease Activity Score 28 (DAS28), Clinical Disease Activity Index (CDAI), 28 swollen joint count (SJC28) and functional status (Health Assessment Questionnaire Disability Index [HAQ-DI]) at cohort entry were selected. Patients were divided into mutually exclusive groups by baseline CVD status as: (1) no CVD/no CVD RFs; (2) CVD including coronary artery disease, myocardial infarction, cerebral vascular accidents, and peripheral arterial disease; (3) no CVD but CVD RFs including hypertension (HTN), dyslipidemia (DLD), diabetes (DM), or smoking. We performed linear regression analyses for each outcome, adjusted for baseline clinical and demographic variables, to determine the independent effect of CVD status on disease outcomes at baseline and one year follow-up.

Results: Of 2033 patients examined, 49.5% had no CVD, 5.4% had CVD and 45.1% had CVD RFs alone. The most common RF was HTN (33%) followed by DLD (19.7%), current smoking (17%), and DM (8.1%). At cohort entry, having a CVD RF was associated with significantly higher DAS28 (β 0.13, 95% CI 0.02-0.26, p 0.04) and HAQ-DI (β 0.16, 95% CI 0.10-0.23, p<0.0001). At one year, CVD RF was associated with worse DAS28 (β 0.17, 95% CI 0.05-0.30, p<0.01) and CDAI (β 0.96, 95% CI 0.05-1.87, p 0.04) but not HAQ-DI (β 0.03, 95% CI -0.02-0.08, p 0.17). Having higher number of CVD RF was associated with worse disease outcomes. No association between CVD status and swollen joint count was observed.

Conclusion: Even in the absence of CVD, traditional CVD RF are associated with greater RA disease severity and disability both at baseline and one year. Self-perceived impact of comorbidity (patient global assessment of health) may be driving this relationship. Moreover, patients with CVD RF may be more treatment-resistant, suggesting that co-management of CVD RF in RA patients may be beneficial on both fronts.

THU0126 FACTORS AFFECTING THE DISCREPANCY BETWEEN PATIENT AND PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS OVER TIME

Pooneh Akhavan1, Mohammad Movahedi2, Claire Bombardier1, 2, 3

1University of Toronto, Mount Sinai Hospital, Rheumatology, Toronto, Canada; 2Toronto General Research Institute, University Health Network, Ontario Best Practices Initiatives, Toronto, Canada

Background: Rheumatoid Arthritis (RA) is a chronic disease that requires regular follow-ups over time. Physicians make treatment adjustments based on their evaluation of disease status and patients' response to treatment while patients' perception of disease activity may change over time.

Objectives: We aimed to assess the discrepancy between patient global assessment of disease activity and physician assessment of disease activity at baseline and after one year in patients with early RA. We also evaluated factors affecting this discrepancy at these two time points.

Methods: Patients enrolled in the Ontario Best Practices Research Initiative (OBRI), a prospective observational cohort of patients with RA who had disease duration of <12 months (early RA) and had visits both at baseline and after one year were included. The discrepancy between patient global assessment of disease activity (PTGA) and physician global assessment of disease activity (MDGA) was calculated by simple subtraction (PTGA-MDGA). The PTGA-MDGA was considered discordant which could be either positive or negative in favor of PTGA or MDGA. Linear regression analysis was used to assess factors affecting PTGA, MDGA, and PTGA-MDGA discrepancy at baseline and one year.

Results: A total of 460 patients with early RA were analyzed. Majority were female (72.4%) with mean (± SD) age of 57 years (±0.6). The discordance rate was 109 (24%) and 99 (21%) at baseline and one year, respectively. In the majority of the discordant cases, PTGA was higher (98 (90%) at baseline and 85 (86%) at one year). Discordant patients had significantly higher fatigue score, health assessment questionnaire disability index (HAQ-DI), pain score, PTGA, MDGA, tender joint, composite measures of disease activity and higher number of comorbidities at baseline.

Multivariable regression analysis showed that the higher PTGA is significantly associated with higher SJC, TJC and fatigue both at baseline and one year and with higher pain score only at one year. Similar associations were found for MDGA except fatigue which was not significant. Multivariable regression analysis showed that the higher discrepancy between PTGA and MDGA is associated significantly with lower SJC (β=–2.75), higher TJC (β=1.17), and higher fatigue (β=0.85) at baseline. At one-year follow-up, higher pain was the strongest factor (β=4.99) for affecting the higher PTGA-MDGA discrepancy compared with SJC (β=–1.65) and fatigue (β=1.24).

Conclusion: Significant discrepancy between PTGA and MDGA exists in about a quarter of patients with early RA at baseline and slightly less after one year. In the majority of these patients PTGA is higher over time. The number of active joints affects both assessments and this effect persists at one year. Clinicians should consider the above associations when making treatment decisions.

Disclosure of Interests: Pooneh Akhavan: None declared, Mohammad Movahedi: None declared, Claire Bombardier: Grant/research support from: Abbvie, Amgen, Bristol-Myers Squibb, Celgene, Eli Lilly, Hospira, Janssen, Merck, Novartis, Pfizer Inc, Roche, Sanofi, UCB, Consultant for: AbbVie, Hospira, Janssen, Merck, Novartis, Pfizer Inc, Sanofi, Speakers bureau: Roche
IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM 5-YEAR FOLLOW UP

Daria Buhanova, Boris Belov, Galina Tarasova, Marina Sergeeva, Yury Raysev, Galina Lukina, Natalia Demidova, Maria Cherkasova. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: In rheumatology, comorbid infections have significant impact on patients' morbidity, mortality and quality of life. Prevention of infections is an integral part of supervision of these patients.

Objectives: The aim of the study is to investigate immunogenicity and safety of 23-valent polysaccharide pneumococcal vaccine (PPV-23) in patients with rheumatoid arthritis (RA) in a five-years period.

Methods: The study included 79 RA patients with ≥2 recent episodes of respiratory tract infections (bronchitis, pneumonia). 52 RA pts were treated with methotrexate (MT), 14 – with lefunomide (Lef), 13– with TNF-α inhibitors + MT. One dose (0,5 ml) of PPV-23 was administered subcutaneously without discontinuing MT/Lef or 28-30 days prior to initiation of TNF-α inhibitors. Control visits were scheduled as follows: at baseline (Visit 1), and in 1, 3, and every year after immunization. 39 out of 110 pts were followed for 24 months, 23 pts – for 36 months, 23 pts – for 48 months, and 18 - for 60 months. Standard clinical examination and lab tests were performed at each visit.

Levels of serum antibodies (AB) to Pneumococcal capsular polysaccharide were measured with VaccZymeTM PCP IgG 2 panels (The Binding Site Group Ltd, Birmingham, UK). Coefficient of post-immunization response (CPR) was determined for each patient as the ratio of AB levels at Visit II, III, IV, V, VI and VII to AB level at Visit I.

Results: 53 (67%) patients did not have any reactions to the vaccine, 26 (33%) patients indicated pain, swelling and hyperemia of the skin (diameter up to 2 cm) at the injection site of the vaccine, low-grade fever.

These typical reactions following vaccination are completely regressed within days without any additional treatment. They were not associated with RA therapy and did not require changes in ist schemes.

THU0129

ASSESSMENT OF LONELINESS IN PATIENTS WITH INFLAMMATORY ARTHRITIS

Hakan Emmungil1, Uluk Ilgen1, Sezin Turan1, Özge Kılıç2. 1Trakya University, Edirne, Turkey; 2Koç University Hospital, Psychiatry, İstanbul, Turkey

Background: Rheumatic disease and psychosocial status have bi-directional impacts on each other. Loneliness, as a component of psychosocial status, may be interrelated with affect and social support and may also be influenced by the disease itself in patients with inflammatory arthritis1.

Objectives: The aim of this study is to document loneliness and associated factors in patients with inflammatory arthritis. Effects of demographic and disease-related factors, functional status, affect, and social support on loneliness, and loneliness on functional status will be evaluated.

Methods: Consecutive patients with rheumatoid arthritis(RA), ankylosing spondylitis(AS), and psoriatic arthritis(PsA), meeting ACR, ASAS, and CASPAR criteria, respectively, were included in the study. Demographic data and general clinical parameters(Table 1) were identified for each patient. Beck depression and Beck anxiety inventory, revised multidimensional scale of perceived social support, HAQ-DI, and UCLA loneliness scale (ULS-8), all validated in Turkish population, were used for the assessments. Nonparametric comparison (Wilcoxon-Mann-Whitney and Kruskal-Wallis) and correlation(Spearman) tests were used to evaluate associations of demographic data, clinical parameters, and depression, anxiety, social support, HAQ-DI scores with ULS-8 score. Multiple regression models were generated for significant associations.

Results: Demographic data, general clinical features, functional status, and ULS-8 scores of disease groups are summarized in Table 1. Among demographic and general clinical parameters, higher number of total drugs and lower education were associated with significantly higher ULS-8 scores (data not shown). Although weak, there were significant correlations between ULS-8 and HAQ-DI, depression, anxiety, social support, and doctor global VAS scores (Table 2). Stronger correlations were observed between HAQ-DI and depression, anxiety, and patient global VAS scores (Table 2). Among demographic and general clinical parameters, only number of drugs was weakly associated with HAQ-DI score (rho=0.18, p=0.037). Two multiple regression models were generated for predicting HAQ-DI and ULS-8 scores. Depression, anxiety and patient global VAS scores remained significant for predicting HAQ-DI after multiple regression with covariates ULS-8, depression, anxiety, social support, patient global VAS scores, number of drugs used, and education status. The only independent predictor was the education status. ULS-8 score did not correlate with DAS28, CDAI, and SDAI in RA; BASDAI, BASFI, and ASDAS in AS; and number of swollen and tender joints, ESR, CRP, patient global, doctor global, pain, and fatigue VAS scores in PsA.

Conclusion: Loneliness is associated with depression, anxiety, lack of social support, and lower education but not with disease activity in patients with inflammatory arthritis. Self-report loneliness, can be a contributing factor to the disability of the inflammatory arthritis.

THU0130

INCIDENCE AND RISK FACTORS OF FALLING IN PATIENTS WITH RHEUMATOID ARTHRITIS

Rym Fakhfakh, Jguirim Mahbouba, Hibatallah Mosbeh, Abir Dghaies, Grassa Rim, Olfa Jmaa, Saoussen Zrour, Ismail Bejia, Mongi Touzi, Naceur Bergaoui. CHU Fattouma Bourguiba, Rheumatology, monastir, Tunisia

Background: People with rheumatoid arthritis (RA) may be at greater risk of falling than the non-RA population [1]. This increased falls risk may be due to RA disease-related impairments including pain, deformity and decreased muscle strength, as well as reduced functioning such as altered gait and a decline in postural stability.

Conclusion: Loneliness is associated with depression, anxiety, lack of social support, and lower education but not with disease activity in patients with inflammatory arthritis. Self-report loneliness, can be a contributing factor to the disability of the inflammatory arthritis.

REFERENCE:

Objectives: The aim of this study was to evaluate the prevalence of falls and its association with clinical data, disease-related outcomes and physical performance tests in patients with RA.

Methods: A cross-sectional study including patients with RA, followed in the Rheumatology Department over a period of 1 month in 2018. The following parameters were evaluated: clinical aspects; fall occurrence in the previous 12 months; pain on a visual analogue scale (VAS); RA disease activity score (DAS28); erythrocyte sedimentation rate (ESR); Functional capacity assessed by the Health Assessment Questionnaire (HAQ); anxiety and depression by the Hospital Anxiety and Depression Scale (HADS) and physical performance, assessed by 3 tests, the Timed Up and Go (TUG), one leg standing balance (OST) and sternal nudge test (SNT).

Results: Forty-eight patients were enrolled, the average age was 55.8 ± 13.9 and the sex ratio was 0.14. The average disease duration was 13.49 years ± 9.12. The average DAS28 was 4.63 ± 1.19 and HAQ was 0.77 ± 0.88. Falls were reported by 44.7% of patients: 27.7% had one fall and 17% had > 2 falls. Patients had a fractures history in 10.9% of cases and dislocations in 6.5% of cases. The HAQ (p=0.04) and c reactive protein (p=0.01) was associated with fall history; the other parameters (Gender, number of medications, age, disease activity and physical tests) showed no associations with history of falls. Physical performance was decreased to: 58.4% for TUG test, 61.7% for OST and 36.2% for SNT. The worst performance in physical tests (TUG, OST and SNT) was associated with older age, higher erythrocyte sedimentation rate, higher HAQ, and increased DAS28 (p<0.05). In addition, hips and especially knees involvement was significantly associated with TUG (p=0.03) and OST test (p=0.003). TUG test was significantly associated with depression (p=0.04). The OST test was associated with higher disease duration (p=0.004), VAS (p=0.006) and tender joints (p=0.001).

Conclusion: It was observed that the occurrence of falls is quite common in this population. The occurrence of falls in this sample of rheumatoid arthritis patients bears no relation to disease activity or physical performance tests. But, falls were associated with functional capacity.

Disclosure of Interests: None declared

THU0131 EFFECT OF METABOLIC SYNDROME ON THE COURSE OF RHEUMATOID ARTHRITIS AND CARDIOVASCULAR RISK

Svetlana Lapshina1,2, Lyubila Feiskhanova1, Luciya Kupkenova1, Ridgesha Sharafutdinova1, Aigu Rakhmetzianov1, Kazan State Medical University, Kazan, Russian Federation; 2Republic Clinical Hospital, Kazan, Russian Federation

Background: Both rheumatoid arthritis (RA) and metabolic syndrome (MS) have an inflammatory component in the pathogenesis and both aggravate cardiovascular risks.

Objectives: The aim is to study the effect of MS on the course of RA and the increase in cardiovascular risk in these patients.

Methods: 100 patients (men 7%, women 93%) aged 21 to 81 years (average age 55.12±14.5) with reliable RA were examined. High activity in DAS28 scale was observed in 68%, moderate - in 30%, low - in 2%, rheumatoid factor (RF) positivity - in 89%, ACCP - 81%. Disease-modifying anti-rheumatic drugs (DMARDs) were given to 60% of patients. Synovitis was present in 45% of patients. The prevalence of MS (NCEP/ATPIII criteria) was identified in 59 patients, according to the level of the ESR, CRP, the presence of the RF, the X-ray stage of RA. There were no differences in the range of received therapy, but the dose of prednisone was higher in the MS+ group (7.8±3.5 vs 6.4±3.69, p<0.05).

Systolic blood pressure (BP) was higher in the MS+ group (128.3±17.3) vs MS- (119.3±15.9). The level of BP correlated (p<0.05) with the severity of pain. The verified AH was present in 42 (71.2%) patients of the MS+ group (1 stage -2, 2 stage -24, 3 stage -16 patients) and in 3 (7.3%) patients of the MS- group (1 stage in 1 patient, 2 stages in 2 patients). The cholesterol level was higher in the MS+ group 5.1±1.1 compared with the MS- group 4.6±0.6 (p<0.01). There was observed a positive correlation (p<0.01) in increasing the mass index of the left ventricle myocardium according to echocardiogram. In patients with MS+, hypertrophy of the left ventricular myocardium was detected according to echocardiogram even with a normal level of BP.

Conclusion: The presence of MS in patients with RA is associated with a higher activity of RA most of all because of pain syndrome. The same time, pain syndrome correlates with the level of blood pressure and MS.

The combination of MS and RA leads to an increase of cardiovascular risk factors: cholesterol level and myocardial hypertrophy, which causes the need of using the echocardiography for this group of patients.

REFERENCE: [1] rheumatoid arthritis, metabolic syndrome.

THU0132 EVALUATION OF CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICAL AGENTS: 3-MONTH FOLLOW-UP

Giorgos Papamichail1, Theodora Markateli2, Athanasios Georgiadis2, Vasilios Xydis3, Haralampos Milionis1, Alexandra Drosos1, Paraskevi Voulgari1, Internal Medicine, University of Ioannina, Greece, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece, Ioannina, Greece; 2Rheumatology Clinic, University of Ioannina, Ioannina, Greece, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece; 3Radiology, University of Ioannina, Greece, Department of Radiology, Medical School, University of Ioannina, Ioannina, Greece

Background: Systemic inflammation is an additional and independent predictor of cardiovascular disease (CVD) in rheumatoid arthritis (RA). It is worth mentioning that lipid levels, blood pressure and other major risk factors of CVD constitute a wide field of investigation in case of treatment with biological disease-modifying anti-rheumatic drugs (DMARDs).

Objectives: The aim of this study is to assess the impact of biological agents on markers of CVD risk in patients with RA.

Methods: This is a prospective, observational study which included biologic-naive RA patients treated with synthetic DMARDs, who had a negative history of CVD. Thirty-one patients and 31 healthy matched-controls (for gender, age and smoking) were compared for total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), triglycerides (TGs), Apolipoprotein A1 (ApoA1), Apolipoprotein B (ApoB) and Lipoprotein A (LpA). Additionally, an ultrasonographic measurement of intima-media thickness (IMT) of carotids was performed by an experienced sonographer to all patients in order to detect the presence of atherosclerosis at baseline. Furthermore, in a subgroup of 19 of these 31 RA patients, the parameters we previously reported (except for IMT) were compared between baseline and a 3-month follow-up.

No significant difference in mean BMI and blood pressure was observed between the RA patients and controls (except for IMT). There was also a reduction in mean systolic blood pressure (15.44) vs 61.68(15.3) and 163.16(28.89) vs 173.11(29.65) respectively; p<0.05]. There was also a decrease in mean diastolic blood pressure (9.74) vs 61.11(10.3) and 101.32(18.64) vs 111.21(20.12) respectively; p<0.05]. ESR (25.53(18.57) vs 19.84(16.44), p<0.05) and DAS28 score (3.41(1.14) vs 2.62(1.12), p<0.05).

Results: As regards the demographic characteristics of 31 RA patients, the mean (SD) age was 54.7 (14.05) years, disease duration was 4.5 (1.3) years, there were 11 (35.5%) men and 20 (64.5%) women and 6 (31.6%) smokers. As far as the immunological profile of patients is concerned, there were 11 (35.5%) patients of the MS- group (1 stage in 1 patient, 2 stages in 2 patients). The presence of MS in patients with RA is associated with a higher activity of RA most of all because of pain syndrome. The same time, pain syndrome correlates with the level of blood pressure and MS.

The combination of MS and RA leads to an increase of cardiovascular risk factors: cholesterol level and myocardial hypertrophy, which causes the need of using the echocardiography for this group of patients.

REFERENCE: [1] rheumatoid arthritis, metabolic syndrome.

TENDERNESS CAN BE REGARDED AS A SIGN OF INFLAMMATION IN RHEUMATOID ARTHRITIS

Irina Gessl1, Mihaela Popescu2, Victoria Schimpl1, Gabriela Supp1, Michael Zauner1, Michala Loiskandl1, Martina Durechova1, Josef S. Smolen1, Daniel Aletaha1, Peter Mandl3, I. Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria; 2Université de Montréal, Montreal, Canada;

Background: In inflammatory joint diseases, joint swelling is regarded as a sign of inflammation, which is associated with structural progression [1–3]. However, the significance of tenderness without swelling is unclear.

Objectives: To determine whether clinical tenderness can be considered a sign of inflammatory joint activity in patients with rheumatoid arthritis (RA), osteoarthritis (OA), or psoriatic arthritis (PsA).

Methods: 3624/50 patients respectively with RA, OA and PsA were included in the study. Each patient underwent clinical examination, followed by an ultrasound examination of bilateral MCP 1-5 (metacarpophalangeal),PIP 1-5 (proximal interphalangeal) joint and wrists; the sonographer was blinded to clinical data. On clinical examination synovial swelling and tenderness were evaluated using a binary scoring method, and tender, non-swollen joints (TNS) were identified. Grey-scale signs of synovitis (GS) and Power Doppler signal (PD) were evaluated using a semiquantitative grading system. Differences of PD signals between groups (RA vs. OA, RA vs. PsA, TNS vs. non-tender non-swollen joints) were calculated by Chi-Square test. Furthermore, joints of RA and PsA patients were tracked back for up to 6 years to identify the time point of the last swelling of that respective joint. Kaplan-Meier estimates for the occurrence of the last time point of swelling were compared between PD positive and PD negative TNS joints.

Results: TNS joints more often showed PD signal in RA patients as compared to OA and PsA (18.7% vs. 11.5% vs. 9.2%, respectively, p=0.015 for RA vs. OA; p=0.01 for RA vs. PsA). TNS joints were significantly more often PD positive as compared to non-tender non-swollen joints (18.7% vs. 10.3% respectively, p<0.01) in RA, but not in PsA (9.2% vs. 7.6%, P=0.54) or OA (11.5% vs. 10.2%, P=0.72) (fig. 1). Kaplan-Meier analysis revealed a significantly shorter time period to last observed swelling in PD positive as opposed to PD negative TNS joints in both RA (45.2 vs. 65.5 months, p=0.017) and PsA (20.6 months vs. 107.7 months, p<0.001), however we found no difference in GS positive vs. negative TNS joints.

Conclusion: The results of this study confirm the current practice of considering tenderness a sign of active inflammation in RA, but imply that this may not be the case in PsA or OA. The fact that shorter time to last swelling was associated with positive PD in TNS joints suggests that, at least in RA, tenderness might reside after prior clinical swelling has resolved.

THU0134 COMORBIDITIES IN >5000 PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING TREATMENT WITH METHOTREXATE IN ROUTINE CARE: PREVALENCE AND IMPACT ON TREATMENT OUTCOMES. AN OBSERVATIONAL COHORT STUDY FROM DANBIO

Bente Glintborg1, Niels Steen Krogh1, Frank Mehnert2, Merete L. Heltland3, 1The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark; 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Methotrexate remains the anchoring drug for the treatment of rheumatoid arthritis (RA). Patients with RA often have comorbidities e. g. diabetes or pulmonary disease. Although methotrexate has been used for decades, little is known about the impact of various comorbidities on treatment outcomes.

Objectives: To describe the prevalence of comorbidities in csDMARD naïve RA patients initiating treatment with methotrexate in routine care and to explore the impact of common comorbidities on methotrexate treatment outcomes (achieving remission and adherence to treatment).

Methods: Observational cohort study based on the Danish nationwide quality registry, DANBIO. Adult RA patients who started treatment with methotrexate (oral or injection) as first csDMARD year 2010-2017 and who had been followed since onset of disease with regular controls were included. Concomitant treatment with other DMARDs were allowed. Treatment outcomes after ~6 months of treatment were identified in DANBIO. Data were censored by April 2018. Seven different comorbidities (Figure) prior to start of methotrexate were identified in the national patient registry (NPR) through linkage by social security numbers.

Impact of each comorbidity was explored as 1) overall methotrexate treatment retention rate and 2) DAS28 remission rate (after 6 months’ treatment). Analyses were by Cox- and logistic-regression analyses (adjusted for gender and age). The comorbidities were included one by one in the models. Finally, similar analyses were performed summed for all the seven comorbidities as any comorbidity yes/no.

Results: 5828 patients were included (66% female, median age 61 (IQR 51-70) years), whereas 906 (15.5%) had ≥1 of the predefined

comorbidities (63% female, median age 68 (60-74) years). Only 70 patients (1.4%) had ≥2 comorbidities. Patients with comorbidities had increased withdrawal rate of methotrexate with hazard ratios ranging from 1:10-2.06 (Figure). Similarly, patients with comorbidities had poorer remission rate with odds ratios ranging from 0.38-0.74 except for previous cancer. **Conclusion:** In this nationwide cohort of >5000 RA patients treated with methotrexate in routine care, approximately 15% of patients had comorbidities at treatment start. Patients with comorbidities had higher rate of withdrawal and poorer remission rates. This warrants specific attention when treating these patient groups in routine care. **Acknowledgement:** Thank you for the Danish departments of Rheumatology for reporting to DANBIO

DETERMINANTS OF DISCORDANCE IN PATIENT’S AND PHYSICIAN’S GLOBAL ASSESSMENTS OF DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS IN THE “REAL” STUDY – BRAZIL

Maria Fernanda Guimarães1, Maria Raquel Pinto1, Gustavo Resende3, Carla Machado1, Ana Beatriz Vargas-Santos3, Cleandro Albuquerque4, Manoel Bertolo5, Paulo Louzada Jr 6, Rina Giorgi9, Karina Bonfiglioli9, Maria de Fátima Sauma13, Ivanio Pereira13, Claiton Brenol12, Murilo Filho1, Maria Fernanda Guimarães1, Maria Raquel Pinto1, Gustavo Resende3, Carla Machado1, Ana Beatriz Vargas-Santos3, Cleandro Albuquerque4, Manoel Bertolo5, Paulo Louzada Jr 6, Rina Giorgi9, Karina Bonfiglioli9, Maria de Fátima Sauma13, Ivanio Pereira13, Claiton Brenol12, Murilo Filho1

**Background:** Discordance between the patient's global assessment of disease activity (PGA) and examiner’s global assessment (EGA) has been described in rheumatoid arthritis (RA) (1,2). Understanding the reasons for this discrepancy is essential in the context of treat-to-target treatment strategy.

**Objectives:** To assess the determinants of PGA and EGA and factors associated with discordance between them.

**Methods:** The REAL study included RA patients from Brazilian public health centers. Clinical, laboratory and outcomes measures were collected. PGA and EGA were rated on a visual analog scale and analyzed. Three groups were defined: no discordance (a difference between PGA and EGA within 3 cm), positive discordance (PGA exceeding EGA by >3 cm), and negative discordance (PGA less than EGA by >3 cm). Multivariate regression analysis was used to identify determinants of PGA and EGA and their discordance.

**Results:** 1151 patients (62.5% female, mean age 56.7 years and median disease duration of 12.7 years) were enrolled. Two factors were associated with PGA in the final multivariate model: one point increase in the pain scale (PS) leads to an increase of 0.62 in PGA; one point increase in HAQ increases by 9.25 points the PGA. The factors associated with EGA were: PS, number of tender and swollen joints (NTJ and NSJ), RF, ESR, CRP and use of corticosteroids. Discordance between patient and physician was found in 30.52%: positive discordance (PD) in 24.6% and negative discordance (ND) in 5.92%. An increase of one point in the NSJ was associated with a 12% increase in the chance of ND. The chance of PD increased by 90% and 2% for each unit increased in HAQ and PS respectively. Finally, the chance of PD decreased by 3% for each point increased in NTJ and by 15% for each point increased in NSJ.

**Conclusion:** In one-third of the assessments, there was disagreement between patient and physician assessments of global disease activity in rheumatoid arthritis and association with work productivity. Arthritis Res Ther. 2016; 18:114.

TNF INHIBITORS IN PREGNANCY: STOP, REDUCE OR CONTINUE? – OBSERVATIONS FROM A PREGNANCY OUTPATIENT CLINIC

Isabell Haase1, Susanna Spaethling-Mestekemper2, Matthias Schneider1, Rebecca Fischer-Betz1,2, Heinrich-Heine-University Düsseldorf, Polyclinic of Rheumatology and Hiller Research Unit, Düsseldorf, Germany; 1Rheumaparxis, Munich, Germany

Background: Women with active Rheumatoid Arthritis (RA) are more prone to relapses and complications during pregnancy. The potential risks of disease activation and treatment during gestation should be weighed in a shared decision prior to conception. An increasing number of women who wish to conceive are being treated with TNF inhibitors (TNFi). Some wish to discontinue or at least reduce therapy while pregnant and require information on opportunities and risks.

Objectives: To study the outcome of pregnancies in women with RA who either discontinued, reduced or maintained their TNFi treatment after conception.

Methods: Pregnancies from an outpatient pregnancy clinic were evaluated before conception, during each trimester and postpartum. Clinical characteristics, disease activity (DAS28-CRP), medication use and pregnancy outcome were analysed. A flare was defined as increase in clinical activity characteristics, disease activity (DAS28-CRP), medication use and pregnancy outcome were analysed. A flare was defined as increase in clinical activity leading to intensified treatment (new treatment with prednisolone or increase in dosage ≥5 mg/day) and/or treatment with intraarticular glucocorticoids and/or (re-)treatment with DMARDs/TNFi. All women received extensive counselling before pregnancy based on current knowledge and subsequently decided to continue or stop TNFi at conception. If they stayed on TNFi and were in remission, women received the suggestion to stretch the therapy intervals in a disease activity guided manner. These real-world data will help to provide women with comprehensive advice on treatment options and risks regarding TNFi therapy at conception.

Results: After exclusion of one miscarriage, 56 completed pregnancies were enrolled and grouped according to their decision to stop (group 1) or continue (group 2) TNFi therapy during pregnancy. The latter were subdivided into those who could stretch the therapy intervals (group 2a) and those who could not (group 2b). Group 1 also contained seven women who received Tocilizumab or Rituximab until conception. Despite low disease activity (DAS ≤3.2) at conception in all groups, a higher flare rate during pregnancy and postpartum was observed after discontinuation of TNFi. In addition, a higher dose of oral prednisolone and more frequent intraarticular therapy was reported in group 1 (table 1). Postpartum, 38.9% restarted TNFi therapy. About half of the women who chose to stay on therapy during gestation were able to stretch the injection interval of their TNFi, which was either Adalimumab (every 3.0 weeks), Certolizumab (median every 4.0 [min 4.0, max 5.0] weeks) or Etanercept (median every 3.0 [min 2.0, max 6.0] weeks) (Table 2). Relapse rate as well as prednisolone consumption was comparable between group 2a and group 2b.

Conclusion: Women with RA who discontinue TNFi at conception face a higher risk of flares during pregnancy and often have an increased demand for steroids to control disease activity. When in remission under ongoing TNFi therapy during pregnancy, it seems possible and safe for women to reduce the frequency of injections in a disease activity guided manner. These real-world data will help to provide women with comprehensive advice on treatment options and risks regarding TNFi therapy at pregnancy counselling.

RHEUMATOLOGISTS’ ADHESION TO THE TREAT-TO-TARGET PRINCIPLE IN EARLY RA PATIENTS WITHIN THE PRAGMATIC CARERA TRIAL: ROOM FOR IMPROVEMENT?

Veerle Stouten\(^1\), Diederik De Cock\(^1\), Sofia Pazmino\(^2\), Kristien Van der Elst\(^2\), Johann Joly\(^1\), Delphine Bertrand\(^1,2\), Rene Westhovens\(^1,2\), Patrick Verschueren\(^1,2\), On behalf of the CareRA study group. \(^1\)KU Leuven, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, Leuven, Belgium; \(^2\)University Hospitals Leuven, Rheumatology, Leuven, Belgium

**Background:** Treating to a predefined target is a principle adopted in guidelines to treat rheumatoid arthritis (RA). It is currently the most efficient strategy to control disease activity, but its implementation in daily clinical practice remains challenging.

**Objectives:** To evaluate rheumatologists’ adherence to a treat-to-target (T2T) approach at a threshold of low disease activity (DAS28CRP<3.2) in patients with early RA during the 2-year Care in early RA (CareRA) study.

**Methods:** CareRA is an investigator-initiated pragmatic multicentre trial, in which patients with early RA and naïve to conventional synthetic disease modifying anti-rheumatic drugs (csDMARD) were included (n=379). Participants were randomized to different remission induction schemes consisting of a csDMARD combination or methotrexate (MTX) monotherapy with and without a prednisone tapering down scheme. Following the T2T approach, specific treatment adaptations had to be performed in case of DAS28CRP<3.2 during the first study year, unless a predefined reason not to intensify treatment was provided. As first step, dose of MTX had to be increased from 15mg to 20mg weekly. As second step, dose of the other csDMARD was escalated in the combination arms and lefunomide was added in the MTX monotherapy arms. From week (w)52 onwards, further T2T was advised but type of treatment adaptation was left at the rheumatologists’ discretion. Adherence to this T2T approach was defined as performing a dose escalation or changing/adding DMARD medication in case of DAS28CRP>3.2 and was evaluated at every study visit during 2 years. Additionally, remission (DAS28CRP<2.6) rates at w104 were compared between patients in which T2T was applied at early RA patients not always treated to target. Only data from patients for which DAS28-CRP scores were available were taken into account to evaluate the low disease activity state.

**Results:** The proportion of patients with DAS28CRP<3.2 was 26% (93/365) at w8, but decreased to a stable average of 16% on the following visits and further diminished to 10% (30/303) at w104. The frequency of T2T adherence in these patients varied from 59% (55/93) at w8 to 17% (5/30) at w104 (Figure 1). The most frequent reason not to intensify treatment during the first study year was that rheumatologists considered the disease already well-controlled. This reason was reported in 50% of non-adherent cases at w8, in 15% at w16, 14% at w28, and 24% at w40. The second most frequently given reason for non-adherence during the first study year was that giving glucocorticoids or NSAIDs temporarily was preferred over changing DMARDs, as reported in 3% of cases at w8, 15% at w16, 27% at w28, and 35% at w40. T2T was applied at all visits in 41 out of 110 (37%) patients needing at least 1 adaptation during the 2-year trial. Of these 41 patients, 36 (88%) were in remission at w104, while of the 69 patients not always treated to the T2T principle, 40 (58%) were in remission at the end of the 2-year trial (p=0.001).

**Conclusion:** This study shows the difficulty of applying T2T strictly, both with and without a fixed protocol to follow. In less than half of patients theoretically in need of a treatment adaptation, treatment was intensified at all visits during the first 2 years of treatment. In the majority of cases rheumatologists gave as reason for overruling the T2T guidance that they estimated disease activity to be sufficiently controlled. However, patients in which the T2T principle was applied strictly, showed higher remission rates after 2 years of treatment.

**THU0139 IS ADDING ANTI-CARP OR ANTI-PADI4 BENEFICIAL FOR DIAGNOSIS OF RHEUMATOID ARTHRITIS?**

Boogdan Kolar\(^2\), Magdalena Drylewik\(^2\), Marek Ciesla\(^1\), Maria Magdari\(^2\)

\(^1\)University of Rzeszow, Faculty of Medicine, Rzeszow, Poland; \(^2\)Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland

**Background:** Post-translatory modification (PTM), such as protein citrullination or homocitrullination (cargamylation) are key issues for the development of RA. There are known more than 300 PTMs. Some of them such as homocitrullination, are of chemical origin, but most of them (over 200) are of enzymatic origin. ACPA, anti-PADI4, anti-CarP and indirectly
RF are originated as a result of such post-translational modifications [1]. From the above-mentioned RA markers only synthesis of anti-CarP is a result of chemical protein modification. The synthesis of anti-PADI4 may facilitate the production of citrullinated proteins and contribute to the formation of ACPA. All of the above markers appear before RA onset [2].

Objectives: The aim of our study is to discover the potential utility of using additional markers (anti-CarP and anti-PADI4) in RA diagnosis.

Methods: 121 RA patients, 82.4% female, aged 52.5±12.3 years (mean ±SD) and 30 healthy controls (HC), 76.7% female, aged 53.2±8.1 years, were enrolled in the study. ACPA, RF, anti-CarP and anti-PADI4 antibodies were determined in serum by enzyme-linked immunosorbent immunoassay (ELISA).

Results: The markers positivity rate was 85.95%, 67%, 55.37% and 46.28% in ACPA, RF, anti-PADI4 and anti-CarP respectively. Among ACPA negative patients we found 44.44% and 16.67% anti-CarP and anti-PADI4 positive results respectively. The data concerning ACPA are gathered in Table 1.

<td>2 (11.1%)</td>
</tr>
</tbody>
</table>

Table 1. The profile of anti-CarP, RF, anti-PADI4 positivity in ACPA(+) and ACPA(-) RA patients.

In HC group we found 0%, 0%, 7.14% and 7.14% positivity in ACPA, RF, anti-PADI4 and anti-CarP respectively. We found 91.7% positivity for ACPA(+) or anti-CarP (+) vs 88.4% for ACPA(+) or RF(+).

Conclusion: The measurement of anti-CarP antibodies may be useful in RA diagnosis. The positivity for ACPA/anti-CarP is even higher than ACPA/RF. This might be caused by the similarity of the origins of ACPA and RF (enzymatic citrullination), while anti-CarP origin is different (chemical carboxylation). It is known that anti-CarP appears years before RA onset and might be used as a potential biomarker for pre-RA diagnosis. We didn’t confirm the usefulness of anti-PADI4 as RA biomarker.

Disclosure of Interests: Bogdan Kolarz: None declared, Magdalena Drygelska: None declared, Marek Ciesla: None declared, Maria Majdan: None declared, Viktorko Korendovych:1,1, Radovan Vasko1, Elena Nikiphorou2, Jan-Gerd Rademacher1, Gerhard A Müller1, Peter Korsten1. 1University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany; 2Whittington Hospital, London, United Kingdom

Background: Rheumatoid arthritis (RA) is characterized by symmetrical involvement of small and large joints. New treatment modalities have not only allowed to achieve clinical remission or low disease activity, but also to halt the radiographic progression of joint destruction. In some patients, the disease progresses and leads to joint destruction despite treatment with disease-modifying antirheumatic drugs (DMARDs). Occasionally, wrist arthritis leads to severe destruction of carpal bones with ankyles, so-called ‘os carpale’. Severely destructive wrist arthritis in an asymmetrical, unilateral pattern has only rarely been reported in the literature and has not been systematically assessed before (1). A severely destructive yet often symmetrical arthritis has been described in seronegative RA patients (2).

Objectives: To systematically analyze the presence of severely destructive unilateral wrist arthritis in a single-center, seropositive RA population and to identify risk factors for its development.

Methods: This is a single-center, retrospective cohort study using routine clinical data. We performed a database search of our RA population for the presence of rheumatoid factor (RF) and/or anti-CCP antibodies (ACPA) from 2011 to 2017. Radiographs were assessed independently by two investigators for the presence of severely destructive unilateral wrist arthritis. Discrepancies were resolved by discussion. Epidemiological data including age, gender, disease duration, occupation, dexterity and smoking status were recorded. Patients with psoriasis, a family history of psoriasis or postramutic osteoarthrosis were excluded. Past and current treatments were recorded. Conventional radiographs of the hands were scored using the modified Sharp score, magnetic resonance images were examined if available.

Results: We identified 1247 patients with either positive RF, ACPA, or both. After exclusion of non-RA diagnoses and radiograph review, 17 eligible patients were included in the study. Of these, 7 were excluded because of incomplete clinical data. All of the remaining ten patients were female (100%). Median age was 58.1 years (33-70), median disease duration was 15.8 years (1-22). Seven patients were right-handed, one was left-handed, in two patients, dexterity was not known. Six patients were smokers, two patients were non-smokers, in two patients, smoking status was not known. Median ACPA levels were 134.6 IU/mL (normal range <5). Median RF 54.2 IU/mL (NR <16). All but two patients were positive for both antibodies; in three patients, ACPA were only mildly elevated (6, 11, and 14, respectively). 6/7 (75%) patients with severe destruction were smokers. In 5/7 (71.4%) right-handed patients, destruction occurred in the dominant wrist, whereas in 2/7 (28.6%) right-handed patients, destruction occurred in the non-dominant wrist.
handed patients, destruction occurred in the non-dominant wrist. Patients received a mean number of 4.7 DMARDs.

**Conclusion:** Severely destructive unilateral wrist arthritis represents a rare phenotype of RA. In our cohort, this type of joint involvement was only present in women, it occurred primarily in the dominant hand (75%), and in smokers (75%). The mean number of used DMARDs was very high. Further studies for assessing the prevalence of this entity, also in sero-negative patients, are required.

**LOW-ENERGY FRACTURES IN RHEUMATOID ARTHRITIS – ASSOCIATIONS WITH GENES AND CLINICAL CHARACTERISTICS**

Lotta Ljung1 2, Kristina Wiberg1, Susanna Järvelin1,2, Lotta Ljung1,2, Kristina Wiberg1, Lisbet Arlés1, Solbritt Rantapää Dahlqvist2.

1Karolinska Institutet, Clinical Epidemiology Section, Department of Medicine, Stockholm, Sweden; 2Umeå University, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden

**Background:** Patients with rheumatoid arthritis (RA) have increased risk of osteoporosis and low-energy fractures. Several genes associated with bone mineralization, osteoporosis or risk of fracture in the general population have been identified.

**Objectives:** To analyse the association between nine selected SNPs and the risk of low-energy fracture, taking clinical patient characteristics into account.

**Methods:** We identified a cohort of patients (n=896, 70% women, age at inclusion 60±14.8 years) with RA according to ACR criteria from the capture area of the register of Umeå injury database, Umeå, Sweden, which enabled identification of low-energy fractures (n=254). The follow-up (mean 8.8±6.1 years, total 7928 person-years) started two years after RA diagnosis but not earlier than January 1, 1993 and ended at the first of December 31, 2011, death, or the first low-energy fracture. Nine SNPs were analysed in all patients with available DNA-samples (n=667) using KASP genotyping assays (LGc genomics Ltd, Hoddesdon, UK):

**DIAGNOSTIC AND PREDICTIVE VALUE OF CAROTID AND TIBIAL ARTERIES ULTRASOUND MORPHOLOGY CHANGES IN FEMALE WITH RHEUMATOID ARTHRITIS**

Olena Garmish, Volodymyr Levchenko, National Scientific Center “M.D. Strazhesko Institute of Cardiology”, Kiev, Ukraine

**Background:** Carotid plaque (CP) is one of the surrogate markers of atherosclerosis. The association of ultrasound carotid and tibial intima-media morphology abnormalities with clinical and laboratory markers of atherosclerosis in patients with rheumatoid arthritis (RA) is uncertain.

**Objectives:** To determine the diagnostic and prognostic value of the carotid and tibial arteries ultrasound changes in women with RA, depending on age, menopause and laboratory parameters.

**Methods:** The study was performed on 105 women with RA according to ACR criteria from the catchment area of the register of Umeå injury database, Umeå, Sweden, which enabled identification of low-energy fractures (n=254). The follow-up (mean 8.8±6.1 years, total 7928 person-years) started two years after RA diagnosis but not earlier than January 1, 1993 and ended at the first of December 31, 2011, death, or the first low-energy fracture. ECHOCARDIOGRAPHIC ABNORMALITIES AMONG HISPANIC PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE CONTROL STUDY

José Ramón Aspiri-López1, Dionioco Ángel Galarza-Delgado1, Iris Jazmín Colunga-Pedraza2, Carolina Marlene Martínez-Flores1, Karla Paola Cuéllar-Calderón2, Ileana Cecilia Reynosa-Silva2, Marielva Castro-González2, Raymundo Pineda1, Guillermo Contreras1.

Background: Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory disease that mainly affects the synovial joints. Subjects with RA have an increased cardiovascular (CV) morbimortality (1). This increase in cardiovascular diseases (CVD) is not explained by traditional risk factors (2). Screening for CVD in RA patients is an essential part of CV risk management. Echocardiography is a simple, non-invasive approach that provides reliable markers for cardiac evaluation (3).

Objectives: To determine the prevalence of echocardiographic abnormalities in RA patients and compare them to matched controls.

Methods: Observational, cross-sectional study. RA patients aged 40 to 75 years that fulfilled the 2010 ACR/EULAR classification criteria and met the inclusion criteria were included. Patients with a previous ultrasound window, history of previous atherosclerotic CVD, ischemic heart disease, cerebrovascular accident or peripheral arterial disease and pregnancy were excluded. Transthoracic echocardiogram was performed and reviewed by 2 board-certified cardiologists. Differences were solved by consensus. Descriptive analysis was done with frequencies (%) and median (q25–q75), and comparisons with Chi-square and Mann U-Whitney's test.

Results: A total of 133 subjects were included. Baseline characteristics are shown in Table 1. Groups were well balanced, with no differences among them. Echocardiographic comparisons are shown in Table 2. Prevalence of abnormal left ventricle (LV) geometry was higher in RA patients (p=0.038), as were mitral and tricuspid valvular dysfunction (p<0.001). The LV ejection fraction was lower in RA subjects (p=0.038), as were mitral and tricuspid valvular dysfunction (p<0.001).

Abstract THU0144 – Figure 1

Conclusion: Genes related to bone metabolism may have a considerable contribution to the already high risk of low-energy fractures in RA.

THU0145 INCIDENCE, TREND AND FACTORS ASSOCIATED WITH OPPORTUNISTIC INFECTION (OI) IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SPAIN. (TREND-AR STUDY)

Ramón Mazzucchelli1, María Velasco Arribas2,3, Elia Perez-Fernandez2, Alberto García-Vadillo3, Natalia Crespi-Villarias2,3, Trend-AR.1 Hospital Universitario Fundación Alcorcón, Rheumatology, Alcorcón, Spain; 2Hospital Universitario Fundación Alcorcón, Internal Medicine, Alcorcón, Spain; 3Fundación Hospital Alcorcón, Clinical Investigation, Alcorcón, Spain; 4Hospital de La Princesa, Rheumatology, Madrid, Spain; 5Health Center Rivolta, Alcorcón, Spain

Background: The epidemiology of hospitalizations for Opportunistic Infections (OI) in patients with rheumatoid arthritis (RA) is unknown despite an increase in RA treatments that confer risk of infection.

Objectives: To analyze the incidence, trend and factors associated with hospitalizations due to OI in patients with RA, in Spain, during the period between 1999 and 2015.
